EDITOR
Prof. Dr. Adarsh Kumar

Forensic Medicine & Toxicology, AIIMS, New Delhi

INTERNATIONAL EDITORIAL ADVISORY BOARD

1. Prof Mete Gulmen Cukurova University, TURKEY
2. Prof. Leandro Duarte De Carvalho, Minas Gerais, Belo Horizonte, Brazil
3. Prof. Donata Favretto (Full Professor) Forensic Toxicology at University of Padova, Italy
4. Prof. Babak Mostafazadeh Department of Forensic Medicine & Toxicology, Shahid Beheshti University of Medical Sciences, Tehran-Iran
5. Prof Halis Dokgoz, Mersin University, TURKEY
6. Prof Jozef Sidlo, Comenius University, Bratislava, SLOVAKIA
7. Dr. Rahul Pathak (Lecturer) Forensic Science, Dept of Life Sciences Anglia Ruskin University, Cambridge, United Kingdom
8. Dr. Hareesh (Professor & Head) Forensic Medicine, Ayder Referral Hospital, College of Health Sciences, Mekele University, Mekele Ethiopia East Africa
9. Dr. Mokhtar Ahmed Alhari (Specialist) Forensic Medicine & Clinical Toxicology, Director of Forensic Medicine Unit, Attorney General’s Office, Sana’a, Yemen
10. Dr. Sarathchandra Kodikara (Senior Lecturer) Forensic Medicine, Department of Forensic Medicine, Faculty of Medicine, University of Peradeniya, Sri Lanka
11. Dr Noha A. Magdie El Rafie, Forensic Toxicology, Ain Shams University, Cairo, EGYPT

SCIENTIFIC COMMITTEE

1. Prof Udai Pratap Singh, Department of Anthropology Lucknow University Lucknow
2. Dr Anil Rahule (Associate Professor) Dept of Anatomy, Govt Medical College Nagpur
3. Dr Shankar Bakkanwar (Associate Professor) Forensic Medicine, Kasturba Medical College, Manipal, Karnataka
4. Dr K. Ravikumar Raksha Shakti University, Ahmedabad, Gujarat.
5. Dr. Pragnesh Parmar (Associate Professor) Forensic Medicine, Valsad, Gujarat
6. Dr Vandana Mudda (Awati) (Associate Prof) Dept of FMT, M.R.Medical College, Guwahati, Karnataka,
7. Dr. Asha Srivastava (Senior Scientific Officer) Forensic Psychology, Central Forensic Science Laboratory, CBI, Delhi
8. Dr. Lav Kesharwani (Asst.Prof.) School of Forensic Science, Sam Higginbottom Institute of Agriculture Technology & Sciences, Allahabad U.P.
9. Dr. Anu Sharma (Associate Prof) Dept of Anatomy, DMCH, Ludhiana (PB)
10. Dr. Shalini Gupta (Prof ) Oral Pathology and Microbiology, Dental Sciences King George Medical University, Lucknow, UP
11. Dr Rituja Sharma, Associate Prof, Law Banasthali Vidyapeeth Jaipur

NATIONAL EDITORIAL ADVISORY BOARD

Chairman
Prof Sudhir K Gupta - Head, Department of Forensic Medicine
All India Institute of Medical Sciences, New Delhi

Members
1. Prof. SK Dhatarwal, Forensic Medicine, PGIMS, Rohtak, Haryana
2. Prof. N K Aggrawal Forensic Medicine, UCMS, Delhi
3. Prof Ajay Ghangale Forensic Medicine Dr DY Patil Medical College, Pune, Maharashtra
4. Dr. Amar Jyoti Fatwory Professor, Forensic Medicine NEIGRIHMS, Shillong
5. Dr. S. Venkata Raghava Professor, Forensic Medicine, Bangalore Medical College, Bengaluru
6. Prof Praveen Arora, Professor Department of Forensic Medicine & Toxicology, SAIMS, Indore
7. Dr. Pankaj Datta (Principal & Head) Department of Prosthodontics, Indraprastha Dental College & Hospital, Ghaziabad
8. Dr. Mahindra Nagar (Head) Department of Anatomy, UCMS & GTB Hospital, Delhi
9. Dr. Virender Kumar Chhoker Professor Forensic Medicine and Toxicology, Santosh Medical College, Ghaziabad, UP
10. Dr. Dayanand G Gannur (Professor) Department of Forensic Medicine & Toxicology, Shri BM Patil Medical College, Hospital & Research centre, Bijapur, Karnataka
11. Dr. Alok Kumar Professor Department of Forensic Medicine & Toxicology, UP Rural Institute of Medical Sciences and Research, Saffal, Etawah, U.P.

## Contents

**Volume 15, Number 1 January-March 2021**

1. Socio-Demographic Profile of Fatal Poisoning in a Tertiary Care Teaching Hospital of Coimbatore District-A Retrospective Study .............................................................. 1  
   *Angayarkanni S, Jeyasingh T*

2. Impact of Pilates Training versus Progressive Muscle Relaxation Technique on Quality of Life in Menopausal Women- A Comparative Study .............................................................. 7  
   *Anjali Bais, Pratik Phansopkar*

3. Comparison of Muscle Length in Dominant Versus Non-Dominant Lower Extremity in Young Asymptomatic Individuals- A Research Protocol .............................................................. 12  
   *Anushree Pawar, Pratik Phansopkar, Kiran Kumar*

4. Isoniazid Mono Resistance: Changing Trends in Drug Resistant Pulmonary Tuberculosis. – A Case Series of 3 Patients .............................................................. 17  
   *Arti D. Shah, Anchal Jain, Apoorva, Kusum V. Shah, Yash Rana , Saket Kumar*

5. Study on Effectiveness of Chakramarda (Cassia tora) Ghrit and Go-Ghrit in the Management of Parikartika (Fissure in Ano) .............................................................. 20  
   *Alok Kumar Diwedi, Kiran Khandare, Pooja Shrivastav*

6. Percutaneous Subclavian Artery Covered Stent Placement Following Inadvertent Subclavian Arterial Cannulation .............................................................. 26  
   *Cinosh Mathew, R Calton*

7. Correlation of Vitamin D level with severity of Coronary Artery Disease(CAD) in patients of Acute Coronary Syndrome(ACS) in a Tertiary Care Centre in Western India .............................................................. 31  
   *Cinosh Mathew, Nishant Saxena, Ashish Sharma, Jayesh Rawal*

8. A Questionnaire-Based Study to Evaluate the Basic Understanding of Pharmacovigilance of the Under Graduate Medical Students of a Rural Teaching Hospital .............................................................. 38  
   *Ervilla E. Dass, Maulin Mehta, Jayant Patharkar*

   *Dhanashri R Ghordadekar, Angela Kapoor*

10. Screening for Upper Cross Syndrome in Asymptomatic Individuals .............................................................. 50  
    *Heena Pathan, Pratik Phansopkar, Waqar M. Naqvi*

11. A Novel Research Protocol to Evaluate Psychological Perception Using Brain Gym Exercises in Physiotherapy Students .............................................................. 55  
    *Vaishnavi V. Siroya, Angela Kapoor*
12. Gaming addiction to Massively Multiplayer Online Games (MMOGs) and Quality of Life..............61
   Divya Thakur, Kamalpreet Shergill, Gurpreet Kaur, Shindbir Kaur, Devakshi Abrol, Harjot Singh, Ashwyn Gill

13. Knowledge, Attitude, and Practice about Informed Consent amongst Resident Doctors at Rural Medical Institute of Central India..............................................................68
   Shashank Gotarkar, Prakash Mohite, Kumar Bijyendra Sourabh, Alka Rawekar

14. Total Elbow Arthroplasty in a Rare Case of Giant Cell Tumour of Humerus: A Case Report........74
   Gajanan Pisulkar, Kiran Saoji, Ulhas Dudhekar, Sridhar Reddy, Shivshankar Jadhav, Mohit Dadlani, Pratik Phansopkar

15. Relationship between Working Tenure and Working Posture with Musculoskeletal Grievance in Batik Madura Workers.............................................................................79
   Galuh Sistha Prabarukmi, Noeroel Widajati

16. Effectiveness of Transport Guidelines on Intra Hospital Transport Practices of Nurses and Occurrence of Mishaps among Critically ill Patients ...................................................87
   Gautam Sakshi, Sembian N, Kumari Vinay

17. Knowledge of Women about the Early Detection Methods of Cervical Cancer in Baghdad City........95
   Iman A Jaber

18. Causative Microorganisms and Antibiotics Susceptibility in Neonatal Sepsis at Neonatal Intensive Care Unit: A Longitudinal Study from Diyala Governorate in Iraq.................................101
   Issam Tariq Abdul Wahaab, Sura Qais Mahmood Almaroof, Zaid Taha Yaseen

19. A Study Evaluating Correlation between Umbilical Cord Attachment on Placenta in Normotensive and Hypertensive Pregnant Females and its Effects on Fetus........................................111
   K M Parmar, Kinjal Jethva, Priyanka Sharma, Nirali Chavda, Hetal Vaisnani

20. A Cross Sectional Discriptive Study of Analysis of Lambdoid And Squamous Sutures Closure by Ct Scan for Age Estimation................................................................................118
   Kalpesh M Zanzrukiya, Lavlesh Kumar, Ashish A Bhalodiya

21. Effectiveness of Laughter Therapy on Reduction of Stress among Nursing Students....................126
   Kanika Guleria, Pushplata Manta

22. Current Trends of Poisoning in Tertiary Care Hospitals Located in a Rural Area of Salem, Tamil Nadu, India..............................................................................................................133
   Koteswara Rao. Vipparla, Vijaya Kumari

23. Epidemiological Profile of Burn Cases among autopsies Conducted in Dept. of FMT, RIMS, Ranchi .....................................................................................................................139
   Kumar Shubhendu, Lishu Chaure, Sanjay Kumar, Tulsi Mahto, Ajit Kumar Chaudhary

24. Systemic Sclerosis and Pulmonary Tuberculosis Associated with Interstitial Lung Disease: A Case Report...........................................................................................................147
   Laksmi Wulandari, Sisilia Yolanda Wijaya

95. Age Estimation from Fusion of Manubrium & Xiphoid Process with Sternal Body: A Radiological Study in Living Individuals from Central India

Ninad Nagrale, Swapnil Patond, Prakash Mohite

96. Assessment of Knowledge and attitude about Medicolegal Aspect of Organ Donation amongst Medical Students

Pande Varsha, Nagrale Ninad, Patond Swapnil

97. Prevalence of Associated Factors of Depressive Symptoms among School Going Children’s

Sonal B. Dhobe, Samruddhi Gujar

98. Bibliometric Analysis of Publications on Dental Caries and Dental Fluorosis from India

Rutuj Waghmare, Roshan Umate, Shobha Joshi, Manoj Patil

99. Effect of Finger and Hand Exercises among Amateur Pianist

S.F. Mariyam Farzana, Ashish Mathew A

100. Analysis of Posture Using Posture Screening Mobile Application among Collegiates

S.F. Mariyam Farzana, Pooja

101. Cognizance Among physiotherapy Clinicians and Students in Pelvic Girdle Dysfunction Qualitative Analysis

S.F. Mariyam Farzana, M.S. Pawan Kumar, D. Malarvizhi

102. Patient Safety Program in a Hospital with Reference to Costs Associated with Patient Falls

Renu Mirchandani, P. Naveen Kumar, Vikram Palimar

103. Physical Therapy Rehabilitation and Care in Post Operative Trans-Tibial Amputation Patient

Renuka Dhole, Simran Jaiswal, Waqar M. Naqvi, Arti Sahu

104. Impact of Workstation Exercise and Ergonomic Exercise on Nursing Population – A Randomized Clinical Trial Research Protocol

Renuka Dhole, Deepali Patil, Angela Kapoor

105. Correlation of Matrix Metalloproteinase-2 and p21 Expressions with Capsular Invasion of Thymoma

Santi Maulina, Etty Hary Kusumastuti, Nila Kurniasari

106. Effect of Graded Theraband Exercise on Myofascial Dysfunctions in Breast Cancer Survivors

Sapana Namadev Jare, Mandar Malawade

107. Morphometric study of Macewan’s Triangle in Relation to Depth of the Sigmoid Sinus Plate

Senthil Kumar B

Simran Jaiswal, Shalaka Dhankar

109. Does Dermatoglyphics An Essential Tool for Predicting Dental Caries? - A Systematic Review

Suganya P, Lubna Fathima, Prabu D, Raj Mohan, Bharathwaj, M.R. Prashanthy
110. Study on the Effectiveness of Abhaya Sunthi Churna and Snehana Swedan in Tamaka Shwasa……661
Suraj Sankh, Jyothy Kothanath Bhaskaran

111. A Study Protocol for Checking Efficacy of Leap Motion Device on Gross Hand Dexterity in Sub-Acute Stroke Patients .................................................................668
Vaidehi kannao, Waqar Naqvi

112. A Novel Research Protocol to Evaluate Psychological Perception Using Brain Gym Exercises in Physiotherapy Students .................................................................672
Vaishnavi K. Siroya, Angela Kapoor

113. Socio-demographic Profile of Deaths due to Poisoning at a Tertiary Care Hospital in Bangalore ……678
Vidusha Vijay, Pradeep Kumar M.P

114. Assess the Effectiveness of “First Aid Training Program” in Terms of Knowledge and Skills Among School Teachers of Selected Schools of Ambala, Haryana”: A Quasi Experimental Study ....684
Vijayata, Yogesh Kumar, Jyoti Sarin

115. Oral Hygiene as a Risk Factor in Periodontitis ........................................................................690
Abdul Majeed Wadi

116. Incidence of Hydatidosis in Slaughtered Animals and their Relation to Public Health at Baghdad Province .....................................................................................................694
Abdulkareem Thamer Mohammed

Agung Sosiawan, Cahyo Pulunggono, Arofi Kurniawan, Haryono Utomo, Maria Istiqomah Marini, Beta Novia Rizky, Mieke Sylvia Margareth Amiatun Ruth

118. Human Age Estimation Through DNA Metilation Analysis Method from Bite Mark Samples in Forensic Identification ........................................................................................................706
Ahmad Yudianto, Mieke Sylvia Margaretta AR, Fery Setiawan, Ma’rifatul Ula

119. Evaluation of Cusp Deflection in Teeth Restored with Various Manipulation Techniques and Types of Composite Restorations ........................................................................714
Ahmed A. Alquzweeni, Mustafa Basim Al-Talqani, Marwah Safaa Ali

120. The Role of Health Education in Promotion of Health Care Waste Management in Khartoum North Teaching Hospital ..................................................................................719
Ahmed Abu-Rayyan, Waed Alahmad, Fatima Fadul ALI Osman, Kamal Elbssir M Ali

121. Effect of Serotonin Concentration and Some Variables in the Sera 6 hours before and after Dialysis on Chronic Kidney Patients with Different Ages in Iraqi Population ..................................727
Ahmed Chyad Abbas, Ahmed Zuhair Alwaeli, Ebithal Chiad Abass

122. Estimation of the Biological Activity of Some Commercial Bleaching Solutions (Hypochlorites) on Pathogenic Bacteria ..................................................................................................731
Ahmed Salih Lateef, Ismail K. AL-Hitti, Atheer A. Khashan
123. Detection of the Some Dominant Aerobic Microorganisms in Burn Injury and Testing their Susceptibility for Different Antibiotics in Najaf

Ahmed Zuhair Alwaeli

124. Effect of Dentifrices with Different Abrasives on the Surface Roughness of a Nano Composite Resins materials

Ala'a Jawad Kadhim, Linz Ali Shalan

125. Coenzyme Q10 in the Follicular Fluid and Its Relation to Oocyte Maturity, Fertilization Rate, Embryo Grading, and Pregnancy Rate

Alaa Abdulateef Mohammed, Zainab Hassan Al-Khafajy, Ass. Prof Dr. Wasan Adnan Abdullhameed

126. Effects of VEGF Gene Polymorphisms on BEV Responsiveness in a Sample of Iraqi Colorectal Cancers Using HRM - PCR

Alaa Tariq, Wiaam Ahmed Al-Amili, Ahmed Zuhair Abdulhameed Alsammarraie, Waleed Jassim Mohammed Alserartee, Sarah Mohssen Mohammed

Alan Tom, Mohammed Salih, N Venkateswaramurthy, R Sambathkumar

128. Evaluation of immunoglobulins IgG, IgM, IgA and Complement Components C3 and C4 Levels in Iraqi full term Neonates with Severe Hyperbilirubinemia

Ali Abdulateef Hassan Al-bayati, Khitam Abdul-Wahhab Ali, Shaimaa Hamid Kareem Aljanabi

129. Aetiology and Findings of Recurrent Chronic Rhino Sinusitis with Nasal Polyposis after Functional Endoscopic Sinus Surgery

Ali Aziz Abed, Ragheed Turky Miteab, Ali Majid

130. Review: Cancer Cells Resistance Strategies

131. Efficacy of Hyaluronic Acid in Patients with Osteoarthritis of The Knee

Ali Hasanain Alhamadani

132. Changes in Interleukins and Follicle Stimulating Hormone in Toxoplasmosis Male Patients

Alia Salim Altemeemi, Noor Kareem Kadhim, Ghufran Saad Nsaif

133. Evaluation of the Acute Flaccid Paralysis Surveillance System of Polio Free in East Java, Indonesia, 2019

Alya Hanifa Rasyidi, Anik Suroiyah, Laura Navika Yamani

134. E-Cigarette Vaping and Periodontium: A Systematic Review

Ameer A. Altabatabaie, Ahmed A. Alquzweeni, Hussein A. Alnajar, Raya Ali Dalol

164. Purified Pyocyanin from Clinical Isolates of Pseudomonas aeruginosa Enhances Antibiotic Sensitivity Against Some Pathogenic Bacteria .............................................999
   Duaa Ghazi, Hasan Faisal Kahya

165. Efficacy of Plyometric Training on the Agility in Police Cadets ...........................................1008
   Dushyant Bawiskar, Pratik Phansopkar

166. Correlation between CD4 T lymphocyte and Candida Species Counts In Oral Candidiasis Patients with HIV / AIDS ..................................................................................1013
   Dwi Murtiastutik, Cita Rosita Sigit Prakoswa, Indah Setyawati Tantular, Evy Ervianti, Afif Nurul Hidayati, Muhammad Yulianto Listiawan

167. Epigallocatechingallate (EGCG) Antifungal Properties for Candida Isolates from HIV/AIDS Patients with Oral Candidiasis in Compare with Fluconazole .................................................1021
   Dwi Murtiastutik, Cita Rosita Sigit Prakoswa, Indah Setyawati Tantular, Yusuf Wirisono, Afif Nurul Hidayati, Sawitri, Muhammad Yulianto Listiawan

168. The Significance of CD4 to the Number of Grown Candida Colonies in Oral Candidiasis Patients with HIV / AIDS ..................................................................................1027
   Dwi Murtiastutik, Cita Rosita Sigit Prakoswa, Indah Setyawati Tantular

169. The Significance of CD4 to the Number of Grown Candida Colonies in Oral Candidiasis Patients with HIV / AIDS ..................................................................................1030
   Dwi Murtiastutik, Cita Rosita Sigit Prakoswa, Indah Setyawati Tantular

170. Impact of Bone Marrow Mesenchymal Stem Cells on Different Body Organs of Albino Rats Exposed To Cadmium Chloride Toxicity: A Systematic Review .....................................1038
   Elham H. Ahmed, Mohammed E. Grawish, Mohamed Abdulrahman, Menatalla M. Elhindawy, Mohamad E. Helal

171. Diagnostic Accuracy of Recto-Sigmoid Index Evaluation on Barium Enema in Hirchsprung’s Disease ......................................................................................................1045
   Emma Ratna Fury, Andy Darma, Alpha Fardah Athiyyah

172. Edible Oils Consumption and the Fatty Acids Profile of the Most Common Consumed Brands in Shiraz, Iran .........................................................................................1052
   Erfaneh Aalipanah, Enayat Berizi, Anoush Khamoushi, Morteza Zare, Zahra Sohrabi

173. Mitigation of the Biofilm Using Nanoparticles By Enhanced by D-alanine and D-proline ...............1062
   Fakhri Alajeeli
174. Detection the Serogroups of Escherichia coli isolates from Urine sample of UTI patients ..........1068
   Fakhri S.Ahmed Ph.D

175. Management of Non-Vital Teeth Discoloration with the Internal Bleaching : A Case Report ........1072
   Dewi Fitria Anugrahati , Rizky Ernawati, Windi Irsya, Yulianti Kartini Sumur, Sukaton, Kun Ismiyatin

176. The Relationship between Antithyroid Antibody and Pregnancy Outcome in Invitro Fertilization and Embryo Transfer............................................................................................................................1077
   Fawz Alaa alikhan, Azhar Mousa AL-Turiahi, Asceel Hassan Bader

177. The Effect of Conventional Method on the Length of Treatment Days for Children Underwent Circumcision at Poniran Khitan Centre Bengkulu .................................................................1087
   Ferasinta, Andri Kusuma Wijaya, Desri Suryani

178. Neutrophil Lymphocyte Ratio and Acid-Fast Bacilli in Tuberculosis ........................................1091
   Haerani Harun, Muhammad Nasir, Sumarni, Rosa Dwi Wahyuni, Dita aridhatamy, Nur Aulia Pratiwi

179. The Extent of the Need for Teaching Forensic Sciences for Law Students in Jordanian Universities 1097
   Hamzeh Abu Issa, Ma’en Juwaihan

180. Does Husband/Partner Matter in Reduce Women’s Risk of Worries?: Study of Psychosocial Burden of COVID-19 in Indonesia..........................................................................................................1101
   *Hario Megatsari, Agung Dwi Laksono, Yeni Tri Herwanto, Kinanty Putri Sarweni, Rachmad Ardiansyah Pua Geno, Estiningtyas Nugraheni, Mursyidul Ibad

181. Effectiveness of Playing Origami Intervention on Improvement of Fine Motor Development Pre School Children ...................................................................................................................................1107
   Harsismanto J, Larra Fredrika, Novia Wati, Padila, Desri Suryani, Yandrizal

182. The ITGA2B gene Polymorphism Associated with Glanzmannthrombasthenia in Sample of Iraqi Patients.................................................................................................................................1113
   Hayderkareemkataa AL-Aidy , EhabDawood Salman, Zaid Jamal Mahmood

183. Isotherms, Kinetics and Thermodynamic Studies for Removal the Valium from Stomach and Intestine Fluids via Adsorption on Egg Shells Powder........................................................................1121
   Hayfaa. J. Sinbah , Majida. H. Khazaal , Nadia. S. Majeed

184. Housing for Elderly in Nursing Home on the Level of Satisfaction in the work Area of Social Service of Surabaya .................................................................................................................................1130
   Hidayatus Sya’diyah, Sukma Ayu Candra Kirana, Diyan Mutyah, Ayu Citra Mayasari

185. The Correlation of DSD Teeth Outline Ratios to Q-Sort Smile Assessment and Smile Mesh Analysis ................................................................................................................................................1137
   Hussein A. Alnajar, Ameer A. Altabatabaie , Ahmed A. Alqzuweeni , Tholfqar majed

186. Pulmonary Artery Hypertension in Acyanotic Congenital Heart Disease Underwent Transcatheter Closure at Dr. Soetomo Hospital ....................................................................................................1143
   I Ketut Alit Utamayasa, Mahrus A Rahman, Taufiq Hidayat, Teddy Ontoseno
187. Correlation between Elevated Serum Progesterone in the Day of Hcg Injection, Metaphase II Oocytes and Their Impact on The Success of ICSI .................................................................1148
   Ibrahim Badr, Hesham Sayed, Yahia Mohammed, Ahmed Mohamed, Mohammed Shehata

188. Nutritional Status, Dust Exposure and Risk Factors for Acute Respiratory Infections for Workers in Industrial Estates ..............................................................................................................1156
   Ichayuen Avianty, Fakhirrrradih Luthfi, Suharto, Nanda Novziransyah, Kipa Jundapri, Rubi Ginanjar, Ade Saputra Nasution

189. Expression of FOXP1 and p53 in Reactive Lymphoid Lesion and B-cell Non-Hodgkin Lymphoma, Large Cell Type ..............................................................................................................1161
   Ita Ellyana, Nila Kurniasari

190. The Correlation between Body Mass Index and Lifting Frequency with Low Back Pain Complaints on Rice Transport Workers in Warehouse of Perum BULOG Subdivre Pematangsiantar.............1168
   Ita Riyana Limbong, Noeroel Widajati

191. Analysis of Genetic Variations And Specific Locus of Banjar Hulu Tribe Through Short Tandem Repeat (STR) Locus Combine Dna Index System (Codis) in Nuclear DNA ..............................................1175
   Iwan Aflanie, Roselina Panghiyangan, Pandji Winata Nurikhwan, Ahmad Yudianto, Toetik Koesbardiati

192. The Changes in Some Hematological Parameters among University Students Due to Stressful Conditions During and after Examinations Period ........................................................................1181
   Jehad F. Alhmoud, Husni S. Farah, Talal Al-Qaissi, Walaa Hamdan, Ghaleb A. Oriquat, Ali Atoom, Khalid M. Al-Qaissi

193. Nurse Educator-Led an Educational Intervention on Critical Care Nurses’ Knowledge Regarding Endotracheal Suctioning .................................................................................................1187
   Jihad Jawad Kadhim, Fakhria Gaber Mhabes

194. Relationship of Low Maternal Vitamin D3 Level and Adverse Early Neonatal Outcomes ...............1197
   Kawakib Hussein Noamam, Thikra Najim Abdulla

195. Caries Risk Assessment in Children Aged 6-12 years based on Parental Knowledge and Its Relationship with BMI and DMFT in Ahvaz ..................................................................................1205
   Leila Basir, Targol Amini, Shabnam Rasti

196. Perianal Care Proven to Reduce the Incidence of Diaper Dermatitis .................................................1212
   Lina Mahayaty, Nani Nurhaeni, Dessie Wanda, Fitriah

197. LIP Prints Patterns: A Study among the Aryan and Dravidian Ethnic Population in India- A Cross Sectional Study ..................................................................................................................1218
   Lubna Fathima, Suganya P, Sunayana Manipal, Prabu D, Bharathwaj, Raj Mohan

198. Detection of Endometrial TB in Patients with AUB using PCR Method of Assessment of Menstrual Blood Flow of Iraqi Females ......................................................................................1224
   Maad Mehdi Shallal, Farah Abdulhussein Salih Al-Asadi, Mohammad Ibrahim Mizaal
199. Nasal Polyps: An Etiological Analysis ........................................................................................................1231
   Magda Abd El-latif, Sayed Kadah, Ahmed Yehia

200. A study of Thyroid Function test and Lipid Profile in Pregnancy .......................................................1238
   Mahantesh Patil, Arpitha M R, Dayananda R, Meera S

201. Characteristics, Diagnosis, Management and Output of Persistent Pulmonary Hypertension of the Newborn at Dr. Soetomo Hospital ........................................................................................................1243
   Mardiyan Aprianto, Mahrus A Rahman, Martono Tri Utomo

202. Factors that affect on the Event of Lung TB in Jati Kudus Health Center .............................................1254
   Maria Ulfa, Windhu Purnomo, Rachmah Indawati

203. Study the Role of Ph in Curli Biogenesis Gene Expression in Enterobacter Cloacae Local Isolates........1260
   Marrib N. Rasheed, Basima Qasim Hasan Al-Saadi, Osama Mohammed Hasan, Noor Yahy Salmon, Sara Faisal

204. Neonatal Death Incidence in Healthcare Facility in Indonesia: Does Antenatal Care Matter? .........1265
   Masruroh, Ah Yusuf, Nikmatur Rohmah, Irfansyah Baharudin Pakki, Anita Dewi Prahastuti Prasojo, Qurnia Andayani, *Agung Dwi Laksono

205. Relationship between sexual desire and premenstrual syndrome in young women in Iraq ..........1272
   Miaad Jasim Mohammed, Ali A. Al-Fahham, Shukriyia Shadhan Al-OgaiI

206. Efficiency of Determination of Elemental Composition of Metals and their Topography in Objects of Biological Origin Using Spectrometers ..............................................................................1278
   Mikhailenko O.V., Roshchin H.H., Dyadik O.O., Irkin I.V., Malisheva T.A., Kostenko Ye.Ya., Gunas V.I., Hel A.P.

207. Association of Pure Tone Audiometry with DPOAE in Students after Shooting Practice at East Java State Police Academy, Mojokerto, Indonesia .................................................................1285
   Mochammad Ridwan Indiyana, H.M.S. Wiyadi, Artono, Nyilo Purnami

208. Pharmaceutical Mini-Tablets Overview ..................................................................................................1291
   Mohammad F. Bayan, Hala M. Sbaih and Mohamed J. Saadh

209. Relationship Between High Sensitivity TNF-α WITH clinical outcome During Admission In Acute Ischemic Stroke .....................................................................................................................1305
   Mohammad Saiful Ardhi, Mohammad Saiful Islam

210. Study the effect of purified alginate from Pseudomonas aeruginosa on Hep G2 and A549 cell lines. ................................................................................................................................................1309
   Mohammed S. Ismaieel, Muthanna Hamid Hassan

211. Efficacy and Safety of Sacral Neuromodulation in Treatment of Refractory Overactive Bladder ......1315
   Mohammed Bassil Ismail, Wameedh Qays Abdulhussein

212. Retinoic Acid Treatment of Human Hematological Malignancies Induces Caspase Dependent and Independent Apoptotic Cell Death .........................................................................................1322
   Mohammed S. Mohammed, Maha Fakhry Altaee, Ahmed Majeed Al-Shammari
   Muhammad Arif Sudianto Utama, Widodo Ario Kentjono

214. The Influence of the GETAR Spiritual Approach on Smoking Behavior of Junior High School Students in Palu City, Indonesia ..................................................1340
   Muhammad Ryman Napirah, Ridwan Amiruddin, Sukri Palutturi, Stang, Aminuddin Syam, Darmawansyah, Rosmala Nur

215. Teaching-Learning Styles & Aids Student’s Preferences among first Year Undergraduate Medical Students in the College of Medicine, University of Missan, Iraq.................................1346
   Mustafa M. Al-Yassiry, Farah K. Aloraibi, Haider Saadoon Qasim Alhilfi

216. The Exposure of Gap Competence causes in Stunting Children Ages 0-12 Months in Makassar Indonesia: Cross-Sectional Study .................................................1354
   Mustamin, Sirajuddin, Mahmud

217. The Interleukin-6 (rs1800797) Variant in Healthy Individuals at Medan City, North Sumatera Province ........................................................................................................1361
   Mutiara Indah Sari*, Siti Syarifah, Milahayati Daulay, Zaimah Z Tala

218. Effect of Malus sylvestris Extract on Histopathological Features of Hypercholesterolemic Wistar Rat (Rattus norvegicus) Fatty Liver .........................................................1367
   Nadhifa Tanesha Aufazhafarin, Alphania Rahmiayu, Ema Qurnianingsih, Arifa Mustika

219. Hyperglicemia in Childhood Acute Lymphoblastic Leukemia During Induction Chemotherapy ....1373
   Nengcy Erlina Tasik Rerung, Andi Cahyadi, Nur Rochmah, Maria Christina Shanty Larasati, Mia Ratwita Andarsini, Muhammad Faizi

220. Correlation of Hot Work Climate with Dehydration on Bricks Workers ........................................1379
   Nesya Shera Putri Iksani, Endang Dwiayanti

221. Equality of Suffrage for People with Mental Disorders in Malang City ......................................1387
   Nofi Sri Utami, Nanik Prasetyoningsih Kuswanto Kuswanto

222. Determining the Exposure of Benzene, Toluene, Xylene (in Condensate ) in a Chemical Laboratory of Natural Gas Company by Chemical Health Risk Assessment (CHRA) .........................1392
   Nora Putri Sabilla, Noeroel Widajati

223. A questionnaire-based Study of Knowledge and Attitude in Healthcare Professionals about Child Sexual Abuse related to POCSO (Protection of Children from Sexual Offences) Act: A Cross-sectional Study ........................................................................................................1398
   Nowsheen Goni, Mukesh Kumar Goyal, Chahat Shikarwar, Chahat Jangir

224. Level of Knowledge and Family Support toward Medication Adherence among Patient with Diabetes Mellitus in Malang, Indonesia..........................................................1406
   Nur Lailatul Masruroh, Alifia Fatehana Pangastuti, Nur Melizza, Anggraini Dwi Kurnia
225. Influence of Exercise Classics on the Development the Volume of Attention of Schoolchildren Aged 8-9.......................................................... 1414
Polevoy G. G.

226. The Possibility of Healing Deep Wounds in Rats Using Helium Neon Laser................................. 1419
Rabab Hajwal Al-Zamily

227. The Role of Legal Sociology in Terms of Covid-19: Large-Scale Social Restrictions (PSBB) in Indonesia ............................................................................................................. 1425
Rahayu Hartini, Yusufa Ibnu Sina Setiawan

228. Factors affecting The Occurrence of Tuberculosis Destroyed Lung..................................................... 1432
Retno Ariza Soeprihatini Soemarwoto, Anse Diana Mesah, Hetti Rusmini, Muhammad Arlek

229. Health Rights for Indonesian Migrant Workers in Malaysia: A Legal Perspective ....................... 1438
Rizka Rizka, Heru Santoso Wahito Nugroho, Arief Budiono, Wafda Vivid Izziyana, Ayesha Hendriana Ngestiningrum

230. Comparison of Clinical Characteristics and Neuroimaging of Cerebral Palsy with and without Epilepsy in Children.................................................................................... 1442
Rizka Yulianti, Prastiya Indra Gunawan, Darto Saharso

231. Association of rs865429 C/T polymorphism in SOST gene with Coronary Heart Disease in Iraqi Type 2 Diabetes Mellitus Patients................................................................. 1451
Ruaa Ali Mohammed Ali, Rasha Shaker Nima

Ruri Kharisma Fitriani, Lutfi Agus Salim

233. Molecular& Antifungal Susceptibility Identification of Candida albicans Isolated from Samples of GIT Children with Diarrhea in Diyala Province Iraq................................................. 1465
Sabah M.Ali, Sarah A. Dawood, Luma T. Ahmed

234. Markers of Bone Turnover in the Evaluation of Diagnosis and Prognosis of Multiple Myeloma in a Sample of Iraqi Patients ................................................................. 1472
Sadik A. Abdullah, Waseem F. Al-Tameemi, Ghassan A.A. Al-Shamma

235. Histological Effect of Androgenic Anabolic Steroids on Liver ................................................................. 1480
Sahar Dakhil Yonis, Asaad Abd Al-Hussain Mohammad Al-Shouk, Alaa S. Hachem

236. Teachers’ Attitude Toward Children with Attention-Deficit Hyperactivity Disorder (ADHD) at Primary Schools in Al-Nasiriyah City, Iraq....................................................... 1488
Saja Mahdi, Ali Kareem Al-Juboori

237. Guidelines for Maintaining Physical Fitness During COVID-19 Pandemic ........................................ 1495
Sakina S. Saifee, Angela Kapoor

238. Effect of Hemodialysis on Some Biochemical Parameters in Diabetic Nephropathy Patients ............. 1499
Salahaldin M. Fahad, Rashied M. Rashied, Waleed N. Jaffal

268. The Effect of Drinking Water Quality on Some Hematological Parameters In Female Laboratory Mice ........................................................................................................................................ 1702
   Zaman Subhi Madlool, Sara Omran Issa

269. Assessment of Nurses’ Knowledge Concerning Early Detection for Hypothyroidism/ Hyperthyroidism in Baghdad Teaching Hospitals .................................................................................... 1708
   Ahmed F. Hassan, Sabah A. Ahmed

270. Assessment of Employees’ Knowledge Concerning Contributing Factors and Early Detection for Prostate Cancer in Baghdad University Colleges in bab-Almudam ......................................................... 1712
   Haider M. Majeed, Hussein Hadi Atiyah

   Jasraj Kaur Bhamra, Waqar Naqvi

272. Morphometry and Morphology of Acromian Process of Scapula .......................................................... 1722
   Kinjal Jethva, Priyanka Sharma, Nirali Chavda, Hetal Vaishnani, K.M.Parmar, A.R.Gandotra

   Manpreet Kaur Bhamra, Waqar Naqvi

274. Estimation of Interleukin-4 (IL-4) and Interleukin-6 (IL-6) Levels in Sera From Patients with Type 2 Diabetes Mellitus .................................................................................................................. 1732
   Mazin Maky Thamer, Chee Fah Wong, Zafir Hassan Ghali

275. Glial Fibrillary Acidic Protein (GFAP) and Cleaved Tau Protein (CTP) Biomarkers as a Forensic Tool for Detection and Assessment of Traumatic Brain Injury ..................................................................... 1740
   Mohamed Kamel Mohamed, Mervat Hamdy Abd Elsalam, Eman Abd Elfattah mohammed Elzohairy, Dina Sabry Abd Elfattah, Ehab Abd Elhalim Abd Elsalam

   Nikita S. Deshmukh, Ashish Bele

277. The Accuracy of Intrinsic Compression Ultrasound Elastography (E-Thyroid) in Differentiating Benign From Malignant Thyroid Nodule ......................................................................................... 1754
   Najlaa Hanoon
278. Comparison of Success Rate of Estrus and Pregnancy between Laser Puncture and Intra Vaginal Progesterone Sponge in Bali Cattle

R. Tatang Santanu Adikara, Herry Agoes Hermadi, Warsito Sunaryo Hadi, Lita Rakhma Yustinasari

279. ACO-based Type 2 Diabetes Detection using Artificial Neural Networks

Aliakbar Tajari Siahmarzkooh

280. A Study for Assessment of Perception and Attitude of Medical Students about Medical Ethics, Consumer Protection Act (CPA) and its Influence on Violence against Doctors

Ankita Kakkar, Sushil Kumar, Archana Verma, Alok Kumar, Raj Kumar

281. To Study the Intervention of Bell’s Palsy by Video Self Modelling through Kinect Azure : A Research Protocol

Madhura R. Darware, Divya Jethwani

282. Impact of Bedaquiline on Multidrug-Resistant Tuberculosis Treatment to Mother and Baby: An Incidental Case

Tutik Kusmiati, Faradila Nur Aini

283. Migraine Headache and Gender Differences of Bagdad City Population/ Iraq

Wael Waleed Mustafa, Samer Shukur Mohammed, Zainab Ali Naser

284. Orofacial Tuberculosis: An Uncommon Manifestation of A Common Disease- A Narrative Review

Padma Charan Patra1, Priyadarshini Choudhury, Shamimul Hasan, Shazina Saeed

285. Role of Vitamin D For Oral Health and Overall Health

K. Sheela, Dhanasekhar Kesavelu

286. Knowledge, Attitude and Practice Towards Management of Trauma to Anterior Teeth among Faculty Members and Undergraduate Students in Dental and Medical Institute in South India

Vignesh Kamath, Harsha Hegde, Vijay Namdevrao Yannawar, Ganesh Ramesh Kotalwar, Amol Sangewar, Swapna Bettanapalya Venkatesh, Smitha Sammith Shetty

287. Effect of Sweet Potato Anthocyanin (Ipomoea Batatas L.) on Levels of Follicle Stimulating Hormone and Folliculogenesis in Rattus Norvegicus Exposed to Cigarette Smoke

Astika Gita Ningrum, Retty Ratnawati, Sri Andarini

288. Correlation between the Expression of E6 HPV with p53 and p16INK4A at Cervical Adenocarcinoma and Cervical Normal

Gondo Mastutik, Alphania Rahniayu, Nila Kurniasari, Anny Setijo Rahaju, Rahmi Alia

289. Correlation of Physical Activity with Fear of Fall in Patients with Total Knee Replacement - A Research Protocol

Nupur Thombare Shalaka Dhankar

290. The Risks of Femoral Nailing in the Positioning of Hemilithotomy on Traction Table Getting A Contralateral Well-Legdrop-Foot

Jasraj Kaur Bhamra, Manpreet Kaur Bhamra, Waqar M. Naqvi

291. Correlation between Workload and Work Environment with Work Stress

Shabrina Firsta Aulia, Putri Ayuni Alayyannur, Endang Dwiwanti, Tri Martiana, Shintia Yunita Arini
292. The Role of Ultrasonography in The Diagnosis of Oral and Maxillofacial Disease ......................................... 1853

Ni Putu Mira Sumarta, David Buntoro Kamdjaja, Roberto Manahan Yantie Simandjuntak

293. Association of Gamma-GT Serum and Nerve Conduction Velocity of Nervus Peroneus Motor Vehicles on Diabetic Polyneuropathy Patients ................................................................. 1859

Januar, Mudjiani Basuki

294. In situ Molecular Hybridization of Kaposi’s Sarcoma Associated Virus (Human Herpes Virus 8) in Nasopharyngeal Carcinoma Tissues ................................................................. 1865

295. Smoke Exposure at Home to the Incidence of Pneumonia in Children Under 5 Years Old.......................... 1872

Eny Dwimawati, Galuh Pradian Yamaringsih, Resmi Pangaribuan, Nina Olivia, Fitrian Pramita Gurning, Muchti Yuda Pratama

296. Factors Affecting Romantic Relationship Satisfaction of University Students ........................................... 1879

Kyu Eun Lee, Hae Kyung Chang

297. Video Self Modelling - An Intervention to Study Bell’s Palsy through Kinect Azure: A Research Protocol ...................................................................................................................... 1886

Madhura R. Darware, Divya Jethwani

298. The Association between Teeth Loss and Oral Health Problems ............................................................. 1892

Aesa Alzaroug Jaber, Alshame M.J.Alsame, Khaled Ovidat Abdalla, Prabhu Manickam Natarajan

299. Relationship between Inflammatory Response and Pathology of Listeria monocytogenes ......................... 1903

Ali Anok Njum, Jabbar Afate ALwan, Yasir Faisal Abbas

300. Epidemiological Study of Burn Deaths at a Tertiary Care Centre in Mumbai ........................................... 1907

Babaso Kalel, Pawan Sabale, Shailesh Mohite

301. Assessment of Occupational Stress in Medical Doctors Working in Tertiary Care Hospital .................. 1913

Dipika Baria, Tejas J. Shah, Shruti Brahmbhatt, Mahavir Rajput

302. Pre-Analytical Errors in Clinical Diagnostic Laboratory: A Crucial Step to Look for Accuracy and Reliability .................................................................................................................. 1919

Tejas J. Shah, Roshni Sadaria, Smita Vasava

303. Primary Prevention of COVID 19 ................................................................................................................. 1925

Preksha Luthra

304. A Critical Appraisal of Inclusions of “Bioethics in Laboratory Medicine” into the Existing Postgraduate Curriculum of Pathology, Microbiology and Biochemistry ........................................ 1933

Anjankar Ashish P, Ninave Sudhir, Mishra Gaurav V

305. Personal Hygiene Practices and Morbidity Pattern among A Tribal Primary School Children Of Maharashtra ......................................................................................................................... 1939

Ashish Wasudeo Khotragade, Ninad Nagrale, Mohd. Junaid

   Shruti Brahmbhatt, Vihang Brahmbhatt, Maulin Mehta, Tejas Shah

307. The Effect of Communication Ability of Care Workers in Charge of Visiting Care in Elderly at-Home Welfare Centers on Quality of Service: with Empathy as Mediator

   Hee Kyung Kim

308. Assessing the Training Needs Regarding ‘Breaking Bad News’ amongst Emergency Medical Services (EMS) Professionals in Pune India

   Parag Rishipathak, Shrimathy Vijayaraghavan, Dr. Anand Hinduja

309. Assessment of Awareness and Preparedness regarding Management of Major Traumatic Haemorrhage in Prehospital Settings amongst EMS Professionals, Pune, India

   Parag Rishipathak, Navnita Sengupta, Anand Hinduja

310. To Assess Awareness Regarding Child Abuse and Neglect , amongst Emergency Medical Professionals in Pune, India – A Pilot Study

   Parag Rishipathak, Monesh Bhandari, Anand Hinduja

311. To Assess Preparedness in Disaster Management among EMS Professionals in Pune, India

   Parag Rishipathak, Monesh Bhandari, Anand Hinduja

312. A Comparative Study Between Nineveh and Tikrit Medical School Teachers Perceptions regarding the Effectiveness of OSCE in Clinical Examination

   Wafa Mahmood Jasim, Zahraa Ahmed Hassan

313. Assessment of Nurses Knowledge about Alzheimer’s disease

   Hussein A. Dabis, Amer A. Sachit, Fatima J. Shinjar

314. Demographic and Clinicohistological Profiles of Women Diagnosed with Breast Cancer at Al-El Wiya Maternity Teaching Hospital / Baghdad: A Retrospective Study

   Zaynab S. Abdulghany, Najim Al-Kalidy, Maeda H. Mohammad, Noor H. Ismail

   Fatima J. Shinjar., and Ali T. Hameed, Hussein A. Dabis

316. Study of Prevalence of Placenta Previa and Circumstances among Pregnant Women in Fallujah Hospital

   Eman Gadban Saleh, Yousra Abdulaziz Mohammed, Mahmood Nezar Mustafa, Zahraa Mohammed

317. Assessment the effects of Mastic Gum Resin, Lawsonia Inermis and Quercus Brantii on Cutaneous Wound Healing in BALB/c Mice

   Kwestan Najm Ali, Hardi Fattah Marif, Hana Sherzad Raoof, Snur M. A. Hassan, Dereen Omer Ramzi

318. Clinical and Histopathological study of black and Red Grape Seed extracts (Vitis Vinifera) effects on the Albino Mice

   Snur M. A. Hassan, Shno N. Hassan, Nian N.N.Maarof

319. Detection of Pork in Canned Meat Products by using DNA-based Methods

   Alaa Tariq Abdulwahid
320. Effects of Adding Dry Mulberry Leaves (Morusalba) in the Concentrate Diet on Digestibility and Some Blood Parameters in Female Goats ................................................................. 2038
   Jassim E. Q. Al-Musawi, Wathiq A.H. AL-Jbory

321. In Vitro Production of Ovine Embryo in Non-Breeding Season ........................................ 2046

322. Isolation and Identification of Lactic Acid Bacteria from Buffalo’s Raw Milk in Basrah Province by Sequencing the 16S rRNA ................................................................. 2054
   Hiba A. Nasar, Samar S. Ghazi, Alaa T. Abdulwahid

323. Evaluating the Efficacy of Some Disinfectants, Sterilizers and Detergents Against Streptococcus Pyogenes Isolates from Tonsillitis Patient in Kirkuk City ........................................ 2060
   Aylan Arslan Ali, Shymaa Hassan Ali

324. Study the Role of Selenium or Zinc as Organic form on some Antioxidant and Liver Enzymes of Rams ........................................................................................................... 2066
   Mohannad. K. Aremnt, Saad Thabit Jassim Alrawi, T.R. Mohammed

325. Cytotoxic activity of Green Zinc Selenide Nanoparticles Against Hep-G2 Cell Lines ............ 2072
   Sabah N. Mazhir, Kadhim A. Aadin, Mohammad M. F. Al-Halbosiy, Nisreen Kh. Abdalameer

326. Cytotoxicity of lipopolysaccharide extracted from Salmonella enterica serovar Typhimurium on Breast Cancer Cell Line mcf-7 ........................................................................ 2079
   Wissam Qadry Mutaab Alqaissy, Aziz L.M., Abdul-Rahman Ibrahim A.

327. Detection of Antiseptic Resistant Genes in Colistin- Resistant Pseudomonas aeruginosa and MDR Klebsiella pneumoniea .................................................................................................................. 2092
   Noor S. Hassan, Mohamed F. Al –marjani, Nadema H. Hussain

328. Detection of HMA5, PCs and MT2 Genes Expression in Vicia faba Under Heavy Metal Stress Using Quantitative Real-Time PCR ................................................................. 2102
   Khalid H. Alobaidi, Zaid N. Altememi, Dhafar N. Al-Ugaili, Jameel R. Al-Obaidi

329. Detection of Tn916 Conferring Tetracycline Resistance in Clinical Isolates of Streptococcus pyogenes . 2109
   Hameed M. Jasim, Abbas Aboud Farhan, Hanan Raheem Hassooni, Adil Hassan, Alhussein

330. Effect of Soft Cheese in Reducing of Lipid Profile and Liver Enzymes for Rats with Fat Disorder ..2114
   Hiba Sabah Elttayef, Mohammed Ahmed Jassim

331. Investigation of Lumpy Skin Disease Virus in Baghdad City ............................................. 2121
   Rasha Basim Abdullatif, Aida Bara Allawe

332. Laboratory Evaluation of the Entomopathogenic Fungi Penicillium Marneffei and Verticillium lecanii Against Culex Pipeins Molestus .................................................................................................................. 2126
   Rabah H Saady, Abdulrahman Jihad Mansoor

333. Molecular Characterizations of a High Pathogenic Avian Influenza H5N8 in Iraq ..............2134
   Ahmed Neama Mahmood, Aida Bara Allawe
334. Novel Molecular Detection of BPV-10 and BPV-11 Genotypes in Al- Anbar, and Baghdad Provinces... 2141

335. Stimulation of Staphylococcus aureus Ligase Enzyme by Magnesium Ion........................................... 2148
Arqam Mohamad Alomari, Aseel A. H. Al-Layla, Ibrahim Faris Ali

336. Study of Bacterial Contaminants and some Chemical Elements of the Euphrates River and Al-Fallujah City Drainage ................................................................. 2157
Shaimaa M. Dawd

337. Study of some Immunological Variables Resulted from Balb/c Mice Injection with Hydatid cysts Protoscolex Antigens ............................................................... 2163
A. O. Humide, Abbdalwahab Hussain, Ezeddin A. Albayyar

338. Study of the Biochemical Markers of Liver and Renal Function in Moderate -To- Heavy Cigarette Smokers’ Men in Mosul City ................................................... 2169
Enaam Ahmed Hamza Al-Dagestani

339. The Effect of Dual-Species Biofilms, Monosaccharide and D-Amino Acids on Pseudomonal Biofilm .................................................................................................................... 2177
Al-Moghira Khairi Al-Qaysi; Safaa Abed Latif Al-Meani; Mushtak T.S. Al-Ouqaili

340. Isolation and Analysis of Nucleotide Sequences of the 16S rRNA Gene of Pseudomonas aeruginosa Isolated from Clinical Samples.......................................................... 2193
Atheer Abdulameer Raheem, Hasanain Khaleel Shareef

341. The Effects of Different Intensive Physical Performances by athletes on Selected Hematological Parameters ................................................................. 2199
Shumoos H Alwaid

342. Role of CoQ10 and IGFBP-1 in Obese Male Patients with Diabetic Mellitus Type II ...................... 2204
Dina A. M. Al-Khafajy, Maysaa J. Majeed, Omar F. Al-Azzawi; Ayad Ismael Khaleel

343. Histological and Morphological Study of Carcinoma Breast of Women ............................................ 2210
Aaya Hamid Al-Hakeem, Marwa Ahmed Meri

344. Isolation and Molecular Identification of proteus mirabilis isolated from hospitals in the capital Baghdad ........................................................................................................... 2216
Mohammed Kaittan Abed, Hasanain Khaleel Shareef

Hind Shakir Ahmed, Hiba Shakir Ahmed

346. The Effect of Training with Rubber Ropes and Controlling the Resistance Arm on the Response Time and some Biomechanical Variables for the Skill of Sending for Wheelchair Tennis Players ... 2232
Maytham Hadi Mahdi

347. Antioxidant Activity and Phytominerals Study of Some Asteraceae Species Growth in Western of Lraq ............................................................. 2239
Assistant prof., Lecturer, College of Education for women, University of Anbar, Iraq; Ashwaq Talib Hameed, Nbaa Mutea Abid Al-ah, Asmaa Wajeh Jumaa
348. The Influence of Cement Spacer Thickness on Retentive Strength of Monolithic Zirconia Crowns Cemented with Different Luting Agents (A Comparative in-vitro Study) .................................2246
Reyam H. Ali, Mohammed Kassim

349. HIV/AIDS Status in Baghdad/Iraq Over Ten Years (2010-2019) ...............................................................2253
Jalil Ibrahim Saleh PhD, Haitham Numan, Nawar Sahib Khalil Ph.D.,

350. Molecular Detection of nan, tly and dsA gene of Propionibacterium acnes Isolated from acne vulgaris in Babylon Province ...........................................................................................................2260
Rabab J H AL-Hasseny, Lamees A. Abdul-Lateef, Hussein Abbas AL-Sultany

351. Effect of Cinnamon Gargel on Healing of Aphthous ...........................................................................2266
Raïda Noori Hamid, Rehab Faisal Ahmed, Wedad Farhan Jabber

352. GC-Mass Spectrometry Analysis of Iraqi Moringa Oleifera Seeds Extract ................................................ 2274
Fiham Jassim AL-Obaidi, Abid A. Thaker, Asmiet Ramizy

353. Correlation Between Serum Ferritin And Liver Function in Thalassemia Patients ...............................2279
Zainab Qasim Muhammad Al-Yasiri

354. Histo-morphometric, Histochemical Solidity Ruling of the Small Intestine in Hamsters and Rabbit According to Different Food ...........................................................................................................2288
Raad Shaalan Ibrahim, Farah Jameel Alhnon, Sarah Shareif Akool, Najlaa Awaied Al-Mansour

355. Awareness of Health Workers in Premature Units At Kirkuk City Hospitals Concerning Neonatal Jaundice .................................................................................................................................2295
Wijdan Abdullameer Kamel, Chateen Jihad Rauf

356. Study of Some Immunity Characters Results of Injection antigenic Staphylococcus sp. in Local Rabbits 2303
Roua Jamal AbdulKhaliq, Hiba M. AlKhateeb, Abdalwahab Bdewi Hussain, A. O. Humide

357. Correlation between Women’s Attitudes and Abstain (Used/Unused) Contraceptive Methods at Primary Health Care Centers in Baghdad City ....................................................................................2309
Maha Khaled Rida, Hawraa Hussein Ghafeel

358. Clinical and Histopathological Study of Diclofenac Sodium- Acetylsalicylic Acid Toxic Effect on Liver of Mice ........................................................................................................................2314
Rana Abdulla salah

359. Dietary Habits of Iraqi Women with Breast Cancer at Oncology Hospitals in Baghdad City: Comparative Study ...........................................................................................................................2322
Hadeel Mousa Mahalhal, Hawraa Hussein Ghafeel

360. Parents’ Knowledge Concerning School Phobia of their Children in Baghdad City, Iraq ......................2329
Abdulmahdi A. Hasan

361. Maternal Anxiety Levels with Newborns in the Neonatal Intensive Care Unit at Hilla Maternity and Childbirth Hospital in AL-Hilla City .................................................................2336
Abdulmahdi A. Hasan
362. Pathological Study of Reproductive Tracts of Awassi Ewes in Fallujah, Iraq
   Ahmed Sami Jarad, Abdul Sattar Faraj Majeed, Qusay Mohammed Aboud, Mustafa Salah Hasan, Waleed Hamid Farhan Ahmed Emad Aboud

363. Incidence Rate and Risk Factors of Ectopic Pregnancy at Maternity Wards in Baghdad City’s Hospitals for the Year 2019
   Heba Samir Naje, Hala Saadi Abdul Wahid, Ekhlas Ali Hussein

364. Lip Thickness with Tongue Space Area Assessment By Cephalometric Analysis for Iraqi Adult Sample with Class II Dental and Skeletal Pattern
   Laith Hamood AL-Salmany, Zena Hekmat Altaee, Ahmed Jassam Al-Naqeeb

   Muthanna S. Farhan, Maadh H. Ahmed

366. The Sensitivity of some Types of Citrus Fruits, the role of the Propolis and the Color of Storage Bags in the Development of Green Mold Caused by Fungi Penicillium Digitatum
   Hiba Hashim Younes, Wa’ad Hamoudi Awad, Theyab A. F. Al-Esawee

367. The response of Brahimi apple’s Cultivar to Foliar Application of Glycyrrhizin Extract (GLE) and Humic Acid (HA)
   Duaa Flaih Hasan Al-Mehemdi, Ali Ammar Ismael Al-Ani

368. A Comparative Study of Cognitive Achievement in Football Among Students who Have Different Learning Styles
   Mohammed Saad Jebur, Jasim Saleh Majon, Hayder Abdulhafdh Shehab

369. Guggulsterone Suppresses Ovalbumin-Induced Inflammation in Rat Asthmatic Model
   Zainab H. Ahmed, Munaf H. Zalzala, Manal A. Ibrahim

370. Study the Role of Helicobacter Pylori Infection in a Group of Iraqi Patients with Colorectal Cancer
   Walaa Talal Abdul-Lateef, Essam Mohammed Abdelullah, Jassim Mohsen Ghadhban

371. A Reliable Quantification Method for Trimethoprim in Pharmaceutical Samples by HILIC-HPLC
   Zahraa Muhsen Hussein, Ashraf Saad Rasheed

372. Assessment of Serum Concentration of Ghrelin and Obestatin in Giardia lamblia Infected Patients: A Case Control-Study
   Rana Talib Al-Nafakh, Hawraa Ameer Mubark, Raad Abdul-Ameer Al-Asady

373. Evaluation of the Efficacy of Beauveria bassiana in Controlling the Periplaneta Americana in Iraq
   Qutebh Ahmed Hajm, Hushm Naje Hmed

374. The Effect of Biomarker (IL-8) on the Tissue of Colorectal Cancer Patients by using IHC Technique
   Zinah Saad Madhloom, Aqeel Shakir Mahmood, Alice Krikor Melconian

375. Prevalence and Risk of Leukemia Reported Cases, Observational Descriptive Statistic from Iraqi Center for Hematology in Baghdad Province
   Ruaa Hameed Abdulridha, Nada Kadum Jawad, Ahmed Tariq Numan
376. Detection of Fungal Toxins Produced by Dermatophytes by using Thin Layer Chromatography
   Abeer Mohammed Ali Al-garawy, Adnan H. Al-Hamadani, Adnan waheed AL- Bederi
   .......................................................... 2434

377. Possible Protective Effects of high- versus low- dose of lutein in combination with irinotecan on
   Liver of Rats: Role of Oxidative Stress and Apoptosis
   Alaa Radhi K, Nada N. Al-Shawi
   .............................................................................................................. 2439

378. The Association between Severity of Dental Caries and Salivary Immunoglobulins in Asthmatic
   Adult Patients
   Ahmed AbdulRazzaq Hammoodi Al-Anbari, Maha Adel Mahmmod AL-Ani
   ..................................................................................................................... 2446

379. Phenotypic and Molecular Characteristics Of Biofilm and other Virulence Genes in E. coli and K.
   Pneumoniae Isolates from Healthy Dairy Cow, Human and Environmental Sources
   Ali A. Kadhum, Mohammed H. Khudor
   .......................................................................................................................... 2452

380. The effect of Exercises By Pressing -Style to Developing A Man-to-Man Defense For Young
   Football Players
   Qasim Muhammad Ali Hazim Ahmed Abdulameer Hamzah
   .......................................................................................................................... 2459

381. Assessment of Mothers’ Knowledge about Febrile Convulsions of Children at Ibn- Albalady
   Hospital in Baghdad City
   Ali Obaed Shneshil
   .......................................................................................................................... 2465

382. Is there an Impact of PAI-1 on the Thrombotic Episode in Iraqi Obese Patients with Corona Virus
   -19
   Elham Abed Mahdi
   .......................................................................................................................... 2471

383. Molecular, Biochemical, and Phenotypic Identification of Phenol and Cresol Degrading Acinetobacter
   baumanni Strain Selected from Al-Rumaila Oil Well
   Noor Mohammad Ali, Aamal Ghazi Mahdi Al-Saadi
   .......................................................................................................................... 2480

384. Evaluating Growth Charts Use among Children Less Than Five Years of Age at Primary Health
   Care Centers in Al-Hillah City
   Muna Abdulwahab Khaleel
   .......................................................................................................................... 2490

385. Complications of Kalazar among Children in Hilla-city
   Ibtesam Khalid Kamil
   .......................................................................................................................... 2495

386. Assessment of Diabetes Patient Adherence to Dietary Recommendation in Diabetics Center in
   Al-Najaf city
   Iman Qasim Kteo Al-hussein , Zahraa Abdull Abbass Taher Al- Khafajy , Haider Mohammed
   Halooob AL- Abedi , Athraa Abbas Al-Zeyadi
   .......................................................................................................................... 2500

387. Impact of Adolescents’ Life Style and Reasons of Skipping Essential Meals upon their BMI at
   Secondary Schools in Baghdad City
   Buthainah Basheer Saleh, Eqbal Ghanim Ma`ala
   .......................................................................................................................... 2507

388. Effectiveness of Some Relaxation Exercises Use by Nurse in Assessment of Vital Signs
   Alaa Abraham Saeed , Sabah Abdullah Jaafar, Dergham Majeed Hameed
   .......................................................................................................................... 2515
389. Effect of Diabetes and Hypertension on Right Carotid Artery Intima Media Thickness and Variable Spectral Waveform Indices And Parameters in Relation To Age for Iraqi Patients

Samar I. Essa, Ahmed Abduljabar Al-Sabbagh, Satar M. Kadam

390. The Effect of Using Competitive and Traditional Methods in Learning Some Basic Gymnastics Skills

Zaid Sami yasir, Diaa Fadel Abbas, Hayder Naji Habash Alshawi

391. Evaluation of Antioxidants Capacity of Non-Enzymatic Antioxidants and its Effect in Glucose Level in Diabetic Patients

Rana Fadhil Mousa

392. Measurement of GSH, SOD and MDA some Antioxidant level after Excises Athletes

Harith Abdelelah Alshukri, Mazin Hadi Kzar, Aied Kareem Abdaun

393. Health Consequence of Gas Filling on the Workers’ Health of Two Cities in Iraq (Comparative Study)

Hussein Ali Mohammed, Wijdan Abdulameer Kamel, Abid Salih Kumait

394. Non COVID Symptoms and its Impact on Quality of Life among the Professionals Residing at Pune City

Sharadha Ramesh, Poonam Yadav

395. Impact of Years’ Experience upon Nurses’ Knowledge and Practice concerning Infection Control at Critical Care Units in Baghdad City

Wafaa Abd Ali Hattab, Alaa Jawad Kadhim, Musaab Majid Abdulwahhab

396. Detection of Biochemical Causes the Diabetic Retinopathy in Diabetes (Type II) Patients in Al-Muthanna Province

Yusra Ali Hameed, Jawad Kadhum Muraih

397. Evaluation of Marginal adaptation at Interfaces Using Composite Resin to Different Setting Amalgam Filling in Class II Cavity Preparation

Mohammed Kassim Gholam, Biland MS Shukri, Haider Hasan Jasim

398. Brain habits, Accuracy and Its Relationship to Self-Confidence for Handball Players

399. Chronic Myeloid Leukemia and Associated Oral Manifestations

400. Legalizing speed Endurance Training According to Some Physiological Indicators for 800-Meter Runners for Youth

Mohammed Amanah Kaittan, Emad Amanah Kaittan, Ahmed Abdulrazzaq Fadhil

401. Salivary Changes with the Age and their Effect on Plaque Related Disease

Haider Adnan, Suha Abdulhussein Hindy, Ali Zaki Naji

402. Evaluation of Morphological (Macroscopic and Microscopic) parameters of placentas in pregnancies complicated by Preeclampsia, Diabetes and Preeclampsia and Diabetes

Malak A. Al-yawer, Nameer F. AL-Kalifa

Socio-Demographic Profile of Fatal Poisoning in a Tertiary Care Teaching Hospital of Coimbatore District-A Retrospective Study

Angayarkanni S1, Jeyasingh T2
1Assistant Professor, Institute of Forensic Medicine, Madras Medical College, Chennai, 2Professor and Head, Department of Forensic Medicine, Coimbatore Medical College, Coimbatore

Abstract

Background: Poisoning poses a major public health problem mainly in developing countries. Because of the rapid industrialization and advancement in agricultural sector, fatality by poisoning also increases day by day. The aim of this study is to determine the socio-demographic profile of fatal poisoning in Coimbatore District. Methods: This retrospective study was carried out in Department of Forensic Medicine, Coimbatore Medical College, Coimbatore, Tamil Nadu with data obtained from fatal poisoning cases brought for postmortem examination from January 2016 to December 2016. Identification of specific poisons were done with chemical examiner’s report. All collected data were analyzed in various possible aspects in the prepared proforma. Results: During the study period the total number of medico legal autopsies conducted were 3675 out of which fatal cases due to poisoning were 600(16.33%) cases. The study showed that the incidence of poisoning was more common among married men ie.303 cases (50.5%) out of 600 total number of poison cases. The incidence was more common in the age group 31 – 40 years in males (86 cases) which formed 14.3 % and in females it is 21-30 years (65 cases) which formed 10.8%. When we observed the religion wise distribution, Hindu males out numbered 369 out of 600 cases which formed 61.5%.

Conclusion: Morbidity and mortality due to poisoning can be minimized by health education, early referral, establishment of toxicological units for detection of specific poisons and appropriate guidance for proper management of poisoning cases at hospitals and primary health care centers.

Key words: Socio-demographic profile; poison; autopsy

Introduction

Poisons were known to antiquity. References to the poisons were found in ancient records worldwide. In prehistoric periods, there were professional poisoners. Orfila, who in nineteenth century brought precise chemical methods in toxicology is considered as father of Modern Toxicology. The first treatise on Indian Medicine was the Agnivesa Charaka Samhita written in seventh century BC. The first textbook on poisons was written by Mathew Joseph Orfila in 1814.

Because of the rapid industrialization and advancement in agricultural sector, the incidence of poisoning is spreading like a wild fire. The chemical substances that are developed to save the agricultural products from rodents and pests act as a double edged sword to mankind. Though there are advancement in medical research and treatment, death due to poisoning still remains in the higher side and it keeps on increasing day by day.

Death due to poisoning is significant medically, legally and socially. Fatality by poisons may be suicidal, homicidal or accidental. Suicidal poisoning is more

common. Accidental poisoning occurs in children less than 5 years of age. Homicide by poison is rare. WHO estimated that approximately 3 million poisoning cases occur worldwide of which 22, 00,000 deaths occur per year. More than 90% of the cases are being reported from developing countries like India and Srilanka.

The aim of this study is to determine the socio-demographic profile of fatal poisoning in and around the Coimbatore city.

**Materials and Methods**

This retrospective study was carried out at the Department of Forensic Medicine and Toxicology, Coimbatore Medical College, Tamilnadu. Details were collected from the history of the case, treatment history and records, inquest papers, autopsy reports and chemical examiners report. Details of fatal poisoning cases brought for postmortem examinations from January 2016 to December 2016 were collected.

We used standard proforma to obtain data from the records to ensure consistency for the whole sample. Information collected includes age, sex, place of death, religion, marital status, medical treatment given, manner of death and chemical analyzer’s report. The collected data was statistically analyzed.

**Results**

This study revealed that a total of 3675 medico legal autopsies were conducted from 1st January 2016 to 31st December 2016 of which poisoning cases constituted 600 (16.3%) (Table 1)

Fatality in males outnumbered the females. Male female ratio being 2.03:1(Table 2) Out of total 600 cases, number of deaths in males is 401(66.8%), in females 198(33%) and in transgender 1(0.001%). Incidence of death by poisoning is more in the month of January 2016, 61 cases (10.2%) followed by 56 cases in February (9.3%) and in April 55 cases (9.16%)(Table 2)

In males, incidence of death by poisoning is more 86 cases in the age group 31-40 (14.3%) followed by 80 cases in age group 21-30 (13.3%),78 cases in age group 41-50 (13%), 69 cases in age group 51-60 (11.5%) , 34 cases in age group 61-70 (5.7%) , 26 cases in age group more than 70 years (4.3%), 24 cases in the age group less than 11-20 (4%) and 4 cases in the age below 10 years(0.6%) (Table 3)

In females, incidence of death by poisoning is more 65 cases in the age group 21-30 (10.8%) followed by 38 cases in the age group 31-40 (6.3%), 22 cases in age groups 51-60 and 61-70 (3.7%), 21 cases in age group 11-20 (3.5%),20 cases in the age group 41-50 (3.3%), 10 cases in age group more than 70 years (1.7%) and nil cases in the age group less than 10 years (Table 3)

In the present study, most of the cases were suicidal 596 cases (99.3%) followed by 4 accidental deaths(0.7%) Accidental poisoning occurs in children less than 10 years of age. There were no homicidal poisoning reported during the study period (Table 6)

**Discussion**

Whatever may be the manner of death, any unnatural death is a tragedy which wastes the precious human life and resources. In the present study male poisoning deaths are more than twice the female deaths with male to female ratio of 2:1. This is consistent with the results in the study conducted by A K Kapoor et al. This is supported by a similar study conducted by A K Batra et al which revealed male poisoning deaths more than twice the female deaths with male to female ratio of 1.0:0.49 which is maintained in more or less same in all age groups., B.R.Sharma et al in which males outnumbered the females, the male: female ratio being 2:1, Dr Kartik Prajapati et al which showed the male poisoning deaths 1.33 times more than the female deaths with a male to female ratio of 1.8:1, Alakesh Halder et al, Dr.S.S.Sandhu et al in which males are most affected than females in deaths by poisoning i.e
75.5%, B.D.Gupta et al⁷ in his study reported that males were prone to death by poisoning (62.1%) compared to females (37.9%) , Rajani V.Bhagora et al⁸ , in this study, poisoning death cases were higher as (57.58%) in males than in female deaths (42.42%). In their study, Dr.S.K.Chaudhary et al⁹ reported that the death due to poisoning in male population was 1.36 times more in comparison to female population with male to female ratio of 1:0.73, B.Suresh Kumar Shetty et al¹⁰ in their study observed that males outnumbered females constituting 69.2% (n=90) and 30.8% (n=40) of cases respectively with a male-female ratio of 2.3:1. In our study the most affected age group of fatal poisoning is 31-40 in males and 21 -30 years in females which is supported by a similar studies done by A K Batra et al² Dr.S.S.Sandhu et al⁶, B.D.Gupta et al⁷, Rajani V.Bhagora et al⁸, V.Koulapur et al¹¹ whom in their studies have reported that the fatal poisoning is more in third and fourth decade whereas it is less common in extremes of ages. This study revealed the maximum number of fatal poisoning occurred in married men. This finding is supported by the similar studies conducted by A K Batra et al², Dr.Kartik Prajapati et al⁴, Dr.S.S.Sandhu et al⁶ who reported that married persons (both sexes combined) outnumber the unmarried persons and constitute for over 62%, 62% and 57.6% deaths respectively. Dr.Virendar Singh et al¹² also observed that more married men (61.28%) were victims than unmarried men in his study. In our study, the incidence of death by poisoning is more in January 61 cases (10.2%) followed by higher incidence in February 56 cases (9.3%) and April 55 cases (9.16%). This is supported by a similar study by Kondrostami et al¹³ which reported that spring and autumn were the most troubling seasons regarding suicidal deaths. In the study conducted by A.K.Kapoor¹ maximum incidence of suspected poisoning admissions were recorded in the summer season comprising of 120 cases (39.9%) followed by monsoon season (32.6%), while for poisoning deaths, a total of 86 cases were recorded in the rainy season (41.9%), followed by summer (36.6%). Both in suspected poisoning cases and suspected poisoning deaths, a minimum incidence was noted in the winter months. In April 2003, a maximum of 34 cases of suspected poisoning were admitted whereas in August 03, a maximum of 28 poisoning deaths were recorded. In a study by A K Batra et al², these peaks were noted in mid-monsoon months of August and September, probably due to socio-economic reasons like monsoon-dependent cultivation practice, agriculture-based economy, crop failures, exorbitant rates of interest and indebtedness to private usuries, financial crisis, hunger, denied minimum wages and increased work and labor pressure in rainy season which lead to constant anxiety coupled with an easy availability of insecticidal poisons, as it is purchased and kept at forms and houses for use when the agricultural activities are at its peak. In the study done by Dr.S.Chaudhary et al⁹ maximum number of poisoning deaths were observed in month of May (13%) followed by month of March (11%) but statistically no seasonal trend is observed in the total number of events. Most of the poisoning deaths in the study conducted by B.Suresh Kumar Shetty et al¹⁰ were reported during the rainy and summer seasons. In a study conducted in Singapore (14), which has two monsoon seasons, the peaks for Indian suicides were noted in April, September and November. In the present study, poison deaths were highest in Hindus, 560 cases out of 600 (93%) followed by 24 cases in Christians (4%) and 16 cases in Muslims (2.6%). This is supported by similar studies (4;7;9) where the maximum number of deaths by poisoning were seen in Hindus when compared to other religions. Incidence of fatal poisoning was more in Hindu people (92.40%) as compared to Muslim (07.60%) in a study conducted by Dr.Kartik Prajapati et al⁴, B.D.Gupta et al⁷ concluded that most of the victims were Hindus, which can be explained by the fact that major population of India is Hindu. Dr.S.Chaudhary et al⁹ in his study reported that the incidence of fatal poisoning was more in Hindus (89.90%) as compared to Muslims (10.10%). In our study, the percentage of cases on manner of death is revealed as suicidal deaths 99.3% (596 cases), accidental in 0.7% (4 cases) and no homicidal cases. B.Suresh Kumar Shetty et al¹⁰ in their study stated that intentional self-poisoning constituted 79.2% (n=103) of these deaths, followed by accidental consumption of poison (19.2%). No case of homicidal poisoning death was reported during the study period. In two cases the manner of death remained undetermined. This report from our study is further supported by the study conducted by Tanuj Kanchan et al¹⁵ in which manner of death was reported as suicidal in 92.9% cases (n = 13) and accidental in one case (7.1%).

Conflict of Interest: None
Source of Support: Self

Ethical Clearance: Ethical clearance and funding were not necessary as it was a retrospective study which included only collection of data.

Abstract

Background: Menopausal women shows common symptoms which includes night sweats and hot flushes, heart distress, disturbances in sleep, depression, irritability, anxiousness, weight changes, physical and mental fatigue, joint and muscle pain. This affects the Quality Of Life of the Menopausal women. Pilates Training has proven beneficial for enhancing Quality Of Life in menopausal women but there is paucity of evidence of effect of Progressive Muscle Relaxation Technique in Menopausal women on QOL. The research is an initiative study that focuses on the effectiveness of PMRT on the various aspects of Quality Of Life of the menopausal women and comparison of the Pilates training and PMRT in order to enhance the QOL of participants.

Aim and Objective: Effect of Pilates training & Progressive Muscle Relaxation Technique on menopausal women’s Quality Of Life and comparison of both the technique.

Methods: 42 participants aged more than 45 years will be randomly categorized in two groups: Group A (n= 21) and Group B (n=21). The study duration will be of 6 months. The pre and post Intervention will be taken from both the group and data will be analyzed with the help of main outcome measure which is Menopause specific Quality Of Life (MENQOL).

Result- The expected result would include the details about whether the measures are effective for improving the quality of life in menopausal women, as well as the comparison of both the interventions. Data will be analyzed using paired t-test.

Conclusion- It will be published after results are analyzed

Keywords- Menopausal women, Quality Of Life, Pilates, Progressive Muscle Relaxation Technique.

Introduction

The concept of menopause is a complete cessation of ovarian function¹. Mean age for Indian women in menopause is 44 years. The symptoms peak between 45 to 55 years and decrease in severity after 55 years².

Most common symptoms of menopause include muscle and joint pain, slow feeling, poor memory, lower back pain and trouble sleeping. The vasomotor and emotional domains reported less often compared with the physical and psychological domains². About 75 per cent of women are reported to experience acute symptoms after menopause. Such adverse changes in physical and mental health may have an adverse effect on Quality Of Life (QOL) as they undergo transition
from menopause. The self-administered questionnaire that works well to classify women by their QOL and find out how their QOL benefits is known as Menopause-specific Quality of Life (MENQOL) questionnaire.

Pilates is a therapeutic exercise intended to enhance strength, stabilizer core muscles, endurance, muscle coordination, posture and respiration. Exercises can be done on mats or require the use of specialized equipment and the concepts of Pilates include centering that occurs by tightening of the body’s muscle core between the ribcage and the pelvic floor throughout exercise, focus where cognitive focus needed to accomplish the activity, balance that needs the posture and movement control throughout the activity, precision that allows the accurateness of the technique of exercise, flow to get smooth movement changes within the course of exercise and most importantly, respiration that needs proper inhalation and exhalation of air from the lungs in combination with the exercise. The Pilates mat training regimen results in young women’s physical and psychological health in terms of body weight, slimming, anxiety, depressed mood, tiredness and quality of life. Pilates helps to enhance both the mental and physical components in women during menopause.

Relaxation offers or helps to reduce anxiety, muscle tension and controls the pain. Progressive muscle relaxation technique (PMRT) is a therapy used since Edmond Jacobson’s implementation in 1938. PMRT involves tensing a muscle and then relaxing the tension; it is based on the psychological claim that people with stress and anxiety have tensed muscles and are able to relieve their pain both mentally and physically by learning how to relieve the tension. Music-accompanied PMRT can be a beneficial therapy to improve pain and QOL in pregnant women with LBP. Relaxation techniques lowers tension rates and enhance autonomic functions, cardiopulmonary performance and lipid profile. Researches had been conducted which shows positive effect of PMRT on cardiac patients, insomnia, chronic pain, anxiety. But there is paucity of evidence of PMRT effect in menopausal women on the QOL.

Sagdeo et al., 2011 conducted a study at Nagpur included 500 cases including 250 cases of rural and urban women stated that Indian scenarios should offer priority to menopausal health as menopausal women have improved life expectancy and population growth and presenting complaints which includes night sweats and hot flushes, heart distress, disturbances in sleep, depression, irritability, anxiousness, weight changes, physical and mental fatigue, joint and muscle pain, bladder problems, vaginal dryness.

Ghafari et al., carried out a review in the year 2009 on 33 diagnosed multiple sclerosis patient stated that PMRT is convenient and contributed to improving quality of life for multiple sclerosis patients.

Akbaş E et al., carried out a review in the year 2018 in which 26 participants were included in Pilates mat training stated that 6 weeks of Pilates training protocol leads to young women’s physical as well as psychological betterment as for the body fat, slimness, anxiousness, depressed mood, fatigue, and Quality Of Life.

Pilates is the physical training focuses on the breathing pattern which also helps in enhancing the QOL during menopause. The progressive muscle relaxation technique (PMRT) also helps to improve the QOL in several other conditions but not in menopausal women. It has been proven that PMRT reduces the stress in post-menopausal women. This intends to whether the PMRT increase the QOL of patient in menopausal women. The research is an initiative study that focuses on the effectiveness of PMRT on the various aspects of Quality Of Life of the menopausal women and comparison of the Pilates training and PMRT in order to enhance the QOL of participants.

**Objectives**

1. Pilates training effect in menopausal women on Quality Of Life
2. To find out the effect of Progressive Muscle Relaxation Technique in menopausal women in view of Quality Of Life
3. Comparison of Pilates training & Progressive Muscle Relaxation Technique on menopausal women’s Quality Of Life

**Methods**

This research is being conducted in local communities in Wardha City, Maharashtra, India after...
ethics clearance is obtained from Institutional Ethics Committee, Datta Meghe Institute of Medical Sciences, and Deemed to be University.

**Study design**: Comparative study

**Study setting**: Local communities from Wardha, Maharashtra, India.

**Participants**:

Inclusion criteria –
1. Any female in the age group more than 45 years
2. Participants willing to perform exercises
3. Menopause without any medical or surgical intervention
4. No contraindications related to performing the physical activity
5. Not indulged in any kind of structured physical activities or exercise program since 6 months

Exclusion criteria-
1. Menopause due to any surgical condition like oophorectomy, hysterectomy
2. Pathologies related to musculoskeletal and cardiovascular system
3. Cognitive impairments and neurological disorders
4. Recent Orthopedic surgery of lower back and lower limb
5. Hormone replacement therapy
6. Subjects on anti-depressant medications
7. History of vertigo or fall in previous 6 months

**Variables**

Outcome measures: Menopausal Quality Of Life (MENQOL)

**Data Source Measurement**-

After using intraclass correlation coefficients (ICC), the test-retest reliability were 0.81 for physical domain, 0.79 for psychosocial domain, and 0.70 for sexual domain, 0.37 for vasomotor domain and 0.55 for QOL. There are certain systematic changes demonstrated in vasomotor domain. The score of face validity was 4.7 out of 5. Validity of the evaluative construct suggested correlation coefficients in which physical domain was 0.60, vasomotor domain was 0.28, psychosocial domain was 0.55 and 0.54, and sexual domain was 0.54 and 0.32, and 0.12 for the QOL. Discriminative construct validity ranges from 0.57 to 0.70 in between all the domains.

**SAMPLE SIZE**: 42

**Intervention**:

**Group A**: Intervention will be Pilates Training Protocol.

**Group B**: Intervention will be Progressive Muscle Relaxation Technique

**Group A**:

A six week protocol has been made. The average length of every session would be 40 to 50 minutes including 5 minutes of warm up and cool-down each. The exercise prescription has been formed by the FITT (Frequency, Intensity, Time and Type of exercise) principle which includes frequency of 3 days a week for 6 weeks. Intensity has been calculated according to Rate of perceived exertion (RPE) scale and the progressions will be done with the same scale and there will be an interval of 10 seconds between each performed exercise. The exercises included in this intervention are considered as beginners and intermediate level exercise in order to fulfill the result. Therapist will demonstrate the activities by visual and verbal instructions to the patient and educate the patient about the correct form of exercise and how to perform it correctly. The main program consisted of exercise that illustrate 6 principles of Pilates includes- 1)Hundred 2) Half roll-down 3) Leg stretch (single and double) 4) Leg circle (single and double) 5) Rolling back (also known as rolling like a ball) 6) Spine stretch forward 7) Shoulder Bridge 8) Criss-cross and progression will be done accordingly.

**Group B**:

Division of body by four muscle group techniques occurs in such manner both upper limb and arms; the
face, neck & shoulder;\textsuperscript{3} the chest, back and abdomen; and\textsuperscript{4} both lower limb. It should be done alone, in a quiet place. Each group of muscles retains tension for 5 seconds and relaxes for 10 seconds.

The participant will be in a quiet place where there won’t be any interruption. They will lie down on back and stretch out in a comfortable manner. Guidance must be given to the participants to keep the muscle group tighter and tenser and to feel it. The participant will inhale deeply and tense first group of muscles for the given seconds. The tension should be in limit that they do not allow any cramps or pain of that muscle group. Relaxation of the muscle group along with exhalation will be done thereafter, which should be complete and sudden. Therapist will ask the participant to notice the differences in muscle group when they are tense and when they are relaxed.

The therapist will then help these muscles relax by advising them to remember what it feels like to relax those muscles in prior activities; this is the relaxation technique and recall. The process of counting involves count of 10 at the conclusion of the completed recall. This includes a profound technique of relaxation. The procedure is planned for 20 days, as well as a training program that could be done with 45 minute sessions.

Expected Results

Pilates training has been effective in Menopausal women for improving the Quality Of Life but Progressive Muscle Relaxation Technique has never been evaluated. The result would include the details about whether the measures are effective for improving the quality of life in menopausal women, as well as the comparison of both the interventions. Once the study result is complete, data will be analyzed using paired t-test and will be presented in the form of research paper.

Discussion

Menopause is defined as complete cessation of ovarian function by which the women experiences various symptoms after menopause which leads to changes in physical and mental health and may have an adverse effect on Quality Of Life (QOL). The aim of the study is to see the effect of both the interventions and compare the two interventions further i.e. Pilates Training versus Progressive Muscle Relaxation Technique on Quality Of Life in Menopausal women. Pilates is the physical training focuses on the breathing pattern which helps in enhancing the QOL during menopause. The progressive muscle relaxation technique (PMRT) helps to improve the QOL in several other conditions but not in menopausal women. In conclusion, this research seeks to explore both the effectiveness of Pilates and the Progressive Muscle Relaxation Technique in menopausal women. The result of the study would help prospective patients enhance quality of life. Outcome measure of the study is Menopause specific Quality Of Life (MENQOL) which is a self-administered questionnaire and it works well to classify women by their QOL and find out how their QOL benefits.

Comparison of Muscle Length in Dominant Versus Non-Dominant Lower Extremity in Young Asymptomatic Individuals- A Research Protocol

Anushree Pawar¹, Pratik Phansopkar², KiranKumar³

¹Final year B.P.T, Ravi Nair Physiotherapy College, Datta Meghe Institute of Medical Sciences, Sawangi (M), Wardha, Maharashtra. India, ²Assistant Professor, Department of Musculoskeletal Physiotherapy, Ravi Nair Physiotherapy College, Datta Meghe Institute of Medical Sciences, Sawangi (M), Wardha, Maharashtra. India, ³Associate Professor & HOD, Department of Musculoskeletal Physiotherapy, Ravi Nair Physiotherapy college, Datta Meghe Institute of Medical Sciences, Sawangi (M), Wardha, Maharashtra. India

Abstract

Background: Muscle length is defined as the length at which the maximum amount of force a muscle is able to produce. This length is determined by the joint angle corresponding to that muscle. Understanding the optimal muscle length as well as its comparison between the extremities is very important as a part of examination in physiotherapy, particularly in the cases of musculoskeletal disorders. Several tests are available for testing the muscle length. However standardize and reliable tests have been chosen to prevent the error while testing. Many studies have shown that there was difference in the lengths of muscle of lower extremity which was assessed in different players. However there is paucity of study on the muscle length of individuals who are completely normal and not the athletes.

Objectives: The objective of this study is comparison between the length of iliopsoas, hamstring, gastrocnemius, rectus femoris in dominant to non-dominant extremity in young asymptomatic individuals aged between 18-25 years.

Methods: Measurement of hamstring, iliopsoas, rectus femoris and gastrocnemius length will be acquired through standard goniometer. The methods of assessment that will be used are; active knee extension (AKE) tests the hamstrings, Thomas and modified Thomas test to evaluate iliopsoas and rectus femoris while prone, figure-four position accompanied by dorsiflexion for gastrocnemius.

Results: Once the study is completed, the parameters of outcome measure will be statistically analyzed and calculated.

Conclusion: Based on the previous data we assume that there can be a significant difference between the muscle lengths of lower limb in normal person.

Keywords: Muscle length; Active knee extension (AKE) test; Modified Thomas test; Thomas test.

Introduction

One important feature of the skeletal muscle is the length tension relationship that reflects possible strength with relevancy the length of muscle. Important parameter during length-tension relation is optimal length of muscle, described as length wherein maximal force will be produced by muscle. This is determined by the joint angle comparable to the optimal muscle length.
This optimum angle shows the operating range in the length-tension relation through the movement of joint along with the excursion of tendon. So knowledge of various aspects of muscle contraction together with its mechanics and physiology is important since it plays a vital role during surgical procedures wherein the optimal length reflects how efficient surgical process could be, it helps in designing primary guidelines for ergonomic advice and in structuring a rehabilitation program that would help to provide more benefit using the advantages of length-tension relationship for an individual muscle.

Another concept namely muscle stress suggests of constant proportionality being balanced among maximum force of muscle and the physiologic cross sectional area. This parameter explains us the limitation in an individual muscle force.

It is common practice for physiotherapist to test length of muscle and flexibility as a section of assessment in patient with musculoskeletal disorders. Muscle length is simply measured by means of corresponding joint angle. Further length is determined on the basis of tests, comparison with normative values and between both the lower limbs. On the basis of this, exercises are been prescribed depending upon the information and other findings that is collected during examination time. Ranges that are obtained form an essential element during initial as well as recurrent clinic examination. Thus, identifying the length of muscle and their differences help us to know whether an individual would need any intervention focusing particular groups of muscle or joints. Also, the ranges obtained that of muscle length helps therapist to recognize individuals with reduced flexibility. This reduction in flexibility may be linked with an occurrence of painful event and injury to muscle of lower limb in future. To estimate the value of muscle length of extremity, it is necessary to make use of different techniques so as to get an objective measurement. Hence researchers have verified certain effectual techniques ensuring that the tests were easy to carry out, had higher inter and intra-tester reliability and they are clinical procedures usually practiced by the therapist.

There are several test available to measure the muscle length in lower extremity. Literature about muscle length testing had shown various techniques to test gastrocnemius length involving; passive range of motion, active range of motion, weight bearing techniques. Despite this, active dorsiflexion test is selected to check the length of gastrocnemius muscle because of its simplicity, reliability and standardization ease. A standard and reliable test that is chosen for the assessment of hamstring muscle length is active knee extension test (AKE) because its proven that it comprises of higher reliability that makes it a standardize test to use for an examination and stabilization of lower limb is achieved by this test, limiting the hip joint motion. Iliopsoas assessment to be done by the Thomas test while Modified Thomas test is chosen for testing the length of rectus femoris as one research have shown goniometer as a reliable tool to measure the hip extension using modified thomas test. It is a common and reliable test.

Parikh et al. 2015 conducted a study on establishing the typical values of muscle length of lower extremity, its comparison between dominant, non-dominant extremity of young elite cricket players having fifteen to twenty years of age. It has been found that decreased flexibility is common risk factor in cricketers and the players can even lose carrier due to an injury. On account of this, a study was done over 100 participants from one stadium. Because there was need to assess flexibility since it has huge impact on player’s performance and also it prevents musculoskeletal injuries, beside injury prevention is more desirable and better way for reducing injury in sports players. This research had helped the sports therapists to form specified muscle length norms. The result of study provided a reference range of muscle length in elite players. There was significant dissimilarity found between the lengths of rectus femoris, hamstrings, iliopsoas, and gastrocnemius of dominant and non-dominant side in these cricketers. Since the finding showed considerable difference between the dominant and non-dominant side in cricket players, it was suggesting the elite cricketers were more prone to the injury.

Marie corkery et al. 2007 done a study on establishing normative ranges for the lower extremities muscle length in seventy-two student of college. It aimed at obtaining the muscle length values in college students. Data was collected separately between males, females and a combined group. As per the result shown by the research a normative set of value was established for the lower extremity muscle length in resting state of
body. Implication of this study in clinical point of view incorporates individual’s examination plus diagnosis. Further they advised use of flexibility as a measure for an injury prediction. Moreover the defined normative data helped to determine flexibility and direct the strategies to resolve the deficits. However, lack of analysis of reliability before beginning with the study was found as a limitation of this work. Certain differences were assumed to be present within the range of measuring error. Less number of subjects as well as restricted age group is the second limitation of this study.

Although many research have been done incorporating muscle length, its normal value and comparison between the extremities, there is need for my study because there is paucity of study that evaluates muscle length in asymptomatic individuals and whether there is any difference in dominant to non-dominant side. Therefore this study will guide the therapist to know whether there is presence of difference in the muscle length of individuals that are normal.

**Objectives:**

To compare the length of gastrocnemius, iliopsoas, rectus femoris and hamstring muscle from dominant to non-dominant side of young asymptomatic individuals.

**Methods:**

**Study design:** observational study

**Setting:** Datta Meghe Institute of Medical Sciences (DMIMS), Sawangi (M), Wardha.

**Participants:**

Inclusion criteria:

- Individuals willing to participate
- Individuals between ages 18 to 25

Exclusion criteria:

- Previous history of surgery in lower extremity or low back.
- Any pathology or recent injury affecting lower limb and lower back (during current three months).
- Medicines or substance intake that would cause an altered sympathetic function.
- No elite athletes are accepted.

**Variables:**

**Outcome measures:**

Age, height, weight, gender, past medical history and surgical history will be recorded prior to the study with the use of questionnaire. Dominant leg will be obtained by asking the subject ‘what would be their preferred leg for kicking a football’. All four muscles will be measured initiating distally and moving proximally, right side before the left one. Both side lower limb muscle length measurement of hamstring, iliopsoas, rectus femoris and gastrocnemius muscle will be obtained using a standard goniometer. A goniometric measurement for the purpose of muscle length testing has shown to be reliable and also has better intrarater reliability than interrater reliability.

Gastrocnemius length will be measured in prone, figure-four position; foot to be measured hanged at the edge of the table. This position maintains the neutral attitude of lower extremity. While giving instruction, prior to starting a test, any trick movement performed by the subject will also be observed. The fulcrum of goniometer will be kept inferior to lateral malleolus, stationary arm parallel to fibula and movable arm lined with lateral aspect of calcaneum. Then subject will dorsiflex ankle and degree of dorsiflexion will be noted. There are many ways for testing the length of gastrocnemius however this position is chosen due to simplicity, less risk of researcher bias and excellent intra-rater reliability.

Active knee extension (AKE) test is chosen for assessment of length of hamstring. The subject will be taken into supine position with contralateral hip stabilize and knee flex to 90° as a starting point of reference. Fulcrum of goniometer will be placed laterally at knee, stationary arm parallel to femoral shaft while movable arm parallel to shaft of fibula. Subject is instructed to perform extension of knee unless a stretch will be experienced in the hamstring muscle and the knee angle will be measured where the subject felt some resistance very initially in the hamstring. A study was carried out for determining the reliability of active knee extension.
(AKE) test among healthy adults. Also some consider that Active knee extension (AKE) is a gold standard test for assessing hamstring flexibility. One research have demonstrated that the active knee extension test is easy to perform and require single person to handle with portable, simple, without any expensive apparatus and had also shown excellent interrater reliability and interclass correlation coefficient (ICC) values are 0.87 and 0.81, standard error of measurement (SEM) = 3.5 and 3.8 degree\textsuperscript{4}.

Assessment of rectus femoris length to be done by Modified Thomas test. The subject will stand at couch’s end with an instruction of holding the opposite knee and bringing towards own chest and further proceed towards supine lying with the one leg hanging outside table. Fulcrum of goniometer will be placing over lateral femoral condyle; stationary arm will be parallel laterally to femur and movable arm aligned with fibula in a line of lateral malleolus. This test will measure the range for knee flexion\textsuperscript{2}. A study on the examination of interrater reliability of goniometric measurement while assessing flexibility of hip extension, results of this study showed that goniometer was reliable instrument that can be used for measuring hip extension flexibility using modified thomas test. Interrater reliability (r=0.91-0.93), Interclass correlation coefficient (ICC) =0.89-0.92\textsuperscript{5}.

For assessing iliopsoas length Thomas Test will be used. The subject will be told to lie on table and the heels hanging out by the edge. The subject will then be instructed to pull leg towards chest to flattened lumbar spine on table. Fulcrum of goniometer will be placed over greater trochanter, stationary arm aligned with the midline of trunk, movable one parallel to lateral aspect of the thigh. This test measures the hip flexion angle. Thomas test has wide acceptance and common clinical tool to measure iliopsoas tightness\textsuperscript{2}. One study has been done about the reliability of thomas test while examining range of motion corresponding to hip. It showed Intrarater reliability=0.52 interrater reliability=0.60, Standard error of measurement (SEM) =1 degree\textsuperscript{6}.

**Study size:** 300

**Expected Results:**

Significant differences have been found in muscle length evaluated in different players. However, it has not been checked in individuals with no symptoms. Hence my study would help in knowing details about normal populations muscle length. Once it is studied and analysis is done, it is going to be presented as research paper.

**Discussion**

Optimum muscle length is the major factor to be considered in the length-tension relationship, whereas joint angle helps in determining the functional range by means of joint movement. Identification and knowledge of muscle length is very important as it has several beneficial role in an individual’s life including; need for an intervention strategies if any, while designing rehabilitation program for an individual, to evaluate pre-competition risk for injury in an athlete, testing the flexibility of muscle since decreased flexibility is commonly resulting into muscle injury. Many studies on the lower limb muscle length have been done in the past years. Such studies have given normative values as well as showed significant difference in an individual’s muscle length of lower extremity so far. But the study was done in a group of players and the result showed significant difference between muscle length of dominant and the non-dominant extremities of this athlete. Also normative set of muscle length values were found for the athletes. This is quite helpful for the sports therapist to know reference data about the players muscle length. However my study will be the first of its kind that would be assessing length of lower extremity muscles in the individuals who are completely asymptomatic. Individuals with past history of lower extremity disease or injury as well as the elite players will be prohibited. This is helpful as we will be able to obtain a data about muscle length in absolutely normal individual. Moreover this study will employ widely used methods for examination which are having appropriate reliability and validity as well as accepted by the researchers, found in literatures and research papers.

**Ethical Clearance:** Taken from institutional ethical committee.

Isoniazid Mono Resistance: Changing Trends in Drug Resistant Pulmonary Tuberculosis. – A Case Series of 3 Patients

Arti D. Shah1, Anchal Jain2, Apoorva3, Kusum V. Shah4, Yash Rana5, Saket Kumar6

1Professor and Head of Department, 23rd year Post Graduate Resident, 33rd year Post Graduate Resident, 4Professor, 5Assistant Professor, 63rd year Post Graduate Resident, Department of Respiratory Medicine, Smt. S.B.K.S. Medical Institute & Research Centre, Sumandeep Vidyapeeth Deemed to be University, Piparia (Vadodara)- 391760 (India)

Abstract

Drug resistant tuberculosis is a major public health concern in many countries including India, Isoniazid resistance (INH) accounts for 7.2 % of new cases globally. In our case series 3 patients had INH mono resistance out of which 2 patients had no previous history anti tuberculosis therapy (ATT). All 3 patients received 6 months of standard regimen under National Tuberculosis Elimination Programme (NTEP). All patients showed clinical improvement. INH mono resistance diagnosis is often delayed due to lack of infrastructure of 1st line probe assay (LPA) at various centres. INH mono resistance if diagnosed early can also help in prevention of Multi drug resistant tuberculosis (MDR TB).

Keywords : INH mono resistance, LPA, MDR TB.

Introduction

Drug resistant tuberculosis is a major public health concern in many countries including India. In 2018 an estimated 3.4 % of new cases and 18 % of previously treated cases had MDR TB worldwide. India contributes to 27 % of MDR TB cases worldwide. The global average of INH resistance without concurrent rifampicin resistance is 7.2 % in new cases and 11.6 % in previously treated TB cases. However treatment is mainly focussed on MDR TB as all cases of rifampicin resistance are considered as MDR TB until proven otherwise. A TB patient can be labelled as INH mono resistance only after documented rifampicin susceptibility has been established. This can be achieved only through 1st line LPA or through culture drug susceptibility testing (DST). It is because of absence of rapid testing for INH resistance effective regimen is delayed and is associated with higher treatment failure.

Figure 1 : Chest x ray PA view showing bilateral upper zone cavities.

Case 1 : A 38 years old non immunocompromised male presented to us with complaints of dry cough, diffuse chest pain and significant weight loss for past 2 months. He had bilateral upper zone cavity on chest x ray posteroanterior (PA) view (figure 1). His induced...
sputum was 1+ for acid fast bacilli (AFB) on sputum microscopy and rifampicin resistance was not detected on cartridge based nucleic amplification test (CBNAAT). He was started on 4 drugs regimen consisting of isoniazid (H), rifampicin (R), pyrazinamide (Z) and ethambutol (E). Patient came back after 3 weeks with worsening of symptoms and now presented with productive cough. His first line LPA was sent which showed INH mono resistance. Then he was started on 4 drugs consisting of R,Z,E and Levofloxacin (Lfx) for 6 months. At the end of 2 months his sputum converted to negative for AFB and showed significant clinical improvement.

Case 2 : A 50 years old non immunocompromised female presented to us with complaints of productive cough, loss of appetite and significant weight loss for past 1 month. She had history of pulmonary TB (PTB) 20 years back for which she was treated with ATT for 6 months. She had left upper zone cavitary lesion on chest x ray PA view (figure 2). Her sputum was 3+ positive for AFB on sputum microscopy. Her sputum sample was sent for CBNAAT and 1st line LPA. She was started on 4 drugs regimen consisting of H,R,Z,E. Her sputum CBNAAT showed no resistance for rifampicin but 1st line LPA showed INH mono resistance. Her treatment regimen was changed to R,Z,E and Lfx for 6 months. At the end of 2 months her sputum was negative for AFB and showed clinical improvement.

Case 3 : A 20 years old HIV negative female presented to us with complaints of diffuse chest pain, loss of appetite and productive cough for past 20 days. She was a known case of sickle cell disease. Her chest x ray PA view showed left lower zone cavitary lesion (figure 3). She was sputum positive for AFB on sputum microscopy and her sputum 1st line LPA showed INH mono resistance while sputum CBNNAT indicated no rifampicin resistance detected. She was started on 4 drugs regimen consisting of H,R,Z,E and was later changed to 6 months of R,Z,E and Lfx. She was sputum negative at the end of treatment and had clinical improvement.

Discussion

In the past INH mono resistance was detected through culture based DST and H resistance was determined at lower and higher concentrations. It is important because if H resistance is present at lower concentration and the TB bacilli is susceptible at higher concentration it can still be used to treat INH mono resistance. But this has not been established in clinical trials.\(^3\) 50 % to 95 % of INH resistant strains contain mutations in codon 315 WT1 of KatG gene and can be detected on 1st line LPA.\(^4\) KatG mutations are thought to cause high level INH resistance whereas low level resistance is caused by InhA mutations.\(^5\) In our case series we have presented 3 cases of INH mono resistance. 1st case diagnosis was delayed as he was thought to have drug sensitive TB based on his history and sputum microscopy. His diagnosis was
further delayed as sputum 1st line LPA is available only after 3 weeks at our institute. He showed significant improvement once he was started on latest INH mono resistance regimen under NTEP. In our 2nd case drug resistance was suspected as she had history of ATT intake in the past. She was started on drug susceptible anti TB drugs as we had no information regarding her resistance pattern and was deteriorating clinically. She was put on 4 drugs regimen for INH mono resistance. In our 3rd case also we ordered for 1st line sputum LPA based on our previous experience. She also improved clinically after being started on INH mono resistance regimen. In 2018 WHO released guidelines for treatment of INH mono resistance. It recommends 6 months of R,Z,E and Lfx in patients with INH resistance with confirmed rifampicin susceptibility. WHO recommends Lfx over moxifloxacin because of drug interaction with rifampicin.6 A 2017 systematic review and meta-analysis on treatment of INH resistant TB with 1st line ATT drugs suggests that such regimens can be suboptimal and lead to treatment failure, relapse or both.7

**Conclusion**

Primary INH mono resistance is on the rise as has been suggested in two of our cases and by their WHO global report 2019. All INH resistant patients must receive 4 drugs treatment regimen as suggested by WHO and NTEP for proper cure and improvement of patients. All INH resistant patients must be closely followed for development for MDR TB. Early diagnosis and treatment is key to management of INH mono resistance.

Study on Effectiveness of *Chakramarda* (*Cassia tora*) Ghrit and Go-Ghrit in the Management of Parikartika (Fissure in Ano)

Alok Kumar Diwedi¹, Kiran Khandare², Pooja Shrivastav³

1PG Scolar, Department of Shalyatantra, Mahatma Gandhi Ayurved College Hospital and Research Centre, Salod, 2Professor & HOD, 3Assistant Professor, Shalyatantra, Mahatma Gandhi Ayurved College Hospital and Research Centre. Salod (H) Wardha, Datta Meghe Institute of Medical Sciences, Wardha

**Abstract**

The term Parikartika is used for the condition of Guda (anus) where cutting and burning pain occurs, also along with this pain occurs in anus, penis, umbilical region and neck of urinary bladder with cessation of flatus. In modern medicine trend of the management depends on the type of the disease, e.g. in cases of acute variety with short history of the problem can be treated on the conservative lines, which results in healing of almost all acute and majority of chronic fissures. Priority must be placed normalization of bowel habits such that the passage of stool causes less trauma to anoderm. The addition of fiber to the diet to bulk up the stool, stool softener and adequate water intake are the simple and helpful measures. In the present study, an effort was made to derive a standard and easily accessible treatment for fissure-in-ano. *Chakramarda* is having vraṇa shodhana andropaṇa properties which can help the Vraṇa (ulcer) to heal rapidly. Its base is Ghrit which itself is having Samskaranuvarti (i.e. it enhances the properties of drug) and healing properties. *Chakramarda* Ghrit is economically beneficial by virtue of easily available ingredients and a time tested classical formulation. Hence, it was selected for the clinical evaluation in the present study. It proved to be significant in managing Fissure in ano, it reduced pain, itching, bleeding and promoted healing. Properties of its chemical constituent’s probable mode of action can be derived that *Chakramarda* is efficient in healing any ulcer like anal fissure.

**Keywords:** Parikartika, Fissure-in-ano, Chakramarda, Ghrit, Samskaranuvarti

**Introduction**

In the age of fast food, there is a shift in the habit of taking food and its timings as well as in the lifestyle that has become sedentary. Both of these causes produce disturbance in the digestive system that leads to many diseases including anorectal disorders such as piles, fissure, fistula, prolapsed etc. constitute a significant category.

Anal Fissure is one of the major causes for pain at anal region. The fissure-in-ano is categorized into two types depending on the clinical symptoms & durations of the disease; viz. Acute and Chronic(1). The two primary signs of this disorder are, bleeding and pain; pain is often unbearable. In long-standing instances, sentinel tag and haemorrhoids can be associated with this. Pruritus ani can be another symptom of this disorder(2). In males anal fissure typically occurs in the midline posterior-90 percent and 10 percent much less frequently. Subsequently, female fissures on the anterior midline are somewhat more common than before. (60:40) (3).

In contemporary sciences Parikartika can be correlated with Fissure in Ano(4). Sources on Parikartika are available from all Bruhatrayi and corresponding writers of Ayurveda. Parikartika (fissure in Ano) is a very common condition. The factors responsible for the causation of Parikartika can be found in various Ayurvedic texts such as *Vamana – Virecana Vypada*, *Basti Karma vypada* and Upadrava of *Atisara, Grahani, Arsa*. In this regard, *Acharya Sushruta* stated the

aetiopathogenesis of disease that if a anyone is impaired, with Mrudukoshta (mild digestive power), Mandagni (poor appetite) in these circumstances, more intake of food has the quality of Rukshna (dry), Ushna (hot), Lavana (salty) etc. Diet which is having such quality will vitiate Vata & Kapha & leads to Parikartika(5). The word Parikartika signifies Parikartanavatvedana around Guda i.e. cutting type of pain. Parikartika also has symptoms such as pain in the, penis, anus, neck of the urinary bladder and umbilical region with flatus cessation(6). In Kashyap Samhita, in the chapter Garbhini Chikitsa, we receive doshik classification, Aetiology, symptomatology and treatment of Parikartika(7). Acharya Charaka further mentioned fissure in ano as a Vataj Atisara complication(8). Chakramarda has Anti-inflammatory activity, Antibacterial, Antifungal Scavenging Activity, Antiulcer, Anti-proliferative activity, Antioxidant activity (9). In Ayurveda Chakramarda is used for the treatment of Pama, Jwara, Kasa, Kandu,Dadru. Rasapanchak of Chakramarda is Rasa-Katu,Guna-Laghu,Ushna, Virya-Ushan,Vipaka-Katu,Karma -Vata-Kaphasamak (10).

**Aim and Objectives**

The aim of the study was to evaluate the effectiveness of Chakramarda (cassia tora) Ghrit and Go-Ghrit in the management of Parikartika (Fissure in Ano). The defined objectives were to evaluate the efficacy of Go-Ghrit in the management of Parikartika as well as to the check and compare the efficacy of Chakramarda Ghrit and Go-Ghrit in the management of Parikartika.

**Material and Methods**

We have conducted a randomized single group blinded study with 30 patients in single group at outpatient and inpatient department of Shalyatantra department. The ethical approval was taken from Institutional ethics committee (Ref no.DMIMS(DU)/IEC/2017-18/7255 on 30/3/2017. We have included the patients from 18 years to 60 years with clinical features of Acute and Chronic Fissure in ano will be included after screening. The exclusion parameters were subject suffering with systemic disorders like Diabetes mellitus, Tuberculosis, HIV Positive, Hepatitis will be excluded as well as known cases of Malignancy, Crohn’s disease, Ulcerative colitis. We have also excluded chronic patient with 4th grade anal spasm. The diagnostic criterion was presence of signs and symptoms Parikartika such as Pain during defecation, Bright-red bleeding and Sentinal tag.

**Methodology**

The Ghrit was made by taking one part of kalka dravya (paste of seeds), four parts of cow ghee and sixteen parts of Drava (water) Table no.1. All the contents were mixed and prepared as per sneha pak vidhi. Leaves were collected from Wardha and nearby area. Ghrit was prepared in Rasa Shala of MGACH&RC by taking direction of subject expert. the dosage was Quantity sufficient for local application of Ghrit after Hot Sitz Bath twice a day during the treatment period. The total study duration was 45 days and assessment period was done on 0, 15th, 30th day and follow up of the patient was taken on 45th day.

Investigations: For the research purpose we did Complete Blood Count, Random Blood Sugar.
**Subjective parameters:** The subjective parameters were Pain, Bleeding per Rectum, Itching, and Tenderness

**Objective parameters:** The objective parameter was Parikartika Healing

**Observations and Results**

Subjective and objective criteria were used to carry out the statistical analysis. Statistical analysis was done by using descriptive and inferential statistics using chi square test, Mann Whitney U test and Wilcoxon Signed Rank Test and software used in the analysis were SPSS 22.0 version and Graph Pad Prism 7.0 and p<0.05 is considered as level of significance. Changes before and after treatment are shown in figure 1, figure 2 and table no. 2.

1. Pain

Comparison of pain in both the groups

Mean pain before treatment in patients of group A was 2.86±0.51 and in group B it was 2.73±0.45. By using Mann Whitney U Test statistically no significant difference was found in mean pain in patients of two groups (u=0.70, p-value=0.48).

Mean pain after treatment in patients of group A was 0.06±0.25 and in group B it was 1.40±0.63. By using Mann Whitney U Test statistically significant difference was found in mean pain in patients of two groups (u=4.55, p-value=0.0001). Percentage of relief in Pain of group A patients was 97.77% and in group B it was 49.99%.

2. Bleeding

Comparison of bleeding score in both the groups

Mean bleeding before treatment in patients of group A was 0.93±0.25 and in group B it was 1.00±0.00. By using Mann Whitney U Test statistically no significant difference was found in mean bleeding in patients of two groups (z=1.00, p value=0.31).

Mean bleeding after treatment in patients of group A was 0.00±0.00 and in group B it was 0.06±0.25. By using Mann Whitney U Test statistically significant difference was found in mean bleeding in patients of two groups (z=1.0055, p value=0.31). Percentage of relief in bleeding of group A patients was 100 % and in group B it was 80 %

3. Itching

Comparison of itching score in both the groups

Mean itching before treatment in patients of group A was 2.20±0.77 and in group B it was 2.33±0.81. By using Mann Whitney U Test statistically no significant difference was found in mean itching in patients of two groups (z=0.61, p-value=0.54). Mean itching after treatment in patients of group A was 0.46±0.50 and in group B it was 0.86±0.74 By using Mann Whitney U Test statistically significant difference was found in mean itching in patients of two groups (z=1.79,p-value=0.07). Percentage of relief in itching of group A patients was 86.66 % and in group B it was 67.77%.

4. Tenderness

Comparison of Tenderness score in both the groups

Mean Tenderness before treatment in patients of group A was 2.80±0.56 and in group B it was 3.00±0.00. By using Mann Whitney U Test statistically no significant difference was found in mean Tenderness in patients of two groups (z=1.44,p-value=0.15). Mean Tenderness after treatment in patients of group A was 0.13±0.35 and in group B it was 1.13±0.63. By using Mann Whitney U Test statistically significant difference was found in mean Tenderness in patients of two groups (z=3.95,p-value=0.001). Percentage of relief in Tenderness of group A patients was 95.55% and in group B it was 62.21

5. Fissure Healing

Comparison of Fissure Healing score in both the groups

Mean Fissure Healing before treatment in patients of group A was 2.80±0.41 and in group B it was 3.00±0.00. By using Mann Whitney U Test statistically no significant difference was found in mean Fissure Healing in patients of two groups(z=1.79,p-value=0.07). Mean Fissure Healing after treatment in patients of group A was 0.20±0.41 and in group B it was 1.20±0.67. By using Mann Whitney U Test statistically significant difference was found in mean Fissure Healing in patients of two groups(z=3.72,p-value=0.0001). Percentage of relief in fissure healing of group A patients was 95.55 % and in group B it was 59.99 %.

Discussion

1. Pain

When effect of Chakramarda Ghrit and Go- Ghrit on Pain was analyzed statistically by using Wilcoxon signed rank test the results were found significant in the patients of both the groups (on 15th, 30th and 45th day). On clinical assessment also Chakramarda Ghrit and Go-Ghrit, both the groups showed analgesic activity. On comparing the mean Pain in both the groups, by Mann Whitney U test statistically significant difference was found. Percentage of relief in Pain of Group A patients was 97.77 % and in Group B it was 49.99 %. Therefore it is clear from the above analysis that Chakramarda Ghrit was more efficient than Go -Ghrit in reducing pain
because of its healing property.

2 Bleeding

When effect of Chakramarda Ghrit and Go-Ghrit on bleeding was analyzed statistically by using Wilcoxon signed rank test the results were found significant in the patients of both the groups (on 15th, 30th and 45th day). On comparing the mean bleeding in both the groups, by Mann Whitney U test statistically significant difference was found (on 15th, 30th and 45th day). Percentage of relief in bleeding of group A patients was 100% and in group B it was 80%. Therefore it is clear from above discussion that Chakramarda Ghrit is more efficient than Go-Ghrit in stopping bleeding caused due to anal fissures which is also because of its wound healing property.

3 Itching

When effect of Chakramarda Ghrit and Go-Ghrit on itching was analyzed statistically by using Wilcoxon signed rank test the results were found significant in the patients of both the groups (on 15th, 30th and 45th day). On comparing the mean itching in both the groups, by Mann Whitney U test statistically significant difference was found (on 15th, 30th and 45th day). Percentage of relief in itching of group A patients was 86.66% and in group B it was 67.77%. From this we can conclude that Chakramarda Ghrit is more efficient than Go-Ghrit in reducing itching because of its antipruritic property.

4 Tenderness

When effect of Chakramarda Ghrit and Go-Ghrit on tenderness was analyzed statistically by using Wilcoxon signed rank test the results were found significant in the patients of both the groups (on 15th, 30th and 45th day). On comparing the mean tenderness in both the groups, by Mann Whitney U test statistically significant difference was found (on 15th, 30th and 45th day). Percentage of relief in tenderness of group A patients was 95.55% and in group B it was 62.21%. From the above discussion it can be concluded that Chakramarda Ghrit is more efficient than Go-Ghrit in reducing tenderness because of its anti-inflammatory and wound healing property.

5 Healing

When effect of Chakramarda Ghrit and Go-Ghrit on healing was analyzed statistically by using Wilcoxon signed rank test the results were found significant in the patients of both the groups (on 15th, 30th and 45th day). On comparing the mean healing in both the groups, by Mann Whitney U test statistically significant difference was found (on 15th, 30th and 45th day). Percentage of relief in healing of group A patients was 95.55% and in group B it was 59.99%. From the above discussion it can be concluded that Chakramarda Ghrit is more efficient than Go-Ghrit in healing anal fissure because of its wound healing property.

Taking into consideration all the observations, results, statistical analysis and its interpretation of the present study, Null hypothesis is rejected and Alternative hypothesis is accepted. Chakramarda Ghrit application in the management of Parikartika (Anal fissure) is found to be more effective as compared to Go Ghrit.

Conclusion

Chakramarda is a medicine used by people particularly for the management of skin disease and wound / ulcer. There have been numerous research works on the same where Chakramarda proved to be an effective medicine. Therefore using this comparison Chakramarda Ghrit was rendered and used for local application in the management of Anal fissure which is considered to be an ulcer, assessment parameters were itching, pain, bleeding, tenderness and healing on the basis of which its efficacy was assessed. The final conclusions were drawn on the basis of the Study observations and results described as follows

- Incidence of Fissure in ano was more common in middle age group.
- Males were more prone to this disease as compare to Females.
- Maximum cases were belonging to middle socioeconomic group, literate, married and having normal build.
- Fissure in ano was also very common in people who were indulged in alcohol, takes mixed diet and having irregular bowel habit.
- Maximum cases in this study belonged to rural habitat.
Majority of cases which reported were having acute fissure in ano following to that chronic fissure in ano with sentinel tag were common.

In this present research work, evaluation of the efficacy of Chakramarda Ghrit in the management of Parikartika (anal fissures) was done by comparing its results with that of Go-Ghrit. In this study, group A (n=15) was subjected to application of Chakramarda Ghrit and in group B, Go-Ghrit was used for application over Parikartika (anal fissures).

By this intervention the targets achieved in Group A (n=15), were that pain, itching, bleeding, tenderness were significantly reduced and healing was significantly more as compared to Group B (n=15) patients, where the Go-Ghrit was applied.

7. **Recommendations for further study**

- The study can be conducted in a substantial sample size.

- Chemical properties of Chakramarda Ghrit should be studied in more details.

- Chemical action of Chakramarda Ghrit in healing anal fissure should be studied.

- Chakramarda Ghrit preparation needs to be more hygienic and should be done with the use of specially designed device or equipment, even more easy method or technique should be find out for its application in order to make patient more comfortable to the treatment.

- Further same study can be conducted in comparison with other Ghrit preparation as well as modern medicaments with additional advanced changes.

Percutaneous Subclavian Artery Covered Stent Placement Following Inadvertent Subclavian Arterial Cannulation

Cinosh Mathew¹, R Calton²

¹Associate Professor, Department of Cardiology, SBKS MI & RC, Waghodia, Vadodara, ²Professor, Department of Cardiology, CMC & H Ludhiana, Punjab, Department of Cardiology, Smt. B. K. Shah Medical Institute and Research Centre, Sumandeep Vidyapeeth Deemed to be University, Vadodara, Gujarat

Abstract

Inadvertent subclavian artery canulation although rare is a life threatening complication of central venous canulation. Its prompt recognition and management by stent placement, thrombin injection, Angio seal or gel foam embolization is essential to minimize fatal complications. We describe a case report of subclavian arterial canulation which was recognized and managed percutaneously by covered stent placement without complications.

Keywords: subclavian arterial; cannulation; covered stent

Introduction

Central venous catheter (CVC) cannulation in the subclavian vein of patients wounded in battle was first described by Aubaniac in 1952. [1] The CVC helps in the management of critical patients in that it provides reliable short to medium term venous access for hemodynamic monitoring, intravenous drug therapy, hemodialysis, parenteral nutrition and rapid fluid resuscitation and is now a commonly performed procedure in ICU setting. [2] Complications of Subclavian vein canulation include pneumothorax, hydrothorax, hemothorax, local hematoma, vascular injury, thrombo-embolism, and site related infections. [3] Inadvertent subclavian artery puncture during subclavian vein cannulation is a known and serious complication of CVC placement which could lead to hematoma, pseudo aneurysm formation, arterial occlusion, embolism, dissection, stroke, severe airway obstruction and even fatal bleeding on sheath removal as it is an anatomically non compressible site [4, 5]. Removal of inadvertently placed CVC followed by manual compression can lead to complications like uncontrolable bleeding and death. [6] Various techniques have been described to treat the subclavian artery after an inadvertent puncture like stent placement, thrombin injection, Angio seal and gel foam embolization. Techniques such as stent graft placement, thrombin injection, Angio seal devices and Gel foam embolization have been used to repair the subclavian artery after inadvertent puncture [7, 8]. We report a case of inadvertent subclavian artery cancellation, which was successfully closed using a covered stent placed percutaneously. A percutaneous approach is appropriate and justified management strategy with lesser complications as compared to surgical treatment. [9-11]

Case Report

A 45 -year-old gentleman, diagnosed with acute pancreatitis had a central venous catheter placement in the surgical ICU. As he was in shock an attempt was made to access the right subclavian vein to place the venous catheter by using an anatomic landmark technique with a 7F triple lumen central venous catheter. However, after gaining access the surgeons noted pulsating blood flow and an arterial puncture was suspected which was confirmed by sending the blood for arterial blood gas analysis. The CVC was not removed due to the risk...
of life-threatening bleeding which may occur and the inability to directly press the arterial leakage site.

The patient was taken to the cardiac Cath lab for an angiography. A bilateral femoral artery approach was made. A 6F JR4 catheter was inserted through the left femoral artery into the right subclavian artery and was used as a diagnostic catheter to inject the dye and visualize the site of subclavian arterial puncture. A 9F sheath was introduced into the right femoral artery and the stent was passed through it. The angiogram showed the entry of the CVC in his proximal portion of his right subclavian artery, after the right vertebral artery. (Fig 1 & 2)

We planned to pull out the catheter and cover the entry point at the Subclavian artery with a covered stent with due precaution to avoid occlusion of right vertebral artery. A Fluency® Plus Vascular Stent Graft (Bard, Inc.) 10 x 40 mm covered stent was positioned in the right subclavian artery (Fig 3), the misplaced venous catheter was removed (Fig 4 & 5). The position of the stent was reconfirmed by dye injection with respect to the site of entry of the catheter and origin of the vertebral artery and the stent was deployed (Fig6)

Immediately we achieved successful hemostasis and it was angiographically confirmed that the subclavian and vertebral artery was patent with no leakage of contrast from the puncture point (Fig 7) The patient was shifted to ICU and recovered and was discharged after 2nd day in a satisfactory condition and has been doing well on follow up. center mid-term results.
Discussion

There is extensive usage of a central venous catheter in critical care units to provide long term access and dedicated access for parenteral nutrition, hemodialysis and management of hydration in pre- and post-operative fasting states. Inadvertent arterial cannulation is seen in 3.2-3.7% of cases of CVC insertion. [12, 13] Usually a mistaken arterial puncture will be known by the spurt of blood from needle before insertion of a large bore canula, chances of arterial cannulation of CVC is very rare. [14] However patients with trauma or sepsis may be in shock and hence may not have pulsatile back flow and dark blood due to hypoxemic status and thus inadvertent arterial cannulation may not be recognized during needle puncture. Various other risk factors for complications in CVC has been described like obesity, short neck, urgent need for catheterization.[14] Arterial cannulation can be prevented by doing CVC cannulation under Ultrasound guidance. [15, 16]

Inadvertent arterial cannulations have been managed by removal of catheter and external compression, endovascular interventions like balloon inflation, stent placement, gel foam or Angio seal, or by surgical exploration and direct repair of arterial trauma. [6, 17, 18]. Inadvertently placed venous catheters have been traditionally removed directly with manual compression this practice is risky in arteries such as the subclavian artery, which are behind the clavicular bone and hence non compressible by direct pressure on skin. For removal of CVC by open surgical method the manubrium sterni, clavicle and first rib have to be resected in an extensive surgery. Direct pulling out of catheter and conservative monitoring for bleeding is not advisable currently because of increased mortality and complications with it and also availability of minimal invasive techniques these days [6, 19]. Endovascular approach is advisable for inadvertent arterial cannulations at sites which are difficult to compress manually or anatomically hidden areas. Subclavian vessels are large and readily accessible from the femoral or brachial approach making them well suited to endovascular therapy.[20] Technical success of endovascular repair in cases of subclavian artery injuries is reported between 94-100% with procedure-related complications between 0-22%. [21] Balloon tamponade has also been described as a accepted technique for endovascular repair of arterial punctures but carry a risk.
of dissection and failure needing a stent placement at the site. There are no randomized control trials or guidelines specifying advantage of one technique over other due to low incidence of such complications reported and broad clinical profile of patients with these complications. However percutaneous stent placement for inadvertent subclavian artery cannulation is a safe and easy procedure to prevent a life-threatening complication.

Conclusion

Inadvertent subclavian artery cannulation and hemorrhage can be a life-threatening complication during a commonly performed procedure. Ultrasound guidance and confirmation with non pulsatile back flow has been recommended as methods to avoid such complication. Manual compression, surgical repair and endovascular repair techniques have been described to handle such complications. We have described a case where inadvertent subclavian arterial cannulation was treated percutaneously with subclavian stent placement.

Correlation of Vitamin D level with severity of Coronary Artery Disease (CAD) in patients of Acute Coronary Syndrome (ACS) in a Tertiary Care Centre in Western India

Cinosh Mathew¹, Nishant Saxena², Ashish Sharma², Jayesh Rawal³
¹Associate Professor, ²DM Cardiology Senior Resident, ³Professor and HOD, Department of Cardiology, Smt. B. K. Shah Medical Institute and Research Centre, Sumandeeep Vidyapeeth Deemed to be University, Vadodara, Gujarat

Abstract

Background: Vitamin D deficiency (VDD) is a widespread problem in developing countries. Recent studies have shown association of Vitamin D deficiency with atherosclerosis and Coronary artery disease. This study was conducted to assess the relationship between Vitamin D and the severity of coronary artery disease (CAD) in patients undergoing coronary angiography.

Materials and Methods: Consecutive patients who underwent coronary angiography for acute coronary syndrome or effort angina were included in a descriptive cross-sectional study and their Vitamin D level was measured. CAD was defined as at least one vessel stenosis >50% on coronary angiography. Vitamin D levels were correlated to the CAG findings as to the severity and number of vessels involved and also to the traditional CAD risk factors.

Results: Vitamin D Deficiency was noted in 70.72% of the population in the study. Patients were classified as normal Vitamin D level (> 30ng/ml), Vitamin D insufficiency (20-30ng/ml) and Vitamin D Deficiency (<20ng/ml). Vitamin D levels had inversely correlated with significant coronary artery disease both for number of vessels involved and severity (p<0.001) and dyslipidemia (p=0.009). No significant association was found between VDD and other risk factors such as age, sex, hypertension, diabetes mellitus and smoking.

Conclusion: Vitamin D deficiency was noted in majority of the patients undergoing CAG and was found to be significantly associated with the prevalence and severity of CAD. However studies involving larger population are needed to evaluate whether supplementation with vitamin D may help in prevention of atherosclerosis and further development of CAD.

Keywords: Vitamin D, Coronary artery disease, Coronary angiography

Introduction

Presently Cardiovascular disease is the leading cause of mortality in India and this has reached epidemic proportions.[¹] In addition to the traditional risk factors of age, hypertension, diabetes mellitus etc, vitamin D Deficiency (VDD) is increasing being recognized to be associated with coronary artery disease and cardiovascular mortality and now considered as a risk factor for coronary atherosclerosis.[², ³] Also studies have shown that Vitamin D deficiency is associated with other cardiovascular comorbidites like diabetes mellitus, hypertension, dyslipidemia, obesity, peripheral vascular disease and heart failure.[⁴, ⁵] It has been shown that vitamin D deficiency affects vascular function,
accelerates atherosclerosis by plaque formation and progression and stimulation of systemic and vascular inflammation by upregulation of proinflammatory cytokines like TNF, IL-6 and upregulation of anti-inflammatory cytokine IL-10. Also Vitamin D has been found to have a role in inhibition of vascular calcification and its deficiency can lead to increased risk of calcified coronary atherosclerotic lesions.

Vitamin D is a fat soluble vitamin which acts like a prohormone and mediates its functions by binding to the nuclear receptor (Vitamin D Receptor). Vitamin D is synthesized in the skin as a pro-hormone on exposure to UltraViolet (UV-B) rays from sunlight as Ergocalciferol (Vitamin D2) and also absorbed in a small extent from the Gasterointestinal tract from food in form of Vitamin D3 (Cholecalciferol) and can be supplemented as Vitamin D3 in medication. All of these forms are activated in the liver to 25(OH)D, and further hydroxylated in the kidney to 1,25-dihydroxyvitamin D[1,25(OH)2D]. The 25(OH)D is a stable form not affected by level of calcium, phosphate and Parathyroid hormone and has a half-life of 2–3 weeks and hence can be used as measure of vitamin D level in blood. The optimal range is reported as 25-80 ng/ml while Vitamin D Insufficiency is reported as < 30 ng/ml and Vitamin D Deficiency (VDD) as < 20 ng/ml. The prevalence of vitamin D deficiency is higher in the developing countries with some studies showing upto 50% of population having VDD. Risk factors for development of Vit D deficiency are (i) decreased intake due reduced sun exposure and malnutrition (ii) decreased absorption due to celiac sprue, inflammatory bowel disease (iii) metabolic factors like liver and kidney disease. Depending on number of vessels involved they were classified into Normal coronaries, single vessel disease (SVD), double vessel disease (DVD) or Triple Vessel Disease (TVD). In addition to routine investigations all these patients underwent Vitamin D [25-(OH)D] level measurement in the Biochemistry Department by an autoanalyzer. A level of Vitamin D > 30ng/ml was considered as normal, 20-30 ng/ml as insufficient and < 20ng/ml as deficient.

Diabetes Mellitus, Hypertension, Dyslipidemia were defined based on standard definitions.

For quantitative variables under different groups undergoing CAG statistically analysis was done by using Mann-Whitney test. For qualitative variables chi square test was used. The data were analyzed using SPSS Statistics for Windows, Version 25.0. Armonk, NY: IBM Corp and inference was drawn. A P value <0.05 was considered statistically significant.

Results

In our study of 263 patients who underwent CAG and Vitamin D level estimation, Vitamin D Deficiency was found in 186 (70.72%) patients, Vitamin D Insufficiency was found in 45 (17.11%) patients while normal Vitamin D level was found in 32 (12.16%) patients. There were 184 males (69.96%) and 79 females (30.03%) in the study population. Severe Vitamin D Deficiency (<20ng/ml) was found in 70.10% males and 72.15% females.

We conducted this study to determine the association of Vitamin D levels with severity of coronary artery disease in patients undergoing coronary angiogram and to establish correlation of Vitamin D Deficiency with conventional cardiac risk factors like Smoking, Hypertension, Dyslipidemia, Diabetes Mellitus and family history of CAD in patients.

Material and Methods

This was a cross sectional prospective study of 263 patients who underwent Coronary Angiography during a 3-month period at a tertiary care hospital in Western India. These included patients were of either gender and aged 18 to 75 years who underwent Coronary Angiography either for Acute Coronary Syndrome (Acute ST Elevation MI, Non-ST Elevation MI or Unstable Angina) or for Stable Effort Angina (symptomatic on medication). Patients who have liver or kidney disease, parathyroid disease, pregnancy, osteomalacia or taking drugs which affected Vitamin D metabolism were excluded from the study. Written and informed consent was taken from patients and their relatives for enrolment in the study.

Patients underwent CAG in the coronary Cath lab (PHILIPS FD-10) and interpretation of CAG was done by senior interventional cardiologist as to the number of vessels involved, severity of stenosis and calcification. The patients were divided into 3 groups based on the result of coronary angiography: Normal coronaries, non critical stenosis (<50% lumen stenosis of any coronary artery), and significant stenosis (>50% stenosis of a major coronary artery). Depending on number of vessels involved they were classified into Normal coronaries, single vessel disease (SVD), double vessel disease (DVD) or Triple Vessel Disease (TVD). In addition to routine investigations all these patients underwent Vitamin D [25-(OH)D] level measurement in the Biochemistry Department by an autoanalyzer. A level of Vitamin D > 30ng/ml was considered as normal, 20-30 ng/ml as insufficient and < 20ng/ml as deficient. Diabetes Mellitus, Hypertension, Dyslipidemia were defined based on standard definitions.

Material and Methods

This was a cross sectional prospective study of 263 patients who underwent Coronary Angiography during a 3-month period at a tertiary care hospital in Western India.
No statistical significant correlation was found between VDD and gender (p=0.732)

On evaluation of Vitamin D level with age, it was found that in the young (<30yrs) VDD was 50% while in > 30 years VDD was 74.43% and it was statistically significant (p=0.0018). (Table 1)

The level of Vitamin D was correlated with conventional risk factors for CAD like hypertension, Diabetes mellitus, Dyslipidemia and Smoking. 140 patients were hypertensive out of which 96 (68.57%) had VDD, while 90 (73%) of non hypertensives had VDD and this was not statistically significant (p=0.431). (Table 2) Similarly on evaluation of VDD with Diabetes mellitus, 163 patients were found to be diabetic, out of which 114 (69.93%) had VDD while 72 (72%) non diabetics had VDD. The difference was not statistically significant (p=0.72). (Table 3)

In our study 197 patients had dyslipidemia out of which 150 (76.14%) had VDD while 36 patients with normal lipid profile had VDD(54.54) and this correlation was found to be statistically significant (p=0.009)(Table4). Meanwhile there were 151 patients with history of smoking out of which 101 had VDD(51.41) while 85 non smokers(42.58) had VDD (p=0.11) which was statistically non significant
The correlation of CAG findings of CAD severity with respect to the Vitamin D level was also evaluated. Number of patients with normal coronaries were 16(6.08%), single vessel disease(SVD) was 81(30.74%), with double vessel disease(DVD) was 123(46.76%) and triple vessel disease was 43(16.43%). Out of patients with normal coronaries 2 patients (12.5%) had Vitamin D Deficiency, patients with SVD 57(70.37%) had VDD, patients with DVD 91(73.98%) had VDD while in patients with TVD 36(83.72%) had VDD. On statistical analysis it was found that for each level of severity of CAD it was inversely related to the level of Vit D and was statistically significant for patients with TVD(p<0.001). Patients with normal Vitamin D levels had less severe coronary artery disease compared to the ones with vitamin D level <20ng/ml. (Table 5). This is represented graphically with the graph showing the percentage of patients with CAD compared to the Vitamin D levels and shows the severity of CAD is inversely related to the level of Vitamin D in these patients (Figure 1)

Discussion

There have been numerous studies in recent times highlighting the association of Vitamin D deficiency with higher incidence of CAD.[12-14] In fact these studies suggest that Vitamin D deficiency can act as an independent risk factor for CAD.[15, 16] Considering the limited data available from this part of India regrading Vitamin D level in patients with CAD this study was undertaken to correlate the risk of Vitamin D Deficiency with the severity of CAD along with their Coronary Angiogram findings.

In our study of 263 patients who underwent CAG, Vitamin D deficiency was detected in 70.72% patients. This number is similar to previous values in studies conducted in India.[17] The main finding of our study is a significant association between measured low Vitamin D level and the prevalence of severe CAD. Furthermore, as evident in figure 1 patients with Vitamin D Deficiency had significant coronary artery disease as compared to those who had normal Vitamin D level (p<0.001). This is in sync with studies by Chen et al, Danik et al etc have showed that low level of Vitamin D is associated with CAD.[13, 15, 18, 19]. Also angiographically it has been shown that the patients with low Vitamin D levels have higher number of coronary artery involvement. [16] In our study too VDD was present in more patients with SVD(70.37%), DVD(73.98) and TVD(83.72) and higher number of coronaries involved as compared to patients with normal Vitamin D levels. (Figure 1) Higher rate of Coronary Artery Calcification was also observed in our study indicating higher plaque burden in patients having VDD.

No significant difference between gender and Vitamin D level was noted in our study (p=0.732). Previous studies have however shown Vitamin D level to be lower in females compared to males [20] and this was attributed to females staying indoor, purdah and ghunghat practices, malnutrition and frequent pregnancies and lactation making them more Vitamin D deficient.

In our study we found Vitamin d deficiency more in the elderly compared to the younger population (p=0.018). This was also seen in previous studies where VDD was observed in elderly and postulated that with advancing age the ability of skin to synthesize Vitamin D decreases as well as they may have reduced renal and hepatic metabolism which affects the pathways of its synthesis. [10, 13]

In our study we found no significant correlation of Vitamin D levels with relation to Hypertension(p=0.431) and patients with Diabetes (p= 0.72). Some studies have shown that Vitamin D level are lower in patients with
hypertension\cite{13, 19, 21} and Diabetes \cite{19, 22, 23}. Smoking inhibits Vitamin D induced translocation of VDR from the nucleus to the cell membrane, VDD has been observed in previous studies in smokers\cite{24} our study found no significant correlation between smoking and VDD(p=0.11). We found dyslipidemia to be significantly correlated with Vitamin D deficiency(p=0.009). This has been observed in previous studies by Rolf et al, \cite{25} Vitamin D deficiency affecting calcium absorption, Triglyceride metabolism, insulin resistance, disruption of lipoprotein metabolism leading to dyslipidemia have been postulated\cite{26}

**Limitations**

This study was conducted on 263 patients and findings should be confirmed in large sample studies before being generalized. This was an observational study and the association of Vitamin D with CAD can’t be postulated as a causal factor for the same and needs experimental and randomized control trials to evaluate this hypothesis further. This was a hospital-based cohort study from a single center and not a population based study and findings cannot be generalized for the entire population

**Conclusion**

The field of interventional cardiology has progressed at a fast rate with newer techniques of stenting techniques and pharmacological advances with dual antiplatelets and statins but still progression of atherosclerosis remains uncontrolled especially in high risk patients. Though conventional risk factors like Diabetes, Hypertension, smoking, dyslipidemia are given importance in the workup of CAD, new risk factors like low vitamin D level are not being recognized and also it can be corrected much easily compared to other traditional risk factors. Our study shows VDD is widespread in India and also has a significant correlation to CAD. More widespread studies involving multiple centres and more patients should be undertaken to study the association further and steps for correction of Vitamin D deficiency in the population should be undertaken.

A Questionnaire-Based Study to Evaluate the Basic Understanding of Pharmacovigilance of the Under Graduate Medical Students of a Rural Teaching Hospital

Ervilla E. Dass¹, Maulin Mehta², Jayant Patharkar³

¹Associate Professor, ²Assistant Professor, Department of Pharmacology, S. B. K. S. Med. Inst. & Res. Centre, Sumandeep Vidyapeeth An Institution Deemed-to be University, At. & Po. Piparia, Ta. Waghodia, Vadodara, Gujarat

Abstract

Introduction: Adverse Drug Reactions (ADRs) have presently been greatly contributing to the hospital admissions, prolongation of the hospital stays, visits to the emergency departments, in turn, contributing to the economic burden of healthcare management. Pharmacovigilance is predominantly concerned with ADRs and drug safety. The basic understanding about pharmacovigilance is essential for future medical professionals as they will come in contact with the patients and can efficiently report the ADRs.

Aim: To evaluate the basic understanding about pharmacovigilance and create awareness in medical students of a rural teaching hospital.

Materials & Methods: This was a non-interventional questionnaire-based study, where medical students from a rural teaching hospital were included in the study. They were distributed a simple questionnaire related to pharmacovigilance basic knowledge, through google form link, which they had submitted. The data was analysed.

Results: Total 92 participants were included in the study. It was found that, 57.8% of these were female and 42.2% were males. Moreover, regarding assessing the basic pharmacovigilance knowledge it was reported that 98.9% were aware about healthcare professionals who can report ADR. Nearly 83.5% were aware about pharmacovigilance. Nearly 70% of the participants had not heard about pharmacovigilance before joining pharmacology lectures. Majority of the participants had never attended any seminar/workshops and agreed to attend in future.

Conclusion: The results indicate that the basic understanding about pharmacovigilance is improving and medical student shows interest about creating awareness related to pharmacovigilance, as it is an important aspect of drug safety. However, to further improve their understanding awareness programs for medical student can be conducted.

Keywords: Adverse Drug Reactions, CDSCO, MBBS students, Medical under graduates, Pharmacovigilance, WHO

Introduction

Paracelsus stated that, all substances (drugs) are poisons; there is none which is not a poison. The right dose differentiates a poison and a remedy¹. The safety and efficacy of the drugs used in the treatment of various clinical conditions in any individual remains complex and multifactorial and difficult to analyse or identify the suspected drug that causes the Adverse Drug Reaction
ADR). Adverse effects usually predict hazard from future administration and warrant prevention, or specific treatment, or alteration of the dosage regimen, or withdrawal of the product. Continuous monitoring of drug effects, side effects, contraindications and outright harmful effects which could result in a high degree of morbidity, and in some cases, even mortality, are essential to maximize benefits and minimize risks. As mentioned by WHO Collaborating Centre for International Drug Monitoring, Uppsala, Sweden WHO promotes pharmacovigilance at the country level. The Central Drugs Standard Control Organisation (CDSCO), New Delhi, has started a National Pharmacovigilance Programme.

Therefore, looking to the above facts, it is important to safeguard patient safety and must be applied at all healthcare establishments. However, deficiency of awareness, training, and underreporting of Adverse Drug Reactions (ADRs) are the major difficulties in the successful application of Pharmacovigilance (PV) programmes.

Adverse drug reactions (ADRs) have presently been greatly contributing to the hospital admissions, prolongation of the hospital stay, visits to the emergency departments, in turn, contributing to the economic burden of healthcare management. Studies have shown that 4.2% - 30% of the hospital admissions, in U.S.A.; occur due to the ADRs. The ADRs that occur, affect the individuals irrespective of their age, gender, weight, race, or ethnicity. This is evident with several epidemiological studies conducted across the world which show that 2.1% - 5.2% of the ADRs have been observed to occur in children contributing to their hospital admissions, of which 39% of the ADRs were considered to be life-threatening or fatal while 10-20% of the ADRs occurred among the geriatric patients, while 11.4% - 35.5% of the visit to emergency department have been related to the ADRs. It has also been observed that 32%-65% of the ADRs were found occurred in geriatric cases admitted to the nursing homes. Thus, the ADRs greatly contribute to the economic burden in healthcare management as the treatment of ADRs is more costly than treatment of the diseased condition. Although, the investigation of the expenditures on the adverse drug events (ADEs) is less, the implications of research makes it clear that the ADRs cause injury to the patients with a disproportionate increase in the expenses to treat these injuries. Moreover, for certain conditions or disease either for the prevention nor for the treatment, there have been no drugs or vaccines proven to be effective and molecules are being investigated and developed as potential therapies or as adjuvant therapies therefore there is need for pharmacovigilance.

Therefore, it is known that pharmacovigilance is predominantly concerned with ADRs, and drug safety. The basic understanding about pharmacovigilance is essential for future medical professionals as they will come in contact with the patients and can efficiently report the ADRs. Hence, the present study was aimed to evaluate the basic understanding about pharmacovigilance and create awareness in medical students of a rural teaching hospital.

**Materials & Methods**

The present observational (non-interventional) questionnaire-based study was conducted over a period of one month at S. B. K. S. Med. Inst. & Res. Centre, Sumandeep Vidyapeeth An institution deemed-to be University; the study was conducted amongst MBBS students. The required permission was obtained. The required consent for participation for the study was obtained from the under graduate students of MBBS. The participants were 92 undergraduate medical students of S. B. K. S. Med. Inst. & Res. Centre, Sumandeep Vidyapeeth An institution deemed-to be University; they were enrolled in the study. A total of 92 questionnaires were shared through google form link (total n=92) which included total 20 questions based on earlier study and other sources. The questionnaires were based on answering from options or as short answers related to the pharmacovigilance basic understanding amongst undergraduate medical (MBBS) students. Data collected was further entered in Microsoft excel sheet and were further analysed.

**Inclusion criteria:** Medical undergraduates from S. B. K. S. Med. Inst. & Res. Centre were included in the study.

Those participants who gave consent.

**Exclusion criteria:** Students not willing to participate in the study or not willing to give consent.
Results and Discussion

The results were evaluated based on the detail questionnaire and its analysis done. The results were grouped as medical students’ knowledge, and basic understanding on pharmacovigilance as shown in Table no 1.

Among the total of 92 participants (n=92) who participated in this present research study; 57.8% of these were female and 42.2% were males. The significant outcome was, 98.9% were aware about healthcare professionals who can report ADR. 83.5% were aware about pharmacovigilance. Majority of them, 96.7% had heard about clinical trials earlier, however only 69% knew about pharmacovigilance in which phase of clinical trial. Almost all, 98.9% knew about suspected ADR reporting form. 94.5 % have heard about PvPI. Nearly 70% of the participants had not heard about pharmacovigilance before joining pharmacology lectures. Majority of the participants had never attended any seminar/workshops and agreed to attend in future. Also, nearly all MBBS students 96.7% were aware about the terminology ADR. The details are listed in table no 1.

(a) Pharmacovigilance comes under Fourth phase of clinical trials.

Q. 4 Pharmacovigilance comes under which phase of clinical trials?
60 / 87 correct responses

![Pharmacovigilance phase distribution chart](chart.png)

(b) Knows about of pharmacovigilance programme in India.

Q. 6 Are you aware of pharmacovigilance programme in India?
91 responses

![Pharmacovigilance awareness chart](chart.png)
(c) Agree that ADRs might result in hospital admission, prolonged hospitalization or might lead to permanent disability or even death.

Q. 7 Do you agree ADRs might result in hospital admission, prolonged hospitalization or might lead to permanent disability or even death?
90 responses

Yes: 91.1%
No: 30%
Not sure: 70%

(d) Had heard about terminology “Pharmacovigilance” before joining Pharmacology Lectures.

Q. 10 Had you heard about terminology "Pharmacovigilance" before joining Pharmacology Lectures?
90 responses

Yes: 70%
No: 30%

The present study provides an important insight regarding the knowledge, about basic understanding on pharmacovigilance undergraduate future clinicians. Almost all the MBBS students have the basic knowledge, however, it is very essential to sensitize the undergraduate students on the importance of Pharmacovigilance program of India, and also regarding Post marketing surveillance Phase.

Hence, this will help us to learn the design and will help us to narrow down the distance between academic knowledge among future clinicians and clinical practice. Majority of the students have given suggestions so as to improve ADR reporting and though majority of them have not attended and seminar/workshop, they are interested in attending such programs.

Conclusion

The results indicate that the basic understanding about pharmacovigilance is improving amongst MBBS students. Also, medical students show interest about creating awareness related to pharmacovigilance, as it is an important aspect of drug safety. However, to further improve their understanding and to sensitize them, awareness programs for medical student can be conducted.
Acknowledgments: Author is grateful to Smt. Bhikhiben Kanjibhai Shah Medical Institute and Research Centre, Sumandeep Vidyapeeth an Institution deemed to be University, Piparia, for permitting to conduct the present study.

Research Funding: No funding involved.

Competing Interests: NIL.

Ethical Clearance: As the present study is based on google form link questionnaire online method and does not involve any risk to humans, the consent from the participants is taken and their identity is not disclosed.

Abstract

Introduction - Osteoarthritis (OA) is an inflammatory disorder of cartilage, degeneration of synovial fluid, osteophyte formation, thinning of joint space and sub-chondral sclerosis. The prevalence of osteoarthritis in India was found to be around 28.7%. Females are generally more affected than males with the ratio of 2:1. Of all the joints knee and hip joint are seen to be most commonly affected joint in OA. Prevalence of knee pain is common amongst housewives due to prolong standing and frequent bending. Strenuous physical activity, especially activities requiring kneeling, knee-bending, stair climbing, squatting, prolonged standing as well as knee injury and trauma have also been linked to a high prevalence of symptomatic knee OA. Knee OA causes pain of various degree depending upon the severity of disease which can cause fear in patients. The fear related to pain can result in decrease in quality of life.

Purpose - Purpose of this study was to assess fear amongst housewives related to OA using fear-avoidance belief questionnaire and the effects of fear on their daily life using WHOQOL-BREF.

Methodology - 200 housewives will be selected according to exclusion and inclusion criteria. Their knee radiography was done to look for level of OA. Then those ladies were interview to find their fear related to disease and its effects and how that affects their quality of life.

Results - Results are awaited till the study is completed.

Conclusion - Conclusion of this study depends upon the result of this study.

Keywords – avoidance; fear; housewives; inflammation; knee pain; osteoarthritis; quality of life;

Introduction

Osteoarthritis (OA) is an inflammatory disorder of cartilage, degeneration of synovial fluid, osteophyte formation, thinning of joint space and sub-chondral sclerosis(1)(2). The radiographic evidence worldwide reflects 25.4% prevalence while 15.4% being symptomatic or clinically defined knee OA worldwide(3). The prevalence of osteoarthritis in India was found to be around 28.7% (4). The prevalence of OA in Maharashtra is 10.2% , in females (11%) and males (7%) (5). Osteoarthritis is more common in female than male, its ratio is approximately 2:1 (6). OA is now recognized as a disease involving the entire joint including periaricular musculature(7). Therefore accordingly, the impairment,
activity limitation, and participation restriction related to OA goes far beyond the radar of synovial joint. OA leads to pain, disability as well as difficulty in joints and restrict the routine movements of human being. No single factor predisposing an individual to OA has been identified, although aging is indeed strongly associated with OA. Genetic factor account for between 39% to 65% of radiographic OA of hand, hip, knee and upto 70% in spinal OA. Of all the joints knee and hip joint are seen to be most commonly affected joint in OA. Strenuous physical activity, especially activities requiring kneeling, knee-bending, stair climbing, squatting, prolonged standing as well as knee injury and trauma have also been linked to a high prevalence of symptomatic knee OA. Malalignment, including varus and valgus deformities, and leg length discrepancy are associated with greater prevalence of knee and hip OA, respectively. Obesity has also shown risk factor for development of knee OA in later life.

OA typically starts insidiously and gradually progresses and may even go unnoticed in some individuals when there is involvement of aneural articular cartilage. Pain is initial symptom. In later stages pain becomes dull aching, chronic and accentuated with episodic severe pain. There can be presence of synovial thickness as indicated by a joint tenderness with effusion, crepitation are felt during joint movement. OA is generally classified by Kellgren and Lawrence’s classification which is based on osteophytes formation using five grades from 0 to 4.

Knee OA more commonly affects the medical joint due to greater load body-weight placed on this compartment. As a result, medial joint space narrowing occurs resulting in pseudo laxity of medial collateral ligament, stretching of lateral collateral counterpart, and a genu varus deformity. Genu valgus occurs due to greater lateral compartment involvement but is less common. A flexion deformity of several degrees can develop quickly in painful knee and contribute to functional leg length discrepancy, decrease step length and quadriceps muscular fatigue or strain. Patellofemoral compartment OA, with hallmark anterior knee pain, can occur in isolation as a result of patellar malalignment, abnormal tracking and loading, and direct trauma to patella.

Vast pharmacological and non-pharmacological treatment protocols are available for osteoarthritis depending upon the severity of the disease. Medical therapies focus on decreasing pain and inflammation. Early aggressive pharmacological therapy is associated with diminished joint damage and long-term maintenance of function. The physical therapy plays a pivotal role in helping patient with minimal disability gain confidence and experience in using self-management skills to deal with the condition.

In Indians, primary OA of knee is more common than secondary OA. It is perhaps due to frequent need of squatting and sitting cross-legged. Prevalence of knee pain is common amongst housewives due to prolong standing and frequent bending. The fear related to pain is seen amongst people. This gives rise in decrease in quality of life.

The World Health Organization Quality of Life Instrument, Short Form (WHOQOL-BREF) questionnaire is a commonly utilized generic measure of quality of life that is used to measure quality of life in healthy people and in different groups of patients. It is a short version of WHOQOL-100 scale which is used in larger research group and clinical trials. WHOQOL-Bref comprises of four main domains which is physical health, psychological, social relationship and, environment. It contains of total 26 item questionnaire that correlates well with the original WHOQOL-100 item questionnaire. It assess the individual’s perception in the context of his/her cultural and value system, personal goal, standards, concerns, satisfaction with life and many more. Of the 26 items, 24 items were used to calculate the four QOL domains: physical health (7 items), psychological (6 items), social relationships (3 items) and environment (8 items). Transformed domain scores range from 4 to 20. A higher score indicates a better QOL. The two remaining items, sometimes used to calculate overall QOL and health, were not used in this study as recommended by the WHO. The WHOQOL-Bref have been shown to display good discrimination validity, content validity and test-retest reliability.

Fear avoidance beliefs are measured by using validated self-reported questionnaire which is created by Waddle et al, the Fear avoidance belief questionnaire. The Fear-Avoidance Beliefs
Questionnaire (FABQ) is a 16-item self-report questionnaire that focuses particularly on patient’s fear avoidance beliefs about physical activity and work may affect and contribute to their pain and concomitant disability. Fields of assessment involves; Activities of Daily Living, behaviour, functional mobility, general health, life participation, mental health, motivation, occupational performance, pain, personality, QOL, self-efficacy, stress and coping(15). The theory of fear avoidance is based on the notion that the patient believes incorrectly that the pain is sign of harm(16). Fear of pain leads to avoidance behaviour, such as rest and consequent avoiding of physical activity can result in worsening of patient’s condition(16). It has been proposed that fear-avoidance behaviours are expressions of a person’s belief system and that alteration of this belief system can cause in a more productive concept of pain and thus more positive behavioural responses, such as a steady return to activity and work(16). This self-reported questionnaire contains 16 questions ranging from 0 to 6 (maximum score of 96; higher score indicates fear avoidance behaviour). The first 5 questions concern to physical activity while the remaining 11 discuss about work. The Physical Activity subscale (FABQ-PA, range from 0 to 24) is the total of component from 2 to 5. The Work subscale (FABQ-W, range from 0 to 42) is the total of component 6,7,9-12 and 15. The overall test-retest reliability of FABQ was found to be good (ICC=0.97)(17). Evidence shows correlation between FABQ and Roland & Morris Disability Questionnaire. The correlation co-efficient for the FABQ was 0.52, the FABQ Work subscale was 0.63 and the FABQ Physical Activity subscale was 0.51(17). The reliability of forty-eight hour test-retest for FABQ has been recorded with a Pearson r of 0.91 to 0.95 and 0.84 to 0.88 for FABQ physical activity scale(14).

Gordon Waddel et al,(1993) conducted a study on FABQ and the role of fear-avoidance beliefs in chronic low back pain and disability in which he reasoned that the importance of fear-avoidance beliefs and showed that specific fear-avoidance beliefs about work are closely related to loss of work because of low back pain(14). Asa Dedering et al, (2013) conducted a study on assessing Fear-avoidance Beliefs in patients with cervical radiculopathy in which he deducted that FABQ can be used for test–retest evaluations as ‘good’ reliability was found. Marcio Massao Kawano et al, (2015) conducted a study on assessing QOL in patients with knee OA in which he interpreted that individuals with OA have a low perception of their functional capacity, functional limitation and pain in QOL. There is a clear link between poor education and low perception of quality of life(18). Rajeetha Miraj et al,(2018) conducted a study on prevalence of knee osteoarthritis in women of rural and urban part of Jaffan in which she reasoned that osteoarthritis was higher in urban areas (42%) than rural areas (16%) (19).

Chirstine Becks Mansfield et al, (2018), conducted a study on the effects of fear-avoidance beliefs on anterior knee pain and physical therapy visit count for young individuals in which he conclude that Fear-avoidance beliefs in adolescents are similar to that seen in adults. FABQ-PA scores did not impact the number of visits used to treat anterior knee pain or functional ability at discharge(20). Sara R. Piva et al, (2009), conducted a study on predictors of pain and function outcome after rehabilitation in patients with patellofemoral pain syndrome in which she concluded that change in fear-avoidance beliefs about physical activity was the strongest predictor of function and pain outcome. The fact that patients who decreased their fear-avoidance beliefs improved function and decreased pain indicates that perhaps fear-avoidance beliefs should be targeted during the treatment of patients with patellofemoral pain syndrome(21). Jack Farr II et al, (2013), conducted a study on quality of life in patients with knee osteoarthritis: A commentary on nonsurgical and surgical treatments in which he concluded that surgical knee OA intervention generally results in good to excellent patient outcome. Knee OA has negative impact on health related quality of life (HRQoL)(22). Fatma Fidan et al, (2012), conducted a study on quality of life and self-reported disability in patients with knee osteoarthritis in which she concluded that patients with knee OA has significant poorer Qol compared with healthy controls. SF-36 is related to the clinical status and functional ability of patients with OA and can be used as sensitive health status measure for clinical evaluation. Also WOMAC can be used as a sensitive measure for disability of patients with knee OA(23).

In this study we hypothesize that due to fear of increasing pain due to movement there was deterioration in quality of life especially in level of independence.
Greater the pain and severity of OA larger will be the deterioration in quality of life.

In this study we are assessing Indian housewives with knee pain/Osteoarthritis with Fear-avoidance Belief Questionnaire and Quality of Life using short form (WHOQOL-BREF).

The objective of this study was to assess Fear-avoidance Belief Questionnaire and Quality of Life in housewives with osteoarthritis of knee joint.

**Aim**

Assessing Fear-avoidance Belief Questionnaire and Quality of Life in housewives with knee osteoarthritis.

**Material and Methodology**

The study will be conducted in DMIMS, Sawangi(M). The study design of this research is going to be cross-sectional study and with observational (survey) study type. Sampling procedure used for this study is purposive sampling method, where every member is selected by chance and every member of the population has an equal probability of being included in the survey.

Sample size - 200

Inclusion criteria - Patient who consent for this study.

Stage 1 -2 of OA according to Kellgren and Lawrence system.

Primary cause of OA.

Exclusion criteria - people who do not consent to participate.

Past history of fractures

Any orthopedic condition making it impossible to perform ADLs.

Secondary causes of OA.

Study duration – 6 months.

Material -

1) Fear- avoidance Belief Questionnaire - The overall test-retest reliability of FABQ was found to be good (ICC=0.97). FABQ Physical activity subscale test-retest reliability (ICC=0.72-0.90). FABQ Work subscale test-retest reliability (ICC=0.8-0.91). Evidence shows that there is correlation between FABQ and Roland & Morris Disability Questionnaire. The correlation co-efficient for the FABQ was 0.52, the FABQ Work subscale was 0.63 and the FABQ Physical Activity subscale was 0.51.

2) Short form WHOQOL- BREF – The WHOQOL-BREF have displayed good discriminant validity, content validity and test-retest reliability. Its sensitivity to change is under assessment. Domain score produced by the WHOQOL-BREF have been shown to correlate at around 0.9 with the WHOQOL-100 domain score.

3) Radiographic image of knee.

**Procedure**

**Permission from head of institute will be taken**

**Ethical clearance**

**Subject will be selected according to inclusion criteria**

**Inform consent shall be filled up**

**The subject will be explained about the study**

**In person administration of questionnaire**

**Data collection**

**Statistical analysis of data to be obtained.**

**figure 1: description of the research protocol.**

Institutional Ethical Committee (IEC) clearance will be obtained prior to the commencement of the study. Participants will be selected as per the inclusion criteria as has been mentioned. Purpose of the study will be explained and inform consent from the participants will be taken. The participants will be given FABQ and short-form of WHOQOL-BREF. After the results have been obtained data will be collected. A statistical analysis will be obtained and the conclusion will be given and a research paper will be created according to the study and published.
Statistical analysis - This is a descriptive study to find frequency and percentage of fear factor and QOL in housewives with knee pain.

Sample size was calculated using the standard formula of

\[ n = \frac{Z_{1-\alpha/2}^2 p(1-p)}{d^2} \]

where,

\[ Z_{1-\alpha/2} \] = standard normal variant error

\[ p \] = expected proportion of population based on previous studies

\[ d \] = absolute error or precision

The data obtained will be assessed using descriptive and inferential statistics. The use of paired-t test will be done for the analysis.

**Expected Result**

The expected outcome will be percentage of fear avoidance belief about physical activity and work which is present in the patients with knee OA. The fear-avoidance scale will be assess depending upon the overall function mobility, ADLs, behaviour, general health, life participation, mental health, motivation, occupational performance, pain, personality, quality of life, self-efficacy, stress and coping. Quality of life will be assessed to find decrease/detoritation in any domain of WHOQOL-BREF due to fear avoidance behaviour. After the completion the study result will be calculated by statistical analysis and will be prepared and published in the form of research paper.

**Discussion**

The research aims to assessing fear-avoidance belief questionnaire and QOL in housewives with knee osteoarthritis.

Our study is supported by a research conducted by Gordon Waddell et al., (1993) in which he concluded that the importance of fear avoidance belief and demonstrated that specific fear avoidance beliefs about work are closely related to work loss because of low back pain\(^{(14)}\). Another study by Marcio Massao Kawano et al., (2015) stated that individuals with OA had low perception of functional capacity, functional limitation and pain in their QOL\(^{(18)}\). In a study by R Piva et al., (2019) interpreted that change in fear avoidance beliefs about physical activity was the strongest predictor of functions and pain outcome\(^{(21)}\). Jack Farr II et al., (2013) deduced that patients with knee OA had negative impact on health related quality of life\(^{(22)}\). An another study by Fatma Fidan et al., (2013) reasoned that patients with knee OA had significant lower QOL as compared to healthy controls\(^{(23)}\).

**Conclusion**

The study will be conducted according to research protocol on the patients with knee osteoarthritis in the institutional setup. In this study we hypothesize that due to fear of increasing pain due to movement there was deterioration in quality of life especially in level of independence. Greater the pain and severity of OA larger will be the deterioration in quality of life. Once the study is completed, data calculation by statistical analysis will be done and published in the form of research paper.

**List of abbreviation -**

1) OA – Osteoarthritis.

2) FABQ – Fear-avoidance Belief Questionnaire.

3) WHOQOL-BREF – The World Health Organization Quality of Life – BREF.

4) AVBRH – Acharya Vinoba Bhave Rural Hospital.

Screening for Upper Cross Syndrome in Asymptomatic Individuals

Heena Pathan¹, Pratik Phansopkar², Waqar M. Naqvi³

¹Final year B.P.T, Ravi Nair Physiotherapy College, Datta Meghe Institute of Medical Sciences, Sawangi(M), Wardha, Maharashtra. India, ²Assistant Professor, Department of Musculoskeletal Physiotherapy, Ravi Nair Physiotherapy College, Datta Meghe Institute of Medical Sciences, Sawangi(M), Wardha, Maharashtra. India, ³Professor and HOD, Department of Community Health Physiotherapy, Ravi Nair Physiotherapy College, Datta Meghe Institute of Medical Sciences, Sawangi(M), Wardha, Maharashtra. India

Abstract

Background: Upper cross syndrome has become prevalent in today’s population. This syndrome refers to tightness of muscles such as pectoralis major, upper trapezius and levator scapulae and weakness of deep neck flexors, scalene, rhomboids, serratus anterior, middle and lower trapezius. Poor posture is associated with imbalance created in musculoskeletal system and common condition to be reported as upper cross syndrome. It is commonly seen in people with forward head posture, desk job workers, dentist, beauticians etc. The resulting clinical presentation is complaint of pain in neck and shoulder, cervicogenic headache, hunched upper-back and rounded shoulder. Children are not as proactive today and the rate of the Upper cross syndrome is on the rise. This deviated posture and sedentary lifestyle continues, where it progresses more as the age progresses in adulthood. Aims and Objectives: To screen, detect, early treat as well as prevent upper cross syndrome in young individuals. Materials and Methods: Asymptomatic individual with 20-40 years of age group will be explained about the procedure before commencement of the study. Posture will be screened using Kinect Azure and REEDCO Posture Assessment Scale will be used for evaluation. Assessment of muscle tightness and weakness will be evaluated using muscle length tests and manual muscle testing.

Results: The expected results would include details about prevalence of UCS in asymptomatic individual. The parameters of outcome measures will be analyzed using the statistical test namely students paired T-test.

Conclusion: Based on previous data we assume it is essential to screen asymptomatic individual to looks for signs of Upper Cross Syndrome for early detection, prevention and treatment.

Key Words: Upper Cross Syndrome, Kinect Azure, Muscle Length Testing.

Introduction

There is a strong association of poor posture with imbalance created in musculoskeletal system and is common condition to be reported as upper cross syndrome. Such posture creates muscle tension as well as limits the mobility.¹

In 1988 Dr. Janda put forth an interesting concept by dividing the muscles into two groups: Postural and Phasic. Postural or tonic muscles are important for maintaining upright posture, have tendency to become tight and hypertonic. Phasic muscles, which include almost all other muscles have tendency to become weak and hypotonic UCS is term coined by Janda use for this misalignment. He claimed that maintain a stooped
sitting posture for prolonged period of time is major contributing factor. Other words including proximal or shoulder girdle syndrome are also known. Upper cross syndrome (UCS) is the tightness, over-facilitation of the levator scapulae, pectoralis major and upper trapezius accompanied with weakened, inhibited serratus anterior, deep neck flexors especially scalene, middle trapezius, lower trapezius and rhomboids. Hyperactive neck muscles on one side are counteracts the under active muscles on the opposite side, forming a ‘X’ pattern.

The crossed in upper cross syndrome refers to the crossing pattern of overactive muscle with counter crossing of the under active muscle. When viewed from side an X pattern can be drawn for these two sets of muscles. The overactive muscles forms the diagonal pattern from the posterior neck with the upper trapezius and levator down and across neck to the anterior neck and shoulder with sternocleidomastoid (SCM) and pectoralis major. The other side of X now depicts the underactive muscles, with the deep cervical flexors down towards the mid/lower trapezius, rombhoids and serratus anterior. As we continually assume the seated, forward head posture driven by electronic devices or poor exercise selection and techniques, this X pattern of muscle imbalance will increase.

It is commonly seen in people with forward head posture, desk job workers, dentist, beautician etc. Different movement can cause upper cross syndrome, but most cases develop through poor posture, specifically sitting or standing for prolonged period of time with head forward. Activities promoting this postural position include use of computers and laptops, driving, watching TV, browsing cell phones, texting, use of apps or games, and reading. Alteration of this muscular imbalance occurs through prolonged periods of attaining a posture in the classroom, work place and also attaining a prolonged and sustained posture for other activities like cooking. Children are not as proactive today and the rate of the Upper cross syndrome is on the rise. This deviated posture and sedentary lifestyle continues, where it progresses more as the age progresses in adulthood.

The resulting clinical presentation is a complaint of pain in the neck and shoulder, cervicogenic headache, hunched upper back and rounded shoulder. The common characteristics to diagnose upper cross syndrome include head constantly bent in forward position, increase cervical lordosis (cervical spine is too curved), increased thoracic kyphosis (the outward curvature of spine in the upper back, shoulder and chest is more), The shoulder are elevated, protracted and round and scapular winging (the shoulder blade sits out). Upper cross syndrome can cause many disorders in the body which includes headaches, degeneration of the cervical spine in early stages and the cervical curvature is also lost.

This is often believed that constant maintenance of muscle contraction and fatigue due to weakness of muscle is known to cause chronic type of pain in cervical region. Therefore, neck muscles strength has vital role in stabilizing cervical region. In addition to the shoulder girdle muscle, the Deep Neck Flexors is an essential for controlling and stabilizing the spine and supporting the head’s weight against gravity.

There is need for this Study so as to screen asymptomatic individuals for UCS signs for early detection, prevention and treatment.

**Objective**

To screen, detect and early treatment and prevention of upper cross syndrome in young individuals.

**Methods**

This study will be carried out in Ravi Nair Physiotherapy College, Musculoskeletal OPD, Sawangi (Meghe), Wardha, Maharashtra, India after approval from Institutional Ethics Committee of Datta Meghe Institute of Medical Sciences, Deemed to be University.

**Study Design:** Cross sectional Study.

**Study Setting:** RNPC Musculoskeletal OPD.

**Participant:** All asymptomatic individuals between 20-40 years of age.

**Inclusion Criteria:**

1. Asymptomatic individuals
2. Age group between 20-40 years.
Exclusion Criteria

1. History of Neck pain, Cervical Trauma Or Surgery
2. Known Thoracic Scoliosis
3. Known Rotator Cuff Tear
5. Cervical Radiculopathy

Variables

Outcome Measures

1. **Kinect Azure**: Karen Otte et al studied Accuracy and reliability of Kinect version 2 for clinical measurement of motor function the results showed most of clinical parameters showed good to excellent agreement with absolutes(30 parameters showed ICC(3,1) > 0.7 and consistency(38 parameters showed r > 0.7) and concluded that the Kinect version 2 will serve as a reliable and valid clinical measurement tool.7

2. **REEDCO Posture Assessment Scale**: Gunther, J.et al studied Reliability of two postural tests in postmenopausal women with osteoporosis test-retest and inter-rater. Results showed that in total RPS scores (Kruskal-WallisNonparametric ANOVA, H=6.96, p=.07) no significant Inter-rater difference was found. However, one item (head tiltPosition) was significantly different between therapists (H=8.049, P=.045). There was no significant test-retest difference in total RPSScores. (Wilcoxon t, p=.5217). One of the 10 RPS items (lower back)was significantly different at post-test (Wilcoxon t, p=.0379).and concluded that inter rater differences in Total RPS scores approached significance, and several individual Scale items showed significant inter rater or test-retest differences. Further improvement of the reliability of the RPS should precede Clinical use as an outcome measure.8

Aim is to screen asymptomatic individual for upper cross syndrome by

1. Evaluating Posture
2. Assessing Tight Muscles of head and shoulder.
3. Assessing Weak Muscle of head and shoulder.

1) Postural Assessment:

The posture will be screened in all views Using Kinect Azure and REEDCO Posture Assessment Scale will be used for evaluation.

REEDCO Posture Score (RPS) is a standard posture assessment and is graded in coronal and sagittal view in head-to-foot and it is administered by visual inspection of 10 postural traits viewed laterally (sagittal view including neck, upper back, trunk, abdomen and lower back) or from behind (coronal view including head, shoulder, spine, hips and ankles.

The scores are marked as follows: a value of 0 equals to poor posture or severe deviation, 5 equals fair posture or minimal to moderate deviation, and a value of 10 equals good posture and a score of 59% or less is recorded as postural dysfunction.

Procedure

Before evaluating posture, the participants will be asked to complete the personal data form including the consent form. Next, in order to assess the posture using REEDCO Posture Scale, the female participants will be asked to wear bodysuit, while male participants will be asked to take off their shirt. Markers will be made on anatomical landmarks on 7th cervical spine, bilateral acromion process, 5th lumbar spine and bilateral iliac crest. After that participant will be made to stand on the
postural grid at provided spot with shoes off in three
different direction: front (coronal view), back (coronal
view), and sideways (sagittal view). Then posture will be
analyzed using Kinect Azure scoring will be done using
REEDCO Posture Assessment Scale.

2) Assessment of Tight Muscles.

1. Pectoralis major

Test: Patient lies in supine lying and clasp the hand
together behind the head. The arm is then lowered down
until the elbow touches the examination table. Test is
positive if elbow does not touch the table and indicate
tight pectoralis major muscle.

2. Pectoralis minor

Pectoralis minor functions along with Rhomboids
and levator scapulae to stabilize scapulae during arm
extension Test: Patient is in supine lying. The examiner
places the heel of hand over the coracoid process and
pushes it toward the examination table. Normally
posterior movement occurs with no discomfort to
patient. Test is positive if there is [muscle tissue stretch]
tightness over the muscle during posterior movement.

3. Latissimus dorsai

Test: Patient is placed in supine lying position
and asked to fully elevate the arm through the forward
flexion. If the muscle has normal length the arm will
extend to rest against the examining table. The test is
positive if scapulae does not lie flat against the table
(scapulae remain protracted).

4. Biceps brachi (Arm flexor)

Test: Patient lies in supine lying with shoulder in
extension over the edge of table with elbow flexed and
forearm supinated. The examiner extend the elbow
which would normally have bone to bone endfeel, if
biceps is normal.

The test is positive if full elbow flexion would not
occur and end feel will be a muscular tissue stretch.

3) Assessment of Weak Muscles

1. Deep Neck Flexors (Longus capitis and longus
collis)

Patient position: supine lying with elbow bent and
hand overhead resting on table

Fixation: anterior abdominals must be strong enough
to stabilize to give anterior fixation of thorax to pelvis
before head can be raised by neck flexors.

Test: Flexion of cervical spine by lifting the head
from table with chin depressed and approximated
towards the sternum.

Pressure against the forehead in posterior direction

Weakness: hyperextension of cervical spine
resulting in forward head posture.

2. Triceps brachi (Arm Extensors)

Patient position supine lying

Fixation shoulder in 90° flexion with arm supported
position perpendicular to table.

Test: extension of elbow

Pressure against the forearm in direction of flexion

Weakness: inability to extend the forearm against
gravity.

3. Serratus Anterior

The patient is in standing position with arm flexed
forward in 90 flexion

The examiner applies backward force to the arm

Test is positive: The medial border of scapula will
wing. The patient also has difficulty abducting or forward
flexing arm above 90° with weak serratus anterior.

4. Rhomboids

Patient in prone lying position. Test arm behind the
body so hand is at opposite side back pocket. (Opposite
back pocket). The examiner places the index finger along
and under the medial border of scapula while asking
the patient to push shoulder forward slightly against
resistance to relax trapezius.

The patient is then asked to raise the forearm and
hand away from the body. If rhomboids are normal the
thumb is pushed away from the under scapula.
5. **Middle Trapezius**

Patient position in prone lying with arm abducted to 90 and laterally rotated. The examiner resisting the horizontal extension of arm watching for scapular retraction to occur normally.

Test is positive if scapular protraction occurs and this indicates that the middle fibers of trapezius are weak.

6. **Lower Trapezius**

Patient in prone lying with arm abducted to 120 and shoulder laterally rotated.

The examiner applies resistance to diagonal extension and watches for scapular retraction which normally occurs. Test is positive if scapular protraction occurs, lower trapezius is weak.

**Discussion**

To our knowledge this will be first study to screen asymptomatic individuals for UCS signs for early detection, prevention and treatment.

Practicing poor posture in daily routine for prolong period of time can lead to muscle imbalance resulting in UCS symptoms such as chronic cervical pain, headache and in long term can also result in degenerative changes in cervical spine. Thus is very important to look for signs of UCS.

Moreover this study will employ well established and widely used methods with appropriate reliability and validity to assess muscle tightness and weakness as well as to analyze posture. Although we assume that after complete assessment of individuals they will have better understanding about importance of practicing proper posture in order to prevent early signs of UCS.

**Result**

Upper cross syndrome has been evaluated in symptomatic individuals and has never been evaluated in asymptomatic individuals. The results would include details about prevalence of UCS in asymptomatic individuals. After completion of study result will be calculated by statistical analysis using paired T-test and will be presented in the form of research paper.

Abstract

Brain Gym is an academic kinesiological program that is promoted and applied with a consistent learning purpose that aims at enhancing performance such as memory, psychological perception and cognitive skills. The technique requires the participant to communicate with a series of activities that help the body to understand the primary behaviour and learn how to coordinate the brain and entire body. Brain Gym activities includes of 26 basic motions, which are believed to improve perception and stimulates brain hemisphere by neural re-modeling to facilitate whole brain learning. By ways of balancing both the side of brain, behavioral difficulties, social and intellectual burdens are expected to be reduced.

Aims and Objective: This study aims to evaluate the psychological perception and decrease depression in the undergraduate physiotherapy students.

Method: Here’s a idea we suggest to check the psychological perception with brain gym intervention and the duration for practices comprises of three days a week session, duration of 25 minutes, which is completed in one hour. The depression anxiety stress scale (DASS 21) is used to evaluate disorder which is a valid and reliable tool. This study will be conducted in Ravi Nair Physiotherapy college, Sawangi, Meghe, Wardha. The duration of the study will be six months. The study design is of before after-type with simple randomized sampling.

Result: The data will be analysed using Student paired t test.

Conclusion: The expected outcome includes the detection of stress, depression and anxiety levels which will be evaluated by using DASS-21. Data analysis will be done using students paired t test and conclusion of the study will be published after the results are analysed.

Keywords: Psychological perception, Depression, Stress, Anxiety, DASS-21, Brain gym

Background

It is an interventional type with before-after study design which focuses on the evaluation of the psychological perception after intervention of brain gym exercise. Brain Gym was developed in 1970 as an educational and psychological training system developed and enforced with a specific learning intent. Brain Gym activities includes of 26 basic motions, which are believed to improve perception and stimulates brain hemisphere by neural re-modelling to facilitate whole brain learning (¹). The neural mechanism and white matter connectivity of the brain is influence by the intervention of the exercises (²).

Brain Gym is a instructional curriculum intended to improve social, mental, emotional and physical efficiency and use 26 moves (³) (⁴). According to Brain
Gym literature, the abstract framework on which brain activity is conceptualised is generally simplified and defined along dimensions: laterality, attention and centring (5). Laterality, the synchronization between the brain’s right and left hemispheres, which is considered important for reading, writing, hearing, communicating and being able to walk and think. Focusing, the ability to process information in the brain, which is connected to perception and lack in attention / hyperactivity. The final section, centring, the top and bottom brain parts organized as necessary to combine rational thought with emotion (5). Brain gym intervention aims at the optimization of activity, social participation, and quality of life, as well as the health condition of people with acute and chronic disabilities. The most beneficial way to stimulate the brain is by incorporating kinesthetic and tactile learning, techniques and audio and visual activities to combine the high- and low-brain functions. Brain exercise contributes to sensory integrity, motor learning and a link between brain and body. Recently, brain-inspired methods have gained more popularity in overcoming command and decision-making challenges (6). A motion in the mental workout has been shown to have increased blood circulation and stability, good oxygen levels and healthy metabolism (7).

As per the founders, the daily practice of brain gymnastics leads to activation and development of various sections of the brain, particularly the cortex which allows for smoother and more organized communication between the two sides of the brain for high-level thinking (8). The brain is a complex organ which focuses on motion and according to Hannaford, “activity is necessary for learning” (9). Brain stimulation is very important in neuro-rehabilitation, reducing atrophy, lessen the risk of brain structure lesions and increasing cognitive performance. It is important therapy for elderly patients with depression, as its neuronal advantages have increased for age-related atrophy exacerbated by neuropathology (10). Neuroimaging research has indicated motor development, improve perception and integral approach involve stimulation of domains of auditory perception and more operation of cerebral cortex. The study describes the importance of brain gym exercise in physiotherapy. Exercise can stimulate the brain in such a way that neurons are often in a condition to handle the different data from outside and are capable of responding to a “corporate member” of their duty in compliance with parts of brain activity using the principle of “brain-body link”. Brain Gym is a great source of personal development, enabling individuals to obtain rapid transformations and also improve the quality of life in a different age group.

Many recent experiments have been carried out to determine the efforts required to enhance and stimulate the psychological perception of brain (11). Perception is defined as a essentially relational process in which visual stimuli is translated progressively into projections which serve as the basis for action (12). If a person is nervous or distressed then automatically the energy is pumped into the brain and the brain loses control, thus caused the primed, unexpectedly impaired reaction. Brain gym training can minimize mental stress and encourage brain concentration and perception (13). Students nowadays are under stress from waking up to not having proper sleep in addition to all the pressure of appraisals and examinations (14). This undoubtedly influences the attitude of the student towards learning and academic success (4).

Dr. Chaitanya Kulkarni, Dr. Sanjivani Ramesh Khandale have done a project to detect the effects of brain gym exercise on the attention span of the young students and concluded that the mechanism of reading, recodeng and comprehension has been improved. Also, the effect of these exercises demonstrated an improvement in eye power and hand control, as well as helping to focus on the same focal point while reading and writing concurrently. E Effendy, N Prasant Conducted a analysis demonstrating the effect of brain gymnastics on the population of Nursing Home Care Medan’s and found that brain gymnastics increased PSQI and HARS score levels in the intervention category and reduce stress and depression, in year 2019 here they have found a significant change in life style and improved quality of life in the elderly patient. Keith J. Hyatt in year 2007, conducted a study on school students and finished with a segment explaining Brain Gym exercises to encourage literacy ability, oral reading comprehension, communication skills, pronunciation and learning, self-esteem, memory, analytical thought, imaginative thinking. Brain exercise has seen to be effective in attention improvement, in research and more on it is shown to be very helpful in enhancing concentration, attention, vision and memory as well as
helping to relieve stress.

This research explores the impact on the psychometric characteristics of undergraduate students in the exercise program called as brain gym\(^{(16)}\). Specially because it seems to be a accurate and easy-to-administer scale, the Depression Scale, Anxiety, and Stress-21 are chosen. The DASS-21 consist of three self-report measures used to assess depression, anxiety, and emotional tension\(^{(17)}\). Depression spectrum tests dysphoria. Anxiety assessment tests autonomic activation, psychological anxiety\(^{(18)}\). Stress is the very common condition faced by students nowadays and causes disturbance in their daily lives.

Thanch Duc Tran, Jane Fisher performed a study on the Efficacy of DASS-21 in a cohort of Northern Vietnamese people in rural communities as a screening tool and the study concluded that it can useful in clinical practice and the components such as depression, and stress levels are determined by summing the ratings for the elements in question\(^{(18)}\).

The research aims to calculate the impact of brain gym exercise on stress, anxiety and depression in the student of undergraduate physiotherapy using the scale of DASS-21 as an evaluation method. The brain gym exercise intervention will be performed in all the subjects and then evaluation of the psychological perception will be conducted.

**Methodology**

The study will be conducted in Ravi Nair Physiotherapy College, after the approval the Institutional Ethics Committee (IEC) of Datta Meghe Institute of Medical Sciences, Deemed to be University, Sawangi (Meghe). The study design is of before after-type with purposive sampling.

- **Study design:** Interventional study
- **Sample Size:** 220
- **Duration of study:** 6 months
- **Inclusion Criteria:**
  - Age group - 18 to 23 years
  - Physiotherapy undergraduate students

- Moderate range according to DASS-21 scale\(^{(19)}\)

**Exclusion Criteria:**

- Not-willing to participate
- Student with migraine headache
- Diagnosed with psychological condition
- History of neurosurgery or cognitive damage

**Outcome Measure:**

- Depression, anxiety and stress scale (DASS-21)

- The DASS-21 is a valid and reliable instrument for determining the mental status, with reliability for depression = 0.81, anxiety = 0.89, stress = 0.78 respectively.

  - The DASS-21 has sensitivity = 89% and specificity = 76%.

**Need of Study**

1. To calculate the psychological perception among undergraduate students in physiotherapy.
2. To reduces depression, anxiety and emotional stress in undergraduate students.
3. To assess the effects on psychometric properties in undergraduate students.

**Procedure**

The Institutional Ethics Committee (IEC) Clearance will be obtained priorly. Students will be selected as per the inclusion criteria that has been mentioned. The participants will be informed the aim of the research and will get informed consent. They will be given pre and post interventional assessment using DASS-21 scale, reading will be recorded and the exercise intervention will be given for a month. After the results have been obtained, data collection will be done and statistical analysis will be obtained and the conclusion will be given and a research paper will be created according to the study and published.
BRAIN GYM EXERCISESTREATMENT PROTOCOL:

The Marching it is done as the beginning as warm up, in which subjects stand straight and lift both the legs continuously slight above (20) (21) for a time duration of 1 minute. A Cross Crawl is performed to enhance the coordination between both the sides of the brain, it is done for time duration of 2 minutes (5 sets of 8 repetition). Subject is instructed to stand straight and lift up the leg up to the chest and touch the knee with opposite elbow(22).

Positive Points helps to improves memory and reduce stress levels. The subject is instructed to breathe deeply and gently press the eyeballs with eyes closed (23) for time duration of 1 min (10 repetition).It helps to stimulate the lateral and side to side coordination. A Step Touch is done and it is performed in standing position and the subject is instructed to simultaneously move right legs toward left and left towards right. should be done for a duration of 5 minutes ( 30 repetition).

A Neck Circles exercise helps to reduce stress on the neck muscle, head movement coordination and move the neck in circular motion for a time frame of 2 minutes (3) (20 repetition). A Cook’s Hook-Up helps it stimulates the neurons and enhances the balance between hand and brain(21), where subject is instructed to extent and cross both the hands and fix the fingers together and internally rotate the hands for a time duration: 5 minutes (repetition).

A Brain Button- This exercise is performed and helps to improve the flow of electromagnetic energy and, helps in relaxation. The subject is instructed to palpate belly button with one hand and other hand over the collarbone and perform circular motion with finger for a time duration of 2 minutes(10 repetition)(17). The Thinking Cap helps to enhance learning speed and mood, increase attention span, and improve memory. The subject is instructed to press the top of ear and the bottom continuously(3)duration:1 minute (15 repetition) (24).

A Lazy Eight helps in boosting eye muscle control, balance, and concentration. The subject is instructed to extend the hand and make the figure of Eight horizontally in front(3) Duration: 1 minute (5 repetition). A Trace X helps to increase attention span and improve focus (25), where the subject to close eyes and imagine a figure of “X” and do eyeball movement the duration is 2 minutes (10 repetition).

Expected Result

Once the study is completed statistical analysis will be done using Student paired t test and presented in the form of research paper.

Discussion

The study protocol aims to evaluate the psychological perception in a undergraduate student by using the DASS-21 scale. We hypothesis that there will be improved ability to concentrate and improved focus. The research will help to prevaricate the effectiveness of brain gym exercise on stressed student and help with strategies involved to decrease stress and anxiety.

The DASS-21 is chosen as the aspects addresses the challenges faced by the current generation i.e. stress, anxiety and depression and it entirely evaluate the mental status of a person. The Adaptive practices for students include everyday life activities, effective speech, cognitive skills, adaptability, and learning skills that are observable and based on national norms.
Conclusion

The expected outcome includes the detection of depression and anxiety levels in Undergraduate physiotherapy students which will be done by using DASS-21. Brain gym exercises as an intervention will be taught to the participants to evaluate the psychological perception and solve their intellectual and behavioural challenge.

Sc. Nursing Intern, Chitkara School of Health Sciences, Chitkara University, India

Abstract

Context: Massively Multiplayer Online Games (MMOGs) are three dimensional games played on personal computers, mobile phones & video games. Millions of people of all ages worldwide participate in gaming and it has become most popular leisure activity for them which sometimes appear to develop problems as a result of excessive gaming, most commonly among young adults/students. Aim: The aim is to assess the relationship between gaming addiction to Massively Multiplayer Online Games (MMOGs) and quality of life among young adults. Setting and Design: Data collection for the present study was conducted at Private University of Punjab, India in April, 2019. A quantitative research approach with descriptive research design was adopted to assess the relationship between gaming addiction to Massively Multiplayer Online Games (MMOGs) and quality of life among young adults. Subjects and Methods: By purposive sampling technique, 100 samples (18-21yrs) meeting the inclusion and exclusion criteria were selected. Statistical analysis used: Descriptive and inferential statistics were used. Results: Findings of the study revealed that 61% young adults/students were non addicted and 39% were addicted to gaming and quality of life was good among addicted and non addicted young adults/students & there is no significant relationship between gaming addiction to Massively Multiplayer Online Games (MMOGs) and Quality of life at p<0.05.

Conclusion: MMOGs can improve quality of life and playing these online games for long hours may have long term ill effects on various components of health.

Keywords: Gaming addiction, Massively Multiplayer Online Games (MMOGs), Quality of life.

Introduction

Online gaming has been renowned among public due to the betterment in the internet and computer Technology. These online games has gain popularity among young generation at a very fast rate and changed from single user to multiuser or Massively Multiplayer Online Games (MMOGs) in which number of players are there to play the game at same time.\[1\] We cannot turn a blind eye to the ill effects of online gaming as youngsters are mainly involved than the older ones. Researchers claimed that video games are the integral part in this era of computer revolution\[1\]. Massively Multiplayer Online Games (MMOGs) are virtual three-dimensional fantasy games in which people compete with each other and with the computer-generated characters of the particular game world. People used to play these online games on their personal computers, smart phones and video gaming consoles are also a part of this.\[2\] Researches shows that gaming has positive as well as negative effect on health such as it improves cognitive functions, improves mood

and ward off anxiety and negative effects includes poor academic performance, adverse effects on health and addiction to gaming in youth. According to WHO (World Health Organization), Quality Of Life (QOL) is defined as an individual’s own awareness in their life related to culture and value system in which they live to fulfil their aims, concerns and standards. It is a broad term for various important realm of life. It is intuitive concept having various areas/dimensions that defines a set standard level for emotional, physical, material and social well being. So this act as an remark about an individual’s or about a society that they can compute the various domains of their life. Undoubtedly such games are a big source of endless entertainment but they also affect the life of people playing these games on regular basis, both in positive and negative aspects.

A great number of scientists and psychologists have claimed that these video games have many advantages and the important and main is that it is making people astute. According to a Psychologist in University of Wisconsin (C. Shawn Green), “Video games change our brain”. Because playing these games help us in recasting of our brain physiological structure in same way as it is recasted during reading, navigating, playing a piano.

In India, most of the gamers are reported to play for more than ten hours straight, and go to sleep without showing any visible signs of their general health being affected, but other players abandon their basic body requirements. They are reported to have lack of personal hygiene, lack of proper nutrition, lack of exercise, and lack of sleep also. In worst case scenarios, people have played these games for so long that they developed deep vein thrombosis (a blood clot) which further resulted as heart attack in them and ultimately death & also affecting their overall health and thus quality of life.

In this modern era we cannot ignore the ill effects of computers on our physical and psychological health. Most of the time the young generation is seen to be more engaged than the older ones with computers. Researchers also said that the development in modern technology is due to computer revolution and computer games are important and integral key aspect of them.

Now days living an ordinary life is not commendatory, but revamping the quality of our living is more recommended and people pay more prominence in improving their life quality wise and consider this as a fundamental goal. This is one of the important and considered as a key indicator since it includes different domains like Physical Health, Psychological, Social relationships and Environment. So basically computing quality of life will help us to identify the societal needs, adjustment programs and budgets. Today, Massively Multiplayer Online Games have become very prevalent among people of different age groups especially adolescents and young adults. Gaming is one the fastest growing and the most economic industry these days. According to a survey conducted by statista.com, it has been found that the total number of online gamers worldwide has massively increased from 1.6 billion in 2014 to 2.2 billion in 2018. They have also estimated an increase of up to 2.6 billion by the year 2021.

Previous studies on gaming addiction to MMOGs and its relationship with quality of life have concluded that addiction to such games has various ill-effects on overall health and is progressively worsening the quality of life of the gamers. Moreover, since India is a country where the rate of playing MMOGs is increasing significantly in young adults and adolescents as it is becoming their favourite leisure activity and many of the youngsters keep themselves busy and diverted due to this. There were very few researches found on this topic and the objective of this study is to find out the level of addiction to MMOGs among young adults and its relationship to the quality of life. No doubt is there that playing this for shorter duration will relax your mind and boost your mood but excess of this can cause serious ill effects on your health. We have studied the published literature regarding this topic and to determine the impact of playing MMOGs upon the quality of life of emerging adults, and young adults particularly at our college level and to critically appraise the evidence was main aim of the study.

### Subjects and Methods

#### Study Setting & Samples

The present research was conducted in private university of Punjab India. Subjects were taken from various departments of the university who used to play
these MMOGS from more than 6 months and falls under the age of 21 years. Only those young adults/ students were considered for participation who were interested to take part in study and all provided written consent before that.

**Assessment Instruments**

In present study, two tools were used, one was Gaming Addiction Scale (GAS) by Lemmens, Valkenberg and Peter to find out the gaming addiction among young adults which consists of total 7 questions and each is measured on a 5 point Likert scale. These seven questions consists of seven criterias of computer addiction such as Salience, Tolerance, Mood modification, Relapse, Withdrawl, Conflict and Problems and if 4 or more criterias are met in a person then the person is diagnosed as addicted (given in DSM section on Gambling). The second tool used was WHO- QOL BREF (World Health Organisation- Quality of Life ) Questionnaire which checked the quality of life among these addicted and non addicted diagnosed subjects and this tool consists of total 26 questions sub divided into four domains such as Physical Health contains seven questions about physical health, Psychological Domain contains six questions, Social relationships Domain consists three questions and Environment domain consists 8 questions respectively and two were general questions not considered under any domain with Maximum Score=108 Minimum Score=36.

**Study Design & Data Collection**

Descriptive research design was used to assess the relationship between gaming addiction to Massively Multiplayer Online Games (MMOGs) and Quality Of Life (QOL) among young adults/ students and quantitatively, data was collected and converted into numerical form to make statistical calculations & reveal results. Non-Probability Purposive sampling technique was used to draw 100 samples from the population after fulfilling the inclusion and exclusion criteria, subjects were provided with Gaming Addiction Scale (GAS) to find out the gaming addiction and WHO QOL BREF (World Health Organisation Quality of Life ) Questionnaire was used to check the quality of life among them. Nature and purpose of the study was explained to the young adults/ students and informed consent was taken from them.

**Results**

p<0.05

Among 39% of addicted young adults/ students in terms of quality of their life, 67% had good level, 26% had very good level, 5% had excellent level, and 2% had average level and none of the young adults/ students had poor level of it. On the other side there were 61% of non-addicted young adults/ students and in terms of their quality of life, 69% had good level, 26% had very good level, none of the young adults/ students had excellent level, 3% had average level and 2% of the young adults/ students had a poor level of it.

A similar study was there on the influence of internet based activities on quality of life which concluded that 14.1% participants believed that their quality of life could be improved by limiting access to internet usage for different activities including playing online games which also emphasized on the fact that playing internet based gaming also affected their quality of life. In our study it has been found that there is weak positive correlation between gaming addiction and quality of life. Contrary to Mr. Pontes’ study, environment domain was found to have been affected the most among subjects in our study.9
In order to assess the relationship between gaming addiction to Massively Multiplayer Online Games (MMOGs) and quality of life among addicted and non-addicted young adults/students, Karl Pearson’s correlation coefficient was used in order to find a relationship between the gaming addiction scores of addicted and non-addicted young adults/students with different domain wise score of WHOQOL-BREF.

Among 39 addicted young adults/students, there was weak positive correlation between gaming addiction score and domain 1, 3 and 4 whereas a weak negative correlation between gaming addiction score and domain 2 at p<0.05. Among 61 non-addicted young adults/students, there was a weak negative correlation between gaming addiction score and domain 1, 2 whereas a weak positive correlation between gaming addiction score and domain 3, 4 at p<0.05. A similar study was conducted on the relationship between computer games and quality of life and it was concluded that playing computer games for long hours can have negative impact on health which may lead to poor quality of life. Similarly, our study concluded that gaming addiction may hamper many domains of quality of life primarily the Environment domain.

Conclusion

In the present study, among a sample of 100 young adults/students, 39 were found to be addicted to Massively Multiplayer Online Games (MMOGs) and 61 were found to be non-addicted. 68% of the population had a Good level of quality of life. There was a weak positive correlation between gaming addiction score and different domains of quality of life (Physical, Psychological, Social relationships and Environment) among young adults/students.

Acknowledgement: We are thankful to our University authorities, our Principal and all the faculty members who helped us at various steps of our research process and most important we are thankful to all the enrolled participants for their valuable time and feedbacks.

Financial Support and Sponsorship: Nil.

Conflict of Interest: There is no conflict of interest.

Knowledge, Attitude, and Practice about Informed Consent amongst Resident Doctors at Rural Medical Institute of Central India

Shashank Gotarkar¹, Prakash Mohite², Kumar Bijyendra Sourabh¹, Alka Rawekar³

¹Assistant Professor, Department of Community Medicine, Jawaharlal Nehru Medical College, Sawangi (M) Wardha, ²Professor, Department of Forensic Medicine, Jawaharlal Nehru Medical College, Sawangi (M) Wardha, ³Professor, Department of Physiology, Jawaharlal Nehru Medical College, Sawangi (M) Wardha

Abstract

Informed consent is the process by which the treating health-care provider discloses appropriate information to the patient so that the patient may make a voluntary choice to accept or refuse treatment. There are few studies done amongst the medical residents in India about informed consent. The residents are the stepping stone of the Medical profession, it is proposed that the perception about the informed consent amongst the residents shall be sought. Hence, the study was undertaken with the aim, to appraise the knowledge, attitude, and practices of residents of all three years toward ‘informed consent taking’ with the objectives of assessing and comparing the knowledge, attitude and practices of obtaining informed consent. The survey questionnaire was circulated and data was collated. It was developed in Knowledge, Attitude and practice domain and analysis was done. Based on the result, it was concluded that, in all three domains, there was ascendancy of Knowledge, Attitude and Practice in three years of resident doctors.

Key words: Informed consent, Knowledge, Attitude, Practice, Resident Medical Doctors.

Introduction

Consent is a lawful right of a patient that decides their involvement in clinical procedures. The meaning of consent is that patients not to be touched or in nevertheless treated without their permission, it considers like an endorsed inquiry for their protection. Consent is a thoughtful agreement between doctor and patient, and in the health-care sector, it gives moral values to maintain the dignity and sanctity of the profession. The concept of consent is an endeavour by which the patient can take part in clinical judgment concerning their treatment and protect every patient against any litigation. Knowledge and approach of consent are foremost important due to encroachment in clinical procedures in the medical field.

Informed consent is the process by which the treating health-care provider discloses appropriate information to the patient so that the patient may make a voluntary choice to accept or refuse treatment. It originates from the legal and ethical right the patient has to direct what happens to his/her body and from the ethical duty of the physician to involve the patient in his/her health care.

Some of the revealing facts about Informed consent for the subjects of Clinical trial can be depicted as the basic ethical principle behind informed consent legalities is to protect the autonomy of human subjects which states that welfare and interests of a subject participating in clinical research are always above the society’s interests and welfare.

ICMR guidelines stipulate that volunteers must be provided all information on physical and psychological risks as well as moral implications of the research. They also stated that research should include an inbuilt mechanism for compensation to cover “all foreseeable and unforeseeable risks” a fact rarely mentioned. 
It is an obligatory duty of health-care professionals to help their patients for taking conversant decisions regarding treatment procedures. Thus, knowledge and approach of consent are foremost important due to encroachment in clinical procedures in the medical field as well as it is also important for the general population.

Nowadays there are physical attacks on practitioners about bad patient outcomes. According to a study by the Indian Medical Association, over 75% of doctors have faced violence at work. There may be multiple reasons behind this but the study by Neeraj Nagpal stated that one of the reasons is consent taking (other reasons are poor communication or Meagre health budget and poor-quality healthcare etc). It also suggested that proper steps should be taken to avoid such incidences like taking proper informed consent (eg. some technical issues like consent in their language, explaining them in detail in their language, for children taking consent from their parent, etc).

There are few studies done amongst the medical residents in India about informed consent. The residents are the stepping stone of the Medical profession, it is proposed that the awareness about the informed consent amongst the residents shall be sought.

Hence, the study was undertaken with the aim, to appraise the knowledge, attitude, and practices of residents of all three years toward ‘informed consent taking’ with the objectives of assessing and comparing the knowledge, attitude and practices of obtaining informed consent amongst all three-year resident doctors of Medical postgraduate students of Medical Institute of central India.

**Methodology**

The study was descriptive cross-sectional survey for resident doctors. Sample size was calculated by complete enumeration method. All the postgraduate students of broad specialties of Medicine faculty in the postgraduate departments were included. The departments included were Medicine, Surgery, Obstetrics and Gynaecology, Paediatrics, Orthopaedics, and Anaesthesia.

Survey questionnaire was prepared as study tool which was pre-validated by the experts of medical education. It was based on 3-point Likert scale.

Survey questionnaire was prepared under three headings as follows:

1. Describing the knowledge regarding informed consent taking including 9 questions
2. Describing the Attitude regarding informed consent taking including 5 questions
3. Describing the Practice regarding informed consent taking including 5 questions

The study was conducted after obtaining the Institutional Ethics clearance.

The data was analysed using SPSS version 20. A Chi-square test was used to compare Junior Residence of 1st year 2nd year and 3rd year doctors to find out the statistical significance.

**Observation and Results**

There were total 216 resident doctors from all 3 years working in the six broad specialty departments of Medical faculty. The demographic profile depicted 115 (54%) males and 101 (46%) females. Out of 216, the first year, second year and final year resident doctors were 70, 72, and 74 respectively.

The overall response rate was 64% (139) and the distribution were 64% (45/70) for 1st year, 68% (49/72) for 2nd year and 64% (45/74) for final year resident doctors.
The survey was sent online as google forms and data collected and collated. The depiction of the same is described in the following tables.

</table>
Table 2, 3, and 4 depicted that the knowledge, attitude and practices of Informed consent amongst all 3 years of residency of postgraduate trainees was adequate in most of the aspects barring few areas and it was increasing as they go to higher levels of their training period.

**Discussion**

Informed consent deemed as an integral part of the doctor and patient rapport as well as delivery of successful treatment. Knowledge and attitude should always in equanimity; once knowledge gets better, attitude and practices will automatically improve.

From the data of the study, it was found that the overall knowledge and attitude of resident doctors for informed consent was adequate. The ascendancy in all three domains was seen in the three years of their training. It was found that the knowledge, attitude and practice with regard to informed consent in medical practice was more in 2nd year in comparison with 1st-year resident doctors and it was more in 3rd-year resident doctors when compared to resident doctors. It was observed that there was an improvement in knowledge, attitude, and practice in 3rd-year resident doctors, but not significant except in few areas like “does patient consent help with treatment” or “do you take patient consent for non-invasive procedures” where it was significant.

In knowledge domain the observations could be inferred as; all three years of the residents were having significant knowledge of informed consent like various types of consent, the importance of signature, consent in disabled patients, and the Consumer Protection Act CPA act. Except for one area that the consent helps in the treatment where the p-value was significant. The first-year students were not sure about this.

The study by Gayatri Gupta et al studied the knowledge of informed consent in consultants and residents and found sufficient knowledge of informed consent. The results of our study were in accordance with their results. Anshika Khare et al stated similar results. Their study proved that knowledge regarding informed consent was superior in both medical and dental practitioners. Our study was also having similar results. The study by Vivek Gupta et al studied the knowledge and attitude of informed consent amongst dental practitioners and stated that dental practitioners had an unbalanced knowledge about informed consent. Shamsa Zafar et studied the awareness of informed consent amongst final year students in Pakistan and found it deficient.

In attitude domain the observations could be inferred as: all students had the attitudinal aspects with regard to informed consent except for taking the consent of the patient/relative for the non-invasive procedure like injections or vaccinations. About 18% of students were not sure about it. Anshika Khare et al revealed in their study that attitude was often not as good as needed. In our study, we get positive results for the attitudinal aspect of informed consent.

The study by Vivek Gupta et al studied the knowledge and attitude of informed consent amongst dental practitioners and stated that dental practitioners with the attitude toward its use in the clinical setting were found very dissatisfactory. The study by Biswajit Chatterji in undergraduate medical students revealed that students generally agreed and subscribed that awareness of ethics was important.

In practice domain the observations could be concluded as; all 3 years of residents are practicing the procedures or processes of informed consent necessary for patient care. The same has been reflected in the study done by Patond et al. Only in one aspect where receiving the copy of informed consent, 10% of JR1, and JR 2 was not sure but the value was nonsignificant. Anshika Khare et al revealed in their study that practicability of the knowledge was often not as good as needed. In our study, the students knew the practical use of informed consent.

The overall findings in the study may be attributed to the institutional policy that, at the commencement of training, the Postgraduate induction program is conducted at University level for all new entrants, where ethicality in medical practices are explained in detail. The same has been reflected by Ashish Jain et al.

Hence, we could conclude that there was an improvement in knowledge, attitude, and practice in 3rd-year resident doctors as compare to 1st and 2nd year. The only limitation for this study was inclusion of only 6 broad specialty. Hence, we recommend to conduct such
type of study in all clinical departments as well as at
different medical colleges of different states of India.

Total Elbow Arthroplasty in a Rare Case of Giant Cell Tumour of Humerus: A Case Report

Gajanan Pisulkar1, Kiran Saoji1, Ulhas Dudhekar1, Sridhar Reddy2, Shivshankar Jadhav2, Mohit Dadlani2, Pratik Phansopkar3

1Professor, 2Junior Resident, Department of Orthopaedics, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Wardha, Maharashtra, India, 3Assistant Professor, Department of Musculoskeletal Physiotherapy, Ravi Nair Physiotherapy College, Datta Meghe Institute of Medical Sciences, Wardha, Maharashtra, India

Abstract

Giant cell tumour forms 4 percent - 5 percent of all bone tumours & 20 percent of all benign bone tumours. It is responsible for 20 percent of bone tumours in China. It is usually single, aggressive locally & accounts for 5 percent of metastasis & 1 percent - 3 percent with malignant changes. Most commonly it is found in people aged 30 to 40 years and in the long bones mainly the meta-epiphyseal region. It is most commonly affects the distal femur, distal radius, proximal tibia and proximal humerus. But the occurrence in the distal humerus is rare. A 50 year old male patient who came with complaints of pain and swelling over right elbow since 3 years. Patient gave history of trauma to right elbow as he met with a road traffic accident. After few days patient noticed swelling which was insidious in onset and gradually kept increasing in size. Patient also had pain in right elbow which was insidious in onset and increased in severity daily. Pain was managed with total elbow arthroplasty and elbow range of motion improved after the surgery. Patient was managed with total elbow arthroplasty and wide resection of tumour which has good functional outcomes, less complications and lower recurrences rates. Patient was followed up at 18 – month and free range of motion of 10º to 110º without pain along with no proof of reoccurrence was noted.

Keywords: Giant cell tumour, Humerus, Arthroplasty, Elbow prosthesis, Rehabilitation.

Introduction

Giant cell tumour (GCT) forms 4 percent to 5 percent of all bone tumours and 20 percent of all benign bone tumours (1). GCT is responsible for 20 percent of bone tumours in China (2). It is usually single, aggressive locally & accounts for 5 percent of metastasis & 1 percent - 3 percent with malignant changes (3). Most commonly it is found in people aged 30 to 40 years and in the long bones mainly the meta-epiphyseal region (4). It is most commonly affects the distal femur, distal radius, proximal tibia and proximal humerus. But the occurrence in distal humerus is rare (5).

Histologically, giant cell tumour is divided into 3 types:

a) Multi-nucleated giant cells resembling osteoclasts

b) Mononuclear histiocytic cells

c) Neoplastic stromal cells – main proliferating cells

Radiologically, giant cell tumour presents as radiolucent lesion without calcifications which are centrally placed inside the bone giving it soap bubble appearance (6).

Giant cell tumour is usually treated with intralesional curettage either with bone cement packing or bone grafting. If the lesion is close to the articulating surface, subchondral bone grafting is done. With these procedures the reoccurrence rate ranges from 10 percent to 40 percent (7).

**Patient and Observation**

In November 2019, A 50 year old male who came with complaints of pain and swelling over right elbow since 3 years. Patient gave history of trauma to right elbow as he met with a road traffic accident. After few days patient noticed swelling which was insidious in onset and gradually kept increasing in size. Patient also had pain in right elbow which was insidious in onset and increased in severity daily.

On examination a diffuse swelling was noted around the distal humerus. The local temperature was raised, and tenderness was noted over and surrounding area of the swelling. The swelling was extending from 18cm distal to tip of Greater tuberosity right side; up to 17cm proximally from radial styloid process; 55cm in circumference at most prominent part with 25cm vertically and 20cm horizontally (Figure 1,2). Margins of swelling are ill defined with soft, doughy, bony hard mixed consistency present. Over lying skin was non-pinch able. A fixed flexion deformity of 60º, along with range of motion of 30º to 80º was noted which was painful. Supination and pronation was painful and restricted.

Radiographs showed an expansile osteolytic lesion in the olecranon fossa of the humerus with involvement of radial and ulnar head resembling a ‘soap bubble’ like appearance. Magnetic resonance imaging (MRI) depicted a well-defined, expansile mass, with altered signal intensity, involving the articular surface of the distal end humerus causing cortical break with extra-osseous extension into adjacent soft tissue; displacing adjacent muscles and the vessels. Patient was advised cytology and the report was suggestive of Giant cell tumour.

The patient was operated with total abscission of the distal humerus along with total elbow arthroplasty. A cemented ‘sloppy-hinge’ total elbow prosthesis (Bakshi, Sis Ortho, Bangalore, India) made of stainless steel was used. A high arm tourniquet was used during the procedure to avoid excessive blood loss.

A postero medial skin incision taken, soft tissues dissected & the ulnar nerve along with blood vessels was identified and isolated. The excision of tumour was done by sharp dissection with a edge of normal tissues & precaution was taken that the capsule was not damaged. The olecranon process along with radial head was excised and removed. The triceps attachment was not resected during the procedure (Figure 3).

Appropriate sized cemented elbow prosthesis was used and inserted (Figure 4). Hemostasis was achieved after removal of tourniquet. Irrigation was done with 3 litres of normal saline and wound was sutured in layers. A suction drain of size FG 10 was inserted. The limb was kept in full extension with an above-elbow slab. The resected tumour mass was sent for histo-pathological examination and the report confirmed the diagnosis of Giant Cell Tumour of bone. After one week of post-operative time, rehabilitation was initiated which comprised of active and passive movement within pain free range and with gradual progression. Stitches were removed two weeks later and was discharged with home program exercises and advised for monthly follow-ups. At 8th month follow up patient had a free range of motion of 10º to 110º without pain along with no evidence of reoccurrence was noted.

Discussion

Giant cell tumour of bone most commonly occurs as anomalous, expansile lytic lesion, with thinned cortex and in later stages may breach the cortex of bone (8). Giant cell tumour results in expansile remodelling of the overlying bone; cortex overlying the tumour mass remains intact. Sometimes tumour contains foci of dystrophic mineralization (9). The most important histological and morphologic feature is multi-nucleated giant cells which may have 100 nuclei with prominent nucleoli. The distinguishing feature of giant cell tumour from other bone tumours or the osteogenic lesions that have benign osteoclast is that the surrounding mononuclear and multinucleated cells that are small in size have nuclei similar to those found in the giant cells.

Surgery is the management of choice. Cementing and/or bone grafting along with curettage is done (10). If the tumour invades the bone cortex along with the joint, an en bloc (total) resection with reconstruction of total joint is the treatment modality of choice. The complications rates among these are very high and are mainly used as salvage procedures if the total elbow arthroplasty fails (11). Excellent functional outcomes and less recurrences rates have been seen in wide resection of tumour and total elbow arthroplasty (12). A well-structured rehabilitation is a vital part in the successful recovery of the patient outcomes to restore patient’s functions (13). Total elbow arthroplasty is another option as it has good functional outcomes and pain relief with less complication rates.

Conclusion

Giant cell tumour is rare condition in lower end humerus and the prompt and accurate diagnosis of the same and total elbow arthroplasty management led to a successful and acceptable functional improvement for our patient. Physical rehabilitation post-surgery in such replacement procedures stands a important aspect in the positive outcomes.

Declaration of Patient Consent:

The authors certify that appropriate consent form was obtained from the patient. In the consent form, the patient has given his consent for his clinical information to be published in the journal. The patient understands that their personal information will not be described.
Author’s Contribution: 

All authors made the best contribution for the concept, assessment and evaluation, data acquisition and analysis and interpretation of the data.

Financial Support and Sponsorship: No Funding Support.

Relationship between Working Tenure and Working Posture with Musculoskeletal Grievance in Batik Madura Workers

Galuh Sistha Prabarukmi1, Noeroel Widajati2

1Research Scholar, 2Professor, Department of Occupational Health and Safety, Public Health Faculty, Airlangga University, 60115, Surabaya, East Java, Indonesia

Abstract

Introduction: Batik is one of the cultural heritages of Indonesian people. Batik is the result of acculturation of Javanese, Hindu and Islam which is written on a sheet of fabric. The process of making batik fabric takes a long time. This condition causes many batik workers experience work related disease, such as musculoskeletal grievance. This research aimed to analyze the relationship between working tenure and working posture with musculoskeletal grievance in Batik Madura workers.

Methods: This research was an observational research with a cross sectional design. The research population was all Batik Madura workers. The sample in this study was 61 Batik Madura workers. The variables researched included working tenure, working posture and musculoskeletal grievance.

Data were collected by observation, filling out research questionnaires, and Nordic Body Map (NBM). The data analysis used was the Spearman correlation.

Results: There was no relationship between working tenure with musculoskeletal grievance with a value of $p = 0.837$ and there was relationship between working posture with musculoskeletal grievance with a value of $p = 0.000$.

Conclusion: The working tenure didn’t have relationship with musculoskeletal grievance. The working posture had a relationship with musculoskeletal grievance.

Keywords: working tenure, working posture, musculoskeletal grievance

Introduction

Batik is one of many cultural heritages in Indonesia has confirmed by UNESCO in 2009 as a masterpiece of oral and intangible human heritage to Indonesia. Therefore, every October 2 is designated as the national batik day on which every community in Indonesia wears a batik shirt. Batik fabrics in Indonesia have various motifs and colors. Batik motifs are created with messages and hopes that are sincere and noble, so that they will bring goodness and welfare as well as happiness to the wearer1. Occupational Safety and Health is a thought and effort made to ensure wholeness and perfection both physically and spiritually so that workers can carry out work activities safely, comfortably, and achieve physical endurance, work power, and a high level of health2. Occupational safety and health must be applied in various types of industries, both formal and informal industries. However, occupational safety and health efforts in the informal industry in Indonesia still lack special attention to informal industry owners. This condition causes workers in informal industries in Indonesia to experience many occupational accidents and work related diseases.

Work related disease is a disease caused by work, work tools, materials, processes, and the work

environment. Work related disease also defined as a health disorder, both physically and spiritually arising from or exacerbated by work activities or conditions work related. Work related disease doesn’t get intervention can cause a decrease in worker productivity which will have an impact on industries in Indonesia experiencing losses. Workers in informal industries such as the batik industry have a great potential to experience work related disease. Data of International Labor Organization showed that every year there was 2.78 person died due to work related disease. Data of Ministry of Health in Indonesia showed that 26.78% of workers in Indonesia experience diseases due to the work they do. One of the work related diseases that can be experienced by batik workers is Musculoskeletal Disorders (MSDs).

Musculoskeletal Disorders (MSDs) is disturbance experienced by workers on muscles, joints and tendons in all parts of the body. Musculoskeletal grievance can be constant or intermittent, that usually persists for a long period of time and is not always attributed to a specific cause. The data of Health Research and Development Agency in 2013 showed prevalence of workers suffering from Musculoskeletal Disorders in Indonesia of 11.9% and workers reporting musculoskeletal grievance of 24.7%. Musculoskeletal grievance caused by many factors. According to Graveling, musculoskeletal grievance caused by repetition, posture, force, and duration. Research conducted by Tjahayuningtyas showed that musculoskeletal grievance caused by age, exercise habit, posture, job tenure, body mass index and workload.

Study related to musculoskeletal grievance in the batik workers have been carried out in Indonesia. Research conducted by Santosa and Ariska in 2018 showed that risk factors affecting musculoskeletal grievance are type of work, age, work procedure, working posture, gender and working tenure. The study of Savitri, Hardian, and Sumekar in 2015 showed that inappropriate working posture when batik making caused musculoskeletal grievance. The study of Ramadhiani, Widjasena, and Jayanti in the batik workers in Kampoeng Batik Laweyan Surakarta showed that working duration and shoulder’s angle while extending are risk factors of musculoskeletal grievance. The research conducted by Isnaini, Bagyono, and Hendrarini in women lighters in the Village of Jarum Klaten showed that musculoskeletal grievance caused by working duration.

Batik Madura is one of informal industries engaged in the manufacture of batik cloth that develops in Bangkalan Regency. In the region, Tanjung Bumi Sub-District is among the largest producer and supplier of batik in Madura. The production activities in Batik Madura composed by several steps, such as the washing of plain mori cloth (Ketel), the drawing of the outlines of batik pattern (Rengreng), the drawing of small designs (Kuri), the application of wax using canting (Essean), the covering of cloth portion in which no designs are drawn (Nebbeng), the process of dyeing, performed twice, and removal or dissolution of wax using boiling water (Lorot). This study aims to determine the relationship between working tenure and working posture with musculoskeletal grievance in Batik Madura workers.

Materials and Methods

This study was an observational study with a cross-sectional design. This study was conducted on Batik Madura’s home industry, Tanjung Bumi Sub-District, Bangkalan Regency, Madura, Indonesia in January 2020. The population of this study was all Batik Madura workers as much as 81 people. The sampling technique in this study used with proportional stratified random sampling. Sample used in this study was all batik workers in Batik Madura’s home industry as much as 61 people.

Measurement of working tenure was carried out by filling out a research questionnaire and interview. Before asking respondents about working tenure, respondents were given an explanation about research implementation and respondents asked to fill out an informed consent if they agreed to take part in the research. Working tenure categorized into beginning, moderate, and long categories. Measurement of the working posture was carried out by observation when the workers during their work activities. The observation was performed by taking pictures of the workers’ working postures during batik production which were then analyzed using the Rapid Entire Body Assessment (REBA). The working posture categorized into low, moderate, high, and very high categories. Next, the respondents were asked to fill a Nordic Body Map (NBM) questionnaire containing 28 limbs presenting with musculoskeletal grievance by inserting a check mark on one of MSD grievance choices namely no pain, mildly painful, painful, and very painful.
according to their individual condition.

The data analysis technique in this study was univariate and bivariate analysis. Univariate analysis was conducted by determine frequency distribution for each variable, such as working tenure, working posture and musculoskeletal grievance. The bivariate analysis was carried out to analyze the relationship between working tenure and working posture with musculoskeletal grievance using the Spearman correlation test with $\alpha = 0.05$.

**Results and Discussion**

**Working Tenure**

<table>
<thead>
<tr>
<th>Category</th>
<th>Frequency (n)</th>
<th>Percentage (%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Beginning</td>
<td>22</td>
<td>36.0</td>
</tr>
<tr>
<td>Moderate</td>
<td>25</td>
<td>41.0</td>
</tr>
<tr>
<td>Long</td>
<td>14</td>
<td>23.0</td>
</tr>
<tr>
<td>Total</td>
<td>61</td>
<td>100.0</td>
</tr>
</tbody>
</table>

The results of working tenure were categorized in to 3 categories, namely beginning, moderate and long. Table 1 showed that 25 respondents (41%) was in beginning category, 22 respondents (36%) was in moderate category and 14 respondents (23%) was in long category.

Working tenure is one of musculoskeletal grievance risk factors. Working tenure can cause musculoskeletal grievance because working tenure will cause fatigue, monotonous, and repetitive work activities, which are the main cause of musculoskeletal grievance\textsuperscript{15}.

**Working Posture**

The assessment of working posture on 61 Batik Madura workers was performed by documenting working posture of the Batik Madura workers during working activities in the form of photos and videos. Then, the documentation results analyzed with the Rapid Entire Body Assessment (REBA) method. REBA way was divided into two clusters, A and B. Cluster A REBA analyzed body parts, namely neck, legs and trunk while Cluster B REBA analyzed body parts, namely forearms, upper arms, and wrists.

The results of working posture assessment with the Rapid Entire Body Assessment (REBA) method were categorized into 4 categories, namely low, moderate, high, and very high categories. Table 2 showed that 27 respondents (44.3%) had working posture in the high category risk level, 20 respondents (32.8%) were in the very high category risk level, 14 respondents (23%) were in the moderate category risk level, and no one respondents in the low category of working posture.

The rigid working posture causes the position of body parts move away from the natural positions. This condition lead the workers have a risk of musculoskeletal grievance

Musculoskeletal Grievance

The assessment of musculoskeletal grievance perceived by the 61 Batik Madura workers was performed by the way of interviews and filling the Nordic Body Map (NBM) questionnaire containing 28 body muscles were felt pain by the workers. The musculoskeletal grievance was categorized into low, moderate, high, and very high categories. Table 3 showed that 25 respondents (41%) in the high category, 20 respondents (32.8%) in the very high category, 16 respondents (26.2%) in the moderate category, and no one respondents in the low category of musculoskeletal grievance.

p-value = 0.837

* Significant at p-value < 0.05

The statistical analyze using Spearman Correlation produced p-value of 0.837. It means that there is no relationship between working tenure with musculoskeletal grievance. This study were in line with the study by M.A, Sabilu, and Pratiwi in 2016 showed that there was no relationship between working tenure with musculoskeletal grievance. The study of M.A, Sabilu, and Pratiwi in 2016 showed that working tenure is a related factor with length of time of someone has worked in a industry. Related to this, musculoskeletal grievance is chronic disease that requires a long time to develop and manifest. Someone has a long working tenure so someone exposed to these risk factors for musculoskeletal disorders then greater the risk for developing musculoskeletal grievance. There is no relationship between working tenure with musculoskeletal grievance on Batik Madura workers because most of the workers are recruited by Batik Madura’s owners during their working period in the beginning category, so that the musculoskeletal grievance felt by the workers are not based on the working tenure the worker has.

Relationship Between Working Posture with Musculoskeletal Grievance

<td>0.0</td>
</tr>
<tr>
<td>Total</td>
<td>16</td>
<td>26.2</td>
</tr>
</tbody>
</table>

p-value = 0.000

* Significant at p-value < 0.05
The statistical test using the Spearman Correlation produced a p-value of 0.000. It means that there was a relationship between working posture with musculoskeletal grievance. Static working posture during working activities cause blockage of blood flow in the body so the body's organs suffer from deficit of oxygen and glucose in the blood. This condition forces body to generate a metabolism byproduct in the form of lactic acid that gives rise to soreness when it builds up. This study were in line with Saputro, Mulyono, and Puspikawati in 2018, the study showed that there was a correlation between working posture and musculoskeletal grievance in batik workers in Virdes Batik Collection. Similarly, Santosa and Ariska also found a correlation between working posture and musculoskeletal grievance in batik artisans with a p-value of 0.001. Unergonomic working posture make up the position of the body parts move away from natural positions. This posture shows strong evidence as a risk factor which can lead to musculoskeletal grievance.

**Conclusion**

This study draws conclusions that the majority of Batik Madura workers have a working tenure in the beginning category, working posture in high category, and musculoskeletal grievance in high category. There is no relationship between working tenure with musculoskeletal grievance in the Batik Madura workers. There is a relationship between working posture with musculoskeletal grievance in the Batik Madura workers.

To avoid musculoskeletal grievance in the Batik Madura workers, workers are advised to break for 20 minutes when working by moving head, leg and body. The owners of Batik Madura advised to do a redesign to workplace starting by providing chair with back support and armrests as well as *gawangan* (a bamboo frame over which the cloth to be waxed is draped).

**Acknowledgments:** We would like to say thank you to all parties that are involved in this study, especially workers and the owners of Batik Madura who have been willing to become the respondents in this research.

Effectiveness of Transport Guidelines on Intra Hospital Transport Practices of Nurses and Occurrence of Mishaps among Critically ill Patients

Gautam Sakshi1, Sembia N2, Kumari Vinay3

1Nursing Officer, Dr. R.M.L. Government Hospital, New Delhi, 2Associate Professor, U.P.U.M.S., Nursing College, Saifai, Etawah, Uttar Pradesh, 3Chitkara School of Health Sciences, Chitkara University, Punjab

Abstract

Background: Intrahospital transport means transporting ill patients for diagnostic and therapeutic procedures within the hospital. Implementation of intrahospital transfer demands a well organized meticulous planning and prompt application of well designed plan.

Objectives: To compare intrahospital transportation practices and occurrence of mishaps during intrahospital transport before and after administration of hospital transport guidelines and to determine the association with situational variables (level of floors and distance of destination)

Methods: Quasi experimental one group pre test post test design was used in the study by event sampling. 55 pre test transport and 62 post test events were selected. IHT guidelines was given to nurses working in operation theater by using demonstration cum lecture technique, one on one teaching provided to individual nurse consecutively. Observational technique was used for data collection. Result showed that the mean percentage of intrahospital practice were higher (89.37%) then pre test (40.03) with a mean difference of 49.33. Computed t value (t=37.46,p=0.000) was statistically significant. Chi square value of occurrence of mishaps regarding intrahospital transport is ($X^2=53.9$,p=0.001) statistically significant. F value between transportation practices with distance from OT were (f=1.68,p=0.16) and Computed t value practices with level of floor were (t=1.60,p=0.39) statistically not significant at 0.05 level of significance. Conclusion Intrahospital transportation guidelines are effective in reducing mishaps and increases transportation practices.

Key Words: Intra hospital transport practices, mishaps, transport guidelines

Introduction

Intrahospital transport (IHT) means transporting ill patients for diagnostic and therapeutic procedures with in the hospital. An assured quality of IHT can be maintained through the ground formula of a significant quality of intrahospital transfer which provides degree of care before, during and after transportation. A close intermediate and continuing communication are required for smooth transfer till the destination department for transfer1. The care of acutely ill patients includes constant monitoring and adequate intervention to protect client from harms or prevent mishaps, it is an integral responsibility of nurses2. Several studies have shown that transporting critically ill patients can lead to alteration in their physiological status and they are at acute risk of increased morbidity and mortality3. Researcher could only locate one study related to effect of transport guidelines on mishaps and none of the studies on transport practices moreover located studies are concerning intrahospital transport focused on I.C.U and emergency rather than Operation theatre’s (O.T) patients, also most of the studies are not recent. However OT patients are under anesthesia and have limited physiological reserves. Hence effect of intervention on reducing the mishaps for OT patients has received little attention. Therefore present study has been conducted to improve the IHT practices and reduction of mishaps in O.T patients (patients who had undergone surgery and are being shifted to destination department from OT’s recovery room). The purpose of
the study was to evaluate the effectiveness of transport guidelines on Intra Hospital Transport Practices of Nurses and Occurrence of Mishaps among Critically ill Patients which miscellaneous causes 64% was highest including oxygen probes(27.33%), ECG leads displacement (19.42), oxygen saturation was dropped in 10.79 patients, 3.59% and 4.31 were reported of altered mental status and arrhythmia respectively, 3 patients out of 64 have been terminated from the transport due to serious adverse effects.

Method and Material

Quantitative research approach and Quasi experimental one group pre test post test study design was used to assess the effectiveness of transport guidelines on IHT practices of nurses and occurrence of mishaps among critically ill patients, Rosswrum and larrabee conceptual frame work was used and figure 1 shows schematic representation of research. Study was conducted in 950 bedded multispecialty teaching hospital which consist of 8 operating theaters consist of three general OT, one neurosurgery OT, one gynae surgery OT, one Cardio thorax OT, one eye OT, one ENT OT and 3 minor OT. Duration of data collection was three months from December 2015 to January 2016. Sample size was calculated using power analysis with 5% significance and 80% power, standard deviation of the transport being studied (σ=7.74) based on previously published study, where as the size of the effect, mean difference (d=3.06) was calculated from annual census of surgery occurred at OT. Event sampling was used to observe the events of transportation and total enumerative sampling method was used to select nurses for checking acceptability of transport guidelines. 55 transport events before administration of transport guidelines 62 transport events after administration of transport guidelines.

Data was collected using three tools for the study tool one: Observational Checklist for Assessment of Intra Hospital Transport Practice first section consist of situational variables which include 2 items place of transport :distance from OT to designated ward (measurement was taken from university architectural department) and level of floors. Section 2 consist of observation checklist for assessment of intra hospital transport practices it comprises of three areas before, during and after transportation with total items 17,10,8 and weightage 48.5,28.5,22.85 respectively, also the level of practice in terms of intrahospital transport were very good (>85%), good (66-85%), average (51-65%), below average (<50%).

Second tool was checklist for assessing occurrence of mishaps, it contains 13 items disconnection of urinary catheter, backflow of urine, disconnection of surgical, displacement of oxygen supply , displacement of saturation probe etc with individual score range of checklist (0-13).Third tool was acceptability scale it was prepared to assess the acceptability of transport guidelines among nurses it contains 5 semantic differential scale consist of 7 items easy, valuable, time saving, practical, beneficial, effective on reducing mishaps , 5 point scale has rating from 1-7, individual score ranges from 7-35.

To ensure content validity of the tool it was submitted to 7 experts from nursing field of medical surgical department and child health nursing department also 2 experts from medical ICU, and surgical ICU were asked to mark one response out of 3 responses like “fully met” “mostly met” “to some extent” and requested to give suggestions and remarks, all three tools were validated after incorporating the suggestions and modifications given by experts, scale content validity index by averaging item content validity was 0.80. Consensus measure of inter rater reliability for observational coding by asking experts from neurosurgery ,emergency department and researcher to mark each tool items against response of dichotomous “yes” or “no” , later cohen’s kappa coefficient was 0.70 for transport practices and 0.72 for occurrence of mishaps was established . Development and validation of guidelines was modified with contribution of health professional from various area, later organization of content, language, practicability and feasibility was established in pilot study, all corrections were incorporated in final intervention. Occurrence of events of transportation of patients who has surgery under general/spinal anesthesia from OT (general, gynae, ortho, ENT, neuro ) to destination wards (recovery ICU, surgical ICU, surgery ward A,B,C) under presence of researcher, also staff nurses who were available during the time of data collection were included into the study, where as events of transportation occurred in absence of researcher or patient who had surgery under local anesthesia or events from pediatric OT and staff nurses
who were not available at the time of data collection were excluded from the study.

Ethical approval from university communication of decision of ethics committee (IEC) project no. 371 was obtained from medical superintendent, written informed consent was obtained from study subject after explaining about the research project and assurance of confidentiality was given. In order to develop rapport, introduction to self and study was given to the nurses working in OT. After obtaining informed consent, from day one to day 14 before intervention 55 events of intra transport practices and occurrence of mishaps were assessed, from day 15 to 19 a transport guidelines through group teaching (45min) was administered including demonstration of two transport events and return demonstration of two events by individual staff nurse. From day 20 to 34 after administration of guidelines 62 events were assessed.

For statistical analysis, using SPSS version 17 both descriptive and inferential statistics were used to compare continuous variable student’s t test was used and chi square to compare percentage p<0.05 was considered statistically significant. Data were expressed as mean% ± standard deviation (SD) the association between mishaps and situational variables were also studied using ANOVA (in the present study the dependent variable (D.V) i.e. intrahospital practices were assessed through checklist, each correct transport practices was scored 01 and incorrect 00. And a total practices score was obtained, therefore to seek association of D.V i.e. IHT practices with situational variables (independent variable (I.V)), ANOVA was used. For ANOVA to be applied D.V should be in interval/ratio scale and I.V should be in nominal/ categorical scale, as practices were measured interval scale by assigning score to them, therefore, D.V in the study was meeting eligibility of ANOVA).

**Result**

Analysis and interpretation of data were based on the objectives and hypothesis to be tested. The objectives of the study were to compare intrahospital transport practices before and after administration of transport guidelines. To compare occurrence of mishaps during intrahospital transport before and after administration of hospital transport guidelines. To determine the association of transport practices with situational variables. To determine the acceptability of transport guidelines among nurses. The following hypotheses were tested at 0.05 level of significance:

H1. There will be significant difference in the mean practice score regarding intrahospital transport before and after administration of transport guidelines.

H2. There will be significant difference in the occurrence of mishaps during intrahospital transport before and after administration of transport guidelines.

H3. There will be significant association of transport practices with situational variables.

In null hypothesis there is no relationship between variables and that any observed relationship are results of chance or sample fluctuations.

In terms of comparison of situational variables, in pre test the majority of events were from OT to ICU(34.5%) followed by surgery B (18.2%) surgery A (18.2%), surgery C(16.4%) and RICU(12.7%). 57.2% events of transport occurred on other floor than the OT, about 47.3% events of transport occurred on same floor at OT, whereas in post test majority of events of transport were from OT to ICU i.e. 33.9% surgery B(21%) surgery A (17.7%) surgery C (16.1%), RICU (11.3%). 54.8% events of transport occurred on other floor then the OT and 45.2% occurred on same floor. Chi square was applied to compare pre test and post events with respect to place of transport ($\chi^2=0.09$, $p=0.24$) level of floor ($\chi^2=2.00$, $p=0.50$) compute chi value was found to be not significant at 0.05 level of significance hence events of transportation were homogenous and comparable in terms of situational variables. Bar graph (figure: 2) shows frequency percentage distribution of transport events and concludes that level of practices were improved.

In pre test range of IHT practice score was 21.87 to 70.58 with mean % and SD 40.03±9.11, median 37 whereas in post test range was 78.12 to 93.75 with mean% and SD 89.37±4.67, median 90, (Table no. 1) computed ‘t’ value ($t=37.46$, $p=0.001$) was found to be statistically significant at 0.05 level of significance which shows that mean difference obtained was true difference and not by chance, Hence intra hospital guideline were
effective in improving IHT practices also in area wise i.e. before, during and after transport (Table no.2) was found to be highly significant at 0.05 level of significance in each area which shows true mean difference and not by chance hence improved IHT practices, therefore H₁ accepted, while assessing effectiveness of transport guidelines in terms of occurrence of mishaps (Table no.3) chi square value regarding intrahospital transport was statistically significant at 0.05 level of significance with disconnection of urinary catheters ($\chi^2 = 2.72$, $p=0.03$) backflow of urine ($\chi^2 = 40.01$, $p=0.001$), disconnection of surgical drain ($\chi^2 = 21.59$, $p=0.001$), showing significance difference obtained of occurrence of mishaps whereas disconnection of oxygen supply, dislodgment of oxygen probe, disconnection of intravenous line ($\chi^2 = 0.09$, $p=0.75$) in pre test 94 times out of 473 (total applicable mishaps) i.e. 19.87% and 25 times out of 542 (4.77%) mishaps occurred in post test and chi square ($\chi^2 = 53.94$, $p=0.001$) was found to be statically significant at 0.05 level of significance. Table no. 4 shows t value was significant and inferred that significant difference in occurrence of mishaps in before and after administration of IHT guidelines was effective on reducing occurrence of mishaps, (in this table all values are calculated in % as the no. of practices were varying, denominators are different in pre and post test, level of ) hence hypothesis H2 accepted. Also, level of acceptability (n=22) regarding IHT guidelines in figure 3 concludes the guidelines were acceptable by nurses in terms of easy, valuable, time, saving, acceptable and practical. In terms of association of transport practices with situational variables (Table no. 5), findings reveals that the transportation practices was not associated with place of transport and level of floor were independent with respond to situational variables hence research hypothesis H₃ was rejected.

Discussion

In respect to aim of the study the intrahospital guidelines were effective in reducing mishaps and increase in level of practice. In the present study pre test depict, the level of practice regarding IHT was below average (79%) in the majority of events whereas in post test, it was very good (79%) in the majority of events followed by good (21%) practices. Also chi value showing comparison between occurrence of mishaps in pre and post test depicts that after administration of guidelines occurrence of mishaps decreased in post (94 to 25, p-0.001) the findings of the study was consistent with the study conducted by H.K Choi et al\(^5\), in which unexpected events decreased significantly (36% -22.1%, p-0.001) and after administration of guidelines disconnection of oxygen supply has increased in (50% to 69.23%,p-0.567) findings of the study was inconsistent with the study conducted by Choi et al, in which line disconnected for oxygen supply decreased (10.1% -2.6%,p-0.19) was also observed that transportation practices were independent of distance of transport’s designation, (p-0.167) finding of the study were consistent with the study conducted by Despoina G.A, & Brokalaki H.\(^6\), that distance from destination did not appear to affect the interruption frequency of patient’s treatment(0.190). Another finding the displacement of oxygen probe in pre test events was 50% whereas in a study conducted by Rao S, Muktule D, Taggu A, & Venkategowda P\(^4\), shows 27.83% of oxygen probe unexpected events has occurred. In present study, out of 55 pre test events 18.18% of doctors, 5.45% of nurses and 100% attendants were present while transporting patients(data collected from one of the item in IHT practices tool), a similar findings shown by Silmara M\(^7\) in which 77.3% of the team were composed of physician, nurse and nurse technician. 50% of oxygen desaturation occurs in 55 pre test events, where as in study done by Kue R, Brown P, Ness C, & Scheulen J\(^8\) reported 8.8% of oxygen desaturation occurred during intra hospital transport. In present study pre test events, 98.19% had poor communication whereas in a study conducted by Beckmann U. Et.al\(^9\), 61% of the incidence reflected to staff management issue including poor communication and inadequate monitoring. The study was confined to small group and lack control group also hawthorn effect was not controlled in the study and extraneous variables like age and severity of illness of the patients were not assessed.

Recommendation

Based on findings of study a replica on large sample can be done to make generalization, randomized control
Trial cab be conducted also experimental study can be done to evaluate the knowledge and attitude of nurse regarding use of transport guidelines. A standardized transportation, further research can be conducted to explore physiological changes and emotional experiences of patients.

**Conclusion**

Intrahospital transport guidelines were effective in reducing mishaps and increases transportation practices. Common mishaps identified were backflow of urine, disconnection of I.V lines, and there was no association found in between situational variables and intrahospital transport guidelines.

Knowledge of Women about the Early Detection Methods of Cervical Cancer in Baghdad City

Iman A Jaber
Instructor, Baghdad College of Medical Sciences

Abstract

Background: Cervical Cancer is considering a public health problem, leading cause of mortality and morbidity among women.

Objective: To assess women’s knowledge regarding cervical cancer and early detection methods

Methodology: A descriptive study was conducted, included (200) women from different levels of education who work in the institute, from 5th November 2018 to 30 April 2019, by using interview technique and self-reporting technique. A non-probability (purposive) sample of (200) women. The questionnaire was used for data collection. The validity was estimated through a penal of experts related to the field of study, and so the reliability was evaluated through a pilot study conduct included (10) women (except from the original sample). Data is analyst through the implementation of descriptive and inferential statistical analysis.

Results: The results of this study show that the knowledge of the study sample was low regarding early detection methods, prevention treatment and there was statistical significant relationship between level of knowledge, and some variables

Recommendations: It was recommended that increase coverage in cervical screening programs from Iraq ministry of health to encourage women in Iraq. In addition, training program should supply in educational institute

Key words: Cervical Cancer, Knowledge Pap Smear and Women

Introduction

Globally, they found cervical cancer is the fourth most frequent cancer among women (1).

Cervical Cancer was a public health problem and a leading cause of mortality and morbidity among women (2,3) and it is the fourth most frequently diagnosed cancer with an estimated 527,600 new cases in 2012 worldwide. It is the fourth leading cause of cancer death with 265,700 deaths among women worldwide in 2012 (4,5) and so it was the fourth most frequent cancer in women with an estimated 570,000 new cases in 2018 appear 6.6% of all female cancers. Approximately 90% of deaths from cervical cancer occurred in developing countries. The high mortality rate from cervical cancer globally could be reduced through a comprehensive approach that includes prevention, early diagnosis, and effective screening and treatment programmers. There are currently vaccines that protect against common cancer that cause types of human papilloma virus and can significantly reduce the risk of cervical cancer (1).

There are contributory factors that make women vulnerable to develop cervical cancer, viral infections (HPV, HIV, and HSV), multiparty, early initiation of sexual activity, multiple sex partners, smoking, low socioeconomic status, diet low in antioxidants, poor hygiene, long-term use of oral contraceptives and immune suppression conditions (6).

The incidence of cervical cancer in Iraq it relatively low, as in most other Islamic countries, yet most of the cases usually present in advanced stages with poor prospects of cure. Earlier studies have illustrated un negligible rates of CIN lesions among Iraqi patients.
complaining of gynecological problems (221) Incidence Rate 1.20 /100,000P (7).

Common risk factors include early age at first intercourse, having multiple sexual partners and a weak immune system. Research evidence has shown that Human Papilloma virus (HPV) is the most important etiologic agent in the vast majority of cases and the cause of 99.7% of cervical cancer cases, which is among the most frequent cancers in women (8,9).

Aim of study: To assess women’s knowledge and attitudes regarding cervical cancer and early detection methods of cervical cancer for the teacher and employer who were working in Technical Medicine Institute, Baghdad

Methodology
A descriptive study was included (200) women from different levels of education who work in Technical Medicine Institute, Baghdad Through using the assessment approach for the period from 5th November 2018 to 30 April 2019. The questionnaire was used for data collection. The validity was estimated through a penal of experts related to the field of study, and so us the reliability was evaluated through a pilot study included 10 women. The questionnaire form was consisted of (3) main part. The data were collected by using interview method and self-report techniques with study participants after obtaining permission from each of them according to the inclusion criteria.

Reliability of the questionnaire was estimated through the use of Alpha Cronbach for the test-retest approach, descriptive statistics (frequency, percentage Cum. Percent, Mean of score (M.S.), and Relative Sufficiency (R.S.)) and inferential statistics (Alpha Cronbach, Reliability Coefficient, Chi Square).The items of women documentation were rated on two level know, and don’t know, and scored as , 2 and 1, respectively ). Mean of score Low (1-1.49), Moderate (1.5 – 1.75), and High (1.76 –2]

Table (3) demonstration that there was statistically significant relationship among studied variable, and level of knowledge

**Discussion**

1 - Demographic characteristics of study sample.

Cervical cancer was the second most common cancer in women, cause high morbidity and mortality worldwide\(^{10}\)

In Iraq, significant knowledge gaps about the relative importance of cancer among the Iraqi community have been demonstrated suggesting a potential to take practical policy decisions that aim at promoting screening though elevating the level of awareness\(^{15}\) Throughout the present study, ) Regarding age group, more than half of women their ages were between (20-39) Years old. This result is agreeing with a study done in Kenya to assess women’s knowledge and attitudes related to cervical cancer the median age of sample was (66.3%) there aged18 to 39 years\(^{11}\)

Regarding to the level of education, the majority of them were Institute & college graduates. This result is similarly with a study it was done in Baghdad to assess teachers’ Knowledge regarding cervical cancer. \(^{13}\)

Furthermore, the study indicated that more than half of sample study in Moderate economics status.
This result agree with study done In Egypt shown that economic status(56%) had enough monthly income. (12)

According to Distribution of reproductive health history for women most of them (96.5%) was (12-14years) (Age at begin first menstrual cycle /years) this result disagrees with study done in Baghdad City who they found that the (2.5 %) had no pregnancy, 40%) had just one. (13) and ( (37.0%) of them had Family history of cancer the (14.5%) with Breast. Study done in Sudan states that can prevent cervical cancer, by prevent smoking, use oral contraceptive, and unsafe sex. (17)

2. Discussion of women’ knowledge related to the early detection.

There is Low of women knowledge, (table 1). this study also disagrees with study in Addis Ababa show that the odds of good knowledge about cervical cancer among government and nongovernmental organization employees were two times higher than among unemployed participants. (18) So, us study done in Chania assess that a total of 15.3% of the participants in this study indicated that they had never heard of cervical cancer previously. (19) so, us there is a deficit level of knowledge and awareness was documented concerning the epidemiology of cervical cancer (15)

3-Discussion the Women’s knowledge about methods, treatment and prevention of cervical cancer

There is low knowledge of women, regarding the total mean of scores (73.7%). In our study the results showed a deficiency in knowledge about methods, treatment, prevention cervical cancer some of the sample had less than (50%) from mean of scores the researcher opinion that the medical worker is one of the most important health knowledge provider and promoter. So, if the medical workers have unsatisfactory knowledge, inappropriate attitude and practice, they would not be spread the knowledge to the community , this study agree with study in Ethiopia, “ that women’s knowledge on cervical cancer was low, despite the high incidence of the disease in Ethiopia. Relatively, a large proportion of the study participants had favorable attitude towards cervical cancer screening attending primary, secondary school and college. (16)

4. Discussion the Association between Level of Knowledge of Study Sample and Studied Variables

There is a statistically significant relationship between studied variable, and level of knowledge this was not agree with study in Tanta, they found no statistically significant difference was found in relation to response to change, and a significant difference was found in relation to education and work. so, education and working environment increase all knowledge and awareness on cancer especially among married women as sexual health constitutes a taboo in our culture. and agreement to our findings, knowledge, Pap smear test were not associated with demographic variables as reported. (14) In addition, this result is corresponding with the study done in Baghdad, which revealed the educational status is positively associated with total knowledge of women on cervical cancer. who have primary, secondary and college/ university education were more likely to have best knowledge on cervical cancer than those who did not have. (15)

Conclusion

It was concluded is that that educated women of sample have deficit knowledge, towards cervical cancer and Pap smear.

Conflict of Interest: Nil

Source of Funding: the source of funding is self

Ethical Clearance: is obtained from the Technical Medicine Institute, Baghdad

Recommendation

1- increase coverage in cervical screening programs from Iraq ministry of health and directed towards women medical practitioners participants in the research - have been approved before the questionnaire is started

2- Long-term education programs should be made available to encourage the female population in the Iraq

3- Training should be supplied to nurses and primary care physicians to motivate screening.

Causative Microorganisms and Antibiotics Susceptibility in Neonatal Sepsis at Neonatal Intensive Care Unit: A Longitudinal Study from Diyala Governorate in Iraq

Issam Tariq Abdul Wahaab, Sura Qais Mahmood Almaroof, Zaid Taha Yaseen

1Lecturer in Department of Anatomy/ College of Medicine, University of Baghdad, Iraq, 2Senior House office in Department of Pediatric/ Neonatology Unit, Diyala Health Directorate, Iraq, 3Senior House Office in Department of Pediatric/ Neonatology Unit, Diyala Health Directorate, Iraq

Abstract

Background: Neonatal sepsis is classified into two types, early-onset and late-onset sepsis, depending on the time of appearance of the clinical features of neonatal sepsis.

Objective: We aim to detect the most common causative organisms of neonatal sepsis and to evaluate the corresponding antibiotics susceptibility in the Diyala governorate.

Patients and Methods: We prospectively collected a convenient sample of 106 sepsis-proven neonates from the neonatal intensive care unit at Al-Batool teaching hospital. We assessed all cases based on clinical features, laboratory investigations, and demographics.

Results: Late-onset neonatal sepsis was predominant (77.4%) among neonates, and it was significantly associated with neonatal prematurity and the mode of delivery at p-values of 0.03 and 0.045 respectively. Premature neonates and those who were the product of cesarean section were more prone to develop late-onset neonatal sepsis with a relative risk of 2.8 and 2.54 respectively. The most common causative microorganism of early-onset neonatal sepsis was found to be Escherichia coli in 45.8% of cases while those causing late-onset neonatal sepsis were mainly due to Gram-negative bacilli represented by Klebsiella pneumonia (46.3%) and Acinetobacter baumannii (24.4%). Multi-drug resistance was evident for most of the causative microorganisms.

Conclusion: To recapitulate, late-onset sepsis appeared was more common among Iraqi neonates, and it was significantly associated with the neonate prematurity and C-section mode of delivery.

Introduction

To date, neonatal sepsis is still a significant cause of neonatal mortality and morbidity, albeit effective modalities of diagnostics and therapeutics implemented by neonatologists worldwide, including those in the developed world. Neonatal sepsis is defined as the bacterial invasion of bloodstream causing non-specific systemic manifestations such as fever, respiratory problems, bradycardia or tachycardia, poor feeding, lethargy, irritability, seizures, abdominal distention, and unexplained jaundice. Neonatal sepsis is classified into two types, an early-onset and late-onset sepsis, depending on the time of appearance of the signs and symptoms of neonatal sepsis. Early-onset neonatal sepsis is diagnosed when the clinical manifestations of neonatal sepsis appear within the first 72 hours of life while the late-onset neonatal sepsis is diagnosed when they appear after the 72 hours of life. Early-onset neonatal sepsis is acquired before and during delivery, and it is either a trans-placental or an ascending infection within the birth canal. The microorganisms expected to cause early-onset sepsis are prevalent in the
maternal genital tract, including Escherichia coli (E. coli) and group B streptococci which are responsible for the majority of cases and may ascend to the amniotic fluid causing chorioamnionitis especially when there is a premature or a prolonged rupture of membranes (PPROM) (5). On the other hand, microbial agents inducing late-onset sepsis are either nosocomial or community-acquired infections and are transmitted to unfortunate neonates (1-5). Many factors predispose the neonates to get an infection (1). Risk factors for early-onset sepsis include maternal infections and febrile illnesses, chorioamnionitis, PPROM, prematurity and low birth weight (4). Risk factors for late-onset neonatal sepsis are invasive procedures, including surgical manipulation, intubation, central venous catheters, resuscitation, mechanical ventilation, and a prolonged stay in the neonatal care units (4).

The causative microorganisms variate spatially and temporally, and from a population to the other (1). Accurate identification of the source of infection, proper use of antimicrobial agents, and the study of antimicrobial susceptibility play essential roles in the prevention and control of neonatal sepsis and its complications, and this will increase the success rate of management of sepsis while reducing the economic burden on the holistic healthcare system, particularly in developing nations (6). It is imperative to know whether the newborn baby has got sepsis, or not, and to detect the type of causative invasive microorganisms, and to start the treatment as early as possible (7). A first interventional approach will reduce the risk of multidrug-resistant bacteria (MDR) which is defined as resistance to three or more antimicrobial classes (8). To date, there is no single test to diagnose neonatal sepsis with high specificity and sensitivity (1-3). Therefore, diagnostic tests must be in correlated in conjunction with assessing the risk factors and detecting the clinical signs of sepsis. Confirmatory laboratory tests include blood, urine, and cerebrospinal fluid cultures (CSF), as well as ESR, C-reactive protein (CRP), differential leukocyte profile, platelet count, latex agglutination tests and Polymerase Chain Reaction (PCR) (9).

In the present study, we aim to detect the causative microorganisms of neonatal sepsis and evaluate the antibiotic resistance in the neonatal intensive care unit in Al-Batool teaching hospital in the Diyala governorate. Our first hypothesis is that late-onset neonatal sepsis is more prevalent in our Neonatal intensive care unit (NICU) and mostly caused by Gram-negative bacilli. The second hypothesis is that multi-drug resistance exists among most of the causative microorganisms.

Materials and Methods

Using a convenient sampling procedure, we prospectively collected 106 sepsis-proven neonates in the neonatal intensive care unit of Al-Batool teaching hospital for the period from the 1st of December 2018 to the 1st of October 2019. We evaluated all the selected cases using clinical examination and laboratory investigations. The laboratory investigations included complete blood count (CBC), C-reactive protein (CRP), blood cultures, and chest x-ray (CXR). All cases enrolled in this study were diagnosed by the presence of at least three out of the following four criteria: 1) Presence of neonatal sepsis risk factors such as prematurity and chorioamnionitis. 2) Presence of two or more signs of the non-specific systemic manifestations such as fever, respiratory problems, bradycardia or tachycardia, poor feeding, lethargy, irritability, seizures, abdominal distention, and unexplained jaundice. 3) Positive CRP and abnormal CBC. 4) Positive culture (2). We also collected data concerning gestational age, the PPROM, mode of delivery, maternal fever, and sex of neonates. A professional laboratory technician collected blood samples from neonates with high clinical suspicion of sepsis for CRP, CBC, and blood culture. The technician collected approximately five cubic centimetres of fresh blood, using aseptic technique, from a peripheral vein from each neonate and sent for biochemical and microbiology studies for cultivation and subsequent processing. Besides, we collected samples of urine and CSF for culture procedures.

The blood samples were cultured under the aerobic condition at 37° C. The cultured blood was observed daily in the first three days to report any visible growth by detecting any one of the following: hemolysis, air bubbles, and coagulation of broth. At the same time, subcultures were made during three successive days on enriched and selective media including blood, chocolate, MacConkey, and mannitol salt agar plates and examined for microbial growth after 24 to 48 hours of incubation. The same procedures were repeated until
the 7th day before the blood culture was considered to be free of microorganisms. The obtained bacterial isolates were identified by microbiological methods including colony characteristics, Gram staining, and biochemical properties like catalase, coagulase and DNase production, hemolytic activity on blood agar plates, and growth on mannitol salt agar for Gram-positive bacteria. On the other hand growth on cetrimide agar, citrate utilization, urease, oxidase, and hydrogen sulfide production were used for Gram-negative bacteria. We used VITEK 2 AST-N327 kits (BIOMERIEUX/France) to validate the identification of Gram-negative bacteria. The results were read using API 32 GN reader. Antibiotics susceptibility was assessed by using the VITEK 2 AST-N327 identification kit in the VITEK 2 compact automated microbial detection system manufactured by bioMérieux France. The tested antibiotics with their minimal inhibitory concentration (MIC) were: Ampicillin 10\(\mu\)g, oxacillin 1\(\mu\)g, gentamicin 10\(\mu\)g, amikacin, vancomycin, ceftriaxone, cefotaxime, ceftazidime and cefoxitin with MIC of 30\(\mu\)g for each, ciprofloxacin 5\(\mu\)g, imipenem and meropenem with MIC of 10\(\mu\)g for each, azithromycin and erythromycin with MIC of 15\(\mu\)g for each, tetracycline (30\(\mu\)g), trimethoprim/sulfamethoxazole (1.25/23.75\(\mu\)g), fosfomycin (200\(\mu\)g), colistin (4\(\mu\)g), tigecycline (15\(\mu\)g) and piperacillin-tazobactam (100/10\(\mu\)g).

We analyzed the data collected by using IBM SPSS version 20, and we expressed the variables as frequencies and percentages. We implemented a Chi-squared test to study the relationship between the onset of neonatal sepsis and each of gestational age, PPROM, mode of delivery, maternal fever, and neonatal gender. We adopted a p-value of 0.05 as the cutoff margin for statistical significance in hypothesis testing.

**Results**

We collected a convenient sample of 106 neonates who had proven neonatal sepsis, and those patients were admitted to the neonatal care unit at Al-Batool teaching hospital from December 2018 to October 2019. We analyzed our data, using descriptive and inferential statistics, in connection with the onset of neonatal sepsis, possible risk factors, to examine the most common causative bacteria in the early and late-onset neonatal sepsis, and to discover the relative antimicrobial susceptibility. Male neonates were 52 (49.1%), and the female neonates were 54 (50.9%) (Table 1, Figure 1).

Among our sample, 24 (22.6%) were of early-onset sepsis, and the remaining 82 (77.4%) were of late-onset sepsis. Preterm neonates accounted for 76 cases (71.7%) and the term neonates attributed to 30 cases (28.3%). PPROM existed in 70 (66%) of cases while the remaining 36 (34%) had an intact membrane. A total number of 67 (63.2%) were a product of cesarean sections, and the remaining 39 (36.8%) were a product of vaginal delivery. There was a history of maternal fever in 69 (65.1%) of cases.

In Al-Batool teaching hospital in Diyala governorate in Iraq, neonates in the neonatal intensive care unit were more prone to develop late-onset sepsis. The most common microorganisms causing late-onset neonatal sepsis included Klebsiella, Acinetobacter baumannii, coagulase-negative staphylococci (Staphylococcus epidermidis, Staphylococcus hominis,
and Staphylococcus haemolyticus), Staphylococcus aureus, and Enterobacter species which accounted for 46.34%, 24.4%, 17.1%, 3.7% and 3.7% of the late-onset neonatal sepsis respectively. Early-onset neonatal sepsis was mainly due to E. coli, Staphylococcus hominis, and Klebsiella, which represented 45.8%, 20.8%, and 12.5% of early-onset neonatal sepsis, respectively (Table 2).

</table>

This study showed that the onset of the development of neonatal sepsis had a significant relationship with the gestational age and mode of delivery as p-values were equal to 0.03 and 0.045, respectively. Besides, the relative risk for preterm neonates to develop late-onset neonatal sepsis was 2.8 which means that there is a 180% increment in the probability of developing late-onset sepsis with prematurity compared with neonates who are born at full-term, while the relative risk for neonates who were products of cesarean sections to develop late-onset neonatal sepsis was 2.54. Thus they are more likely to develop late-onset neonatal sepsis by 154% more than neonates who were products of vaginal delivery (Table 3).

The antibiotic resistances of the most common causative microorganisms, which were responsible for causing late-onset neonatal sepsis, were as following as shown in table 4: Klebsiella was resistant to penicillins, cephalosporins, and aminoglycosides, while it was sensitive to azithromycin, colistin, imipenem, and meropenem in 78%, 70.7%, 41.5% and 31.7% of cases respectively. Acinetobacter baumannii was 100% resistant to the tested penicillins, cephalosporins, and aminoglycosides, but it was sensitive to colistin and tigecycline in 95% and 60% of cases respectively. Staphylococcus epidermidis was resistant to the tested penicillins, cephalosporins, and aminoglycosides except for vancomycin since it appeared to be sensitive to vancomycin and tigecycline in 100% of cases.
respectively. Staphylococcus hemolyticus appeared to be resistant to most of the tested antibiotics, while it was sensitive to tigecycline, ciprofloxacin, and vancomycin in 80%, 60%, and 60% of cases respectively. Staphylococcus aureus was resistant to most of the tested antibiotics, but it was sensitive to ciprofloxacin, tigecycline, and vancomycin in 100%, 75%, and 75% of cases, respectively. Enterobacter species were resistant to most of the tested antibiotics, while it was sensitive to ciprofloxacin, tigecycline, and cefoxitin in 100%, 100%, and 50% of cases respectively.

On the other hand, the antibiotic resistances of the most common causative microorganisms, which were responsible for causing early-onset neonatal sepsis, were as following as shown table 5: E. coli was resistant to the tested penicillins, cephalosporins and aminoglycosides except for amikacin since it appeared to be sensitive to meropenem, imipenem, amikacin and ciprofloxacin in 90.9%, 81.8%, 81.8% and 63.6% of cases respectively. Staphylococcus hominis was resistant to most of the tested antibiotics, but it showed 100% sensitivity to each of tigecycline and metheprome. Proteus species were 100% resistant to the tested antibiotics except for amikacin, meropenem, fosfomycin, and tazocin, where they were 100% sensitive for these antibiotics. Pasteurella pneumotropica was 100% resistant to the tested antibiotics except for amikacin and meropenem since it appeared to be 100% sensitive for each one of them.

Discussion

Neonatal sepsis remains the major cause of morbidity and mortality in most of the neonatal intensive care units internationally. Hence, we should continually update our knowledge on the causative microorganisms, possible risk factors, and the emergence of multi-drug resistance microbial strains which drastically affect the outcome of management. Physicians should aim to facilitate the emergence of a potential empirical antibiotic therapy depending on the knowledge of their epidemiological factors and the antimicrobial susceptibility in connection with spatial and temporal epidemiology of neonatal sepsis (6). Our study showed that the Iraqi in the Diyala governate were more susceptible to develop late-onset neonatal sepsis (77.4%). Besides, the onset of the development of neonatal sepsis had a significant relationship with the gestational age and mode of delivery as p-values were equal to 0.03 and 0.045, respectively. Thus premature neonates were more prone to develop late-onset neonatal sepsis than term neonates as the relative risk was 2.8, and those who were the product of cesarean section appeared to be at a higher risk of developing late-onset neonatal sepsis as the relative risk was 2.54. Furthermore, multi-drug resistance was a problem for most of the causative microorganisms. The most common causative microorganism of early-onset neonatal sepsis was Escherichia coli in 45.8% of cases, and the second most common causative microorganism was Staphylococcus hominis which is a member of coagulase-negative staphylococcus and was present in 20.8% of cases. In contrast, those causing late-onset neonatal sepsis were principally Gram-negative bacilli, represented by Klebsiella pneumoniae (46.34%), Acinetobacter baumannii (24.4%), and coagulase-negative staphylococci (17.1%).

Jiang et al. (2014) mentioned that late-onset neonatal sepsis occurred in 71.9% of cases, and late-onset neonatal sepsis was more common in premature infants (11). In Kosovo, Julia (2018) found that the incidence rate of neonatal sepsis was 18.9% among them, 63.6% were EOS, and 34.6% were LOS (12). In Norway, Ronnestad (2005) reported that the incidence of LOS was 19.7% among neonates with low birth weight less than 1500gm and the most common pathogens were coagulase-negative staphylococci followed by Candida species (13). In Croatia, Stemberger and tešović (2012) found that preterm infants were more prone to both EOS and LOS and the most common causative agents of EOS were gram-negative rods including E. coli, Klebsiella species, and Pseudomonas while those causing LOS were staphylococci and enterococci (14). Similarly, Gowda et al. (2017) found that late-onset neonatal sepsis had a significant relationship with the prematurity (15). Kilani Basamad (2000) reported that E. coli was the most common causative agent of early-onset sepsis (16). In Australia, Bray et al. (2019) stated that E. coli and GBS were the most common causative agents of EOS in preterm and term babies, respectively (17). Berardi A. et al. (2019) mentioned that LOS was significantly associated with prematurity in Italian and the most common causative organisms were coagulase-negative staphylococci, E. coli, Staphylococcus aureus and Enterobacteriaceae (18). In India, Dudeja (2020) stated that in developing countries the more commonly encountered pathogens in causing neonatal sepsis were Gram-negative organisms represented by Acinetobacter and Klebsiella species, as well as E. coli (19). In 2011, Stoll and coworkers stated that the most significant pathogen in preterm infants was E. coli (20). Jiang and colleagues (2014) declared that the most encountered microorganism in the early onset neonatal sepsis were group B streptococci and E. coli (11). In 2015, Ansari and collaborators confirmed that the coagulase-negative staphylococcus, Staphylococcus aureus, Acinetobacter species, and Klebsiella pneumoniae were the most common etiological agents of late-onset neonatal sepsis (21). Jiang et al. (2014) stated that among the most common pathogens causing late-onset neonatal sepses were Klebsiella pneumoniae and Acinetobacter baumanii (11). On the other hand, Lee and associates (2004) stated that they did not encounter E. coli septicemia since early-onset neonatal sepsis was minimal in their study sample (22). Arild Ronnestad and Tore Gunnar Abraha (1998) found that coagulase-negative staphylococci were the main causative organism in the early and late-onset neonatal sepsis (23). Berger et al. (1998) reported that the most common pathogen causing early-onset sepsis was group B streptococcus (24).

These heterogeneities of the results from those existing studies might associate with the geographic and temporal variations of specific populations, and other differences related to demographics, ethnicity, the climate, and the environment, and the overall status of
the healthcare system. Our study has some limitations, including the relatively small sample size from a single tertiary healthcare centre using a covenant sampling method, the implementation of convenient sampling, and the lack of random selection of patients. Hence, future studies, including randomized controlled trials and meta-analytic studies in combination with predictive modelling and machine learning algorithms, are essential (25). Furthermore, the prolonged hospital stay, improper application of infection control programs, overcrowding of neonates, and the improper use of empirical therapy might be the aetiology behind the increment in the incidence rate of late-onset neonatal sepsis and the spread of hospital-acquired infections in our hospital. Therefore, regular and vigilant monitoring, evaluation of the neonatal intensive care unit measures, and reviewing the proper use of antimicrobial therapies are necessary to prevent and eliminate late-onset neonatal sepsis.

Conclusions

Late-onset neonatal sepsis appeared to be more common in our tertiary healthcare institute than early-onset neonatal sepsis. Klebsiella pneumonia, Acinetobacter baumannii, staphylococcus epidermidis, and Staphylococcus haemolyticus were the most common causative microorganisms. Late-onset neonatal sepsis appeared to be significantly associated with the prematurity and caesarian section. The increment in the incidence of late-onset neonatal sepsis and the antimicrobial resistance, including the horrific multi-drug resistance, necessitates the avoidance of overcrowding of neonates in intensive care units, minimizing the use of invasive interventional, the unnecessary use of broad-spectrum antibiotics, and the prolonged duration of treatment. Indeed, the application of infection control programs in the neonatal intensive care unit is critical to prevent and the development of neonatal sepsis.

Conflicts of Interest: The authors declare no conflict of interest.

Funding: This study has no external funding.

Ethical Considerations

The ethics committee and the institutional review board of Al-Batool teaching hospital approved the study in 2018. The authors carried out the work described in this manuscript following the Code of Ethics of the World Medical Association (Declaration of Helsinki) on medical research involving human subjects, the EU Directive (210/63/EU), and the uniform requirements for manuscripts submitted to biomedical journals and the ethical principles defined in the Farmington Consensus of 1997. We acquired informed consent from the parents, or the guardians, of each patient. The patients were not subjected to further risk, and we dealt with their information dealt with complete confidentiality, and only the data curator had access to them, while other researchers were blinded.

Abstract

Introduction: Well nourished newborn is a reflection of adequate placental function. The umbilical cord that connects fetus and placenta can attach itself to placenta at different placenta. The incidence of central, eccentric, marginal and velamentous cord insertion is 18%, 73%, 7% and 1-2%, respectively. This insertion type significantly influences fetal growth and pregnancy outcomes.

Methodology: This study was conducted in Department of Anatomy of SBKS MIRC, Vadodara. This was a comparative study between normotensive and hypertensive group in which 500 subjects, in each group were included. Insertion of umbilical cord on placenta was determined and fetal growth and outcome with type of insertion were correlated.

Results: The two groups were comparable in terms of demographics. Higher proportion of those in hypertensive group had marginal insertion of umbilical cord (23.40%) as compared to 2.90% in normotensive group. Mean systolic (150.10±7.51mmHg) as well as diastolic blood pressure (91.23±4.00mmHg) was higher in those with marginal insertion of placenta. Mean fetal birth weight and APGAR score at birth and 5 minute and proportion of fetus reaching full term, live births were low in those in the hypertensive group especially in those with marginal insertion of placenta.

Conclusion: Thus it can be concluded that abnormal attachment of umbilical cord on placenta has significant impact on fetal growth and influences the outcomes of pregnancy directly and indirectly.

Key word:- Placenta, Umbilical cord, Cotyledon, Hypertension, Hypotension, Fetus.

Introduction

Adequate placental function results in well nourished newborn. Umbilical cord connects fetus and placenta and delivers oxygen and nutrients, throughout pregnancy, to the developing fetus. Thus, development of the umbilical cord determines and influences fetus growth. The site of cord insertion can be central, eccentric, marginal(Battledore) or velamentous (into fetal membranes) each occurring with an incidence 18%, 73%, 7% and 1-2%, respectively. [1] The attachment is considered marginal when cord attaches itself to placenta within 20mm from the placental edge. The insertion is called velamentous when umbilical cord inserts in to the chorio-amniotic membranes instead of placental mass. [2]
Two different theories can explain this variation in attachment: i) “placental migration theory or trophotropism”, which states that, to achieve better perfusion, placenta migrates towards the richly vascularised areas as the gestation advances. ii) “blastocyst polarity theory”, which specifies that malpositioning of blastocyst during implantation results in abnormal cord insertion. [3]

Various literatures have debated the significance of abnormal insertion of umbilical cord. It has been reported that marginal insertion is associated with increased frequency in abortions, malformed foetuses. It is also correlated with neonatal asphyxia and premature labour. Velamentous cord insertion results in lack of protection of Wharton’s jelly to the vessels and this makes the vessels prone to rupture and/or compression and can thereby cut off umbilical blood flow, acutely, which increases risk of perinatal death. [4]

Poor obstetric outcomes are observed in those with abnormal cord insertion. There have been reports of rise in fetal malformations, birth of neonates that are low weight, preterm induction of labor, intrauterine growth restriction, vasa previa, low APGAR scores and intrapartum complications. Shanklin DR et al, reported that in newborn weighing less than 2.5 kg, velamentous or marginal umbilical cord insertion was common. [5] Rath et al observed that hypertensive mothers’ commonly have marginal insertion of cord. [6]

We conducted this study to evaluate types of umbilical cord insertions on placenta in normotensive and hypertensive pregnant females and correlate this finding with fetal outcomes.

Methodology

This study was conducted in Department of Anatomy of SBKS MIRC, Vadodara. This was a comparative study between normotensive and hypertensive group in which 500 subjects, in each group, were included. It took five years for the study to get completed and the period of study was from Jan’12 to Dec’17. Fetal parameters were recorded. Morphology and Morphometric of placenta was evaluated. Insertion site of umbilical cord was noted. We calculated minimum distance between placental margin and insertion site of umbilical cord using a measuring scale and the same was labelled as ‘d’. The mean radius, denoted as ‘r’, was calculated from the surface. Insertion percentage was calculated using the formula: \((d/r) \times 100\). High insertion percentage suggests central insertion on the other hand low insertion percentage was suggestive of marginal insertion. The insertion was categorised as central (76-100%), eccentric-lateral (51-75%), eccentric-medial (26-50%) and marginal (0-25%). The collected data was entered into MS Excel and was analysed. Mean + SD and frequencies were calculated wherever appropriate. The level of significance was estimated using unpaired ‘t’ test.

Results

A total of 1000 cases, 500 hypertensives and 500 normotensive pregnant females were enrolled. In the hypertensive group, 25% (n=125), 50% (n=250) and 25% (n=125) had gestational hypertension, pre-eclampsia and eclampsia, respectively.

Patients enrolled were in 20 - 35 years age range.

It was seen that significantly higher proportion of patients in hypertensive group had marginal insertion of placenta as shown in Table 1.

Discussion

Various studies have implicated role of marginal insertion of umbilical cord in the placenta with induction of hypertension.\[7, 8\] In the present study it was seen that marginal attachment of placenta was common in those in hypertensive group. However, ‘eccentric’ insertion of the umbilical cord was reported in both normotensive and hypertensive groups by certain authors.\[3, 9\]. The difference may be due to the fact that these authors enrolled pre-eclamptic females in hypertensive group where our study enrolled those with gestational hypertension and eclampsia as well. And as confirmed in the findings of Udainia A. et al with the increase in the severity of PIH, the umbilical cord insertion on placenta shifts marginally and may even become velamentous.\[9\]

Additionally, we observed that in those with marginal insertion of placenta the blood pressure was on higher side as compared to other type of insertions in both the groups. There are two different theories, one that
suggest that hypertension lead to marginal attachment and other that marginal attachment of placenta induces hypertension. Cai LY et al and Jain A et al have reported that hypertension is induced by abnormal insertion of placenta. [3, 9]

Authors like Udaina A et al, Jain A et al have reported low birth weight in those with marginal attachment [3, 9]. In the present study also it was observed that fetal weight was low in those with hypertensive group as compared to normotensive group and was lowest in those with marginal attachment of placenta. Thus our finding is consistent with literature that abnormal cord insertion is correlated with intrauterine growth restriction (IUGR), this may be because abnormal insertion of umbilical cord may impact the nutrient and oxygen transfer across placenta. [3, 10] The reason for abnormal nutrient transfer may be that the in such circumstances of abnormal attachment, density of vessels in placenta is low as against when the insertion is normal; also an increased vascular resistance may be encountered on account of long fetal stem vessels. [3]

We observed low mean APGAR scores at birth and at 5 minutes in those in the hypertensive group, especially in those with marginal attachment of placenta. Similar to our study Heinonen S et al observed low APGAR score at 1 minute and 5 minutes after birth in those with abnormal placental attachment as compared to those with normal attachment of placenta. [12]

Brody S, et al., observed that battledore placenta may sometimes be responsible for the premature initiation of labour. This may be because of interference with fetal circulation which causes fetal embarrassment and upset the balance of opposing forces existing between the uterus, placenta, and fetus for the maintenance of pregnancy and thus induces labor prematurely. [11] In the present study, it was observed that preterm deliveries occurred commonly in the hypertensive group and that more frequently in those with marginal insertion of placenta. In the study by Heinonen S et al, prematurity was observed in 13.9% of the cases with abnormal placental attachment as compared to 6.1% of the cases in those with normal placental attachment. [12] Similar to our study the authors, Heinonen S et al, also observed higher fetal mortality and increased ICU requirement in those with abnormal placental attachment.

Conclusion

Thus it can be concluded that abnormal attachment of umbilical cord on placenta has significant impact on fetal growth and influences the outcomes of pregnancy directly and indirectly.

A Cross Sectional Descriptive Study of Analysis of Lambdoid And Squamous Sutures Closure by Ct Scan for Age Estimation

Kalpesh M Zanzrukiya1, Lavlesh Kumar2, Ashish A Bhalodiya3

1Associate Professor, 2Professor & Head, Dept of Forensic Medicine & Toxicology, 3Assistant Professor, Department of Radiology, SBKSMIRC, Sumandeep Vidyapeeth, Vadodara

Abstract

Background—Identification is fixation of an individuality by various physical and biological parameters. An individual’s age determination is very important in various civil and criminal medicolegal cases. Age estimation by cranial sutures closure is an old method. This study was conducted to analyze closure of lambdoid and squamous sutures for age estimation in living individuals by CT scan.

Objectives—To study the pattern of closure of lambdoid and squamous sutures with relation to age of person. To detect bilateral and bisexual variations in same.

Materials & Methods—We had done a descriptive cross-sectional study by CT scan head of 130 living adult persons and analyzed them for closure status of lambdoid and squamous sutures in co-relation to age.

Results—In Lambdoid suture complete closure observed 5yrs earlier in upper 2/3rd(L1&L2) parts of right side than left side in both sex while while complete closure observed very late ages(>75yrs) or not at all(lapsed union) in lower 1/3rd(L3) part. Both sides of Squamous sutures follow more or less same pattern for closure in relation to age and sex while complete closure observed at very late ages(>75yrs) or not at all(lapsed union).

Conclusion—Closure of Lambdoid and Squamous sutures should be used only as corroborative to other criteria and evidences for age estimation as they might be unreliable as standalone until proven otherwise.

Key Words: Age determination, Lambdoid suture, Squamous suture, CT scan, Identification.

Introduction

Age is a primordial parameter for identification of an individual. Determination of exact age is needed for living individuals in various civil disputes like employment, marriage, attainment of majority, property dispersal, voting rights, senior citizenship, competency as witness and in various crime disputes like rape, infanticide, kidnapping, juvenile delinquency, mercy for capital punishment and criminal responsibility1. At different periods of life, different methods are utilized for scientific age estimation like weight, head-circumference and crown heel length in fetus and newborn; dentition and radiological examination of bones in children and adults under age of 25 years. Scientific age estimation is more complex after age of 25 years. Only few parameters are helpful in this stage of life such as closure of cranial sutures, changes of symphysis pubis, appearance and fusion of segments of sternum and sacrum2-5.

Closure of the skull suture is considered a fairly reliable index for age determination between 25 and 40 years of age. It can estimate age only in range of a decade2,3.

Morphological methods are studied & being used in autopsy cases. Radiological methods like X-ray, computed tomography(CT) scans, MRI and 3D constructed CT scanning & MRI, though costly is being used now in living persons and in virtual autopsy.

Materials and Methods

This study was conducted during September 2012 to October 2014 by Forensic Medicine & Toxicology
department in collaboration of Radiology department at Govt. Medical College & New Civil Hospital, Surat. Institutional ethics committee approval obtained for this research. We included the living adult subjects of of 18 yrs & above with minimum two valid age or birthdate proof documents e.g. birth certicate, driving licence, rationcard, aadharcard etc. Persons with medical history of head injury or disease with cranium damage. pregnant females were also excluded due to radiation hazards.

The age of subjects were ranging from 15 years to 92 years. For equal distribution of samples, we made total 13 strata of age groups with difference of 5 years of age i.e. 15-19yrs, 20-24yrs, ..., 70-74yrs and 75yrs and more. In each group, 5 male and 5 female subjects were enrolled by simple randomization. So, total 65 male and 65 female subjects were studied after obtaining informed consent. Because of high cost of CT scan imaging procedure and only healthy (cranium wise) subjects included in our study, the size of study sample remained quiet restricted. Axial CT scans of skull done at different level for bony window. CT scan machine used was 6/16 slice Siemen Company model ‘SOMATOM Emotion 6’. CT scan images were analysed for ectocranial fusion of segments of Lambdoid and Squamous sutures bilaterally.

The Squamous sutures were analysed as a whole on both sides whereas, based on the methods of Broca\(^6\) and Singer\(^7\) the Lambdoid suture was subdivided into three parts upper 1/3rd-L1-Pars Lambdica, middle 1/3rd-L2-Pars Intermedia & lower 1/3rd-L3-Pars Asterica on both sides.

**Observations & Results**

Table 1: Age and gender co-related findings for ectocranial closure status in Lambdoid suture.
The LR1 part of suture noted open in subjects of age group of 35-39 years and younger in both sex, but it was in closing process in early fifties and found closed in majority (4 or more in strata) in age group of 60-64 years and older in both sex. The closure starting observed earliest at 36 years of age in male and 35 years of age in female and complete closure observed earliest at 45 years in male and 51 years in female. The closure starting observed earliest at 36 years of age in male and 35 years of age in female and complete closure observed earliest at 45 years in male and 51 years in female. The LR2 part of suture was open in subjects of age group of 40-44 years and younger in both sex, but it was in closing process in late forties and found closed in majority in age group of 65-69 years and older in both sex. The closure starting observed earliest at 36 years of age in male and 35 years of age in female and complete closure observed earliest at 45 years in male and 51 years in female. The LR3 part of suture was open in subjects of age group of 40-44 years and younger in both sex, but it was in closing process in late fifties and but no complete closure found in clear majority till last age group of study in both sex. The closure starting observed earliest at 45 years of age in in both sex and complete closure observed earliest at 60 years in male and 65 years in female.

The LL1 part of suture was open in subjects of age group of 30-34 years and younger in both sex, but it was in closing process in late forties and found closed in majority (4 or more in strata) in age group of 65-69 years and older in both sex. The closure starting observed earliest at 36 years of age in male and 35 years of age in female and complete closure observed earliest at 45 years in male and 51 years in female. The LL2 part of suture was open in subjects of age group of 40-44 years and younger in both sex, but it was in closing process in late fifties and found closed in majority in of 65-69 years and older in both sex. The closure starting observed earliest at 40 years of age in in male and 44 years in female while complete closure observed earliest at 48 years in male and 51 years in female. The LL3 part of suture was open in subjects of age group of 40-44 years and younger in both sex, but it was in closing process in late fifties and no complete closure found in clear majority till last age group of study in both sex. The closure starting observed earliest at 45 years of age in in both sex and complete closure observed earliest at 60 years in male and 65 years in female. Lambdoid suture closure observed from Lambda point towards base of skull on both sides.

Table-2 describes the age and gender co-related findings for ectocranial closure status in Squamous or Temporo-Parietal suture.

The SQR(right squamous suture) was observed open till age group of 50-54 years and in closing process in late sixties but no complete closure found in clear majority till last age group of study in both sex. The closure starting observed earliest at 55 years in male and 54 years in female. Complete closure was observed earliest at 72 years in male and 70 years in female. The SQL(left squamous suture) was observed open till age group of 50-54 years and in closing process in late sixties but no complete closure found in clear majority till last age group of study in both sex. The closure starting observed earliest at 55 years in male and 54 years in female. Complete closure was observed earliest at 72 years in male and 65 years in female.

</tbody>
</table>

Table-5 shows comparison of various studies from India and USA regarding complete closure of Squamous sutures ectocranially at ages.

So, we can see that Lambdoid sutures and Squamous sutures closure noted at different ages in different populations.

**Limitations & Recommendation:**

Sample size is quiet small due to feasibility issues. More studies may be done in other regions enrolling identical populations to limit bias factors like climate, diet & nutrition, inheritance, race which was not considered in present study.

**Conclusion**

Cranial suture closure is fairly reliable method for age estimation in elderly age with Lambdoid suture & Squamous sutures. Very much variation is observed in terms of age of complete closure especially in lower 1/3rd of Lambdoid suture and Squamous suture. Incomplete closure and lapsed union seems common until at and over the age of 75yrs in same. No significant difference observed in age of closure of these sutures between male and female sex. However, upper two thirds of Lambdoid suture closure is observed 5yrs earlier on right side than left side. Closure of Lambdoid & Squamous sutures should be used only as corroborative to other criteria & evidences for age estimation.

**Conflict of Interest:** None declared.

**Source of Funding:** Self funded.

Effectiveness of Laughter Therapy on Reduction of Stress among Nursing Students

Kanika Guleria¹, Pushplata Manta²
¹Assistant Professor, ²Nursing Tutor, Chitkara School of Health Sciences, Chitkara University, Punjab, India

Abstract

Context: Stability of hormones are being effected by consistent stress in the human body which leads to changes in thoughts and situations that make the individual perplexed, restless or anxious. Laughter therapy is the antidote for stress. It helps to release serotonin in brain which is essential for the uplift of mood.

Aim: The aim of this research is to find out the efficacy of laughter therapy on the decline of stress.

Setting and design: Data collection for the commenced study was conducted at Sri Sukhmani College of Nursing and Amar Professional College of Nursing, Dyalpura, District Mohali, Punjab. A quantitative approach with “Quasi-experimental design” was adopted to conduct this research.

Methods and Material: Technique used for selecting the subjects was purposive sampling technique. 60 subjects were selected and sub grouped into experimental and control group (30 each). 5 point likert scale i.e. Sheldon Cohen”s (1983) Perceived Stress Scale which includes 10 items, was selected to evaluate the level of stress among nursing students.

Statistical analysis used: Descriptive and inferential statistics were used.

Results:

• Before implementation of laughter therapy, it was identified that stress scores were approximately same in both the groups.

• After implementation of therapy, it was identified that stress scores in the experimental group was lower than the control group.

Conclusions: Study concluded with the result that stress level is alleviating among student nurses with help of laughter therapy.

Key Words: Effect, Laughter therapy, Stress, Nursing students.

Introduction

Stress can be defined in a number of ways and every individual faces it in their everyday life. But the most important part of an individual is to manage it. Stress may lead to benefits or drawbacks; it leans on one’s view that how to perceive and take over it. If the stress is not managed adequately, sentiments of dejection, anxiety, and restlessness may occur. Stress can only be minimized by using adequate coping techniques which brings balance in the human body and mind.

In the nutshell, Student nurses most commonly face the following stresses i.e.

- Societal stress,
- Monetary stress,
- College stress, and
- Clinical field stress.

Societal pressure doesn’t mean having individuals around you. It incorporates dread of speech, showdowns, and overseeing authority obligations.

Monetary stress is faced when students are in lack of resources (Example: Money Crisis).

Academic/college stress in students can be due to learning for finals concerning rank competition or dread of failure in finals. Clinical area stress includes clinical placements, fear of making mistakes, and interactions with other staff members.

Students confront numerous stressors and hindrances during student life. Nursing student encounter’s even “more stress” as compared to their buddies registered in other courses. Accordingly, various researchers proclaimed that level of stress is high in student nurses. Nursing students are prone to different types of stresses because of the ever-changing environment of college. Increased stress level is supposed to influence students’ wellbeing and scholastic functions.

So as to lessen the degree of stress, various relaxation techniques and exercises have been utilized. Among this laughter is considered as the finest stress busting. Laughter is the human’s best gift for coping and endurance. The silent strength of laughter is triggered whenever we laugh and need of laughter is much more in this stressful world. “Freud stated in his theory that laughter therapy releases tension and psychic energy”, it is a coping mechanism for when one is upset, angry or sad. 15 minutes of laugh is equaled to the benefit of two-hour sleep, 15 minutes laugh adds two days life span. It stimulates the brain, respiratory, nervous, hormonal, and muscular systems. Many researches evidenced that laugh increase the secretion of serotonin in brain which is essential for the uplift of mood. It also triggers the discharge of endorphins (body’s natural analgesic) and produces a general feeling of prosperity. Dr. Leeberk investigated that stress hormones can be decreased by therapy of laughter. According to Jhonson Thomas (2011) in Maharashtra, 70% of subjects have become short-tempered and suicide rates are inclined with respect to raise in age only due to stress, but there has recently been an alarming increase in self-destructive behaviors among youngsters because of stress.

Laughter therapy has various benefits in stress management like it helps to decrease the stress hormones like “cortisol, epinephrine (adrenaline), dopamine” and also reinforces the health-promoting hormones like “endorphins”. Laughter helps to discharge tensions, physically as well as emotionally; which also keeps the heart healthy. Laughter changes the emphasis beyond outrage, stress, and pessimistic feelings in an advantageous manner than any insignificant distractions. Laughter assists us to connect with others in easy means that can uplift the mood of people around us which may lead to healthy social interaction and a decline in the level of stress.

I. Based on own personal experience, the researcher felt that nursing students experience a lot of stress due to competition, topographical versatility, new way of life, exams, tests, grades, extended periods of time of contemplating, work, family and other individual responsibilities, students also face the difficulties of clinical practice and strict disciplinary lodging life, monetary burden, dispute with friends or classmates, scholastic pressure as well as in the clinical area as they have direct contact with patients. There are many physiological and psychological changes in the body due to stress that may lead to various mental and physical illnesses. As many of studies have revealed that there is an increasing number of suicide due to stress among students and many of the previous researches have shown the benefits of laughter therapy in reduction of stress, but few studies have shown its impact on nursing students, therefore need for conducting the study is recognized among nursing students.

Subjects and Methods

A quantitative research approach with a quasi-experimental research design was adopted to accomplish the objectives of the survey i.e. to determine the effectiveness in reduction of stress level among nursing students with assistance of laughter therapy. Control
group and manipulation (i.e. intervention) was included. But randomization was not done due to the non-availability of a large number of subjects with stress level much higher than average as per eligibility criteria for the study. Two different colleges were included for the study, one for the experimental group and one for the control group to prevent contamination in April 2016. The experimental group was selected from Sri Sukhmani College of Nursing and the Control group was selected from Amar Professional College of Nursing, Dyalpura, District Mohali, Punjab. Purposive sampling technique was utilized to select 60 subjects (30 in each group). A survey was done in both the settings among all the nursing students present at the time of data collection to identify the stress level using the Perceived Stress Scale. 103 subjects were surveyed in a setting chosen for the experimental group, 39 subjects had “much higher than average stress”, 28 had “slightly higher than average stress”, 26 had “average stress” and 10 subjects had “slightly lower than average stress”. Out of 39 subjects who had “much higher than average stress”, 30 subjects were conveniently selected in the experimental group. Whereas 88 subjects were surveyed in a setting chosen for the control group, 35 subjects had “much higher than average stress”, 21 had “slightly higher than average stress”, 19 had “average stress” and 13 subjects had “slightly lower than average stress”. None of subjects had “much lower than average stress” in both the settings. Out of 35 subjects who had much higher than average stress, 30 subjects were conveniently selected in control group. Subjects who have much higher than average perceived stress level as measured by Perceived Stress Scale were included in study. Perceived Stress Scale by Sheldon Cohen (1983)\(^9\), the standardized tool was selected to determine the stress level among student nurses. The tool was considered for study after extensive review of literature and experts’ opinion. Tool consisted of 2 sections. Section- A: Demographic profile (It consisted of personal information about the nursing students such as age, gender, course, types of family, family income, residence, living arrangement, and marital status), Section-B: Perceived Stress Scale (This section consisted of 5 point likert scale i.e. Sheldon Cohen’s (1983) Perceived Stress Scale which includes 10 items, out of which 4 are positive statements and 6 are negative statements). Co-efficient alpha reliability of this scale is 0.84. Researcher got the training and certificate from psychologist for laughter therapy. Pre test of all the students was done in both colleges by using Perceived Stress Scale. A written informed consent was taken from each study sample. Laughter exercise sessions had been taken by researcher for experimental group for 15-20 minutes every day for 10 days. Everyday laughter therapy was started by doing deep breathing exercises. Laughter therapy was done in group with techniques greeting laughter, hearty laughter, milkshake laughter, one meter laughter, cell phone laughter, argument laughter and appreciation laughter. Deep breathing exercise was done after every two laughter exercises to relax the participants and it was also done at the end of each session. No laughter therapy was given to the control group. After 10 days, the post-test stress level was conducted among both experimental & control groups using the Perceived Stress Scale, and the researcher thanked the participants for their cooperation & interest during laughter therapy sessions. Approval from the ethical and research committee of Sri Sukhmani College of Nursing was taken before starting the study.

Results

100% subjects were females in both the groups. In experimental & control groups, majority of the subjects (76.66%, 70%) fall under age group of 17-20 years, 100% subjects were females and single and 70%, 63.33% were undergoing B.Sc.(N) course. In the experimental group, 56.66% subjects belonged to nuclear families whereas in the control group 50% each belonged to joint family and nuclear family. In experimental group, 26.66% each had family income every month between Rs.10,000-20,000, Rs.20,001-30,000, and Rs.30,001-40,000 although in control group half of the subjects (53.33%) had family income per month between Rs.10,000-20,000. In the experimental group & control group the majority of subjects (86.66%, 90%) were presently living in the hostel and nearly half of the subjects (50%, 43.33%) belonged to rural areas. For matching of experimental & control group chi-square test was applied for each demographic variable. For all the variables the value of chi-square was identified non-significant at \( p \leq 0.05 \). Hence, both groups were considered homogenous [Table 1].

In the experimental group, the mean post-test stress scores (15.13 ± 1.776) of subjects was less from
control group (22.43 ± 1.9241), to find the difference unpaired t-test was applied, the value of t was 15.270 at df 58 and p = 0.000, which was found to be statistically significant at p level ≤ 0.05. And in control group, the mean pretest stress scores of subjects (22.73 ± 1.9640) was found approximately similar to the mean posttest scores (22.43 ± 1.9241), to find the difference one of the Parametric test was applied i.e. “paired t-test”. The value of t was 0.9312NS at df 29 was identified to be statistically non-significant at p level ≤ 0.05. The mean post-test stress score of subjects in the experimental group (15.13 ± 1.776) was lowest than mean pre-test scores (23.40 ± 1.811), to find the difference “t-test” was used, value of t was 23.262 at df 29 which was identified to be statistically significant at p level ≤ 0.05 [Table 2].

In experimental & control group during pre-test all (100%) nursing students had much higher than average stress. During post test in experimental group, 56.66% subjects had average stress, 43.33% had slightly higher than average, none of the subjects had much higher than average stress whereas in control group none of the subjects had average stress, 16.66% students had slightly higher than average, and 83.33% students had much higher than average stress. Figure 1 shows that After the implementation of laughter therapy in experimental group less than half had slightly higher than average stress, more than half had average stress and none of subjects had much higher than average stress whereas in control group where laughter therapy was not administered, majority of subjects had much higher than average stress and very few had slightly higher than average stress.

Table 3 depicts that using ANOVA and t test, in experimental group no significant correlation was identified among post test stress scores and demographic variables, age (t=1.7435), course (t=0.1649), type of family (t=1.6514), family income (F=0.0206), residence (F=0.2025), and living arrangement (t=0.1586) at p level ≤ 0.05. Hence, it can be inferred that the post test stress scores in experimental group was not associated with any of the demographic variables of nursing students.

Table 4 depicts that using ANOVA and t-test, in control group no significant correlation was identified in between post-test stress scores and demographic variables, age (t=0.8447), course (t=1.1414), type of family (t=1.0454), family income (F=1.1540), residence (F=0.6738) and living arrangement (t=0.8499) at p level ≤ 0.05. Hence, it can be inferred that the post-test scores in Control group was not associated with any of the demographic variables of nursing students.

Discussion

These findings are supported by the findings of the studies conducted by Karabacak U (2012)\textsuperscript{10} which concluded that majority i.e. 38 (74.50%) of subjects had higher stress and 13 (25.49) of them had low stress. Another study conducted by Sheu S, Lin HS, Hwang SL (2002)\textsuperscript{11} revealed that majority of nursing students 428 (76%) has higher stress, 133 (23.07%) had moderate stress; the most documented stressors were inadequate knowledge and skills, caring for patients, and assignment burden.

In this study laughter therapy was administered and it was advantageous in lowering stress among the nursing students which is supported by the findings of studies conducted by Scott E (2009)\textsuperscript{12} which concluded that after laughter therapy programme total mean score decreased from 5.25 ± 2.01 to 3.02 ± 1.02, the findings of this research study provide evidence that laughter therapy is effective in reducing stress. Berk AR (2005)\textsuperscript{13}, Seaward BL (2003)\textsuperscript{14} which revealed that after laughter therapy in post test 76% subjects had mild stress and 24% had moderate stress, the distinction between pre
and post test stress scores was significant at p < 0.05 level. It was found that, no relationship exist between post test stress level between nursing students and their selected demographic variables in both the groups. These findings are supported by the findings of studies performed by Nicolas AK, Rod A Martin (2010)\textsuperscript{15}, Rahul M (2010)\textsuperscript{16} which concluded that there was no considerable correlation within post-test stress level with their selected demographic variables of nursing students.

Conclusions

Our quasi-experimental study reveals that the pre-test stress scores in both groups were approximately similar. However,

- In Experimental group, mean post-test stress scores were less as compared to mean pre-test stress scores after implementation of laughter therapy.
- In Control group, the mean pre and post-test stress scores were approximately similar. Hence, it is concluded that stress level among nursing students is reduced by use of laughter therapy.

Therefore, the research hypothesis is accepted and it is identified that no correlation was found between the post-test stress scores of student nurses and their selected demographic variables in both groups. (Experimental & Control)

Current Trends of Poisoning in Tertiary Care Hospitals Located in a Rural Area of Salem, Tamil Nadu, India

Koteswara Rao. Vipparla¹, Vijaya Kumari²
¹Assistant Professor, ²Associate Professor, Department of Forensic Medicine, Annapoorna Medical College and Hospital, Salem, Tamilnadu, India

Abstract

Time wise epidemiological studies are important to find out the trends of poisoning in each region. The present study was conducted by collecting data regarding age, sex, marital status, religion, occupation, type and manner of poisoning of cases which got admitted and treated over a period of 3 years to know the current pattern of poisoning in tertiary care hospitals located in a rural area of Salem, Tamil Nadu.

Total number cases studied were 170 cases, Among them 60 cases (35.3%) belonged to 21-30 yrs, males were 86 cases (50.6%) and females 84 cases (49.4%), both the sex were almost equally distributed, 103 cases (60.6%) were married, 151 cases (88.8%) came from rural area, 160 cases (94.1%) were suicidal and all belonged to Hindu religion. Occupation-wise 56 cases (32.9%) were house wives, students 51 cases (31.8%), followed by farmers, laborers and others. Coming to the type of poisons, maximum were organophosphorous compounds 38 cases (22.4%), followed by Paraquat, 3% yellow phosphorous, oleander seeds and others.

Keywords- Poisoning, epidemiology, age, Organophosphorus

Introduction

Any substances which make life better, if not used wisely and with proper care can become dangerous to human life and those substances can be termed as poisons¹. A poison can be any substance that can harm our body when ingested, inhaled, injected, or absorbed through the skin. The history of poison stretches as early as 4500 BC to the day it was discovered in ancient times and was mainly used by the ancient tribes and civilizations as a hunting tool to kill their prey and enemies².

According to WHO (World Health Organization) data of 2012, approximately 193,460 people died due to unintentional poisoning, 84% of which occurred in low and middle income countries³. The incidence of poisoning in India is among the highest in the world and is estimated that more than 50,000 people die every year from toxic exposure in India which is common cause of morbidity and mortality. This figure could be just the tip of the iceberg and most cases of poisoning actually go unreported especially in third world countries⁴. About 99% of these deaths occur in developing countries like India. Over the last few decades agricultural pesticides have been commonly used for intentional self-poisoning due to their easy availability⁵.

Organophosphorus poisoning is very common mainly in farmers in southern India due to its easy availability and parathion being frequently used. Thus, due to the easy accessibility of these compounds, a large number of suicidal cases are encountered ⁶. In addition to that, snake bites are acute emergencies in tropical and subtropical countries with heavy rainfall and humid climate⁷.

Along with these various household poisons, plant toxins, drugs and other miscellaneous agents are being used for poisoning. This study is carried out with above mentioned interest and also to know incidence of poisoning which varies from place to place. Therefore it is very important to perform regional studies periodically to identify the extent and evolution of the problem. By this study we can make out the commonest poisons encountered, types of poisoning, and nature of poisoning and socio-demographics in and around Salem. The resulting evaluation will be instrumental in prevention and management of future cases along with providing proper education to all.

Materials and Methods

The present study was conducted at Annapoorna Medical College & Hospital, Salem, Tamil Nadu, after obtaining approval from the institutional Ethics committee. Data of poisoning cases that were brought to the casualty and got admitted and treated over a period of 3 years, 2016-2018 was collected after obtaining permission from the Tertiary Care Centers attached to Vinayaka Mission’s Research Foundation, Salem. The patients included in the study are those who had undergone exposure to poison either by household or agricultural pesticides, stings, snake bites, industrial toxins, toxic plants, drugs or other miscellaneous products. Cases brought dead and died in the Casualty are excluded from the study. The following data regarding type, nature of poisoning, Socio-demographics were collected from hospital records. The obtained data were entered into Microsoft excel and SPSS version 23.0. Descriptive statistics and frequencies were used for data presentation.

Results

The data of 170 admitted and treated poisoning cases over a period of 3 years was collected from May 2016 to May 2018. Among these cases individuals belonging to age group 21-30 are 60 cases (35.3%) which are the maximum. The number of cases above 50 yrs and below 10 yrs were only 9 cases (5.3%) and 4 cases (2.4%) respectively (Table-1) which indicates most of the cases belong to young adults. Coming to sex distribution, males are 86 cases (50.6%) and females 84 cases (49.4%), males are on higher side. 103 cases (60.6%) are married and 151 cases (88.8%) came from rural area. Out of 170 cases a total of 160 cases (94.1%) were suicidal 8 cases (4.7%) were accidental (Table-2). If we look into the occupation 56 cases (32.9%) were housewives, students 51 cases (31.8%), followed by farmers, laborers and others (Table-3). All the 170 cases (100%) belonged to Hindu religion. Coming to the type of poisons, maximum were organophosphorous compounds 38 cases (22.4%), followed by Paraquat, 3% yellow phosphorous, oleander seeds and others (Table-4)

Discussion

Poisoning cases are one of the major socioeconomic burdens on the community. Trends of poisoning vary from place to place and needs to be addressed periodically. Although there is tremendous progress in the field of medicine, poisoning is considered to be one of the major causes of morbidity and mortality in India. In this study, maximum number of poisoning cases was seen in the age group between 21-30 years followed by 11-20 years and less in extreme ages. Similar findings were observed in previous studies. This can be described by the fact that young people put up with stress, financial problems, unemployment, marital conflicts, failure in love etc. Poisoning cases were more in males than females which were also observed by previous studies. This is because of high exposure of men to various agrochemicals and occupational hazards at work. But in studies, done in other countries showed female predominance. With respect to marital status, were married and were unmarried which was similar to the study. Majority of the poisoning cases were observed in rural area, because of its easy availability, lack of immediate medical care. Other studies have reported similar reports. But study conducted by showed poisoning cases were more seen in urban areas as compared to rural areas. Coming to the religion, all the victims were Hindus which were almost similar to the study conducted by where most of the victims were Hindus followed by Christians and Muslims. This is probably because Hindus are the majority of population in India. With regard to manner of death most of the cases were suicidal than followed by Accidental cases which were similar to other studies. This signifies committing suicide by poisoning is easiest method because of easy availability of various agrochemicals and other substances. In this present study poisoning is seen mainly in housewives followed by students and farmers. But in study carried out by Prashant Gupta et al states more poisoning cases in farmers followed by housewives and students. This increasing trend of poisoning in housewives indicates that they are under lot of psychological stress because of family conflicts and other related issues. In this study the commonest poisoning encountered was the organophosphorous compounds, followed by Paraquat and 3% yellow phosphorous. This was consistent with the observations made in previous studies where Organophosphorous compound is the main poison consumed. In the present study, we observed Herbicide Paraquat as second highest poison consumed, this signifies the awareness of people about this highly toxic compound which has no antidote and high fatality rate.

Conclusion

The younger generation of both sexes happens to be affected by poisoning every year and the incidence is increasing day by day. Though there are restrictions for sales of agrochemicals and drugs, the susceptibility to these poisonous substances should not be overlooked. So it is very much important to bring out rapid changes and further strengthen the laws regarding sale of agrochemicals and drugs. This will definitely reduce the misuse of these harmful substances by general public. Farmers who frequently handle agrochemicals should be properly educated and trained regarding safety measures. All hospitals mainly in rural areas should be well equipped to treat poison cases. Hospitals should have mandatory access with poison information centers to get relevant information of the particular poison for prompt treatment. Focus should be given for psychological counseling of patients to prevent suicide by poisoning. Periodically the policy makers should review and implemented poison prevention measures.

Abstract

Introduction: Every year, it was found that burns caused by fire were responsible for about 265,000 deaths globally. More than 90% of fatal fire-related burns occur in developing or lower and middle income countries (LMICs). Out of this, South-East Asia alone accounts for more than half of these fire-related deaths. In South East Asian region, death due to Burns in girl / women is more than that of Tuberculosis, HIV/AIDS and malaria combined. In India, burn injury is found to be one of the major causes of death, especially in females. The problem of death due to burns in developing countries like India is primarily due to various socio-cultural factors prevalent in the country. Some of these factors include poor housing conditions, poor maintenance of electrical appliances, and customs of wearing dresses like sarees or dupatta, practice of dowry, illiteracy level and poverty.

Material and Method: Materials for the present study were collected from the medico legal autopsies of 296 burn cases, performed at the mortuary of Rajendra Institute of Medical Sciences (RIMS), Ranchi, during the period from January 2018 to December 2018. A detailed performa was designed with a definite set of questionnaire which formed the basis of this study.

Results: In our study, out of the 296 cases, the most common age group involved was 21-30 years with a female sex predilection (female to male ratio of 1.5:1). As far as the marital status is concerned, most cases were of married men and women (66.22%) involving mostly Housewives (43.25%). The most common time period involved was between 4 PM to 10 PM (35.47%). Most of the cases took place at home (75.34%).

Conclusion: Our study primarily focuses on the epidemiological profile of data involving burn cases in this part of India which is relatively a backward area comprising of a majority of tribal population.

Keywords - Burn, female, young, married, housewives

Introduction

Fire has been known to mankind for about 400,000 years. Most of the communities believe that the whole universe is made up of five essential elements. Water (Jal), Air (Vayu), Earth (Prithvi), Sky (Aakash) and Fire (Agni). So, this way fire or burns have great importance in our life. The use of fire in various aspects has not only added to our comforts but also added to our misuses by increasing the risk of burns. Fire can be considered as man’s first double-edged sword, evidenced throughout history; it has served as well as destroyed mankind1. Burn injuries are dry thermal injury caused due to contact with raw heat such as flame, radiant heat or some heated solid substance like metal or glass, to the body surface2. Mammalian tissue can survive only within a relatively within narrow range of temperature, 22-440

Thus burning usually occurs due to contact with flame it may be caused due to contact with hot metal or any other hot solid or hot liquid. The severity of burning very extremely depending on the degree of heat, period of exposure, intensity of heat and age of the person. Burn injury of the skin is characterized by the damage to skin tissue from hot (scald, flash, flame, contact), cold, electrical, chemical, radiation, sunlight, or other sources. Burns constitute one of the most common causes of morbidity and mortality worldwide. They can result in significant disfigurement, physical impairment, work loss, psychological problems, and considerable economic burden. Prevention of burn is considered the best strategy to reduce the overall burden of burns. The impact and the management of burn injury depend on the severity of burn. Although minor burns can be treated at outpatient clinics, the management of patients with severe burns requires multidisciplinary approach in specialized burn care centers. The local treatment of burn wound should address the major concerns of wound care including anti-inflammatory treatment, wound coverage, and prevention of infection and scar formation. Although superficial burns may be managed with topical treatment, deep burns require excision and grafting. The major challenges for treating physicians are to control the infection to avoid development of sepsicaemia and its related complications. Burn injuries and their sequel pose a public health problem. Every year, it was found that burns caused by fire were responsible for about 265,000 deaths globally. More than 90% of fatal fire-related burns occur in developing or lower and middle income countries (LMICs). Out of this, South-East Asia alone accounts for more than half of these fire-related deaths. In South East Asian region, death due to Burns in girl / women is more than that of Tuberculosis, HIV/AIDS and malaria combined. In India, burn injury is found to be one of the major causes of death, especially in females. The problem of death due to burns in developing countries like India is primarily due to various socio-cultural factors prevalent in the country. Some of these factors include poor housing conditions, poor maintenance of electrical appliances, and customs of wearing dresses like sarees or dupatta, practice of dowry, illiteracy level and poverty. The precise numbers of burns incidence is very much difficult to arrive due to large population and lack of incident reporting. The loads of over-population, illiteracy, low socio-economic status, poor standards of safety at home and at work place, corruption etc. has caused a significant rise in burns cases.

The aims and objective of this research work is to study the epidemiology of burns, especially in married women in this region of the country and find out certain reasons and causes of burns and its related deaths.

**Materials and Methodology**

The present study was carried out in the Department of Forensic Medicine & Toxicology, Rajendra Institute of Medical Sciences, Ranchi for a period of one and half year from January, 2018 to December, 2018. The materials for the present study were dead body brought for medicolegal autopsy from various police stations of Ranchi District (Jharkhand) at the Forensic Medicine Department of RIMS, Ranchi. During the study period total 3440 cases were autopsied, out of which only 296 cases where death were due to burns. The information regarding the age, gender, socio-demographic, manner of burns, time of incidence, place of incidence, occupation, etc were gathered from the police papers like inquest report, dead body challan etc, and through detailed interviews of the relatives, neighbours, friends, and police officials accompanying the dead bodies. In case of hospital deaths, hospital papers were also examined. A predesigned tested questionnaire (enclosed as annexure- I) was used to record the information.

Before proceeding with the dissection of the body, external examination of the whole body was carried out very carefully and minutely. The general build of the body was noted and its age, sex verified. The different regions of the body were carefully inspected, one by one and details of the injuries present on them were noted. As routine, a detailed and thorough postmortem examination was carried on every case. To make the study more systematic and error free, a Performa was designed and tested to record detailed observation of post-mortem examination including other relevant detailed information. The findings noted were carefully compiled, analyzed and tabulated. The results were presented in form of tables.

**Inclusion criteria:**

1. All cases of deaths due to Burns coming for post
mortem.

2. Cases considered for study will include subjects of all age group of all genders.

Exclusion criteria:

1. Highly decomposed bodies.
2. Cases of Postmortem Burns.

Results

The present study was conducted in the Department of Forensic Medicine & Toxicology, Rajendra Institute of Medical Sciences, Ranchi for a period of one year from January 2018 to December 2018. Total 3440 cases were autopsied during the period of study, out of which 296 cases were of death due to burns. This comprised 8.60% of the total post-mortem conducted in the department during the study period.

The observations on various aspects were recorded and are being presented here in form of various tables.

Discussion

There is relative lack of published information about burn injuries in Jharkhand. Present study with a relatively small sample size has revealed pattern of burn injuries among reported cases from a tertiary care hospital of Ranchi, Jharkhand.

The present study was conducted in the Department of Forensic Medicine & Toxicology, Rajendra Institute of Medical Sciences, Ranchi for a period of one year from January 2018 to December 2018. Total 3440 cases were autopsied during the period of study, out of which 296 cases were of death due to burns. This comprised 8.60% of the total post-mortem conducted in the department during the study period.

Age wise distribution:

Most common affected age group in this study was 21–30 years which is consistent with findings of many other epidemiological studies on burn from different part of India like Sawney CP et al\textsuperscript{7}, Ahuja RB et al\textsuperscript{8}, Rai A et al\textsuperscript{9}, Chauhan A et al\textsuperscript{10} and Dalbir Singh et al\textsuperscript{11}.

Gender wise Distribution:

In our study it was observed that the female to male patient ratio was 1.5:1 indicating increased vulnerability of female to burn which is comparable with other findings. A very big sample size (N= 26880) study was conducted at KGMU, Lucknow and reported that female: male ratio 1.4:1\textsuperscript{12}.

The findings of present study is also in concurrence with the other studies done in different regions of India like Kumar P et al\textsuperscript{13}, Lal P et al\textsuperscript{14} and Bhardwaj SD et al\textsuperscript{15}. Earlier studies done by Korah MK et al\textsuperscript{16} and Prasad CS et al\textsuperscript{17} on deceased burn patients from this institute had also reported higher percentage of female victims.

Occupation Wise Distribution of Cases:

Occupation wise distribution of death due to burns revealed that maximum cases belong to housewives in this study. In the studies conducted by Gupta RK and Srivastava AK (1988)\textsuperscript{30}, and Dalbir Singh et al 1997\textsuperscript{31}, similar observation was reported that burns incidence was more common in housewives.

Substantially higher female preponderance in present study might be due to a larger population of Jharkhand resides in rural areas where females are mostly housewives engaged in household works. Unsafe cooking practices like Angithi which uses Koyla, chullas uses wooden and use of kerosene lamps are common in rural areas which expose them to flame burn and kerosene burn. These could be other reasons after intentional injuries due to burn for higher number of female patients reporting to hospital. This higher proportion of female burn admissions is consistent with that of many low- income and middle-income countries such as 53% in Egypt\textsuperscript{18}, 56% in India\textsuperscript{19}, 56% in Iran\textsuperscript{20}, 64% in Sri Lanka\textsuperscript{21} and 67% in Turkey\textsuperscript{22}. Studies from high-income countries report higher proportions in males\textsuperscript{23-26}.

This preponderance of female burns in the current study is likely to be related to the role of women in the family where they take care of cooking, baking and other functions involving heating and cooking equipment. In addition, young females are more likely to be affected by intentional self-harm burns. This interpretation becomes more convincing when we notice that 84% of burns occurred at home and 94% of intentional self harm burns were females.

Distribution based on Marital Status:

Marital status wise distribution of death due to burns revealed that the maximum number of burn victims were married (66.22%) followed by unmarried (33.44%). Least number of cases was from widows.

In the present study, the independent risk factors for intentional self-harm were among female married victims was probably because of the increasing familial stress due to day to day problems like unemployment, illiteracy and poverty, which together give rise to greater issues like marital disharmony and dowry. These results are consistent with the findings of other researchers like Adamo C et al\textsuperscript{27}, Srivastava AK\textsuperscript{28}, and Vaghela Prithwiraj Singh et al\textsuperscript{29} and they were in contradiction to the findings of the studies from other developed countries. The unmarried victims group mostly included men of the adolescent age group and the reasons behind their deaths were rivalry, carelessness at the work place and frustration which arose due to a failure in love/examinations.
Distribution of cases Based on Place of Incidence:

The findings of present study showed that majority of incident of burns occurred at home followed by outside of home and working place. Similar observation was reported by various different authors worldwide. Studies involving admissions for all burns and all ages indicate that the majority of injuries occur at home including 56% in Nigeria, 57% in Turkey, 58% in Israel, and 63% in Norway. In the United States 66% of all hospitalized burns are reported to have occurred at home. In the low-income and middle income countries, the kitchen is the room where burn incidents most commonly occur. Majority of incidences occurred in kitchen. This is because the housewives working in kitchen are more prone to hazards of fire. It was followed by incidences occurred in living room. Most of the suicidal victims prefer closed spaces like living room. This finding is consistent with studies done by Subrahmanyam M and Attia AF et al.

In the studies conducted by Vaghela Prithviraj Singh C et al (2012), Mostafa M.Afify et al (2012) and Shinde A.B. Keoliya A.N. (2013) in other part of India and revealed that burns incidence were more common at home.

Distribution of cases Based on Time of Incidence:

Time of incident wise distribution of death due to burns reveals that maximum numbers of burn cases occurred between 4P.M. to 10 P.M. followed by 10 A.M. to 4 P.M. in my study. In the study conducted by Akhter J.M. and Nerker et al (2010) found that the peak incidence of burn occurred between 5A.M to 10A.M (47.4%) followed by between 11P.M to 4A.M (29.8%) which is not similar to our study. There is no universal division of periods of a day. Hence for sake of convenience, a day was divided in three hourly periods. Maximum number of cases 19 (17.43%) were reported in early evening hours during 18:00 hours to 20:59 hours. This is usual time of cooking by housewives in India. This increases chances of exposure to hazards of fire. Minimum number of cases 7 (6.42%) were reported early night hours during 00:00 hours to 02:59 hours. This finding is consistent with studies conducted by Sharma BR et al and Singh D et al. This is sleeping time for most of the peoples. The cases occurred during this period were due to fall of lamp over bed or body while the victims were asleep. This is not consistent with study done by Akhter JM et al, who observed maximum number of incidences 48.59% in early part of the day followed by 29.13% during evening. This might be due to the fact that Akhter JM et al conducted study in rural part of India which involves majority of agrarian population. They are usually exposed to fire in early morning for cooking, warmth and heating water.

In the study conducted by Mostafa M.Afify et al (2012) observed that majority of the burn incidence occur at night time (53.8%) which is not similar to my study. In the study conducted by Shinde A.B. Keoliya A.N. (2013) found that the peak incidence of occurrence between 10P.M to 06P.M (46.8%) followed by between 06A.M to 2P.M (26.6%) and between 2P.M to 10P.M (26.6%) which is not similar to my study.

Conclusion

- Out of the total 3440 cases autopsied during the period of study, 296 cases involved death due to burns.
- Most common age group affected in this study was 21–30 years closely followed by the age group 11-20 years.
- There was higher preponderance of female cases in this study with a female to male ratio of 1.5:1.
- Maximum number of burn victims were married (66.22%) followed by unmarried (33.45%).
- Burn incidence was seen more commonly in housewives (43.25%) followed by labourers (26.35%) and students (22.92%).
- Majority of incidence of burns occurred at home (75.34%) followed by outside home (17.57%) and working place (7.09%).
- Maximum numbers of burn cases occurred between 4P.M. to 10 P.M. (35.47%) followed by 10 A.M. to 4P.M. (28.72%).

Systemic Sclerosis and Pulmonary Tuberculosis Associated with Interstitial Lung Disease: A Case Report

Laksmi Wulandari¹, Sisilia Yolanda Wijaya²
¹Associate Professor, ²Resident, Department of Pulmonology and Respiratory Medicine, Faculty of Medicine, Universitas Airlangga – Dr. Soetomo General Academic Hospital, Surabaya, Indonesia

Abstract

A 59-year-old man had complaints of shortness of breath, thickened and dry skin especially on both hands. Results of thoracic HRCT obtained interstitial lung disease. A year after, the patient underwent geneXpert sputum test because he still complained of coughing with white phlegm and tightness while doing activity. The test obtained Mycobacterium tuberculosis 2+. He received anti-tuberculosis drugs. One month after infection, the patient was evaluated for Mycobacterium tuberculosis, while administration of anti-tuberculosis drugs was continued for up to 8 months. In the second year, the patient had severe restriction, and was given advanced anti-tuberculosis drugs in the sixth month.

Keywords: Systemic sclerosis; interstitial lung disease; tuberculosis

Case Report

A 59-year-old man, a private employee, had a history of smoking >10 years and had stopped since the last 8 years. He had no history of alcohol consumption and autoimmune thyroid disease (ATD) therapy. The patient visited hospital with complaints of thickened and dry skin, especially on both hands (Figure 1), and chest pain during activity. Transthoracic echocardiography and echocardiography results showed left ventricular hypertrophy and mild pulmonary hypertension.

History and physical examination led to suspected SSc. Then, the patient underwent chest X-ray examination (Figure 2). We obtained reticulogranular pattern in the right and left paracardial and cardiomegaly. Acid-fast staining was then carried out on sputum, but we found a negative result.

We performed a chest HRCT X-ray and obtained a reticular pattern image on the posterobasal of the right-left inferior lobe of the lung. These findings supported the characteristics of ILD (Figure 3). Based on the examination results, we conducted an assessment based on 2013 American College of Rheumatology (ACR) / European League Against Rheumatism (EULAR) criteria for the SSc classification (Table 1). The patient was then diagnosed with SSc and ILD. The...
patient was given with 7 cycles of immunosuppressant cyclophosphamide treatment, followed by cyclosporine for 3 months, then azathioprine for 6 months. The results of pulmonary function examination did not show restriction and obstruction.

One year after being diagnosed, the patient returned to the hospital complaining of a weak body, increased tightness during activity, coughing with white phlegm in the last 1 month, and night sweats. The patient was then hospitalized and underwent treatment for pneumonia. Sputum aerobic cultures showed the presence of Klebsiella pneumoniae. Ceftazidime 1-gram therapy was given every 8 hours intravenously according to the results of antibiotic sensitivity. Chest X-ray evaluation was examined and provided the following results in Figure 4.

GeneXpert results showed medium *Mycobacterium tuberculosis*, while rifampicin resistance was not detected. Examination of acid-fast sputum smear was carried out and the results were 2+. Category 1 tuberculosis treatment was started in this patient with ATD 3 tab 4 FDC.

Two months later the patient came back to the hospital with complaints of shortness of breath while doing activities. Physical examination of the patient showed anaemia in conjunctiva and “velcro” crackles in the lower third of right and left hemithorax. Laboratory tests showed pancytopenia as a side effect of the ATD. Initial management of the patient was nasal oxygenation, cessation of azathioprine and ATD FDC due to pancytopenia. The ATDs given were 750 mg levofloxacin every 24 hours orally, 300 mg INH every 24 hours orally, 1250 mg pyrazinamide every 24 hours orally, and 750 mg ethambutol every 24 hours orally, PRC transfusion 1 flask/day, 4 mg methylprednisolone every 24 hours orally and 5 mg amlodipine every 24 hours orally.

The congestion decreased after 3-day clinical treatment. Thoracic HRCT evaluation showed fibro infiltrates with multiple cavities and tree-in-bud pattern in the right lobe of right and left lungs, tree-in-bud pattern in the inferior lobe of the right lung, cystic bronchiectasis in right lung lobe, bronchial wall dilatation and tram track sign in posterobasal segment of the inferior right-left lung, and multiple enlargement of lymph nodes with the largest size ± 0.6 cm in the right axilla, ±0.5 cm left, and ±0.3 cm in the lower right paratracheal. Sputum aerobic cultures showed the presence of Klebsiella pneumonia (figure 3).

Hb and leukocytes decreased to 8.8 g/dL and 670/uL. Transfusion of PRC 1 flask/day was provided up to Hb=10 gr/dL. Immunosuppressant treatment was restarted with the administration of 180 mg of mycophenolic acid every 24 hours orally. One month after discharge, based on the results of consultations with clinical experts, the patients were given with ATDs 300 mg INH and 750 mg ethambutol for continuation phase for 8 months.

In the sixth month of the continuation phase ATD, the patient stated that complaints of tightness were still present, but the patient could be more comfortable with activities and no coughing. Examination of lung function was carried out and severe restriction was obtained. Phase of the ATD was continued and SSc-ILD treatment was followed-up with mycophenolic acid.
Figure 1. Skin on both hands thickened and dry

Figure 2. Chest X-ray post one month
Figure 3. Chest HRCT in the first year (A) and in the second year (B)

Figure 4. Chest X-ray Just like the chest X-ray of the previous year, reticulogranular pattern of the right and left paracardial, and cardiomegaly, were still visible, but now there was also a pattern of fibroinfiltrates.
Discussion

SSc is a heterogeneous disease and its pathogenesis is marked by 3 things, which are microvascular vasculopathy, autoantibody production, and fibroblast dysfunction resulting in an increase of extracellular matrix depositions. The gold standard to diagnose SSc is not found yet. American College of Rheumatology (ACR) made criteria to classify SSc in 1980 but the sensitivity and specificity were low. These criteria then updated by a joint committee between ACR and European League Against Rheumatism (EULAR) in 2013 with higher sensitivity and specificity (>90%) (3, 4).

Management of SSc includes early diagnose, early diagnose of internal organ involvement, identification of patients with risk of new organ complication, and deterioration of disease related to nonpharmacological therapy. Pharmacological management of SSc includes therapy of involved organ with the recommendation from EULAR (5).

Cyclophosphamide is recommended for ILD related to SSc (SSc-ILD) even though the side effect is quite much, especially in a progressive ILD (recommendation A). Azathioprine orally can also be given as an active therapy in SSc-ILD after administration of cyclophosphamide. A randomized controlled trial to compare effectivity of mycophenolate mofetil and cyclophosphamide in a patient with SSc-ILD and the result showed that both are equal in improving forced vital capacity (FVC) but the recommendation for mycophenolate mofetil usage is not made yet (5-7).

The pathogenesis of SSc is still unclear. Patient with the genetic predisposition of SSc, an external trigger makes the pathologic process start. Triggers of SSc can be a virus/bacteria (pathogen), chemical substance and pollutant (e.g, silica), Human Leucocyte Antigen/HLA (such as B8, DR5, DR3, and DR52), or a phenotype changing of body cells. SSc is a result of 3 related processes which are fibroproliferative vasculopathy of small vessels, abnormality of the innate and adaptive immune system that produce autoantibodies and cell-mediated autoimmunity, and fibroblast dysfunction that cause excessive accumulation of collagen and another extracellular matrix in the skin and internal organs (8).

Endothelial damage is the main process in SSc. Endothelial dysfunction causes the decrease of endothelial NO synthase (eNOS) enzyme production so that the production of basal nitric oxide decrease and lead to vasoconstriction of small vessels in extremities. This process causes hypoxia in peripheral extremities. Innate system immune will produce pro-inflammatory cytokines after exposure to external or internal triggers. Adaptive immunity in SSc is Th2 dominant. The t-cytotoxic cell in a patient with SSc play a role in adding the damage of endothelial with granzyme and Fas/FasL. Debris from the result of the apoptotic cell will become an antigen and trigger B cell to form autoantibody. The antigen in the body also binding with autoantibody, which is then along with cytokines, worsen the damage of endothelial and stimulate fibroblast to deposited collagen (9, 10).

Fibrosis is the end of the pathogenesis of SSc which continues to occur during the life of the patient. Fibroblast of a patient with SSc is having dysfunction due to trigger that continuously causing collagen deposition in skin and internal organs, includes the lung. Accumulation of collagens causes massive fibrosis in lungs and alveolitis which is then called SSc-ILD (9, 10).

There is an immune system dysfunction in a patient with SSc-ILD causing them to be easily triggered by external factors such as viral/bacterial infection, also pollutants that can cause disease manifestations even though only in a small amount (11).

Diagnose of SSc-ILD is accomplished by combining the presence of clinical symptoms, physical examination, pulmonary function test, and radiological finding. The patient can be asymptomatic in the early stage and then complain about dyspnea on effort, unproductive cough, and chest discomfort. In physical examination, “velcro” crackles can be found in auscultation. Pulmonary function test shows a decrease of diffusion capacity (DLCO) and forced vital capacity (FVC). HRCT showed infiltrate or subpleural density starts from the posterior segment of the inferior lobe, interstitial reticular infiltrates, and subpleural honeycombing. Traction and cystic bronchiectasis are the advanced forms of progressive disease course (12).

Indonesia is an endemic country of tuberculosis (TB) so patient with the immunocompromised state is in a very high risk of TB infection. Diagnose of TB is
assessed with the presence of clinical symptom of the respiratory tract which is a productive cough for more than 2 weeks, along with systemic symptoms and confirmed by microbiological and radiological findings. Detection of *Mycobacterium tuberculosis* (MTb) in the acid-fast bacilli staining or molecular rapid test is a gold standard to diagnose TB (13).

The side effect of ATD can be a hematological disorder and immune-mediated pancytopenia is one of them. The underlying mechanism of this emergence is the effect of immunity, interaction with the enzymatic pathway, and direct inhibition of the hematopoiesis system. The incidence of hematologic side effects is reported to be related to the use of rifampicin and also to isoniazid, pyrazinamide, and ethambutol but with a lower incidence than rifampicin (14, 15).

SSC-ILD has a poor prognosis with increasing mortality. The survival rate of patients with severe SSC-ILD is 30% at 9 years. The fastest decrease of pulmonary function and radiological worsening occurs in the first 3 years after the onset of disease (12).

**Conclusion**

Patient with SSC-ILD is susceptible to TB infection and the clinical symptoms of both diseases are very similar, making it hard to be diagnosed. SSC-ILD is a progressive disease and the presence of TB can cause deterioration of the ILD itself, decrease of pulmonary function, and decrease of patient’s quality of life. This case is reported to highlight the importance of early detection of TB in a patient with immune disease and ILD. Appropriate management including the management of side effect is very important to prevent progression and improve the quality of patient’s life.

A Study Protocol for a Randomized Trial on Effect of Safe Patient Handling (SPH) program on Rehabilitation Outcomes and on Safety of Physical Therapists in Rural Hospital

Poulami Bhandakkar¹, Deepali Patil², Angela Kapoor³
¹Final Year Student, ²Associate Professor, ³Assistant Professor, Department of Cardio-respiratory Physiotherapy, Ravi Nair Physiotherapy College, Datta Meghe Institute of Medical Sciences(DU), Wardha, Maharashtra, India

Abstract

Introduction: Patient management and intervention practices are a crucial component of patient treatment in the hospitals. In recent times the focus is put on early and regular mobilization of patients to boost recovery during and after hospitalization. Increase in inpatient mobilization to improve patient treatment raises a physiotherapist’s physical demands and therefore risk of injury. With the context of a patient mobilization program, better work procedures and decrease in physiotherapist’s injuries while working, SPH program will be incorporated.

Purpose : The goal of this research is to evaluate the effect of SPH program and mobilization in context of efforts to improve quality of health care and safety of patients as well as the physical therapist.

Method : There will be 2 groups, intervention (SPH) and comparison (no-SPH) each group will consist of 20 patients. The intervention group will be consisting the patients admitted in rehabilitation unit for the first three months of the research and the comparison group will consist the patients admitted in rehabilitation unit in the last 3 months of the research. Intervention group will undergo rehabilitation with SPH program which will include equipments like lifts based on ceiling and floors, sit to stand supports, motorized hospital beds and ambulation aids.

Result : Statistical analysis will be conducted. Comparison will be made on a variety of characters such as age, duration of stay and diagnosis to determine equivalence between the groups. Evaluation of the impact of SPH program on recovery outcome will be done by linear regression model. FIM scores of intervention group at admission and discharge will be compared to the comparison group FIM scores at the time of admission and discharge. The linear regression model will represent the graphical overview of the mean mobility scores at the time of admission and at the time of discharge for each group.

Conclusion: The publication of conclusion will be done after conducting the study and obtaining the results through statistical analysis.

Keywords : Safe Patient Handling(SPH) program, physiotherapist, mobilization , moving and lifting.

Introduction

Recent trends in improving patient care in acute settings include early and regular patient mobilization; however, this may add to the physical demands on patient care staff, raising their risk of injury(1). Manual patient management procedures result in repetitive physical loads that can result in injuries in health care settings. SPH program have been introduced in response
to high rates of injury from health care providers\(^{(2)}\). Therapeutic patient handling tasks pose a substantial risk for the therapist to sustain work related musculoskeletal disorders than typical patient handling tasks do because the therapists are exposed for longer amounts of time to high mechanical loads\(^{(3)}\). This program of SPH and mobilization is going to take place in the context of incorporating worker safety procedures associated with patient handling into a wider effort to improve patient care through early and regular patient mobilization and implementing safe equipment and practices for patient handling and mobilization\(^{(1)}\).

Patient management and intervention practices are a crucial component of patient treatment in the hospitals. In recent times the focus is put on early and regular mobilization of patients to boost recovery during and after hospitalization. Increase in inpatient mobilization to improve patient treatment raises a physiotherapist’s physical demands and therefore risk of injury. With the context of a patient mobilization program, better work procedures and decrease in physiotherapist’s injuries while working, SPH program will be incorporated.

Programs for safe patient handling and mobilization of patients are focused on data from biomechanical studies demonstrating that proper biomechanics may not prohibit musculoskeletal disorders which are work related and are caused due to shifting, raising or repositioning the patients. Instead of relying on traditional body mechanics to protect the physical therapists, safe patient handling program provides steps that reduce the weight that the therapist can physically raise and offers guidance on how to use the equipments for mobilization and handling the patients\(^{(4)}\). However S P H program equipment were intended to minimize physical exertion during patient handling tasks and not necessarily to alter the rehabilitation process\(^{(4)}\).

While originally designed to protect health care staff from accidents associated with transporting and treating patient, safe patient handling procedures have been developed as a viable strategy of intervention to improve patient recovery\(^{(4)}\). Rehabilitation services, in particular, are seen to be significantly affected by safe patient handling program. In conventional rehabilitation environment therapist offer patient practical mobility support (e.g., ambulance and transfers), rehabilitating patients to walk and transfer by picking them up and protecting them physically\(^{(2)}\). In addition to increased therapist and patient safety, therapist have observed that S P H programs have increased patient involvement and activities, and therapist were able to mobilize the bariatric and medically complex patients in rehabilitation\(^{(2)}\). Advanced equipment for patient handling is used in rehabilitation settings with SPH programs to help or pick up patients, especially when patients are hefty or dependable\(^{(2)}\). The program will be designed such that it will provide more flexibility to the therapist while working on recovery programs to reduce the risk of overloading\(^{(2)}\).

In view of the number and variety of S P H programs and the fact that they radically modify the patient care, the impact of S P H programs on the functional well being of the patient in recovery needs to be immediately investigated. This work will assess the impact of an safe patient handling program on patient’s functional independence as calculated by Functional Independence Measure (FIM)\(^{(2)}\).

**Objectives**

1. To assess the impact of safe patient handling on recovery of the patient.

2. To observe if there is decrease in patient care worker injuries after incorporating safe patient handling program.

3. The goal of this research is to evaluate the effect of S P H program and mobilization in context of efforts to improve quality of health care and safety of patients as well as the physical therapist.

**Material and Methodology**

The study will be conducted in Ravi Nair Physiotherapy College, after getting the approval from the Institutional Ethics Committee (IEC) of Datta Meghe Institute Of Medical Sciences Deemed to be University, Sawangi (Meghe)

**Study type:** Retrospective cohort study.

**Study setting:** Rehabilitation unit of hospital.

**Study duration:** 6 months.
**Outcome Measure:** Functional Independence Measure (FIM) scale.

Validity of Functional Independence Measure (FIM) – ICC > 0.83.

Reliability of Functional Independence Measure (FIM) - ranges from 0.86 to 0.88.

**Equipment included:**
1. Performing lifts which depends on floor and ceiling
2. Sit to stand assists
4. Ambulation aids.

**Inclusion criteria:**
1. Patient admitted to the hospital for stay of more than 3 days
2. Patients in Out Patient Department (O P D) coming for rehabilitation.
3. Patients with diagnosis of disorder related to musculoskeletal system.

**Exclusion criteria:**
1. Any patient who is critically ill on ventilator
2. Any patient who had a stay of less than 2 days or fewer
3. Any patient who is unwilling to participate.

**Sampling type:** Simple random sampling.

**Sample size:** Twenty in intervention group.
Twenty in non-intervention group.

**Procedure**

Ethical clearance will be obtained from IEC. Data will be obtained from medical records of patients admitted to the hospital, patients will be selected on the basis of their stay in the hospital and diagnosis. Inclusion criteria and exclusion criteria will be implemented. The research will consist of two groups, intervention group (S P H) and comparison group (no-S P H) each group will consist of twenty patients. The intervention group will be consisting the patients admitted in rehabilitation unit for the first three months of the research and the comparison group will consist the patients admitted in rehabilitation unit in the last three months of the research. Intervention group will undergo rehabilitation with S P H program which will include equipments like lifts which depend on floor or ceiling, sit to stand support, motorized hospital beds and ambulation aids.

**Data / Statistical Analysis**

Statistical analysis will be conducted. Comparison will be made on a variety of characters such as age, duration of stay and diagnosis to determine equivalence between the groups. Evaluation of the impact of S P H program on recovery outcome will be done by linear regression model. F I M scores of intervention group at admission and at discharge will be compared to the comparison group F I M scores at the time of admission and at the time of discharge. The linear regression model will represent the graphical overview of the mean mobility scores at the time of admission and at the time of discharge for each group.

**Expected Result**

Considering the high rates of injuries therapists are going through, these services may potentially play a significant role in reducing accidents and at the same time allowing for successful recovery of the patient.

**Discussion**

S P H and mobilization strategy dramatically lowers the workplace injury rates for the physiotherapist(5). Use of mechanical patient lifting equipment has proven to not only avoid musculoskeletal injuries but also reduce the discomfort and damage while manually lifting patients(6). S P H and mobilization also increases the job satisfaction of a health care worker(7). Measurement of the effect of the program is important for clinical management evaluation of the success of recovery services and its long term effect on functioning of the patients(8).

Studies show that the S P H programs results in comparable or even slightly better mobility results for majority of patients. This may alleviate concerns among therapists who fear that S P H programs can lead
to dependency and interfere with functional mobility recovery\(^{(2)}\). Several researches indicate that mechanical patient lifts can help lower the rates of musculoskeletal injuries in therapists\(^{(9)}\).

Less is known concerning the effects of S P H programs on the carrying out of simple everyday tasks (A D Ls), for example dressing or bathing, combing\(^{(4)}\). One of a kind element in the S P H program is embedded and integrated usage of safe handling of the patients and mobilizing equipment for patients and practices in patient care program to improve patient mobility with goals to maintain proper safety of the therapist\(^{(1)}\).

Further research works are required to identify comprehensive guidelines for the S P H program, tailored to variable patient care settings and work requirements\(^{(5)}\). Strategies should be pursued to promote the use of mechanical lifting tools, as fewer amounts of accidents can be expected with its increased use\(^{(10)}\). Aim of the physiotherapy rehabilitation involves maintaining the range of motion and avoiding deformity. It is also necessary to promote active movements to improve trunk control and postural balance\(^{(11)}\). Physical activity and exercise play an significant role to maintain adequate state of health\(^{(12)}\). Positive effects of physiotherapy interventions are gaining trust, confidence of the patient during the rehabilitation process\(^{(13)}\). To prevent differences in the recovery phase between the two groups, recovery time for the both groups should be equal. Evidence of this research will support the patients and the therapists by having a rehabilitation process which is safe and reliable\(^{(14)}\).

**Conclusion:** Recovery does not seem to be hampered by the use of Safe Patient Handling Program. There may be irrational concern among therapists that the use of equipment may result into dependency.

**Ethical Clearance:** The study will be conducted in Ravi Nair Physiotherapy College, after getting the approval from the Institutional Ethics Committee (IEC) of Datta Meghe Institute Of Medical Sciences Deemed to be University, Sawangi (Meghe).

Patient’s Knowledge and Satisfaction Regarding Nursing services and Physical Infrastructure of a Tertiary Care Hospital Situated in Rural area of Northern India (Haryana)

Manisha Rani¹, Jyoti Phougat²

¹ Former Assistant Professor, Pediatric Nursing Department, Maharishi Markandeshwar Institute of Nursing, Maharishi Markandeshwar (Deemed to be University), Mullana, Haryana, India (At Present: Nursing Officer Deputed as Nursing Tutor, Pediatric Nursing Department, Nursing College, All India Institute of Medical Sciences (AIIMS) Bhopal (M.P.), India). ² Assistant Professor, Pediatric Nursing Department, M.M. Institute of Nursing, MMDU, Mullana, Haryana, India

Abstract

Background: Nowadays health care quality is a universal concern. The health sector is changing rapidly due to the escalating requirements and desires of patients. The most appropriate method to measure a client’s experiences about available hospital services is a patient satisfaction survey. Present study aimed to assess patient’s knowledge and satisfaction regarding nursing services and physical infrastructure.

Methods: 330 patients were selected by purposive sampling technique attending various indoor departments of the selected hospital. Self-structured checklist and three-point rating scale each containing a total 90 sets of items used to assess knowledge and satisfaction. The reliability coefficient for the knowledge tool was 0.87 by KR 20 and satisfaction was found 0.85 by Cronbach’s Alpha.

Result: Study results showed that more than half (59.7 %) patients had very good level of knowledge regarding availability of services. 72.4% & 69.7% of patients were satisfied with Nursing services and physical infrastructure facilities respectively. Item wise distribution of level of satisfaction among patients regarding nursing services reveals that “nurses hear you carefully(64.5%)”, “explain patient’s condition to the family (64.5%),” and “Adequate space in ward (75.5%)” was found ranked 1st with the highest satisfaction, whereas “provide psychological counseling”, “Toilet facility and cleanliness(32.1%)” was found ranked lowest. A significant low positive correlation found between mean knowledge and satisfaction scores regarding nursing services and physical infrastructure as evident by computed ‘r’ value (0.38)

Conclusion: Using these necessary responses from the patients, various shortcomings can be pointed out and notify to hospital administration for improvement of the nursing care services & physical infrastructure.

Key Words: knowledge, satisfaction, Nursing services, Physical Infrastructure, Quality care

Introduction

Satisfaction, like quality, is multifaceted construct¹. Satisfaction of clients premised on multifarious strands in a health care organization. Client’s expectancy and his perception with health care and services are directly congruent². Among all the methods, assessment of client’s satisfaction is the vital for the evaluation of Excellencies in a health care organization. It is important to assess the satisfaction rate of the services which will evaluate whether the services are useful or not³. In the recent epoch, many dimensions together with behaviour of employees, patient staff interaction along with administration issues of the hospital and physical surroundings are crucial aspects of patient satisfaction⁴. A happy patient has higher adherence to treatment protocols and goes for routine follow up for his ill health⁵. Pragmatic evidences confirm that

Corresponding author:
Manisha Rani

Contact No. +91 9416429127
majority of health care organizations in India are meagrely involved in the assessment of satisfaction rate. The long queues in the OPD areas, little and unkempt waiting areas, poor condition of bathrooms, unsympathetic approach of health care workers bear articulate testimony to the current fact. Entire considerations make the assessment of patient’s satisfaction with health system even highly necessary. In recent years, patients have become a lot conscious to their rights and cognizant regarding their health. They demand best health care in each facet. Patient’s feels unsatisfied when services received by them are not according to their expectations. Developed countries have many research studies and literatures on satisfaction of patients with health care services but this number is very less in case of developing countries including India. Patient satisfaction with nursing services is highly important to any health care agency as care provided by nurses comprise most health care suppliers because nurses take care of patients for twenty four hours on a daily basis. A German study on the determinants of patient satisfaction in patient care from 2011, by Schoenfelder et al. concluded that satisfaction with nursing services and care has the foremost vital impact on overall satisfaction. Satisfaction assessment will offer valuable and exclusive insights into routine health care in hospital. It is broadly accepted as an autonomous dimension of quality of care as analysis of patient satisfaction includes “internal” (inward-looking) aspects of hospitalization, which frequently stay unrecorded, like communication, warmth or interaction. Satisfaction of patient regarding health care facility situated in a rural area is of vital significance for providing quality services to patients, so keeping this point in consideration; the present research study was conducted to assess patient’s knowledge and satisfaction with nursing services and physical infrastructure in a tertiary care hospital situated in a rural area of Northern India (Haryana).

Material and Methods

Study Design and Study Area:

This was a cross-sectional study based on a descriptive survey design conducted in a tertiary care center situated in the rural part of northern India. The hospital is a center for undergraduate and postgraduate medical teaching and has an operational strength of 940 beds. The hospital has 20 departments and provides outpatient consultations and inpatient services to patients presenting to the hospital from other levels of care or on self-referral. Patients are mainly seen in the Outpatient Department causality unit and special clinics. It receives patients from within Haryana, and the neighboring states of India (Uttar Pradesh, Himachal, Punjab, and Chandigarh). The majority of patients are indigenous Hindu, although the Muslim and Sikh ethnic groups also constitute a substantial proportion of the clientele. Clients with various occupational backgrounds like farmers, private, and govt. service holders, businessmen, etc get the benefit of services present over here.

Ethical consideration was taken from the Maharishi Markandeshwar University institutional ethical committee (under project number 575). Written informed consent was also obtained from all the participants before starting the study Data for the study was collected from clients admitted in medicine, surgery, orthopedics, neurosurgery, and gynecology ward of MMIMS&R hospital Mullana, Ambala, Haryana.

Sample Size and Sampling Technique:

Using a Non-probability Purposive sampling technique a sample size of 330 was taken to detect the level of knowledge and satisfaction among the study participants regarding nursing services and physical infrastructure. However, patients referred or advised for or admitted to the Intensive care unit / cardiac care unit/emergency with conditions related to psychiatry or labour, and those with critical health issues were excluded.

Tools and Technique of Data Collection:

A structured knowledge checklist and rating scale were prepared to assess the knowledge and satisfaction regarding nursing services and physical infrastructure among indoor patients. Both tool consisted of 90 items each divided into 2 parts according to areas of hospital services- nursing services, and physical infrastructure among indoor patients. In knowledge tool each item consist maximum 1 score and minimum score 0. The score obtained by the indoor patient were arbitrarily categorized into four levels- Very good (>75%), Good (61-75%), Average (50-60%), Poor (<50%).
Rating scale for level of satisfaction had a score of 3 points i.e., satisfied score as 3, partially satisfied as 2, dissatisfied as 1. The score obtained by the indoor patient were arbitrarily categorized into three levels: Satisfied (>75%), Partially satisfied (50-75%), Dissatisfied (<50%).

Both tools were validated by 7 experts in the various nursing fields. An interview technique was used to collect the data of the present study.

Reliability of the structured knowledge checklist and Rating scale was computed using Kuder Richardson 20 (KR-20) and Cronbach alpha methods which was found 0.87 and 0.85 respectively. The tool was found valid, reliable, and feasible for the purpose of the study.

Statistical analysis Collected data were entered into Microsoft Excel software and data cleaning was performed. Data were analyzed using SPSS IBM Statistics version 20. Descriptive statistics were generated using mean, standard deviation (SD), frequency, and percentages. Analytical statistics like correlation coefficient and Chi-square test was used to see correlation and association. The value of P < 0.05 was considered statistically significant.

Results

Description of sample characteristics

Frequency and percentage distribution was computed to describe the sample characteristics of the sample. The baseline sample characteristics of the participants showed that 47.9% patients were females and 52.1% were males and as regard to the religion 61.4%, 26.7% patients was Hindu and Muslim respectively, 11.6% was Sikh, and 0.3% belong to Christian religion.

Less than half, (35.2%) patients were having education up to primary school and, (3.6%) were having senior secondary education. Family income of 46.1% patients was Rs <5000 and only 5.5% were having Rs >20,001& above per month. More than half patients (51.5%) were from joint family, and other 48.2% were from nuclear family. As regard to previous hospitalization 52.1% were admitted previously in hospital and 47.9% were not admitted previously and as regard to the type of hospital 32.4% admitted previously in private hospitals previously and 19.7% admitted in government hospitals. More than half (68.8%) have less than 2 visits in hospital previously and, 3.9% has more than 4 visits. Nearly half number of patients, (42.4%) had 1-4 days length of stay and, 9.7% had more than 12 days length of stay in the hospital.

Area wise frequency and percentage of levels of knowledge among indoor patients regarding nursing services and physical infrastructure

More than half (59.7%) (74%) patients were having very good level (>75%), and 12.7% & 2.7 % patients were having below average level (<50%) of knowledge regarding availability of nursing services, and physical infrastructure of hospital respectively.

Frequency and percentage of level of satisfaction regarding nursing services, and physical infrastructure

Findings shows that more than half (72.4%) (69.7%) patients were satisfied with nursing services and physical infrastructure facilities respectively. (as shown in figure 1)
Figure 1: Bar Graph Showing the Percentage of Level of Satisfaction among Indoor Patients Regarding Nursing Services and Physical infrastructure

Item wise distribution of level of satisfaction among patients regarding nursing services

Results reveal the frequency, percentage and rank order of level of satisfaction regarding various Nursing services. Among these, “hear you carefully” and “explain patient’s condition to family” was found 64.5% ranked 1st, “treat you with respect and courtesy” was found 63.3% ranked 2nd. “Provide comfort during nursing care” and “provide psychological counseling” was found ranked lowest as shown in table no. 1

r = 0.113 at 0.05 level of significance * significant

NS=Non significant

Chi square value showing the association of knowledge score regarding availability of nursing services and physical infrastructure with selected sample characteristics

Results of Chi square association indicates that Type of family (10.47) and present medical conditions (5.99) was found statically significant at 0.05 level which indicate that rate of scoring of knowledge was dependent on type of family and present medical condition, as most of the patient who belonged to joint family have more level of knowledge as they received information from family members and their relatives and the patient with acute illness were more oriented and able to receive information regarding available health care services.

The finding also revealed age, gender, religion, marital status, education, family income per month, number of visits, previous hospitalization was found statistically non significant at 0.05 level.

Chi square value showing the association of satisfaction score regarding availability of nursing Services and hospital infrastructure with selected sample characteristics

A chi square association with level of satisfaction indicates that Religion (20.96), occupation (9.79), and type of hospital (6.48) were found statistically significant at 0.05 levels which indicate that satisfaction was dependent on religion, occupation and type of hospital previously admitted.

The findings also revealed that age, gender, type of family, marital status, education, family income per month, number of visits, previous hospitalization was found statistically non significant at 0.05 level.

Discussion

Results of our study shows that 81.87% patients have overall satisfaction regarding nursing services. In nursing services, “nurses hear carefully” and “explain patient’s condition to family” was found 64.5% ranked 1st, treat patients’ with respect and courtesy was found 63.3% ranked 2nd, maintained personal privacy was found 63% ranked 3rd. These results were found to be consistent with the study conducted by Olowe A Folami F (2019) to assess patient satisfaction with nursing care in selected wards of the Lagos University Teaching Hospital (LUTH). The findings revealed that 77% of the patients showed excellent satisfaction with the quality of nursing care received during their stay on the ward. 43.3% clients explained that nurses explanations were clear about test and treatments, nurses willingness to answer the questions were stated satisfactory by 48.3% patients.49.1% were satisfied by the nurse’s friendly and kind behaviour. More than half (60.8%) stated nurses skills and competencies in very good category but only 12.5% were satisfied with privacy during treatment9.

Findings of our study revealed that for Physical infrastructure.”Adequate space in ward” was found 75.5% ranked 1st, “proper electricity supply and ventilation” was found 74.5% ranked 2nd, whereas “Toilet facility and cleanliness” was found 32.1% ranked lowest. These results were found to be consistent with
the study conducted by Rajkumari B, Nulla P (2017). Nearly one third of the patients, 243 (32.4%) were not satisfied with the cleanliness of the ward. Overall 43.7% patients were poorly satisfied with physical facilities of the hospital. Out of 5 headings under physical facilities, “toilet and its cleanliness” score the least.

Medicolegal cases: A Potential Source of Coronavirus (SARS-CoV-2) Infection in Indian Police Personnel

Mayank Gupta1, Amit Kumar Nayak2, Praveen Kumar Tiwari3, Taneesha Gupta4, Surendra Kumar Pandey5

1 Assistant Professor, Department of Forensic Medicine, 2 Assistant Professor, Department of Anatomy, 3 Research Scholar, Department of Forensic Medicine, 4 Junior Resident, Department of Obstetrics and Gynaecology, 5 Professor, Department of Forensic Medicine, Institute of Medical Sciences, Banaras Hindu University

Abstract

India accompanies the world witnessing a rapidly spreading global pandemic of Covid-19. On 24 March, the Government of India ordered a nationwide lockdown that triggered the mass migration of daily wages workers back to their native states. Without prior testing for SARS-CoV-2, it imposed a new challenge towards the authorities to prevent the possible spread of infection. The study aims to determine the infection status of migrants who died in the jurisdiction of Varanasi district during their journey and the possible risk of spread of Covid-19 to frontline workers. The study was conducted between 24 March 2020 and 10 July 2020. A total of 6 cases came to our department who died during travel. The nasopharyngeal and oropharyngeal swabs were taken after the body arrived in the mortuary and sent for detection of SARS-CoV-2 by RT-PCR method to the Viral Research and Diagnostic Laboratory (VRDL), Department of Microbiology of our Institute. A total of six cases were included in this study, of which 3 were positive for SARS-CoV-2 while others were negative. None of them had symptoms of Covid-19 infection, such as respiratory difficulties, sore throat or fever. The guidelines issued by the Ministry of Health and Family Welfare were limited in scope to hospital deaths and lacked guidelines to be followed by police personnel while investigating unnatural deaths. This brings the police personnel at risk of contracting Covid-19 infection as the cases are getting tested after the arrival at mortuary. The only way of protection is prevention, which mandates laying down the guidelines at the earliest.

Keywords: Covid-19, migrants, medicolegal cases, police, guidelines

Introduction

India accompanies the world witnessing a rapidly spreading global pandemic of Covid-19. On 31 December 2019, the Wuhan health commission reported the first case to the country centre of disease control (CDC) and WHO with pneumonia of unknown diagnosis in Wuhan, China. With the accelerated transmission and mortality of disease, the WHO declared it as a public health emergency of international concern and outbreak on January 30, 2020. On February 11, 2020. Covid-19 was named severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). As the continuous expansion and transmission of diseases continued and affected several countries, the WHO declared Covid-19 as a pandemic on 11 March 2020.

In India, the 1st case of Covid-19 was reported on 30th January 2020, and the first death was reported on 12 March 2020. On 22 March, India observed a 14-hour voluntary public curfew at the request of the government. With the rapid increase in the number of cases, on 24 March, the Government of India ordered a nationwide lockdown for 21 days, affecting the entire 1.3 billion population of the country. With a highly contagious nature of infection and an increase in the
number of cases, on 14 April, the government of India extended the nationwide lockdown until 3 May, which was followed by two-week extensions starting 3 and 17 May with substantial relaxations.  

Since 1 June 2020, the government has started unlocking the country in three unlock phases by dividing the area into different zones on the basis of infection - (i.e. the area). Red, orange and green hot spot and barring containment zones.  

With factories and workplaces shut down and the lockdown imposed on the country, millions of migrant workers were left with no livelihood. They had to deal with income loss, food shortages and unpredictability about their future. Subsequently, hunger and insufficient food stocks became a bigger curse for them and their family. The nationwide restriction ceased daily wage workers at their place with no work and money, and they initiated walking or bicycling hundreds of kilometres back to their home district, with transport restrictions due to the lockdown. The government protection norms of sanitation and social distancing could not be followed by these migrants since they travelled together in large groups.  

Even though later in May the government launched special trains and buses, due to starvation and lack of money, the migrant chose to travel in the cargo compartments of trucks and containers or travel by foot together in large groups ruining the corona protection norms.  

More than 300 deaths were reported until 5 May 2020 due to reasons other than Covid-19 because of unplanned migration of daily wage labourers and marginalized migrants. Eighty deaths were reported on the Shramik Special trains while travelling back home: in a period of a month, they had begun.  

This massive migration without prior testing for SARS-CoV-2 imposed a new challenge towards the authorities to prevent the possible spread of infection.  

The study aims to determine the infection status of those migrants who died in the jurisdiction of Varanasi district during their journey and the possible risk of spread of Covid-19 to the Frontline workers through them.  

### Material and method  

The cases for this study were selected from the dead bodies of migrants brought into the mortuary of our department for medicolegal postmortem examination from the various police stations of Varanasi. The study was conducted between 24 March 2020 and 10 July 2020. A total of 6 cases were reported in our department with death during or after travel.  

History regarding the symptoms before death and circumstances of death were collected from the following sources:  

1. The papers sent by police for medico legal autopsy:  
   (a) Inquest report,  
   (b) Copy of the first information report (F.I.R.),  
   (c) Hospital records/reports if available, etc.  

2. From the interrogation of the concerned personnel –  
   (a) Police constables accompanying the dead bodies, and  
   (b) Attendants/relatives, friends and others of the victim.  

The nasopharyngeal and oropharyngeal swabs were taken after the body arrived at our mortuary and were sent for detection of SARS-CoV-2 infection by RT-PCR to the Viral Research and Diagnostic Laboratory (VRDL), Department of Microbiology of our Institute.  

### Results  

**Case 1** – A 45-year-old male started walking from New Delhi towards Bihar. He died in Varanasi jurisdiction on 16/04/20. The body was sent for autopsy. Keeping in view the history of travel from New Delhi and the history of tachypnoea before death (mentioned in the inquest report), autopsy was withheld, and swabs were taken on 17/04/2020. Report – negative on 18/04/20. Later, autopsy was conducted, and it was concluded that death was due to starvation.  

**Case 2** – A 26-year-old male coming from New Delhi by motorcycle met an accident on highway in Varanasi
jurisdiction. He immediately fell unconscious and was admitted to the district hospital. He died, and the body was sent for autopsy on 04/05/20. Report – negative on 06/05/20. Later, autopsy was conducted, and it was concluded that death was due to head injury.

**Case 3** - A 37-year-old male coming from New Delhi met an accident on highway in Varanasi jurisdiction. He immediately fell unconscious and was admitted to the trauma centre of our institute. He died, and the body was sent for autopsy on 04/06/20. Report – negative on 04/06/20. Later, autopsy was conducted, and it was concluded that death was due to head injury.

**Case 4** - An 85-year-old male coming from Mumbai by Shramik special train died suddenly on 31/05/2020 during the journey. History taken from relatives revealed 2 episodes of vomiting without any history of fever, sore throat, cough or shortness of breath. There is no evidence of any external injury on the body as per police inquest. Autopsy was withheld, and swabs were taken on 01/06/2020. Report – positive on 01/06/20. The police were informed, and autopsy was waived off.

**Case 5** - An 81-year-old male coming from Mumbai by Mahanagari express train died suddenly on 25/06/2020 during the journey. History taken from relatives reveals that he collapsed suddenly while refilling the water on the platform, but there was no history of fever, sore throat, cough or shortness of breath. There is no evidence of any external injury on the body as per police inquest. Autopsy was withheld, and swabs were taken on 25/06/2020. Report – positive on 27/06/20. The police were informed, and autopsy was waived off.

**Case 6** - A 28-year-old male came from New Delhi to Azamghar (Uttar Pradesh) by personal vehicle on 04/07/2020. He was admitted to the Trauma Centre of our institute on 06/07/2020 with a history of head injury caused by alleged assault. There was no history of fever, sore throat, cough or shortness of breath. Swabs were taken on 07/07/2020. Report – positive on 07/07/2020. He died on 07/07/2020, and the body was sent for postmortem examination. The autopsy was conducted with proper precautions, and the cause of death was injury to the head.

**Discussion**

A total of six cases were included in this study, of which 4 arrived from New Delhi, while the other two arrived from Mumbai. The test reports of the 3 deceased who arrived from New Delhi were ‘negative’, and their autopsy was conducted afterwards. The remaining 3 deceased tested positive, of which 2 had travelled from Mumbai via train and one from New Delhi by personal vehicle. The police and district administration were informed immediately, and autopsy was waived off by the police in case numbers 4 and 5, while autopsy was conducted with proper precautions in case number 6. After being disinfected by 1% sodium hypochlorite solution, all the bodies were handed over to the police in a leakage proof body bag (disinfected by 1% sodium hypochlorite solution on the exterior) for cremation.

**Symptoms of the deceased**

As per the history taken from relatives, co-travellers and police, none of them had symptoms of Covid-19 infection, such as respiratory difficulties, sore throat or fever. Instead, there was a history of vomiting just before death in one (case 4) and sudden collapse of the other (case 5), and both were aged above 80 years. The exact cause of death could not be established in case numbers 4 & 5 as the autopsy was waived off, while the last patient died due to injury to the head.

In case numbers 4 & 5, it is worth noting that both cases did not have typical manifestations of Covid-19. This could mean either they were asymptomatic and died due to some other underlying cause, or they died from Covid-19 with atypical presentations. Most pathological studies are in consensus with the clinical features and clinical course of the disease in general. However, the disease is also known to cause pathological damage to organs such as the heart, liver, kidney, brain, blood vessels and other organs.

Meghan E. Sise et al. (2020) presented a case report titled ‘Case 17-2020: A 68 year old man with Covid-19 and Acute Kidney Injury’ who was finally diagnosed with acute kidney injury and its connection with severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) infection.13

Carolin Edler et al. (2020) conducted an autopsy - based study titled Dying with SARS-CoV-2 infection—an autopsy study of the first 80 consecutive cases in Hamburg, Germany. Out of 80 cases studied aged
between 52 and 96 years, corresponding to three different categories, 76 cases (95%) were classified as COVID-19 deaths, whereas four deaths (5%) were defined as virus independent non-COVID-19 deaths. Pneumonia accompanied by a fulminant pulmonary artery embolism was observed in eight cases whereas peripheral pulmonary artery embolisms were opined to be the cause in nine cases. Deep vein thrombosis was present in 40% of the cases. As per the author, this is the largest autopsy based study of patients infected by SARS-CoV-2.\(^{14}\)

Andrews et al. conducted a case study titled “First confirmed case of COVID-19 infection in India: A case report” describing a female aged 20 years returned from Wuhan, China on January 23rd 2020. Initially, she only had mild sore throat and rhinitis. She was conscious, oriented and afebrile, with other findings such as pulse rate 76/min, blood pressure 100/70 mmHg, respiratory rate 12/min and oxygen saturation 97 percent in the free atmosphere. General examinations were within normal limits, and she recovered well on symptomatic treatment.\(^{15}\)

Raman Swathy Vaman et al. (2020), in their study titled “A confirmed case of COVID-19 among the first three from Kerala”, India, reported a male medical student aged 23 years studying at Wuhan University, China returned to Kasaragod on 27 January. He developed mild infection in the upper respiratory tract on 30th January. The next day, he was admitted to the District Hospital Kasaragod. On physical observation, the patient was conscious, oriented and afebrile, with no paleness, icterus, cyanosis, clubbing, oedema or lymphadenopathy. Blood pressure was 118/78 mmHg, pulse rate was 88/min and respiratory rate was 14/min. Cardiovascular and respiratory systems were normal. Mild congestion of the throat was reported without any significant enlargement or membrane seen in the tonsil.\(^{16}\)

Lechien, J.R et al. (2020) conducted a study titled Olfactory and gustatory dysfunctions as a clinical presentation of mild-to-moderate forms of coronavirus disease (COVID-19): A multicentre European study investigating the dysfunction in confirmed COVID-19 infected cases concluded that as the disease and the virus both are just out and still evolving. As per the study, the infected patients may present solely with dysfunctions of the olfactory and gustatory systems without other symptoms, and it should be recognized as an important symptom of COVID-19 infection by the international scientific community.\(^{17}\)

J.E. Morley and B. Vellas (2020) in an editorial titled Covid-19 and older adults stated that seriously affected patients with acute respiratory distress syndrome can develop myocardial illness leading to mortality along with kidney and liver disease. They also stated that COVID-19 affects the central nervous system by invading it, which causes a rise in inflammatory cytokines expected to be responsible for delirium. Older people may experience an increase in delirium even without a high fever, which is uncommon in comparatively young people.\(^{18}\)

**Government of India guidelines regarding autopsy of Covid-19 positive medico-legal cases**

As per the available scientific literature to date, the survival of viruses gradually decreases with time in a dead body, but there is no specific time limit to declaring the body noninfective. Therefore, it is advisable to adopt precautions because dead bodies can be a potential source of infection, especially for those who come in contact during the initial period.

The cases of unnatural deaths are medico-legal cases that warrant an investigation into the cause of death by police and autopsy if required. The process is known as police inquest (Section 174, The Code of Criminal Procedure -1973), which includes visiting and examining the crime scene and the deceased by police and request for an autopsy if required. This means police is the first responder if such a death occurs outside the hospital, which makes them vulnerable to contracting the infection.

There is a comprehensive guideline issued by the Ministry of Health and Family Welfare (MoHFW) dated 15/03/2020 titled - ‘Covid-19: Guidelines on Dead Body Management.’ The guidelines were based on the current epidemiological knowledge about the COVID-19. At that time, India had travel-related cases and few cases of local transmission. At that stage, all suspected/confirmed cases were isolated in a health care facility. Hence, the document was limited in scope to hospital deaths.\(^{19}\)
This document was, however, coming up short of a guideline to be followed by police personnel while visiting at a crime scene, investigating, handling and transporting a case of unnatural death. As mentioned above, all the cases were tested for Covid-19 after they arrived at mortuary or hospital. The police, unaware regarding the Covid-19 status of the deceased beforehand, did not follow the standard precautions such as the use of personal protection equipment while investigating, handling and transporting such cases to the mortuary for medico-legal autopsy. This brings the police personnel and all those involved at risk of contracting Covid-19 infection as the cases are getting tested after the arrival at mortuary.

This is happening as India lacks a proper guideline to be followed by police while handling medico-legal cases. With cases increasing exponentially, this is of utmost importance to lay down at the earliest, a guideline for the police in handling the unnatural deaths in medico-legal cases, train them for the same and provide them with sufficient resources to protect themselves from contracting the Covid-19 infection.

The following propositions can be considered while drafting the guidelines:

1. It is in goodwill of the police that Covid-19 testing should be done in every case of unnatural death before starting the inquest, preferably at the site of death rather than waiting for a day or two.

2. If the case is positive, the police must use personal protection equipment (PPE kit) during the investigation and transportation of the body.

3. Autopsy to be done in very selective cases.

**Conclusion**

The current pandemic is still ongoing, and the scientific community is still learning new things about this disease. The only way of protection is prevention, especially in the case of frontline workers, be it healthcare workers or police. This mandates laying down the guidelines at the earliest.

**Acknowledgment:** The Author would like to thank the faculty and staff of the department for their valuable support and help with data collection from autopsied cases.

Lunar Cycle and its Correlation with Unnatural Death in Different Age Group

Mayank Gupta¹, Amit Kumar Nayak², Praveen Kumar Tiwari³

¹Assistant Professor, Department of Forensic Medicine, Institute of Medical Sciences, ²Assistant Professor, Department of Anatomy, Institute of Medical Sciences, ³Research Scholar, Department of Forensic Medicine, Institute of Medical Sciences, Banaras Hindu University

Abstract

It is believed abstraction that the Planets and stars influence human health and psychology is a popular notion in astrological science in India. However, debates are still ongoing about the exact effects and their extent and quality. This study aims to deduce the correlation between unnatural deaths in different age groups and the lunar cycle in 2819 cases. The cases were selected from the dead bodies brought into the mortuary of the department for medico-legal postmortem examination from the various police stations of Varanasi between the duration of 1st January 2013 to 17th July 2014. The compiled data were studied and analyzed statistically by employing the ‘one-way parametric ANOVA.’ It was observed that out of 2819 cases the most affected age group was between 21-40 years (52.4%) followed by the age group 41-60 years (23.1%) and 13-20 years (13.7%). The insignificant rise in unnatural death among different phases of the lunar cycle of different age groups indicates minimal correlation and association with the lunar cycle. A detailed study may be done in the future considering one parameter at a time.

Keywords: Full moon day, New moon day, Unnatural death

Introduction

It is believed abstraction that the Planets and stars influence human health and psychology is a popular notion in astrological science in India. However, debates are still ongoing about the exact effects and their extent and quality.

The moon and paranormal activity have often been associated with each other. The common belief is that a full moon is the most favorable time for paranormal investigations. Others believe the best time to experience paranormal activity is two or three days before or after the full moon and new moon. Why? No one can say for sure. One theory about investigating during a full moon is an increased gravitational pull on the earth from a full moon. This event could cause the ascend in paranormal activity.

C P Thakur, Dilip Sharma (1984) randomly selected 3 police stations of Bihar (India), i.e. Gaya Sadar, Kirtya Nand Nagar, and Sonari. Each at least 300 km apart from another. The number of crimes that occurred during 1978-82 was noted each day. Data were pooled and analyzed by the computer using a basic programming method. It was observed that the incidence of crimes committed on full moon days was notably higher than on any other day. Although a small peak in the number of crimes was observed on new moon days, it was insignificant as compared to those committed on other days¹.

Owen C et al. (1998) carried out a prospective study of lunar cycles and violent behavior. The study established no significant relationship between total violence and aggression or level of violence and aggression and different phases of the moon².
Biermann T et al. (2005) conducted a population-based study to assess the influence of the lunar phases on suicides according to age, sex, and chosen method. The study was conducted in Middle Franconia between 1998 and 2003 for a total of 3054 suicides (1949 males and 1105 females) cases. No significant connection was observed between the full, absent, and moon’s interphases and suicides. Nevertheless, a weak association was present between the no moon days and the inclination of the non-violent methods of suicide in men aged less than the median of 40.2 years. They concluded that there was no relationship between suicide and different phases of the moon.

A similar sort of study titled ‘Suicides and the lunar cycle’ was done by J.M. Gutiérrez-García and F. Tusell (1997) in which the results were no different from Biermann T et al. (1997).

Jay Karan et al. (2010) in their study titled ‘Full Moon Days and Crime: Is there any association?’ found that there was no noteworthy difference in crimes happening on full moon days and other days (p = 0.07). On stratification, there was no difference between full moon days of the week, and the same non-full moon day of the week except on Wednesday.

A study conducted by Joseph A. Schafer et al. (2010) in United States titled ‘Bad moon on the rise? Lunar cycles and incidents of crime’ and a similar study executed by Teresa Biermann et al. (2009) in Germany, titled ‘Relationship between lunar phases and serious crimes of battery: a population-based study’ also concluded that there is no correlation between the lunar cycle and incidence of crime.

Varinder S. Parmar et al. (2014) did a study using three different definitions of a full moon. The result was different in different definitions of a full moon. Therefore, they quoted that the different definitions of “full moon” may relate to the discrepancies in the findings of full moon studies. There is a need for standardization of the definition of the “full moon” for future research.

Mayank Gupta et al. (2015) studied homicidal and suicidal deaths and their correlation with the lunar cycle. The study reveals a rise in incidences of homicide and suicide during the full moon but is statistically insignificant.

**Material and Method**

The cases in the present study were selected from the dead bodies brought into the mortuary of the department of Forensic Medicine, Institute of Medical Sciences, BHU for medico-legal postmortem examination from the various police stations of Varanasi. The total duration of the study was 18.5 months (1st January 2013 to 17th July 2014). A total of 2819 cases were taken in this study, which includes deaths by suicide, homicide, and accidents.

The history regarding the circumstances of the unnatural death and other relevant data were collected from the following source:

1. The papers sent by police for the medico-legal autopsy:
   a. Inquest report,
   b. Copy of the first information report (F.I.R.),
   c. Death certificate if hospital death is there,
   d. Suicidal notes/other relevant reports, etc.
   e. Hospital records/reports if available, etc.

2. From the post-mortem register maintained by our department

The compiled data were studied and analyzed statistically by employing the ‘one-way parametric ANOVA’ and the results of the analysis have been presented in various tables that were discussed and concluded.

**Observations and results**

The study includes 2819 cases and it aims to deduce the correlation between unnatural deaths in different age groups and the lunar cycle. The cases were categorized in the different age groups, i.e. 0-12 years, 13-20 years, 21-40 years, 41-60 years, 60 years onward.

The lunar cycle has been divided into three categories:

1. Full moon days (includes 2 days before and after the full moon event)
2. New moon days (includes 2 days before and after
the no/new moon event)

3. Rest of the days (i.e. excluding 1 and 2)

A total of 19 events of full moon and new moon each occurred during 18 and half months of the study. It was observed that out of the 2819 cases, the age group affected most was between 21-40 years (52.4%) followed by the age group 41-60 years (23.1%) and 13-20 years (13.7%). The extreme of ages, i.e. below 12 years and above 60 years contributes 3.7% and 7.1% respectively to unnatural deaths.

**Table - 1** indicates the rate of incidence of unnatural deaths over the different phases of the lunar cycle. It is observed that the rate is found to be in the following order:

- Full moon days (5.22) > overall rate (5.02) > new moon days (4.98) and the rest of the days (4.98).

The rise in incidences during the full moon days over the others is statistically insignificant as indicated by the P-value (0.712).

**Table - 2** indicates the rate of incidence of unnatural deaths of the children below the age of 12 years over the different phases of the lunar cycle. It is observed that the rate is found to be in the following order:

- Rest of the days (6.42) > overall rate (6.12) > full moon days (5.93) > new moon days (5.50).

The rise in incidences during the rest of the day over the others is statistically insignificant as indicated by the P-value (0.267).

**Table - 3** indicates the rate of incidence of unnatural deaths of the children between the ages of 13-20 years (i.e. adolescent age group) over the different phases of the lunar cycle. It is observed that the rate is found to be in the following order:

- Full moon days (6.27) >> overall rate (5.85) > new moon days (5.84) > rest of the days (5.67).

The rise in incidences during the full moon days over the others is statistically insignificant as indicated by the P-value (0.516).

**Table - 4** indicates the rate of incidence of unnatural deaths in the age group between 21-40 years over the different phases of the lunar cycle. It is observed that the rate is found to be in the following order:

- Full moon days (5.58) > overall rate (5.36) > rest of the days (5.33) > new moon days (5.25).

The rise in incidences during the full moon days over the others is statistically insignificant as indicated by the P-value (0.630).

**Table - 5** indicates the rate of incidence of unnatural deaths in the age group between 41-60 years over the different phases of the lunar cycle. It is observed that the rate is found to be in the following order:

- The full moon days (5.84) > rest of the days (5.71) > overall rate (5.70) new moon days (5.55).

The rise in incidences during the full moon days over the others is statistically insignificant as indicated by the P-value (0.796).

**Table - 6** indicates the rate of incidence of unnatural deaths in the age group above 60 years (i.e. geriatric age group) over the different phases of the lunar cycle. It is observed that the rate is found to be in the following order:

- New moon days (6.56) > full moon days (6.33) > overall rate (6.03) > rest of the days (5.82).

The rise in incidences during the full moon days over the others is statistically insignificant as indicated by the P-value (0.329).

Discussion

To start with the hypothesis, the incidence of unnatural death increases in and around full moon days or new moon days or both. To prove this hypothesis, we compared the ‘mean’ of unnatural deaths overall and also those occurring in different age groups to the lunar cycle.

The overall distribution of victims of unnatural death

When we compared the overall ‘mean’ of unnatural deaths in different phases of the lunar cycle, namely the full moon period, new moon period, and the rest of the day. It is found that there is a rise in the mean incidence of unnatural deaths in the full moon period over the new moon period and also the rest of days.

Jay Karan et al (2010) in their study in Surat, Gujarat reported that there was no significant difference in crime events on full moon days and non-full moon days when compared by the Chi-Square test (p = 0.07). Except on Wednesday, no difference was observed between full moon day and corresponding non-full moon day of the week^{5}.

Joseph A. Schafer et al (2010) using police, astronomy, and weather data from a major southwestern American city, reported that there is no correlation between lunar cycles and rates of reported crime^{6}.

Oderda GM, Klein-Schwartz W (1983) found that a larger proportion of total calls to the center, and unintentional poisoning calls occurred during the full moon period. A significantly higher number of unintentional poisonings occurred during the full moon period^{11}.

The age-wise distribution of victims of unnatural death

Out of 2819 studied cases, the largest number of victims of unnatural death belonged to 21-40 years of age group which constituted more than half of the total victims (52.4%) followed by 23.1% in 41-60 years age group. The study also revealed that the extreme age groups, i.e. up to twelve years (i.e. pediatric age group) and sixty years and above (i.e. geriatric age group) were found to be minimal 3.7% and 7.1% respectively as the victims of unnatural death. The high mortality in the age group of 21-40 years can be due to more outdoor activities, the use of high-speed automobiles, also the adventurous nature of the people of this age group. Also, these victims were found bearing most socially active life and responsibility, so they are much exposed to accidents, rivalry, betrayal, stress, and business/property disputes resulting in higher deaths.

When we compared the ‘mean’ of unnatural deaths during different phases of the lunar cycle in the different age groups separately, it is found that except for the
extremes of ages (i.e. pediatric and geriatric age groups as mentioned), all the other age groups show a rise in the mean incidence of unnatural deaths in the full moon period over new moon period and also the rest of days.

The pediatric age group shows fall during the full moon and new moon periods as compared to the rest of the day. While in the geriatric age group, the rise is in new moon days.

The study shows that this rise in mean value during different phases of the lunar cycle is not consistent in all age groups. It is also found that none of these rises in mean value has got any statistical significance.

Oderda GM, Klein-Schwartz W (1983) found that different phases of the moon had no effect with regard to the victim’s age or sex or treatment location.\(^\text{11}\)

When we compared the ‘mean’ of unnatural deaths during different phases of the lunar cycle in the gender groups separately, it is found that there is a rise in the mean incidence of unnatural deaths in the full moon period over new moon period and also rest of the days in both male and female groups.

The study shows that this rise in mean value during different phases of the lunar cycle, which although is consistent in both the groups, it is also found that none of these rises in mean value has got any statistical significance.

Oderda GM, Klein-Schwartz W (1983) found that different phases of the moon had no effect with regard to the victim’s age or sex or treatment location.\(^\text{11}\)

**Conclusion**

The present study is done over 2819 victims of unnatural deaths, the majority of the victims belonged to 21-40 years of age group (52.4%) and the rise in the unnatural deaths during a particular phase of the lunar cycle among different age groups is not consistent. It is also seen that there is an overall rise in the unnatural deaths in the ‘full moon period’ as compared to the other parts of the lunar cycle. Since no rise in the different parameters separately or overall is found to be statistically significant, the study finally concluded that there might be a correlation between unnatural death and the lunar cycle, but there is no association between them in our preliminary study.

In this study, we considered new moon days along with full moon days, which is not the case with many other studies. Also, we took two days back and forth of the new moon and full moon days, which is again the strength of our study. Although this study is not conclusive, further studies can be carried out in two different ways. Firstly, taking one parameter at a time might throw some more light on the association. Secondly, by including the cases in which incidence doesn’t lead to death as well. This may lead to more specific results, and if any, positive association is found, it will be very beneficial to take the necessary steps to bring it down.

Abstract

The healthcare sector has a vision of providing the best medical facilities to their patients leading to better health care and minimum of medical errors. The healthcare sector tries to provide the patients access to high quality medical devices, safe and security, effective technology and safe products for their health. Increasing complexity of medical technology and consequences for training and outcome of care. The healthcare sector has created a safe sense of services with enhanced and swift technology which is patient reported outcomes to help the patients rate the quality and working of the hospitals to get a clearer picture. This is possible only with the help of technology and this research paper is a primary data based exploration where techology is in the centre.

Key Words: Health care, Technology, Safe services and outcomes.

Introduction

In the era of technology all industries are opting for technology for development and innovation in their field. Technology in today’s World is being adopted by every industry and is playing an important role in industries and in our lives¹. Like all the industries we can see that technology is taking over the healthcare sector focusing on saving lives. In the field of medical sciences, technological innovations in medical devices are taking place all around the World². Medical technology has a vast field of innovation that is innovation in sustaining lives. The technology innovation can be seen in the areas like biotechnology, Information technology, pharmaceuticals and development of medical devices and equipment’s³. The growth in innovations in healthcare sector can be seen from small innovation of bandages and ankle braces to complex innovations like MRI machines, artificial organs, etc. The innovation in the medical devices has focused on integrating innovations into medicines. The innovation in medical devices with integration of telehealth has also lead to robotic surgeries which focuses on helping doctors to do surgeries with the help of robotics sometimes even without their physical presence⁴. Thus technology is trying to work easy and save more and more life. Medical technology is innovating with intensive growth and research in the area the technology has introduced new equipment’s to hospitals making their work easy and complex surgeries successful, not only this technology in healthcare sector has connected thousands of patients and doctors from all around the world. Increasing complexity of medical technology and consequences for training and outcome of care⁵.

Study conducted by Yan Wei, Hao Yu, Zude Guo, on the topic “Hospital efficiency and utilization of high-end technology medical equipment”. In this paper the researcher focused on the relationship between the hospital environmental characteristics and their utilization of high-tech medical equipment⁶. The research focused on the cost and quality of the medical devices used and efficiency of the hospitals in adopting the devices. The researcher found that the use of Computed Tomography(CT) and Magnetic resonance imaging(MRI) in hospitals have increased with hospital cost inefficiency⁷. The researcher aimed to understand the adoption of new medical devices by hospitals and their cost controlling activities in hospitals. The study found out that the relationship between quality improvement of
devices and cost control is very complex due to high cost of technology adoption. The research found out that the hospitals do a comparison to check the benefits with the cost of using high end devices. The main reason of using these devices are quality improvement and increase in income.

Study conducted by Bupe. G. Mwana, Charles Mbohwa on the topic “An assessment of the effectiveness of equipment maintenance practices in public hospitals”. In the research the researcher has found that the use of medical devices is increasing around the World and so are the complexities with the use of the devices. The aim of the study was to analyze the practices adopted in hospitals to maintain the medical devices to reduce the errors happening due to mishandling of the devices. The study conducted found out the maintenance strategies and challenges faced in the maintenance. The study by the researchers found out that devices failure and unavailability of the devices was high due to faulty schedules for devices, high breakdown in the devices was seen due to shortage of skilled manpower. The shortage of skilled manpower affected the service provided to the patients and lead to poor maintenance of the medical devices, not only the shortage of employees the improper training of the employees leads to mishandling of the devices and causes injuries to the patients. The error usually occurs due to lack of staff training and due to non-maintenance of a proper team to look after the maintenance and repairing of the medical devices. The researcher says that the staffs are not trained about the complexities of the devices that are updated timely.

Research Methodology

The data is collected with the help of structured questionnaire. The data is analyzed with help of the statistical software known as SPSS which has used various statistical methods for the analyzing of the data which will be represented with the help of graphs, charts etc. The analysis of the questionnaire on the topic “Role of high technology medical devices and its uses in patient care: Study in reference to Delhi & NCR Hospitals” where sample size was 201.

Hypothesis Testing for the Study

Hypothesis has been formulated on the basis of objectives framed for the study. Since study is moving around the uses of technology in health care industry. Formulated hypothesis is being testing with the help of t-test analysis has been used, data is normally distributed which indicating that, t-test could be applied.

**H0** – There is no significance relation between, carelessness of nurses causing medical errors and untrained professionals using high end technology causes medical error.

**H1**- There is significance relation between, carelessness of nurses causing medical errors and untrained professionals using high end technology causes medical error.

### Table -1 Paired Sample correlation

</tr>
</tbody>
</table>

After analyzing data with SPSS, calculated value of p= .000, since standard value is 0.05. Thus calculated value is less than the standard value. So the researcher fails to accept the null hypothesis i.e. there is significance relation between, carelessness of nurses causing medical errors and untrained professionals using high end technology causes medical error. Which means that carelessness of are due to untrained staff or nurses that uses high technological medical devices and these untrained staff due to carelessness causing medical errors.

**H0** – There is no significance relation between, the use of clinical information to improve patient safety and technological devices that increases patient safety.

**H1**- There is significance relation between, the use of clinical information to improve patient safety and technological devices that increases patient safety.

After analyzing data with SPSS, calculated value of p= .006, since standard value is 0.05. Thus calculated value is less than the standard value. So the researcher fails to accept the null hypothesis i.e. there is significance relation between, the use of clinical information to improve patient safety and technological devices that increases patient safety. Which means that clinical information system is used for improvement of patient safety and this device increases patient safety in hospitals. Thus clinical information system proves to be a technology that is successful in patient safety thus reducing medical errors.

With the increase in technological devices in healthcare sector it is very important for the staff to understand the complexities and working of the devices. The technology in healthcare sector is innovating every year which has made training a very crucial part of proper implementation of the devices as these devices are not only using high tech mechanisms they are also becoming more and more complex which requires timely training for better safety and quality which will reduce medical errors. The implementing cost of high end technological medical devices are very high as agreed by the respondents on the question, that, whether cost of implementing high technological medical devices are high. The dependence of healthcare sector in technology is increasing with time and this has led to new innovations of devices and has focused for on saving lives by providing better diagnosis, better surgical procedures and improvement in the health of patients.

The devices focus on saving lives and making healthcare a safe sector.

The respondents believe that high technological medical devices increase patient safety as 86.1 percent of respondents agree that devices has turned out to be safer and has particular standards that maintain patient safety at each level. The devices though complex help the healthcare sector in better quality and safety. Medical devices also help in reducing medical errors as agreed by the respondents as 86.6 percent agree that high end technological medical devices are successful in reducing medical errors. Though successful implementation of the devices depends on the staff i.e. then trained staff as agreed by 80.1 percent that is 161 respondents out of 201 agree that if staff is trained the implementation of the devices would be done rightly reducing medical errors.

Suggestions for the study

· Timely training should be given to the staff in healthcare regarding working of the devices

· The implementation of the devices should be on the basis of environment

· Regular maintenance and repairing of the devices to be done to reduce medical errors
Safety standards should be followed by all the hospitals and a standard format for all should be used.

Internal and external audits should be conducted in the sector to keep a check on the machines.

Devices should be up to dated according to international standards.

Only technical staff should be allowed to use the high technological medical devices.

The training should be done in a specified framework with goals set prior to the training of the staff so that the staff is accountable for themselves.

Authors Declaration

Conflict of interest – This is to declare that all of us are authors of the following manuscript titled “Role of high technology medical devices and its uses in patient care” and we hereby agree to the following:

1. All of us the authors have read the manuscript and take responsibility for its contents.

2. We have taken special care towards the language and grammar of the article and certify it is correct to the best of our knowledge.

3. We have no conflict of interest.

4. Similarity index is less than 10 percent.

Online Classes during COVID-19 Pandemic: Anxiety, Stress & Depression among University Students

Mridul1, Bandana Bisht2, Dhariti Sharma3, Navdeep Kaur4

1Tutor, 2Professor, 3Tutor, 4Associate Professor, Chitkara University College of Nursing, Chitkara University, Himachal Pradesh, India

Abstract

COVID-19 pandemic has not only put people at risk of developing physical illness but also face mental distress. This pandemic disease is impacting almost every sector of economy as well as Indian education sector that includes school, colleges and institutes. As everything is virtual with no physical movement most of the mental health illnesses were triggered rapidly such as Depression, Anxiety and Stress. A cross-sectional descriptive study design was done to assess the level of Depression, Anxiety and Stress in grad students who were undergoing online classes and the population for research study was all students studying in bachelors’ program of universities. The sample size was 159 students and the tool used for the research study was DASS 21. The researcher concluded that majority of students experienced moderate Depression 27(16.98%), Anxiety 27 (16.98%) and stress 23 (14.46%) due to online classes.

Keywords: Online classes, COVID-19 Pandemic, Depression, Anxiety, Stress.

Introduction

COVID-19 pandemic has not only put people at risk of developing physical illness but also face mental distress.1 Due to current COVID-19 pandemic, life of the people had taken upside down. It has made a huge change in daily routine, life style, eating habits and sleeping pattern of everyone. The new normal education world is learning from home with minimal physical stimulation.2

The students are under the constant fear of contracting the virus or loosing their loved ones due to this deadly virus. The fear of this pandemic disease is increasing day by day which leads to harmful effects both at the individual level and societal level.3

To combat with COVID-19 a stress management guide, “Doing what matter in time Stress “is given by WHO. This kit contains self-help technique to combat stress. Many states and educational institutions are coming up with tele counseling for mental health services. Still increased cases of Depression, Anxiety and Stress are being reported from various part of the world. Deterioration in mental health may lead to other life-threatening diseases.4

COVID-19 is impacting almost every sector of economy as well as Indian education sector that includes school, colleges and institutes. As everything is virtual with no physical movement and academic stress have led to many most of the mental health disorders. Almost every work is put on hold due to this pandemic disease.5 The large scale industries were closed which drastically affect the economy and all the institutions were closed due to which students all over the world were worried regarding examinations, their future. The teachers are trying their level best to teach students as online classes were conducted on regular basis for the students.6 These online classes lead to various psychological consequences in students.7

To assess these psychological consequences, a study was conducted using a standardized tool DASS 21 which was developed by Lovibond and Lovibond.8 This tool consists of 21 questions to assess Depression, Anxiety and Stress.9 The symptoms of depression are characterized by low self esteem, hopelessness, lack of positive attitude, lack of interest in life, social isolation, sadness, insomnia, feeling of guilt and disturbed...
Anxiety usually occurs with depression. It is a state of fear, apprehension, subjective feeling of anxious affect with autonomic arousal and skeletal muscle tension. Stress is a feeling of emotional, physical tension. The person also experiences irritability, restlessness, impatience.

As there is a complete change in education system, family dynamics and the social life during lockdown students are experiencing various psychological problems. So the prevalence of Depression, anxiety and stress is more among students. The various demographic variables also have great impact on Depression, anxiety and stress level of students. Therefore, the researcher conducted a cross sectional study with the aim to find stress, anxiety and depression in university students who are attended classes online. Also, association between demographic variables and presence of mental health issues was assessed.

**Methodology:**

**Research Design:** A cross-sectional descriptive study design was chosen. 159 students who were attending online classes and willing to participate in study were selected using purposive and snow ball sampling. Informed consent was taken from the study participants to assure anonymity and confidentiality of data. Data was collected using a standardized tool DASS 21. This tool is four-point rating scale which consists 21 items to assess depression, anxiety and stress separately with minimum score of 0 and maximum score of 163. Higher the score in each category and more will be level of ailments such no, mild, moderate, severe and extremely severe. Data was collected from participants from 9/07/20 to 15/07/20. Researcher collects the email id of the students of different streams. Google forms were used to collect the information from students. Google form consists of consent form and structured questionnaire. This form was sent to students and they were asked to circulate the form in their contacts. The students were asked to revert back within a week. Collected data was checked for completeness and analysis was done using SPSS latest version 25.

Figure 1 Level of Depression among college students undergoing online classes during lockdown
The above bar graph shows that majority of students 79 (49.68%) were normal, 16 (10.06%) had mild depression, 27 (16.98%) had experienced moderate depression, 22 (13.83%) had severe depression, 15 (9.43%) were under extremely severe depression.

![No. of College Students](image)

**Figure 2 Level of Anxiety among college students undergoing online classes during lockdown**

Above pie chart shows that majority of students 69 (43.39%) were normal, 20 (12.57%) students had mild anxiety, 27 (16.98%) students experienced moderate anxiety, few students 13 (8.17%) had severe anxiety, 30 (18.86%) students experienced extremely severe anxiety.

![No. of College Students](image)

**Figure 3 Level of Stress among college students undergoing online classes during lockdown**

Above bar graph shows that majority of students 100 (62.89%) were normal, 14 (8.80%) students experienced mild stress, 23 (14.46%) students were under moderate stress, 15 (9.43%) students had severe stress, minority of students 7 (4.40%) experienced extremely severe stress.
Conclusion

This study concluded that online learning has a great impact on mental health of university students and causing stress, depression and anxiety of various levels. Majority of students experienced moderate Depression 27(16.98%), Anxiety 27 (16.98%) and Stress 23 (14.46%) during online classes. More research is needed to find best possible coping strategies to assure mental health and to find out innovative yet effective ways of learning.

Abstract

Stress is based on the physical, mental, or emotional reaction to events which cause tension in the body or mind. Different types of diseases affect the human body, some of which may have an unknown etiology. It is one such etiology that predisposes many diseases. Dentists often come across patients in their everyday practice showing signs of stress and about their oral manifestations in the form of recurrent aphthous ulcer, oral lichen planus, and temporomandibular disorders, xerostomia, burning mouth syndrome, bruxism, periodontal disease, dental caries. Identification of such an emotional or psychological disorder stands to benefit both the patient and the practitioner. Consequently, psychological management should be considered when treating patients with any of these psychosomatic disorders. This review literature discussed common oral manifestation of stress.

Keywords: Stress, psychosomatic, anxiety, depression

Introduction

Anxiety and depression are among the psychological disorders that are most prevalent. Such diseases can cause physical and physiological changes in the body, no exception being the oral cavity. Oral diseases involving psychosomatic etiology have been known in medicine for a long time but until now these psychosomatic etiology have not been verified. Since oral mucosa is highly sensitive to emotional factors such as stress, depression and anxiety; oral diseases may occur as a direct emotional experience or as an indirect consequence of psychological changes.1,2 Stress is characterized as an emotional, physically or mentally reaction to the situation that trigger physical or mental stress.3 Oral disease including psychosomatic etiology has long been recognized in medicine and behavioural or emotional factors can serve as a risk factor that can affect oromucosal disease initiation and progression.4,5 Some of the common oral manifestation are given below.

Recurrent Aphthous ulcer

The function of stress that causes in episodes of Recurrent Aphthous Stomatitis (RAS) is still unknown. Acute psychological conditions are typically believed to play a role in the production of repeated aphthous ulcers. Stress may also cause bite of the cheek or lip, or exacerbate actions which cause damage to the oral mucosa. Stressful conditions are expected to induce a temporary rise in salivary cortisol and immune regulation activities in inflammation through raising leukocyte quantities and activity.6 The lack of a clear correlation between stress level and frequency of RAS episodes indicates that psychological stress can serve as a cause or catalyst instead of an etiological factor in susceptible patients with RAS.7

Burning mouth syndrome (BMS)

Depression, anxiety, personal oral dryness, age, prescription, taste disturbances, intake of L-thyroxines, disease and enhanced BMS-associated salivary flow rate, according to study.8 Burning mouth syndrome is related to burning tongue, lips and other mucosal surfaces. Post-menopausal symptoms were assessed significantly by burning throughout the patient’s mouth. Sleep disturbances occurred frequent in patients suffering from burning mouth syndrome. Treatment can be given after finding specific etiological factors for every individual patient including symptomatic relief and management of any related behavioural or psychological disorders.9
Lichen planus (OLP)

Research on the etiopathogenesis of many somatic diseases indicate control of several factors that have additive action, including psychological and social ones. Depending on this, lichen planus is regarded as a psychosomatic disorder, the etiopathogenesis of which is not yet completely understood. The mental and emotional profile of OLP patients was evaluated and the incidence of stress and anxiety was often correlated with an exacerbation of oral lichen planus lesions.\(^5\) It was therefore, also suggested that OLP can be understood as a psychosomatic condition. Study reported a significant correlation between stress and OLP. In addition, the study evaluated a group of patients with anxiety and found a statistically significant higher prevalence of oral lichen planus.\(^10,11,12\)

Xerostomia

Dry mouth syndrome, also known as xerostomia, is an unexplained saliva decrease and may be common in patients with psychological disabilities. Mouth-dryness influences the quality of life.\(^3\) For young adults, the factors are typically associated with stress, anxiety, depression and deficits for nutrition. Consumption of alcohol including the use of illicit drugs can both be significant contributors to dry mouth etiopathogenesis.\(^13,14\) The frequency of reduced secretions of the salivary gland differs in the general population.\(^8\) Overall, xerostomia is more prevalent in females than in males.\(^15\) Secretion of saliva may be influenced by numerous factors like stress, anxiety and depression, age, prior care or cancer radiotherapy, medicines and other factors.\(^16-20\)

Periodontal disease

stress can also have an adverse impact on periodontal tissues. Gum issues are more common in individuals with mild stress.\(^21\) Among other research it was found that along with behavioural and physiological processes stress and depression can be associated with periodontal destruction. In addition, avoidance of dental hygiene during times of stress and depression was related to the loss of periodontal tissues attachment and loss of teeth.\(^22-24\) During World War I, necrotising ulcerative gingivitis has been classically seen from military personnel, possibly due to several risk factors including poor oral hygiene, extreme psychological stress and malnutrition.\(^25\)

Dental caries

Weakens the immune system and reduces stress tolerance to cariogenic bacteria\(^26\) by serum increase, salivary catecholamines and also corticosteroids. The body’s cortisol level is increased throughout stress trying to produce acid that could be determined by litmus testing on the tongue creating a suitable bacterial environment. One research found that children either with or without dental caries differs greatly significantly in urinary catecholamine mean values.\(^27,2\) Reducing salivary secretion resulting in decreased removal of cariogenic bacteria-Subjective oral dryness with unstimulated salivary flow have been significantly correlated with psychological stress \(^28,29,3.\) By serious psychological eating habits that contribute to numerous snacks and more dietary intakes of sugar.\(^4\) By impaired self-care practices (oral hygiene) resulting in poor oral hygiene providing a favourable atmosphere for bacteria.\(^30,31\)

Bruxism

The psychological function is associated with depression, anxiety and mental stress, that perform an important role in the occurrence and perpetuation of bruxism, its severity and frequency. Study found a relationship with anxiety and with signs of depression and symptoms in bruxers. Depressed, nervous, and emotionally stressed individuals are often known to be more predisposed to develop bruxism, particularly during sleep, as a reaction to everyday emotional stress release.\(^32-36\)

Temperomandibular disorder (TMD)

The actual cause of TMD is unclear but is considered multifactorial.\(^8\) Various TMD etiological factors reported in medical literature include psychological factors such as personality traits and behaviour, occlusal differences, inadequate dental care, joint laxity, chronic joint micro damage, overloading / overuse of joint structures, and parafunctional habit. The psychological, physiological, social and emotional problems are also taken into count. Psychosocial factors are most often associated with TMD patients, among various etiological factors of TMD. TMD patients encountered stressful living circumstances before TMD symptoms developed.\(^37-39\)
**Myofascial Pain Disorder**

Schwartz is the first one to include the patient’s psychological structure as a predisposing factor for the condition of myofascial pain disorder (MPDS). According to him, stress was a leading cause of clenching and grinding activities leading to spasms of mastication muscles. Myofascial pain, according to Travell and Simons, stems from trigger points, which are isolated focal hyperirritable spots throughout the taut bands including its skeletal muscles. A research found that long-term musculoskeletal pain conditions affect about 10 per cent of the United States of America’s population. One such musculoskeletal disorder is syndrome of myofascial pain. As Simon and Backstrom have described, stress is characterized as the reaction of the human body to something like a demand imposed upon it, which would lead to negative effect on the body such as MPDS.40-43

**Conclusion**

Patients that shows sign of stress and their oral manifestations in the form of xerostomia, dental caries, periodontal problem, BMS, RAS, OLP, TMD and MPDS frequently come across through their regular practice dentists. Identification of such emotional and psychological illness helps the patient as well as the clinician. Consequently, psychological treatment should be addressed when treating patients with such psychosomatic disorders. Dentists often meet patients with psychosomatic disorders in their everyday practice, patients with emotional disorders often experience oral signs and knowledge of these emotional disorders helps both the patient and the clinician.

Parental Perception on the Effect of Various Factors in a Dental Clinic Affecting Child’s Behaviour

Neethu Ann Preethy¹, Deepa Gurunathan²
¹Postgraduate Student, ²Reader, Department of Paediatric Dentistry, Saveetha Dental College and Hospitals, Saveetha Institute of Medical and Technical Sciences, Chennai-, Tamil Nadu, India

Abstract

Background: Societal, professional views and parenting styles have evolved tremendously over the years. Thus, it is important to understand the parental perceptions on the various factors influencing child behaviour in the dental clinic.

Aim: To record and evaluate the parent’s views regarding the various factors that influence child behaviour in a dental clinic.

Materials and methods: A cross sectional study was conducted among 164 parents who were asked to complete a close-ended questionnaire divided into 4 categories- dentist, dental clinical settings, dental treatments and child related factors. This data was analyzed using descriptive statistics.

Results: According to the study results, the parents perceived that the dental treatments and dental settings played a significant role (p< 0.05) that affected the child’s behaviour in a dental clinic. There was no significant differences between the “yes” and “no” responses for the dentist and child related factors.

Conclusion: The parental attitudes and styles are constantly changing as the society evolves. Thus it is important to understand and reassess their beliefs and update our way of managing the dental setup and treatments regularly.

Keywords: child, behaviour, dental care, parent, perception

Introduction

Dental fear prevails to be a major source of problem while managing and treating children in the dental setup. While adult patients tend to develop their own anxiety coping strategies throughout the years, this task often becomes the responsibility of the dentist in pediatric dentistry. The origin of dental fear and uncooperative behaviour of children and proper understanding of it may aid in helping the pediatric dentists to plan and adopt appropriate behaviour management strategies.

Dental fear and behaviour have a multi-factorial origin broadly divided into personal characteristics, environmental factors, or situational factors. Dentists recommend various behaviour guidance methods based upon the child’s health, special health care needs, dental needs, type of treatment required, consequences of no treatment, emotional and intellectual development, parents’ preferences, dentist’s preferences and skills.

The impact of dental atmosphere on child is a major aspect. Every child is considered unique and a major aspect of behaviour management deals with understanding parental perceptions and determining factors that influence child’s behaviour. Over the years, there has been a changing trend in the parenting styles, and societal and professional perceptions. Dentistry always aims to place emphasis on the human aspect of
Thus, it is important to understand the parental perceptions which will present an opportunity to work together and select the best method to provide a safe, effective and comfortable dental visit. Studies related to environmental factors are few and most of the studies were conducted in European and South-East Asian regions. Environmental and situational factors have been previously studied as potential causes of dental fear and behavioural problems but such results have been found to be inconsistent. Hence, the aim of this study was to understand parents’ perception regarding the factors that influence child’s behaviour in a dental setup in Chennai, India.

**Materials and Methods**

The present study was a cross-sectional study conducted in the Department of Paediatric Dentistry, Saveetha Dental College and Hospitals. The study design was reviewed and approved by the Institutional Review Board (SDC/PEDO-1704/19/014).

**Participant selection:**

A total of 170 parents who visited the Department of Pediatric Dentistry for their child’s dental treatment were included. Amongst that 164 parents agreed to participate in the study. The parents of children who required special needs or have associated systemic conditions were excluded. Thus, parents of children with normal developmental milestones and with at least one prior dental visit were included in the study.

A validated questionnaire was provided to the parents and asked to complete within treatment hours. The questionnaire comprised of 16 close ended questions divided into 4 categories: dentist, dental setting, dental treatment and child related factors.

**Statistical Analysis**

Based on the information collected, responses were recorded, processed and a descriptive analysis was followed.

**Results**

The results of 164 participants were tabulated and analyzed accordingly. The majority of the parents who brought their child for dental treatment belonged to the age range of 31-40 years (52%) and the least belonged to 41-50 years (17%) with a distribution of 43% males and 57% females (Table 1).

The major reason for bringing the child for dental visit (Table 2) was pain (40%) followed by decay (24%), routine check-up (15%), trauma (11%) and other reasons (10%). According to responses recorded from parents in terms of yes or no (Table 3), the probabilities of the t-test for the four parameters under evaluation were dentist (p=0.0989), dental settings (p=0.0187), dental treatment (p=0.00018), and child related factors (p=0.17809).

According to the results, the parent’s perception in respect to two parameters such as dentists and child factors, there was no significant difference noted between the two responses [Yes or No] (p> 0.05), whereas there was a significant difference noted for the factors: dental settings and dental treatment (p<0.05).
Discussion

Getting to understand and learn about parents’ perceptions regarding various factors in dental clinic and thereby making the parent understand about the influence of various factors in dental clinic play a major role in establishing a positive dental outcome [12].

As per the study results, 62% of parents agreed that the attitude, attire and gender of the dentist affect the child’s behaviour in dental clinic. Amongst that, dentist’s attitude (70%) and dentist attire (60%) were believed to play a role in child behaviour. There was no major difference in the results when the gender of the dentist was taken into criteria. Thus, to gain the trust of the children and parent, the dentist’s attitude, body language, and communication skills play a crucial role in creating a positive dental experience for the child and parent [13].

Over the years, there has been a concern that the white coat and professional clothing worn by the dentist can increase anxiety in the children. The protective mask may also act as a stressor for the child and thus it is recommended to introduce the child to the dental environment without the mask [14]. It was found that 58% of parents preferred non-white coat attires and formal attires among dentists [15, 16]. In a study conducted in India, it was noted that children preferred their dentists to wear dental scrubs and white coat but were highly anxious on seeing their dentist with any protective wear [17].

American Academy of Pediatric Dentistry (AAPD) describes that the orientation of dental environment and atmosphere play an important role influencing the child’s behaviour in dental clinic [13]. According to the present study, friendliness of staff and pleasantness of the dental set up such as colour, decoration etc. affects the child’s behaviour according to 70% and 71% of parents respectively. Thus a cumulative of 70.5% parents agreed that the dental settings in general played a crucial role in child’s behaviour in dental clinic. The results are in accordance with another study which exhibited the effects of the atmosphere and dental settings on the child’s behaviour and emotions [18]. The children exhibited positive emotions towards bright colours (e.g., pink, blue) and negative emotions towards dark colours (e.g. black, brown) [19]. Thus the use of child friendly colours like blue and yellow enhances a positive dental attitude in the child’s mind [20].

Dental healthcare environment is getting more competitive everyday and patients are more demanding than before [21]. The results show that the dentists should pay attention to the dental settings in addition to focussing on the treatment which in turn will motivate the children to undergo the dental procedure in a well behaved manner [5].

According to our study results, 69% of parents agreed that the dental treatment has an effect on the child’s behaviour. Amongst that, 73% agreed that the treatment duration affects the child’s behaviour, which is similar to previous studies [5, 22]. The dental instrument’s sound and noise influence the child’s behaviour according to 79% of parents and the type of dental procedure was believed to have some effect on the child according to 74% parents. In a similar study, 77% of parents agreed that the type of procedures, such as drilling/ restoration and the sight of instruments cause fear and anxiety in the child; however, it is known that procedures like injection may produce a high level of anxiety [23].

63% of parents agreed that the presence of parents during treatment might influence the behaviour of the child. However, a study stated that the presence/absence of parents did not have any effect on the child’s behaviour [24]. When the timing of the dental appointment was taken into criteria, 56% of the parents in our study felt that early morning or afternoon dental appointments had some impact on the child’s behaviour. Early morning appointments are preferable for young children as they are more rested and thus cooperative. The children may become tired or cranky from missing nap during afternoons or later periods of the day [25]. However according to a study by Lechner, timing of the day of the dental appointment had no significant effect on child’s behaviour [26]. Thus, it can be stated that time scheduling for dental appointment should be more dependent on convenience than possible behaviour effect based scheduling [27].

49% of parents in our study stated that the child related factors such as age, gender, previous dental experience and diet of a child including the previous dental experience of the child’s sibling had an influence on the child’s behaviour. A longitudinal behavioural
study stated that the child undergoing dental care was directly influenced by the psychomotor development of the child [28]. 59% of parents agreed that previous dental experience of the child might have influenced the child’s cooperation towards the dental treatment. It is said that a previous traumatic experience in a dental clinic or during hospitalization for any other reason can also provoke anxiety and fear in the child [29, 30].

Previous dental experience of the child’s sibling and the gender of the child were considered to impact the child’s behaviour according to 50% and 48% of the parents in this study. One study stated that girls are more willing to visit the dentist and cooperate compared to boys of the same age [23]. The diet consumed by the child is believed to affect the child’s behaviour according to 37% of parents in the current study. Diet is proven to affect the cognitive ability and behaviour of children and adolescents [31].

This study is the first of its kind carried out in India for the evaluation of parental perception about various factors affecting the child’s behaviour in a dental environment. One possible limitation of this study might be the small sample size. Thus, further research in a prospective intervention based method is required to ascertain whether understanding of parental perceptions can serve to be an effective tool in the prevention of child’s behavioural problems; and also study the changing trends in various countries.

Conclusion

Dental treatment and dental settings play a key role affecting the child’s behaviour according to the perception of the parents in our study. The success of any paediatric dental practice not only depends on the skills of the dentist but also depends on the patients and their parents. Thus gaining a positive dental experience from both the child and the parent is necessary. This relies on the understanding and constant updating of the changing parental styles and attitudes of the society.

Abstract

The epilepsy is a symptom complex of several disorders of brain function characterized by recurring seizures. Practically epilepsy is not a disease but a symptom that may lead to further mental diseases. It includes loss of consciousness, excess movement or loss of muscle tone or movement, disturbances of behaviour, mood, sensation, and perception. Only the patient experiences the Epileptic fits or seizures causing a “sensation” within him/her. Most important thing in the epilepsy first aid management we have to stay calm; most seizures last less than a few minutes. Help the person having the seizure from getting hurt by moving any nearby objects out of the way, as necessary. The research includes Quantitative approach and quasi experimental non-equivalent control group pretest-posttest design. Total 60 patient’s family members (30 in experimental group and 30 in comparison group) were recruited. Conveniently 1 hospital were selected and then the sample was chosen by convenience sampling technique. Tools in the study were selected variables, structured knowledge questionnaire and structured expressed practices scale. The mean post-test knowledge score of experimental group was higher (14.67) than the mean post test score of comparison group (9.77) which was found to be statistically significant (‘t’ = 2.21, p = 0.00**) at the 0.05 level of significance. The mean post-test expressed practices score of the experimental group was higher (91.87) than the mean post-test expressed practices score of comparison group (74.50), which was found to be statistically significant (‘t’ = 14.46, p =0.00**) at the 0.05 level of significance. No significant association was found among knowledge scores and expressed practices scores regarding first aid management of epilepsy among patient’s family members with selected variable. Video assisted teaching was effective to improve the knowledge and expressed practices regarding First aid management Epilepsy among patient’s family members as there was a significant difference between experimental and comparison group.

Key words: Video assisted teaching, Knowledge, Expressed Practices, Patient’s family members, First Aid, Epilepsy

Introduction

Chronic non-communicable illnesses are a major health care problem in evolving countries and neuropsychiatry disorders reason for more than a quarter of the global burden of disease. Mental sicknesses are major contributor to the universal drain of disease. From this, epilepsy is one of the most common and serious brain disorders in the world. It affects at least 50 million people in the world including Asian countries. The pervasiveness of active epilepsy in developing countries range from 5 to 10 per 1,000 people. The worldwide prevalence rate of epilepsy varies from 2.8 to 19.5 per
1,000 of the general population and is more prevalent among children. The estimated prevalence of epilepsy is 8–13 per 1,000 people.1

“Epilamabavian” means “to seize or to take hold of”. The term “epilepsy” is derived from such a Greek word. To the Greeks, epilepsy was a sacred disease; it was a disease of the brain. Later, it become known as “the falling sickness diseases condition”. Regardless of the insight gained into epilepsy, lack of knowledge, stigma and fear are still associated with this problem. People think epilepsy is a curse from god1

The epilepsy is a symptom complex of several disorders of brain function characterized by recurring seizures. Practically epilepsy is not a disease but a symptom that may lead to further mental diseases. It includes loss of consciousness, excess movement or loss of muscle tone or movement, disturbances of behaviour, mood, sensation, and perception.2 Only the patient experiences the Epileptic fits or seizures causing a “sensation” within him. Perception of a strange light, unpleasant thought, visual changes, unpleasant smell and auditory changes are some of those sensations. These sensations are subjective feelings commonly known as ‘Aura’. Strong emotions, intense exercise, music or flashing lights can be the cause for activating the seizure’s in few people.2

Inadequate knowledge regarding the treatment routine and first aid management of the epileptic fits has caused various injuries (loss of teeth, injuries to the head, fracture and dislocation) during the epileptic fits. Various practices have also been documented such as placing a key in the hand of the patient, administered liquid orally, applying pressure to restrain the body, putting some objects into the mouth to force the teeth open.

**Material and Method**

The is a quasi-experimental study was conducted during the period from October 2019 to January 2020 in Haryana, India. Total 60 patient’s were selected from Maharishi Markandeshwar Institute of medical Sciences and Research and Hospital OPD (Psychiatric department 30 in experimental and 30 in comparison group) by using convenience sampling technique. Video assisted teaching programme was provided to experimental group.

**Inclusion criteria**

Study included patient’s family members who were

- Available at the time of data collection
- Willing to participate in the study
- Who can understand Hindi

**Exclusion criteria**

The exclusion criteria excluded teachers who were:

- Not available at the time of data collection

**Phase I:** The investigator visited Psychiatric OPD all days from Monday to Saturday. A structured knowledge questionnaire and expressed practices scale was used for the data collection after obtaining informed written consent. The study participants were given Video Assisted Teaching Programme on first aid management of epilepsy. In this VATP, all the details like epilepsy, causes of epilepsy manifestations and role of family members in first aid management thought provoking video to educate them.

**Phase II:** 7 days after intervention period, the post test were conducted when family members comes along with patient’s again. Pre and Post test results were analysed using SPSS 20.

**Study tool and study variables:** Part A- Selected variables Details age, gender, qualification, marital status, treatment, religion, stay with patient, previous knowledge on first aid management for epilepsy. Part B- Structured knowledge questionnaire the investigator asses the knowledge by using Structured knowledge questionnaire. Part C Structured expressed practices scale the investigator asses the knowledge by using Structured expressed practices scale.

**Results**

**Distribution of the data based on** mean, mean difference, standard deviations of difference, standard error of mean difference and ‘t’ value of knowledge score of patient’s family members regarding First Aid Management of epilepsy before administration of VATP in experimental and comparison group. Table no. 1=
The mean knowledge score (9.40) of experimental group was lower than the mean knowledge score of (9.67) of comparison group with the mean difference of 0.26. The computed ‘t’ value (0.54) was found to be statistically non-significant at 0.05 level of significance which inferred that both the groups were homogenous in terms of knowledge at the baseline. Table no= 2 expressed practices before administration of VATP regarding First Aid Management of epilepsy in experimental and comparison group. The mean Expressed practice score (68.57) of experimental group was higher than the mean Expressed practice score (67.13) of comparison group with the mean difference of (1.43) the computed ‘t’ value (1.30) and (p=0.19) was found to be statistically non-significant at the level of 0.05 level of significance which inferred that both the groups were homogenous in terms of expressed practice at the baseline. Table no=3 in experimental group, there was statistically significant weak positive correlation between knowledge and expressed practice and was statistically significant at 0.05 level of significance, but in comparison group, there was no statistically significant correlation between knowledge and expressed practice.

Discussion

The present study aimed to evaluate the effectiveness of video assisted teaching on knowledge and expressed practices regarding first aid management of epilepsy among patient’s family members in selected Hospital of Ambala, Haryana. The total number of patient’s family members is 60. In present study, half of the family members (33%) belong to age group of less than 40 years. These findings are consistent with the study conducted by Howard Ring, James Howlett, Mark Pennington (2018) where they found that half aged 18–65 years with an ID and epilepsy under the care of a community ID team and had had at least one seizure in the 6 months before the trial.

Conclusion

The findings of the study results show that Video Assisted Teaching Programme (VATP) effective in increasing the knowledge and expressed practices among patient’s family members as there was a significant difference between the experimental and comparison group.

Variation in the Shapes of Coronoid Process of Dry Human Mandible of Gujarat Region

Nirali Chavda1, Priyanka Sharma2, Kinjal Jethva3, Kantilal Parmar4, Hetal Vaishanani 5, A.R.Gandotra6, G.V.Shah7

1Tutor, 2Assistant Professor, 3Associate Professor, Department of Anatomy, 4Associate Professor, Department of P Anatomy, 5Professor, 6HOD and Professor, Department of Anatomy, Smt.B.K.Shah Medical Institute and Research Center Sumandeep Vidyapeeth and Institution Deemed to Be university, Vadodara

Abstract

Introduction: Coronoid process is single the bony processes of the ramus of the mandible. It is a thin, triangular eminence, which is flattened from side to side. It differ in shape and size. The importance of frequency in the shapes of Coronoid process is important for maxillofacial surgeons as a graft material as well as for anthropologists for the detection of races.

Aim: To determine the different shape of Coronoid process of mandible in both sides.

Materials and Method: The Present study was conducted on 50 mandibles from the department of Anatomy, Baroda Medical College, Baroda. Variations in the shapes were observed, and photographs were taken.

Results: Triangular shape of Coronoid process was most prominent as compare to hook and round shape. Triangular shaped Coronoid was seen in 70% shaped (Type: I) followed by Rounded shaped 26%, Hook shaped was least 4% respectively.

Conclusion: This study will be helpful for maxillofacial surgeons, anatomists, forensic researchers, anthropologists.

Key Words: Mandible, Coronoid process, Triangular, Rounded, Hook.

Introduction

The mandible is the bone of the jaw bone. It is the largest, strongest, and lowest bone of the face and bears the lower teeth. The mandible is horseshoe-shaped and consists of Three parts: a horizontally-oriented body and two vertically oriented rami.

Body: The body of the mandible is U-shaped and it presents:

1. Two surfaces
   (a) External surface.
   (b) Internal surface.

2. Two borders
   (a) Superior border of the body is called alveolar process.
   (b) Inferior border or base of the mandible presents a small depression digastric fossa on either side near the median plane.

   It gives attachment to the anterior belly of the digastric.

Characteristic on the external and internal surfaces of the body:

The outer surface of the body of the mandible presents the following features:

Symphysis menti: It is a faint median ridge on the external surface of the body.

It marks the line of fusion of the two halves of the mandible at the age of 2 years.
The symphysis menti expands below into a triangular elevation termed mental protuberance.

It forms the point of chin, the base of which is limited on each side by the mental tubercle.

The inner aspect of symphysis menti possesses four tubercles called genial tubercles arranged into two pairs: upper and lower.

The upper pair provides attachment to genioglossus muscles and lower pair to geniohyoid muscles.

Mental foramen: It lies below the interval between the premolar teeth and provides passage to mental nerve and vessels.

Oblique line: It is the continuation of the anterior border of the ramus.

It runs downwards and forwards to with regards to the mental tubercle.

Incisive fossa: It is a shallow depression just below the incisor teeth.

The internal surface of the body in each half of the mandible presents the following features

I) Mylohyoid line is a prominent oblique ridge that runs obliquely downwards and forwards from behind the 3rd molar tooth to the symphysis menti below the genial tubercles.

II) Mylohyoid groove lies below the posterior end of the mylohyoid line. Mylohyoid nerve and vessels run in this groove.

III) Sublingual fossa is a shallow area above the anterior part of the mylohyoid line and lodges sublingual gland.

IV) Submandibular fossa is a slightly hollowed out area below the posterior part of the mylohyoid line and lodges submandibular gland.

Ramus of the Mandible

It is more or less a quadrilateral vertical plate of bone that projects upwards from the posterior part of the body.

The ramus presents the following features:

Two surfaces

(a) Lateral surface.

(b) Medial surface.

Four borders

(a) Anterior.

(b) Superior

(c) Inferior.

(d) Posterior.

3. Two processes

(a) Condylar process, a strong upward projection from postero superior part.

Its upper end is expanded to form head. Neck is the constricted part below head

and presents a depression on its anterior surface called pterygoid fossa.

(b) Coronoid process, a flattened (side to side) triangular protrusion from anterosuperior part.(2,13)

Coronoid process derived from the Greek word “korone” meaning “like a crown.

The Coronoid process of mandible is a thin, triangular process projects upward and slightly forward.

This process gives attachment to two important muscles of mastication Temporalis muscle attached to apex whole of the medial surface and anterior part of lateral surface.

Rest of the lateral surface gives attachment to masseter.

It varies in shape and size.

The Knowledge of variation in the shapes of Coronoid process is important for maxillofacial surgeons as a graft material as well as for anthropologists for the detection of races.(3,7)
Aims and Objectives

Aims: To determine the different shape of Coronoid process of mandible in both sides.

Objectives

Depending upon the observation was categories into 3 types.

I Type 1: Triangular: the tip of coronoid process straight upward.

II Type 2: Hook shaped in which the tip of coronoid process was pointing backward.

III Type 3: Rounded: tip is rounded.

Materials and Method

The cross sectional study was performed in Department of Anatomy in Baroda medical college, Vadodara, Gujrat.

A total of 100 dry mandible (50 right side and 50 left side) bones were studied from teaching collection of the Anatomy department. The bones belonged to mature specimens but the exact ages and gender of the specimens were not known. All the mandible selected were dry, complete and showed normal anatomical features and bones showing pathology were excluded from study.

All measurement was carried out by the same instrument.

The data were then entered and analysed using the Microsoft Excel 2010.

The following parameters of the shape of Coronoid process mandible were observed.

SHAPE OF THE CORONOID PROCESS:
Different shape of Coronoid process of mandible in both sides.(6,8)

OBSERVATION

Figure I showing triangular shaped coronoid process which is more observed in current study.(6,7,13)
**TYPE:II ROUNDED SHAPE**. Figure II showing Rounded shaped coronoid process which is less observed in current study.

**TYPE :III HOOK SHAPE**

Figure III showing Hooked shaped coronoid process which is very few observed in current study.
### Results

Frequency of various shape of coronoid process in total side with percentage. (6, 7, 13)

Tanveer A(2011)13, Vikas Desai (2014)16, A Quadri that observed variation in shape of coronoid process triangular shaped frequency near by to what observed in current study.(6,7)

Conclusion

Current study, out of 50 mandibles triangular shaped coronoid process was establish to be majority wide spread keep to rounded shaped next hook shaped.

i) Awareness of frequency of shape of coronoid process helpful for the maxillofacial surgeons as it can be used as an excellent graft for reconstructive surgeries .(3)

ii) frequency shape of coronoid process caused by unilateral chewing habits, muscular pull on the process and hormonal factors.(3)

iii) Knowledge of Variation In Shape is useful Dental Surgeons In Oral & Maxillofacial Surgeries.(7)
IV) Coronoid process can be easily garner as a donor bone.

V) The coronoid process appear to be suitable for paranasal augmentation.

application is also use because its size and morphology fits into the paranasal region, with the advantages of biocompatibility, availability, and reduced surgery time for harvesting.

Development of Physical and Mental Abilities in Fulfilling Children’s Rights in the Program of ‘Kampung Anak Negeri’ in Surabaya

Novira Maharani Sukma¹, Irawati¹
¹Lecturer at Faculty of Law, Diponegoro University, Indonesia

Abstract
As an obligation to protect the children, both physically and mentally, every child must be provided in accordance with their welfare by providing guarantees for the fulfillment of children’s rights. The Indonesian government’s concern for the protection and fulfillment of children’s rights has actually existed since the enactment of Law Number 4 of 1979 concerning Child Welfare. However, until the promulgation of the Child Protection Act to date, welfare and fulfillment of children’s rights are still far from what they should be, mostly for street children and neglected children. The purpose of this research is to study how the efforts to fulfill children’s rights through the program specifically for street children and neglected children. The method used in this research is normative juridical. Based on the results of the study, that the Kampung Anak Negeri Program in Surabaya was made as a social service for the fulfillment of children’s rights in the orphanage system, including meeting the needs of food, clothing, and shelter, as well as mental and spiritual guidance, behavior, children’s talents, and business skills that can improve child welfare after leaving later.

Keywords: physical development, education, mental abilities, children’s rights, Kampung Anak Negeri, Surabaya.

Introduction
The Indonesian state guarantees the protection of the human rights of its citizens, including the rights possessed by children. This is marked by the protection and fulfillment of children’s rights in the 1945 Constitution of Indonesia as well as several other laws and regulations, both national and international. The protection of children’s rights is strengthened by the ratification of the Convention on the Rights of the Child through Presidential Decree Number 36 of 1990 concerning Ratification of the Convention on the Rights of the Child.¹

The principles of protection for children, among others, are regulated in the Convention on the Rights of the Child which has been ratified by the government through Presidential Decree No. 36 of 1990 which sets out general principles for child protection, namely non-discrimination, the best interests of the child, survival, and child development, and respect for children’s participation. This principle is also accommodated in the provisions of Law Number 35 of 2014 concerning Amendments to Law Number 23 of 2002 concerning Child Protection. This is done so that the principles of protecting children can be applied in Indonesia. The Constitution stated that the poor and neglected children are interrupted by the State. These neglected children also have rights as a whole child who must also be given protection and guarantee for the fulfillment of their children’s rights.

The Indonesian government’s concern for the protection and fulfillment of children’s rights has actually existed since the enactment of Law Number 4 of 1979 concerning Child Welfare. However, until the issuance of the Child Protection Law to date, the welfare and fulfillment of children’s rights, especially street children
and neglected children, are still far from being expected. Abandoned children according to Article 1 point 6 of Law Number 35 of 2014 concerning Child Protection are children whose needs are not properly fulfilled, whether physically, mentally, spiritually, or socially. Street children are an example of neglected children. Many parties underestimate street children or children with juvenile delinquency problems. However, the Surabaya Government does not have high concern for the future of street children in Surabaya. This is evidenced by the establishment of the program of Kampung Anak Negeri which is under the guidance of the Surabaya Social Service. The program was established with the aim of fostering street children, school dropouts, and children with Social Welfare Problems.

Research Methods

The approach method used in this research is the normative juridical approach method. The normative research method is a study that analyzes law both written in the book, as well as law that is decided by the judge through judicial process. This research uses descriptive analytical research method, which is research that generally aims to describe systematically, factually and accurately on a certain matter, regarding the characteristics, characteristics, or certain factors related to the fulfillment of children’s rights. Data collection techniques that will be used in this study, the authors use literature study. To increase the source of data in this study, interviews were also conducted with the management of the Kampung Anak Negeri Surabaya, thus completing the results of this study.

Children’s Rights in Indonesian Laws and Regulations

The rights of the child based on Article 52 paragraph (2) of Law Number 39 of 1999 concerning Human Rights are human rights and for its interests the rights of the child are recognized and protected by law even when in the womb. Children’s rights apply when the child is in the womb where the child needs protection to live. Then when he is born he needs to maintain his life and wants an increase in the standard of living.

Children have the right to legal protection from all forms of physical or mental violence, neglect, ill-treatment and sexual harassment while they are in the care of their parents or guardians, or other parties who are responsible for caring for the child. In addition, children are entitled to protection from every activity of economic exploitation and any work that endangers them so that they can interfere with their education, physical health, moral, social and mental spiritual life.

Law No. 39 of 1999 concerning Human Rights stated that children have the right to protection by parents, family, society and the state; children with physical and or mental disabilities have the right to receive special care, education, training and assistance at the expense of the state, to ensure their life in accordance with human dignity, increase self-confidence and the ability to participate in the life of society, nation and state; children have the right to worship according to their religion, think and express themselves under the guidance of their parents and/or guardians; children have the right to know who their parents are, to be raised and cared for by their own parents. When the child’s parents are unable to raise and care for their child properly and in accordance with this law, the child may be cared for or adopted as a child by another person in accordance with the provisions of the laws and regulations; children have the right to receive education and teaching in the framework of personal development according to their interests, talents and intelligence level; children have the right to associate with children of the same age, play, have recreation, and be creative according to their interests, talents and level of intelligence for self-development; children have the right to get proper health services and social security, in accordance with their physical and mental and spiritual needs; the child has the right to receive protection from economic exploitation activities and any work that endangers him, so that it can interfere with his education, physical health, moral, social life, and mental spirituality; children have the right to receive protection from activities of sexual exploitation and abuse, kidnapping, child trafficking, and various forms of abuse of narcotics, psychotropic substances and other additives; children have the right not to be subjected to mistreatment, torture, or inhuman punishment. The death penalty or life sentence cannot be imposed on a child offender.

Law No. 35 of 2014 concerning Amendments to Law Number 23 of 2002 concerning Child Protection stated that child protection is all activities to guarantee
and protect children and their rights so that they can live, grow, develop, participate in an optimal manner in accordance with human dignity, and receive protection from violence and discrimination. Children’s rights are part of human rights that must be guaranteed, protected and fulfilled by parents, family, community, government and the state. Children’s rights in Law No. 35 of 2014 stated that children have the right to live, grow, develop and receive protection from violence and discrimination; children have the right to worship according to their religion, think and express themselves according to their level of intelligence and age; children have the right to know their parents, to be raised and cared for by their own parents. If the parents cannot guarantee the child’s growth and development, or the child is neglected, the child has the right to be cared for or adopted as a foster child or adopted child by someone else in accordance with the provisions of the applicable laws and regulations; children have the right to obtain health services and social security in accordance with their physical, mental, spiritual and social needs; children have the right to education and teaching in the context of personal development and intelligence level according to their interests and talents. Especially for children with disabilities are also entitled to receive special education, while for children who have advantages are also entitled to special education; children have the right to rest and take advantage of their spare time, associate with children of the same age, play, have recreation, and be creative according to their interests, talents and intelligence level for self-development; children with disabilities are entitled to rehabilitation, social assistance and maintenance of social welfare; children have the right to receive protection from acts of abuse, torture, or violence.

Development of Physical and Mental Abilities in Surabaya’s Kampung Anak Negeri

Legal products of the laws and regulations governing the protection of children’s rights in Indonesia have provided a comprehensive and adequate aspect in children’s rights. However, in implementation in community life there are still many shortcomings in fulfilling children’s rights, including many cases such as street children, dropped out of school, exploitation of children for the economy, physical and non-physical violence, and sexual violence. However, the fulfillment of children’s rights has not been carried out optimally, especially for street children, school dropouts, and children with Social Welfare Problems. Their presence is increasing in number, causing anxiety for the general public if they are not properly nurtured. Because it is feared that it will have a negative impact on public order and security. Homelessness creates risky conditions for homeless children and adolescents, for example, malnutrition, loss of parental support, affiliation with deviant peers, dropping out of school, and so on. This state of risk has devastating physical, emotional, social and educational impacts on young people.

Based on these conditions, since 2009 the Surabaya Government has established the Kampung Anak Negeri Program as a sustainable and structured program in order to foster and ensure the fulfillment of the rights of street children, school dropouts, and children with social welfare problems in Surabaya. This program was formed as an effort to create and provide a decent life for them because they are an integral part of the state as the nation’s next generation. According to Erni Lutfia, Head of the Technical Implementation Unit of Kampung Anak Negeri, the children here come from various backgrounds. They come from street children, school dropouts, and children with social welfare problems who were caught by the raids on the municipal police. Until now, a total of 35 children live in Kampung Anak Negeri. Their age range is between 7 and 18 years. Education is an essential right to citizen. Article 28 of the Convention on the Rights of the Child (1989), recognizes the right of every child to a free primary education, and encourages the development of secondary education that is accessible and available. This right is essential to all societies in order to promote and achieve of stable and harmonious relations among nations and build the good citizens for the future.

The education provided in Kampung Anak Negeri is in the form of formal and non-formal education. For formal education, Kampung Anak Negeri collaborates with nearby schools. Meanwhile, for children who have dropped out of school or dropped out, they will be included in pursuing packages, so that they can still receive education. On the other hand, non-formal education is in the form of interest and talent training, as well as entrepreneurial skills.
The shelter in Kampung Anak Negeri is somewhat different from a shelter. Children are free to play even outside the shelter area. However, there are still disciplinary boundaries that they must obey, such as going to school, attending interest and talent training, praying and reciting the Koran. So that the method applied can make children who live feel comfortable and have fun. The approach taken by the companions there is also somewhat different from the others, a companion must understand the child’s psychology. Not only that, the figure of the companion there must also be a substitute father or mother for them, so that they still feel affection. Through the programs that have been carried out, some of these children have both regional and national achievements. For example, a child, AM (14) won first place in the 38 kilogram class boxing competition in the East Java Youth Amateur Boxing Championship in 2017. In bicycle racing, a child, MM (7) won third place in the KONI Bike Race Championship in Surabaya. Another child, LAP (16) has won in the same field second place in the Third Series Early Age Bike Race, Chairman of ISSI Central Java. From the martial art branch, MH (14) has won the award for early childhood champion in Surabaya.

While living in Kampung Anak Negeri, the children will be financed for their education until they graduate by the Surabaya Government, and even assist them to find work. In fact, there has been cooperation with five-star hotels in Surabaya, so that they can work there. In addition, they are also taught entrepreneurship, such as being a barista at the Children’s Coffee Shop belonging to the Surabaya Social Service. The method applied in the program has shown success, as many of these children have graduated from school and found jobs. The program received appreciation from the Minister of Women’s Empowerment and Child Protection, and plans to adopt the program to be implemented throughout Indonesia. The program is also one of the supporters of Surabaya being designated as a City Fit for Children in 2019 with the main title.

**Conclusion**

The fulfillment of children’s rights, especially for street children and school dropouts, in the Kampung Anak Negeri in Surabaya has been carried out well. Children are in the phase of growth and development, so they need to get guidance and shade in order to have mental and social maturity. Initially they live and live on the streets and drop out of school, transforming into a better life. They are given shelter and shelter. In addition, they are also provided for their primary needs, educational rights, mental and spiritual guidance. So that children can have the widest opportunity to grow and develop optimally both physically, psychologically and in social life.

Awareness of Medico Legal Aspects of Clinical Practise and Common Medico Legal Issues among Medical Graduates

Padmakumar.K 1, Ajith Paleakkara2

1Professor & Head, 2Assistant Professor, Department of Forensic Medicine & Toxicology, Jubilee Mission Medical College & Research Institute, Thrissur, Kerala

Abstract

Background: Medical practitioner is expected to have skills and knowledge in his field along with legal aspects of practise of Medicine, various medico legal issues and management of such issues. The study will help us to know the areas of weakness with regard to handling of medico legal issues among the medical graduates and can suggest remedial measures to improve the learning process.

Method: Data will be collected by giving a printed questionnaire which consists of seventeen questions related to basic knowledge of medico legal issues and its management. This will be done only after taking consent. The participants are required to answer by agreeing or disagreeing the statements given or by giving simple answers to the questions. Data will be analysed using Microsoft excel & SPSS Software and results will be presented with frequency and percentage and will be illustrated within charts and tables. 120 medical graduates participated in the study and study showed an existence of gap in the learning and practical knowledge about medical legal issues and its practise.

Conclusion: Regular training to update the knowledge of medico-legal issues is necessary to ensure continuous improvement of the quality of health care delivery and better administration of justice.

Key words: Forensic Medicine, Medico legal awareness, Medico legal issues

Introduction

A Medico-legal case is a case of injury or illness where the attending doctor, after eliciting history and examining the patient, thinks that some investigation by law enforcement agencies is essential to establish and fix responsibility for the case in accordance with the law of the land. (1) The decision to register any case as a medico legal case rests solely with the doctor who attends the case. A doctor must always exercise his judgement independently and with complete objectivity. To exercise this judgement, it is desirable that every medical practitioner should know various offences affecting human body as per law of the land. It is also desirable for the medical practitioners to know various acts, rules regulations and protocols related to procedures to be followed in the conduct of each and every medico-legal examination. In India these topics are included in the curriculum of Forensic Medicine and Toxicology.

This subject is currently taught during the second phase of MBBS course and extends for a period of eighteen months. Once they complete this phase they enter in to the final phase of MBBS course which is of twenty four months. When the medical students are graduated they are expected to judge, handle and follow the protocol for the medico legal cases based on their knowledge they acquired during their second phase of medical course.

A Registered Medical Practitioner has legal, ethical and moral responsibility to the society in their day to day clinical practise. So a medical practitioner is expected to have skills and knowledge in his field along with good ethical standards and legal awareness. (2) Lack of knowledge of Legal Medicine and legal aspects of practise of Medicine is an important issue that needs to be addressed. Hence a study is planned among the medical graduates who are getting trained in Jubilee Mission Medical College & Research Institute, Thrissur,
in Kerala.

Success of health care system not only depends on the medical knowledge, skills and attitude, also includes awareness on the legal, ethical and moral responsibility to the society. It is also pertinent that medical Profession is guided by various legal statutes. Ignorance of such legal statutes is no excuse for any dereliction of duty. Teaching of various legal statutes related to medical field, medico legal issues, protocols and guidelines to manage medico legal issues is required to equip medical practitioners with adequate knowledge which enables them to deal with various medico legal issues.\(^3,4,5\) This will help in application of medical knowledge in administration of justice. The present study is to assess the awareness related to handling of medico legal issues among the health care providers, which reflects both quality of care and administration of justice.

**Objective of the study:**

Objective of the study was to assess the awareness of medical graduates regarding medico legal aspects of clinical practise, common medico legal issues and guidelines and protocols related to such issues.

**Materials & Methods**

Descriptive Cross sectional questionnaire based study

Place of study: Jubilee Mission Medical College & Research Institute, Thrissur

**Inclusion Criteria:** Medical graduates completed Compulsory Rotatory residential Internship programme junior residents, Tutors and demonstrators.

Exclusion criteria: CRRI trainees, MBBS students.

**Data Collection and analysis:**

Data was collected by giving a printed questionnaire which consisted of seventeen questions related to basic knowledge of medico legal issues and its management. This is done only after taking consent. The participants were required to answer by agreeing or disagreeing the statements given or by giving simple answers to the questions. Data was analysed using Microsoft excel & SPSS Software and results are presented with percentage and illustrated with tables.

**Results**

A total of 120 medical graduates were participated in the study. Out of the 120 graduates, 48 participants are doing their post-graduation. All 120 participants responded to all the questions in the proforma and the percentage of correct and wrong responses are shown in Table-1.

Discussion

Registration of Medico legal cases:

There is no stipulated time period beyond which an MLC cannot be registered is a false statement but more than 50 per cent of the doctors responded to this statement by saying there is a fixed time for registration of medico legal cases. The decision to register any case as a medico legal rests with police and patients or his attendants is a wrong statement. The decision to register any case as medico legal rests solely with the doctor who attends the case. This was not known to 36.67 per cent of graduates. These two basic concepts in medico legal cases shall be known to each and every medical practitioner. When a medico legal case has been registered in a hospital, a fresh registration is not required in the institution where the patient is referred to for further management. Only 50 per cent doctors responded like this. The only duty of registered medical practitioner is a mention must be made in admission document that the case is already registered in the previous institution. If the case is not registered in the first hospital a copy of the reference letter shall be attached along with the medico gal certificate/ report.

Brought dead to hospital

All brought dead cases to the hospital need to be informed to the police by the attending doctor. The time and date on which dead person was brought to the hospital, name of the accompanying person and alleged history shall be noted. It’s the duty of the attending doctor to send the intimation immediately to the police and transfer the dead body to the mortuary. 35.83 per cent doctors considered this need not be informed to legal authority.

Consent for physical examination:

Only 20.83 per cent participants knew the minimum age for giving consent for physical examination is 12 years. As per section 89 of Indian Penal Code a Child below the age of 12 years and a person with mental illness cannot give a valid consent to suffer any harm which may result from an act done in good faith and for its benefit. (6)

Reporting in sexual assault cases

When a 16 year old survivor of an alleged case of sexual assault is brought to hospital which agency is to be informed by the duty medical officer was a question asked in the study, only 37.50 graduates responded to this correctly. As per section 19 of the protection of Children from sexual offences act 2012, any person who has apprehension that an offence under this act is likely to be committed or has knowledge that such an offence has been committed, he shall provide such information.
Examination of an arrested person:

Whenever an accused person under arrest is brought for the conduct of a medico legal examination with a requisition from a police officer not below the rank of a Sub inspector of police and such person refuses consent for the said medico-legal examination, the medical officer should examine the person even using reasonable force, as per provisions of Sec.53 of Cr.P.C. This is correctly given only by 57.50% medical graduates participated in the study.

Consent during emergency

When an emergency procedure is required to save the life of a person who is unable to give consent (like unconscious person), whether the doctor will be legally protected if he performs the procedure without the consent of patient? The answer is yes and response from 89.17 doctors was found correct. As per Section 92 of Indian Penal Code, consent is absolutely dispensed with when the circumstances are such as to render consent is not possible or when, in case of person incapable of assenting, there is not one at hand whose consent can be substituted. (8)

Infamous conduct

If a medical officer under the influence of alcohol treats a patient, it amounts to Infamous conduct. 45.00 per cent medical graduates depicted this as Medical Negligence.

Samples in poisoning cases

Medical Officers should be aware of the importance of preserving the material objects like stomach aspirate, vomitus particles, blood, urine, faeces, remnants of food and medicine etc.. the examination of which may help to identify the injurious agent, in cases where such facts may have to be established in a Court of Law at a later stage. 63.33 per cent doctors correctly mentioned at least useful samples for poison detection. While collecting blood sample from a person to estimate blood alcohol level, spirit is routinely used as an antiseptic is a false statement and responded correctly by 76.67 per cent doctors. While collection of blood, the solution used to disinfect is iodine, ether or seventy per cent ethyl alcohol, the sample may be mildly contaminated the sample and can give a deceptive high value. (9)

MTP and consent

While performing termination of pregnancy as per MTP Act 1971, consent of pregnant woman alone is sufficient if she is above the age of 18 years and mentally normal. This is a true statement and is given correctly by 78% of doctors.

Euthanasia in India

Even though Passive Euthanasia is legally permitted in India by a recent verdict by the Supreme Court, 75 per cent of participants said it is not permitted legally in India. The intent to kill makes euthanasia as a crime under the Indian Penal Code till recently. But Supreme court in a landmark judgement on 9 March 2018 declared the right to die with dignity as a fundamental right and passed an order allowing passive euthanasia in the country and issued guidelines in recognition of “living will” made by terminally-ill patients.

Certification of injury

Physical examination of a person without his consent is assault except in situations specified by the Law. Hence consent should be obtained before conducting any medico-legal examination on the body of the person except in situations where the injured person directly comes to or is brought by anyone for treatment of injuries; poisoning etc. (10) 47.50 per cent graduates said consent is mandatory

Dying declaration

A dying declaration forms a basis for conviction without any corroborative evidence if it is reliable and truthful. A dying declaration recorded by a competent magistrate has a significant reliability or acceptability than oral evidence or a dying declaration recorded by the investigating officer. (11) 32.50 per cent graduates participated in this study was not aware of this concept.

Usefulness of curriculum

From the above responses of medical graduates it can be stated that many gaps exists in their knowledge
about many important aspects of their day to day clinical practise related to medico legal issues. All the concepts which reflected in the questionnaire asked in the study are covered during second phase of MBBS in the subject of Forensic Medicine and Toxicology. 68% of doctors said the curriculum they underwent is sufficient to impart necessary information and awareness in managing common medico legal problems. But the result of the study does not support this view of the graduates.

Medical Council of India in 2019 implemented the competency based curriculum with a view to create an Indian Medical Graduate possessing requisite knowledge in skills, attitudes, values and responsiveness. The subject of Forensic Medicine and Toxicology extends over a period of two and a half years during the second and third phase of MBBS. The teaching learning of this subject is aimed at producing a graduate who can demonstrate a clear understanding of medico legal responsibilities in primary and secondary sittings. The Medical graduates who participated in this study were of the view that the newly implemented Competency Based Curriculum and the extension of the subject of Forensic Medicine & Toxicology to final phase of MBBS course will be helpful to the medical graduates for better alignment of medico legal knowledge and clinical practise.

**Conclusion**

Many gaps detected in the learning of the subject of Forensic Medicine and Toxicology and medico legal awareness after graduation. The competency based curriculum in the subject of Forensic Medicine & Toxicology which is introduced in the year 2019 may reduce the gaps in the learning and practising to a great extent. The internship programme must contain training programmes to make medical graduates aware of medico legal aspects of clinical practise and also to develop skills for medico legal examination and management. The post graduates students irrespective of their subjects shall be given training programs to improve their understanding of medico-legal responsibilities.

**Limitations of the study:** The study participants are graduates from a single institution and graduates doing their post-graduation in the same institution.

**Ethical Clearance:** Clearance has been obtained from the Institutional Ethical and Research Committee prior to the study.

**Conflict of Interest:** None to be declared

**Funding and support:** None

Effectiveness of Education and Information Technology on Menopausal Syndrome among Rural and Urban Premenopausal Women

Parimala.L1, Kaviya.S2

1Vice Principal, Department of Medical and Surgical Nursing, 2B.Sc (N) IV Year Student, Saveetha College of Nursing, SIMATS, Chennai, India

Abstract:

Background: Menopause is defined as the point in time when menstrual cycles permanently cease due to the natural depletion of ovarian oocytes from aging. The diagnosis is typically made retrospectively after the woman has missed menses for 12 consecutive months. Pre-menopause is a biological stage in a woman’s life when she is no longer fertile and is marked by the cessation of menstruation. The study aimed to assess the effectiveness of education and information technology on menopausal syndrome among rural and urban premenopausal women.

Methods: Pre experimental research design was used with 50 rural premenopausal women and 50 urban premenopausal women samples who matched the inclusion criteria were selected by simple random sampling technique. Demographic variables were collected by self structured questionnaires. The results of the study are in rural, 31(62%) women had adequate knowledge in pre test and 40(80%) in post test, 15(30%) women had moderate knowledge in pre test and 10(20%) in post test, 4(8%) women had adequate knowledge in pre test. In urban 42(8%) women had adequate knowledge in pre test and 39(78%) in post test, 7(14%) women had moderate knowledge in pre test and 11(22%) in post test, 1(2%) women had adequate knowledge in pre test on menopausal syndrome among rural and urban premenopausal women.

Conclusion: The study concludes that majority of the women had a negative outlook towards premenopausal syndrome and their management. After providing information regarding premenopausal syndrome and management women had a positive outlook.

Key Words: Education and Information Technology, Premenopausal Syndrome, Management and Menopause

Introduction

Menopause is defined as the point in time when menstrual cycles permanently cease due to the natural depletion of ovarian oocytes from aging. The diagnosis is typically made retrospectively after the woman has missed menses for 12 consecutive months. It marks the permanent end of fertility and the average age of menopause is 51 years. It is a natural process just as puberty is natural. Puberty prepares a girl and bear children and menopause prepares women to cease to be able to conceive. Both cause sudden changes in one’s body, puberty by introducing hormones and menopause by withdrawing them1-2.

The term menopause is derived from two Greek words ‘meno’ and ‘pause’ meaning “month” and “stop”. Thus it is perm Menopause is the permanent cessation of menstruation at the end of a woman’s reproductive life due to loss of ovarian follicular activity. It is the point of time when the last and final menstruation occurs. The clinical diagnosis is confirmed following stoppage of menstruation (amenorrhea) for twelve consecutive months in absence of any other pathology3-5.

Pre menopause is the physiological termination of normal menstrual cycles. Pre menopause is generally caused more early than the normal age which is associated with the cessation of the menstrual cycles6,7. Pre menopause occurs when the ovaries virtually stops
producing the estrogen which generally leads the fertility aspect of the women to shut down. Because pre menopause is a very important period in women’s life; informed knowledge of what to expect will go a long way to prepare a woman for what is to come during menopause proper, especially because each woman’s transition from pre menopause to menopause may differ drastically due to the difference in the amount of the male hormone androgens that may be produced, which accounts for the devastating secondary male characteristics often exhibited by menopausal women.

Perimenopause or menopausal transition is the stage of a women’s reproductive life that begins several years before menopause, when the ovaries gradually begin to produce less estrogen. It usually starts in the women’s forties. Perimenopause lasts up until menopause, the point when the ovaries stop releasing eggs. In the last one to two years of perimenopause, the decline in estrogen accelerates. At this stage, many women experience menopausal symptoms. Since menopause is due to the depletion of ovarian follicles/oocytes and severely reduced functioning of the ovaries, it is associated with lower levels of reproductive hormones, especially estrogen. Low estrogen can result in vasomotor instability (such as hot flushes and night sweats), psychological changes (such as mood swings, depression, and difficulty concentrating), insomnia, genital tract atrophy (such as vaginal dryness, painful intercourse, and urinary incontinence), and skin changes (such as thinning and decreased elasticity). Lower androgen levels (male hormones) can contribute to the loss of sex drive. Any abnormal vaginal bleeding should be reported immediately to your doctor, since this may represent a precancerous or cancerous condition of the uterus or endometrial lining.

In general, menopausal symptoms are burdensome to many women who suffer from them. Although the impact of these symptoms on health-related quality of life has been reported across a variety of populations incorporating different instruments, the burden these symptoms pose to society through increased healthcare utilization and lost productivity and wages has not been well established. The objective of this study was to evaluate the impact of menopausal symptoms on health-related quality of life and productivity and quantify the economic burden. Though studies exist on menopausal women, only a few focused on the health of these women. Midlife is thus a time to focus on oneself and to seek resources from within the family and community to maintain and enjoy equilibrium. Women need knowledge about what to expect and how to cope with changes during menopause. Hence the investigator has planned to conduct a comparative study to assess the level of knowledge and intervention on signs, symptoms and management of menopausal syndrome among rural and urban premenopausal women.

**Material and Methods**

A pre experimental study was chosen to assess the effectiveness of education and information technology on menopausal syndrome among rural and urban pre menopausal women. The study was conducted in two different settings one in Singanodai Village (rural) and another in Thirukkadaiyur (urban). 100 samples 50 samples from rural pre menopausal women and 50 samples from urban premenopausal women (40-55 years) who meet the inclusion criteria were selected by using simple random sampling technique. The data to assess the knowledge was collected by using the self structured questionnaire. The collected data were analyzed by using descriptive and inferential statistics.

**Result**

The present investigation in rural area brings about that majority of the women belong to age bunch between 46-50 years who moderately replied (90%), dominant part of them belong to Hinduism (84%), a large portion of the women had grade school education (56%), larger part of them were hitched (74%), most of them share joint family is(68%), the greater part of the ladies were now not working (76%), the vast majority of them accumulated wellspring of data from wellbeing camp (72%), majority of family income is lesser than 10000 (86%).

The present study results in urban area depicts that women with age bunch of 40-45 years answered moderately (88%), majority of them were Hindus (74%), most of the people had high school and primary school (28%), majority of them were married (72%), majority of them reside joint family (54%), most of the people were currently not working (72%), the vast majority of them accumulated source of information from community
health nurse (64%), majority of them had family income between 11000-30000 is (68%).

### Discussion

The present study in rural area the pre test data shows that, 31(62%) has adequate knowledge, 15(30%) has moderate knowledge and 4(8%) has inadequate knowledge. The post test data revealed that in rural area, 40(80%) has adequate knowledge and 10(20%) has moderate knowledge. The present study in urban area the pre test data shows that, 42(84%) has adequate knowledge, 7(14%) has moderate knowledge and 1(2%) has inadequate knowledge. The post test data revealed that in urban area, 39(78%) has adequate knowledge and 11(22%) has moderate knowledge.

This study is supported by Paudyal et al. (2014) who conducted the study to assess the Knowledge on perimenopausal symptoms among women attending Lumbini Medical College Teaching Hospital his results depicts that 63.4% of respondents had poor, 33.8% had fair and only 2.8% had good level of knowledge.
regarding menopause. The reason behind the poor knowledge may be due to less appropriate source of information as majority of the women (81.2%) discuss their problems with their friends or relatives but not with doctors or nurses. Concerning hot flushes as a perimenopausal this study revealed that, almost half of the respondents (49.3%) answered that it is one of the perimenopausal symptom

According to Park and Lee, 2011 Korean postmenopausal women had more negative attitudes toward menopause and a low level of performing health promoting behaviors. Hot flush is one of the most commonly reported symptoms during menopause and it is referred to as vasomotor symptoms along with night sweats.

**Conclusion**

The study concludes that majority of the women had a negative outlook towards premenopausal syndrome and their management. After providing information regarding premenopausal syndrome and management women had a positive outlook.

Clinical Study of Combined Endoscopic And Percutaneous Management of a Late Complication Following Tension-free Vaginal Tape (TVT) Anchored Stone for Female Stress Urinary Incontinence

Patel Mikir¹, Nahar Gaurav¹, Pavan Kumar Tungala², Patel Harsh²

¹Assistant professor, Department of Urology, Sumandeep Vidyapeeth, Dhiraj General Hospital, Piparia, Vadodara,
²Resident, Department of General Surgery, Dhiraj Hospital, SBKS&MIRC, Sumandeep Vidyapeeth, Pipariya, Vadodara, Gujarat

Abstract

TVT is a simple and less-invasive variation of the suburethral sling with higher success rates¹. It has been rapidly gaining popularity worldwide but it has also lead to increasing number of patients presenting with associated complications. Bladder erosion through the bladder wall occurring predominantly within the first 2 years the placement of TVT is producing tension or in the close proximity of the bladder..Formation of a calculus in the urinary bladder secondary to an intravesical mesh erosion is relatively infrequent rare and delayed complication.Owing to the scarcity of the data on mesh erosion there is no consensus regarding the ideal approach to remove the mesh Combined endoscopic and percutaneous approach should be opted as the preferred approach .Open surgery should be opted only if minimal invasive approach fails.

Keywords: stress urinary incontinence, sling surgery, stone, endo urology

Introduction

TVT is a simple and less-invasive variation of the suburethral sling with higher success rates¹. It has been rapidly gaining popularity worldwide but it has also lead to increasing number of patients presenting with associated complications. Bladder erosion through the bladder wall occurring predominantly within the first 2 years the placement of TVT is producing tension or in the close proximity of the bladder..Formation of a calculus in the urinary bladder secondary to an intravesical mesh erosion is relatively infrequent rare and delayed complication.

Case 1

A 55 year old post-menopausal woman was operated and TVT applied for genuine stress urinary incontinence 6 years ago, postop course was uneventful. Patient had come with complaints of dysuria and suprapubic pain with recurrent UTI since 6 months in spite of repeated treatments with antibiotics. On evaluation USG KUB and Xray pelvis it was found to be bladder stone formed over intravesical eroded portion of sling. Intraoperative cystoscopy revealed to be a bladder stone anchored to the intravesical eroded TVT mesh. A 26Fr Amplatz sheath after serial dilation was placed percutaneously at suprapubic region under endoscopic vision. Then the suprapubic approach used to fragment the calculus was done by laser lithotripsy. After that transurethral excision of the exposed mesh was performed with holmium Yag laser & adequate traction using percutaneous suprapubic amplaz. With the use of grasping forcepely while performing cystoscopy by a rigid nephroscope in order to pull together with the intravesical eroded portion of sling out of the bladder wall. Operative time was around
25 min. Postoperative course was uneventful. Suprapubic and perurethral catheter were removed on second and seventh post operative day respectively. Patient is asymptomatic on 1 year follow up.

**FIGURE 1:** XRAY PELVIS & ULTRASONOGRAPHY SHOWS BLADDER STONE

**FIGURE 2:** ENDOSCOPIC VIEW OF TWO ENDS OF BLADDER STONE
Case 2

A 52 year old lady had stress urinary incontinence and was treated by tension-free vaginal tape 1 year before presentation. Her main complaints include persistent stress urinary stress incontinence since the early postoperative period. Gynecological examination revealed urethral hypermobility with grade III cystocele. CT(Computed tomography) Urography revealed a vesical calculus fixed to the right lateral wall of urinary bladder. On cystoscopy, an encrustation over the bladder wall is seen where the polypropylene mesh has eroded the wall. It was fragmented using pneumatic lithotripsy. The transurethral resection of the mesh and surrounding bladder mucosa was performed. The operative time was 20 min. The patient was discharged on postoperative day one. During postoperative follow-up two months later, the bladder was healed completely on cystoscopy.

Case 3

A 65 year old obese lady was referred with severe urgency, urgency urinary incontinence,dysuria, occasional hematuria and recurrent urinary tract infection to urology opd. She was operated and TVT applied for pure stress urinary incontinence 3 years ago without any complication and normal postoperative course. On sonography and Xray KUBIt showed bladder stone formed over eroded part of sling which had infiltrated the bladder. Cystoscopy revealed to be a bladder stone anchored to the intravesical eroded TVT mesh. A 24 Fr Amplatz sheath after serial dilation was placed percutaneously at suprapubic region under endoscopic vision. Then the suprapubic approach used to fragment the calculus was done by laser lithotripsy. After that transurethral excision of the exposed mesh was performed with holmium Yag laser & adequate traction using percutaneous suprapubic amplaz. With the use of grasping forcep while performing cystoscopy by a rigid nephroscope in order to pull stones together with the intravesical eroded portion of sling out of the bladder wall. Operative time was around 25 min. Postoperative course was uneventful. Operative time was around 25 min. Postoperative course was uneventful. Suprapubic and perurethral catheter were removed on second and seventh post operative day respectively. Patient is asymptomatic on follow up.

Discussion

Although TVT procedure is simple and minimally invasive procedure there are many serious complications such as bowel and bladder perforation, small bowel obstruction, retropubic hematoma, vessels injury and tape erosion in to urethra, vagina and urinary bladder. Traditionally an open cystoraphy approach is preferred during which a wide excision of the mesh is performed. However, various endourological approaches have been performed in the last decade which includes conventional laparoscopic transvesical single-port procedures, transurethral procedures and suprapubic-assisted transurethral procedures.

An isolated transurethral approach represent a lease invasive method but its association with residual mesh in the detrusor is high which may lead to irritative voiding symptoms secondary to urinary tract infection. Usage of Single-port laparoscopic approach had been reported to provide a “radical” excision but being a more invasive and certainly more complex than a transurethral approach is a disadvantage. A safe, simple, minimally invasive, successful treatment option is Combined endoscopic and percutaneous approach in which radical removal can be done with minimal bladder damage. It is alternative to both the transvaginal and transabdominal approach to extract stone and excising intravesical mesh.
Conclusion

Owing to the scarcity of the data on mesh erosion there is no consensus regarding the ideal approach to remove the mesh. Combined endoscopic and percutaneous approach should be opted as the preferred approach. Open surgery should be opted only if minimal invasive approach fails.

Medicolegal Evaluation of Burn Injuries- An Autopsy Based Study

Pradeep Kumar Nayak\(^1\), Bibhuti Bhusana Panda\(^2\), Sudhansu Sekhar Sethi\(^3\)
\(^1\)Assistant Professor, FMT, Hitech Medical College, Bhubaneswar, Odisha, \(^2\)Associate Professor, FMT, SCB Medical College, Cuttack, Odisha, \(^3\)Assistant Professor, FMT, SCB Medical College, Cuttack, Odisha

Abstract

Even before the primitive man learnt to use fire, he has been a victim of it. Our study was carried out over a period of 2 years starting from 1\(^{st}\) September 2012 to 31\(^{st}\) August 2014 at SCB Medical College, Cuttack, Odisha on burn deaths. Aim and objective of the study was to know demographic pattern, cause of death and relation of body surface involved.

The rate of burn death was 16.7\% of the total autopsy. Female victims outnumbered male victims with a female to male ratio approximately 3.2 : 1. Majority of the cases belong to adolescent and young adult (11-40 years) age group. Maximum no. of victims were married. In most of the cases fatal period was within 24 hours. Most of the deaths occurred when >40\% of TBSA is involved. Most of the victims died within 1 week. More than 80\% of TBSA are involved in majority of cases of shock, whereas a wide range of TBSA(30-100\%) is involved in cases of septicaemia. Major cause of death in burn was septicaemia.

Key words: Burn, demography, cause of death, body surface involved

Introduction

A Burn is an injury which is caused by application of heat or chemical substances to the external or internal surfaces of the body, which causes destruction of tissues\(^9\). Thermal burns and related injuries are a major cause of death and disability affecting the entire world and more so to the developing countries like India. According to The estimated annual burn incidence in India is approximately 6-7 million per year. The high incidence is attributed to illiteracy, poverty and low level safety consciousness in the population\(^15\).

The problem of burn in developing countries like India, are largely related to the nature of domestic appliances used in our country. Conventional methods like using wood, leaves, straw, open chullha, kerosene stove, kerosene lamps, LPG and natural gas stove are used for cooking, heating and lighting purpose. Various socio-cultural factors present in our country also contribute at times. In our society, accidental burns in women occur commonly, which they are more vulnerable to, as most of the women (housewives) spend their time in the household especially in the kitchen. Mortality due to burn injuries is higher because of lack of awareness among people and lack of availability of health care services.

Suicidal trend is also increasing in our country due to many socio-economic factors like abolition of joint family, domestic quarrel, mental depression due to failure in exam/love, drug addiction, mental illness, chronic disease and disability etc. Sometimes people resort to criminal act like murder, rape and to conceal the crime, they burn the body to report it as a post-mortem burn. Rapid industrialization and increasing fire disasters due to many causes are other factors contributing to the burden of disease in developing countries like India. Many established factors decide the fate of burn affected patients, but still some hidden factors are there which decide their mortality. Assessment of outcome in burn patients following admission to a burn centre may be
useful to determine the requirements of nursing care, diagnostic modalities, medical treatment, surgical interventions and rehabilitation therapy.

**Aim and Objective**

1. To determine the demographic distribution of burns.
2. To study the various causes of death in burn injuries.
3. To link the survival rate to the body surface involvement.

**Material and Method**

This study was conducted at S.C.B Medical College & Hospital, Cuttack, Odisha during the period of September 2012 to August 2014. In this study all burn cases brought to the Central Morgue, SCBMCH, Cuttack irrespective of alleged manner were taken into consideration. Case history was taken from the attendant in Burn Unit as well as from the attendant of the deceased, accompanying police personnel, inquest report & dead body challan in the mortuary during autopsy. In this study, the treatment record as well as all the necessary laboratory investigations there in are also taken into consideration. The detail case history, circumstantial evidence where available, treatment records, laboratory investigation reports, autopsy findings were analysed and compared.

**Exclusion Criteria**

Instantaneous deaths due to burns involving muscles, bones, showing features of charring as well as features of post-mortem burns are excluded from the study. Also all the Paediatric burn cases admitted to the Department of Paediatrics, S.C.B Medical College & Hospital are excluded from this study.

**Results**

A total of 301(16.7%) cases of burns had been reported out of 1799 cases of all types of autopsies. Sex wise distribution of burn cases in the study period wherein the females represent 230(76.4%) cases and males represent 71(23.6%) cases. The average female to male ratio is found to be 3.2:1.

</table>
Tab.1 depicts the incidence of burn cases according to age and sex. 81.6% of the total cases belong to adolescent and young adult (11-40 years) age group. The peak incidence is observed in the age group 21-30 years involving 120(39.8%) victims, followed by 11-20 years comprising of 79(26.2%) victims. On sex wise analysis, the peak incidence in males is found to be in 21-30 years age group, comprising 26 (36.6%) cases followed by 19(26.7%) cases in 31-40 years age group. In females also the sufferers are mostly encountered from 21-30 years age group comprising 94 (40.8%) cases, followed by 11-20 years age group accounting 72 (31.3%) of the cases. This indicates that the susceptible age group for both male and female is 21-30 years.

</table>
Tab.6 depicts the relationship between total body surface area involved and cause of death. More than 80% of TBSA are involved in majority of cases of shock, whereas a wide range of TBSA (30-100%) is involved in cases of septicemia.

**Discussion**

The reason for gradual rise in burn death cases could be due to increase in population, lack of awareness and other social as well as environmental factors.

Females are more prone to the burn incidences because of their involvement in kitchen work. Moreover in a developing country like India, females are married earlier than males in the family and are exposed to social and family stress much earlier than males. The other reasons which contribute significantly for female preponderance are traditional clothing pattern in Indian women, illiteracy, lack of awareness, mental stress, suicidal and dowry deaths.

The reason for maximum sufferers encountered from the age group 21-30 years followed by the age group 11-20 years may be due to the fact that it is the productive age, when they are generally active and exposed to hazardous situations both at home and work. Females in this age group are mostly engaged in cooking and wear clothes like sarees, dupatta which catch fire easily.

The triggering factors for suicidal burns in married females could be young age at the time of marriage combined with inability to cope with the physical and psychological stress of marriage, harassment from in-laws. Accidental burns may be due to inadequate precautions during cooking and wearing of the loose clothes like sari. Burn as a convenient means of bride killing also contributes towards the higher incidence in the said age group and sex.

On analysing the data further, and concentrating on the duration of marriage of the married females, it is observed that majority of deaths occurred within 7 years of marriage and among them maximum within the first three years of marriage.

From above presentation it is found that most of the fatality occurred when >40% of TBSA is involved and the percentage of burn surface area increasing the duration of survival is decreasing.
While relating total body surface area involved to the cause of death we found more than 80% of TBSA are involved in majority of cases of shock, whereas a wide range of TBSA (30-100%) is involved in cases of septicaemia. As regards the cause of death, maximum number of victims died as a result of Septicaemia followed by Neurogenic shock and Hypovolaemic shock. Jain R et al (2011)\textsuperscript{10} and Gupta R et al (2012)\textsuperscript{6} agree with our study. But Dasari H et al (2008)\textsuperscript{5}, Kaulapur V V et al (2011)\textsuperscript{12}, Chawla R. et al (2011)\textsuperscript{4} reported dissimilar results as compared to our study.

The finding of the present series depicts septicaemia as the most important factor for the cause of death as it cause devitalisation of tissue leaving extensive raw areas, which usually remain moist due to the outflow of serous exudates. The exposed moist area along with the dead and devitalized tissue provides the optimum environment favouring colonisation and proliferation of numerous microorganisms, which is further enhanced by the decrease of the immune response.

**Conclusion**

In our study, we observed that most of the victims are married females of younger age group. Majority of the victims died due to septicemia within 1 week of hospitalization with burns involving more than 40% of the total body surface area. Each factor has got some influence on the fatality of the burnt victims. However, the factors like feminine gender of younger age group and most importantly the percentage of burn are the prime factors which are mainly responsible for mortality in the burn victims. Development of burn wound infections, indicating the decrease in natural defences responsible for counteracting them, is another major factor influencing the mortality of patients.

Eating Attitudes Test Students Using EAT-26 Questionnaire among Physiotherapy Undergraduate Students

Prasad B. Risaldar1, Akshata Raut1, Arti Sahu2, Waqar M. Naqvi3

1Final year Student, 2Sr. Resident, Department of Community Health, Ravi Nair Physiotherapy College, Datta Meghe Institute of Medical Sciences, Wardha, Maharashtra, India, 3Professor and Head of Department, Community Health Physiotherapy, Datta Meghe Institute of Medical Sciences, Wardha, Maharashtra, India

Abstract

Introduction: Increased number of high BMI individuals eventually leads them to low self-esteem, low self-evaluation which can lead to self-destructive behaviours such as uncontrollable dieting or overeating. Thus, in order to evaluate the eating attitudes a study is conducted among the undergraduate students. Incidence of fast food is increasing rapidly day by day especially in the young individuals, with improper food eating habits at irregular intervals which includes increased intake of carbonated soft drinks in young individuals, due to which there is increased risk of various health hazards out of which the most commonest health hazard is increased risk of obesity in young population especially of urban region obesity also affects the individuals in different aspects such as lethargy, psychological disturbances and physical inactivity leading to increased risk of cardiovascular complications. EAT-26 questionnaire is a screening measure which helps in determining whether you might have an eating disorder that needs professional attention. This questionnaire is a screening measure and is not designed to make a diagnosis of an eating disorder or to replace the place of a professional consultation.

Objective: The objective of the study was to get the number of individuals at risk and to analyse the change in the food habits.

Study design: The design of the study is Observational with 1 month study duration.

Result: 44 students were having inappropriate eating disorder whereas 156 students were having normal eating habits.

Conclusion: 22% of students are at risk of eating disorder tested by EAT 26 questionnaire.

Keywords: EAT-26, eating habits, fitness, Health risks.

Introduction

Increased number of high BMI individuals eventually leads them to low self-esteem, low self-evaluation which can lead to self-destructive behaviours such as uncontrollable dieting or overeating. The components of contention and impulsivity were drawn as forecasting aspects of losing weight in therapeutic participants and the degree of inhibition and counter-regulation of social behaviours is related to the severity of obsessive unhealthy eating issues. Thus, in order to evaluate the eating attitudes a study is conducted among the undergraduate students. A maladaptive perfectionism should be checked for disorder in eating attitudes for anorexia nervosa and bulimia nervosa symptoms.

Incidence of fast food is increasing rapidly day by day especially in the young individuals, with improper food eating habits at irregular intervals which includes increased intake of carbonated soft drinks in young individuals, due to which there is increased risk of various health hazards out of which the most commonest health hazard is increased risk of obesity in young population especially of urban region obesity also affects the individuals in different aspects such as lethargy, psychological disturbances and physical inactivity leading to increased risk of cardiovascular complications. Life expectancy, honors thesis and body mass were big determinants related to dysfunctional dietary behaviour. The greater the body mass, the greater the chance that eating patterns could have become irregular. The food habits and the usage of soft drinks are at high risk to affect the lives of the young individuals in almost every aspect of life including the most important thing at the young age i.e. productivity. Nutrition consumption is linked with compulsive overeating rising in incidence. The prevalence of food addiction range is based on the criteria including age, and level of body weight. Emotions like frustration, anxiety, disappointment, and joy trigger the feeding reactions like consuming pace, food taste, and digestion. Psychological mindset has major impacts on consuming habits and behaviors, as feelings impair the regulation of fundamental processes of action and cognitive mechanisms.

Thus, in order to assess or evaluate the pattern of eating attitudes in young individuals their different tools/scales out which an EAT 26 QUESTIONNAIRE screening tool is used in order to assess the ‘eating disorder risk’ among the undergraduate physiotherapy student.

ED physiology tends to be overrepresented as opposed to the general majority of individuals with mental disorders. For people with neurodevelopmental disorders the demographic distribution for EDs is indeed not twice as significant as in the community at large. Originally designed for AN subjects, EAT represents mainly the AN prodromal symptoms, which reflects, in part, the comparably low results in the research analysis, with most of the respondents, particularly men and women, who are of ideal weight or overweight / anorexic. It is important to improve awareness about the degree and complexity of the difference among ED and ESSENCE towards being flexible to cope and establish care plans particularly for such clients. There seems to be an inadequate work in to the overlaps among ESSENCE and ED for adolescents and young adults. Diet dysfunctions, assessed with EAT, were much more prevalent and present than what was seen in the wider population, whereas in older EDs were far more severe. In the present ESSENCE sample, a substantial majority of instances had a dietary psychopathy without meeting the conventional ED requirements; nevertheless, these individuals may experience from their distressed feeding and require medical attention for a variety of reasons. In response to the claim, the EAT ratings showed that the amount of potential sub-threshold instances was slightly higher than expected from preceding research.

A practitioner with maladaptive eating habits or an ongoing unhealthy lifestyle (ED) may adapt nutritional treatment for his or her personal convictions on diet and lifestyle, thus jeopardizing evidence-based practice and, possibly, the safety and quality of care under their treatment. Past findings on this demographic have produced inconsistent outcomes, with others suggesting a greater incidence of disordered eating among learners in nutrition and dietetics compared to students undertaking certain degrees.

The screening for the eating disorder is based on the assumption that early detection can lead to early treatment to reduce the serious complications. Unhealthy food intake are characterized by a broad variety of dietary disturbances, including nutritional and nutrition problems, nutrition limits, and unsanitary and excessive obesity treatment practices.

**Methodology**

The clearance from institutional ethics committee was obtained. 200 students from the Ravi Nair Physiotherapy College were selected for the study as per the inclusion and exclusion criteria. The participants were informed about the study and the students who were willing was asked to fill the EAT-26 questionnaire. The questionnaire link was shared with the participants. After the students filled the form the results were analysed.
Procedure

The permission from the Head of Institution was obtained for the study and further permission was obtained from the institutional ethics committee. Then, the selection of the target population was done according to the inclusion and exclusion criteria. The participants who were willing to participate were explained about the study and the EAT-26 questionnaire was shared with them, after that the statistical analysis was carried out. (as shown in the flow chart)
Results

According to the feedback received from students it has been found that 44 students were having inappropriate eating habits whereas 156 students were having normal eating habits. (as shown in the pie chart)

![Pie chart showing 22% inappropriate eating habits and 78% normal eating habits]

I. EAT-26 results interpretation

Discussion

A huge mental parameter that intervenes in promoting bad eating habits has proven to be self-esteem for both males and females. Critical thinking, which is nonetheless strongly associated with fortitude, has proven unbiased and has no influence on bad eating behaviours.

Trying to cope with socio-cultural patterns is definitely a big part of the pressures of everyday, needing creation of responsive resources and toughness. The possible second leading up to the incident binary that describes poor dietary sentiments in emerging teenagers was identified as intellectual ability, defined as a trait, skill, or ability to detect and word orally and in writing expressed feelings, and control its own sentiments, i.e. explicitly suppressing them or focusing entirely on new people. Irrational role entails spree wanting to eat that is flawed to health assistance, even sometimes participating in food addiction. Yes, distractibility is also linked to people consuming externally. Nevertheless, the specific set of addictive feeding demeanour – emotional feeding, both in women and people, is often closely tied.

Along with a comprehensive article, roughly 10–30 more for each cent of the respondents struggle from hygiene-impacting personality traits and climates that urgently require the attention of the government and health care professionals. Dietary patterns in this research include ideas, values, emotions, habits, and diet relationships. Interpretation of muscle mass focuses on the individual mass assessment as ‘malnourished’ or ‘normal BMI’ or ‘obese’ versus the actual body composition.

The main problem of both emerging people’s and parents’ narratives was the lack of understanding of the existence and therapeutic treatment of feeding issues across the numerous clinicians employed at all stages of care. Inferential statistics by elderly patients presents healing with binge eating as a larger trend that extends far recovering mass. Optimizing medical expertise at certain tiers is obviously vital to timely identification and prediction, it is however significant to emphasize that therapies provide a proper balance here between required intent to improve safety, physical safety and behavioural quality of life-being.

ED has a hereditary component, such as with evolutionary, personality psychology and endemic
factors, as noted in the creation. In the light of both our recent data and past data, the physical differences or personal attributes may become critical drivers defining the implications of the distorted personal relationships 12.

The severity of the effects of dietary disabilities as well as dysfunctional food choices is just the same that it has already been related to intensified distress. Individuals with eating disorders suffer elevated incidence of certain psychiatric conditions, healthcare, congenital anomalies, role-playing abnormalities, suicidal ideation, shorter life expectancy and very case fatality levels 13.

Disillusionment with the body confidence and eating problems are considered a powerful classic example of anguish all through puberty. This vital time of life is profoundly impacted by the inherent emotional feelings of anxiety, depression, despair and denial of attraction of teenagers and adults, particularly females. Rising prevalence of undernutrition has indeed been linked with accelerated urbanization and dietary change, marked by elevated intake of Western diets rich in processed sugars, added high in fat and sugar, along with insufficient physical activity. It is difficult to ascertain the intricacies of the engagement among behaviour and preferences, self-esteem perspectives, BMI, and dietary habits such as aerobic exercise by logistic regression solo, and most of it has been partly described by prior studies 14.

A large variety of unmerited weight management interventions for someone who has a shifted awareness of their mass. They can have excessive weight habits handles, such as shedding, extreme or unjustified foods prohibition, overeating and use of additives redesigning body mass. Compulsive eating traits highlighting the differences during teenage years, likely since adolescence is a physical tests era containing major teenage body modifications growing ever more self-conscious and dismissive of their kingdom 15.

Conversely, it has been seen in current history that previous reports have undoubtedly exaggerated the incidence of disordered eating of many people, and in reality it is still increasing significantly amongst males. In any culture there are unique beauty ideals for male and female, so dynamic performance where there is little consensus between the beauty picture and the desired model. Myths about body identity can contribute to a number about severe problems, involving severe depression, binge eating and poor self-esteem. It is indicated that self-esteem, delineated as some extent of worth that an individual considers for oneself, exert an intimate ties only with social mores of any civilization. As mentioned previously, poor self-image and high probability self-esteem as a potential factor for anorexia nervosa and their interrelationships are commonly evaluated 16.

Conclusion

The eating attitude assessment was used to check the eating habits and the risk of eating disorders among students which showed that 22% of students were at risk of eating disorder tested by EAT-26 questionnaire.

Effectiveness of Active Release Technique verses Conventional Physiotherapy in Management of Upper Cross Syndrome

Prasad Risaldar¹, Pratik Phansopkar², Waqar M. Naqvi³

¹Final year B.P.T, Ravi Nair Physiotherapy College, Datta Meghe Institute of Medical Sciences, Sawangi(M), Wardha, Maharashtra, India
²Assistant Professor, Department of Musculoskeletal Physiotherapy, Ravi Nair Physiotherapy College, Datta Meghe Institute of Medical Sciences, Sawangi(M), Wardha, Maharashtra, India
³Professor and HOD, Department of Community Health Physiotherapy, Ravi Nair Physiotherapy College, Datta Meghe Institute of Medical Sciences, Sawangi(M), Wardha, Maharashtra, India

Abstract

Background: In upper cross syndrome (UCS), weaker neck flexors, anterior and middle serratus and lower trapezius along with rhomboids usually develop, and tightness of the levator scapulae, pectoralis major and upper trapezius are biomechanically adapted. Active Release Technique (ART) helps to reduce discomfort and improve the range of movement. Also, Active Release Technique (ART) is a manual procedure which is also being used for other soft tissue rehabilitation as well as for the management of the scar tissues. UCS and neck pain is common with uncomfortable job postures as well as in stress and anxiety, due to which muscle dysfunction starts which can further followed by altered posture around the neck.

Aim and Objective: To evaluate the effects of Active Release Technique verses conventional physiotherapy in management of upper cross syndrome physiotherapy.

Materials and Method: 35 patients will be grouped in two groups. Both groups will be treated for six sessions. Group A will be treated with active release technique and static stretching along with hydrocollator pack. The patients coming under Group B, conventional physiotherapy would be given which include upper trapezoid stretching, levator scapulae and pectoralis major as well as rhomboid strengthening, deep neck flexors, lower trapezius along with the hydrocollator pack.

Result: The parameters of outcome measures in interval of pre and post treatment will be analysed using the statistical test namely students paired T test.

Conclusion: Based on the previous data of ART we assume it will be beneficial in relieving the symptoms involved in UCS.

Key Words: Active Release technique, Upper cross syndrome, Physiotherapy

Introduction

Neck is a body part between the head and the shoulder and it also connects the head with the body.

Corresponding Author:
Dr. Pratik Phansopkar
Assistant Professor, Department of Musculoskeletal Physiotherapy, Ravi Nair Physiotherapy College, Datta Meghe Institute of Medical Sciences, Sawangi(M), Wardha, Maharashtra, India
Email: drpratik77@gmail.com ORCID ID- http://orcid.org/0000-0003-3635-8840

The position of the neck and the bottom of the head and shoulders is at greater risk as people sit in the wrong way for long periods of time as there is a rapid rise of time span in the following activities like studying, writing or using a computer.

In upper cross syndrome (UCS), there will be weakened neck flexors, anterior and middle serratus and lower trapezius along with rhomboids, and you will observe the tightness of the levator scapulae, pectoralis major and upper trapezius. This condition is assigned cross name because it can draw “X” (a cross) across the upper body, in UCS primarily muscle imbalance occurs,
which eventually happens in tonic and phasic muscles.\textsuperscript{2}

Individuals with upper cross syndrome may exhibit the following features which can be text neck posture, rounded upper back, elevated and prolonged shoulders, winged scapulae, and reduced thoracic spine mobility. The root of symptoms in mechanical neck pain is not well known, but has been hypothesized to be linked to various anatomical structures, especially the cervical spine’s zygapophyseal or uncovertebral joint. A major reason of neck pain is awkward working posture, anxiety, fatigue, heavy lifting and physically challenging jobs.\textsuperscript{3}

Manual material handling tasks can sometimes lead to the initiation of the musculoskeletal disorders, for example, employees who do their work in an unacceptable role or in an unhealthy posture and perform the same behavior during their working day.\textsuperscript{4} UCS may lead to irregular kyphosis in thoracic spine, as well as changed glenohumeral joint, altered cervical spine biomechanics, can result in loss of cervical curve and may lead to cervical spine degeneration. Changes in musculature function, in people having UCS frequently may cause these individuals to experience chronic headaches.\textsuperscript{3} The occurrence of such disorders can be affected by various factors such as unsuitable posture at work and lack of regular exercise. Data suggests that in the shoulder-girdle and cervico-thoracic area 6-48 percent of the UCS population complain of pain.\textsuperscript{4}

Mechanical neck pain usually presents as neck and/or shoulder pain with mechanical features which may include signs triggered due to sustained postures of the neck, neck movement, or cervical muscle palpation. The root cause of mechanical neck pain symptoms is not completely recognized. Uncomfortable job posture, anxiety, exhaustion, heavy weight lifting and physically demanding jobs are typical causes of the neck pain.\textsuperscript{5} Mechanical dysfunction, which triggers unusual joint movement, is a common cause of neck pain, because abnormal cervical joint mobility inside the joint capsule can restrict neck motion. What’s more, unbalanced soft tissue around

The head and neck structure can set limits on the head’s range of motion (ROM) and cause discomfort to the neck. Therefore, once the muscle dysfunction starts, traditional muscle imbalance trends and altered posture follow.\textsuperscript{6}

Active Release Technique (ART): The Active Release Technique (ART) is a manual procedure for the soft tissue rehab requiring the removal of scar tissue which can cause or which is causing discomfort, stiffness, muscle fatigue and irregular symptoms such as mechanical muscle dysfunction, myofascia and soft tissue.\textsuperscript{6} Furthermore, in patients with a partial tendon tear. ART has been documented to be beneficial for carpal tunnel syndrome, Achilles tendonitis, and tennis elbow, all of which include soft tissue near joints in the distal body parts). ART also has effectiveness in minimizing pain and increasing ROM in patients with a partial tendon tear). Most patients with chronic neck pain experience pain and limitation of movement caused by soft tissue dysfunction.\textsuperscript{6} ART helps to reduce discomfort and improve the range of movement. Thacker D. et.al. determined the use of Active Release Technique (ART) and use of prescribed exercises and they demonstrated progress in the anterior head carriage relative to traditional physical therapy with prescribed exercises.\textsuperscript{7}

Jun Ho Kim. et.al. determined the effects of the active release technique on discomfort and cervical range of movement in cases with prolonged neck pain and result in post sessions were, the Active Release Technique (ART) showed substantial increase in each parameter of the neck joint and no notable effects were present in the conventional physical therapy management.\textsuperscript{6}

Samy S. Abu Naser. et.al. determined a knowledge-based neck pain management method and an description of neck diseases were identified and described, disease causes were sketched and disease care was given at any time possible.\textsuperscript{1}

As for now there stands a paucity of studies on the upper cross syndrome. The aim of the study is to treat the patients with the upper cross syndrome through the process of the Active Release Technique (ART) and prescribed traditional or conventional physiotherapy treatment and to compare their effects that can affect cervical flexibility and to improve the symptom parameters. The goal is to enhance flexibility by using the method called Active Release Technique.

**Objective**

To evaluate the effects of Active Release Technique verses conventional physiotherapy in management of
upper cross syndrome physiotherapy.

**Methods**

This study will be carried out at Ravi Nair Physiotherapy College (RNPC), Musculoskeletal OPD, Sawangi (Meghe), Wardha, Maharashtra, India after approval from Institutional Ethics Committee of Datta Meghe Institute of Medical Sciences (DU).

**Study design:** Interventional study

**Study setting:** ‘Ravi Nair Physiotherapy College (RNPC), Musculoskeletal OPD, Sawangi (Meghe), Wardha, Maharashtra, India’.

**Participants:**

Inclusion criteria - i. mechanical neck pain

ii. Age group between 18-35 years

iii. Based on assessment for neck pain

Exclusion criteria- i. History of trauma or surgery in cervical region.

ii. Traumatic pain

iii. Cervical pathologies

iv. Subjects taking analgesics/muscle relaxants

v. Cervical pain with radiculopathy

vi. Non-cooperative patients

**Variables**

Outcome measures:

1. Neck Disability Index (NDI) Scale

2. Visual Analog Scale (VAS)

3. Cervical ROM

4. Length of Muscle (Pectoralis Major)

**DATA SOURCE MEASUREMENT**

1. The NDI Scale validity and reliability is high, the NDI exhibits excellent reliability (ICC = 0.88; [0.63 to 0.95]). (8)

2. The VAS has good validity and reliability score the ICC for all paired VAS scores was 0.97 [95% CI = 0.96 to 0.98]. (9)

3. Reliability score of cervical goniometer ranged from 0.999 to 0.931 for all cervical movements (r=0.999-0.931). (10)

4. The length of muscle (Pectoralis Major) will be calculated for the length of the pectoralis major muscle before the start of the treatment session and after the 6th treatment session.

**Sample Size: 35**

Group A: 18 patients will be treated with the process of the active release technique and also by static stretching.

Group B: 17 patients will be treated with the process of conventional physiotherapy which will include specific prescribed exercises.

Sampling technique is purposive sampling method as in this short duration of study finding maximum many cases of upper cross syndrome will be difficult so 35 is selected as sample size.

**Procedure**

The institutional ethics committee (IEC) clearance will be obtained before the start of the study. A proper consent will be taken from the patients and the patients will be thoroughly explained about the study. The patients who wish to participate in the study will be taken into isolation in order to respect their privacy and will be given the Visual Analogue Scale (VAS) to assess the pain before the start of the treatment and the Neck Disability Index (NDI) will be given to assess the disability present before treatment at the neck and will be categorised into either group by random sampling using envelop method which will be namely Group A and Group B.

The people placed under the group A will be managed according to the active release technique and by the static stretching along with the hydrocollator pack. The patients coming under the group B will be managed with the conventional physical therapy would include the upper trapezoid stretching, levator scapulae and pectoralis major as well as rhomboid musculature strengthening, deep neck flexors, lower trapezius along
with the hydrocollator pack with six to eight layers of towel over the hydrocollator pack.\(^3\) Active Release Technique (ART): The ART will consist of protocols on both sides for the pectorals, the levator scapulae, and the upper trapezius. The treating physiotherapist must examine the subjects for the musculature involved at each scheduled session. During a therapy session, the active release procedure will be administered once to the musculature involved for 8-10 minutes. The physiotherapist would then only perform the procedure to the musculature that was found to be affected during the examination process.\(^7\)

Static Stretching: For levator scapulae stretching, the subjects will be advised to take the seating position holding the seat with one hand to prevent depression of the shoulder, then relaxing and turning the neck to the opposite side by keeping another palm behind of the skull and gradually moving below towards the underarm. They will be asked to keep the stretch for 15-20 sec on each side, with 2-3 reps. Repeat stretching 2,3 times per session.

Participants will be supposed to be in the standing position in front of the door frame with elbow bent at 90\(^\circ\) for the pectoral muscle stretch and to lean forward without going forward. The stretch is felt around the anterior chest and is kept with around 2-3 reps per session up to 15-20 sec.

**Conventional physiotherapy:**

Exercises: Exercises which will be used for the treatment of Upper Cross Syndrome (UCS) will be as follows:

Cervical Nod: The patient will be told to lie down on the floor or to stand up against a wall, pretending to touch the back of your neck to the wall or floor behind you. It is not going to strike, but you can feel your chin tuck slightly and the head lift crown. That would almost look like you’ve got a double chin. Placing a rolled up towel behind the neck may be useful in having something to push into. This motion strengthens the muscles on the front of the neck and lengthens the muscles at the base of the head, thereby helping to establish an ideal balance of length / strength in the cervical spine (back). Perform the repetitions for 10 – 15 times.

Resistance band row: The physiotherapist should make a loop of the resistance band around anything that is about hip-height (usually a door knob is good and preferred). Then, facing the door knob or anchor point, the patient is told to keep the body tall and the elbows in (not splaying open) while the patient is using both the upper limbs (UL) to pull the resistance band towards him. Depending on the resistance band tension the patient is allowed to change the standing position. The patient will be told to bring together the shoulder blades, and to draw back the elbows. He / she will be told to raise the chest and to hold the heart engaged. He / she will be asked to perform 15-20 repetitions depending on the band’s resistance), the release will also be applied with the hot pack.

**Expected Results**

Once the study result is complete, statistical analysis will be analysed using paired T-test and presented in the form of research paper.

**Discussion**

To our knowledge, this study will be the first study to evaluate effects of the active release technique in upper crossed syndrome and also to compare the effects of active release technique with the conventional physiotherapy treatment. According to the previous studies the effects of conventional physiotherapy in management for the upper cross syndrome is proven, but to our knowledge, this will be the first study to compare the effects of active release technique with the conventional physiotherapy among UCS patients. More over this study will employ well established and widely used methods with appropriate reliability and validity to assess the pain, neck disability, cervical ROM and the length of muscle. The limitation of the study would be the active release technique may not be effective as conventional physiotherapy treatment in UCS patients to help in alleviating the neck disability and to improve the cervical ROM of the patients. Therefore, this study intends to compare active release technique and conventional physiotherapy treatment in UCS patients.

Significance of Measuring Dimensions of Lumbar Lamina and Spinal Canal – A Cadaveric Study

Priyanka N. Sharma¹, Manoj Kulkarni², A. R. Gandotra³
¹Ph.D. Scholar (Assistant Professor), ²Professor, ³Professor & HOD, Department of Anatomy, Smt.B.K.Shah Medical Institute and Research Center Sumandeep Vidyapeeth and Institution Deemed to Be university, Pipariya, Vadodara, Gujarat

Abstract

Introduction: The incidence of lumbar nerve root compression and surgeries for its treatment like laminectomy, laminotomies are increasing. Similarly, intralaminar screw insertion and use of laminar hooks for stabilization is also gaining popularity. The dimensions of lumbar lamina are of importance for designing of lumbar spinal implants used. Method: The present study was undertaken to measure vertical height of lumbar lamina and width of lumbar vertebral canal in cadavers. Lumbar spine was exposed from posterior midline approach in 20 formalin preserved cadavers. The dimensions of lumbar lamina L1 to L5 were recorded with the help of Digital Vernier Caliper after removal of soft tissue from the vertebrae. The data was analyzed using SPSS software version 23. Result: Range of transverse width of vertebral canal of L1 and L2 was 14-23 mm. It gradually reduces in L3, L4 and L5 (12-21 mm). There was no significant difference in width of vertebral canal between Male and female. Mean height of lamina at junction with transverse process at L2 was (25.7±2.8mm) which reduced from L3, L4 and was lowest in L5 (20.8±2). Mean height of lamina at junction with Spinous process increased from L1 to L2 (27.55±3.3) and decreased from L3, L4 and L5 being smallest (24.3±2.7). The gender, right and left differences for the dimensions of lumbar vertebral lamina were statistically insignificant. In 35 percent cases the spinous processes were fused which was an accidental finding. Conclusion: The data so collected will be of great significance for spinal surgeons and for designing of implant around this region.

Key words: Lumbar vertebrae, Lumbar canal, Lumbar lamina, Spinous process

Introduction

The incidence of lumbar nerve root compression and surgeries for its treatment like laminectomy, laminotomies are on the rise. Placement of laminar hooks & insertion of intralaminar screws, during surgical treatment of lumbar spine disorders, is gaining popularity. The knowledge of morphometry of lumbar vertebrae is crucial for surgeons during surgical interventions and placement of implants locally¹⁻⁹. The dimensions of lumbar lamina are also essential for designing of lumbar spinal implants. So, the present study was undertaken to measure dimensions of lumbar lamina and lumbar vertebral canal.

Material & Method

This cadaveric study was carried out at the Department of Anatomy of a medical institute in India. Ethical approval to undertake the present study was obtained from the Institution Ethical Committee (IEC). Lumbar vertebra studied in 20 formalin-fixed adult human cadavers (10 female and 10 male). The age range of the cadavers was 60–95 years (mean, 77.5 years). We included sample in study which had intact vertebral column without any previous dissection, without any surgical procedures, without any trauma pathology of
spinal cord. We exclude sample from study which had carried out any surgical procedure, any external visible deformity of the vertebral column and external sign of injury. The cadavers were placed in a prone position on a flat table with hips extended. The skin was reflected from lower thoracic to sacral region and superficial and deep muscles of the back were identified and excised. The lumbar vertebrae counting from sacrum upward and cleaned. After taking measurements of lamina of L1 to L5 posterior neural arch was excised to measured transverse width of the vertebral canal with the help of Digital Vernier Caliper. The data was analyzed using SPSS software, version 23. For comparison, the level of significance (p value) is kept at 0.05.

**Result**

On both the sides, the mean height of lamina at its junction with transverse process at L2 was found to be highest (25.7±2.8mm), which gradually found to reduce from L3, L4 and was lowest in L5 (20.8±2). Bilaterally, the mean height of lamina at its junction with Spinous process was found to increase from L1 to L2 (27.55±3.3) and decreased from L3, L4 and L5 being smallest (24.3±2.7) (Table 1).

On both the sides, the mean height of lamina at junction with spinous process at L2 was found to be highest which gradually found to reduce from L3, L4 and was lowest in L5. We did not find any statistically significant difference for dimensions of lamina between Males & Females or between right & left sides. We did not find any statistically significant difference for dimensions of lamina between Males & Females or between right & left sides (Table 2).

Transverse width of Vertebral canal is also known as interpedicular distance. The present study found that the range of transverse width of vertebral canal of L1 and L2 was 14-23 mm. It gradually reduced in L3, L4 and L5 (12-21 mm). The mean transverse width of vertebral canal was compared at all the vertebral levels between males & female using two sample T tests. There was no significant difference in width of vertebral canal between Male and female at any level (Table 3 & Fig 2).

Discussion

Clinical significance of morphometric study of Lumbar Canal and Lamina is a well-established fact.

Standard Laminectomy surgery is routinely performed to relieve the symptoms of nerve compression in lumbar canal stenosis. It is also done for lumbar disc herniation. The use of intralaminar screw and laminar hooks is also gaining popularity. Laminar screws are used for spine fixation during fractures and in scoliosis correction. The knowledge of morphometry of lumbar lamina is thus of paramount importance for spinal surgeons for performance of laminectomy & successful placement of implants locally.

The present study has generated a data base for cadaveric study of gender-wise dimensions for lumbar vertebrae lamina. The present study has measured the
different dimensions of lumbar vertebrae in cadavers with the use of digital vernier caliper. Azu et al (2016) in their study have asserted that direct measurements may give more accurate and reproducible results compared to those from imaging technique10. Tharani et al (2018) have studied the height of lumbar vertebra lamina on dry vertebra14. The mean height of lamina in their study was found to be smaller than that of present study bilaterally. However, in their study also the mean height of L2 lamina was found to be largest and showed gradual decrease from L3-L5. This finding is analogues to the present study. The research has established that the anatomical narrowing of the lumbar vertebral canal and intervertebral foramina may cause compression of the cauda equina and the emerging nerve roots. The manifestations of compression are pain in the lower back and lower limbs on walking, weakness and paraesthesia along the distribution of the affected nerve roots.

Transverse diameter of the lumbar vertebral canal (interpedicular distance) is a reliable index for the assessment of the size of the canal2. So, the present study has attempted to determine the data base for transverse diameter of lumbar vertebral canal. There was no significant difference in width of vertebral canal between Male and female at any level.

The result of present study for transverse width of vertebral canal varies from the previous reports in the literature. Tarek et al (2013) in their study have reported that the mean transverse width gradually increases from L1 to L5. He has reported that the transverse diameter in lumbar vertebral canal are 1 to 1.5 mm higher in males while in present study the it was found to be higher in females5.

**Conclusion**

The present study has determined the dimensions of lumbar vertebral canal & lamiae in Indian population. The data so collected will be of great significance for spinal surgeons dealing with this region and also for designing of implant used around this region.

**Acknowledgement:** I express my sincere gratitude to the generous donors who donated their bodies for academic and research purposes. Without cadavers this research would have not been possible.

**Source of Funding:** No funding.

**Conflicts of Interest:** The author declares no conflict of interest.

**Ethical Clearance:** Ethical approval to undertake the present study was obtained from the Institution Ethical Committee (IEC)

Screening for Lower Cross Syndrome in Asymptomatic Individuals- A Study Protocol

Priyanka Sahu1, Pratik Phansopkar2, Kiran Kumar3

1Final year B.P.T, Ravi Nair Physiotherapy College, Datta Meghe Institute of Medical Sciences, Sawangi(M), Wardha, Maharashtra, India, 2Assistant Professor, 3Associate Professor and HOD, Department of Musculoskeletal Physiotherapy, Ravi Nair Physiotherapy College, Datta Meghe Institute of Medical Sciences, Sawangi(M), Wardha, Maharashtra, India

Abstract

Background: lower cross syndrome results from muscle strength imbalance in the lower segment. It is characterized by specific pattern of muscle weakness and tightness that cross between the dorsal and ventral sides of the body. In lower-crossed syndrome, the patient typically has anterior pelvic turn, elevated lumbar lordosis (swayback), and weak abdominal muscles. Inaction may also have a detrimental effect on the mechanics of the body, such as immobilization, disuse or excessive postural discomfort, such as sitting at the workstation for long periods of time and poor posture .It also involves tightness of the iliopsoas, rectus femoris, fascia lata tensor, adductor group, gastrocnemius, and soleus. Pressure biofeedback device is used for the purpose of measuring and treating the transverse abdominis muscle. This study is needed because over time due to prolonged daily activities and lack of regular exercises in young people, this leads to muscle imbalance which leads to low back pain in this population. The goal of the study is to screen for lower cross syndrome in asymptomatic individual.

Aim and Objective: To screen for lower cross syndrome in asymptomatic individual.

Materials and Methods: Based on the inclusion and exclusion criteria, 300 individuals will be included in the study and the respective evaluation procedure for lower cross syndrome will be carried out.

Result: The expected results would include the data about whether lower cross syndrome would be detected in the asymptomatic individuals. Data will be analyzed using paired T-test.

Conclusion: based on the previous data of test and assessment we assume it will be beneficial in relieving the symptoms of lower cross syndrome.

Keywords: lower cross syndrome, Kinect azure, pressure biofeedback unit, Thomas test.

Introduction

Lower Crossed Syndrome (LCS) is a musculoskeletal condition characterized by unique patterns of muscle weakness (Abdominals and Gluteus Maximus) and tightness (iliopsoas and spinal extensors) that connect the dorsal and ventral sides of the body. This postural difference will lead to future Low back pain. This research therefore attempts to establish the screening of lower crossed syndrome in young people.

Lower cross syndrome is also known as pelvic cross syndrome or underkruz syndrome1, resulting in a disparity of muscle strength between deep abdominal musculature and gluteus medius , and gluteus maximus. This is a syndrome of postural distortion which affects the lower kinetic chain. The patient typically has anterior

pelvic turn, elevated lumbar lordosis (swayback), and poor abdominal muscles in lower-crossed syndrome. These patients usually suffer from severe low back pain, piriformis syndrome and anterior pain in the knees. The lower cross syndrome involves oblique rectus abdominis, gluteus maximus, medium gluteus and hamstring. It also involves iliopsoas tightness, rectus femoris, tensor fascia lata, adductor group, gastrocnemius, and soleus. It results in anterior pelvic movement, lumbar spine hyperlordosis, flexion hips and hyperextended knees. From a variety of scenarios such as chronic, repeated, running acts, low-cross syndrome can develop. Inaction may also negatively impact the body’s mechanics, such as immobilization, disuse or constant postural pain, such as sitting for long periods of time and bad posture at the workstation. Lower cross syndrome is described in two distinct ways: one in the lower back and one in the hip. Rehabilitation of the lower cross syndrome is based on the Sherrington law of reciprocal inhibition which states that the opposite muscle relaxes when one muscle is shortened or tightened. So the pelvis, hip joint and lumbar spine will relax, with the stretching of compressed muscles and muscle strength. Some muscles are overactive while others are inhibited as the muscles respond to protect the body from damage or pain.

As a result, joint stress is altered and muscle tiredness is increased. Postural or anti-gravity muscles are more readily activated for these defensive reactions. Meanwhile, muscles with predominantly dynamic or physical function appear to be impaired when physical stress occurs. When muscles react to prevent or reduce physical injury, normal patterns of movement are changed. Muscle strength affects performance of released motion. Additional effects of muscle imbalance include altered joint mechanics that cause unequal distribution of articular pressure and altered rotational centers that eventually contribute to joint instability and pain. The combination of strong and weak muscles induces changes in movement patterns resulting in changes in joint biomechanics leading to secondary degenerative changes. With a limited range of joint motion due to chronic tightness of the muscle, secondary associated joint hypermobility problems may occur.

Pressure biofeedback unit is used for the evaluation and treatment purpose of the transverse abdominis muscle. If the lordosis is deep and small, then the imbalance is mainly in the pelvic muscles; if the lordosis is shallow and extends into the thoracic region, then the imbalance predominates in the muscles of the trunk. Janda considered muscle imbalance to be an impaired relationship between muscles prone to tightness or shortness, and muscles prone to inhibition. According to the source, our body primarily has two types of muscles, which are postural muscles such as iliopsoas, lumborum quadrates, erector spinae, back rotators, and phasic muscles such as abdominals, hip extensors, etc. He noted that static or postural muscles are predominantly tending to tighten. Individuals in the age group from late adolescence to 40 years are extremely involved in everyday life and are subject to different stresses.

In contrast to older people, the age-related changes in this age group are minimal. One of the most interesting hypotheses in physical medicine is that the fundamental mismatch between postural and phasic muscles in and around the pelvis perpetuates tension, strain and altered patterns of movement that account for the re-injury of these main structures.

Janda noticed that the hip flexors become shortened or tight due to prolonged static postures, such as sitting at a desk all day. The brain will therefore automatically start shutting down or inhibiting the muscles of the glutei that are on the opposite side. Now, due to the forward pelvic turn and hip flexion contracture, the imbalance pattern facilitates increased lumbar lordosis and over activation of hip flexors compensating for the weak abdominals.

Hip extension would be limited due to tightened psoas, and the presence of an inhibited antagonistic gluteus maximus would create a poor quality of hip extension because the contra-lateral lumbar erector spinae and ipsilateral hamstrings would have to become overactive and eventually tight to perform the necessary hip extension instead of the gluteus maximus. Low back pain is a common problem and lower crossed syndrome is one of the threatening combinations of lower back structures with biomechanical muscle dysfunction due to excessive stress. People with such postural imbalance
sometimes complain of lower back pain and, if left unchecked, this postural imbalance may trigger a chronic lower back pain that becomes more difficult to correct at later stage.

Das S, Sarkar B, et al. This study showed that the prevalence of lower crossed syndrome was higher in females than in males of the same age group. It was also found that there is insignificant difference between males and females of the same age group in iliopsoas (left sided) tightness. But there is a significant difference in length of spinal extensor, abdominal strength and maximum strength of bilateral gluteus, right iliopsoas length between males and females of the same age group, and females are more prevalent in developing weakness of these muscles. However in this study, the prevalence was not significant to the number of individuals screened.¹

There is need for this study because over the period of time due to prolonged daily activities and lack of regular exercises in young individuals, leads to muscle imbalance leading to low back pain in this population. Therefore the awareness regarding regular exercise and stretching would be possible by, screening individuals for lower cross syndrome flags in asymptomatic individuals for early detection, treatment, and prevention.

**Objective:** To screen for lower cross syndrome in asymptomatic individual and to prevent lower cross syndrome in the young individuals.

**Methods**

This research is being conducted in local communities in Wardha City, Maharashtra, India after ethical clearance is obtained from Institutional Ethics Committee, Datta Meghe Institute of Medical Sciences, Deemed to be University. Based on the inclusion and exclusion criteria, 300 individuals will be included in the study and the following evaluation procedure will be carried out.

**Study Design:** Observational study

**Settings:** Datta Meghe Institute of Medical Science, Sawangi Meghe, Wardha

**Participants:**

Inclusion criteria:

1. Asymptomatic individual,
2. Patients willing to participate

Exclusion criteria:

1. Chronic low back pain
2. Disc herniation,
3. Neurological deficits,
4. Respiratory conditions,
5. Patients who are not willing to participate or uncooperative.

**VARIABLES:**

Outcome measures:

There will be assessing of the following muscles:

1. **Postural assessment**- The posture will be evaluated with Kinect Azure which will provide detailed evaluation of posture in anterior, posterior and lateral view.³ Typically, Kinect data showed excellent validity and could be used to predict dynamic foot work. This approach has also been used for other anatomical measurements, including calculation of the curvature of the spinal cord, patient size, and lung function of the respiratory volume.

2. **Thomas Test**- This test is used to measure hip flexor muscle flexibility, which includes iliopsoas, rectus femoris, pectineus, gracilise, tensor fascia late and sartorius. The patient is normally supine, investigate excessive lordosis. Flex one hip, bring the knee to the chest to flatten the spine / support the pelvis. The patient keeps a flexed hip to the chest. If anterior tightness leg is present, the leg will lift off the bed. Intrarater reliability =0.52 interrater reliability =0.60, SEM =1 degree.⁴

3. **Gluteus Maximus Strength Test**: The patient’s position is inclined to lie with one knee flexed up to 90 degrees. The patient lifts the thigh from the table while the examiner pushes the thigh raised towards the table. Compare bilateral muscle strength. The ICCS Ranged from 0.76-0.85 and from 0.75-0.83.⁵

4. **Psoas Major Strength Test**- The patient position is supine with one leg elevated, abducted and
foot rotated externally 45 degrees. The patient elevates the leg and examiner resists it and stabilises the opposite ASIS. Compare the muscle strength bilaterally. It has a inter examiner reliability of cohane k unweighted score (κ- 0.67).  

5. **Modified Schobers test:** It measures the amount of flexion in the lumbar. The position of the patient is on his back while the examiner is standing. A mark is made on the vertebral column at the level of PSIS. Mark 5 cm below it and 10 cm above it, then ask to touch the toes. Unless the rise in distance between the two fingers on the spine of the patient is less than 5 cm then this is indicative of restricting lumbar flexion or overly active erector spinae. The high values of Intraclass Correlation Coefficients (0.83 for flexion and 0.68 for extension) also indicated high reliability for between-days measurements.

6. **Modified Thomas test:** this test is for rectus femoris muscle Patient posture is likely to lie with knees bent to 90 degrees, the examiner asks patients to resist while pushing against the flexed knee. Compare the strength of the muscles bilateral. it is having interrater reliability (r =0.91-0.93; ICC= 0.89-0.92) 

7. **Transverse Abdominal Muscle**- The patient position is prone lying asks to pull in the stomach by increasing abdominal pressure stabilising the lumbar spine.

8. **Active knee extension test:** It is used to measure the length of the hamstring muscle and the extent of active knee extension in the hip flexion role. The patient lies supine with and is advised to move his leg to full hip flexion with arms raising his forearm to the chest; the patient is advised to vigorously flex the knee from the starting position to the full tolerable stretch in the hamstring muscle. Measure the angle with the goniometer. This test has excellent interrater reliability with interclass correlation coefficient (ICC) values of 0.87 and 0.81, standard error of measurement (SEM) = 3.5 and 3.8 degrees.

9. **Pressure biofeedback unit:** A system used to test transversus abdominis. It is a simple instrument that records varying pressure in an air-filled pressure cell. This allows identification of body along with the spinal movements. This system functions as a stabiliser and can be used for activities focusing on joint protection and stabilization. This study found 0.47 [95 percent confidence interval (CI) 0.20 to 0.67] intraclass correlation coefficient (ICC) for inter-observer reliability, and 0.81 (95 percent CI 0.67 to 0.90) ICC for test-retest reliability.

**Study size:** 300

**Discussion**

Muscle dysfunction is one of the most significant risk factor of low back pain in the young population. Lower Crossed Syndrome (LCS) is a muscle imbalance that includes tightness of hip flexors, lower back muscles and abdominal weakness, gluteus maximus muscle; that alters the distribution of biomechanical force in lower back region and can lead to chronic low back pain. There is lack of literature which states the screening of lower cross syndrome in asymptomatic individuals. The present study will be conducted with the aim of screening the asymptomatic individuals suffering from lower cross syndrome.

In the pelvic cross syndrome originally suggested by Janda, the pelvis is more dorsal and this is associated with imbalanced trunk muscle coactivation with more dominant activity found in the extensors termed as posterior pelvic cross syndrome. Conversely, pelvis is more anterior in the other large category and this is associated with a predominant tendency for more flexor activity, known as anterior pelvic cross syndrome.  

**Expected Results**

Lower cross syndrome was detected in the young individuals but no study has been done on asymptomatic individuals. The result would include data about whether the measures taken were effective for screening lower cross syndrome. Once the study result is complete, data will be analysed using paired t-test and will be presented in the form of research paper.

Unnatural Deaths in the Paediatric Age Group in a Tertiary Hospital at Bangalore: An Autopsy Study

R K Varma¹, P Shruthi², S R Jagannath ³

¹Assistant Professor, Department of Forensic Medicine and Toxicology, Gitam Institute of Medical Sciences and Research, Vizag, ²Associate Professor, Department of Forensic Medicine and Toxicology, Saveetha Medical College, Thandalam, Chennai, Tamilnadu, ³Professor and Head, Department of Forensic Medicine and Toxicology, Kempegowda Institute of Medical Science, Bengaluru, Karnataka

Abstract

Background and Aim: During transition from childhood to adulthood, people are exposed to various hazards having potentiality lead to unnatural deaths by distorting physical, mental and social wellbeing. Studying pattern of unnatural deaths helps stakeholders to formulate policies for prevention of loss of important human resource.

Materials and Methods: A descriptive study with purposive sampling was conducted at KIMS Hospital and Research Centre, Bangalore from 2013 to 2015 wherein the data using pre-tested structured proforma was collected from autopsies of unnatural deaths among pediatric age group (0-18 years). The details pertaining to the Socio demographic characteristics, pattern of injuries and cause of death was ascertained from the police reports, reliable attendants of the deceased, histopathological /hospital records and postmortem reports. The data obtained from this study was analyzed statistically by presenting the data in the form of appropriate tables and graphs, computing the descriptive statistics like mean, median, standard deviation and percentages.

Results: Out of 832 cases, 703 (84.5%) were unnatural deaths, amongst which 8.8% cases were of paediatrics of age group. In that (82.2%) 51 cases belonged to 12-18 years, followed by 5-12 years and preschool age (3-5years) each with 4 cases (6.5%), 3 cases (4.8%) are of toddlers (1-3) years and no cases were reported among infants. Male preponderance was seen 35 cases (56%). Maximum number of deaths occurred during evening times i.e., 30 cases (48.39%). In the present study, maximum number of victims were from social class II i.e., 38 cases and least among social class I with only 1 case. Out of 62 cases , 37 cases (60%) were intentional deaths (1 case (3%) is homicidal and 36 cases (97%) were suicidal) and 25 cases (40%) were unintentional deaths. In the present study out of 36 suicidal cases, Hanging was the most preferred method used to commit suicide with 26 cases (42%), followed by burns and drowning with 1 (8%) case each. Out 62 cases, only 12 (19%) cases were treated before death and remaining 50 (81%) were not treated prior to death.

Conclusion: This study indicates that there is an immense responsibility for the parents and caregivers in supervising their children. The public health burden of all unnatural deaths needs to be estimated to provide a rational basis for policy decisions to implement necessary interventions.

Key Words: Unnatural deaths, Paediatric age group (0-18years), Suicide.

Introduction

It’s been aptly said that “Child is the father of Man” and indeed the health status of a community is reflected by the pediatric age group (0 to 18 years) in a given area. It is estimated that all over the world, more than 26,000 children under the age of five mostly from developing
countries die every day.\(^1\) India contributes one-sixth of the world’s population, 29.5% of which belongs to the 0–14 year age group.\(^2\)

A child of today is subjected to so much of stress starting from strained relationship between parents resulting in broken homes, expectations to perform better at the academic arena, comparison between children, sense of self neglect etc. The pattern of deaths among paediatric age group has changed from infections towards social etiologies during the last decades. Injury and violence are major killers of children because of the effects on social, physiological, economic and medical issues throughout the world, responsible for deaths in children and young people under the age of 18 years each year, causing public health issues.\(^3\)

Keeping this in mind, a study was undertaken with the objectives to describe the demographic profile, to assess the proportion and causative factors of unnatural deaths in paediatric age group. The rationale of determining the features and pattern of medico legal deaths in childhood will contribute to the establishment of a database for the formulation of national and international policies helping to lower the mortality rate in the paediatric age group.

Methodology

Using pre-tested structured proforma, data were collected from all cases of unnatural deaths among paediatric age group (0-18 years) brought to KIMS Hospital and Research Centre, Bangalore for a period of 18 months for autopsy. The details pertaining to the demographic characteristics, manner, time and place of death were ascertained from the investigating police officers, police reports and reliable attendants of the deceased. The data obtained from this study was analyzed statistically by presenting the data in the form of appropriate tables and graphs, computing the descriptive statistics like mean, median, standard deviation and percentages.

Results

During the period (November 2013 to April 2015), 832 cases were brought for post mortem examination; out of which 703 (84.5%) deaths were due unnatural causes. Out of 703 cases of unnatural deaths, 62 (8.8%) deaths were of 0-18 years age group. Out of 62 cases, Male:Female ratio was found to be 1.29:1. Age wise distribution showed that 3 cases (4.8%) belonged to 1-3 years (Toddler), 4 (6.5%) cases were of the age group 3-5 years (Pre-school), 4 (6.5%) were of 5-12 years (School age) and 51 (82.2%) were of 12-18 years (teen). (Fig 1)

The maximum number of unnatural deaths occurred during evening times i.e. 30 cases (48.39%) and the least number of cases were recorded between 12 am to 6AM (3 cases, 4.84%). (Table 1)

As per the Modified Kuppuswamy scale (update for February 2019), this study of 62 cases had maximum victims from social class II i.e., 38 (61%) cases and least among social class I i.e., 1 case which accounted for 2%. (Fig – 2)

Amongst the 62 unnatural deaths in paediatrics, 37 (60%) cases were intentional and 25 (40%) cases were unintentional. 1 case of intentional death (3%) was homicidal and 36 cases (97%) were suicidal in nature. Homicidal deaths was of a male victim, while in case of suicidal deaths 14 victims were males and 22 were females.

Hanging was the most common manner of death with 26 cases (42%) (12 cases males and 14 cases of females) out of 62 cases, followed by 10 cases (15%) of R.T.A (8 cases of males and 2 cases of females) and the least common were seen in electrocution and strangulation, accounting to 1 male victim case each (2%). (Table 2)

Out of 36 suicidal cases, Hanging was found to be the most preferred method used (72%), followed by poisoning (22%), burns and drowning accounting to 3% of cases each. Depression followed by failure in studies, family problems, love failure and ill health issues were found to be the reason for committing suicide. 1/4th of them had previously attempted suicide.

Out of 25 cases of unintentional deaths, 40% cases were due to road traffic accidents followed by drowning and fall from height (24% each) with the least being due to electrical shock (4%). Out of 62 cases, more than 3/4th of them did not receive treatment prior to death (Table 1)

**Discussion**

During the 18 months of study, only 62 cases of unnatural deaths among paediatric age group 0-18 years were studied. It represents only a part of problem of unnatural deaths among paediatric age group in Bengaluru as such cases are distributed in different mortuaries catering to different regions/areas of Bengaluru.

Among 62 cases of unnatural deaths in paediatric age group more deaths were seen in the age group of 12-18 years (Teens) i.e. 51 (82.2%) cases. The mean age of the males was 16.0 years while that of the females was 14.8 years in Ohene’s and Meel’s report. Unnatural deaths increase with age, since there is more violence expected in older children. This could be attributed to mental instability and hormonal influence. Proper parental guidance and suitable moral support should be provided for the same.

35 (48.2%) cases were males and 27 (51.8%) cases were females. The male-to-female ratio was 2.1:1, as recorded in Sally’s report. This might be because males are more prone active, curious and adventurous by nature.

Majority of unnatural deaths in the study occurred during evening (48.39%) and mid morning (29.03%). There must be an immense responsibility for the parents and caregivers in supervising this age group. Most of the victims were from Middle class in 85% of cases and least among Upper class i.e. 2%. An administrative policy of the country thereby plays a vital role in mortality and morbidity rates. Financial security of the weaker sections should be enhanced. 60% (37 cases) of the cases were intentional and 40% (25 cases) were unintentional deaths. Among unintentional deaths, 97% (36 cases) were suicidal and 3% (1 case) was homicidal in nature. Suicide in the past decade is an increasing trend with the increasing population of India, according to the National Crime Records Bureau. According to recent study, the suicide rate per 100,000 population among females of 10-19 years was 11.98, while it was 11.9 per 100,000 population among males of the same age in Sri Lanka by 2011. Suicides tended to be more prevalent among older teenagers. At that stage of life, teenagers...
feel distressed about their grades, sex, future plans, and jobs. Children less than 14 years of age less frequently suffer from psychiatric disorders, family conflicts, or romantic disappointment. Moreover, children do not develop insight in the definitiveness of death before the age of 12 or 14 years.

Hanging was the most common method of suicide in Canada for child victims of suicide between the ages of 10-19 years. In the present study the most common reason for committing suicide is depression in 53% of cases. As reported in literature, psychological autopsy has a paramount importance on elucidating death investigation on children and adolescent suicide, regarding the analysis of the implied risk factors. In these cases, psychological autopsy was fundamental to understand the suicidal behaviour and to determine the manner of death. From the present study among unintentional deaths R.T.A is the most common cause accounting for 40% followed by Drowning and Fall from Height with 24% each. Traffic crashes are the leading health threat to children in many countries.

This may be due to the increased involvement of males in outdoor business and increased usage of vehicles by males. Alcohol abuse may be another factor which could be associated.

Conclusion

Unnatural dying is abrupt, and traumatic. Violence, Violation and Volition are its unique dimensions. Unnatural deaths among paediatrics are predictable and preventable. Education and employing effective strategies has a role to play in prevention, especially when it is paired with technology and legislation. If not preventable, prompt and immediate care should be provided in order to save the life of the victim.

Estimation of Time Since Death from Na\(^+\) Ion Concentration in CSF

Rajesh S. Chintalwar\(^1\), Anurag Kesarwani\(^2\), Shailendra G. Dhawane\(^3\)

\(^1\)Assistant Professor, Department of Forensic Medicine and Toxicology, Government Medical College, Shahdol, Madhya Pradesh, \(^2\)Department of Biochemistry, Government Medical College, Shahdol, Madhya Pradesh, \(^3\)Professor, Department of Forensic Medicine and Toxicology, Government Medical college, Nagpur

Abstract

In the present study 100 medico legal cases examined for Na\(^+\) ion concentration in CSF (cerebrospinal fluid) at different postmortem interval in the department of Forensic Medicine Indira Gandhi Medical College, Nagpur. Analysis revealed that there is decrease in sodium ion concentration with PMI, and shows negative coefficient correlation r= -0.721. (p<0.001), the least square regression equation is found to be \(y = -1.027x + 138.7\), where \(y\)= sodium ion concentration (independent variable) and \(x\)= time since death (dependent variable). The sodium ion concentration in CSF decreases after death and it is statistically significant but individual variation is such that we can’t accurately calculate postmortem interval from sodium ion concentration.

Key Words: Na\(^+\) ion concentration, time since death, postmortem interval (PMI)

Introduction

Time since death that is the interval between death and the time of post-mortem examination also called as “Post-mortem interval”. It provides a clue to the investigating officer to institute suitable enquiries to apprehend the persons likely to be responsible for the crime and to eliminate the innocent ones.\(^1\) As per earlier study it was concluded that the sodium in CSF decreases with increasing post-mortem interval and decrease is not significant and hence cannot be utilize precisely to estimate post-mortem interval.\(^6\)

Therefore an attempt has been made with optimistic hope and expectation by carrying out a study of estimation of time since death from Na\(^+\) ion concentration in CSF

Material and Methods

100 medico legal autopsies were selected where the exact time of death was known and the body had been kept in prevailing room temperature.

Inclusion criteria

1) Only those cases are included in the study whose time of death is known.

Exclusion criteria

1) Any cases of head injury, brain pathology, bleeding diathesis were excluded.

2) Decomposed bodies were excluded.

3) Cases of diabetes and if during postmortem examination kidney and liver shows gross pathological abnormality those cases were excluded.

The cranial cavity was opened in usual way and the vault will be removed to expose the brain and dura.
Dura is gently cut from the vault region of the brain both cerebral hemispheres are separated apart from midline by left hand to expose corpus callosum 10ml plastic disposable syringe with wide bore canula (18 gauge) is inserted on the posterior and depended part of corpus callosum for 1.5cm depth. The needle is directed posteriorly, downwards and slightly laterally in each hemisphere and cerebrospinal fluid was withdrawn and immediately centrifuged and analyzed for sodium ion on Dimension Xpand plus automatic analyzer (indirect ion selective method) after centrifugation, in the dept. of biochemistry IGGMC Nagpur.

Observation and Results

In the present study out of 100 cases 68 cases were males 32 cases were females, 37 cases were studied in summer, 38 cases were studied in rainy days, 25 cases were studied in winter. Environmental temperature ranges from 30 - 46°C in summer, 22 – 39°C in rainy days and 18 – 33°C in winter. Cause of death was poisoning in 24 cases, blunt trauma to chest in 11 cases, coronary artery disease in 16 cases, burns in 13 cases, hanging in 9 cases, snake bite in 1 case, septicaemia in 10 cases, drowning in 2 cases, peritonitis in 3 cases and 3 were bilateral pulmonary consolidation cases. The cases were grouped into four groups on the basis of postmortem interval (PMI) i.e. 0-6, >6-12, >12-18, >18-25. The list PMI observed was 2 hours and maximum was 25 hours.

The below table and graph is showing decrease in sodium ion concentration with PMI, and shows negative coefficient correlation $r=-0.721$. ($p<0.001$).

The mean value is 127.37mEq/L and value ranges from 103mEq/L to 144mEq/L with a standard deviation ±9.48 mEq/L. The sodium ion values showed a significant negative correlation coefficient $r = -0.721$ (i.e. Na$^+$ values decrease with time since death) which is statistically significant. ($p<0.001$)

The least square regression equation is found to be $y = -1.027x + 138.7$, where $y =$ sodium ion concentration (independent variable) and $x =$ time since death (dependent variable)
Table showing distribution of cases in different postmortem interval, with mean values and standard deviation, and range of values of Na⁺ ion in that postmortem interval

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

The 95% limits of confidence interval of CSF sodium ion, at 0-6 hour postmortem interval are 134.32±2.75 mEq/L, at >6-12 postmortem interval are 130.71±2.58 mEq/L, at >12-18 hour postmortem interval are 123.35±3.49 mEq/L, at >18-25 hour postmortem interval are 117.39±1.83 mEq/L.

**Discussion**

Nauman H.N. (1958) had analyzed 157 samples of postmortem CSF consisting of 131 males autopsied on the average 10.5 hours after death. He found that the postmortem CSF sodium ranges from 107 to 150 meq/L, with an average of 127 meq/L.²

Paulson G.W. and Stickney D. (1971) evaluated the postmortem CSF for sodium. In his 17 cases studied from postmortem interval of 1.5 hour to 17 hour, the value at six hour is 120 and 149 meq/L (2 cases); at 11 to 14 hours, the value was 138 and 129 meq/L (2 cases); and at 17 hour, it was 130 meq/L (1 case). He noted that there was fall of sodium in the postmortem period.³

Karkela J.T. (1993) studies the sodium in the postmortem CSF of 40 different adult cadavers. The samples were drawn at 2, 4, 10 and 24 hour after death and found mean values for Na⁺ 141 mmol/L at 2 hour, 139 mmol/L at 4 hour, 131 mmol/L at 10 hour and 122 at 24 hour.⁴

Bardale R. V. and Dongre A.P. (2004) studied CSF in 100 medicolegal cases. They noted that there was decrease of sodium concentration with increasing postmortem interval, at sixth hour of PMI, the values ranges between 88.3 to 210 meq/L with an average of 124.8 meq/L and SD 20.01. There was decrease of sodium at 12 hour PMI with range of 56.4 to 175.4 meq/L with a mean of 103.46 meq/L, and SD 18.12. By 18 hour after death, the value of sodium ranges from 42.1 to 152 meq/L with a mean of 85.60 meq/L, and SD 18.73.⁵

Yadav J et al (2007) Results revealed a significant correlation of sodium and potassium ion in CSF up to 25 hours of time since death. The study concludes that changes in CSF electrolytes are a significant parameter to estimate time since death.⁶

We found the mean value is 127.37 mEq/L and value ranges from 103 mEq/L to 144 mEq/L with a standard deviation ±9.48 mEq/L. The sodium values showed a significant negative correlation coefficient r = - 0.721 (i.e. Na⁺ values decrease with time since death) which is statistically significant. (p<0.001)

My findings are consistent with Yadav J et al, Bardale R. V and Dongre A.P., Karkela J.T., Paulson G.W. and Stickney D. and Nauman H.N.

**Conclusion**

The sodium ion concentration in CSF decreases after death and it is statistically significant but individual variation is such that we can’t calculate postmortem interval from sodium ion concentration.

Effect of Vachadi Ointment in the Management of Scabies - A Case Report

Rakesh Khatana¹, Renu Rathi²
¹PG Scholar, ²Prof., Department of Kaumarbhritya, Mahatma Gandhi Ayurved Collage Hospital & Research Centre, Salod Wardha (Maharashtra)

Abstract

Introduction: Skin disease has a high prevalence throughout the world. Scabies is contagious and can spread quickly through close physical contact so it is an acute communicable disease. It is highly prevalent in young children. The present study is aimed to show the effect of Vachadi ointment on scabies in children. Scabies is characterized by nocturnal itching, vesicular or pustule eruptions, with small red bumps and blisters. According to Ayurveda Scabies can be correlated to Pama. Pama is one of the eighteen types of Kushtha (Skin Disease) according to the Charak Samhita (Chikitsa-Sthana) which is caused by vitiation of Kapha and Pitta Dosha. Case Description: A 10 years old male patient brought with complaints of itching in between the fingers of both the hands, wrists and forearms since 10-12 days. On local examination, vesiculopustular lesions were present along with dry scaly patches over both the hands, wrists and forearms. Effect of the treatment was assessed on the basis of clearance of lesion and relief from itching. Conclusion: After intervention of the Vachadi ointment for 14th day, there was a marked improvement in symptoms like itching, scaling, and discharge. So, it can be said that Ayurveda has a better remedy for skin related complaints.

Key words:- Pama, Scabies, Communicable, Vachadi, Kushtha

Introduction

Skin is largest and most important organ of the body as it protects the internal organs from the harmful environmental influences. Many agents can affect the skin they may be varying in nature - physical (trauma, heat), chemical (strong acids) and biological (variety of organisms). The skin has several inbuilt mechanisms for interacting with the environmental agents and most of the times the skin is able to protect it from those agents. The protective ability however, may not always be able to deal with the environmental stimulus and this leads to the production of skin disease.¹ Skin diseases in Ayurveda are described as Kushtha roga. There are seven Mahakushta and eleven number of Shudra Kushtha roga are explained.² All Kushtha Roga are Tridoshaja in nature but according to dominancy of Dosha they can be classified according to Dosha. Pama Kushtha is one of the Shudra Roga which in Pitta-Kapha predominating.³ It is contagious and widely spreader disease throughout the world. Pama Kushtha characterized by many small Pitikas, Srava, Kandu, Toda and Daha that may be considered as scabies in contemporary science.⁴

Scabies is major public health problem with an estimated prevalence of 130 million cases worldwide. The prevalence varies from 0.35 to 46%.⁵ The highest rates are found in countries with hot, tropical climates, where infestation is endemic. Scabies is more prevalent in overcrowded communities with low socioeconomic conditions. The point prevalence in the general population of rural India is about 13%, In Maharashtra 81% of inmates of an orphanage in rural area,⁶ 72% of
cases are seen in the age group below 16 year. It may spread in a group of population within a short period of time due to close contact or skin to skin contact and contaminated clothes. Scabies, a common cause of itching is produced by infestation with the mite *Sarcoptes scabiei var hominis*. Poor hygienic condition and overcrowding, permitting close body contact favour the transmission of the disease. Mites of scabiei colonize the Horney layer of the human epidermis cause dermatitis. [8] *Acharaya Susruta* explained *Vachadi* Ointment in *Chikitsasthan* in the management of *Pama*. [9]

**Materials and Methods**

**Place:** *Kaumarbhritya* OPD of Mahatma Gandhi Ayurved College, Hospital & Research Centre, Salod (Wardha).

**Case Report:**

A 10 years old male patient brought with complaints of itching in between the fingers of both the hands, wrists and forearms, Itching intensifies during night time, since 10-12 days.

**On Examination:**

1. Papulo-vesicular lesions with discrete presentation and distributed bilaterally over hands, wrists & forearms.

2. Multiple erythematous papules, Round shaped with a well-defined border measuring from 0.1 to 0.2 cm in diameter, with no scales.

3. Multiple spherical vesicles with a size range measuring from 0.2 to 0.3 cm in diameter with erosion that has already healed and crusted.

**History of present illness:**

According to his Father, patient was asymptomatic 1-2 week back. But since then patient had developed few rashes in between the fingers and started itching. This itchiness started from his fingers first which widespread to his wrist, forearm within last 6-7 days. Furthermore, he said that the itchiness worsens at night and his sleep was disturbed by intense pruritus. History of pyrexia was denied. They had consulted to nearest doctor and taken treatment for the same and got no satisfactory result then patient came to Mahatma Gandhi Ayurveda college hospital & Research Centre, Salod Wardha.

**Past History:**

Not significant

**Family History:**

Previously, his elder brother had experienced the same complaint. Also, he had a history of sharing the same room and bed with his brother.

**Preparation of the Trial Drug:** The drugs will be prepared as per standard procedure mentioned in *Rasatarangini*; 

Vachadi Ointment will be prepared in Department of RSBK of Mahatma Gandhi Ayurved College, Hospital and Research Centre, Salod (H), Wardha.

**Flowchart Of preparation Vachadi Ointment**

Course powder of *Vacha, Daruharidra & Sarshap* will be taken in Equal proportion

16 times water will be added to these drugs and heated on Mandagni till it is reduced to ¼ quantity to prepare a Quath.

Decoction will be filtered in steel container & Sarsap Tail in 1/8 quantity will be added and again heated on Mandagni till attains Sneha Siddhi Lakhanas.

Tail will be filtered and will be kept in an air tight container.

To this processed oil Paraffin-wax will be added in a proportion of 1:5 and stirred continuously till an ointment like consistency is obtained.
The ointment will be stored in an air tight container and dispatched in tubes measuring 20 gm each.

Discussion

As per Ayurveda literatures, Pama Kushtha is Pitta-Kapha dominant Vyadhi and Kandu, Srava, Pidika etc. are the clinical feature. Vachadi Ointment having mainly Tikta, Kashaya Rasa, Ruksha, Laghu Guna, Sheeta Virya, Katu Vipaka hence they are Kapha-Pitta shamaka and acted as Vranaropaka, Shonitasthapaka, Kushthaghna. Externally application of Vachadi ointment for Shodhana (cleaning), Ropana (healing) of lesions, as well as Vranaropaka, Twachya property. Pathya-apathy and hygiene maintenance were also advised to patient. Child has followed the treatment protocol and Pathya-apathy properly and responded very well with treatment.

Conclusion

Hence it is concluded that external use of Vachadi ointment and proper hygiene maintenance are highly effective in the management of Scabies (Pama Kushtha).

IEC No: DMIMS/DU/IEC/2017-18/7245

**Inclusion Criterion:**

- Diagnosed cases of Pama Kushta, irrespective of caste, religion, sex or socio-economic status.
- Children between the age group of 3 to 15 years.

**Exclusion Criterion:**

- Patients suffering from any other systemic disorders such as Skin Tuberculosis, Leprosy etc.
- Kushtha other than Pama/scabies.
- Pama associated with immunodeficiency disorder such as HIV.
- Scabies with crust or hyperkeratosis and Secondary infection, Urticarial etc.

**Criteria for discontinuing or modifying allocated interventions:** Subject will be withdrawal from the study if any untoward incidence, features of drug sensitivity or any other disease or problem arises, the subject will be offered free treatment till the problem subsides

**Follow up period after treatment:** 14th day after treatment.

**Primary Outcomes:** Changes in the symptoms of Gridhrasi such as Kandu (Itching), Toda (Pain) and Daha (Burning).

**Secondary Outcomes:** To observe the changes Pitika (Eruption) and Srava (Discharge)

**Statistical analysis:** The data will be analysed by using paired t-test & Wilcoxon rank sum test.

**Time duration till follow up:** The patient will be followed up during treatment 21 days.

Follow up period – 3rd, 7th and 14th

**Time schedule of enrolment, interventions:** Diagnosed patients of Pama Kushta (Scabies) will be enrolled in the present study after fulfilling the inclusion criteria.

**Data management:** The data entry coding will be done by PI
Ethics and dissemination: Research ethics approval; approval from research ethics committee has taken no:- IEC No: DMIMS/DU/IEC/2017-18/7245

Consent or assent: The written assent will be taken from the patient before starting the study. During the study the confidentiality of each patient will be maintained.

Dissemination policy: The data will be disseminated in future clinical work and also paper publication.

Authorship eligibility guidelines and any intended use of professional writers

Informed consent materials: Model consent form and other related documentation will be given to participants and authorized informants with all the information.

Discussion

In the Pama there is predominance of Pitta and Kapha which leads to discolouration of skin like Shyava, Aruna and Shweta Varna Pidika associated with Pitta related symptoms like Daha, Toda and Kapha related like Kandu, Strava. The Vachadi ointment is mainly Tikta, Katu and Kashaya rasa predominant. All the drugs of Vachadi ointment are having Tikta and Katu Rasa which are having Aampachak, Raktaprasadaka, Kushtagha, Daha Prashamaka and Kaphahara properties so it is considered to be very much effective in the treatment of Pama Kushta. Laghu, Tikshna and Ruksha Guna subsides Kapha thereby increases Agni which helps in the removing Agnimidyaya and clears tiny Srotas by removing Aam. Laghu Guna of the compound helps in Lekhana and Poshana which has reduced the Pidika of Pama mainly. Tikta Kashya Rasa and Laghu Guna do the Lekhana Karma and Kapha alleviation too. Vachadi ointment by virtue of its natural properties alleviates Vata and reduces Kandu which is one of the main symptoms of Pama. Vachadi ointment has three drugs Vacha, Daruharidra and Sarshap which is indicated in Pama Kushta.

Expect Result

All the drugs have Antibacterial, Antiviral, Anti-inflammatory, Anti-allergic and Antimicrobial Activities. Vacha has wound healing and Anti-inflammatory properties. Daruharidra has properties of quickly healing wounds and has excellent drying quality which relieves moisture. Its paste applied externally can instantly relieve pain and inflammation. Daruharidra applied externally can relieve skin diseases and itching.

Conclusion

Pama in Modern parlance has similarity with the skin disease Scabies. Pama being Kshudra Kushta has Kapha-Pitta dominance with its involvement of Tridosha which can be evident by observing its signs and symptoms. The drug will be shown evidence to be a safe preparation in paediatric practice. The drug will be well accepted by children due to external application.

Palmar Dermatoglyphics and Idiopathic Epilepsy – A Systematic Review

Rashmi C Goshi
 Assistant Professor, Department of Anatomy, JSSMC, Mysuru

Abstract
Dermatoglyphics is the science which deals with the study of dermal ridge configuration on the digits, palms and soles. Etymologically this term is harmonious blend of two words Derma – skin; Glyphe – carve. It gives the impression that something has been carved out of the skin. The entire human body is clothed with the skin which happens to be the largest and most important organ of the body. However, the skin on the ventral sides of the hands and the plantar sides of feet is exclusively designed and is corrugated with the ridges and configurations which are functionally useful as they help in the grasping without which the objects would easily slip away from the hands. Dermatoglyphic traits are genetically determined. Dermatoglyphic abnormalities are due to genetic or other factors that express their effect before the end of 5th month of foetal development. The permanency of finger patterns, the extreme variability from one individual to the other and easy analysis are some of the reasons for its wide application in a variety of conditions. Abnormality in the genetic configurations of parents is inherited by children and is reflected in the dermatoglyphic pattern. Hence dermatoglyphic study proves to be a very useful, easily applicable, inexpensive, indispensable tool as an indicator in the diagnosis of hereditary diseases in patients. The etiology of the epilepsies allows a classification of syndrome features into two groups – idiopathic or cryptogenic epilepsy, which has isolated primary symptoms without apparent cause and is probably hereditary and finger print configurations are inherited with an embryonic origin common to nervous system. Their attractions indicate pleiotropic effects of the genotype responsible for enaphalographic irregularity and convulsive seizures.

Key words: Dermatoglyphics, Epilepsy, Finger prints.

Literature
Over the past 150 years, dermatoglyphics has been a useful tool in understanding basic questions in biology, medicine, genetics and evolution, in addition to being the best and most widely used method for personal identification.4 History of Dermatoglyphics. The scientific study of papillary ridges of hands and feet is credited as the beginning with the work of Joannes Evangelista Purkinje in 1823. William Herschel (1858) was the first to experiment with fingerprints in India. He noticed the use of thumb prints as a form of signature amongst illiterate Indians and clearly established the fact that fingerprints did not change their form over time. Sir Francis Galton (1892) published the book “Finger Prints” and in doing so, significantly advanced the science of finger print identification. He demonstrated the epidermal ridge configurations did not change throughout postnatal life. He divided fingertip patterns into three groups Arches, loops and whorls. Sir Edward Henry (1893) established the modern era of finger print identification. Morris Hawthorne Wilder (1902) pioneered comprehensive studies on methodology, inheritance and racial variation of palmar and plantar papillary ridge patterns, as well as fingerprints. Cummins and Midlo (1926) were the first to coin the term Dermatoglyphics. The main thrust of their research was on Down’s syndrome and the characteristic hand formations. Charles Midlo MD (1929) together with

DOI Number: 10.37506/ijfmt.v15i1.13420
others published “Fingerprints of palms and soles”, a bible in the field of dermatoglyphics. Cummins (1935) proposed, that direction of epidermal edges was determined by growth forces and contour of volar skin at the time of ridge formation. Henry (1937) limited the designation of the term ‘whorl’ to those configurations having ridges that actually encircle a core. He named more complex patterns as ‘composite’. Penzose LS (1945) conducted dermatoglyphic investigations of his research into Down’s syndrome and other congenital medical disorders. Galton Center (1965) contributed to the development of dermatoglyphics and formulated the measurement to establish the position of displaced axial tri radius in terms of atd angle, as well as establishing the inheritance of its position in the palm. Sarah Holt (1968) published the book “The genetics of dermal edges” and summarized the statistical distributions of dermatoglyphic patterns in both normal and congenitally affected individuals. Hirsch and J.V. Schweichel (1973) emphasized that the neuroepithelium plays an important part in the development of dermatoglyphic patterns. Schaumann and Alter (1976) published a book “Dermatoglyphic in medical disorders” which summarizes the findings of dermatoglyphic patterns associated with congenital defects and significant markers of prenatal events. Babler (1987) reported that there is a relationship between the volar pad shape and the epidermal ridge configuration. He also suggested the association between the shape of the distal phalanx and the pattern type. Dr. Alexander Rodewald (2001) diagnosed many congenital abnormalities with 90% accuracy from the features of the hands. Dr. Stovens(2003), claims to diagnose schizophrenia and leukemia with 90% accuracy from the patterns on the hands alone. Cummins (1936) noted the significance of pad regression and initiation of epidermal ridge differentiation. In addition, recent embryologic studies have suggested that plantar, palmar and digital creases develop concurrently with volar pads[12,13] rather than as a consequence of early flexion movements. Development of epidermal ridges: Epidermal ridge morphogenesis has been reported by Kolliper. The critical period of primary ridge differentiation is between 11 and 17 weeks. This finding has been confirmed by Blechschmidt[25], Penrose and O’Hara[26], Okijima[27] and Babler. Epidermal ridges first appear as localized proliferations in the basal layer of the epidermis during the 10th week post fertilization. Primary ridges proliferate rapidly to keep pace with the increasing separation of adjacent ridges due to general growth of hand. This proliferation produces the branching and islands, the miniature. Hale[23] was able to show that the tendency of ridges to multiply was greatest during the period of maximum difference between the increase in surface area of hand and increase in ridge breadth. Primary ridges increase in width and penetrate deeper into the underlying dermis. Secondary ridges or furrow folds correspond to the furrow of surface ridge. Concomitant with secondary ridge formation is the termination of primary ridge formation. From 17 to 24 weeks, secondary ridges continue to proliferate and develop in a manner similar to that of primary ridges. At 24 weeks the epidermal ridge system has an adult morphology. Hirsch and Schweichel reported that ridge formation initiated along the laterodistal portion of the digit and proceeded in a proximomedial direction with the center of pad initially being free of ridges. Factors influencing ridge configuration: Current research suggests that genetic component of dermatoglyphic traits operates indirectly on ridge configuration through ontogenetic factors, eg: pad topography, growth rates and stress on the epidermis that influence ridge alignment. Epidermal ridge growth : From the initial appearance of primary ridges around 11 weeks, prenatal growth of primary ridges can be divided into 3 basic components – Width of the primary ridges Amount of penetration of the ridge into the dermis
3) Spacing or separation between adjacent primary ridges. Dermatoglyphic patterns form on finger pads prenatally and remain unchanged throughout the life. It can aid to the diagnosis of genetically and nongenetically determined diseases which cause distortion of patterns. Recently Penrose and O’Hara used electron microscopy to study the epidermal ridge development. Okijima and Miller reported the techniques to study surface ridges of the fetus. Personal identification:
Finger prints are constant and individualistic and can be the most reliable measure for personal identification. The secretions in the finger print contain residues and various chemicals and can be detected and used for forensic purpose and for criminal identification. It is important in medicolegal cases and disputed paternity positive identification using finger print can be established only if 16 – 20 points of similarity exist in the miniature. Concerning the distribution and degree of heritability of palmar main lines, it should be remembered that the differentiation of dermatoglyphics occurs during 3rd and 4th month of foetal life and that the lines remain constant after birth. Therefore except in size, the dermal configurations do not vary with age and are practically independent of environment effect.

Line A is considered to be an important indicator of the general direction of ridges coursing over a large area of palm (Wolt, Bsehane and Reinvein 1964). A-d ridge count has been used in pedigree studies. The mean count on left hand was significantly larger than on the right by approximately nine ridge (p<.01). This bilateral asymmetry of line A was evident in both sexes. (Cummins and Midlio 1961) Genes of additive effect ailing without dominance would be expected to give correlation coefficients of 0.5 for both parent child and sib-sib comparison (Fisher 1918). The theoretical correlation coefficient for child and midparent is 0.71 (Penrose 1949).

Calculation of the correlation coefficient between relatives for both the total finger ridge count (Holt 1961) and the a-b ridge count (Pons, 1964) have yielded values in close agreement with those expected on theoretical grounds for polymeric systems with genes of additive effect. The A-d ridge count appears to resemble the a-b and finger ridge count in that variation in this feature is largely under genetic control and subject to the influence of genes with additive effect. However conclusions are still contradictory. The results suggest a significant familial correlation (except spouse) indicating the involvement of familial component to the variation of dermatoglyphic traits. Segregation analysis reveals the transmission of genetic effects in the families which follows the Mendalian model. Major gene involvement with Mendalian expectation regarding finger dermatoglyphics is confirmed for all analyzed traits. However there is no evidence of significant support for major gene affect or environment effect on palmar a-b ridge count.

The history of dactylography as a fool proof tool for identity establishment has special significance in India – the first finger print bureau, established for medicolegal purpose in the world was at Calcutta. Today, digital dermatoglyphics form an indispensable and reliable tool for criminal investigation at internal level. Forensic scientists could extend their expertise and experience in dermatoglyphics to aid clinicians in medical diagnostic investigation.

Epilepsy is a chronic brain disturbance of varied and complex origin. Epileptic syndromes are classified mainly by brain location (generalized, partial or focal) and seizure type (clinic, tonic akinetic simple, absence or unconsciousness) which, together with electro-encephalographic studies, define the differential diagnostic (Delgado-Escueta et al 1982, Lancet 1990). The etiology of the epilepsies allows a classification of syndrome features into two groups – idiopathic or cryptogenic epilepsy, which has isolated primary symptoms without apparent cause and is probably hereditary. Second group is symptomatic epilepsy of genetic or acquired origin associated with other clinical features. Symptomatic epilepsy is due to cranial traumatism or as a result of infection, intoxication, brain tumours, hypoglycemia, drug abstinence etc. Jacksonian Seizures displayed only molar manifestation without impairment of consciousness and are typical among focal epilepsies. The genetic investigation carried out by Wenberg (1912) is of special historic interest because it was the first statistical segregational analysis of a human pathological condition. (McKusick 1992). Research on genetics of various epileptic syndromes has been reported and models designed for analysis of its familial segregation. (Anderson et al 1982) Isolated
idiopathic epilepsies with Mendelian inheritance do not encompass 5% of hereditary convulsive syndromes (Anderson and Hauser 1993) which are predominantly associated with chromosomal aberrations, metabolic disturbances and neurological deficiency. Other genetic molecular approaches involve neurotransmitters, inhibition of gamma amino butyric acid (GABA) synthesis in gerbils (Gerbillus) susceptible to epileptogenic factors (Fukuyama et al 1979) produced convulsive activity of similar origin to human epilepsy in the temporal lobe. (Osolsen et al 1984) Fere (1905) may have done the pioneer study on finger prints in epileptics. Many investigators reported several studies of finger prints in epileptics. Many investigators reported several studies of finger prints in individuals affected by non-specific types of epilepsy (Portius 1937; Brown and Paskind 1940; Katzenstein – Sutro 1945; Cherrill 1950; Alter 1966; Rosner et al 1967; Razavi 1975; Lopez and Lopez 1977; Karitono et al 1979; Schaumann and Mayerdorf 1979; Schaumann et al 1982; Cisarik et al 1985; Marinina and Drabktsina, 1988). Results revealed significant differences in loop frequencies in the left hand among male and female whole subjects. Considering separately each finger tip, the comparison between epileptic groups exhibited highly significant differences (p<0.01) in loop frequencies in right and in the left finger, the values being higher among generalized epileptics. The largest statistical differences were detected in finger III & I between epileptics and control. This suggests an epigenetic connection between embryonic regions I – III and normal physiology of CNS. Schaumann and Mayerdorf (1979) found an increase in radial loops in white adult patients with idiopathic epilepsy. In the non white group, the tented arch (At) pattern was completely absent in male generalized epilepsy and their control. Previous research among adult males with idiopathic epilepsy showed lower TRC values, although not significant at the 5% level of probability, comparatively to the controls (Schaumann and Mayerdorf 1979, Schaumann et al 1982). As in nearly all populations (Saldanha 1968), the TRC means were significantly higher (p<0.05) in male than in female groups for both epileptics and controls. The high evidence of arches on I & IV fingers, of raketoid loops on all fingers and especially IV & V, of the papillary ridges disposition as a dense and very dense network at thenar / I of the finalization of the line T’s direction of palm’s field 11 and 12 instead of 13 which contribute to enriching the clinical image of epilepsy’s dermatoglyphic diagnosis, at least for the patients living in Maldivian.

It has been opined that any epidermal ridge alteration in individuals prone to epilepsy may have a distinctive dermatoglyphic feature (Schaumann & Alter 1976). Idiopathic epilepsy of primary generalized epilepsy type is a tendency to have seizures when there is no structural abnormality in the brain. The primary cause could be genetic and a number of genes have been mapped Baulac et al (2001) and Brismar (2000). The dermatoglyphic traits, which presented a significant difference, were a-b ridge count, lateral deviation, palmar pattern and finger tip pattern. Mean values of a-b ridge count were more in epileptic patients, especially in left hand, than controls. The ratio of ulnar and radial deviations in control was 1:3 while in epileptics it was 1:5. Arch type of palmar patterns were showing a very significant difference between controls and cases. Frequency of loops was much more and vestiges were absolutely absent in cases. The frequency of Arch type of finger tip pattern was more in controls. A first and very important deviation at the level of affected people’s palm is a very strong reduction of models frequency in interdigital spaces IV & III. The strong decrease of distance a-b much below the average value was recorded in Romanian population. A higher frequency of cases was observed in which the papillary ridges from Thenar / I are arranged as a dense or very dense network.

Abnormalities of early development including genetic disorders. On literature review, it was noticed that hardly few studies have reported the association between dermatoglyphics and idiopathic epilepsy. Authors have found two significant variables in males diagnosed with idiopathic epilepsy. (i) decreased ‘a-b’ ridge count on both palms (p<0.1) and (ii) more frequent existence of transverse sulcus. The mean age of onset of epilepsy was 15.8 years in males and 13.9 years in females. 18.4% of the male patients and 10.2% of female patients were products of consanguineous marriage; 12% of male and 22% of female patients had family history of epilepsy. Various studies have shown different variations in the qualitative and quantitative parameters of palmar dermatoglyphics in Epilepsy patients.
Priya Ranganatha found no significant difference in the a-b ridge count between patients and controls in males and females. Difference in ‘atd’ angle between patients and controls in males and females was not found to be significant.\textsuperscript{19} A Study on finger tip patterns on comparison of epileptics with controls, in males, with hands combined, loops and arches were increased and whorls were decreased (\(p<0.05\)). In females, with hands combined, arches and whorls were increased and loops were decreased (\(p<0.03\)). Significant differences have not been observed for the patterns in hypothenar area / interdigital area and flexion creases.\textsuperscript{21} The authors distinguished correlation between dermatoglyphic features and form of epilepsy, type of course and pathogenic forms.\textsuperscript{22} Dermatoglyphics characteristic in epileptic patients varied in groups with different clinical characteristics (age at the onset of disease and the duration of the latter, the daily development of paroxysms at the same time, a tendency toward a stable course, the presence of psychic states and the resistance to therapy). Statistical task solving rules for diagnosing epilepsy in children were elaborated. The correct computer aided diagnosis on the basis of dermatoglyphic examination was made in 70\% of epileptic patients.\textsuperscript{23} A dermatoglyphic study of adult Caucasian males with a confirmed diagnosis of epilepsy was carried out. A multivariant analysis was employed on an enlarged patient sample. Variables found to be significant were decreased a-b ridge count on both left and right palms (\(p<0.001\)). Tests of eigenvalues showed only one value to be significant and accounting for 71.8\% of the intergroup variation.\textsuperscript{24} The data are important for medical genetic consultation and provide information for the theory of genetic issues in epilepsy.\textsuperscript{25} Significant findings in qualitative analysis of male epileptic patients showed increase in frequency of radial loops on finger tips of right and left index fingers and decrease in frequency of whorls on right thumb, index, ring and left ring fingers. In female epileptics there was increase of inter-digital fourth pattern VIII in both hands. Significant findings in quantitative analysis of epileptic patients included increase of total finger ridge count in male and female epileptics.\textsuperscript{28} Authors reported a k289m mutation in GABAA receptor \(\gamma_2\)-subunit gene (GARG2) that segregates in a family with a phenotype closely related to GEFS+, an autosomal dominant disorder associating febrile seizures and generalized epilepsy previously linked to mutations in sodium channel genes, thus providing the first genetic evidence that a GABAA receptor is directly involved in human idiopathic epilepsy.\textsuperscript{29} The comparison of palmar pattern types revealed significant difference between symptomatic and controls for right second inter digital area and left hypothenar area. Digital pattern intensity index was higher in epileptics than controls.\textsuperscript{31} The significantly increased prevalence of dermatoglyphic abnormalities in epileptics and in their parents suggests a polygenic mode of inheritance. Thus the view that convulsions are inherited by a single dominant gene with incomplete penetrance needs to be reexamined.\textsuperscript{32}

**Conclusion**

One of the most important parameter of dermatoglyphics is the inheritance. Understanding of development of dermatoglyphic traits requires to view it as a living history of prenatal development. Hence it is important in the medicolegal cases of disputed paternity. It has very crucial role in the diagnosis of Monozygotic and dizygotic twins. Degree of affection of investigated epileptics is correlated with the presence in the palmar dermatoglyphics of significant variations.

Abstract

Introduction: The mortality rate of epileptic patients has increased despite advances in the treatment of epilepsy. Several studies have indicated that changes of micronutrient homeostasis led to seizures. The anticonvulsant valproic acid affects the intracellular concentration of micronutrients.

Objective: To compare the serum concentrations of micronutrients zinc and iron in paediatric patients with epilepsy before and after administration of valproic acid.

Method: A prospective cohort design study was conducted in children with epilepsy from July to December 2019 in the outpatient department of paediatric neurology, Dr. Soetomo Regional Public Hospital, Surabaya, Indonesia. Serum concentrations of micronutrients zinc and iron were measured using the colorimetric method. Statistical analysis used paired t-test with p<0.05 being considered significant.

Results: The study sample comprised 20 children with epilepsy. There were 13 (65%) males. Eight (40%) children were in the 1-5 year age group. Seizure type was generalised in 18 (90%) patients. The mean serum iron concentrations before and after valproic acid treatment were 23.9±16.8 µmol/L and 25.8±16.4 µmol/L respectively (p=0.700). The mean serum zinc concentrations before and after valproic acid treatment were 13±16.8 µmol/L and 26.8±15.4 µmol/L respectively (p=0.004).

Conclusions: There was a statistically significant increase in the mean serum zinc concentration after valproic acid treatment in children with epilepsy. There was however no statistically significant increase in the mean serum iron concentration after valproic acid treatment in children with epilepsy.

Key words: epilepsy, micronutrients iron and zinc, valproic acid, children.

Introduction

Globally, 50 million people are affected by epilepsy with more than half of the cases occurring in children¹.

Corresponding author:
Darto Saharso
Department of Child Health, Faculty of Medicine, Universitas Airlangga/ Dr. Soetomo General Hospital. Jl. Mayjen Prof. Dr. Moestopo No. 47, Airlangga, Surabaya, East Java, Indonesia

In Indonesia, there are 700.000-1.400.000 cases of epilepsy, with 70.000 new cases every year and about 40-50% of these are children². Valproic acid affects intracellular zinc concentration, the zinc transporter (ZnT1) playing a role in intracellular zinc homeostasis. Serum zinc concentration may decrease as a result of valproic acid, being affected by the dietary intake of zinc, stress, serum albumin concentration and the metabolic state of the patient³. An alteration of iron metabolism, consisting of an increase of non-transferrin bound iron (NTBI), occurred in 24 epileptic patients receiving valproic acid monotherapy⁴. This study was conducted
to observe the effect of anti-epileptic drug valproic acid on the serum concentrations of zinc and iron.

**Objectives**

To compare the serum concentrations of micronutrients zinc and iron in paediatric patients with epilepsy pre- and post-administration of valproic acid.

**Method**

A prospective cohort observational analytical study was conducted from July to December 2019 in children aged 18 years or less with newly diagnosed epilepsy in the Outpatient Department of Paediatric Neurology, Dr. Soetomo Regional Public Hospital, Surabaya, Indonesia, using valproic acid monotherapy. The characteristics of the study population (age, sex, seizure type, laboratory examination and electroencephalogram (EEG) were recorded. Serum concentrations of micronutrients iron and zinc were measured using the colorimetric method. Statistical analysis used paired t-test and p<0.05 was considered significant.

A written statement of agreement was obtained from the parents or guardians for the child’s participation in the study. Ethics Approval was obtained from Health Research Ethical Committee of Regional Public Hospital of Dr. Soetomo Surabaya before commencing the study.

**Results**

The study sample comprised 20 children. The basic characteristics of the study sample are shown in Table 1.

The mean serum iron concentration before treatment was 23.9 ± 16.8 µmol/L and the mean serum zinc concentration before treatment was 13 ±16.8 µmol/L. The mean serum iron concentration after valproic acid treatment was 25.8 ±16.4 µmol/L and the mean serum zinc concentration after valproic acid treatment was 26.8 ±15.4 µmol/L. The results of the analysis using paired t-test showed a significant difference between the mean serum concentrations of zinc before and after valproic acid treatment in patients with epilepsy (p = 0.004). However, there was no significant difference found between the mean serum concentrations of iron before and after valproic acid treatment in patients with epilepsy (p = 0.700).

The correlation between anaemia and serum iron and zinc levels after valproic acid therapy is shown in Table 3.

**Discussion**

In this study of epileptic children 65% were males. This was similar to the study by Serdaroglu et al (2004) where there was male predominance. In our study 40% were in the 1-5 year age group. Topbas et al (2012) also found most epileptics to be 1-5 years old. In our study 50% of patients were anaemic. Zareifar et al (2012), reported that haemoglobin concentration was significantly lower in children with epilepsy. In our study only 25% of patients had a family history of epilepsy. This is similar to the study by Omar et al (2016) where there was a family history of epilepsy in 25% cases. In our study 90% had generalised seizures. In the study by Andrianti et al (2016) generalised seizures were the predominant type. EEG examination is vital to confirm the clinical diagnosis of epilepsy, classification of epilepsy type, epileptogenic focus, treatment evaluation, and prognosis determination. However, the first EEG was normal in 55% of our cases. However, it should be remembered that the EEG was done when the patient was not in seizure (inter-ictal). In our study 35% of children with epilepsy were malnourished. In a study by Hardaningsih et al (2016) malnutrition status based on WLZ score <-2SD proved to be one of status epilepticus risk factors in children with seizure.

The zinc status in man is measured by the zinc concentration in plasma and serum. However, this is not a good indicator since less than 1% of the zinc total in the body is circulating in the plasma and also because the plasma zinc concentration is affected by hypoalbuminemia, haemoconcentration and acute phase response. Children in developing countries received inadequate zinc intake. A study by Soltani et al (2016), explained that zinc concentration decreased in children with epilepsy before starting administration of anti-epileptic drugs. In our study, children with epilepsy, prior to receiving valproate acid treatment, had low serum zinc concentrations in 10 (50%), normal serum zinc concentrations in 6 (30%) and high serum zinc concentrations in 4 (20%). The mean zinc concentration was 13±16.8 μmol/L.

A study conducted in man about valproate acid mechanism in zinc metabolism remains controversial. This study obtained a mean serum zinc concentration of 26.8 ±15.4 μmol/L after the administration of valproate acid. This indicated an increase of zinc concentration compared to that before the administration of valproate acid. High concentrations were obtained in 14 (70%) patients and normal concentrations in 6 (30%) patients. Two patients had the same high zinc serum concentrations before and after the administration of valproate acid. Analysis using paired t-test showed a significant difference of mean serum zinc concentration before and after administration of valproate acid. Analysis using paired t-test showed a significant difference of mean serum zinc concentration before and after administration of valproate acid. This study also found normal zinc serum concentration, as a result of 1% zinc serum concentration from all zinc of the body and did not describe the state...
of total zinc in the body. According to Verrotti et al. (2002), the effect of long term administration of valproic acid treatment in 36 patients with epilepsy before and after the 1 year-treatment showed that zinc concentration was normal.

In our study, children with epilepsy, before the administration of valproic acid had low serum iron concentrations in 6 (30%) and normal serum iron concentrations in 14 (70%) patients. The mean serum iron concentration in children with epilepsy before administration of valproic acid was 23.9 ± 16.8 µmol/L and mean serum iron concentration after administration of valproic acid was 25.8±16.4 µmol/L. This indicated an increase of iron serum concentration before and after the administration of valproic acid treatment. However, in this study, after the administration of valproic acid, serum iron concentration was normal in 12 patients, low in one patient and high in 7 patients. From the paired t-test, it was shown that there was no significant difference in mean serum iron concentrations before and after valproic acid treatment in patients with epilepsy (p = 0.700).

The serum iron level in each individual may vary 10-40% because of the change in iron absorption, bone marrow uptake on iron, or iron deposit expenditure. Besides, iron serum concentration is determined by iron absorption in the intestines, iron deposit, the speed of haemoglobin breakage and new haemoglobin formation.

The increase in serum iron concentration after valproic acid treatment resulted from change in iron homeostasis; consequently, the free iron in plasma or non-transferrin-bound (NTBI) iron began to accumulate in the blood and this resulted in increased serum iron concentration. The NTBI iron was finally inserted in the tissue by an unknown mechanism, which caused the impairment of cells and tissues. In most patients, excessive iron was a result of NTBI uptake from the circulation. Similar results were found in the study by Ounjaijean et al. (2011), stating that 24 patients with epilepsy receiving VPA monotherapy caused an iron metabolism change, therefore an increase was found in NTBI. In our study, mean serum iron concentration was normal after valproic acid treatment, similar to the study by Soltani et al. (2016), where serum iron concentration did not change.

Conclusions

Serum concentration of iron and zinc on pediatric patients with epilepsy increased after valproate acid treatment.

Conflict of Interest: The authors declare that there is no conflict of interest regarding this research.

Source of Funding: The authors received no specific grants from any funding agency in the public, commercial, or not-for-profit sectors.

Ethical Clearance: This study was approved by the Ethical Committee of Dr. Soetomo General Hospital, Surabaya No. 1547/KEPK/X/2019

Palashkshar ointment in the management of Abhyantar Gudarsh – An Ayurvedic Management Protocol

Ravikumar S Suryawanshi1, Kiran Khandare2

1Associate Professor & HOD, Department of Shalyatantra, R.K. University Ayurvedic College & Hospital, Rajkot-Bhavnagar Highway, Kasturbadham, Rajkot – 360020, Gujrat, India, 2Professor & HOD, Shalyatantra, Mahatma Gandhi Ayurved College Hospital and Research Centre. Salod (Hi) Wardha, Datta Meghe Institute of Medical Sciences, Wardha

Abstract

Background: Hemorrhoids or piles are a common ailment among adults. More than half of men and women aged 50 years and older will develop hemorrhoid symptoms during their lifetime. This disease Gudarsha comes under the heading of Mahagada, as it is Dirghakalanubandhi, Dushchikitsya in nature, Tridoshaj and involves the Marma and it is well known for the chronicity and difficult to treat. Aim & Objectives: To evaluate the effect of local application of Palash Kshar Ointment in Management of Abhyantar Gudrsha.

Methodology: The study is prospective randomized controlled clinical trial. Total 60 patients will be selected for this study, which will be further divided randomly into two groups. Each group consists of about 30 patients. In which group A, will be trial groups and group B will be control groups. Every patient will be observed at regular follow up. On 7th, 14th, 21th, 28th Day. Results– Results will be drawn from the observations of objective parameters. Conclusion – Conclusion of the study will be drawn on the basis of statistical data calculated from the collected data.

Keywords:- Internal Haemorrhoid, Abhyantar Gudarsh, Palashkshar Ointment, Palash Kshar.

Introduction & Rationale

According to Acharya Sushruta, due to Hetu (like Viruddha – Aahar, Adhyashana, Stree- Prasanga, Utkatasana, Prustha – yaan, Veg – Vidharan etc.) Dosha Prakop occurs. The main Hetu is Mandagni, which is mentioned as ‘Visheshto Mandagne’. These prakupeet Doshas alone or all together with or without Rakta, enters in the pradhan Dhamani (main channel), go downward and reach at Guda. By vitating the Gudavalies, Produces the Mansa-Prarohas are known as Arsha1. The management of abhyantar Gudarsha i.e. Internal haemorrhoid is mainly divided in four types:- Bheshaj Chikitsa (Medicinal Treatment), Ksharchikitsa, Agnikarma (Cauterisation), Shastrakarma (Surgery).

In application of Kshar, intervention of doctor is necessary and compulsory. To make the process convenient for patient to apply the Kshar at internal haemorrhoid and to avoid doctor’s intervention for application of Kshar, Concept of application of Kshar by patient himself is presumed and for this purpose the Ointment of Kshar is preferred.

Therapeutic treatment of haemorrhoids ranges from dietary and lifestyle modification to radical surgery, depending on degree and severity of symptoms.2,3 The primary objective of most topical treatment aims to control the symptoms rather than to cure the disease. The number of topical preparations contains various ingredients such as local anaesthesia, corticosteroids, antibiotics and anti-inflammatory drugs.4 No radical topical is available. Hence radical non surgical treatment
form of topical ointment is need of time.

Although effective but traditional Pratisarniya Ksharkarma is more complex and tedious process. So modification in it is necessary. Kshar ointment is modification of Kshar Pratisaran. Previous study with Yava Kshar ointment was done. Siktha tail is previously used as a base for Kshar ointment preparation is proven safe and effective as a base. This showed encouraging results. But Yava Kshar is difficult to prepare and also expensive. Palash kshar is used as Pratisarniya Kshar at many places and is very effective. Hence Palash Kshar is used in current study in place of Yava Kshar. Palash Kshar ointment which is an ointment of Palash Kshar with base Siktha taila is modified technique for Ksharkarma which will be used in current study.

**Purpose of the study:-**

1. Number of patients for per rectal bleeding secondary to internal haemorrhoids are more. Topical ointment as a radical treatment is not available hence its complete study is necessary and feasible.

2. Palash kshar is used from years as a Pratisarniya kshar for management of internal haemorrhoids. Hence it is ethical to use Palash kshar Ointment in the management of internal haemorrhoids.

3. In application of kshar, intervention of doctor is necessary and compulsory. To make the process convenient for patient to apply the Kshar at internal haemorrhoid and to avoid doctor’s intervention for application of kshara, concept of application of Kshar by patient himself is presumed and for this purpose the Ointment of Kshar is preferred.

4. Haemorrhoid is disease associated with per rectal bleeding which is one of major reason for anaemia and ultimately blood transfusion. Many patients refuse for surgery due to their personal reasons and wants conservative management. So interest is developed in radical management of internal haemorrhoids using local application of Kshar ointment

**Aim –**

To study effect of Palash Kshar Ointment in management of Abhyantar Arsha.

**Research Question**

Whether Palashkshar ointment is effective in Abhyantar Arsha Chikitsa to reduce per rectal bleeding and size of internal haemorrhoids?

**Hypothesis**

Hypothesis of this PhD thesis will be -

*Palash Kshar* ointment applied locally at internal haemorrhoids once a day for 14 days is effective in reducing per rectal bleeding and degree of internal haemorrhoids.

**Hypothesis**

**H0** = *Palash Kshar* ointment applied locally at internal haemorrhoids once a day for 15 days is not effective in reducing per rectal bleeding and degree of internal haemorrhoids.

**H1** = *Palash Kshar* ointment applied locally at internal haemorrhoids once a day for 15 days is effective in reducing per rectal bleeding and degree of internal haemorrhoids.

Clinical Study

Figure 2 Flow diagram of Clinical Study

Methodology

1] Type of Study Design :-

Randomized open labelled controlled clinical study

2] Location of Study:

Clinical Study:- Patients will be randomly selected from the OPD of the Dept. of Shalya Tantra of M.G.A.C.H & R.C. Salod (Hirapur), Wardha. A written informed consent will be obtained by counseling the patients of Arsha (Internal Haemorrhoids) for participation in the study. The selection of method of patient will be Lottery method of Simple Random Sampling.

Drugs:- Drug Name:- Palash (Butea Monosperma)

Part used - The leaves, Flowers, Seeds, gum and stem. The parts will be collected in their respective Dravya-Grahan Kaal. The trial drugs will be collected from the local area and certified by Foundation for Revitalisation of Local Health Traditions, Banglore (FRLHT) and the Standardisation of Palashakshara will be done in Pharmacy of the Institute of M.G.A.C.H & R.C. Salod (Hirapur), Wardha.
3] **Duration of Study:** In the schedule of Ph.D course. (3 year)

4] **Plan of study:**

A) **Kshar ointment**

1) Preparation of ointment base *Siktha Taila* 7

2) Preparation of Ointment.

   a. Preparation of *Palash Kshar* Ointment base *Siktha taila* i.e. *Palash Kshar* 1 part and *Siktha taila* 5 part.

**Methodology**

The study is prospective randomized controlled clinical trial. Total 60 patients will be selected for this study, which will be further divided randomly into two groups. Each group consists of about 30 patients. In which group A, will be trial groups and group B will be control groups.

**Selection criteria for patients:**

- The patients having clinical symptoms of internal hemorrhoids will be included in study irrespective of sex, religion, diet habit.
- Patients having age between 21 years to 70 years.
- The patients of IInd and IIIrd degree internal haemorrhoids will be included in this study.

**Rejection Criteria for patients:**

- The patients of piles having previous history of haemorrhoidectomy.
- Pregnant woman will not include in this study.
- Patients taking other treatment from any pathya for the same problem during clinical trial.
- Patients who are suspected of serious systemic disease i.e. DM, TB, malignancy, Syphilis or having portal obstruction
- Patients Suspected of carcinoma of rectum, proctalgiafugax, chron’s disease, fistula in ano & where it is contraindicated
- Patients with severe anaemia i.e haemoglobin less than 5%

**Withdrawal Criteria for patients:**

- The patients not following protocol of study.
- Patients requiring emergency treatment or surgical treatment or other treatment
- Patients not ready to continue treatment.

**Treatment allowed for patients:**

- Patients requiring treatment for hypertension or other life saving activity
- Haematronics, Blood transfusion.
- Any short term treatment not more than 5 days for sudden onset disease like fever, which will not disturb protocol of study.

**Methodology**

**Group A : Study Group**

Local Application of *Palash Kshar* Ointment with Pathya

**Group B : Control Group**

*Palash Kshar Pratisaran* with Pathya

**Pathya for both Groups**

- Hot sitz bath twice a day
- Advice the patient to keep the local site hygienically clean.
- Laxative – Avipattikar Churna 2-6 gm at bedtime with lukewarm water (Dose will be adjusted as per requirement of patient. when constipation waill not be relieved dose may be increase).
- Dietary control will be advised.

**Treatment of subject**

**Period**

**Group A : Trial Group** – Once a daily for 14 days.

**Group B : Control Group** – Once a week for 4 weeks

**Dosage for both groups** – as required depending upon surface.

**Dosage schedule** – After defecation in morning once a day.

**Route of administration** – Topical (Locally on internal haemorrhoids)
Procedure for local application of Palash Kshar ointment:

Patient will be taken for local application after Hot sitz bath patient will be given lithotomy position i.e the patients is positioned supine comfortably with the knees flexed and abducted and buttocks projection well over the edge of table. The legs should be flexed at the hips and knees. Then local application at haemorrhoids will be applied. After that, a sterile pad kept at the anal verge to avoid soilage of clothes.

Procedure for local application of Palash Pratisarniya Kshar:

Patient will be taken for local application after Hot sitz bath patient will be given lithotomy position. The Kshar karma will be performed with the help of slit-type proctoscope under local anesthesia. Kshar will be applied on internal hemorrhoids one after the other. After application on each hemorroid, the applied Kshar will be cleansed with lemon juice after changes in colour approx one to three minute. Yashtimadhu ghruta is applied over haemorrhoids. After that, a sterile pad kept at the anal verge to avoid soillage of clothes.

Assessment –

Graduation of Internal Haemorrhoids (As per Goligher): -

I - Haemorrhoids projecting slightly in lumen of anal canal, when veins are congested at defecation.

II - Haemorrhoids prolapse out of the anus on straining, but return spontaneously to the anal canal when motion has been passed and the defection has ceased.

III - Haemorrhoids prolapse but don’t reduce spontaneously and remain prolapsed afterwards and have to be replaced digitally.

IV - Completely irreducible haemorrhoids, usually are long standing and acquire a component of skin.

P/R Bleeding grade:

I Grade – 0 to 5 drops

II Grade – 6 to 15 drops

III Grade – 16 and above drops

Discharge –

Severe - Changing sanitary pads or cotton pads minimum 2 times a day

Moderate - Changing of pads once a day only

Mild - No requirement of pads

Nil - Area is completely dry

Complication Assessment

To assess anal pain -

Severe - To relieve from pain, analgesic injections are required/Pain or discomfort dose not reduce after oral analgesics.

Moderate - To relieve from pain, oral analgesics are required.

Mild - Feeling discomfort within tolerable limit, no requirement of analgesic either orally or in other route.

Nil - No discomfort in any manner in the site, no analgesics.

Tenderness standard assessment:

Severe - Patient feeling pain by touching perianal area. Not possible to perform P/R examination.

Moderate - Little finger P/R can be done, patient feeling very much tolerable pain

Mild - Index finger P/R done with very much tolerable pain

Nil - Index finger insertion to anal canal without any pain or discomfort

Every patient will be observed at regular follow up. On 7th, 14th, 21st, 28th. For visual recording the regular photographs of selected patients from each group will be taken for observing the local changes at internal haemorrhoid.

Routine investigations of all patients and some specific investigations will be carried out as and when required.
A. Lab Investigations -

Laboratory Investigations will be carried out before including the patient’s under the study to rule out any other pathological conditions.

a. Routine Hematological Investigation –
   a. Complete Blood Count
   b. Random Blood Sugar

b. If Required:
   a. Urine Examination - Routine & Microscopic
   b. Stool Examination - Routine & Microscopic
   c. Biochemical Examination –
   d. Histopathological Investigation

Criteria for assessing the Result:

Completely Cured: Complete relief in all parameters

Improved: Improvement in 1 or 2 parameters

Uncured: When there was no improvement in any parameter.

Complication: When there was any complication due to hypersensitivity reaction to ointment (i.e. Itching, Severe pain, infection)

Observation

Maintained records & analyzed data collected after the study will be the source of observation & results drawn consequently will be discussed in the dissertation.

Statistical Analysis

Statistical Analysis will be done on observed results irrespective of sex, religion, socio-economic status, occupation, etc.

The confidence limit will be fixed at 95% and the level of significance will be at 5%. Paired and unpaired ‘t’ test will be applied for objective parameter and chi square test will be applied for subjective parameter. If required Mann Whitney U test may be applied for subjective parameter.

Discussion

After obtaining the analyzed data Discussion will be done according to Ayurvedic and Modern text will be done.

Response Evaluation on Single Common and Uncommon EGFR Mutation on First-Generation EGFR-TKI Therapy in NSCLC Patients

Rena Arusita Maranatha¹, Laksmi Wulandari², Gatot Soegiarto³

¹Department of Pulmonology and Respiratory Medicine, Faculty of Medicine, Universitas Airlangga-Dr. Soetomo General Academic Hospital, Surabaya 60286, Indonesia, ²Thoracic Oncology Division, Department of Pulmonology and Respiratory Medicine, Faculty of Medicine, Universitas Airlangga-Dr. Soetomo General Academic Hospital, Surabaya 60286, Indonesia, ³Clinical Immunology Division, Department of Internal Medicine, Faculty of Medicine, Universitas Airlangga-Dr. Soetomo General Academic Hospital, Surabaya 60286, Indonesia

Abstract

Objective: To compare the response of first-generation EGFR-TKI (epidermal growth factor receptor-tyrosine kinase inhibitors) in non-small cell lung cancer (NSCLC) patients with single common and uncommon EGFR mutation.

Methods: Patients were divided into two groups, the uncommon (exon 21 L861Q, exon 18 G719X, exon 18 delE709) and common EGFR mutation group (exon 19 deletion, exon 21 L858R). Health-related quality of life (HRQOL) using EuroQol EQ-5D® questionnaire, body weight, performance status (PS), Response Evaluation Criteria in Solid Tumors (RECIST) on chest CT, progression-free survival (PFS) and overall survival (OS) was recorded during TKI therapy.

Results: The value of HRQOL was stable and PS was constant in both groups, body weight was constant in uncommon group (42.1%) and increased in common group (44.1%; p=0.165). The uncommon group showed mostly progressive disease in RECIST (47.4%) while the common group showed mostly partial response (42.2%; p=0.007). PFS in the uncommon group was 4 (2.0-6.0) months and 7.0 (2.0-21.0) months in the common group (p=0.001). OS in the uncommon and common group were 4.00±1.71 months and 10.00±6.94 months (p<0.001), respectively.

Conclusion: NSCLC patients with common EGFR mutations showed a better response and survival rate compared to uncommon EGFR mutations on first-generation TKI therapy.

Keywords: NSCLC, EGFR mutation, tyrosine kinase inhibitor, uncommon, common.

Introduction

Lung cancer is a leading cause of cancer-related death worldwide. In 2018, more than 1.6 million individuals were diagnosed with lung cancer and five-year survival is roughly 17% for all stage1-2. There are substantial evolutions in the management of non-small cell lung cancer (NSCLC) in the most recent decade. Analysis of immunology and genomic tumor biomarker have now become a regular examination in NSCLC, notably adenocarcinoma. One of the gene alteration examinations that has been generally applied is the
epidermal growth factor receptor (EGFR) mutation. About 90% of all EGFR mutations are deletion of exon 19 deletion and point mutation L858R in exon 21. Meanwhile, less-common EGFR mutations, likewise called “uncommon”, “rare”, “nonclassical”, or “minor” are about 10% of all EGFR mutations. They might comprise of insertion at exon 20, point mutation at exon 18 or compound mutations².

EGFR tyrosine kinase inhibitors (TKI) is one of the significant discoveries in the treatment of lung cancer. Longer progression-free survival (PFS), a better quality of life and lighter drug side effects were seen in patients given first-generation EGFR-TKI compared to patients receiving standard chemotherapy. Most patients with EGFR mutations respond well to EGFR-TKI, yet a few patients don’t show the expected response³. These uncommon mutations are sensitive to first-generation EGFR-TKI in a lesser degree than common mutations.

A comprehension of the therapeutic response of various EGFR mutation to TKI is important in deciding a patient’s treatment. This encouraged the authors to observe the therapeutic response of patients with a single uncommon EGFR mutation after first-generation EGFR-TKI compared to common mutations in Indonesia.

**Methods**

Participant of this study were lung cancer patients who were treated at a tertiary hospital. Patients with stage III and IV NSCLC⁴, bearing EGFR mutation, had at least one measurable lesion (>10 mm on CT scan) were included. Patients who had incomplete initial and follow-up data, had previously received cytotoxic chemotherapy for NSCLC, had complex or TKI-resistant exon 20 T790M mutation were excluded.

This retrospective study was run from January 2016 to May 2019. The total sampling approach was done to obtain the number of participant in this study. Participants were divided into the common and uncommon mutations group. The common mutation group consisted of exon 19 deletion or exon 21 L858R and the uncommon group consisted of either exon 18 G719X, exon 18 delE790, or exon 21 L861Q.

The study procedure included collecting data from medical records of patients who received first-generation EGFR-TKI as first-line therapy. First-generation EGFR-TKIs available for use in Indonesia were Gefitinib 250 mg (Astra Zeneca Ltd, Surabaya, Indonesia) and Erlotinib 150 mg (Astellas Pharma Inc., Jakarta, Indonesia). Gefitinib or Erlotinib was taken orally, once daily. Information taken from medical records were the health-related quality of life (HRQOL), body weight, performance status (PS), and Response Evaluation Criteria in Solid Tumors (RECIST) of Chest CT. HRQOL was measured utilizing the EuroQol EQ-5D® questionnaire in Indonesian version. The questionnaire comprised of 5 simple questions, covering physical symptoms and other functional domains⁵. The EuroQol EQ-5D questionnaire in Indonesian version was declared valid and reliable to measure the HRQOL of lung cancer patients with α=80.84⁶. PS was measured by the World Health Organization (WHO) scale. Chest CT was interpreted with RECIST⁷ and the CT scan utilized was Hitachi type RH-6G-E31 series number 12G173J (Hitachi-Aloka Medical, Mitaka, Tokyo, Japan). PFS and overall survival (OS) were also observed.

The results of the study were presented in the form of mean±standard deviation (SD) or median (minimum-maximum) and percentage (%). The statistical analysis used was independent t-test or Mann Whitney test (p<0.05). Statistics analysis used IBM SPSS Statistics software version 23.0 (IBM Corp., Armonk, NY, USA).

**Results**

**Characteristics of Participant**

There were more male and smoking patients in the uncommon group (Table 1). Better initial performance status was seen in in the common group. Most of the EGFR mutations in the uncommon group and common group were exon 21 L861Q (52.6%) and exon 19 deletions (64.7%; p<0.001), respectively. Most participant received Gefitinib EGFR-TKI therapy (76.9%).

**Response Evaluation in the Common and Uncommon Group**

Most patient in both groups had a constant score of HRQOL value and constant body weight after receiving EGFR-TKI therapy. Results of the CT Scan demonstrated that RECIST of most patient in the uncommon group
(47.4%) was progressive disease, while partial response was seen in most participant in the common group (42.2%; p=0.007; Table 2).

**Progression-Free Survival**

PFS could be observed in 11 and 82 participants of the uncommon and common group, respectively. The average PFS of participant common groups was longer in the uncommon group (Table 3).

**Overall Survival**

OS could be observed in 19 participant in the uncommon group and 82 out of 121 participant in the common group. The average OS of participant common groups was longer in the uncommon group (Table 3).

Discussions

Previous studies have revealed lesser responses in uncommon mutations compared to common mutations\(^3\). In this study, most participants in the common group experienced partial response (PR), while most participant in the uncommon group experienced progressive disease (PD). The discovery that affinity of the first generation TKI to the uncommon EGFR mutation protein was lower than the affinity to common EGFR mutation of protein might play a role in this response. Up to 6-14 times higher concentrations of gefitinib are needed to inhibit the growth of cells expressing mutations G719X and L861Q, respectively when compared to cells expressing L858R\(^8\). Another comparable study found that a higher concentration of first-generation TKI was needed to cause a 50% inhibition in uncommon mutations compared to common mutations\(^9\).

In the common group, a superior response rate was seen in exon 19 deletion compared to exon 21 L858R. This finding is consistent with the results of a meta-analysis of earlier studies\(^10\). Evidence that exon 19 deletion has higher autophosphorylation rates and higher sensitivity to first-generation TKI compared to exon 21 L858R mutations\(^11\) might clarify the distinction in response rate between the two common mutations. RECIST of other uncommon mutation subtypes are dominated by progressive disease (PD), akin to the findings of previous studies where the response rate of
the uncommon mutation subtype is remarkably low\textsuperscript{10,12}. However, on the other hand, a subtype of uncommon mutation that showed a better response rate than other mutation subtypes in this study were L861Q.

Participants in the uncommon group had a shorter PFS and OS median compared to the common group. PS and smoking status are independent predictors of OS in lung cancer. In the uncommon group, the proportion of patients with good PS was less and the extent of patients with smoking history was greater than the uncommon group. This characteristics explain the shorter survival rate seen in patients with uncommon mutations\textsuperscript{13}.

HRQOL, a patient-reported outcome (PRO), was also a significant endpoint in numerous NSCLC-related studies\textsuperscript{5,14} besides response rate and survival. A large portion of the patients in both groups showed the constant EQ-5D score, indicating no HRQOL difference was found between the two groups. These conditions may be influenced by several factors, for example, employment, education, marital status, and other comorbid diseases\textsuperscript{15,16}.

In contrast to cytotoxic chemotherapy, EGFR-TKI can be given to patients with any PS with fairly good therapeutic outcomes\textsuperscript{17}. In this study, the extent of patients with initial poor PS was more noteworthy in the uncommon group than the common group. However, the evaluation of the PS of the two groups did not show significant improvement after TKI therapy. The presence of confounding variables, for example, other comorbid diseases and presence of TKI adverse effects, may likewise influence the subsequent PS. Weight loss is said to be a prognostic factor of diminished survival, decreased quality of life and more symptoms in lung cancer patients\textsuperscript{18,19}.

The limitations of this study were the small number of patients in the uncommon mutation group and the retrospective character of the study. Some baseline characteristics, such as current smoking status, duration of smoking, body mass index, presence of comorbid diseases and adverse effects of TKI, could not be fully obtained from the medical records. Further research for uncommon mutations is expected to analyze good therapeutic modalities for each subtype.

**Conclusions**

Advanced NSCLC patients with common and uncommon EGFR mutations demonstrated no significant difference in HRQOL value after receiving first-generation TKI, as observed from the EQ-5D score, PS and body weight in the two groups. However, the response rate and survival of common mutations were significantly better compared to uncommon EGFR mutations on first-generation TKI therapy.

**Ethical Approval:** Ethical approval for the research was attained at the ethics committee of hospital (1007/KEPK/III/2019).

Abstract

Background: In biological system, cells are considered as dynamic and complex structures likewise cellular disintegration is also a complex process which occurs in a sequence. Therefore, these autolytic cellular changes have been investigated by forensic pathologist in an attempt to find markers that may assist in determining the time of death. In this study we attempt to analyse the efficacy of oral soft tissues specifically salivary gland in concluding the time since death.

Methodology: After obtaining approval from the human ethical committee, informed consent from the relative of the corpse and the investigating police officer, demographic information, as well as post mortem number was recorded. Submandibular Salivary Gland was collected for histopathological analysis during routine autopsy procedure. The specimens were fixed immediately in 10% formalin, processed, sectioned and stained with haematoxylin and eosin. The stained sections were evaluated under light microscope for histopathological changes.

Conclusion. The histopathological changes in the autopsied salivary gland tissue can be used as an adjuvant to estimate the post-mortem interval.

Keywords: autopsy, histopathology, oral tissue, post-mortem interval, salivary gland,

Introduction

Forensic investigation is deemed in case of person identification, to conclude the cause of death and to determine the time of death. Accomplishing the post-mortem interval (PMI) time is most challenging task in forensic investigation. There are variety of methods available to conclude the PMI such as measurement of body temperature (12-24hr), gross changes that occur after death (unreliable), (Loss of corneal reflex and changes in the eye, algor mortis, livor mortis, rigor mortis, decomposition and putrefactive changes), entomology, muscle action potential, biochemical analysis of food in stomach and intestine, electrolytes in blood, CSF, intraocular and synovial fluids, histological and histochemical study of degenerative changes in various organs and tissues, DNA quantification, analysis of organic compounds from the buried soil, radionucleotide assays. Histopathological aspect of the autopsied tissue can predict the vitality at the time of an event, the time interval since a finding was caused. In some instances histopathology can help in reconstructing an event thereby leading the investigating team, hence

Phone Number: 9840996439
E-mail address: dr.rajkumari@yahoo.com
histopathology had become an integral part in forensics medicine.\(^2\) Of all the merits it is highly reliable and economic.

Pradeep GL et al., quotes that microscopically evident cellular changes in the post mortem tissues can be appreciated only after 10 hours and so they recommend tissue examination at 10hrs interval while Gururaj N and Sivapathasundharam B noticed significant cellular changes at 24 hrs interval.\(^3\) Bardale R\(^4\) observed significant changes between 6-12hrs, Yadhav AB et al., acclaim 8 hrs interval,\(^5\) However in our study we have considered the minimal time limit to record the histopathological changes i.e., 8hrs interval. There are many studies conducted on the histological analysis of labial mucosa and gingiva but studies on salivary gland is least explored specifically related to post-mortem interval and in this study we analysed the histopathological changes of salivary gland to conclude the PMI.

### Materials and Methods

The study sample comprised of autopsied submandibular salivary gland tissue (n=12) obtained from the Department of Forensic Medicine, Chengalpattu Medical College and Hospital as per Helsinki Declaration (Institutional Ethics Committee Ref No. SBDCH/IEC/10/2018/20). Only those bodies that were not subjected to refrigeration during the period between death and arrival at the mortuary and the instances of death that occurred due to road traffic accident (RTA) without any injury to face and jaws involving the study site were included in our study while all other cases including RTA with injury and presence of pathological lesion to the facial region and the study site, freezed corpse were excluded from the study.

Demographic information and post mortem number was recorded for all the corpse included in the study. Autopsied submandibular salivary gland tissues were further investigated for histopathological alterations. The acquired specimens were immediately fixed in 10% formalin, followed by routine tissue processing and sectioning, later they were stained with haematoxylin and eosin. The stained sections marked with appropriate reference number were examined under a light microscope by two independent observers, the study details were blinded. The observed histopathological changes in the acini (cytoplasm and nucleus) as well the connective tissue were categorized according to the time interval.\(^4,5\)

### Results

The submandibular salivary gland comprising of both serous and mucous acini undergo degeneration at various intervals. Initially the serous acini undergo cellular alterations followed by mucous acini. The acinar architecture is distorted in mucous acini at prolonged time interval. The various histopathological changes are shown in figure 1 and 2. The observed histopathological changes in the mucous, serous acini and the connective tissue are given in table 1.

Figure 1. The acinar architecture is maintained in both serous as well as mucous acini at the initial stages but the acini exhibit cellular and nuclear changes.
Discussion

Histological assessment of autopsied tissue otherwise known as forensic histopathology clues about the vitality and the time interval of an event such as infliction of wound or aspiration of foreign material. Histopathology also concludes the cause of death,\textsuperscript{6} however the post-mortem interval assessment from the microscopic changes of oral tissues is at primitive stage.

Cellular changes in a naturally degenerating cell involves a complex sequence of events which is usually brought about by variety of enzymes. Tracking these cellular changes at post mortem may clue about many incidents that happened when the individual was alive.\textsuperscript{3}

There are few studies on post-mortem assessment of salivary gland of which one study was related to lymphocytic infiltration in labial salivary gland\textsuperscript{7} while the other was on histological assessment of the salivary gland to study the impact of hanging ligature.\textsuperscript{8} two were related to age assessment.\textsuperscript{9,10} Nery et al in 2010 studied rat sublingual salivary gland at various post mortem death intervals (0, 3, 6, 12, 24 hrs),\textsuperscript{11} Bardale R in 2013 studied human submandibular salivary gland to estimate the time since death.

In our study sample of mixed salivary gland (submandibular salivary gland), though there were remarkable cytoplasmic and nuclear changes in both serous and mucous acini they were not so critical to consider as a predictor for post-mortem interval assessment. However, the architectural changes are highly promising, where only the serous acini undergoes degenerative changes at the earlier stage itself. Loss of cell adhesion and cell wall disruption leads to clumping of nucleus to the centre of the acini both serous and mucous forming a filigree pattern in the later stage that is between 16-24hrs. Our study results are consistent with that of Bardale R and Nery et al.,\textsuperscript{4,11} where they have also reported that serous acini are faster to undergo

Figure 2. The acinar architecture is distorted in serous and mucous acini at the later stages, also there is homogenization of collagen fibres.
autolysis while mucous acini undergo degenerative changes close to 24 hrs.

**Conclusion**

Through this study, it is evident that histopathological changes in mixed salivary gland can aid in predicting post-mortem interval. Though there is environmental influence on the autolysis, different oral tissues from the same person have to be evaluated for exactness of the timing. Also there are very little scientific evidence regarding the utility of microscopic aspect of oral tissues in the prediction of post-mortem interval. The gap must be over-ruled by including forensic dentist and oral pathologist in routine autopsy procedure.

Influence of Melatonin in the Treatment of Experimental Enterobius Vermicularis Infection

Shaimaa A. Shlash¹, Noor M. Hasnawi², Hussein A. Kadhum³

¹Professor, Pharmacy College/Kufa University, ²Research Scholar / Pharmacy College / Al-kafeel University, ³Research Scholar / Dentistry College/ Al-kafeel University

Abstract

This study aims to realization the conceivable therapeutic of melatonin effects experimental against Enterobius vermicularis in rats. Implement this experiment during the period from August 2019 to January 2020. E.vermicularis infected with male wistar rats orally with dose 15mg/kg melatonin former of body weight for 30 day showed significantly reduction in the number of eggs and worms compared with rats orally with dose 15mg/kg melatonin accompanying and untreated rats for 30 day (P < 0.05).Histologically in intestine examined show increase numbers of leucocytes produce, necrosis significant scatter and reduction this parasite of tissue in rats treated with melatonin. This results show influence of melatonin in the control on Enterobiosis and suggestion that this drug usefulness in Enterobius vermicularis infection therapy.

Keyword: Eggs, Worms, Enterobius vermicularis, Melatonin, Former.

Introduction

Enterobius vermicularis is helminthes more common human parasitic Nematoda infected the bowel but the children worldwide may reach to 40 million infestations in USA and Europe especially school students (¹). Infection may be associated with poor hygiene or behavioral environments in family overcrowded and orphanages where transfer the eggs pinworm from person to another by finger polluted or via anus into mouth directly may transmit by eat contaminated food indirectly (²). The clinical symptoms occurs because the migration of the gravid female worst at night when lays eggs lead to excitement, lack sleep, appetite and weight decrease , vomiting and abdominal pain (³).

There are many drugs can be help in eliminated on pinworm else will not be beneficial, most common drug is mebendazole family these killed the adult worms only addition to increased resistance these drugs wherefore need for the development of new methods for control and enucleate of the parasitic disease (⁴).

Recently studies suggests that melatonin immune enhance function through presence of melatonin receptor in immune organs, Melatonin is biological processes recurring naturally hormone synthesized in most the pineal gland to blood of mammals also is synthesis in deferent cells, tissues and organs like lymphocytes, skin, eyes and gastrointestinal duct (⁵). Melatonin has been examination studies in parasitic, virus and bacterial infestations (⁶). Act the melatonin to promote antigen display, phagocytic activities and production of monocytes (⁷). Melatonin have important immune-modulatory effects e.g. Plasmodium that hepatocytes colonies and red blood cells will causes in death of malaria through that melatonin have precursors derived from the tryptophan will calcium release and modulate the cell cycle of P. falciparum (⁸). The melatonin treatment with Schistosoma mansoni act on decrease oxidative injury and increase permanence of hamster infected (⁹).
The goal of this study to specify influence of melatonin drug against *Enterobius vermicularis* by examined in rats.

**Materials and Methods**

**Collection eggs of *Enterobius vermicularis***:

Eggs were collected from infected children of school in Al-Najaf city, gathered in anus they suffer from anal itching by transparent adhesive tape (10), these eggs incubation at 36°C in wet flask for 5 days, most eggs were ivied released through vexation of the body, these eggs contained within larva notice circulation movement after three from incubated inside shell, some of them hatch naturally as expressed (11) kept unit used in the experiment.

**Preparation of Melatonin Solution**

Consider melatonin slightly soluble in water so used dimethyl sulfide and ethanol (DMSO/Germany) to dissolve. Take 2 mg / milliliter 99.9 DMSO-melatonin were prepared as stock solution (12).

**Preparation and Infection Animals**

90 male wistar rats were weight 100-110 g kept under light period 12h light and 12h dark where divided into three groups each group contain 30 rats were placed in plastic cages contain food and water with a floor furnished with sawdust, good ventilation and continuous cleaning of the cages,500 eggs number within movement larva examined under microscopic were counted from eggs sedimentation by slide chamber, group one were 30 rats infected with 500 egg of *E.vermicularis* only orally as control without drug, group two (Former) were 30 rats were inoculated melatonin pretreated for 7 days before the infection daily orally at dose of 15 mg / kg body weight where dissolved in distilled water then give oral 500 eggs for 30 day and group three (Accompanying) inoculated melatonin with eggs daily at dose of 15 mg / kg body weight give oral 500 eggs for 30 days. Three groups were examining the stool after 10, 20 and 30 days of infection by microscope.

**Histology Animals**

Rats were numbness with 2.5 pentobarbital and postmortem, intestine were reapers then inglorious 10 formaldehyde to make a histological section of the infection and treated, eosin-haematoxylin stain then examined by microscope in magnification of 100x (13).

**Statistical analysis**

Results were calculated by analyses data the one way by ANOVA test and statistical significance between groups analyses when (P < 0.05).

**Results**

As shown in table (1) , there is a significant reduce in *E.vermicularis* infection in rats treated with melatonin former at the dose of 15 mg/kg which were 1 and 0 for eggs and worms respectively, while there is a significant decrease in *E. vermicularis* infection in rats treated with melatonin accompanying at a dose of 15 mg/kg which were 21 and 10 for eggs and worms respectively, both after 30 day of treatment compared with control without treated were 390 and 495 for eggs and worms respectively after 30 day of infection. This may due to protective effect of melatonin is put off the appearance of disease, retard death and reduce the mortality rate.

Discussion

Enterobiosis is a human intestinal parasitic disease caused by pinworm infects a lot of people especially children causes symptoms e.g. anal itching, painful or difficult urination, irritation, insomnia repeated infection causes weakened immunity and may lead to death in the absence of treatment (14). Because of resistance to conventional drug and repeated infection, must search for alternative drugs and low toxicity (15). In the present study used melatonin drug is suggested that can therapeutic differ agent like immune enhance functions, antioxidant effect, bacterial, fungi viral, and parasites infections, shown significant reduce E. vermicularis with melatonin former when dose 15 mg/kg were 1 and 0 for eggs and worms respectively while significant decrease E. vermicularis with melatonin accompanying when dose 15 mg/kg were 21 and 10 for eggs and worms respectively, both after 30 day of treatment compared with control without treated were 390 and 495 for eggs and worms respectively after 30 day of infection, this indicates that give melatonin former enhances of the immune response, as in Table 1.

This may due to protective effect of melatonin is put off the appearance of disease, retard death and reduce the mortality rate (16), these study consistent with (17) that melatonin have control through of experimental the Trypanosoma cruzi infection and lead to reduce the parasitemia levels in rats. Another reported by (18) that melatonin drug cellular immunity activity by increased production lymphocyte in Toxoplasma gondii infected in rats. As in other study show reduce Leishmania infection to 40 in hamsters infected during the when serum melatonin being high compare to animals infected when melatonin level being low, this indicates that melatonin receptors plays an important role in leishmaniases treatment (19).

As shown in the current study, it have been seen in histological analysis for untreated section granuloma fashioning in the intestine, necrosis, adenoma and hemorrhage of the bowel (20).

There was a statistically increased numbers of leucocytes production which observed in both the accompanying and former melatonin treatment observation tissues necrosis scatter among regions and inflammatory cells sneak shrill comparison with E. vermicularis infection only (P < 0.05) may due to melatonin increased immune-modulatory activates and have ability on stimulate innate immune cells in positive attachment between melatonin and phagocytic efficacy with infected (21).

This study agreed with (22) showed that exogenously manage melatonin significant reduced the amoebic necrosis areas also increased of leukophagocytosis and number of the dead amoebae.

In other study Trypanosoma brucei parasite was given the melatonin infected rats make histological changes in pineal gland where caused in reduce plasma level which may due to release of inflammatory mediators and become not inroad cell (23).

The Observational Study of Reduction in Inflammatory Markers and Simultaneous Reduction in Joint Inflammation in Patients of Rheumatoid Arthritis Treated by Leech Therapy

Sheetal Asutkar¹, Kiran Khandare²

¹Professor, Dept of Shalyatantra, Shri Ayurveda College, Nagpur; ²Professor & Head, Dept of Shalyatantra, MGACH&RC, Salod, Wardha

Abstract

The sense of pain in arthritis carries the highest stigma among the sufferers as well as the treating physicians. It makes the life miserable for the patients along with the disability the disease rheumatoid arthritis causes, which can be correlated to Aamvata in Ayurveda. There are the conventional treatment options which are available in the form of shodhana and shanmana. Besides NSAIDs and corticosteroids in modern medicine rendering many side effects Ayurveda offers drugless healing art in the form of jaloukavacharan also known as leech therapy which is known for the anti-inflammatory and analgesic, anesthetic actions of leech salivary gland secretions. Hence, a protocol was designed for the doctoral research on “Study of inflammatory markers in patients of Rheumatoid Arthritis treated by leech therapy”, for the assessment of subjective parameters of pain, swelling, redness, tenderness, loss of function of joints assessed by standard criterion, and objective parameters like CRP and ESR before and after leech therapy for 10 sittings on alternate days. Observations were taken on day 0 and day 21, and follow up taken on day 30 and day 45. Statistical tests were applied which revealed significant results of anti-inflammatory effect of leech therapy on CRP (relative change 23.54%), with p value =0.0001, than ESR (relative change 10.30). Leech therapy was found to be having highly significant effect on pain score (relative change 57.62%), followed by tenderness score (relative change 72%) and followed by significant increase in walking effect (relative change 56.67%). There was statistically significant improvement in other subjective parameters of assessment like swelling on ankle (relative change by 11.73%), knee joint (relative change 10.29), redness (relative change 25%), walking effect (relative change 72%), rise in local temperature (relative change 61.90%) with p value 0.0001 with co-relatable clinical improvement.

Keywords- Leech Therapy, Inflammatory markers, Aamvata, Rheumatoid arthritis, analgesic, anesthetic

Introduction

The aim of all Medical Sciences is to provide better health to every human being so as to have a disease free life. With this aim the Indian System of Medicines with respective doctrines are trying their best for one goal i.e. “Conservation of Health by Natural Methods using Nature”. World Health organization is also trying it’s best to integrate all Medical systems to achieve the goal of “health for all”. Ayurveda medical science with its holistic approach has to play a vital role in this direction. “That’s the ideal medicine, which relieves from all kinds of miseries,” says Charaka.¹ Drug, is not necessarily be given orally. Ayurveda speaks about many modes of healing art, even surgery and para-surgical techniques. Among the para-surgical measures, Raktamokshana enjoys a place of pride since the dawn of medical history. Raktamokshana is a technical term employed to denote the para-surgical procedures to expel out the vitiated blood from selected areas of the body, by specific methods.²

The prevalence of RA is between 0.5 and 1% of adults in the developed world with between 5 and 50 per 100,000 people newly developing the condition each year.³ Of the variety of researches done in arthritis, most of them are done on subjective parameters like pain, swelling, tenderness, etc but not on objective and
specific parameters like Inflammatory markers (CRP and ESR) which carries a point value in ACR/EULAR scale. The ultimate goal of treatment is to reduce pain, decrease inflammation, and improve a person’s overall functioning but associated with them are the systemic side effects and prolonged use is not recommended. New classification criteria overruled the “old” ACR criteria of 1987 and are adapted for early RA diagnosis. The “new” classification criteria, jointly published by the American College of Rheumatology (ACR) and the European League against Rheumatism (EULAR) establish a point value between 0 and 10. In these, of the 10 points, 1 point is attributed to elevated ESR (erythrocyte sedimentation rate), and or elevated CRP value (C-reactive protein).5

Aetna Journal considers medicinal leech therapy experimental and investigational for treating cancer pain, epidermoid cysts, knee osteoarthritis, inadequate arterial supply or tissue ischemia, priapism, rheumatoid arthritis and other musculoskeletal diseases, and for all other indications because of insufficient evidence of its effectiveness.6

**Research gap analysis** - All the studies done till now are with some Ayurveda pharmacological intervention and Leech therapy and based on subjective parameters like Pain, Swelling etc. less emphasis was given on the objective parameters like Markers of Inflammation (CRP and ESR)

**Research question** - Can the study of inflammatory markers in patients of Rheumatoid Arthritis may be of utility to ascertain efficacy of Leech Therapy with reference to pain, inflammation and swelling?

**Aim** - Assessment of the efficacy of Leech Therapy in the patients of Aamvata (Rheumatoid Arthritis) by evaluation of reduction in Inflammatory Markers(CRP and ESR)

**Objectives** - 1) Pre and Post treatment evaluation of inflammation, CRP and ESR in RA patients.

2) To compare the anti-inflammatory effect(Pain and Swelling) of Leech Therapy Pre and Post treatment in patients of Rheumatoid Arthritis (wsr. Aamvata)

3) To compare the levels of CRP and ESR after leech therapy in RA patients

**Anticipated translator component**

1. A more easily available natural mode of management of RA (Aamvata) in the form of leech Therapy may be introduced in routine practice.

2. If the hypothesis is proven and Leech therapy is found to be effective in the reduction of levels of CRP and ESR , a non-pharmacological method which is used as Biotherapy may be introduced in reducing the markers of inflammation in patients of RA.

3. Similarly, leech therapy is a known para-surgical tool in the treatment of some peculiar features of arthritis like joint pain and restricted movement, hence, it can be validated in this study on RA, for re-establishment.

**Research Design:**

Nature of study: Experimental Study.

Study type: Open label single group experimental study

Commensurate Sample Size: Total 61 patients were selected, allocated into a single group by convenience sampling method.

**Variables** – CRP (evaluated by quantitative method), ESR (evaluated by quantitative method), Pain (VAS scale), Swelling (Metric method), Redness (present/Absent), Tenderness (Dr. Frank Painter’s scale), Rise in local temperature (Present/absent) were the variables and criteria of assessment in the patients of RA.

**Review of literature** - Amavata is one of the crippling diseases, claiming the maximum loss of human power. It is not only a disorder of locomotor system but is a systemic disease and is named after its chief pathogenic constituents i.e. Ama and Vata. Sandhishoola, Sandhishotha, Stabdhata and Sparshasahyata are salient features of the disease. The disease Amavata run a chronic course and Jadya, Sankocha, Anga vaikalya etc. are responsible for crippling of the patients in the long run.7

This disease can be correlated to Rheumatoid Arthritis that stands parallel to Amavata in its clinical features. RA is a chronic inflammatory arthropathy, which most commonly affects middle aged women. Despite intensive research, the aetiology of Rheumatoid Arthritis remains unknown. In spite of available
treatment options, it cripples the patient for the rest of his life. Moreover, it affects the younger and middle aged people, substantially hampering the economy and affecting the productivity of the society and subsequently of the Nation. Thus, the disease has great challenge to the Clinicians and Researchers.8

According to the symptomatology Amavata is very similar to rheumatoid arthritis, a disease of unknown aetiology. So many hypotheses have been put forward to explain its aetiology but still the research is going on. Nowadays theories of autoimmune mechanism, genetic susceptibility and free radicals are most commonly incriminated role in etiopathology of Rheumatoid Arthritis. The diagnosis is made mostly on the basis of a person’s signs and symptoms. X-rays and laboratory testing may support a diagnosis or exclude other diseases with similar symptoms.9

**Inflammatory markers** - The Erythrocyte sedimentation Rate (ESR) and C-reactive Protein (CRP) are blood tests that are Markers to detect Inflammation. These are certain useful blood tests to help diagnose and monitor the inflammatory activity and response to treatment in diseases like Rheumatoid Arthritis, diabetes, Alzheimer’s disease, Osteo Arthritis, Cellulitis, SLE, etc. The “new” classification criteria, jointly published by the American College of Rheumatology (ACR) and the European League against Rheumatism (EULAR) in 2012 and 2019 establish a point value scale between 0 and 10 to diagnose RA based on the levels of ESR and CRP. In these, 1 point is attributed to elevated ESR (erythrocyte sedimentation rate) or elevated CRP value (C-reactive protein).10

**Leech Therapy** can be defined as the use of leeches in medical treatment. This therapy helps in letting out impure or deoxygenated blood from given area with the help of leech bite. The Leech sucks blood from the site as well as transmits some enzymes in its saliva having anesthetic, anti-inflammatory, anticoagulant, vasodilatation effect etc. thereby giving prolonged oozing effect from the site of bite. Studies suggest that leech SGS (Salivary gland secretions) contains more than 150 bioactive substances and has anti-edematous, bacteriostatic, analgesic, resolving actions. It eliminates microcirculation disorders, restores damaged vascular permeability of tissues and organs, eliminates hypoxia, reduces blood pressure, increases immune system activity, detoxifies the tissue, releases it from the threatening complications, such as infarct, stroke, improves bio-energetic status of the organism through rejuvenation. Hence Leech Therapy has been established as one of the most efficacious therapies in Ayurveda but due to lack of relevant evidence not in vogue.11

**Materials** - Leeches and Leech Lab and other procurements as per the SOPs of Jaloukavacharana12 and tablets of Paracetamol

**Leeches and leech lab**

Photos of patients with RA on knee joints

![Photos of patients with RA on knee joints](image2.jpg)

Pics no 4,5,6,7
Photos of patients with RA on ankle joints

Pics no 8,9,10,11

Inclusion Criteria—Patients in the age group 20 to 70 yrs. with special features of RA were selected for study like two or more swollen joints and with elevated erythrocyte sedimentation rate (ESR), and or elevated CRP value (C-reactive protein) were selected for the research protocol.

Exclusion Criteria—All infective types of Arthritis, pregnant ladies, lactating mothers, HIV and Hbsag positive patients, patients on treatment of IHD, patients with bleeding disorders.

Methods—The patients suffering from Aamvata (RA) in whom knee joints were involved is the target population.

Patients of Aamvata, whether sero positive or sero negative, in whom CRP and ESR were raised were chosen for leech therapy. Painful Knee joint and ankle joint (were preferred for Leech therapy). Leech Therapy was done on alternate day. Such 10 sessions were done. On every instance, 2 or 3 leeches (small to moderate size were applied which were found to suck 5 to 15 ml of blood as average.

This is a single group interventional Study in which pre and post treatment assessment was done on certain objective parameters like markers of inflammation i.e. CRP and ESR and subjective parameters like pain, swelling, redness, tenderness, rise in local temperature, restricted movements of joints. Blood investigations like CBC, CRP, ESR, RA factor, Bleeding time and Clotting time, HIV and Hbsag were performed prior to leech therapy. CRP, ESR, BT and CT were repeated after leech therapy.

The observations were taken on day 0 and day 21 of leech therapy. Leech Therapy was performed on alternate day on affected joint according to the standard operating procedures of Raktramokshana by Jalouka, on preferably the knee and ankle. The observations were compared before and after therapy and statistical data drawn quantitatively.

Results and Discussion

In the doctoral research “Study of inflammatory markers in patients of rheumatoid Arthritis treated by leech therapy”. the sample size was 61 calculated as a convenience sampling with simple randomization. The distribution of patients according to various parameters was done. Statistical tests were applied and data is drawn which is described in tables.

Table no 1- Distribution of patients according to gender-

<table>
<thead>
<tr>
<th>Category</th>
<th>No. of patients</th>
<th>Percentage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Male</td>
<td>28</td>
<td>45.9%</td>
</tr>
<tr>
<td>Female</td>
<td>33</td>
<td>54.1%</td>
</tr>
</tbody>
</table>

Table no. 1 reveals that, of the 61 patients, 28 were male and 33 were female.

Table no 2- Distribution according to Chronicity of Symptoms

<table>
<thead>
<tr>
<th>Duration (months)</th>
<th>Number</th>
<th>Percent</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 to 6</td>
<td>16</td>
<td>26.23</td>
</tr>
<tr>
<td>7 to 24</td>
<td>28</td>
<td>45.9</td>
</tr>
<tr>
<td>More than 24</td>
<td>17</td>
<td>27.87</td>
</tr>
</tbody>
</table>
Table no 2, reveals that, when 3 groups were formed to classify the chronicity like 0 to 6 months, 7 to 24 months and more than 24 months, maximum no of patients ie 28 were found in 7 to 24 months group.

**Table no 3-Distribution of subjects according to Type of Pain**

<table>
<thead>
<tr>
<th>Type of pain</th>
<th>Number</th>
<th>Percent</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bheda(Throbbing)</td>
<td>13</td>
<td>21.31</td>
</tr>
<tr>
<td>Daha(Burning)</td>
<td>13</td>
<td>21.31</td>
</tr>
<tr>
<td>Kartanvata(cutting)</td>
<td>11</td>
<td>18.03</td>
</tr>
<tr>
<td>Toda(pricking)</td>
<td>13</td>
<td>21.31</td>
</tr>
<tr>
<td>Vruschik danshvata</td>
<td>11</td>
<td>18.03</td>
</tr>
</tbody>
</table>

According to the distribution of type of pain, Table no 3, the type of pain on highest frequency was toda, Bheda and dha ie13 patients each were found to suffer from pricking, throbbing and burning type of pain.

These were the demographic criterion illustrated in n-61.

**Table no 4 -Summary table showing effect of leech therapy on important parameters**

<table>

<td>0.0001</td>
</tr>
</tbody>
</table>
Results-The table no 4 above reflects the overall effect of leech therapy on the clinical assessment parameters like pain, swelling, redness, tenderness, rise in local temperature, restricted movement and walking effect. The effect of therapy was also assessed on pathological parameters like inflammatory markers CRP and ESR at the end of 10 leech sessions on alternate days. The overall effect was assessed on day 21 of therapy, that shows significant effect on all the important parameters statistically with p values =0.0001 which is highly significant. Maximum relative change was found in walking effect in the patients of RA which is found to be 72.06%. The relative change in pain score is found to be 39.22%. In Swelling it was found to be 57.62% in knee and 11.73% in ankles. The relative change in tenderness and redness on joints are found to be 61.82% and 30.61% respectively. The relative change in range of motion is 94.15% and in rise in local temperature, it is found to be 61.90%.

Discussion-These findings are the outcome of the anti-inflammatory and analgesic effect of enzymes in leech salivary gland secretions like bdellins, eglins, factor Xa inhibitor, protease inhibitors, tryptase inhibitors, Cathepsin G, histamine like substance, Hyaluronidase, carboxypeptidase inhibitors, acetyl choline, and Anesthetic substance, and anti-coagulant substance called Hirudin and hirustasin which cumulatively give the relative change effects of reduction in pain, swelling, redness, tenderness, rise in local temperature, and improved walking effect stated as above as p=0.0001 level of significance. The combined effect of the multiple bioactive salivary secretions like pain killer action, analgesic anti-inflammatory action, anesthetic properties, thrombolytic effect, tissue rejuvenation effect, anti-ischemic effect, renders the improvement in the pain, swelling, stiffness of the joint and improvement in the restricted movement of joint13.

As Leech therapy is effective in giving pain relief, reducing swelling, redness, tenderness and local warmth is also reduced improving the restricted movement of joints of lower limb. Singh et al state that all the improved characters play a combined role on the walking effect of the patient thereby improving the quality of life of the patient.

Results-The relative change in CRP after leech therapy is found to be 23.54% which is found to be highly significant. The relative change in ESR levels is found to be 10.30% which is statistically somewhat less significant.

Discussion-These findings can be justified by the fact that Overall anti-inflammatory effect of leech therapy by the virtue of various enzymes in its salivary gland secretions gives the reducing effect on inflammatory markers.14 Besides, the difference in the rate of reduction of both CRP and ESR can be justified by the fact that plasma half-life of ESR is up to certain weeks to 2 to 3 months, while that of CRP is 19 hours. Hence for plasma ESR levels to reduce, takes a long span of time which may be in months, because even if the disease process is over ESR is found to be high with other confounders in coexistence. CRP on the other hand is a protein which increases when the inflammatory process is activated in the body with peak plasma levels for 19 hours and regression later. Hence it is the rate of synthesis which
determines the response to treatment. Hence after 10 sittings of leech therapy, if CRP levels are deterred by 23.54% then it is found to be a significant difference with arrest of inflammatory process at a certain level. CRP being a specific marker of inflammation, is a significant finding as a regressed marker after treatment with leech therapy.

Limitations of the present study-

As the effect of leech therapy on CRP and ESR could be found to render statistically significant but parametrically less significant results, it can be used as an adjuvant therapy in the treatment of Aamvata.

Immediate post-doctoral Research direction & Suggested future studies-

Ø This study should be done on large population.
Ø Multicentric, Interdisciplinary research with RCT design should be conducted.

Achievable translatory component:

Ø Many patients suffering from Rheumatoid Arthritis(Aamvata) having inflammatory arthritis and painful joints along with features of stiffness and inability to walk can be effectively treated with Leech therapy on Joints.
Ø CRP is a marker of inflammation which is significantly attainable by treatment with leech therapy.

Declaration of new knowledge generated:

Ø Leech Therapy is significantly effective in decreasing the CRP to a significant level and ESR to considerable levels and effectively renders pain relief to the patients of Rheumatoid Arthritis.

Ethical Clearance- Taken from Institutional ethics committee, JNMC, Saongi, Wardha, in 2016

Comparative Study of *Palashgudavarti* and Diclofenac Sodium Suppository in the Management of Acute Fissure in Ano (Parikartika)-An Ayurvedic Management Protocol

Shubham Golokkumar Biswas¹, Devyani Dasar²

¹PG Scholar, Department of Shalyatantra, ²Associate Professor, Shalyatantra, Mahatma Gandhi Ayurved College Hospital and Research Centre. Salod (Hi) Wardha, Datta Meghe Institute of Medical Sciences, Wardha

Abstract

Background - Anal Fissure is one of the major causes for pain at anal region. The two primary signs of this disease are pain and bleeding, and pain is often unbearable. In males anal fissure typically occurs in the midline posterior- 90 %, and 10 % midline anterior. Subsequently, female fissures on the midline anteriorly are significantly more frequent than posteriorly (60:40). In contemporary sciences *Parikartika* can be correlated with Fissure in Ano. Objective- The objective of the prospective study is to find the efficacy of *Palashgudavarti* & Diclofenac Sodium Suppository in the management of Acute Fissure in ano (*Parikartika*). Material & Method: The present study is designed as a Randomized single blind parallel in which 60 patients will be enrolled. Varti will be applied for local application once a day. Assessment will be done 0th, 7th day, 14th day, and 28th day. Results: The changes are expected to be observed in subjective parameters such as pain bleeding per rectum with itching as well as with objective parameters such as *Parikartika* Healing. Conclusion: The study is expecting the nonsurgical management of fissure in ano with respect to the impact of *Palashgudavarti* & Diclofenac Sodium Suppository. The research is expecting to be baseline and benchmark of the prospective studies in Acute Fissure in ano (*Parikartika*).

Keywords: *Parikartika*, fissure in ano, *Palashgudavarti*

Introduction

Lifestyle disorders are one of the most common condition seen in society. Lifestyle diseases are mainly caused by improper work pattern, stressful life, improper diet intake and improper sleep habits. These causative factors produce indigestion which leads to various lifestyle disorders specially anorectal disorders like piles, fissure in ano, fistula in ano etc. constitute a significant group. Among all anorectal disorders, fissure in ano is the most common disease. Anal Fissure is one of the major causes for pain at anal region The fissure-in-ano is categorized into two types depending on the clinical symptoms & durations of the disease that is Acute and Chronic fissure in ano. The two primary signs of this disorder are, bleeding and pain; pain is often unbearable. In chronic conditions, sentinel tag and haemorrhoids can be associated with this. Pruritus ani can be present sometimes with this disorder¹. In males anal fissure typically occurs in the midline posterior- 90 percent and 10 percent much less frequently. Subsequently, female fissures on the anterior midline are somewhat more common than before. (60:40)²

*Parikartika* can be correlated with Fissure in ano in modern medical sciences. There are different causative factors of *Parikartika* such as *Vamana–Virecana Vypada*, Basti Karma vypada and *Upadrava* of *Atisara*, *Grahani*, *Arśa*, *Udāvarta*³. In this regard Acharya *Sushruta* explained the pathogenesis of disease⁴

The word Parikartika means Parikartanavatvedana around guda i.e. cutting type of pain. Parikartika also has symptoms such as pain in the penis, anus, neck of the urinary bladder and umbilical region with flatus cessation. References about Parikartika are available from all Bruhatrayi and also mentioned in kashyap samhita and later authors of Ayurveda.

Methodology

Trial design: Randomized single blind parallel.

Study setting: Diagnosed Patients will be selected from Shalyatantra OPD & IPD of M.G.A.C.H. and R.C. Wardha.

Figure 1 Flow diagram of the study procedure

CTRI NO- CTRI/2020/09/027734

IEC No- MGACHRC/IEC/August-2020/97

Inclusion Criteria:

- Patients willing for the consent
- Patients with age group of 20 yrs to 50 yrs
- Patients with clinical features of Acute Fissure in ano will be included after screening.
- Patients irrespective of gender, occupation and economic status will be included

Exclusion Criterion:

- Patients suffering with systemic disorders like Diabetes mellitus, Tuberculosis, HIV Positive, and Hepatitis B.
- Known cases of Malignancy, Crohn’s disease, Ulcerative colitis will be excluded.
- Chronic patient with 4th grade anal spasm will be excluded.

Criteria for discontinuing or modifying allocated interventions: Patients will be withdrawal from intervention if any harmful incidence, signs of drug allergy or any problem will occur; patient will be offered treatment free of cost till the disease subsided.

Follow up period after treatment: 28th day after treatment.

Primary Outcomes: Changes in the symptoms of Fissure such as Pain, Bleeding, Itching.

Secondary Outcomes: To observe the changes Healing

Statistical analysis: Wilcoxon rank sum test.

Time duration till follow up: Follow up days is 0th, 7th, 14th, 28th days.

Time schedule of enrolment, interventions: Diagnosed patients of Fissure in Ano will be enrolled in the present study after fulfilling the inclusion criteria.

Interventions- One Varti of 2gm will be taken for local application after Hot Sitz Bath once a day during the treatment period.

Groups - Two groups with 30 patients in each.

<table>

</tbody>
</table>

Recruitment: Patient will be recruited by single arm study

Implementation: Principal invigilator will register subject.

Data collection methods: Randomized

Assessment criteria:
a) Subjective criteria

1. Pain - Vas Scale
2. Bleeding per Rectum – Truncated rectal score for rectal bleeding
3. Itching – Numerical Rating Scale

b) Objective criteria

1. Parikartika healing – Southampton wound scoring system

Data management: Principal investigator will do coding of data.

Ethics and dissemination: Permission for research has been taken from Institutional Ethical Committee ref no. IEC No: MGACHRC/IEC/August-2020/97

Consent or assent: Written informed consent will be obtained from the patient.

Dissemination policy: For future research results will be disseminated and research will be published in reputed journal

Informed consent materials: All the research related document and consent form will be given to the patients.

Discussion

In Ayurveda, palash is used for the treatment of vrana, gulma, bhagnasandhana, grahani, arsha, gudaroga\(^7\). Rasapanchak of Chakramarda is Rasa-Katu, tikta, kashaya, Virya-Ushan, Vipaka-Katu, Karma-Vata-Kaphahara\(^8\). Palash has anti-inflammatory activity, analgesic, antifungal activity and anti-ulcer activity\(^9\) It is known for Vranaropak properties. Fissure in ano is longitudinal tear in the anoderm distal of anal canal. In contemporary sciences surgical treatment available for fissure in ano are sphincterotomy, lord’s dilatation, fissurectomy, but these surgical procedures having adverse effects such as bleeding, infection, incontinence\(^10\). To sort out these problem we need treatment which is easily applicable and non surgical
Expected result and conclusion

Palash has anti-inflammatory activity, analgesic, antifungal activity and anti-ulcer activity. The predicted outcome of this analysis is that group A with intervention is more effective intervention to group B. It is effective in subsiding the symptom of *parikartika* such as pain & bleeding per rectum, itching. Patients who take all follow-up after treatment will have less chance of symptom reoccurrence.

Abstract

Digestion is a main process of human body. Food is essential for body and digestion, conversion of food takes place in digestive tract. *Annavaha Srotas Dushti* leads to indigestion, anorexia, lack of interest towards food which leads to Anorectic disorders like *Arsha, Parikartika* etc. Contrarily this seems to be an increasing incidence of the commonest of all anal disease, i.e. Haemorrhoids and fissure in ano. Though *Sushruta* has described detailed of, however as lifestyle has been changed significantly therefore it is of great importance to study other causes of Haemorrhoids according to modern era. Hence, the diseases of ano-rectal area are the commonest of all the diseases of GI tract. This study aimed at *Annavahsroto-dushti* and its relation in Pathogenesis of *Arsha Vyadhi* and its management. They were well known for time immemorial to the physician and surgeon due to the worldwide distribution and trouble caused by them.

**Keywords**- Annvahasrotas, Anorectal, Arsha.

Introduction

Digestion is a main process of human body. Food is essential for body and digestion, conversion of food takes place in digestive tract. *Annavaha Srotas* is the channel for transportation, digestion and absorption of food. *Annavaha Srotas Dushti* leads to indigestion, anorexia, lack of interest towards food which leads to constipation and may results in Anorectic disorders like *Arsha, Parikartika* etc. Contrarily this seems to be an increasing incidence of the commonest of all anal disease. Though *Sushruta* has described detailed of, however as lifestyle has been changed significantly therefore it is of great importance to study other causes of Haemorrhoids according to modern era. Hence, the diseases of ano-rectal area are the commonest of all the diseases of GI tract.

The incidence of Anorectal disorders are increasing as compare to other disorders, bleeding per rectum is one of the commonest symptom. The lifestyle disorders such as anorectal disorders, hypertension, Diabetes mellitus are also caused due to unhealthy diet, indigestion, change in lifestyle, improper diet schedule and time, improper posture of sitting, mental stress etc. *Sushruta Samhita* has mentioned in *Arshanidanam* that the one who suffers from *Mandagni* which leads to *Vatapra t kopa* alone or in combination with other *Dosas* and causes symptoms such as gudashoola, saraktamalapravrutti, gudadaha etc.

In modern texts, due to improper lifestyle and improper diet there is indigestion of food which cause hard stools. Hard stools are main causative factor for haemorrhoid, which leads to constipation and increased abdominal pressure. This leads to increased venous engorgement of the haemorrhoidal plexus and cause of prolapse of haemorrhoidal tissue. This may result into bleeding per rectum, thrombosis, inflamed haemorrhoids. This study aimed at *Annavahsroto-dushti* and its relation in Pathogenesis of *Arsha Vyadhi* and its preventive management. They were well known for...
time immemorial to the physician and surgeon due to the worldwide distribution and trouble caused by them.

**Aim:** Annavahsroto-dushti and its relation in Pathogenesis of arshaVyadhi.

**Objective:** To Review Annavahsroto-dushti with respect to arsha vyadhi.

**Materials and Methods**

Thorough review of literature related to Srotas and relevant topics was done through the Ayurved Compendia, various other Ayurved texts and textbooks of contemporary science. The references from internet and journals were also critically reviewed. The study had initiated for Affirmation of Annavaha Srotodusti leads toarsha vyadhi.

**Review of Literature**

**ANNAVAVA SROTAS**

Channels carrying anna (food) is called annavaha srotas.

*Annava Srotas* is the channel for transportation, digestion and absorption of food

*Annava Dhamani* plays vital role in the Priṇan Karma of Rasa Dhātu by carrying paramshukma Tejobhuta, properly digested, PanchbhauticAhararasa to whole of body. *Amasaya* is the storage site of the Panchbhautic Anna and along with the *Vamaparshwa*. Amasaya is considered as Moolasthān with storage point of view, *Annava Dhamanīes* as conduction point of view and *Vamapārśwa* as clinical point of view.

**Mula (root)**

*Annava Srotas* originates from amasaya (stomach) and Vama Parsva

*Annava srotas* are two in number and they have their origin in amasaya (Stomach) and annavaha Dhamani (anna carrying dhamanies)

**Nidan (etiological Factors)**

Excess intake of food, eating during improper time, consumption of unwholesome food, due to impairment in agni

**Annava Srotodusti Lakshana**

When annavahasrotas get injured or damaged it causes distention of abdomen, pain, aversion towards food, vomiting, thirst, blindness, death(4).

Lack of interest towards food, anorexia, indigestion, vomiting sensation

**Arsha**

**Nidana (Causative factors)**

**Nidan of SahajaArsha**:

- Mithya aahara and vihara of matruja and piitruj
- Poorvajanmakarma

**According to Sushruta**

Shonita and shukra vitiatan

**Samanya Hetu :**

**Aaharaj Hetu:**

- Virudha bhojana,Pramitbhojana, Asatmya-bhojana
- Guru, Sheeta, madhura, abhishyandi, vidahi aana seavana
- Matsya, Varaha, Mahisha, Aja- Mansa
- Krusha-Prani Mansa, Shushka Mansa
- Nava shuka Dhanya, Ati-snehapan
- Dadhi, Ikshu Ras, Ksheer etc.

**According to Sushruta**

- Virrudhashana, Adhyashana

**Viharaja hetu**

Streeprasanga, utkutasana, prushtayana, vegavidharana

**Vishesha Hetu**

**VatajaArshas**

- Excessive intake of Kashaya, Tikta, Katurasa
- Ruksha, Sheeta and Frequently taking diets in
· Laghuguna Aharadravyas
· Less intake of food
· extremely less quantities
· Intake of Rukshamadya
· More exposure to wind
· Oversexual indulgence

Pittaja Arshas\(^{(7)}\)
· Excessive intake of food having 
Vidahi properties
· Intake of alcohol
· Anger
· Hot place and time
· Exposure to sunlight and fire
· Over exercise
· Excessive intake of pungent, sour, salty Rasas, Kshara and Ushna, Tikshnaguna Aharadravyas

Kaphaja Arshas\(^{(8)}\)
· Excessive intake of sweet, salty and Day sleeping
· Lack of exercise
· sour Rasas and Snigdha, Sheetaguna of Ahaaradravyas
· Mental inactivity
· Cold place and time
· Exposure to eastern wind

**SAMPRAPTI (PATHOPHYSIOLOGY)**

According to Shushruta due to nidan of arsha mainly due to mandagni it cause vitiation of doshas as single or more along with rakta and doshas move downwards through the mahadhamani reach to the guda which affects gudavalitraya and cause arsha

According to Charaka Arsharoga is produced due to vitititian of all doshas which follows bahya and aabhyantararogmarga and affect gudavalitraya

**Samprapti Ghataka**

Dosha - Tridosha
Dushya - Tvak, mamsa, meda, rakta
Srotas - raktavaha and mamsavaha srotas

Srotodusti - Sanga, siragranthi

Udbhavasthana - amaapakvasayotbhava

Vyaktasthana - Gudavalitraya

Rogmarga - bahya and abhyantarara

Agni - Jataragnimandya

**In the aspect of kriyakala**

These are the six stages of manifestation of disease. It has mentioned only by sushruta. The managementof each shat kriyakaal stages is different. The symptoms are aggravated after the sthana sanshaya avastha. Hence if treatment is given before this avastha then it will not occur.
**CHIKITSA VIVECHANA** (TREATMENT)

In contemporary sciences surgical treatment available for haemorrhoids such as higation and haemorrhoidectomy, rubber band ligation, sclerotherapy, but these surgical procedure having adverse effects such as bleeding, infection, incontience, strangutation etc but surgery is not only option for piles it can be cure by preventive and curative measures.

**Management**

**Preventive measures**
- *Nidanparivarjana*
- *Snehana*
- *swedana*
- Sama agni – keep agni in equilibrium condition
- *Pachana*
- *Deepana*

**Curative measures**
- Medical
- Parasurgical-Kshara* sutra,Agni karma,Raktamokshana
- Surgical- Chedana

**Apathya in Arsha**

**Diet:**

Heavy food, Vishtambhi, Vidahidravya like Chilies, Spices, food stuffs made of rice, fried food, Maidaproduet,

excessive intake of oils, Non vegetarian foods Curd, etc.

**Habits:**

Lack of exercise, sleep in day time, Constant sitting on hard objects, Excessive riding, straining during defecation etc.
Pathya(9)

Diet:

Milk, Takra (Mattha), wheat, Cow ghee, Green vegetable etc.

Habits:

Regular diet, exercise, proper sleep, etc.

Observations and Results

Health defines Ayurveda as “Samadosha, samagni, samadhatu malakriyah Prasannatma indriyas manah swath abhidayate (10)” For healthy life agni should be in sama avastha.

In this modern era due to improper diet habits and changing in lifestyle cause annavahasrotadusti and causes agnimandya leads to indigestion which is causative factors of various disorders. Hence irrespective of any disorder agni should be consider first. Hence agnipariksha is so important to examine by physician.

Discussion

Arsha is a problem related to life style, age, occupation and dietary factors. It is a very terrible condition, patient is afraid of defecation because of pain with bleeding per rectum. Hard stools, improper bowel habit are most common symptoms. Due to that it hampers the digestive system and cause agnimandya. Hence agni should be in samaavastha first. Ayurvedic formulations which gives deepanpachana effect can be used and improve the malapraavrutti. Also intake of proper diet is necessary and nidanparivarjana is important factor to be considered.

Conclusion

- Annavaha srotodusti is mainly responsible for indigestion.

- Agnimandya is main reason for Arsha which is due to improper diet habit which leads to annavahasrotodusti.

- Therefore if person follows proper diet it keeps agni balance and proper bowel habits that will prevent from anorectal disorders.

- Hence, person should focus on the diet plan what should eat and what should be avoided.

- Prevention is always better than cure.

Association of Poor Sleep with Low Back Pain among Symptomatic and Asymptomatic Population: A Research Protocol

Sneha Nemade¹, Pratik Phansopkar², Waqar M. Naqvi³

¹Final year B.P.T, Ravi Nair Physiotherapy College, Datta Meghe Institute of Medical Sciences, Sawangi(M), Wardha, Maharashtra, India, ²Assistant Professor; Department of Musculoskeletal Physiotherapy, Ravi Nair Physiotherapy College, Datta Meghe Institute of Medical Sciences, Sawangi(M), Wardha, Maharashtra, India, ³Professor and HOD, Department of Community Health Physiotherapy, Ravi Nair Physiotherapy College, Datta Meghe Institute of Medical Sciences, Sawangi(M), Wardha, Maharashtra, India

Abstract

Background and Objectives- Low back pain (LBP) is the key contributor to ages of disability. Although Low back pain puts an immense economic strain on healthcare services, this disease is responsible for impacting people’s daily lives. Low back pain is a widely common illness impacting persons of all ages. Sleep is an intricate and fundamental organic element with the social objective of keeping up homeostasis by methods for various physiological frameworks. Sleep quality has gained interest for people with musculoskeletal pain conditions as a contributing factor to the outcome. Sleep consistency has created consideration as a risk factor to the outcomes for people with MSK pain disorders. Some studies show a bidirectional link between intensity of pain and sleep quality. Recent attention to the combination of inflammatory processes in pain on the one side and sleep on the other, contributes to neuro-immunological mechanisms that may contribute to the near connection between pain and sleep.

Aim and Objectives- To study association of poor sleep with low back pain among symptomatic and asymptomatic population.

Materials and Method- All asymptomatic and symptomatic individuals with low back pain in the group between 35-50 years of age will fill the survey using Visual Analogue Scale (VAS) and Insomnia Severity Index Questionnaire, and further data will be analyzed.

Result- The parameters of outcome measures of both the group of low back pain individuals will be analysed using the statistical test namely students paired T-test.

Conclusion- Based on the previous studies we assume that there should be a positive association between both poor sleep and low back pain.

Key words- Low back pain, sleep, Visual Analogue Scale, Insomnia Severity Index.

Introduction

Low back pain is the main contributor to ages of disability affecting as many as 84% of all individuals at some point in their lives.¹Low back pain (LBP) is characterized as pain between the costal margins and lower gluteal folds, which is typically followed with severe movement restriction, may be correlated with
leg-related pain (‘leg pain’) and may not be correlated with fracture, direct trauma or systemic diseases such as neoplastic, infectious, vascular, metabolic or endocrine related processes.\(^2\)

Low back pain is a very common symptom. Low back pain is estimated to be the world’s leading cause of disability and the sixth largest contributor to the global disease burden, suggesting a prevalence of 9.4\(^{\circ}\).\(^3\) It occurs in high-income, middle-income, and low-income countries and all age groups from children to the elderly population. Globally, years lived with disability caused by low back pain increased by 54% between 1990 and 2015, mainly because of population increase and ageing, with the biggest increase seen in low-income and middle-income countries. Low back pain is now the leading cause of disability worldwide.\(^4\)

Low back pain is a global concern which is growing slowly leading to population ageing. Low back pain can be said to affect all age groups and is commonly related to sedentary jobs, smoking and obesity.\(^5\)

Non-specific LBP is characterized as LBP not induced by any familiar cause\(^6,7\) which accounts for 90–95 percent of LBP cases. Non-specific LBP is reported to have an eighteen percent incidence point.\(^6\)

Although Low back pain puts an immense economic strain on healthcare services, this disease is responsible for impacting people’s daily lives. Low back pain is a widely common illness impacting persons of all ages.\(^6,8\)

In 2015 Global Burden of Disease Report, where illnesses are evaluated by how much hindrance they cause in ages lost with inability, Low back pain was positioned as world’s biggest supporter of disability.\(^9,10\)

Sleep plays a vital part in human development, metabolism, and cognitive and physical rehabilitation. Past findings have demonstrated that sleep deficiency and prolonged lack of sleep may have a detrimental effect on executive performance, thinking and memory, response rate, auditory alertness and mood. Insufficient sleep hours have also been shown to influence on metabolism and endocrine activity and awareness.\(^13\)

Sleep disorder is a rising public health concern worldwide. It can be influenced by environmental, cultural and behavioural factors and is estimated to have a prevalence of 10 to 48%. Sleep deficiency and sleep disorders can increase the risk of chronic hypertension, overweight / obesity, cardiovascular disease and psychological issues, thereby impacting both the quality of sleep and the overall quality of life.\(^3\)

Sleep disorder is a rising public health concern worldwide. It can be influenced by environmental, cultural and behavioural factors and is estimated to have a prevalence of 10 to 48%. Sleep deficiency and sleep disorders can increase the risk of chronic hypertension, overweight / obesity, cardiovascular disease and psychological issues, thereby impacting both the quality of sleep and the overall quality of life.\(^3\)

Poor sleep additionally gives a significant and complex threat factor for a wide number of physiological issues and physical disorders, dementia, chronic pain, DM and all-cause mortality.\(^15,16,17\) Poor sleep quality among people with chronic low back pain appears to be related to worse pain, affects poor physical function, and pain catastrophizing.\(^18\)

Sleep is important and its deprivation will result in serious consequences. Experimental studies in healthy volunteers (without pain) have shown that induced sleep deprivation contributes to musculoskeletal pain and...
enhanced pain sensitivity to noxious stimuli through either a decrease in sleep length or a disturbance in sleep architecture.11

Back pain and poor sleep quality are public health issues. Sleep deprivation has created consideration as a risk factor to the outcomes for people with MSK pain disorders. Some studies show a bidirectional connection between pain and sleep quality.1,19 Recent attention to the association between inflammatory processes in pain, on one side, and sleep, on the other, leads to neuro-immunological mechanisms which may lead to the close correlation between pain and sleep.19

Sleep recovery in healthy volunteers after a duration of prolonged sleep deprivation has also been shown to produce an analgesic effect close to that caused by non-steroidal anti-inflammatory drugs. In addition, improved sleep quality in patients with debilitating conditions, such as osteoarthritis and chronic musculoskeletal pain, is substantially associated with pain intensity reductions. Eventually, earlier work also shows a clear correlation between sleep disturbance and musculoskeletal pain production. A study in Finland found that sleep disruption is a good predictor of adolescents experiencing low back pain.11

Murase Kimihiko et. al. (2015) performed a study showing that an enormous example of everyone not just indicated a peak going rate of knee and LBP, yet in addition that LBP and knee were firmly connected to less sleep and poor sleep standard, independent of other elements.15

Min Chun Young et. al. (2018) performed a study that found the relation between self-respond sleeping period and musculoskeletal discomfort in the older Korean community by making use of the KNHANES dataset. This research, stated that excessive sleep period is prevalent in any musculoskeletal pain individuals and is more common in multiple site joint pain subjects.20

Vinstrup et Jonas. Al. (2019) records strong dose-response relationship between arbitrary baseline sleep ratings and low back pain follow-up risk for health care staff, with substantial correlations observed in both sensitivity tests. Taking into consideration the high incidence of musculoskeletal conditions in occupational health groups.14

Research investigating the effect of sleep disruption on low back pain severity have shown a substantial correlation between sleep quality and intensity of pain, exhaustion, subsequent-day function and psychological distress. Individuals with low back pain who have sleep issues and more extreme pain have also been reported to be at higher risk of being hospitalized for low back pain than people with good sleep quality. These findings suggest that poor quality of sleep may be associated with exacerbations of low back pain; however, no direct association has been measured in low back pain to date.11

A critical issue in standard clinical practice is that sleep disruptions make treatment of LBP more difficult, suggesting a greater risk for it to become chronic. Longitudinal routine practice studies would be useful in exploring this and in developing a potential research agenda in this area; If sleep disturbances were associated with a higher risk of LBP becoming chronic, it would make sense to routinely assess and potentially treat the quality of sleep in LBP patients (whether or not they are seeking care), and to develop randomized controlled trials to determine whether treating sleep disturbances improves the outcome of LBP treatment.21

Although it has been shown that poor sleep and LBP are associated, but a little scientific information is available between the association of poor sleep in asymptomatic individuals and symptomatic low back pain individuals and vice versa.

Objectives
- To evaluate effect of poor sleep on LBP
- To evaluate poor sleep association with low back pain in asymptomatic individuals

Methods
This study will be carried out at Ravi Nair Physiotherapy College, Musculoskeletal OPD, Sawangi (Meghe), Wardha, Maharashtra, India after approval from Institutional Ethics Committee of Datta Meghe Institute of Medical Sciences, Deemed to be University.

Study design: Observational study

Study setting: Ravi Nair Physiotherapy College, Musculoskeletal OPD, Sawangi (Meghe), Wardha, Maharashtra, India
Participant: All asymptomatic and symptomatic individuals with low back pain in the group between 35-50 years of age

Inclusion criteria
- Both male and females
- Age group 35-50 years
- Population with low back pain
- Asymptomatic population
- Population having baseline LBP

Exclusion criteria
- Low back pain with radiculopathy
- Chronic low back pain patients
- Patient on sedatives

Variables

Outcome measures:
- Insomnia Severity Index
- Visual Analogue Scale

Data source measurement
- **Insomnia Severity Index** – The (ISI) contains seven items that measure insomnia’s severity and consequences, and all items are graded using a five-point Likert scale (0 = no problem; 4 = very severe problem). A total score is obtained after summing up all the responses and the total score ranges from 0 to 28, where 0–7 indicates insomnia, 8–14 indicates insomnia at the subthreshold, 15–21 indicates moderate insomnia, and 22–28 indicates severe insomnia. Reliability for Insomnia Severity Index (intra-class correlation coefficient, ICC2,1−0.84) (Pearson’s coefficient r−0.45). 22

- **Visual Analogue Scale** – The Visual Analog Scale (VAS) is a straight line of 10 cm with endpoints describing extreme limits such as ‘no pain at all’ and ‘pain as severe as it may be.’ On the line between the two endpoints the patient is asked to mark his pain level. The distance between ‘no pain at all’ and the mark determines then the pain of the subject. It is a valid and reliable tool for rating low back pain. \( r = 0.767 \) to \( r = 0.943, p = 0.000 \). 25

Study size – 200

Group A – 100 Symptomatic low back pain individuals

Group B – 100 Asymptomatic individuals

Sampling technique is simple random method.

Procedure

Institutional ethical clearance will be obtained before beginning the study. 200 subjects, between the age group of 35-50 years with low back pain symptomatic and aged matched asymptomatic subjects from Ravi Nair Physiotherapy College and Musculoskeletal OPD will be explained about the study procedure based on the inclusion and exclusion criteria. A proper consent will be taken from the patients and the patients will be explained about the study. The patients who wish to participate in the study will be taken into isolation in order to respect their privacy. After the consent is taken, with sample size of 200 two groups will be divided i.e. Group A- 100 symptomatic low back pain individuals and Group B- 100 asymptomatic individuals. VAS ratings will be taken for Group A subjects having low back pain and Insomnia Severity Index scale will be evaluated for both the groups of symptomatic and asymptomatic individuals. Subjects will be asked to fill the questions with the answers best suited to them. Data will be collected and documented for data analysis.

Expected Result

The result would include if poor sleep is a risk factor for low back pain or vice versa i.e if both are associated with each other. Using the INSOMNIA SEVERITY INDEX (ISI) And VISUAL ANALOGUE SCALE (VAS) the study would be carried out. Once the study result is complete, statistical analysis will be analysed using paired T-test and presented in the form of research paper.

Discussion

The point of this study is to check the relationship of poor sleep with LBP among both symptomatic and asymptomatic people. In spite of the fact that in
numerous investigations some relationship between poor sleep and low LBP have been appeared, however an exceptionally low logical data is accessible which shows the relationship of poor sleep with asymptomatic people and symptomatic people and the other way around.

To draw a close attention, this research will look at the association between the two that is poor sleep and LBP and how they are associated which can be very helpful in treating the LBP cases. Even, to make sure that these factors like poor sleep if hampering the treatment for LBP. To check the relation between the both and to check if poor sleep leads to LBP or if LBP leads to poor sleep or if both are interlinked to each other using the Visual Analogue Scale and the Insomnia Severity Index.

Effectiveness of Pippalyadi and Suranadi ointment in management of Arsha (Haemorrhoids)

Suraj Rathod¹, Kiran Khandare², Pooja Shrivastava³

¹Post Graduate Scholar, Department of Shalyatantra, ²Professor & HOD, Shalyatantra, ³Assistant Professor, Shalyatantra, Mahatma Gandhi Ayurved College Hospital and Research Centre. Salod (H) Wardha, Datta Meghe Institute of Medical Sciences, Wardha

Abstract

Arsha is a common anorectal disease so associated with bleeding per anum. It can be compared to Haemorrhoids according to modern science. Haemorrhoids are dilated veins in the anal canal. Through all the modern modalities of treatment in haemorrhoids are universally accepted but all have some or other limitations. In Ayurveda various measures have been mentioned for the management of Abhyantar Arsha, among which lepa karma is one of them. Various study have been done on the application of various lepa so prepared have been conducted depending upon the sign and symptoms. In this study the effectiveness of Pippalyadi and Suranadi ointment were compared which were so mentioned in bhaishajya ratnakalari. In this present research work efforts were made to provide the treatment which is non-invasive, easy to implement, effective and not need any hospitalization. In this study 30 patients of Arsha were selected as per criteria of selection randomly irrespective of religion, socio-economic status and were divided in 2 groups of 15 patients each. Group-A was treated with Pipplyadi ointment advised for 15 days twice a day as local application. Group-B allotted Suranadi Ointment given twice a day for local application for 15 days and accordingly the result were assessed. Pippalyadi and Suranadi ointment were prepared according to the texts and the ointment was used for local application on the patients of Arsha. Lastly, it was concluded that both the ointments have shown significant results in the patients without any side effects.

Keywords: Arsha, Haemorrhoids, Pippalyadi and Suranadi ointment, Lepa, Raktaastarava, Degree of prolapse.

Introduction

Ano-rectal disorders are progressively increasing in the society. Out of many of the causes, some important are sedentary lifestyle, irregular and inappropriate diet, prolonged sitting or standing and certain psychological disturbances too. Arsha is one among the ano rectal diseases which occurs in Gudapradesha, which is a sadhyopranahara Marma[1]. In Arsha bleeding per anum is the principal symptoms. Arsha is a gift of modern diets and busy lifestyles and many people are suffering from some sort of Anorectal disorder, it may be simple constipation to complex carcinoma, in which prominent disorder is Arsha. It is manifested due to multifold factors viz. disturbed lifestyle or daily routines, improper or irregular diet intake, prolonged standing or sitting, faulty habits of defecation etc. which results in derangement of Jatharagni leading to vitiation of Tridosha, mainly Vata Dosha. These vitiated Doshas get localized in Guda Vali and Pradhana Dhamani which further vitiates Twak, Mansa, and Meda Dhatus due to Annava shrotodushhi leads to development of Arsha.

In modern medical science Arsha can be compared with haemorrhoids. Hemorrhoid often described as “varicose veins of the anus and rectum”. Hemorrhoid are dilated, tortuous or varicose veins occurring in relation to the anus and originating in the epithelial
plexus formed by radicals of the superior, middle and inferior rectal veins. While other scientists considered it as displacement of anal cushions. Thomson wrote that it occurs through vascular hyperplasia in the anal sub mucosa, possibly through dysfunction of the shunts. According to the John Goligher pile’s seems to be more appropriate for this condition as all hemorrhoid do not bleed.

Haemorrhoids are divided into two categories- internal and external haemorrhoids. Internal haemorrhoids means it is within the anal canal and internal to the anal orifice and the external haemorrhoid is situated outside the anal orifice and is covered by skin. The two varieties may coexist and the condition is called intero-external haemorrhoids[3].

In the management of Haemorrhoids, the procedures, which are in practice at present in modern surgery, are laser surgery, rubber band ligation, sclerotherapy, bipolar diathermy, infrared photoocoagulation, cryosurgery, infra-red coagulation and hemorrhoidectomy, but all procedures have their limitations[4]. Though all the modern modalities of treatment in haemorrhoids are universally acceptable but all have some limitations. In ancient Ayurvedic compendia various palliative measures have been mentioned in the management of Abhyantar Arsha, lepa karma is one among them. Lepa is one of the type of abhyantar sneha. Basically lepa is application of paste of medicated plants mixing with oil. According to sushruta thickness of the lepa should be around 3-5 mm, whereas according to Acharya charak it is 1/3rd of Angustha. Lepa is prepared by grinding and crushing the herb together into a fine paste form. If the drugs are in dried form then it is to be made into paste by triturating it into paste with water, milk, ghee or oil.

In this present research work efforts were made to provide the treatment which is non- invasive, easy to implement, effective and were not need any hospitalization. To fulfill the above criteria the present research study were conducted to compare the effects of Pippalyadi lepa and Suranadi lepa in management of abhyantar Arsha, which are described in Bhaishajya Ratnavali 9th Chapter[6]. Application of lepa over internal haemorrhoids and its preparation were a difficult job therefore in order to make that easy, ointments were prepared out of the same ingredients.

**Aim and Objective**

- To evaluate the efficacy of Pippalyadi Ointment in management of Arsha.
- To evaluate the efficacy of Suranadi Ointment in management of Arsha.
- To compare the effects of Pippalyadi Ointment and Suranadi Ointment in management of Arsha

**Materials and Methods**

**Drug Review**

Pippalyadi ointment and surandai ointment were prepared according to classical reviews so mentioned. The preparation has been described in detail and pharmaceuticals analysis is given below.

**Pharmaceutical analysis:**

The raw materials were collected from reliable source and were authenticated from Department of Dravyaguna and it were analysed in Pharmaceutical Laboratory, Sawangi Wardha and the findings are as follows:

1) **Pippalyadi ointment**

- Loss on drying at 105°C : 1.053
- Spreadability: 4.7gm.cm/sec
- pH : 5.7
- Peroxide value: 5.82
- Iodine value: 17.28

2) **Suranadi ointment**
§ Loss on drying at 105°C : 1.21
§ Spreadability : 6.5 gm.cm/sec
§ pH : 6.12
§ Peroxide value : 6.28
§ Iodine value : 15.37

Organoleptic characters

1) **Pippalyadi Ointment**
- Color : Greenish
- Texture : Smooth
- Odour : Characteristic

2) **Suranadi ointment**
- Colour : Yellowish
- Texture : Smooth
- Taste : Characteristic

**Clinical Study**

In this study total 30 patients of Arsha were selected and divided in two groups and Pippalyadi and Suranadi ointment were administered. Group A was treated with Pippalyadi ointment for 14 days twice daily as local application whereas Group B were given Suranadi ointment for 14 days as local application.

**Inclusion criteria**

§ Diagnosed without any major systemic disorder’s cases of first and second degree internal haemorrhoids.

§ Age group of 20 to 50 years, irrespective of their sex, occupation, & economic.

**Exclusion criteria**

§ Haemorrhoids that are thrombosed, third degree and fourth degree.

§ Haemorrhoids associated with fissure in ano, fistula in ano, perianal abscess, rectal polyps, rectal prolapse and rectal CA.

§ Patients having tuberculosis, AIDS & Hepatitis, Ulcerative colitis, Crohn’s disease & Pregnant women.

**Diagnostic criteria**

Diagnosis was made on the basis of physical examinations by performing thorough P/R examination i.e inspection, palpation, digital and proctoscopic examination.

**Investigations**

Routine hemogram, blood sugar, routine and microscopic examination of urine and stools were carried out.

**Grouping and posology**

In this present study total 30 patients were take which were further divided into two groups,

GroupA and GroupB each containing 15 patients by using simple randomisation method. In this study 30 patients of Arsha were selected as per criteria of selection randomly irrespective of religion, socio-economic status. All these patients were diagnosed with the help of criteria of diagnosis. Patients attending O.P.D of the hospital were examined prior to the start of treatment with respect to the Performa. The treatment protocol comprised of. Application of paste. In both the groups. In GroupA Pippalyadi lepa Was applied whereas in Group B. Suranadi lepa was applied.

The total duration of the treatment was 4 weeks with regular follow up at 7th day, 15th day and 30th day. All the patients were advised to take light and easily digestible diet and avoid incompatible foods.

**Observations were recorded and noted as follows:**

| 1) Total number of patients recruited in the Study | 35          |
| 2) Number of patients who completed study       | 30          |
| 3) Number of patients who had taken Pippalyadi Lepa | 15          |
| 4) Number of patients who had taken Suranadi Lepa | 15          |

Preparation of ointments Preparation of **Pippalyadi** ointment:
Grade 1  | No prolapsed. Just prominent blood vessels.
Grade 2  | Prolapsed upon bearing down but spontaneously reduce.
Grade 3  | Prolapsed upon bearing down and require manual reduction.
Grade 4  | Prolapsed and cannot be manually reduced.

All the drugs viz. Pippali, Saindhav, lavan, Kushta, Shirish and Snuhi are made into a fine powder. Til tail is taken into clean stainless vessel and placed over mild heat until it starts foam appearing. Then beewax is added to 1/5th of til tail, when all the wax is completely melting in oil, it is filtered and kept in another vessel. It was used as base for preparation of ointment called as siktha tail. In this tail fine powder of all above drugs were added and stirred. This mixture then attains thicker consistency as wax cool down and made into a soft paste.

**Preparation of Suranadi ointment:**

All the drugs viz. Suran, Haridra, Chitrakmool, Sudhha Tankan and Guda are made into a fine powder. Til tail is taken into clean stainless vessel and placed over mild heat until it starts foam appearing. Then beewax is added to 1/5th of til tail, when all the wax is completely melting in oil, it is filtered and kept in another vessel. It was used as base for preparation of ointment called as siktha tail. In this Siktha tail fine powder of all above drugs along with Guda were added and stirred. This mixture then attains thicker consistency as wax cool down and made into a soft paste.

**Mode of action**

**Mode of action of pippalyadi ointment:**

**Assessment criteria**

**Subjective Criteria** - presence of clinical signs and symptoms of abhyantar Arsha.

1. Constipation

<table>

**Objective criteria**

**Statistical Analysis**

Subjective symptoms were statistically analyzed by applying nonparametric test like ‘Wilcoxon Sign Rank test’ within group to compare the results before and after treatment results. For the comparison between the group for subjective criteria ‘Mann Whitney U’ test was applied. Level of significance were taken at 5%.

**Assessment of Results**

Assessment of the result was done based on the relief of signs and symptoms i.e bleeding per rectum , pain, constipation, degree of prolapse, discharge and reduction of pile mass.

**Observation and Result**

In was so observed that out of the total 30 patients which were further divided in two groups of 15 each. The first group i.e Group A in which pippalyadi ointment was used showed a significant difference in the condition when the follow up was taken on Day 7, Day 14 and Day 30. The ointment showed gradual improvement in the symptoms including bleeding (raktastrava) and the degree of prolapse on the Day 30 as compared to that on Day

0. Whereas when comparison was done within each follow up in the case of constipation (malavastambha) no significant improvement was observed in Group A.

Looking over the second group i.e Group B in which suranadi ointment was used it showed the same results,
stating much improvement in the symptom of bleeding. Further showing a bit less improvement in the degree of prolapse as compared to the Group A in the followups. And in the case of constipation this ointment showed very slow response and stating lesser improvement in the Day 14 and Day 30 followups. This could be better understood by the table so given below

**Pippalyadi ointment -Group A**

<table>

**Discussion**

The number of patients so found were more among the lower economic group. It was also found that they had irregular dietary habits and were consuming spicy food on regular basis. It was also observed that Out of 30 Patients in the study, 05[16.7%] patients were doing moderate nature of work, 13[43.3%] patients were having sedentary work, while 12[40%] patients were having strenuous work in nature.

Most common symptoms of Arsha includes Agnimandya, Vankshana Shool, Svara Krishata, Asarata,Klama, Jwara, Shotha,Vaman, Peenasas, Arochak, Angamarda and many more[7]. The basic line of treatment for Arsha includes Ksharkarma, Bhes'hajhikitsa, Agnikarma and Shastrakarma[8]

Applicaton of various ointment including Kasis, hartaala, saindhav, karvir, vidang, karanj, krutvedhan, jambuk, arka, bhumi, amalaki, danti, chitrak, alark, snuhi sidd tail are used[9]. Vegadharana, atistreesanga, utkatukasana, prushtayana, atapasevana, atijalapana, vanama, basti, poorva desha vayu sevana, viruddha dravya in rasa, veerya, vipaka these things should also be avoided to maintain good health and prevent further complications.

Pippalyadi Ointment contains Pippali having Laghu, Snigdha, Tikshna guna and madhura, katu rasa which is acts as Vatakaphashamaka. It is also having properties like Antibacterial, Antifungal, Anthelmic. Saindhav lavan, Kushta is having properties like Kaphavatajita, Raktashodhaka. Shirish acts as Shothahara, Tridoshahara. Shirish and Snuhi are having properties like kashay rasa and astringent by nature immediately helps in stopping bleeding due to its Rakta Stambhana Karma. So due to combine effects of all drug bleeding,
inflammation, pain is stopped due to this Ointment which was act locally to relieve the pain and bleeding in arsha.

**Suranadi Ointment** having Suran, Haridra, Chitrakmoool, Sudhha Tankan and Guda. Surana is having properties like Raktapittakara, Deepana, Kaphahara, Ruchya having katu and kashay ras which stop bleeding in hemorrhoid. Haridra is

Kushtaghna, Lekhaniya, Kandughna, Vishaghna. Chitrak is Shothahara, Kaphavatahara, Arshohara, Shulahara,; locally act as shoolhara and relive pain and stop the bleeding.

Statistical analysis shows that both the ointments i.e Pippalyadi and Suranadi were found to be effective in treating the Degree of prolapse, Raktastrava and all the other symptoms of Arsha.

**Conclusion**

The prevalence of Haemorrhoids are progressively increasing in the society due to various factors like disturbed lifestyle, improper or irregular diet intake, prolonged standing or sitting, faulty habits of defecation.

Modern treatment in hemorrhoids are universally acceptable but all have some limitations and chances of recurrence of hemorrhoid are often more. In ancient Ayurvedic texts comforting measures have been mentioned in the management of Abhyantar Arsha, Lepa karma is one among them. It can be concluded that Arsha could be healed by the application of Pippalyadi and Suranadi Ointment. Effect of Intervention of Pipalyadi ointment seen significant on Day 30 as compare to Day 0 for Bleeding (Raktasrava) and Degree of prolapsed. It was observed that there is no significant difference statistically found in constipation among the follow up i.e. Day 7, 14 and Day 30. Similarly, Suranadi Ointment has also found effective in Bleeding (Raktasrava) and Degree of prolapsed and not observed significant in constipation. It was found to be effective in treating various symptoms and the notable point was that there were no adverse effects of the drugs after treatment.

Yet there are few limitations of the study. This study can be done more sample so that the results can be generalized. Along with this intervention of local application, few additional oral drugs can be added to obtain better results, as arsha has also treated with deepan, pachan drug to improve agni of patients and other modern modalities could also be kept in mind.

Abstract

Phenylketonuria (PKU) is an inborn error of phenylalanine (phe) and tyrosine (tyr) metabolism. It is an autosomal recessive disease occurred due to deficiency of liver enzyme phenylalanine hydroxylase (PAH). Hence, phe is not converted to tyr and phe is accumulated in the body. Phe thus channeled to alternative routes of metabolism and forms Phenylketones excreted in urine. Early treatment is essential to prevent mental retardation and other intellectual disabilities. Dietary treatment remains the main cornerstone to manage PKU since last 3-4 decades. A diet low in Phe supplemented with special amino acids formulas must be started soon after diagnosis within seven days of life. Inspite of good results obtained from dietary treatment in PKU, still there are some issues with palatability of the dietary formulations. There are also issues of nutritional deficiencies of vitamins like calcitriol and cobalamin (B12). Poor cognitive and executive functions have been observed in patients who do not follow proper dietary treatment. Attempts have also been made to increase the palatability of food under dietary management. Role of large neutral amino acids (LNAAs) and glycomacropeptides (GMP; found in bovine milk) as a newer dietary management have also been explored. In recent era, advances occurred in terms of genetic therapy and enzyme replacement therapy which opened a new door towards management of PKU. In this review, various treatment aspects of PKU are discussed and explored.

Keywords: Phenylketonuria, phenylalanine hydroxylase, phenylketones

Introduction¹-⁶

Phenylketonuria (PKU) is an inborn error of phe and tyr metabolism. It is caused mainly due to mutations in the gene coded for phenylalanine hydroxylase (PAH) which is located on long arm of chromosome 12. This mutations lead to decrease catalytic activity of PAH which affects the catabolism of phe (Figure 1). PAH is located in liver and requires tetrahydrobiopterin (BH4) as a co-factor to convert Phe to tyrosine (Tyr) (Figure 1). In PKU, accumulation of phe is due to deficiency of either PAH or its cofactor BH4. Accumulated Phe take alternative routes to form phenylketones like phenylpyruvate, phenyllactate, phenylacetate which are excreted in urine. These ketone metabolites lead to severe central nervous system disability which if left untreated cause irreversible damage. Other clinical features associated with untreated PKU may include sensory and motor dysfunction, skin manifestations and seizures. Changes in behavior and psychic disturbances can become apparent as the age progresses.

Early diagnosis is essential in PKU to prevent irreversible damage to brain. Currently newborn screening (NBS) program is undertaken for initial diagnosis in the first week of life and further screening can be done for BH4 responsiveness in case of atypical PKU. The incidence of PKU varies widely around the world. The average incidence is 1:10000 live births worldwide. India has lower incidence (1:25000 live births) as compared to western countries (1:1500 live births). At present, there is no cure for PKU. However, the cornerstone of the management of PKU is dietary therapy. Diet low in Phe supplemented by amino acids formulations is recommended. Early diagnosis by NBS along with commencement of dietary therapy has played a role in prevention of intellectual impairment but still neurophysiological and neuropsychological impairments persist in already treated patients of PKU. Moreover, some issues are also there with vitamin deficiencies like calcitriol and B12. Nowadays attempts have been made to cope up with issues occurring with dietary therapy. Advanced food and formulas which increase the compliance towards dietary therapy for example incorporation of large neutral amino acids (LNAAs) and glycomacropeptides (GMP) have been studied in detail and introduced. Still further studies are also required in this direction to establish their full impact. Cofactor BH4 responsive patients respond well to BH4 therapy with success rate of only 30%. Recently, newer modalities came into existence and under research like enzyme replacement/ substitution therapy and gene therapy. In this review, we aim to summarize current and future perspectives of management of PKU.

**Current Treatment**

**Diet therapy**

Phe is an essential amino acid. Apart from protein synthesis, phe helps in synthesis of tyr and in turn helps in synthesis of important metabolic substances derived from tyr. In PKU, defect in the conversion of Phe to Tyr makes Tyr an essential amino acid. Therefore, the technical challenge of the dietary treatment is to
formulate a phenylalanine-controlled diet that allows the reduction of systemic Phe concentration, satisfactory tyr provision, and optimal growth and development. Diet low in Phe remains the mainstay of the treatment in PKU. This should be supplemented with special amino acids formula so that proper growth can be ensured. During infancy, Phe free milk lowers the blood levels of Phe. As levels approach the therapeutic range, phenylalanine is added using measured amounts of normal milk and then adjusted until serial blood controls have stabilized. When child puts on solid diet, the diet is progressively adapted with the following main principles: High-protein foods (meat, fish, eggs, dairy, and wheat products) are excluded. Foods with low protein content (milk, vegetables, and fruits) are used to meet the required amount of Phe. Diet restriction is somewhat easier in infancy as it is mainly controlled by parents but it is difficult as the child gets older due to his/her likes and dislikes with the food items. Other important factor that affects the dietary management is the blood Phe concentrations which varies from country to country. Consequently, compliance with the diet is often poor, especially when the patient reaches adolescence, as evidenced by poor control of blood Phe concentrations in this age group. Long-term maintenance of the diet is important for proper management, because it has been observed that patients find it difficult to return to the normal dietary regimen after a long period of unrestricted dietary intake. 7-10

Earlier it was believed that continuation of dietary therapy after childhood has no role because excess phe has no any role after brain development. But some studies showed poor scholastic performance after discontinuation of diet therapy. Moreover, females having PKU when reached to their reproductive age have higher risk of having baby with maternal PKU syndrome. This can be manifested as small brain size and poor brain development, growth retardation in-utero, cardiac defects and a characteristic facial appearance in the affected infant. As a result of these studies, it was recommended that diet therapy should be continuing life-long. 11, 12

Although Phe restricted diet is successful in curtailing intellectual impairment in PKU patients, there are certain issues (non-compliance) still remain with current diet therapy. These are poor compliance to synthetic diet formula, persistence of neurological or psychosocial issues and poor quality of life inspite of early intervention, deficient nutritive supply, financial burden of special diet, difficult dietary regimen to follow, psychosocial and emotional factors, knowledge of disease and its outcomes, attitudes towards healthcare providers, no reimbursement of food supplements in some health care systems. There is an existence of problem in the diet therapy in PKU patient when provided with aspartame (L-aspartyl-L-Phe methyl ester). It is commonly used as an artificial sweetener and it releases Phe, L-aspartic acid and methanol when gets metabolized. Hence, aspartame should be avoided. Stringent diet therapy leads to nutritional deficiencies. The reported deficiencies are vitamin D, B12, calcium and iron which further aggravate the symptoms in PKU patients. 3, 8, 13-16 These issues stimulated mankind to have other alternatives to be made in diet therapy.

**Tetrahydrobiopterin (BH4, Sapropterin) treatment**

BH4 is a natural cofactor required by PAH for the conversion of Phe to Tyr. Some mutations are also associated with BH4-sensitive phenotype of PKU. The benefit of administering synthetic preparation of BH4 in patients with non-classical (atypical) PKU was first studied by Schaub et al. Pharmacological doses of BH4 may reduce the blood Phe levels was first demonstrated by Kure et al. Thus the patients were called BH4-responsive. Two formulations of BH4 have been studied clinically (6R-BH4 dihydrochloride and sapropterin dihydrochloride) but only sapropterin dihydrochloride is approved by the US Food and Drug Administration, the European Medicines Agency, and in Japan for therapeutic use. A single daily dose of 10-20 mg/kg is sufficient to maintain stable blood Phe level over 24 hours. There are other benefits of BH4 treatment which were also observed like improvement in Phe tolerance, improvement in long-term neurological outcomes, decreased in depression and panic attacks especially in females. It was also observed that BH4 supplementation can be appropriate for patients with milder biochemical phenotype. It is less useful in classical PKU. 3, 17-20

**Newer dietary approaches**

**Large neutral amino acids (LNAAAs)**

Phe, Tyr, tryptophan, and the branched-chain amino...
acids (BCAAs) are considered as LNAAs. They share the common amino acid transporter to cross blood brain barrier. In PKU, high Phe levels compete with entry of other LNAAs which can lead to deficient formation of important neurotransmitters and hence neurological symptoms develops. Keeping this fundamental aspect into consideration, supplementation with LNAAs other than Phe could provide another potential treatment approach. LNNAs exert its effect by competing with phe for transportation at two different sites that is across the blood-brain barrier and across the intestinal mucosa. A double-blind, placebo-controlled study also showed a reduction in blood phenylalanine from baseline of 39% during short-term treatment with LNAAs.13, 21-23

**Glycomacropeptides (GMP)**

During making of cheese, GMP produced as a by-product. It is a 64 amino peptide with no Phe residues and rich in valine, Isoleucine and threonine. Therefore, food made from GMP can be a rich source of protein for PKU patients. Study showed that GMP diet significantly decreases urea production, helped in maintenance of protein concentration and phe utilization. It has also been found that taking diet made from GMP for breakfast promoted satiety and improves compliance.5, 24-26

**Future (Newer) Treatment**

**Gene therapy**

PAH is only expressed in liver. So gene therapy involves production of recombinant PAH gene which is targeted to hepatocytes. Viral vectors like adenoviral and adeno-associated virus (AVV) vectors have been used in various studies to know their role for the transfer of this gene in PKU mouse model. Recombinant AAV vectors have been used to deliver PAH gene to the liver in a mouse PKU model, allowing correction of PAH up to one year. But over the time, the vector lost due to continual turnover of hepatocytes and in turn developed immunity. Yagi et al used an AAV8-pseudotype vector with a self-complementary AAV genome and they had achieved excellent liver transduction and expression of PAH with complete reliving of symptoms and normal blood phe for over one year. Skeletal muscle is preferred over liver for gene therapy due to easy accessibility and longer cell life. However, new strategies are still required to extend gene transfer efficacy.3, 13, 27-29

**Enzyme replacement/substitution therapy**

**PAH-based fusion proteins (Enzyme replacement)**

PAH-based fusion proteins which specifically target PAH to the liver have been explored. Mice with PKU were injected PAH-based fusion proteins intravenously. Decreased in Phe level within several hours has been noted. But this intervention may be less tolerable clinically due to frequent injections of fusion proteins. Moreover model used in this experiment was not homologous to human PKU but still it can be the alternative if homologous model is used.3, 13, 30

**Phenylalanine ammonia-lyase (PAL, Enzyme substitution)**

PAL is used as enzyme substitution therapy. PAL an enzyme normally found in plants and fungi. It catalyzes the removal of amino group of phenylalanine to ammonia and transcinnamic acid, the latter of which is then quickly converted into hippuric acid and excreted in urine (Figure-1 red box). Study done in mouse model by injecting PAL showed decreased Phe level but due to repeated injections immune response was developed which decreases its half-life. To overcome the issue, recombinant PAL (with polyethylene glycol polymers so-called PEGylation) is used to avoid the immune-mediated degradation of the enzyme and thus longer half-life is achieved. Oral route is preferred than the Parenteral route to achieve compliance to therapy. But again, to maintain enzyme stability is a big issue which can be overcome by using encapsulation or using live microorganism as a delivery systems. Use of probiotics like lactobacillus and genetically modified probiotics in transporting and delivering PAL have also been gained attention and tried.3, 8, 13, 31-34

**Conclusion**

Prompt initiation of low-Phe diet immediately after diagnosis made by newborn screening maximally prevents intellectual impairment in early treated PKU patients. Compliance to the diet therapy is the main issue especially in adolescence and adulthood which in turn lead to impaired blood Phe control and poor outcome with respect to psychosocial and cognitive assessments. BH4 supplementation can be appropriate for patients with milder biochemical phenotype (Non-
classical PKU) as compared to Classical PKU. Newer dietary approaches have been introduced to increase compliance to diet therapy. Data suggested that use of LNAAs is recommended only in adult patients who have non-compliance to stringent diet regimen. Addition of GMP into low-Phe diet has shown to improved palatability and some beneficial effects but still further studies should be undertaken to establish its safety and efficacy. Newer and future treatment modalities for PKU are now under development. They are mainly focused on the basic defect of PKU i.e. catalytic activity of PAH. Gene therapy by using suitable vectors to transfer PAH gene to liver and skeletal muscle have been tried. Under enzyme replacement and substitution therapy role of PAH associated fusion proteins and PAL (PEGylated form) have been explored respectively. The latter has reached phase III clinical trials but still its efficiency is the major issue. Studies related to the use of probiotics to produce and deliver PEGylated form of PAL are still ongoing to establish its safety and efficacy. Nevertheless, enzyme replacement/substitution therapy has been found efficacious in mouse model of PKU but still they all require in depth research and clinical testing. These treatment modalities can also be applicable to other inborn error of metabolism and data from this study highlighted the need for development of alternative therapies for PKU patients irrespective of genotype, phenotype or gender.

Abstract

Objectives: The aim of this analysis is to investigate the correlation between knowledge, attitude, and behavior with cadmium level in the industrial population. Methods: This research is a non-experimental study with cross-sectional method. The subjects are 108 respondents live in industrial area. Questionnaires were used for measuring the level of knowledge, attitude, and behavior. Cadmium levels were measured using Atomic Absorption Spectrophotometry (AAS). Results: The result showed a strong correlation between levels of knowledge factor and cadmium with \( r = -0.272^* \) in the population of industrial areas. Meanwhile, knowledge have significant correlation with attitude \( (r = 0.528^{**}) \). Conclusion: Knowledge factor has the significant relationship with cadmium levels in the population of industrial area. The government is suggested to improve the knowledge of the people in the industrial area in order to prevent high levels of cadmium. Therefore, the negative impact of metal waste exposure on health can be minimized.

Keywords: Cadmium, Knowledge, Behavior, Attitude, Industrial area

Introduction

Recently, industrial sector in Indonesia has been significantly increased by the time. From the data obtained from the Statistics Indonesia database in 2017, various kinds of industries about 33.577 have already growing rapidly and predicted to continue to expand (1). This is the case with data provided by CEIC (World of Macroeconomic Data) which reports that the Indonesian industry prediction index increased by 2% in February 2020, which shows an increase of 0.8% from February 2020 (2).

With the increase in the number of industries, it will certainly be very beneficial for the country, especially in terms of improving social and economic welfare. If viewed from the other side -factory waste- are of particular concern, especially because of their impact, which is currently being followed up. Although indirectly and in inconspicuous amounts, exposure to airborne metallic waste in factory effluents can cause some health problems if accidentally inhaled or exposed to air or food. Many researches have shown that heavy metals can cause respiratory problems, cancer, and even death (3-5).

Cadmium is one of the heavy metals found in factory waste (6). Cadmium comes from the air mixed with the results of air waste and water waste in equipment found in factory machines in chimneys. Cadmium is reported to have many cases of exposure from children to adults (7,8). Previous research states that the level of cadmium exposure is increasing every year for someone who lives around industrial areas. Cadmium exposure
causes various health problems such as cardiovascular disease\(^{(9)}\), impaired kidney function \(^{(10)}\) and itai-itai disease \(^{(11)}\).

Although evaluations continue to be carried out at a factory and the waste disposal regulations have been reviewed according to government policy standards, there are still cases of poisoning in someone who lives in an industrial area. Recent evidence suggests that adult people who live near industrial areas in the Amazon for more than 2 years have high cadmium levels \(^{(12)}\). The generalizability of much published research on this issue is problematic. However, habits and lifestyles have a strong relationship with a sufficient level of attitude and knowledge to address how to live in the industrial area. Up to now, far too little attention has been paid to know the correlation between knowledge, attitudes, and behavior correlated with blood cadmium levels. This paper attempts to show that basic factors can be a major cause for significant cadmium exposure. In this study, we focused on knowledge, attitudes, and behavior as basic factors of cadmium blood exposure.

### Materials and Methods

This study is a cross-sectional study design with a total sample of 108 people living in an industrial area. There are many criteria of inclusion such as: had a minimum of 1 year stay in an industrial area; distance of residence (within a radius of 5 km from industrial locations); and there are no respondents who had cardiovascular risk factor. The sample in this study was taken by purposive sampling from the study population living around an industrial area.

5 mL blood plasma from 108 respondents have been measured with atomic absorption spectrophotometry (AAS) in wavelength about 357.9 nm. Total cadmium content test method refers to the SNI 06-6989.17-2004 standard for testing metal content with AAS. The materials were obtained from the Laboratorium Terpadu Diponegoro University. A calibration curve is made to get the regression line equation then proceed with the measurement of the blood sample that has been prepared. Calculation of metal content is calculated using the equation below:

\[
\text{Total Concentration of Cadmium (mg/L)} = \text{Concentration} \times \text{fp (the dilution factor)}
\]

The questionnaire consisted of 10 questions to determine the level of knowledge, 15 questions to determine the level of attitude variables, and 10 questions for the level of behavioral factors (a total of 35 questions) distributed to 108 respondents (data not shown). The Cronbach’s Alpha value for all questionnaires is > 0.6 and all question items have a positive correlation ranging from 0.3 to 0.6 so it can be assumed that all of the questionnaire question items are valid and reliable. The totals of these statements were then used for further analysis using Pearson’s correlation. In this study, the relationship between the factors of attitude, behavior, and knowledge was correlated with cadmium data that had been done previously.

### Findings

The results obtained showed that the level of cadmium exposure was 82.41% which exceeded the normal threshold, namely > 50 ng/mL. The next result was followed by the normal category which was not much different from the abnormal category, namely 8.33% and 9.26%, respectively (Table 1).

In this study, we divided it into three levels for each factor. These factors include knowledge, attitudes and behavior. The results obtained from the data tabulation show that the knowledge that has a high level of respondents is 55.56%, the attitude has the highest proportion and 100% has a high attitude, then for behavior, it has a low level of 46.30 with the proportion highest in the observed population (Table 2).

**Discussion**

Cadmium (Cd) is a metal that can cause toxicity and is a risk factor for cardiovascular disorders. It was also stated that Cd is classified as toxic for humans and plants (13). In humans, exposure to Cd that is too high in the long term can cause various cardiovascular compilations including hypertension, as well as other diseases such as decreased kidney function and many other organ disorders (8). Cadmium has atomic number 48, atomic mass number 112, melting point 321 °C, and boiling point 765 °C is an element that is odorless or tasteless, and is very toxic (13). One of the mechanisms of action of cadmium is to cause oxidative stress (14). After entering the body, cadmium can replace the ion content in the body from the cytoplasm and membrane proteins such as ferritin which will reduce ion levels. These free ions will later experience oxidative stress through the Fenton reaction (15,16).

In industry, cadmium waste gets special attention, because metal compounds are a type of pollutant that has a high level of toxicity even though the exposure is at low concentrations (17). According to Yu et al (2010) (18), in a study conducted in the Hangzhou area, China stated that industrial areas have the highest level of Cd when compared to several other places such as residences and highways. This is consistent with the research we conducted where the cadmium contained in the respondents we studied was in a high range. Approximately 82.41% of the total population we studied had levels of exposure to blood cadmium that exceeded the toxicity threshold with acute toxicity levels, meaning that they exceeded 50 ng / mL. Cd found on a normal blood test is <5.0 ng / mL, with most results in the range 0.5 to 2.0 ng / mL (19). Lack of nitric oxide (NO) will cause decreased homeostasis of blood vessels which will lead to endothelial dysfunction (20). Impaired endothelial function will cause oxidation stress and will later become a factor in the occurrence of cardiovascular disease (21). This shows a high urgency because if it is not followed up immediately, it is feared that it will increase the level of exposure and the level of disease that is at risk of causing death. Previous research has shown that cadmium levels are reported to be significantly higher among residents in industrial estates than among non-exposed residents (22). Our study shows that knowledge is negatively correlated with knowledge with a correlation coefficient of -0.272. The results of the analysis indicate that the
increasing knowledge will have an effect on decreasing metal content and vice versa. According to Adebamowo (2006) (23), the domain factor that is very important for the formation of one’s actions is called knowledge. Our results are consistent with this statement, where there is a correlation between attitude and knowledge with a correlation coefficient of 0.528. This shows that with increased knowledge, it will be followed by an increase in attitude. The existence of this linear relationship has convinced us that knowledge is an important factor in improving attitudes in dealing with environmental pollution that occurs around industrial areas. With more attention to knowledge, it is hoped that cadmium levels will decrease(23).

Our results show no correlation between knowledge and behavior. Another research also shows that environmental knowledge does not have a significant direct effect on pro-environmental behavior(24). The study explains that although there is no significant relationship between knowledge and behavior, knowledge remains an important factor in determining a person’s attitude and behavior. Our research shows that there is a relationship between attitude and behavior with a correlation coefficient of 0.269. This relationship is classified as having a positive correlation, namely the higher the attitude, the higher the behavior factor. In other words, we found that knowledge does not have a direct impact on behavior, but that the awareness of attitudes will create a behavior that is aware of environmental pollution. In our research, cadmium metal exposure is more pronounced. This is in line with research conducted by Faize and Akhtar (2020)(25) which conducted studies on students regarding increasing knowledge and attitudes to the environment which can be done by providing further explanations with nature and providing understanding of scientific argumentation that increases knowledge and attitudes.

Conclusion

Our study shows a correlation between the knowledge factor and cadmium levels with a negative correlation, where the increased knowledge will cause a decrease in cadmium levels. The knowledge factor also has a positive relationship with the attitude factor, if increased knowledge is carried out it will improve attitudes. Attitude factors correlate with behavioral factors, so that if there is an increase in attitude as a result of increased knowledge, behavior can also increase. Therefore, from the results of our research, it is very important for the local government to evaluate the knowledge improvement of people living in industrial areas in an effort to reduce the impact of cadmium exposure and minimize cardiovascular risk due to long-term exposure. Increased knowledge can be in the form of increased education, further education on cadmium exposure, and can also be in the form of other programs to increase the knowledge factor. Thus, research on the knowledge factor of reducing cadmium levels can also be applied as suggestions for further research in the future.

Conflict of Interest: The authors declare there is no conflict of interest.

Source of Funding: This work was supported by the University of Brawijaya under Grant number 3905 in 2019 and also supported by Laboratorium Terpadu Universitas Diponegoro and World Class University (WCU) Program University of Brawijaya.

Ethical Clearance: This research was carried out when it had received ethical clearance from the UB Ethics Commission, Faculty of Medicine with number 014/EC/KEPK. Respondents included in the inclusion criteria determined in the study were given informed consent and a statement to be willing to participate in this study. If the respondent is not willing, it will be excluded and not included in the study.

Abstract

Corona virus disease -19(COVID-19) is caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV2). Primarily it causes respiratory illness in humans. The pandemic caused by the virus started in 2019 in Wuhan, China. Later it was declared as pandemic by WHO. In this article I am reviewing the coronavirus along with its microbiological structure, transmission, pathogenesis, clinical features and its management. The virus is a single stranded RNA virus. The virus enters the respiratory tract via mucous membrane of mouth or nose. It binds to ACE TYPE 2 receptor and causes alveolar edema and its destruction leading to decrease in gas exchange which further leads to hypoxaemia finally leading to acute respiratory distress syndrome (ARDS). It most patients COVID19 presents with mild symptoms and they doesn’t require any medical intervention. But patients presenting with severe symptoms needs vigilant medical attention and may require ventilatory support. Most common symptoms are fever, dry cough, shortness of breath, fatigue, nasal congestion. The infection spreads via droplet from an infected person. Infection with this virus may lead to severe inflammatory response leading to release of cytokines which causes increased capillary permeability and vasodilatation leading to hypotension which further leads to decrease in blood supply to multiple organs leading to multiple organ failure. There is increase chances of morbidity and mortality among elderly and in those with comorbidities. In elderly the chance of fatality is way more than younger people. No one drug has been found yet as the ultimate treatment of COVID-19. Many drugs are under clinical trial and researches are going on for vaccine as well. But until we get a definitive cure the only escape we have is prevention and the only means to do that is to practice social distancing, proper hand hygiene and sanitation.

Keywords:- SARS-CoV2, pathogenesis, transmission, ACE 2 receptor, alveolar edema, ARDS, prevention, Ground glass opacities, hydroxychloroquine, remdesivir.

Introduction

Coronavirus term is derived from corona that means crown like and this crown like morphology is seen on electron microscopy. This morphology is due to club shaped peplomers arising from the envelop.

Coronavirus is enveloped, single-stranded, positive-strand RNA virus. It is belongs to the order Nidovirales. This coronavirus family consists of pathogens for many animal species including humans. The recent pandemic is caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV2).1 After the rapid spread of coronavirus in various parts of the world, World Health Organisation (WHO) declared it as PANDEMIC.

During the start of corona virus infection it presents in a similar fashion like common cold and many times patient might be asymptomatic. Theryby they transmit the infection to others unknowingly via droplet spread. People of older age and people with comorbidities are at high risk of contacting the infection because of their weakened immune system and comorbidities their immune response is compromised which render them more susceptible. Most patients of younger age present with mild symptoms and do not need any as such medical attention foe their recovery, all they need to do is to self isolate themselves so as to brake the chain of transmission. But at the same time the elderly need...
medical assistance to survive.

**CORONAVIRUS LINEAGE:-**

**ORDER- Nidovirales**  
**FAMILY- coronaviridae**

The Coronavirinae and the Torovirinae are the two subfamilies of the family Coronaviridae. The coronavirinae is again divided into four genera: Alphacoronavirus, Betacoronavirus, Deltacoronavirus and Gammacoronavirus. Coronavirus is widespread and maximum variety of genotypes infect bats. But Alphacoronavirus and Betacoronavirus are subcategories which affects the humans.1,2,3

**MICROSCOPY:-**

Coronavirus is an enveloped virus. It has a large plus-strand RNA genome of size the 27-32 kb. It is capped and polyadenylated and its diameter is 80nm to 160nm. The Coronavirus genome confer a 5' cap and 3' poly-A tail. Numerous eminent surface projections are present, they cover the viral surface completely, this gives them the crown like appearance. The size of the surface projection is about 20 nm. 2/3rd of RNA of coronavirus codes for non structural proteins and rest of it code for essential structural protein. 1,3

**ESSENTIAL PROTEINS:-**

*Spike proteins-* The coronavirus spike protein is a type I glycoprotein that forms the peplomers on coronavirus particles. Coronavirus binds to specific cellular receptors through the spike protein. After the attachment of virus to the cellular receptor, the spike protein undergoes a conformational change which allows the fusion of viral membranes with the cellular membranes. The spike protein is vital for entry of virus, its cell-to-cell spread and for determination of tissue tropism. Spike is the major determinant of tropism and pathogenicity and is responsible for initiation of viral infection.

*Membrane protein-* This protein is present in abundance on the membrane. It plays a role in viral assembly and host interactions. Glycosylation of M proteins occurs for virus and host interaction. It can be N or O glycosylated.

*Envelop protein-* integral membrane protein. Plays important role in viral assembly.

*Hemagglutinin esterase(HE) -* HE glycoprotein is responsible for formation of second type of spike on group II coronavirus. The second type of spike is smaller and allows binding of virus with sialic acid on host cell surface glycoprotein.

*Nucleocapsid protein-* Is a phosphoprotein which binds with viral RNA and act as a regulator for viral RNA synthesis. So this protein is essential for transcription and pathogenesis.

*Replicase protein-* They can determine the rate of viral replication so it affects tropism and pathogenesis.

Spike protein is a glycoprotein which exhibits high grade of mutation whereas in rest of the structural proteins no significant mutation is seen in COVID-19. Severe acute respiratory syndrome coronavirus 2 (SARS-CoV2) when compared with severe acute respiratory syndrome coronavirus (SARS-CoV) showed less preserved models of Spike protein.

Its incubation period ranges from 1 to 14 days and its clinical features resembles to that of SARS-CoV and MERS-CoV that is cough, cold, fever, dyspnea, chest tightness etc. SARS-CoV and COVID-19 shows alike clinical features because both of them binds to angiotensin converting enzyme 2 (ACE2) receptor in lungs.3,4

**EPIDEMIOLOGY:-**

*Origin – Zoonotic(most likely Bats).*

*Intermediate host - Humans.*

Spread of coronavirus occurs from one person to another via direct contact with an infected person or via droplet spread through coughing or sneezing.

The Reproductive ratio for COVID-19 is roughly between 2 to 4. Reproductive ratio is degree of transmissibility which denotes the no. of people that can get infected from a single infected person.

*Attack rate- 30- 40 %*

*Case fatality rate( CFR)- 3.4% world wide*
Timeline:-
- China notifies WHO on 2019-12-31
- First US case in Seattle 2020-1-15
- WHO declared pandemic on 2020-3-11
- National emergency on 2020-3-12

TRANSMISSION:-

It is a droplet infection, that is it spreads through tiny droplets released from nose and mouth of infected person when they cough or sneeze. The droplets can settle on the people around as well as on various surfaces. And the virus can spread if the virus enters the mucous membranes of mouth or nose of the person who comes in contact with those infected surfaces. For how long the viruses will survive on any surface depends on its type. Surfaces can be disinfected within 1 to 2 mins by using 62% to 71% alcohol rendering the virus inactive.1,5

Viability of coronavirus on different surfaces:-

- Airborne droplets-3hrs
- Porous surfaces(cardboard, paper, fabric)- upto 24hrs
- Hard, shiny surfaces(glass, countertops, plastic, satinless steel)- upto 72hrs

So it is very important to have as less contact as possible with surfaces which could have been in contact with many persons and to follow proper hand washing and sanitising techniques to decrease transmission by fomites. Despite the fact it is not possible to avoid touching all the surfaces so the only option there is to avoid touching the mucous membranes and to wash hands regularly. Alcohol based sanitisers and disinfectants can also be used to sanitise hands and surfaces respectively. There are few evidences suggesting feco-oral transmission. It has been found that stool might contain virus. And in such cases rectal swab comes positive

SARS-CoV2 is more transmissible than SARS-CoV, due to increased binding of spike proteins to ACE2 receptors as a result of mutation of spike protein.

PATHOGENESIS:-

SARS-CoV2 is a droplet infection. It means that it spreads via respiratory droplets which are released in the environment by coughing or sneezing. It can also spread via direct contact with an infected patient.

For binding of virus with host cell 2 receptors are needed ACE-2 receptor and TMPRSS-2(trans membrane protease serine precursor 2) receptor. After binding to these receptors membrane fusion and endocytosis occurs and endosome is formed. pH inside the endosome is acidic. Then uncoating of virus occurs and ssRNA is released. In the presence of chymotrypsin like protease, translation occurs leading to formation of RNA dependent RNA polymerase and non structural proteins (NSP). The RNA dependent RNA polymerase enters the nucleus via importin channel and forms multiple copies of ssRNA. The ssRNA comes out and assemble with the NSP and forms the complete virus. The virus comes out of the cell via exocytosis. This causes activation of macrophages which causes release of cytokines like IL-6, VEGF etc. This leads to organ damage.

Through the mucosal membranes viral agent enters inside the body of host then it enters inside the respiratory tract, travels there finally enters alveoli in lungs. in the alveoli type II pneumocytes are present, they carry a receptor for SARS-CoV2 that is angiotensin-converting enzyme 2 (ACE2) receptor. SARS-CoV2 binds with ACE2 receptor. The binding occurs because of high affinity of S glycoprotein present on the outer membrane of the virus towards ACE2 receptor. After the binding is complete endocytosis of virus occurs inside the cytoplasm of type II pneumocytes. Following endocytosis the lysosomal enzyme breaks down the lipid bilayer of the viral agent.

The ribosomes of the host cell is utilised by SARS-CoV2 for translation of mRNA into polyproteins which then forms the structural framework of virus.

Then initiation of self replication of polyproteins occurs which leads to an increase in the viral load in the patient. In the process of self replication SARS-CoV2 uses the RNA-dependent RNA polymerase present in the host. The polyproteins are then proteolysed by enzymes present in the host cell following which formation of various structural proteins like spike protein, E protein, nucleocapsid etc takes place. These proteins combines with the single stranded RNA which is formed by replication and forms the mature Virus.
The mature virus comes out of the type II pneumocytes by a process called budding. And during this budding the type II pneumocytes are destroyed. This destruction of type II pneumocytes causes release of specific inflammatory mediators which then leads to stimulation of macrophages. The stimulated macrophages in response release specific cytokines like IL-1, IL-6 and tissue necrosis factor-alpha (TNF-α). In case of acute inflammation IL-1 & IL-6 are released which causes fever. These specific cytokines enter the blood and causes contraction of the endothelial cells of blood vessels and they also causes smooth muscle dilatation. These two actions result in an increase in capillary permeability which further leads to leak of plasma into the interstitial spaces finally causing alveolar edema. The other major problem that occurs due to type II pneumocyte destruction is decrease in surfactant production. This is one of the primary functions of type II pneumocyte. The surfactant is the substance which maintains the surface tension and prevent the collapse of the alveoli. But due to decrease in surfactant production surface tension increases causing alveolar collapse. Due to the alveolar collapse there is :- Impairment of gas exchange. Due to this refractory hypoxaemia occurs.

There is an extensive increase in the work of breathing due to impaired gas exchange in an attempt to inspire as much air as possible against a collapsed alveolus as well as against interstitial edema. This mechanism leads to ARDS that is acute respiratory distress syndrome. Another feared complication alongside ARDS is disseminated intravascular coagulation. Disseminated intravascular coagulation (DIC) is what leads to the development of multi-organ failure.

During the destruction of type II pneumocytes inflammatory mediators are released they cause a neutrophil influx inside the alveolus. Neutrophils will destroy the virus by releasing reactive oxygen species and proteases. While destroying the virus the neutrophils causes destruction of all the alveolar cells as well.

Type I pneumocytes play an integral role in gas exchange so their destruction causes impairment of gas exchange. Type II pneumocytes produces surfactant so their destruction causes increase in surface tension which further leads to alveolar collapse. There is collection of fluid in the alveolus which consists of destroyed slough off cells and cellular debris that contains type I & II pneumocytes, macrophages & neutrophils resulting in formation of consolidation. The consolidation further interferes with the gas exchange, causing cough, dyspnea & hypoxemia. Hypoxaemia stimulates peripheral chemoreceptors causing the sympathetic stimulation leading to increase in rate of respiration and heart rate as a compensatory measure for decreased partial pressure of oxygen.

One of the most common complication seen here is systemic inflammatory response syndrome (SIRS). This is seen in case of progression of infection when the specific cytokines enters the vasculature causing increased capillary permeability. This increase in permeability of capillaries leads to leakage of plasma in the interstitial tissue spaces. This dumping of plasma in the extravascular space decreases the blood volume. Also the vasodilatation that happened due to the cytokines further decreases the total peripheral resistance (TPR). The decrease in both the blood volume and TPR leads to a considerable drop in blood pressure that is hypotension. This leads to insufficient perfusion of organs and this can anytime progress to multi-system organ failure. Every organ manifest in its own ways. Elevation of blood urea nitrogen (BUN) and creatinine is seen in c/o insufficient kidney perfusion. This elevation is seen because kidney is unable to filter the needed amount of BUN and creatinine from blood and this finally causes acute renal injury and renal failure. The circulating cytokines also enters the central nervous system CNS via the vascular system. The main site of action in CNS is hypothalamus. The IL 6 and IL 1 acts on the hypothalamus. Hypothalamus is the part of brain which maintains the body temperature. When IL-1 and IL-6 attains high concentration in hypothalamus release of prostaaglandins takes place and this disrupts the normal temperature of the body and resets the core body temperature to higher than normal resulting in fever. This means that one of the most universal and common symptom that is fever is caused due to elevated levels of IL-1 & IL-6.\textsuperscript{1,3,5,6,7}

**Clinical features:**

The duration between onset of symptoms and death varies from 6 to 41 days but it actually depends upon the age and immune status of the patient. The incubation
period is shorter among older individuals. India is still in better shape because the mortality rate is less compared to others.

Median timeline observed:

Day 1 – exposure to COVID-19

Day 5 – presentation of 1st symptom

Day 10 – dyspnea

Day 12 – hospital admission

Day 13 – ARDS

The people with comorbidities like asthma, diabetes and hypertension are at a higher risk. Other risk factors are patients on ACE inhibitors and ARBs as they cause upregulation of ACE-2 receptors. And this leads to an exponential increase in replication of the viral genome and it leads to increase in severity of the disease. And this also explains why people with hypertension are at a higher risk. This also explains the severity of infection in elderly as compared to younger people.

People at extreme of ages are at higher risk. Elderly people are at a comparatively higher risk because of the physiological change taking place in their lungs due to ageing. As age progresses the respiratory muscles get atrophied leading to reduction in respiratory functions. There is a significant decrease in lung capacity. Also the immune barrier becomes weak and the mucociliary clearance of the airway decreases. There is one more theory which suggests that with age no. of ACE2 receptors increases rendering the old people at higher risk of infection as compared to adults. Cardiovascular symptoms are also seen with COVID-19 patients. This is seen when the disease progresses and due to progression the immune system becomes defective. Myocardial injury also occurs due to cytokine storm as a result of imbalanced response between type 1 & 2 helper T cells.8,9

In the early phase the symptoms resembles common cold like cough, fever, cough and its difficult to differentiate but as the virus replicates and the viral load increases the severity of symptoms increase.

Damage to the alveolar epithelial cells causes fibrotic changes which leads to dyspnea, cough and hemoptysis. Multiple peripheral ground-glass opacities were observed in subpleural regions of both lungs in some patients on hospital admission. Every person gives a varied response depending upon his immune status. So the severity of symptoms and the fate of disease directly depends upon the state of immune system of patient. This explains why elderly, immunodeficient people and people with comorbidities show severe symptoms and higher mortality compared to those who are comparatively healthy with a stronger immune status.

ACE 2 receptors are also present on enterocytes, so gastrointestinal symptoms can also be present. Technically as coronavirus is enveloped so it shouldn’t have causes any GIT symptoms, but it does sometimes.

Generally in early stage the symptoms are not specific like fever, non productive cough, cold, bodyache, generalized weakness lethargy with or without diarrhea. Patient may also complaint of difficulty in breathing that is dyspnea. As the disease progress hypoxia may develop leading to ARDS (acute respiratory distress syndrome). In such situation mechanical ventilation is given to the patient in ICU. Patients spO2 is closely monitored. And in such cases the chance of secondary bacterial pneumonia increase. the commonly involved organisms are staphylococcus aureus, streptococcus pneumoniae, klebsiella pneumonia & hemophilus influenzae.

So the common symptoms are fever, dry cough, shortness of breath, myalgia, fatigue, sputum production, lymphopenia, nasal congestion, chills/night sweats.

Uncommon symptoms are headache, hemoptyis, diarrhea, confusion, rhinorrhea, chest pain, nausea, vomiting, sneezing.

Complications are Acute Respiratory Distress Syndrome (ARDS), secondary infection, ventilator associated pneumonia, septic shock, acute renal injury, hypoxemia, acute cardiac injury.8,9,10

EXTRAPULMONARY MANIFESTATIONS OF COVID-19:-

Neurologic – headache, dizziness, encephalopathy, ageusia, myalgia, anosmia, stroke

Renal – proteinuria, hematuria, acute kidney injury

Hepatic - elevated aminotransferases, elevated
bilirubin

Gastrointestinal- nausea, vomiting, diarrhea, abdominal pain, anorexia

Cardiac- myocardial injury, myocarditis, cardiac arrhythmias, cardiogenic shock, myocardial ischemia, acute cor pulmonale, cardiomyopathy

Endocrine – hyperglycemia, diabetic ketoacidosis

Dermatological – petechiae, livedo reticularis, erythematous rash, urticaria, vesicles.

BIOCHEMICAL CHANGES:-
- CBC- leukopenia & lymphopenia
- Increase BUN
- LFTs- increase AST/ALT
- Increase D-dimer, increase CRP, increase LDH
- Increase IL-6, increase ferritin
- Decrease procalcitonin

INVESTIGATIONS:-
-LAB DIAGNOSIS:
1) Antigen detection- coronavirus antigen in respiratory epithelial cell can be detected by ELISA using specific monoclonal antibody
2) Electron microscopy- shows morphology
3) RNA detection by RT-PCR:- can detect RNA in respiratory secretions.

RT-PCR: it stands for reverse transcriptase polymerase chain reaction. Via reverse transcriptase DNA is formed from the RNA of the virus and then it is amplified for detection.
4) Serum antibody detection by ELISA or hemagglutination.

- IMAGING:-
  a) Chest Xray: hazy bilateral peripheral opacities
  b) CT scan : ground glass opacities(GGO), crazy paving, consolidation.

CT scan is not done in every patient. It is indicated only in patient with moderate to severe symptoms and/or worsening respiratory status.

CO-RADS

Standardised reporting system based on CT findings is CO-RADS. It gives the level of suspicion.

<table>
<thead>
<tr>
<th>LEVEL OF SUSPICION</th>

Typical appearance of COVID-19:- Peripheral bilateral ground glass opacities (GGO) with or without consolidation or visible interlobular lines (crazy paving). Multifocal GGO of rounded morphology with or without consolidation or visible interlobular lines (crazy paving). Reverse Halo sign (Atoll sign) or organising Pneumonia or spider web.

Indeterminate appearance:- multifocal, diffuse, peripheral or unilateral GGO with or without consolidation lacking a specific distribution and are non rounded and non peripheral. Very few small GOG.

Atypical appearance:- presence of isolated lobar or segmental consolidation without GGO. Discrete small nodules(centrilobular, tree in bud). Smooth interlobular septal thickening with pleural effusion.

Very atypical appearance:- cavitation, calcification, tree in bud, bronchiolitis, nodular pattern.\textsuperscript{11,12}

</tbody>
</table>

CT severity score:- scoring based on the % of each of 5 lobe involved. Each lobe is given individual score and then sum is calculated.

- >5% involvement = score 1
- 5-25 % involvement = score 2
- 26-49% involvement = score 3
- 50-75% involvement = score 4
- >75% involvement = score 5

Score ranges from 0 (no involvement) to 25 (maximum involvement).

- if score <8 = mild
- if score 9 to 15 = moderate
- if score >15 = severe\textsuperscript{13}

MANAGEMENT OF COVID-19:-

Symptomatic management, supportive care and prevention of transmission forms the mainsaty of management. Social distancing is the most affective tool we have to break the chain of man to man transmission. Most patients presents with mild to moderate presentation ranging from mild symptoms to mild pneumonia. And the patient with mild symptoms recover on their own with any medical interference, all that is needed for them to do is to isolate themselves to break the chain of transmission. Vitamin c & d, zinc, selenium etc are being tried as measures to prevent from viral infections specifically respiratory.

Many drugs are under clinical trial. Hydroxychloroquine is being used widely in the treatment of COVID19 but there is no solid evidence to tell about its efficacy. And some studies even suggest that it is increasing the risk of cardiac arrest. REMDESIVIR is another drug under trail. Remdesivir inhibit viral replication. It is an adenosine analog. Multiple trials
are going on but no one drug has been narrowed down yet.\textsuperscript{14,15,16,17}

Drugs under trial are :-

- Hydroxychloroquine- inhibit entry of virus by inhibiting ACE-2 & TMPRSS-2 receptor, inhibit endocytosis by increasing pH inside endosome.
- Nafamostat – TMPRSS-2 blocker
- Lopinavir , Ritonavir- protease inhibitor
- Remdesivir , Ribavirin, Favipiravir- RNA polymerase inhibitor
- Ivermectin – importin inhibitor
- Immunomodulators
  a. corticosteroids, hydroxychloroquine
  b. anti IL-6 – tocilizumab, sarilumab
  c. anti VEGF- bevacizumab
  d. plasma exchange

Control measures:-
- isolation of patient
- quarantine of exposed people
- travel restrictions if needed
- personal protective equipment- gloves, gowns, goggles etc.
- frequent hand washing with soap and water
- use of alcohol based sanitizer
- sanitization of surfaces which come in direct contact
- use of masks and shields at public places
- avoid personal contact with sick patient\textsuperscript{18,19,20}

Conclusion

This is a review article on coronavirus in which I have dealt with its basic morphology, transmission ,pathogenesis , common clinical features and management. This is an emerging pathogen , not much information is present regarding this virus. It is primarily causes respiratory infection and spreads via droplet from person to person. Mostly is causes mild symptoms like cough , fever, cold , headache, loss of taste and smell. But in severe cases is can cause dyspnea , ARDS, pneumonia and even multi organ failure. It attaches to ACE 2 receptor and causes fluid dysregulation in the respiratory tract leading to alveolar edema leading to dyspnea. On CT scan ground glass opacities are a consistent finding. Mutiple drugs are under trial but no one drug has been proven 100% affective. Drugs like hydroxychloroquine, ivermectin , remdesivir etc are being used. Still the best remedy remains social distancing, sanitising and using personal protective equipment.

Abstract

Summary: Currently, we can see, covid19 is quite a concern because of its mortality and even morbidity rate. Since no cure is present till date it’s more important for people to take basic care to increase their immunity. One modality for prevention of such diseases can be through Ayurveda, which has different therapies and medicines to deal with diseases as well as measures to take basic care and to boost immunity of individuals. AYUSH helps with those basic methods in one’s life. This article discusses the necessity of ayurveda in order to cure this type of air born diseases. Ayurveda mainly emphasizes on body response to any cure as well as role of chakra healing in covid19. Susruta helps find chakras in our body and chakra helps to communicate with different diseases via factors like air, water, earth, fire etc. Ayurveda is the oldest cure and best way to connect body with mind and soul. It brings you more near to nature and helps you calm yourself in different situations. It also molds your perspective and the way we see things.

Conclusion: Lifestyle adaptation with proper dincharya and ritucharya is quite effective to ensure healthy living and protect ourselves by building our immunity. Ayurveda acts as an immunity booster and effective in combating infectious diseases.

Keywords: Janapadodwasma (Covid19), ayurveda, herbs, dincharya and ritucharya in covid19.

Introduction

Janapadodwasma and covid19

The world is terrified due to pandemic corona virus disease (COVID-19) which is mainly caused by severe acute respiratory syndrome Corona virus (SARS-CoV-2). This is considered as Janapadodwasma (destructions of states or kingdoms or country) in ayurveda. Moreover COVID-19 infection may be correlated with Vata-Kaphaja Sannipataja Jwara (a type of fever mentioned in classical Ayurvedic texts with severe complications and and problems to one’s living) (¹). Thus we have to understanding the concept of COVID-19 and its management principles based on ethics of Ayurveda. The main aim of management principle includes correction of the Vikruta (contaminated) Vaya (air) and Desha (place/continent etc.) and improving the immunity and lifestyle for prevention of disease as well as the management of COVID 19 patients by various herbal or herbo-mineral combinations which is mainly based on the stage/severity of the disease along with which patients are asked for follow up for recovery to avoid the recurrence. In this aspect the management of COVID-19, role of Ayurveda experiments are proved more beneficial in asymptomatic, mild and moderate stages. Further, clinical studies on these drugs should be conducted to make sure evidence for safety and efficacy on COVID-19 for wider acceptance and implementation of Ahara, Vidhis, Dinacharya and Sadvritta in National Health Policies for improving disease resistance. In ayurveda it is termed as Janapudhwamsa; in Caraka Samhita its concept has already been described, Caraka Samhita being a nodal text helps you to understand it better and it is also correlated with pandemics and epidemics too (²,³). According to this janapudhwamsa is classified into two group based on their causes; (⁴,⁵)

- First- occurring due to natural causes
- Second- occurring due to manmade causes.

All two of them mentioned above are further classified into four groups that is:

1. Vitiation of water
2. Vitiation of climate
3. Vitiation of land and
4. Vitiation of air

Etiology of janapdodhwamsa

**Water:**

Water is considered to be harmful (vitiating) when –

1. Water has different texture, taste, color, odor or smell,
2. Water that is muddy and is turbid and
3. The water which doesn’t have any type of aquatic animals in it.

**Climate:**

Some Features of destruction or vitiation of climate includes-

1. Unseasonal climate variations,
2. Regular climatic agitation, earthquakes, meteorites, etc and
3. Presence of poisonous fumes that veil the skies.

**Land:**

Land is considered to be problematic or vitiating when-

It is rife with grass or weed, withered and dry, major of forest resources are damaged and are excessively moist – like it has no predatory animals like birds, vultures, jackals, serpents and carnivores, a bog or marsh and is riddled with smoke and Dust.

**Air:**

Vitiation of air is considered when –

Air is constant without any movement, turbulent and fear full, like moist, hot, dry and blowing in opposite directions frequently, huge cyclones, harmful and toxic gases in it etc.

These all are responsible for violation of climate, water, air, land and finally leading to epidemic and pandemic. Now since we are clear about, how janapdodhwamsa work, there are some ways to understand the spread of air born infection in ayurveda.

**Comprehending infectious diseases (air born) in Ayurveda**

One of the terms being regularly used is “Bhuta” which can be found in various scripts in ayurveda .one of the example of this is the text of Panchamahabhootas (6) – where they have explained the foundation and basis of the microorganism and the macro organism of this world. Panchamabhootas has been used for all microorganisms commonly known as ‘Jeevanus’. The character that microorganisms or microbes play in manifestation of disease has never been hidden and known since the time of Vedas. , Krimi (worms that leaves inside human body), Bhuta (ghosts), Jantu (creatures), Rakshas (demons), Jeevanu (bacteria), and Pishacha (vampires) these terms have been used to describe them. The “Panchamabhootas” are therefore classified on the basis of visibility and on the basis of infection(4,5). Thus, spread of these diseases is main concern to deal with.

**Transmission of infectious diseases**

In ayurveda one of the renowned personality Susruta has describes that the manner of spreading of infectious diseases is mainly through contact with an diseased person frequently, food sharing and having physical contact via respiratory droplets , using materials such as combs, napkins, towels, blankets, bed sheets, etc. and exchange of body fluids in terms of sexual contact. Interestingly in ayurveda they all have cure for these spreads but before knowing, how to control them, one should know how Ayurvedic medicine work with pathogens in our body. Thus to continue further lets first understand the basic concept of approaching Ayurvedic medicine in individuals.

**Pathogenesis of infectious diseases and Ayurvedic approach**

There is no as such description describing how pathogens work and what the basic of occurrence of those pathogens is. There are diseases like Agantuj Jwara (external factors leading to fever), Agantuja Atisara (Diarrhea), Ajirna (indigestion due to infection), Visuchika (Cholera leading to diarrhea), etc are some scenarios where vitiation of Doshas take place which occur mainly because of infectious diseases, this can be
related with the infectious agents. In rest of the scenario or cases, no different descriptions are available for this type of infectious diseases and are usually known by the type of infectious diseases.

Time of Disease origin, its development and progression of any infection is written in the description in Shat Kriya Kala - here one thing is important to note that according to the line the main agenda of ayurveda is obtaining this stage of Dhatus Samya – (that is equilibrium of Dhatus) (3) and to study about these things that being grasping the knowledge of Hetu (refers to etiological factors), Aaushadha (Drugs or medicines) and Linga (clinical presentation)(4) for healthy person as well as diseases person its important to free them from these pathogens so that there healthy life could be maintained and the person is treated in order to stabilizes his efficiencies back. In pathogenesis according to above mentioned stages the progression of disease is being assessed (5) and thus they are considered as the stage of treatment. This mainly includes corrupting the situation of Malas, Dhatus and Dosha.

- First stage - Dhatu
- Second stage – Dhatu and Malas
- Last stage and third stage- differentiation or complication

In first three stages there is lodgment of infective agents which are disturbing the Dhatas. The bodily elements are spoiled by factors such as environment, diet, indulgence, modification of lifestyle.

In the last stage of pathogenesis there is migration and circulation. It is caused by the Vayu by the means of Rasa (blood circulation, lymphatics, interstitial fluid, etc) (6). these circulating Doshas accumulate in places where it doesn’t affect or temper the body element (6,7). It means that, the knowledge of infection is good to Ayurvedic scholars.

How dincharya and ritucharya will help in Covid-19?

“Ayurveda extensively describes many ways on preventive care through Dinacharya and Ritucharya, which means daily and seasonal regimens. It is basically a plant-based science and improving immunity has been emphasized in many number of ways in Ayurveda literature,” says senior Ayurveda specialist Dr S Sarangapani. (8,9)

Dincharya helps u to emphasize on things that we were ignoring since long time. It’s a high time one should make a proper timetable to spend their day more efficiently. Do yoga, eat healthy, talk to your elders, be good to people, try to find your weakness and way out of it, learn new things, and use the time to grow every day. Yoga bring u peace, it cures your body help u to analyze things more clearly. It’s a food to your soul.

While ritucharya is more Ayurvedic secrets for seasonal eating. Where ritu stands for seasons and charya stands for guidelines. Our body is designed in specific manner which mainly help us to work with different natural conditions including different seasons. These guidelines help us to follow a proper diet and lifestyle which include detox treatment.

According to ayurveda year is mainly divided into two time periods - uttrayana (cold climate) and dakshinayana (hot climate). Uttrayana further is divided into - season of sharath, hemanta, and shishira. While dakshinayana is divided into season of vasant, grishma, and varsha. (9,10,11)

Thus eating according to seasons helps built immunity and prepare body to fight with any seasonal infection that harms your body. There is two pictures that help you with the dincharya and ritucharya understanding.
COVID-19
Coronavirus Disease 2019

10 WAYS YOU CAN HELP THE ELDERLY AND PEOPLE WITH UNDERLYING CONDITIONS LIVING WITH YOU

Monitor their health for symptoms of COVID-19, like fever, cough, and difficulty breathing.

If anyone in the household has symptoms, avoid physical contact and take heightened prevention measures.

If they have COVID-19 symptoms, contact a healthcare provider immediately.

Encourage them to maintain a healthy lifestyle: eat nutritious foods, get enough sleep, don’t smoke, stay active and limit alcohol use.

Regularly clean and disinfect surfaces and keep the house well ventilated.

Avoid sharing objects like glasses, cutlery and towels.

Make sure they have at least a month’s stock of all their regular medicines in case it’s necessary to stay home. Encourage them to follow medical advice about medication.

Follow social distancing measures in your area and avoid shared spaces and large gatherings.

If going to the doctor, wear a mask, if available, and avoid public transport if possible.

Be kind and show empathy. Talk and listen to them. Help them cope with stress.

Info graphic: COVID-19. Ways you can help the elderly and people with underlying conditions living with you.
Boosting Immunity

HOW TO MAKE AYURVEDIC HAND SANITIZER AT HOME

herbal sanitizer comprise of combination of alcoholic extracts of Ocimum sanctum (Tulsi), Azadiractindica (Neem) and Eucalyptus globulus (Nilgiri) using suitable excipients; which can be used as a ready-made herbal hand sanitizer.

Even if Ocimum is not available one can use nail paint remover with aloe vera gel and rosewater for making hand sanitizer.

Herbal prevention for boosting immunity in covid19 pandemic

It’s important now to take care of ourselves and young ones and elders in this pandemic.

The best Ayurvedic medications which are affective and economic can be found very easily in households we usually use it in our daily basis. Some of them are mentioned below with their properties.

Ginger used for cold and cough

Ginger is very effective home remedy for cold and cough. Ginger root have anti-inflammatory properties, ginger and shogal can help relieve sore throat, reduce congestion and soothe an upset stomach. These compounds can also kill rhinoceroses (nasal wall thickening and secretion), which cause colds. Make ginger tea with honey and drink it three or more cups per day until you feel good this help you to cure cold and cough.11

Facial steam good for Runny Nose

It is already a traditional to take hot steam to treat runny nose. Steam cleanses your nostrils and helps relieve mucus and blocks caused by it. How to do it?
– Place your face over steam water, cover with cloth or towel to make sure no steam goes out and breathe deeply through your nose. Do this for 20 to 30 minutes at a time twice a day. Make sure you take a break if your face becomes too hot. Then inflate your nose to get

Figure1: immunity boosters in covid, By M. Sai Gopal
rid of mucus (don’t try too harshly). You can also add a few drops of decongestant essential oils (like Vicks, eucalyptus oil) to your facial steam water. Eating spicy foods also helps prevent runny nose and unblock nostrils (12).

Gargle with warm, salty water to treat any sore throat

Sore throat is very common, they can be mild or can be severe leading to voice getting worse though they can even get better than themselves within a week. A sore throat is mainly and majority of time is caused by a virus (such as a cold or flu) or smoking. Its Very rare that they can be caused by bacteria. If you are also suffering from a sore throat, gargle with warm, salty water for at least 5 minutes thrice a day(13).

Drink lots of water if diarrhea is the problem

Many a times, diarrhea resolves on its own. This condition also can be caused by various factors including viruses, bacteria, parasites, food intolerance and digestive disorders. If it’s Diarrhea, you need to quickly take fluids to treat dehydration. So, drink plenty of water, Taking probiotics, eating green bananas can also help reduce the symptoms of diarrhea. Chamomile and peppermint are also useful to treat diarrhea(14).

At last role of dhoopana in ayurveda

Dhoopana is a method by which drugs of herbal, herbo-mineral or animal origin are used for fumigation so as to heal Varna (words), Yonivyapada (vaginal disorders), Karma Rogas (ear diseases), Nasa Rogas (arterial diseases), Guda Rogas (arterial diseases), Gatra Daurgandhya; to disinfect Bheshajagara, Vranagara, Sutikagara, Shastrakar-maghruha, and Kumaragara and also to sterilize Asavas and Aristas (15,16,17).

Ayurveda has a broader scope for improving immunity and combating infections like Covid-19 (18,19,20). A number of ayurvedic herbal drugs are being trialed as antiviral herbals in Covid-19 (21,22).

Conclusion

So it is been clear that apart from well known medical help from ayurveda in this pandemic ,importance of it have been declined, in spite of the fact that it plays a major role in peoples life by boosting their immunity.

In ayurveda According to Charaka (renowned Ayurvedic practitioner) – where he said that disease is the combination of two things namely which he named it as Dosha (3 substances present in human body –vata, pitta, and kapha) and Dhatus (metals) and the gifted qualities of Doshas are more dominating over Dhatus. This proves that our body responds quickly after getting affected by pathogens regularly.

If our body is infected it can easily be treated through this methods. Though it has already been seen that not every time herbs help to heal patients and fails to prove its value for treatment of microorganism, but it is well known that ayurveda have always helped one to boost immunity and make individuals body more stronger against microorganism, so these herbs or medicine are tend to increase body’s action against diseases

Before this, the mentioned herbs should be the prime initiative for one’s to deal with this covid19 situation. Its more effective and economical. There are many articles that are available on this topic the more u read the more u can help yourself to protect from this pandemic. Ayurveda is just most basic form to hold your roots; there is always a reason that our ancestors followed this culture of dincharya and ritucharya. Meditation, eating healthy, suryanamaskar, early to bed , early to wake up, helps to form a clock (alarm) to people body that make their organ work in a systematic manner.

Concluding to this, Ayurveda might have not produced cure for this pandemic problem, but its been proven that it for sure helps people to boost their immunity against covid19.

Abstract

Corona virus (Covid-19) is a pandemic disease, it is a crisis situation faced all over the world. The corona virus originated in bats and was transmitted to humans in the month of December 2019 from Wuhan China. Corona virus is the infectious disease and it attacks on respiratory system and causes respiratory illness that can spread from one person to another person by droplets i.e sneezing, coughing. In India, as on date recorded Corona virus cases are 207615, recovered cases are 1,00303, total deaths 5815 as on 30 August 2020. Indian Government has declared lockdown all over the states to save the life of the citizens. This is a very critical situation mostly for vulnerable population means children. After lockdown children are getting bored, due to separation from friends, peer group and their daily routine of playing is creating lots of anxiety for children. Children’s social life and leaving have been affected. Lockdown of pandemic disease, Closure of schools has affected the education of children and younger’s also. The school closures are liable to boredom to the students and caused learning gap among the children belonging to lower or higher socioeconomic status families. In this condition we have to understand the children psychology and we need to engage them in creative and interesting activities at home, also need to give them some learning task regarding studies so their cognitive and psychomotor function will be improved. This short communication concludes with the key learning for the parents of children on how to engage school going children during lockdown in Covid 19(Pandemic).

Keywords: Covid-19, Pandemic, Lockdown, Engaging, School kids.

Introduction

Corona viruses are a large family of viruses which may cause illness in animals or humans. In humans, corona viruses causes respiratory illness ranging from the common cold to more severe diseases such as Middle East Respiratory Syndrome and Severe Acute Respiratory Syndrome [1]. It is an infectious disease and can be spread through droplets from one person to another person those in contact with a person infected with corona virus [1]. The World Health Organization has officially declared COVID-19 to be a pandemic and has called on “all countries to continue efforts that have been successful in reducing the number of cases and halting the spread of corona virus infection.” The primary purpose of Lockdown is to stay at home and to prevent spread of corona virus in community and maintain communal space [2]. Lockdown has started in phase. The 1st phase was from 25th March 2020 to 14th April 2020 for 21 days, 2nd phase from 15th April 2020 to 3th May 2020 for 19th days and 3rd Phase from 4th May 2020 to 31st May 2020. In this crisis, children’s are the vulnerable population they are physically and psychologically disturbed due to disturbances in their daily routine and separation from their friends and peer group, closed relatives. Parents are worried how to engage their children during lockdown [3].

EFFECTS OF LOCKDOWN ON SCHOOL GOING CHILDREN

During this Covid 19 pandemic disease children are luckily safe because of early decision of school closure by state government and central government but it has made profound effects on children’s well being. Lockdown make more adverse impact on children
belongs to lower socioeconomic status as it is widening learning gap because access to mid-day meals is the primary reason so many Indian students attend school, if the lockdown continues for much longer, there is a chance that India’s dropout rate—which is already among the world’s highest—might increase further[4,5].

According to United Nations Educational, Scientific and Cultural Organization (UNESCO), about 0.32 billion students in India have been affected because of school closures due to the Covid-19 pandemic (UNESCO 2020). Of these, almost 84% reside in rural areas while 70% attend government schools. As of 2015, the average dropout rate across secondary schools in India was 17.06% with higher numbers for rural areas [6].

Although parents having access to technology are gradually switching to online education for the studies of their children while others are still not able to do so. It is important to provide practical support to parents and caregivers, including how to talk about the pandemic with children, how to manage their own mental health and the mental health of their children and tools to help support their children’s learning. Now is the time to step up international solidarity for children and humanity and to lay the foundations for a deeper transformation of the way we nurture and invest in our world’s youngest generation [3,7].

Although children are not the face of this pandemic, they risk being among its biggest victims. From socioeconomic impacts to physical and mental effects due to mitigation efforts, the corona virus pandemic is a universal crisis, that for some children, the impact will be lifelong.

**NEEDS OF SCHOOL GOING KIDS DURING LOCKDOWN.**

The school going children have different types of needs like emotional and physical needs. The emotional needs are like love, affection, need of comfort. The physical needs of school going children are safety, security, warmth, comfort, trust, food, clothing, safe drinking water, fresh healthy air, a secure surrounding environment, time for indoor and outdoor games, adequate amount of quality sleep and rest. In this period working parents are getting adequate amount of time to care for their children because of work from home due to lockdown. It’s a good opportunity for parents to see their children in growing stage closely.

Along with all needs education is also must for children, it’s a part of their future and they are future of tomorrow. So we cannot separate them from studies, parents has a greater responsibility belonging to lower or higher socioeconomic status to help their children to impart the knowledge. So their cognitive function will be improved. The school is important for such kids as they not only learn but also get therapy sessions. Plus, there is a dedicated person working with each child [8].

Plan Daily Activities During Lockdown

1. Practice and teach yoga:-

It’s a good chance for the parents to teach Yoga to their kids during this lockdown at home. Otherwise busy parents are free during lockdown hence this time can be utilized for teaching yoga to their kids. Yoga helps in improving health and can also increase their immunity power and make them stronger. This lockdown can also be used to make kids understand the importance of good health and to teach them some healthy habits. Things learned during this young age of their life will remain with them forever and will help them to become fit throughout their life [9].

2. Arrange cooking class at Home

Lockdown is very good opportunity to teach your kids some easy to make recipes at home, by this they will come to know how food is made and what are the ingredients required to prepare food. This habit will help them in future too, like if they are going out for some higher studies or so all alone, then in such case they can cook for themselves and for others too and can become self dependant [9].

3. Try to teach them new languages

Many scholars in the history were well versed with more than one language; it helped them to understand literature of different countries and helped them to gain more knowledge. In today’s generation also knowing multiple languages is an additional benefit. In fact for taking admissions in various foreign universities you should be aware of their local language by considering all these things this lockdown period can be utilized for teaching or ask them for teaching new languages. You can use online available sources for the same or can also use various You Tube channels for teaching your kids. As whole family is at home kids can learn and practice new things with family members also [9].

4. Teach your kids art and craft

You can involve your kids in art and craft, this will help them to learn new things and they will remain busy during lockdown, it will also increase their creative level. You can teach them to make easy, simple craft projects which will help them to grow and show their artistic talent. This activity will help them in free from stress, tension and irritability due to lockdown period. You can also teach your kids how to prepare wooden or cloths puppets toys in a very easy manner at home, how to make simple ornaments by using various things at home [9, 10].

Following is the online arts activity taken by a private school during lockdown [10].

5. You can teach kids - art of writing letters

Writing letters in various formats is also an art you can teach your kids during this lockdown at home. Writing on wooden things, or mixing letters in an artistic manner can be taught during this period of lockdown. By this kids can learn how letters can be written in different formats; they may create some new formats of letter writing and most importantly it will help them to improve their handwriting [9, 10].

Following is an example:
6. Engage with Lego and puzzles games

Lego toys are so popular among children, in this game they can pass time and at the same time they can learn some basic things of physics. You can start with simple structures and can slowly move towards more critical steps with respect to your kids understanding [9].

7. Make Plan a scavenger hunt

In simple words it is called ‘ Luka Chhippi’ hide some things in your house at different places without knowledge of your kids and ask them to find it out, to make this game more interesting you can give them some clues. This will help kids in using their brain and will help them in developing their brain. They will also improve their thinking capacity [9].

8. Tree Plantation and Surrounding Cleaning

You also can teach your children importance of trees and plants in our lives, how they provide oxygen and their importance for Rain in the country. A small tree plantation drive at home will work for this; children will get connected with the soil also. During this break we can also teach children’s the importance of cleaning in life, how it is important with respect to stop spreading diseases. A daily morning cleaning drive around and inside the house will help them to understand the meaning and importance of cleaning; collecting garbage and dumping it into the dust bin will also help them in becoming a good citizen. We can also teach them how some specific in-house garbage can be converted into compost, we can teach them practically how compost can be make in-house and how it is better than readymade compost available in the market and how it is beneficial for the development of the soil.

9. Have an indoor picnic:

In covid19 nobody will allow children to go outside and play outdoor games according to their choice, as a result again they will became bore, we can handle this situation by arranging small picnic at home for children. Grab a sheet and whatever food children have, let them enjoy a living room picnic. Identify some indoor innovative games, which they will enjoy along with other family members during this in-house picnic, it will become helpful in engaging children and will also keep them refreshing time by time.

10. Story telling

In this period of lockdown telling inspirational, motivational stories can also help parents for engaging their children. It has both benefits as it will keep them engaged and also they will learn new things. Grandparents in this regards are the best story tellers, they should take interest for telling various stories to their grandkids. Story reading can also be useful as it will help in continuing their reading habits and will also learn new things. If stories having various characters they voice over can also be used for each character, which will keep children more engaged in stories. We can also provide them with different story books like pictorial story books etc, we can also engage them by playing stories on you tube or by playing audio CDs on our players and can ask them to listen carefully, this will make them a good listener too.

11. Play with the cat or other domestic animals

Some families are very much fond of cats or other domestic animals like dogs, parrots etc. We can teach children about importance of these animals in lifecycle, we can also teach them as how to take care of these animals, how to feed them. As a result children will also start loving and caring these animals. This will help them grow in a better loving and caring person.

12. Wash your car and two wheelers

Almost every family these days is having four wheelers at their place. This generation kids are very much interested in these machines. This interested of kids can be utilized to overcome boredom during this period of lockdown. We can teach them how to clean the car from inside, how to wash it with solutions, we can also introduce them to the small parts of the vehicle, also we can teach them how can particularly runs or about important documents required for having a car at home. This will help them to find out their own solutions during the times of emergency and will also help in engaging them during lockdown.

13. Singing and Making a song and dance

Singing and dancing are very important with respect to relaxing our body and mind. Making or writing new songs and converting them into the tunes can become a great engagement activity for kids during this period of
lockdown. Encourage your kids to write songs in their own words, later ask them to mold the same in beautiful tune, this will improve their writing skill, will also force their brain to think in different manner. We can simply engage them by playing dance songs at home and ask them to dance as per their wish, if you are good at dance you can teach them different steps.

Quarantine means isolation it does not mean just getting bored at home. There are various activities that can be arranged for killing boredom of your child, for keeping them engaged and to feed them physically as well as mentally. Stay home, stay positive and enjoy much needed rest with your family!

As a parent, you can utilize this time to DEVELOP GOOD HABITS in children at home during Covid 19 pandemic.

How to deal with a defiant child as a parent?

Understand what really going on

Decision fatigue: Giving them as many choices as you can

Treat them like an adult

Instead of giving them chorus, give them problems to solve

Ask their opinions and give them some control over their lives

Discussion

The present article is related to Covid 19 pandemic for short communication, it’s very difficult period for all. But in this period most vulnerable population in society are kids. They are getting bored so as parents it is our responsibility to engage them with various enjoyable activities like indoor games. We can plan various activities to keep them physically and mentally engaged. It will help them grow normally and free from stress and tension. It’s a good chance to explore their hidden talent. They can spend their whole day very nicely with creational activities. In this period we have to treat them like matured kids to encourage them so that they will do all activities whatever told to them and we will get the required output out of these activities.

Conclusion

Schools are closed due to the COVID-19 pandemic outbreak for an uncertain period of time, parents face the daunting task of figuring out how to help their kids learning and more likely how to keep them enjoyable and free from psychological health issues and physical health issues, while social distancing is either required or encouraged. It has become important than ever to make time to sit with their kids and plan their day. We all know that keeping positive feelings and thinking promotes well-being and community and parents may plan to schedule game nights, face time calls with relatives, friends for their children and include them in activities they find fascinating.

Abstract:

Background: This study states that, the environment became polluted even after consistent efforts by various governments and organizations. Pollution due to various factors was out of control all over the world and it was badly affecting human lives as well as the mother earth. It was very essential to control these pollutants because the environmental and health interaction was closed, but it was not possible practically. Lockdown due to Covid 19 has played a very vital role in controlling these pollutants; it has given a much needed break to our mother earth.

The outbreak of Covid-19 viruses started in Wuhan, China in the month of December 2019. After its outbreak, it’s called as Covid-19 worldwide. By March 2020, World health organization declared it as a global pandemic disease. This disease has forced complete world at almost a stop these days no human movements are allowed unless and until it is really needed or is an emergency situation, the government has taken very strict steps to control the spread of this disease all over the world and various country governments have declared lockdown in their respective countries. Everybody is restricted from moving outside their houses, even all vehicles are restricted, shops and factories are compulsorily restricted from functioning. Closed factories and companies are showing considerable positive effects on health. Otherwise in developing country like India environmental pollution has serious impact on people’s health it was badly affecting human respiratory and cardiac system and due to which peoples were losing their lives. Water pollution was affecting human digestive system, renal system. But now due to controlled global warming communicable diseases are reduced. Ban on vehicles reduced traffic pollution, reduced accident rates too. Peoples are at rest at their houses, they are showing many positive behavioral changes as they are spending quality time with family, they are engaged in cleaning their home regularly. Due to this lockdown unlike human being’s nature too got its much needed break after many centuries. Conclusion: Aim of this study is to compare the situation of pollution and other related factors before and after lockdown along with its comparison and to identify unseen positive effects of the Covid-19 lockdown which we have never seen before. If all these positive effects continued for a long time, then it will definitely become beneficial for the living creatures as well as to mother earth.

Key word: Covid 19, Effects, Lockdown, Positive, Pandemic, Unseen.

Introduction

The world has never experienced a lockdown situation arises due to Covid 19 before, almost all the countries in the world are under influence of Covid 19. In India, to control spread of Covid 19 pandemic disease government has declared complete lockdown since 25th March to 14 April 2020 and it is now extended up
to July 31, 2020 to break chains of Covid 19 through maintaining social distancing.

Covid-19 pandemic lockdown has shown never seen before positive effects all over the world, which was otherwise not possible in the world through human efforts. People all over the world are at home, transportation has completely been stopped and industrial shutdown has been imposed as a precautionary measure to control the spread of Corona virus worldwide. It is showing so many positive effects on factors like air pollution, sound pollution and water pollution, global warming, other communicable diseases, sanitation, hygiene, behavioral changes in human beings too seen, controlled road traffic accidents and many others. These positive effects can be seen after lockdown during covid19 pandemic.

1. Air pollution

In India, the main motto behind imposing nationwide lockdown was to stop the spread of the novel corona virus, as by studies we came to know that this virus spreads through the air, droplets, touch and hence social distancing should be maintained.

Almost all factories, markets, shops, and regional places are closed all over, public transport is also suspended, construction work is halted, the government of India is forcing its citizens to stay home and practice social distancing whenever they go out for unavoidable reasons. So this closure of factories and transport, etc. are showing very good signs with respect to reduction of Air pollution.

Sources of air pollution

There are various sources responsible for air pollution.

1. Vehicles are one of the major causes of air pollution as they release pollutants like Carbon dioxide, Carbon monoxide, Ozone, Sulpheredioxide, Hydrocarbons etc.

2. Industrial wastes are also responsible for air pollution, thermal power stations produces heat which is very harmful for the environment and health.

3. Anthropological sources are responsible for respiratory diseases and cardiovascular diseases.

But after lockdown all sources of air pollutions and pollutants are under control, which helped to reduce respiratory diseases and cardiovascular diseases among vulnerable population in India.

Impact of Air Pollution

Air pollution not only causes severe effect on the environment, but also on human beings too like it damages the lungs in ageing people, it causes allergic irritation in the sense organs. It results in reduction of life span of people. Acid rain destroys soil nutrients. But all these severe effects are somewhat under control due to lockdown as pollutants released into the air are under control.

After lockdown, Air quality in cities like Delhi and Lucknow is improved. The most significant impact was seen in PM2.5, NO2 and CO levels. During the lockdown period the SO2 levels showed less significant decline. Harmful gases like nitrogen dioxide, etc., which are released by vehicles and power plants, etc., are very harmful with respect to the health of the people. These substances are dangerous as it can reach deep into the lungs and can spread into other organs and the bloodstream, can cause serious health issues. Now, due to lockdown air pollution is under control, hence people are feeling more comfortable; their visits to the Doctor’s clinic are decreased up to considerable level.

Research Facts about Air Pollution in India

It is observed that, most of companies do not follow rules with respect to the environment and safeguard the community people. A survey done in 2015 showed that, India is world’s seventh environmentally unsafe country. Bangalore is declared as an asthma city as around 30 % children are suffering from asthma caused due to air pollution. The cancer patient’s rate is also increasing in India. As per the survey done by the National Cancer Control Program by the year 2026 about 1.4 million people may suffer from cancer.

Earlier, due to numerous natural and anthropogenic causes, Northern India was considered as one of the major hot spots of pollution until lockdown in 2019 due to various sources such as dust, industrial and vehicular pollution, etc, this region was always considered as most polluted area. These sources were harming air quality and peoples safety. One of the key sources of pollution
was the dust storm, which occurred every year during the month of March-June\(^4\).

Now a day’s air quality in India’s major cities is improving by 60 % as compared to last year\(^5, 6\).

<table>

*Small particulate matter of 2.5 microns or less in diameter.

2. Sound pollution

Sound pollution too makes an adverse impact on human health and their activities. The main sources of sound pollution are vehicles sound, transportation etc.

Before lockdown sound pollution in India was horrible, noise pollution was affecting both physical health and mental health of the people. Higher or continuous sound for a long duration can damage physiological health. Noise pollution is associated with several health conditions, including cardiovascular disorders, hypertension, high stress levels, tinnitus, hearing loss, sleep disturbances etc\(^8\).

But after lockdown from the month of March, traffic is minimized on road, factories are not allowed to function; social functions and large gatherings are banned, so due to this and other such reasons sound pollution has reduced to a considerable level.
Table: 3 Sound pollution in Delhi in the month of April in 2019 and after lockdown sound pollution in 2020 in the same month reduced at level 9.

</tr>
</tbody>
</table>

3. Water pollution

Restrictions on the sailing of ships and boats in the water are becoming very useful with respect to cleaning of water resources. This has never been happened earlier and it was never ever possible to clean water resources with such purity by human efforts for even developed countries. These changes are observed these days due to non-interference of humans in all types of waters, a ban on ship transport, cruises and fishing ships, etc. In general we can say nature is having its time. Fishes are easily visible or fearlessly coming out of water in many cities of the world. Many famous rivers in the world are more clear now like the river Ganges in India is very clear from its source due to lockdown, the government is trying its level best to clear it for so many years but never succeeded but lockdown did impossible possible 10.

As most of the major industries are closed, it is resulting in saving of water up to a large extent, as industries use huge amounts of water during various processes like cleaning, washing, etc.

Industries generally flow their harmful waste water into the sea or in a river and due to that drinking water became contaminated and contaminated water caused waterborne diseases among children’s 1. But now a day as industries are closed this waste water is not at all mixing into the regular water sources and this is directly affecting in the clear and pure water.

Diseases, causes due to water pollution in children’s

Diarrhea,

This is a common waterborne disease that often affects children under the age of five. In severe cases; the symptoms include dizziness, fatigue, pale skin, and loss of consciousness 11.

Cholera

Cholera is caused by contamination of food or drinking water by the bacteria Vibrio cholera. The symptoms are like diarrhea, cramps on the abdomen. It occurs mainly in children and causes morbidity and mortality 11.

Typhoid

Typhoid is caused by contamination of food or drinking water by the bacteria salmonella typhi bacteria transmitted by contaminated water. The patients developed prolonged episodes of fever, loss of appetite, nausea, headache, constipation, and loss of body weight 11.

During lockdown the government is playing very essential role in improving access to safe water and sanitation of the areas, a number of steps undertaken at the individual level are also proving very essential in cleaning of water.

4. Sanitation and hygiene

Sanitation and hygiene level has tremendously increased in India during this period to avoid spread of Covid 19.

Study report on challenging to Hygiene Improvement in Developing Countries in 2019 stated that hygiene is a condition or activity that should be preserved in the community in order to avoid communicable diseases and improve social outcomes. Lots of developing countries are struggling to maintain this. Most of these challenges include poverty, lack of political participation, lack of full community participation, inadequate gender equality, lack of effective interaction among community and behavioral problems. Several measures have been proposed to reduce these challenges, including community 12.
During lockdown due to Covid-19 pandemic every hospital is also taking extra efforts to maintain cleanliness all over the world to prevent cross infection and contamination.

So it is observed after lockdown that, more awareness is created between community people and health care personnel towards sanitation and hygiene from various sources and they are implementing it too.

5. Behavioral changes during lockdown

Physical Health: Community peoples are more aware regarding social distancing, hand washing practices, wearing masks, cleaning and reusing masks. They are also aware about steps to be taken after continuous wearing mask if they developed mild headache, nausea vomiting etc.

1. They are paying special attention towards their health like regular exercises, diet control, etc., it helps to control blood pressure, blood sugar, free from stress and tension.

2. People these days are trying to understand their family, their needs which is resulting in a strong bond amongst themselves and it’s a good chance to forget and forgive family affairs through good interpersonal relationship.

3. They are getting close to the nature, many peoples who are at their native places or villages for relaxation and are spending more time with nature by activities like cleaning of the gardens, watering plants, farming etc.

4. They are gaining knowledge as reading habit has been increased due to lockdown, as peoples are now having lots of free time they have now developed the habit of reading, which is resulting them in gaining knowledge and improving memory.

5. People have started saving resources like money, grains and vegetables, etc., they are using them as per actual need only. This lockdown has showed people’s uncertainty of life and has taught them the importance of saving resources that may be money or other resources.

Mental Health: Human beings all over the world are continuously engaged in various activities in a generation; they were over-worked, over-burdened since generations and finally got this much needed rest. While maximum of them are working from home, they are these days not forced to cross polluted traffic to reach the office, they are getting quality time to spend with their families. They got time after so many generations to read, to sleep peacefully and to eat to their heart’s content this will indirectly effect on human health, will help in reducing human stress and in developing human body strength, reducing diseases in current and coming generations.

In a report on the effect of working hours on sleep and mental health in 2017, indicated that longer working hours cause the poor physical and mental health of the individual. Too long working hours are having adverse effects on quality of sleep. It’s a rather significant problem that has impacted both employees and the profitability of the company. The association between these symptoms and the sleep disturbances was positive.

But now after lockdown every person got a break from their busy schedule for self realization.

A moment of self-realization: The great outcome of this Lockdown is we realized the need of making changes in our lifestyle and thought process. Now the condition is that youngsters are getting enough time to share their feelings, ideas and valuable thoughts with their family members and friends and colleagues. It’s a very good time for younger’s to keep stress free mind.

If everybody will keep themselves engaged like this in their lives there will be no pathway to come negative thoughts in a person’s mind. After lockdown in the future if this situation will be continue ultimately a reduction in mental illness and suicidal cases due to stress and tension among younger’s in India may be observed.

5. Road traffic accidents

There are almost no people or less people on the road due to lockdown resulted in less number of accidents and street crimes. Police presence in almost every vital place and closed borders has helped in low rate in burglary and vehicle thefts all around the world. Proper checking at the borders has restricted criminals from entering the borders of other districts or states.

This lockdown has shown a positive impact on road traffic accidents too, apart from its original purpose of controlling the spread of Covid-19 as only essential
vehicles are only allowed on road with permission; it has reduced accident rates too.

Decrease in drunk and drive cases are also remarkable during this period as wine shops all over have been shut down. Accidents due to youngsters rash driving have also decreased these days as they are not allowed to move outside due to strict police and traffic control arrangements by various governments.

No constructions services are allowed to function during this period also factories and industries manufacturing non-essential goods too have been shut down till further notice has created a very positive effect on related resources and decrease in pollution as with respect to different studies industrial pollution accounts for at least half of the pollution in the country, especially in populated cities like Delhi, Mumbai, Kolkata, Bengaluru and so on. Traffic movement has been reduced to almost zero in all the cities around the country. Various photos of deserted roads have flooded on social media, with more and more people staying indoors and not daring to move out of their homes during this outbreak of Covid 19 pandemic.

Mortality and injuries resulted from road traffic accidents are serious issues in India and are increasing general medical, social and economic issues. Approximately 2,650 people die annually and 9,000 get injured every year due to traffic accidents. In 2013, the most recent year that data is available for, 137,423 people died and 469,900 people were injured as a result of road accidents in India. The distribution of road traffic deaths and injuries has been found to be different according to age, month, and periodically. The people of the economically developed age group 30-59 years were the most vulnerable among people of all age groups. It was concluded that India is facing the worsening situation. There is an urgent need to consider the difficult situation of road deaths and injuries.

Table 4: In Acharya Vinoba Bhave Rural Hospital, DMIMS, Sawangi, Wardha, Maharashtra, India. In causality in between March to June 2019 daily 15-16 road accident cases were registered and in 2020 in between March to June daily only 5-6 cases are registered due to road traffic accidents.

<table>
<thead>
<tr>
<th>Road traffic accidents cases</th>
<th>In 2019 in the month of March to June in an average patients are registered</th>
<th>In 2020 in month of March to June in an average, patients are registered</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>1,830</td>
<td>610</td>
</tr>
</tbody>
</table>

Benefits of reduction in accidents cases

1. Less Hospitalization.
2. Decrease in long term disability among younger generation and others.
3. Decrease loss of life and injury.
4. Decrease in financial burden on family.
5. Reduced stress and tension among family members.

2. Global warming

This lockdown due to Covid-19 is showing a number of positive effects on earth; in fact, we can even say our planet is getting a much-deserved rest for so many years. World temperature was at its high due to global warming, various kinds of pollutions, etc., which was otherwise not possible to reduce or to adjust at a normal level but this lockdown has helped a lot in reducing this high temperature. As cities now can see blue skies and clearer water, water, animals to enjoy this phase as there is no human interference and increased purity level of water. Areal images taken from satellites...
of various countries from space are clearer than ever due to this clean and clear level of air. In coming future this deduction in global warming will definitely result in avoiding thousands of deaths due to global warming as well as it will help reduce some dangerous diseases all over the world\textsuperscript{17}.

Earlier as per study the effects of global warming on South Asia were very thinkable like steady sea level rise, increased cyclonic activity, and changes in ambient temperature and precipitation patterns. Increased landslides and flooding were projected to have an impact upon states such as Assam. Rise in sea level had a submerged several low-lying island in the Sundarbans, displacing thousands of people. The first among the countries to be affected by severe climate change was Bangladesh. There was a reduction in fresh water availability, disturbance of morphological processes and a higher intensity of flooding. Regarding local temperature rises, it was 3.3 °C with the min-max range as 2.7 – 4.7 °C. For Tibet it was 3.8 °C and min-max figures of 2.6 and 6.1 °C \textsuperscript{18}.

In 2019, India witnessed high temperature second – longest period in the last 31 years between March 7 and June 2. Long heat waves swept through 23 states which killed almost 300 people in India\textsuperscript{19}.

Impact of excess heat on the human body

After over heating the human body requires evaporative cooling even in low activity movement. If the heat level exceeds, humidity in human body shows the adverse effect as it can convert into Dehydration, Hyperthermia and Heat stroke. Heat illness effects on many organs and system, including brain, heart, kidney, liver, etc\textsuperscript{20}.

Recent research has mentioned that prolonged exposure to heat causes physical exertion and dehydration; these factors can lead to chronic kidney disease in India \textsuperscript{21}.

But due to lockdown in the year 2020, temperature, level in-between the months of March to June is low as compared to last year 2019. In future also if the earth gets a similar pollution free and heat waves free break, then ultimately heat exposure, illness and diseases will be reduced.

In Mumbai and Delhi temperature is decreased as compared to last year\textsuperscript{22}.

<table>
<thead>

</table>
Overall this Covid 19 lockdown has increased so much positive and good signs in people all over the India, if people continue these good practices, even after Lockdown, then it will definitely help in decreasing communicable diseases in India in coming future.

Discussion

It was not possible ever to control all types of pollution or remove pollutants from air, water, etc. Due to this mandatory lockdown nature got a break after so many centuries where there is no human interference, no pollution and hence automatic nature got its time to clear it all and health positive effects are also seen.

After lockdown if Government takes strict steps to control various types of pollution, the rate of related diseases will ultimately reduce.

If sanitation and hygiene maintenance will continue communicable disease prevalence will reduce in adult and children.

Road traffic accident reduction can prevent long term disability and mortality among people especially in younger’s.

If younger’s will get adequate time for themselves, then ultimately a reduction in mental illness and suicidal cases in younger’s can be maintained.

Conclusion

This compulsory lockdown has shown many positive effects all over the world, in the most important is air pollution has decreased to almost zero, which has shown improvement in the Ozone layer. Global warming has also reduced to a considerable level. People all around the world are more serious about sanitation and hygiene. Lockdown has also shown positive effects on both human animal behaviors, both are in their respective places without any interference and are enjoying their time. Accident rates have increased to a considerable low. Overall, this lockdown has many never seen effects on human life, the environment and animals.

Even after this Covid 19 lockdown, if we succeed in maintaining same sanitation and hygiene, limited use of resources, etc. then it will become definitely beneficial to coming generations.

A Critical Appraisal of Bioethical Inclusions in Aetcom Module for Competency Based Undergraduate Medical Education as Prescribed by Medical Council of India

Gaurav Mishra¹, Sudhir Ninave², Abhilasha Dass³, Ashish Anjankar⁴
¹Researcher, Associate Professor, Department of Radiodiagnosis, JNMC, Sawangi, Wardha, ²Professor and Head, Department of Forensic Medicine, JNMC, Sawangi, Wardha, ³Assistant Professor, Department of Conservative Dentistry and Endodontics, SPDC, Sawangi, Wardha, ⁴Associate Professor, Department of Biochemistry, JNMC, Sawangi, Wardha, School of Advanced Studies, Datta Meghe Institute of Medical Sciences (deemed to be University), Sawangi (Meghe), Wardha, Maharashtra

Abstract

Background – Critical appraisal of AETCOM Module with reference to Bioethical inclusions vis-à-vis professional ethics inclusions needs appraisal for purposes of judicious operational mix of two, so that learner is oriented in all-round manner so that optimal results thereto stand generated with at par status in commensuration with “The UNESCO Universal Declaration On Bioethics And Human Rights”.

Methods – Rapid review of literature with reference to AETCOM Module for identification of Bioethical inclusions in it with reference to Bioethical principles included in UNESCO declaration specially those applicable to profession and not propagation or advocacy. Critical appraisal of identified Bioethical inclusions with reference to their conformity with bioethical principles as applicable to profession included in UNESCO declaration and to work out appropriate inclusion of non-included bioethical principles in form of structured competencies and their incorporation in AETCOM module with reference to their placement, learning levels, mode of assessment.

Conclusion – This study deals with mapping and matching of competencies included in AETCOM module with UNESCO universal declaration on human rights and bioethics giving recommendations which can fulfil realised omissions in present AETCOM module thereby leading to its simplification and adoption.

Key words: AETCOM, AETCOM module, UNESCO, Bioethics, Bioethical principles. Post graduate curriculum, medical education.

Introduction

“Bioethics is a term that has arisen from but is broader than issues of ethics in human research. It addresses ethical issues arising from accelerating technological advances, that can potentially threaten human life itself or affect relationships between human beings and their environment. It focuses on protecting the environment and making it safe for the future generations”¹

The term Bioethics was coined in 1926 by Fritz Jahr in article about a ‘bioethical imperative’ regarding the use of animals and plants in ‘scientific research’².

In the year 1970, the American Biochemist Van Rensselaer Potter used the term to correlate the relationship between the Biosphere and the growing population. It was his work which laid the edifice for what has been known as ‘Global Ethics’, a discipline that centres around the linkage between biology, ecology, medicine and human values³, ⁴.

Sargent Shriver, the spouse of Eunice Kenedy Shriver, claimed that he had invented the word

Corresponding author:
Gaurav Mishra
Researcher, Associate Professor, Department of Radiodiagnosis, JNMC, Sawangi, Wardha
“bioethics’ in the living room of his home in Bethesda, Maryland in 1970. He stated that he thought of the word after returning from a discussion earlier that evening at Georgetown University, where he discussed with others a possible Kennedy family sponsorship of an institute focused around the “application of moral philosophy to concrete medical dilemmas”.

Realistically speaking the various posers in regard to ethicality in the domain of medicine in the context of life sciences has not only been a subject of one but to relatively new academic ventures in the field of ‘Bioethics’ and ‘health and human rights’. The core essence of the collage that has been formulated emanates from the concept of human dignity entitled to every individual in the form of an accruable human right independent of any or every discrimination of any and every type including those of gender, caste, creed, colour, faith, belief, religion, ethnicity, trade, occupation, calling, vocation, socio-economic status and geographic location.

It is in this backdrop it is evident that the scope of bioethics continues to expand with the advent of scientific inventions with respect to their rapidity and technological innovations emerging thereto in an open ended manner.

According to Andorno et al, there is interlinkage of bioethics with human rights within the Universal Declaration. International documents have all referred to human rights as well as dignity together and therefore, invocation of human rights has been a crux in laying down global bioethics principles as well. Also, it is being rightly expressed that this interlinkage in between the two entities will foster a new era of development and regulations in the current perspectives of international law.

Taking stock of the overall global situation, the academic committee of the Medical Council of India in the process of formulating a detailed draft pertaining to competency based undergraduate medical education invoked a module titled ‘AETCOM Module’ (Attitude, Communication, and Ethics), which was notified in the year 2018 and is incorporated in the ‘Assessment Module for Undergraduate Medical Education’. It has also been availed for the orientation of full time teaching faculty of the various medical schools, in India under the ambit of the Medical Council of India vide the aegis of National Faculty Development Programme, run through various recognized Nodal and Regional Centers by it as a standing mechanism for the same.

The curricular requirement which was in the context of competencies attributable to Indian Medical Graduate in line and tune with the Global Competencies had to have the vital components of

a. Knowledge (Cognitive)
b. Attitude (Affective)
c. Skill (Psychomotor)

The said curriculum includes structured affective domain in the curriculum and the contemplated competencies thereto are invoked in the AETCOM Module depicting therein in terms of their:

a. Initiation
b. Inculcation
c. Consolidation
d. Certification

The said competency based curriculum for undergraduate medical education that has incorporated AETCOM Module as an integrated part of the said structured curriculum has been notified with the prior approval of the Government of India, by the Medical Council of India and has become operational in the country from the current academic year 2019-20 in an onwards manner.

The United Nations Educational, Scientific and Cultural Organisation was established on 4th November, 1946 with its respective headquarters at Paris, France. Since the inception of UNESCO, the main area of its work has been the ethical issues in relation with science and scientific advancements especially, those made in the direction of life sciences along with devising and developing normative standards on an international level. As rightly mentioned by Aldous Huxley, the first Director General of UNESCO, that if science and scientific perspectives are to be making any contribution to the betterment of mankind, it was essential to balance out the scientific applications against values.
It is in this context that a critical appraisal of the AETCOM Module with reference to its Bioethical inclusions vis-à-vis professional ethics inclusions needs to be looked into for the purposes of an judicious operational mix of the two, so that the learner is oriented on the said arena in an around manner so that optimal results thereto stand generated.

**Aim**

To critically analyze the Bioethical inclusions in the AETCOM Module included in the competency based medical education curriculum for the undergraduate medical education prescribed by the Medical Council of India with reference to Bioethical principles incorporated in UNESCO Declaration.

**Objectives**

1. To identify the bioethical inclusions in the AETCOM Module at various phases incorporated there under with reference to their conformity with Bioethical principles in UNESCO Declaration.

2. To critically analyze the bioethical inclusions in the AETCOM Module so identified in regard to their conformity with reference to Bioethical principles applicable to profession as included in UNESCO Declaration.

3. To suggest update or broadening of the ethical inclusions in the AETCOM Module so as to make them commensurate with the Bioethical principles incorporated in UNESCO Declaration.

**Materials and Methods**

**Period of Study**: 1/1/2020 to 30/6/2020 - six months

**Place of Study**: School of Advanced Studies, JawaHarlal Nehru Medical College, Sawangi(Meghe), Wardha

**Design**: Descriptive Study

**IEC Approval**: Ref. no. DMIMS(DU)/IEC/Dec-19/8671 – From Institutional Ethics Committee, Datta Meghe Institute of Medical Sciences, Wardha dated 31st December, 2019. (attached)

**Procedure**: Rapid review of literature with reference to AETCOM Module for the purposes of identification of the Bioethical inclusions in it with reference to Bioethical principles included in UNESCO declaration specially those applicable to profession and not propagation or advocacy.

Further, to critically appraise the conformity of the bioethical inclusions in the AETCOM Module with reference to their conformity with the bioethical principles as applicable to the profession in the UNESCO declaration.

Then, to work out the appropriate mitigation of the AETCOM Module by incorporating the non-included bioethical principles as applicable to profession incorporated in UNESCO Declaration by structuring it in the form of a competency including commensurate with the level of undergraduate medical education.

**Data**: Identifying Bioethical inclusions in the AETCOM Module and their placement in the competency based medical education curriculum for the undergraduate medical education in vogue from the academic session 2019-20 and onwards in the various medical colleges under the ambit of Medical Council of India.

Critical appraisal of the said identified Bioethical inclusions with reference to their conformity with the bioethical principles as applicable to the profession included in UNESCO declaration.

Further, to work out the appropriate inclusion of non included bioethical principles in the form of structured competencies and their incorporation in the AETCOM module with reference to their placement and learning levels including their mode of assessment.

**Collection Tool**: Critical appraisal of the AETCOM Module document and its placement in the competency based medical education curriculum as against the Bioethical principles as applicable to profession in the UNESCO Universal Declaration.

**Analysis**

1. Bioethical inclusions were identified in the AETCOM Module.

2. They were analysed with reference to their conformity with the bioethical principles as applicable
to profession incorporated in UNESCO declaration.

3. They were appraised to decipher any inadequacy thereto, and the non-inclusions were worked out in the form of core competencies and an attempt was made to incorporate these in the existing AETCOM Module by working out their placement, learning level and modes of assessment, as well.

Results and Discussion

This study analysed a total number of 54 competencies, both core as well as non-core as included in the AETCOM module with their respective learning domains, levels as per Miller’s pyramid, the professional year they are intended to be taught and assessed in as against the principles included in the UNESCO Universal Declaration laid down by the UNESCO.

The competencies included in the AETCOM module were core (n=39) and non-core (n=15). All 54 competencies in the AETCOM module reflected either single or multiple principles as per the UNESCO universal declaration of human rights and bioethics. Therefore all 54 competencies in the said module were identified as professional ethical inclusions. With regards to professional bioethics, 49 competencies were excluded except competencies 3,4,5,7 and 53 which were bioethical inclusions in the wake of the respective basic bioethical principles. So, we have 49 competencies under professional ethics and 5 competencies under professional bioethics in the AETCOM module.

Amongst the UNESCO Universal Declaration, principles 3 to 20 were listed as professional bioethical inclusions which were directed towards the learner and his profession directly. The remaining principles were directed towards the states, international affairs and regulation i.e. advocacy. These were therefore excluded.

So, we had two sets – one set of AETCOM module competencies and another set of UNESCO universal declaration principles.

Of the total number of AETCOM module competencies, 21 competencies had their learning level as K standing for Knowledge or the cognitive domain as per Bloom’s Taxonomy and KH level standing for Know How as per the Miller’s Pyramid. Remaining 23 competencies had their learning level as S standing for Show or the psychomotor as well as the affective domains s per Bloom’s Taxonomy and SH level standing for Show How as per the Miller’s Pyramid.

Therefore, it can be noted that 21 competencies dealt with the cognitive domain and 23 competencies dealt with higher domains of learning – psychomotor and affective.

The verbs utilized for the cognitive domain were “enumerate, describe, identify, discuss and defend” respectively. The verbs utilized for the higher domains of learning were “demonstrate, administer, communicate, identify, discuss, defend” respectively. The common verbs utilized in both cognitive as well as higher domains of learning were “identify, discuss and defend”.

Article 18 – decision making and addressing bioethical issues was reflected in maximum number of competencies (n=44 competencies). This was followed by article no. 3 – Human dignity and human rights (n=33 competencies) and Article 4 – Benefit and harm (n= 30 competencies). Further, article 13 – solidarity and cooperation was noted to be reflected in 17 competencies followed by article 8 – respect for human vulnerability and personal integrity (n=10 competencies). Then article 5 – autonomy and individual responsibility was reflected in 9 competencies and articles 6,9 and 10 (article 6 – consent, article 9 – privacy and confidentiality, article 10 – equality, justice and equity) were reflected in 8 competencies each. Article 7 – persons without the capacity to consent was reflected in 7 competencies followed by articles 11 and 12 (article 11 – non-discrimination and non-stigmatization and Article 12 – Respect for cultural diversity and pluralism) were reflected in 6 competencies each. Articles 14,15 and 20 (Article 14 – Social responsibility and health, Article 15 – Sharing of benefits and Article 20 – Risk assessment and management) were reflected in 5 competencies each. This was ultimately followed by article 19 – ethics committees (n= 3 competencies). Thus the article which had the maximum reflection was Article 18 – decision making and addressing bioethical issues(n=44 competencies) followed by article no. 3 – Human dignity and human rights (n=33 competencies) and Article 4 – Benefit and harm (n= 30 competencies). The article 19 – ethics committee had the least reflection
(n=3 competencies).

However, the articles 16 and 17 (article 16 - Protecting future generations and Article 17 – Protection of the environment, the biosphere and biodiversity) had no reflection in the AETCOM module.

These principles need to be articulated in the AETCOM module by working out their placement, learning level and modes of teaching and assessment.

Suggested competencies framed for commensurating article 16 – Protecting future generations –

1. Describe the impact of life sciences on genetic constitution and future generations with regards to medical profession.

2. Identify, discuss, defend and demonstrate the impact of life sciences on genetic constitution and future generations with regards to medical profession.

Suggested competencies framed for commensurating article 17 – Protection of the environment, the biosphere and biodiversity –

1. Describe the interconnection between human beings and other forms of life.

2. Describe the importance of appropriate access and utilization of biological and genetic resources.

3. Describe the importance of respect for traditional knowledge.

4. Describe the importance of role of human beings in the protection of the environment, the biosphere and biodiversity.

5. Identify, discuss, defend and demonstrate the interconnection between human beings and other forms of life.

6. Identify, discuss, defend and demonstrate the importance of appropriate access and utilization of biological and genetic resources.

7. Identify, discuss, defend and demonstrate importance of respect for traditional knowledge.

8. Identify, discuss, defend and demonstrate importance of role of human beings in the protection of the environment, the biosphere and biodiversity.

The competencies framed for article 16 are two – first covering the cognitive domain and second covering the psychomotor and affective domain with K,KH and S,SH levels in Miller’s pyramid respectively. The professional year in which first competency can be included for teaching and assessment is the third professional year of MBBS undergraduate course for covering the cognitive domain whereas the second competency can be included in the fourth professional year of the MBBS undergraduate course for covering the psychomotor as well as affective domains.

The competencies framed for article 17 are eight – first four covering the cognitive domain with K and KH levels in the Miller’s pyramid and the remaining four covering the psychomotor and affective domains with S and SH levels in the Miller’s pyramid respectively. The professional year in which the first four competencies for article 17 be included for the purposes of teaching and assessment is third professional year of MBBS undergraduate medical education for covering the cognitive domain and the remaining four competencies be included in the fourth professional year for the purposes of covering the psychomotor and affective domains.

Modes of teaching these competencies are didactic lectures as well as large and small group discussions, focussed group discussions. Modes of assessment for the cognitive domains can be in the form of short answer questions, long answer questions or multiple choice questions as a part of the respective theory examination.

Modes of assessment of the psychomotor and affective domains can be in the form of viva voce, oral examination, clinical case presentation, standardised patient and simulated scenarios.

Conclusion and Acknowledgement

The present study deals with the mapping and matching of the competencies included in the AETCOM module with the UNESCO universal declaration on human rights and bioethics. This has brought out subsequent omissions which need to be taken care of in order to make the AETCOM module commensurate with...
the UNESCO universal declaration and therefore, make it better and standardised on global and international level. Omissions so envisaged along with points brought out in this study in the form of recommendations have been supplied with suggested competencies in addition with their placement, learning level and modes of teaching and assessment. These recommendations can be envisaged as suggestions which can fulfil the realised omissions in the present AETCOM module set of competencies and thereby lead to its simplification and adoption.

Awareness of Physiotherapy among Higher Secondary Students- A Survey

K. Jothi Prasanna 1 Ayesha Farvin Z2

1Assistant Professor, SRM College of Physiotherapy, SRM Institute of Science And Technology, Kattankulathur; 2Student, SRM College of Physiotherapy, SRM Institute of Science And Technology, Kattankulathur

Abstract

Background: Physiotherapy is a kind of art among various health care professional. It is the rapidly emerging allied health profession in India. It is engaged with promoting health and maximizing potential. Students are the budding generation where the knowledge regarding physiotherapy as a treatment must be developed. This study focused on students in Thanjavur District since the term physiotherapy as health care service is rising gradually nowadays. The main objective of this study is to scrutinize the level of awareness of physiotherapy among the students who are the vitals of the upcoming generation.

Objective: The purpose of the study is to assess the level of awareness of Physiotherapy among Higher Secondary students in Kumbakonam of Thanjavur District. subjects and methods: A structured survey questionnaire depicting the awareness with three components namely Knowledge Attitude and Belief towards physiotherapy is distributed around 200 students of ARR Matriculation Higher Secondary School in Kumbakonam. The responses were collected from the students for the statistical data analysis. result and conclusion: The awareness regarding all the three aspects were significantly less. It is said that there will be in chance of creating the awareness among students unless the professionals themselves include in the repletion and improvement of the field.

Keywords: Physiotherapy, Awareness, Higher secondary, survey questionnaire

Introduction

According to World Confederation of Physical Therapy (WCPT) it is a profession mainly aims at providing health care to people in order to regain and retain the functional ability throughout the life span.1 The ultimate goal of every physiotherapist is to retain one’s functional ability by all means. The physiotherapist mainly concentrates in rehabilitating a patient and making his independent as possible the condition permits. He is not only a therapist but also a companion to the patient and his family in making them understand the current scenario of the patient and a brief counselling is given to their care taker.

Physiotherapy was initially started by the World’s great physicians namely the Hippocrates and Galen. It played an important role during the First World War and at the time of Polio outbreak. The above mentioned events were responsible for the development and enhancement of Physiotherapy during century back.2 In India Physical Therapy emerged in the year 1952 due to Poliomyelitis. Under the support from World Health Organization, the Indian Government and the BrihanMumbai Municipal Corporation (BMC) undertaken the responsibility in opening the first physiotherapy institution in Seth G.S. Medical College and K.E.M. Hospital in the year 1953.3

Physical Therapy have a wide range of scope. It plays a vital role in every stream namely orthopedics, Neurology, Cardio Respiratory, Sports, Gynecology,
Pediatrics etc. Recent years back the term physical therapy usually meant to deal with pain and assumed that only massage is given by a therapist. According to the study done by Anila Paul in the year 2015 the awareness of physiotherapy in general population is less. Usually patients are referred to physiotherapist by a physician. The therapist must gain confidence from the patient so that the treatment goal will be achieved easily, quickly and effectively. Physiotherapist can work in a hospital or set up a clinic by his own and also have a home visit.

Physical therapy is a highly emerging profession nowadays. The need of physiotherapy in each hospital and health center must be increased. Earlier in medical field the people where more aware about Doctors and also Nurses. Even students of science stream were asked to become a Doctors. This concept is to be changed and people in various cities of our county must be more familiar to the term physiotherapy. It is always said that when we try to impart knowledge regarding anything, it must be given at very early stage. Students are the budding generation where we can take an issue to the next level. Unfortunately students of this generation are lacking in deciding their future career. It is certain that every student must start planning about their future at the time of adolescence. Especially students of rural area in Tamil Nadu are not aware of any recent updates in medical field even if they belong to science stream.

Many studies have been done on medical and non-medical profession, anganwadi workers, and college students regarding the awareness and perspective of physiotherapy in the community. Even studies on school students have been done in Sri Lanka, Saudi Arabia even in North India.

We physiotherapy keenly concentrate in inventing new techniques and exercise protocol for various disability. Recognition of a field in the community not only depends upon the advance treatment available in it, it actually deals with how the technique reach nook and corner of the country. This basic concept is an important factor in physiotherapy as an emerging profession mainly in Tamil Nadu.

As per the knowledge there is no study done in Tamil Nadu on higher secondary students regarding the awareness of physiotherapy. Hence objective of my study is to scrutinize the knowledge of physical therapy among school students in a particular school in Tamil Nadu.

**Methodology**

The study design is a non experimental study-observational type. This survey was mainly conducted among 200 higher secondary students of ARR Matriculation Higher Secondary Students of Kumbakonam. The awareness of physiotherapy was determined using a self-structured survey. The students were selected based on their inclusion and exclusion criteria. Students who fall into the following categories were selected namely age 16 to 18, both Boys and Girls, all groups students and only English medium student were selected. Students who belong to Tamil medium and not willing to participate were excluded from the study.

**Procedure**

Students of ARR Matriculation Higher Secondary School in Kumbakonam were selected based on the inclusion and exclusion criteria. The students belonging to 11th and 12th standard were taken. The study was completely explained to the management and permission was obtained to take information from the students. At first approached the class teacher regarding the study and then each groups in the school were approached and explained the study and a questionnaire were given. After the completion the questionnaire it clearly stated that the data obtained will be used only for the study purposes.

A survey questionnaire depicting the awareness of physiotherapy in three components namely knowledge attitude and belief were constructed and initially distributed to the professionals for any correction. A pilot study using this questionnaire was done with a sample size of 10 for any difficulty in understanding. The pilot study showed a reliability of 0.7. After the pilot study satisfaction the questionnaire were distributed to the school students.

The questionnaire consists of four sections namely, section A includes demographic information (like name,
age, gender, group), section B includes questions that deals with the knowledge regarding physiotherapy, section C includes questions that deals with belief towards physiotherapy and section D includes questions that deals with attitude of physiotherapy. The section B, C and D each questions have two option, YES (OR) NO.

The students were given enough time to complete the questionnaire and the data were collected for the statistics. Statistical Package for the Social Science version 23 were used for the data analysis.

**Discussion**

Among 200 samples. There was about 143 males that is 71.5% and female 28.5% (57). According to this study 62% of students were aware of the term physiotherapy that is the were familiar to the term but the concept of this field was not clear. The knowledge gained about physiotherapy was mainly from their friends, relatives. This study showed that the lack of knowledge was due to misunderstanding the role of physiotherapy with other health professional. Since there are limited number of clinic in the particular locality the students were not able to recognize the role of physiotherapy in the society. In spite of the misunderstanding students were able to find that certain task like prescribing medicine, injection, x-ray was not the work of this profession. One of the previous study in conducted in Ishikawa High School Students states that the term physiotherapy was known to many students by mass media. But in this study the student’s attention towards physiotherapy by means of mass media was very low.

Regarding the role in surgery and ICU was not known by the students as they do not have any idea. As they consider intensive care unit is mainly for the critically ill patient is only under the guidance of Doctors. It seems that students have a confusion on physiotherapy participation in first aid. The indulgent of physiotherapy was not able to distinguish by the students so there was a negative feeling on their treatments. Even they don’t know whether modalities are used in the clinic. This population finds that there is no necessary for a physiotherapy set up in a village, but they believe in it. The students strongly agree that physiotherapy only deals with pain management because as per their knowledge the physiotherapist is confused with masseurs.

According to the attitude pf physiotherapy, the students mostly know the value in sports. There are many electives available in this field but the idea about this is not reached to everyone. This is interesting that since one or two hospital in that particular area are present with very few physiotherapist and patient with fracture or stroke are recommended to the physiotherapist. So the students the value of this field in the fracture and stroke management. As nowadays there are lot of scope for physiotherapist in obstetrics and gynecology, even students considers that there is no role of physiotherapy in this field as they did not taught regarding the scope of physiotherapy in various fields.

As there are many new technology available in physiotherapy and new modalities only very few are aware of this. There is an advent of newer techniques
in physiotherapy, which is supposed to be reached nook and corner of small towns and cities. It is a great disappointment that physiotherapy itself has not reached the small town and cities.

It is stated that the source quality and quantity of information concerning the physiotherapy profession for higher secondary students are very less.

One of the previous study that was done on Kanagawa Prefecture, the high school students nearly 95.4% were aware of physiotherapy. Similar study carried out in Saga Prefecture the percentage of students aware of physiotherapy was about 54. However these studies were not considered as they included students taking part in physiotherapy related organizational skills so that the level of awareness was comparatively high. As physiotherapist our aim should not only deal in preventive and curative measure, there must be a broad community based rehabilitation. This can be achieved by creating awareness in schools of small towns by means of camps, seminars and workshop.

This study reveals that there must be a great initiative in developing the knowledge, belief and attitude towards physiotherapy in every school. This helps the students to understand the role of physiotherapy as a profession and also a career wise.

**Conclusion**

This study was designed to determine the knowledge belief and attitude towards physiotherapy by higher secondary students of Kumbakonam in Thanjavur District. The awareness regarding all the three aspects were significantly less. It is said that there will be in chance of creating the awareness among students unless the professionals themselves include in the repletion and improvement of the field.

Use of Social Web and Perceptions of Professional Behaviours Regarding Social Web Postings among Physiotherapy Students

K. Jothi prasanna1 Priyanka B2
1Assistant Professor, 2Student, SRM College of Physiotherapy, SRM Institute of Science and Technology, Kattankulathur, Chennai 603203, Tamil Nadu, India

Abstract

Background: Social media websites which facilitate exchange of user-generated content has enormous potential in health care which allows Physiotherapists to post educational information for patients also to share ideas as it acts as a great source of information for research and learning. Objective: To survey students enrolled in professional physical therapy programs regarding their use of social web and perceptions of professional behaviors regarding social web postings. Materials and Methods: A non-experimental observational type of study has been done with 100 Physiotherapy students of three different years and were selected according to the selection criteria. The survey instrument was provided to participate in the study addressing students use of social web. Results and Conclusions: Students are unaware about the social media policy and its importance. Students should learn about the privacy concern and professional boundaries. There is a need for social media policies and education regarding the proper use of social media.

Key words: Social media policy, Digital professionalism, privacy concern, Health care providers,

Introduction

Social media is used as the means of communication for general population as it acts as a great platform for patient engagement and creates opportunities for creativity and innovation for Physiotherapy program. The use of social web is more prevalent among all age groups and professions and this have been connected to health care professionals. They are also provided with tools for sharing information on medico legal aspects of health and on promoting health behaviors. Since social web plays a vital role in providing health information to the community Specific attention is required to address the gap between Physiotherapist and patient in health care delivery service.

Although Social media plays abundant role in health care development and patient engagement, on the contrary it could also possess possible legal, ethical and licensing issues due to its inappropriate use. New professionals becoming familiar with the professional health care environment may be particularly vulnerable to this sort of ethical issues. To avoid such circumstances students must be provided with the knowledge social media policy and what is appropriate/ inappropriate to post on social media. Gragnon and Sabus suggested that developing digital professionalism among Physiotherapy students may result in improving the quality of treatment care and patient wellfare.

Physiotherapists are intended to work with patients quite more often than the general physicians. At times there may arise conflicts of interests between patient and the Therapist in providing best treatment due to difference of opinion of patients on treatment techniques. To overcome such scenario Physiotherapists must provide quality treatment respecting the patient’s privacy concerns. Provided with the social media policy still queries remain on how to maintain professional boundaries with patients while using social media.
Studies show that seeking information about patient through online is actually helpful in knowing the truth and also in gathering more information on patient’s condition. This information seeking could get affected by intruding privacy concern of patient and uncleared ethical dilemmas regarding professional boundaries. It also prevents its users from benefitting through social web interaction.

Health care professionals using social web sites must focus on their responsibilities as their postings on the wall could reflect their professionalism. The adoption of Digital professionalism and discussion on social media policy may be the best method to teach students on the appropriate use of social media. However proper data on the physiotherapist students use of social media and its postings is required to implement such discussion forum. Hence this study aimed to survey students regarding their use of social media, social media postings, their judgements about behaviors of others using social media and their own rating of privacy concerns.

**Materials and Methods**

**Participants:** This study surveyed Undergraduate Internship and first and second year Post Graduate Physiotherapy students. The survey instrument was distributed to all the three-year students (N=100) of both the genders who were volunteered to complete the survey. It was limited to particular group based on their clinical exposure and practical experiences of duration of minimum 6 months.

The survey instrument used in this study was similar to the Instrument used in the other published studies enquires about Familiarity with their professional program and its social media policy, personal use of social media. Also enquires about posting habits, rating of behaviors according to their perception, acceptable use of social media and privacy concerns relating to various scenarios. The focus of this study was aimed at the students’ knowledge of social media policy, rating of acceptable behaviors of other people’s posts to social media site and rating of level of privacy concern to various scenarios which is applicable to their clinical practice.

**Data Analysis**

The statistics were calculated using the SPSS 20 software. Descriptive statistics were made on the participants gender, year of program and age. The frequency and percentage of each response under category were calculated and tabulated.

**Results**

**PARTICIPANTS:** This study surveyed Physiotherapy students of about 100 in total. Among which 57 participants are from Undergraduate Internship, 19 from Post Graduate first year and 24 from Under Graduate second year which included 50 male and 50 female participants. When asked about their professional program’s social media policy 74% of the respondents did not know about it. 79% did not know if their sites were being monitored by their professional program but almost 70% of the respondents thought that employers would monitor their social media sites as a screening tool prior to their employment.

**Level of Privacy Concern:**

Over 30% of Respondents thought that Posting pictures and videos of a de-identified patient is not a privacy concern. 40% don’t know that it is wrong to enquire about his patient’s progression through a third person. 31% reads an email with de-identified information and 19% had no concern about it. 53% thought it is definitely a privacy concern to share a picture of a patient with a pressure sore with his classmates. 38% of respondents thought that it is not a concern to post a picture of himself/herself with the patients.

**Discussion**

Social media acts as a communication tool between the patient and the Therapist for patient engagement.² The unprofessional content of students in their social websites can reduce their own dignity which in turn reduces confidence of patients towards Therapist.⁴

Health care professionals skips communication through online due to the ethical dilemmas arising related to patients’ privacy concern and posting of inappropriate contents in social media.¹⁴ Digital Professionalism is an indeed method to teach Physiotherapy students regarding social media policy and instruct them on appropriate use of social web sites. Adopting such measures might reduce the chances of ethical dilemmas faced especially by the New professionals.³

Although all the Physical therapy programs have social media policy most of the students did not about its existence and did not read the policy even if they are aware about it. This information suggest that the educational
institution must focus on the social media policies and make sure about its awareness among the students. Since implementation of Digital Professionalism is much more important way in reducing the rates of legal and ethical issues the Physiotherapy educators must support its development.3,6

Students are found to have difference of opinion on what to be posted and what not through online. This could be due to the lack of knowledge and awareness of social media policy. Students' response regarding posting of pictures on social web sites shows majority of participants did not have such experiences whereas few others are found to have posting pictures of classroom and lab activities, with a patient, kissing a person of same gender which is completely depicting their personal activities which has not be addressed in the social web sites. Some behaviors in one’s personal life (harassing, abusing) might have legal impacts on their professional life.10

When the subjects were asked to answer according to their beliefs, few answered that it is acceptable to pass on a comment containing profanity or discriminatory language and few felt acceptable for disparaging remarks about faculty. The appropriateness of social media contents posted by the students might not be felt accepted by others.4,8 So if they have a feel that their social media sites has been monitored by their institution it has to be ensured by the students regarding the appropriateness of contents. Adam G. Pizzuti et al., (2020) concluded that studies are needed to analyse the utilization of social media platforms efficiently for better healthcare related education.15

Students are often unaware that their unprofessional behaviors in the social media sites can have an influence on their Professional life particularly when it comes to violating the rules of Indian Association of Physiotherapy and World Confederation for Physical Therapy. When questions were asked regarding privacy concerns, over 20% of the participants responded that it is not a privacy concern to share the pictures or video of a patient in the social web sites. 38% felt not a privacy concern to post the pictures with the permission of his patient. Over 40% did not know that it is not a privacy concern to enquire the progression of a patient and thinks not a privacy to share information regarding his patient to their friends.

Carlos DeLas Heras- Pedrosa et al., (2020) concluded that patients expect hospitals to identify their problems and interact regarding health care conversation as patient engagement is still lacking in this digital world of communication.16 The rapid development of social media has replaced face to face interaction. It enhances communication by creating a comfortable environment for patients in order to interact for treatment purposes.17

Students must be taught with the social media policy and its importance and they should be reminded that their own perceptions of appropriate of social web postings might not be the same as compared with their patients, faculties and employers. Posting pictures of patients without their consent should be prevented. The proper use of social media by Health care professionals must take the following points into consideration- Be informed, Think before your post something in social web sites. Protect your Professionalism and reputation.18 Class Discussion and workshops on Digital professionalism appears to be the best method of understanding implications, positives and negatives of using social websites.3

Conclusion

Students are unaware about the social media policy and its importance. The perception of students regarding social web postings might not be the same as others and this has to be reminded. Students should learn about the privacy concern and professional boundaries. There is a need for social media policies and education regarding the proper use of social media.

Limitations and Recommendations

The number of participants surveyed in this study is limited. Students were included from various three years of programs having differences in their practical experience. Almost half of the participants are from the Internship the practical experience of Interns is comparatively less than the Post graduates. So future studies can be concentrated on the selective year of program.

Abstract

Purpose: To review the Clinical Trial Registry of India (CTRI) for clinical trials registered for the interventions for the treatment of dry eye disease.

Methods: CTRI was manually searched by using the different key words related to the dry eye. Trials registered after 2009 were included in the analysis. All the parameters like type of interventions, phase of trial, sample size etc of the each trial were extracted in the predesigned proforma. Descriptive statistics was reported in the form of frequency and percentages.

Results: Total 35 trials were registered since 2010. Majority were phase 4 trials (Post Marketing Surveillance). More than half of the registered trials were related to the ayurvedic products. Most frequent allopathic intervention was lubricant and most frequently used comparator was Carboxy Methyl Cellulose. Range of sample size in different trials was 30-300.

Conclusion: A good number of trials related to the ayurvedic drugs are registered for dry eye. There is a need for similar research efforts for allopathic interventions.

Key words: COVID-19, Dry Eye Disease, Research

Introduction

Coronavirus disease (COVID-19) emerged in December 2019 in China and became pandemic situation worldwide within no time. COVID-19 pandemic has affected more than 215 countries across the globe and many of these countries faced a complete lockdown1,2. Various sectors including routine on job work, academic teaching, field work has come to an stand still due rapid and complete shutdown of all activities3. This had led to increase in scrree time and potentially might cascade to outbreak of Dry eye disease.

Dry Eye Disease (DED), as the nomenclature suggests is a condition characterized by dryness of eyes that may lead to tear film instability, hyperosmolarity, chronic inflammation and neurosensory abnormalities ultimately causing damage to ocular surface4. In contrast to earlier belief, the disease is no longer limited to old age population and has started precipitating in...
early life years of an individual (5). Premature occurrence of DED is often associated with compromised quality of life. In India the reported prevalence of DED ranges from 5 to 35% and is often influence by environmental conditions, life style factors and geographic locations (6, 7). However, there may be substantial gap in terms of claimed prevalence of the condition as significant heterogeneity exist between the methods of diagnosis and there may be an underestimation of the disease due to undiagnosed asymptomatic patients (8). This is partly contributed by the complex and unknown pathophysiology and epidemiology of the disease, subjective symptoms and poor correlation between the discomfort experienced by the patients with the objective clinical scales (9). Mores with pandemic of COVID-19, this constantly evolving definition of the disease might become a public health challenge with reference to its classification, its management and relevance to local context.

With this complex nature of the disease and associated clinical burden, periodic update of the treatment strategies are essential. In last decade several newer treatment agents have emerged with promising results globally (10). However, the landscape assessment of the trials registered from developing countries especially India has not been undertaken yet. Clinical trials forms the main source of evidence-based medicine and hence the backbone of clinical practice. With increase in screen time and possible outbreak of DED, present paper aims to provide a recent update on the clinical trials registered from India to address DED during last decade to understand if there is any need to foster the research on DED.

Methods

We accessed the clinical trial registry (http://ctri.nic.in/Clinicaltrials/login.php-last access on February 2020) using the search terms “dry eye” or “ocular surface”. The present communication is limited to trials registered after 2009 and investigating the effect of drugs on DED only. The trials studying effect of surgical or any other intervention were excluded from the review.

Results

A total of thirty-five trials were registered since the year 2010 and were at different stages of development (table 1). Majority (28%) of the trials were at post marketing surveillance phase (phase 4) and Efficacy trials phase 2 (28%). Very few registered trials were in Efficacy (phase 1) and Multi-centric efficacy phase (phase 3). Though the number of registered interventions for treating DED from India were substantial and comparable with global trends, majority of the trials assessed efficacy of Ayurvedic formulations (66%) (Table 2). Twelve trials (34%) were clinical drug trials where the most frequent category was involving lubricants. It was also observed that around 17% registered ayurvedic formulation trials were retrospective in nature. The sample size in individual trial ranged from 30 to 300. Eight of the registered trials have used Carboxy Methyl Cellulose as comparator, while 10 trials had no drug as comparator.

Discussion

This study was designed with the aim of evaluating different clinical trials registered in Clinical Trials Registry of India (CTRI). Present evidence synthesis clearly indicates that reasonably good amount of clinical studies are initiated by Indian investigators and also registered to address DED. The review suggests an increasing interest of the Ayurvedic preparation for Dry Eye. India is recognised hub for use of ayurvedic medications with apparently broad spectrum of therapeutic potencies, similar registered trails with Ayurvedic formulations is an expected finding (11,12,13). It also suggest that researchers are looking forward to evaluate age old ayurvedic formulations through well designed, rigorous clinical trial methodologies (14,15). With an increasing penetration of mobiles, net and digital innovations, DED needs to be considered as a serious challenge for ophthalmic morbidity (16,17). There is also urgent need for an advocacy effort towards willingness of the policy makers, clinicians and researchers to identify DED as a public health threat. Lastly a careful follow up for disseminations of these trial results culminating into scientific publication should also be advocated to substantiate findings further. Post COVID-19 pandemic and increased screen time as new normal, there is need to foster and invest into research for novel molecules as DED might create a big potential market looking for need of solutions.

**Abstract**

Due to ongoing pandemic, majority of the academic teaching is executed on online platforms, leading to extended screen time. Anecdotal evidence suggests long-term ophthalmic impact of extended screen time. Present study was carried out to document eye related problems amongst adult university/college students undertaking online classes to document the effects of online teaching. An online survey method was undertaken in the month of July, 2020 amongst university/college students of Gujarat using google form. All possible social media platforms were used to collect the data from students of Gujarat. Epi Info and SPSS were used and both descriptive and inferential analysis was performed. A total of 620 students from the various streams participated in the study where around 56.5% were female respondents. The majority of students (88% of participants) had noticed eye problems out of that 39.1% of participants felt that online teaching as a reason. Headache (54.0%) was the most common problem experienced by the participants followed by Pain in eyes (34%) and Watering (26.3%). To conclude online teaching has led to increased eye strain and other eye-related problems in university/college going students and risk factors for severity included sessions attended per day, the distance at device kept, and the enjoyment level. In spite of the high incidence of ophthalmic issues, none of the respondents contacted any ophthalmologist for the same.

**Keywords:** university/college students, online learning, COVID-19

**Introduction**

Coronavirus disease (COVID-19) emerged in December 2019 in china and became pandemic situation worldwide. COVID-19 pandemic has affected more than 215 countries across the globe and many of these countries faced a complete lockdown. Among all the sectors academic sector was among the first few sectors that faced rapid and complete shutdown of all its activities.¹ Due to this complete lockdown universities have been closed and exams were postpones which creates a huge pressure on higher education institutions and students². According to UNESCO, over 320 million students in Indian schools and colleges are currently impacted.³ Hence the academic teaching is executed on online platforms⁴,⁵,⁶.

Besides this collegians and youngsters are known to have a long duration of screen view be it use computers, tablets, mobile phones, or gaming consoles. The lockdown has further compounded the problem with the virtual classes, making it increasingly difficult to reduce the screen time of young eyes. Digital eye strain (DES), also known as computer vision syndrome, involves a range of ocular and visual symptoms and prevalence of it is 50% or more among the computer users.⁷,⁸,⁹ There are evidences that usual longer screen time are related to ocular symptoms reported like eye strain,
irritation, burning sensation, redness, blurred vision and double vision due to rapid change in accommodative mechanism. These symptoms commonly managed by non-pharmacologically management includes correct ergonomic practices, the use of appropriate lighting while using devices, careful positioning of the digital device, screen distance and taking breaks.

Besides online teaching a current situation of lock down and various restrictions has also led to a rapid change in the routine lifestyle of individuals and there is more dependency on TV, mobile and laptop to watch movies/series, attend webinars and video calls. Present study is focused on college / university going students to evaluate the ophthalmic impact of online teaching. The two main objectives of the study are to document the various effects of online teaching and to identify the associated risk factors.

Methods

An online survey was conducted in the month of July,2020 amongst university/ college going students of Gujarat to document the effects of online teaching. For the data collection google form was created and sent to all students of various academic colleges of Gujarat. All possible social media platforms like WhatsApp, Facebook and emails were used to reach out the maximum number of students. Snow ball sampling method was used to get the more participants. Any university/college going student (irrespective of stream) and wishes to be a part of a survey irrespective of gender and grades/semester can participate. Those who were not willing to participate and not filled the form were excluded from the study and those who filled the forms were considered to have an implied consent to the study.

Data was entered and cross-checked using Excel spread sheet. Data analysis was performed using statistical software like Epi Info version 6.01 and SPSS 20.0. Both descriptive and inferential analysis was carried out to get the better understanding. Inferential analysis was carried out at 95% CI level.

Results

A total of 620 individuals had participated in the study. Out of these total 620 participants maximum participants (69.6%) were from medical stream. Out of 620 participants,56.5% participants were female and majority of them (90%) were belongs to age group 25 years and younger than that. At the time of survey 56.1% participants had glasses. The mean age of the participating students was 21.5 years with a SD of ± 2.9 years. [Table 1.]

About 73% of the total participants attended at least one online teaching session per day and very few participants (5.8%) had attended more than 3 session per day. Each of the online session was around 45-60 minutes. It was documented that only 15.5% participants were enjoying the online teaching over the actual learning while others either did not find any difference between both formats or were not enjoying online session. Majority of the participants (67.3%) used mobile for the online lectures. Almost one fourth of the total participants were not able to attend online classes for more than 30 minutes continuously and felt like leaving in between due to various reasons most common being distraction or pain in eye/watering. On inquiring about distance, they maintain between eyes and device around 46.6 % were not adhering to any distance, whereas around 34% used the device to less than 40 cms. [Table 2.] Apart from online education almost 60% had to undertake 1-3 hrs of additional studying per day. Overall 8.7% of the participants felt they had improved learning by Online teaching.

Table 3. Suggests that more than three fourth of the total participants felt that online learning is more strainful to their eyes. Almost 88% participants had noticed any problem related to eyes. Out of those who included in the present study around 88 % complained eye issues. Out of those 88% (n=545) who had noticed any ophthalmic challenges, 39.1% participants felt that mentioned problems started after beginning of online teaching, however, very few participants (14.1%) had visited eye specialist for the problem experienced. Headache (54.0%) was the most common problem experienced by the participants followed by Pain in eyes (34%), Excessive rubbing of eyes (29.5%), Watering (26.3%) and redness in eyes (15.5%). [Table 4.]

Results revealed that the problems like excessive rubbing of eyes, pain in eyes, redness, headache and
watering were noticed less in the participants who were enjoyed the online classes compared to others. It has been also found that this difference is statistically significant for the excessive rubbing of eyes (p = 0.006), headache (p = 0.007) and watering (p = 0.024).

Above mentioned problems (except redness and watering) were noticed more in the participants who look at the screen at < 40 cms distance followed by > 40 cms distance and variable distance. This difference is statistically significant for the excessive rubbing of eyes (p = 0.007) and pain in eyes (p = 0.002). Those who attended 1 or less than 1 session of online teaching or webinar per day had experienced less problems compared to those who attended > 1 to 3 sessions or > 3 sessions per day. Those who attended more 3 sessions per day experienced more problems related to eyes. Found difference is statistically significant for the pain in eyes (p = 0.000), redness (p = 0.036) and headache (p = 0.033). [Table 5.]

**Discussion**

The current study sought to document the effect of online teaching and to identify associated risk factors. Findings of the study signify that most of the student (88%) experienced eye problem due to online teaching which is similar to prevalence of computer vision syndrome found in engineer and medical students of Chennai. Even there is more free time due to lockdown, students cannot really focus into their study because of this ongoing pandemic effect and their study has affected much more than usual.

Results shows that the only 15.5% students enjoying the online teaching. However, it was found that the almost 74% students liked studying through online teaching in the study conducted by Shatakshi Lall, & Nardev Singh.

Attending classes online without break is strainful to their eyes said to be causing problems like dry eye syndrome, burning sensation in eyes, watering, redness, headache, excessive rubbing of eyes. Out of all these reported symptoms head ache was the most common (50.4%) problem experienced by the students which is quite similar to the study conducted on university students in UAE. This study reveals that those who are attending more than 3 sessions per day experiencing more ophthalmic problems. Joowon Kim et al. also found that longer daily smartphone use was associated with a higher likelihood of experiencing or having ocular symptoms. Advantages of online and Digital education were highlighted by Allen and Saxena.

**Conclusion**

Online teaching has affected the young population which has reported a trend of ophthalmic complaints. Online teaching has increased eye strain and other eye related problems in university/college going students and affected their study. Eye related problems experienced by the students during the process of online teaching are associated with the variables like no. of sessions attended.
per day, distance at device kept and the enjoyment level. Excessive rubbing of eyes is associated with level of enjoyment and at what distance device is kept, pain in eyes is associated with at what distance device is kept and no. of sessions attended, redness is associated with no. of sessions attended, headache is associated with level of enjoyment and no. of sessions attended while watering is associated with enjoyment level.

Abstract
The dissemination of COVID-19 has contributed to the closing of educational institutions around the world. Such closing accelerated the creation of online learning environments within these institutions, ensuring that learning would not be interrupted. The coronavirus pandemic tested the ability of the centers to cope with a problem that involves online and remote intervention. Most have not been educated, so it is necessary to investigate the motives for providing online classes to students, which go beyond the confinement era. The vast majority of children have no previous experience of remote learning previous to the pandemic. Since the COVID-19 pandemic has destroyed people’s usual lifestyles around the globe, the virtual world has come to the rescue. Like several institutions, schools have already transferred their focus to interactive networks to take classes online. Video conferencing tools such as Zoom and WebEx are commonly used and learning management systems such as Infrastructure Canvas, Blackboard and Google Classroom. In addition, applications such as Proctorio, a Google Chrome plugin that tracks students taking online tests, are available. In India, too, all educational institutions have been suspended by the government as part of the national lockdown, which has impacted learners ranging from school-learning to post-graduate students.

Keywords: E-learning, Lockdown, digital platform, COVID-19.

Introduction

Due to COVID-19 pandemic, the doors of schools and colleges are barred all over the country. Approximately 1.5 billion student studies are affected by COVID 19. The entire education system has changed since the pandemic. The teaching and learning process is part of the digital platforms. This digital platform is known as e-learning. E-learning is a completely different learning experience for Indian students. Web-based computing, distributed learning, online learning, or internet-based learning is another term for e-learning. A method of learning based on formalized learning with the aid of electronic tools is known as e-learning. While education may be centered in or out of schools, the use of computers and the Internet is a core component of e-learning. E-learning may also be defined as a network facilitating the sharing of skills and expertise and delivering education to a wide number of recipients at the same or different times. Earlier, it was not widely embraced as it was believed that this method lacked the human aspect needed for learning. E-learning or online education allows users to obtain access to world-class learning experience where regular higher education may not be feasible due to income, personal or other restrictions. In countries like India, there is a tremendous desire for e-learning to take its shape. India is the second-most populous nation in the world. The power of every nation is its inhabitants, and India has a population of 134 crores, or 1.34 billion. One of the best places in the world to take advantage of these new e-learning developments is a nation like India. Today, India is host to many of the new e-learning developments in education that developing countries have been using for a very long time. As we remember, the whole world is facing a very deadly virus called COVID-19. Due to the worldwide outbreak of Coronavirus, the governments of most countries have directed the closure and advised people to stay in their
homes and be healthy. Likewise, the Indian Government has ordered a full lockdown. Education is known to be the foundation of our nation in India. Owing to the lockdown, the education system has been significantly disrupted because schools and universities cannot be accessed, so the main challenge is how to educate children when living at home. In order to address this issue, the idea of e-learning is being adapted by schools and colleges to educate their students. In fact, e-learning proved to be helpful during the COVID-19 crisis. More students have opted for Ed-tech and other online training outlets during this current pandemic. Online networks such as Vedantu, Unacademy and Byju’s have provided free access to live classes to help students learn easily from their homes, and there has been a huge increase in students using these educational applications. Online platform educators have already begun to take more live classes. Formerly, there were two common categories of e-learning: distance learning and computer-assisted teaching. Where distance learning is preferred for those living in rural areas, information technology is used to give guidance to learners and computer-assisted training uses computer tools to help provide stand-alone digital learning and teaching programs.

**Role in Medical Education**

The need for the hour is to bring e-learning into medical education. The Indian Medical Council (MCI), the governing body for medical education in India, has recognized the value of technology and has included the use of electronic means in the broad competency “Lifelong Learning Dedicated to Continuous Development in Skills and Knowledge”. Indian medical graduates must have acquired this expertise at the time of graduation. The student must constantly learn new skills to keep up to date with the newest technologies, which are generally deemed impossible to do in the absence of technology. The use of e-learning will help them accomplish the aim of continuous professional growth, given the vastness of the program, the shortness of time and the often overburdened schedule. Recognizing the value of information technology for today’s doctors, the General Medical Council in the United Kingdom further claims that medical graduates should be able “to make efficient use of computers and other information technologies, including information storage and retrieval”. From a mere ‘content spreader,’ teachers are gradually becoming ‘learning facilitators’, which is supported by e-learning tools that offer a range of online resources. E-learning systems can be used to increase all learning fields, including cognitive, psychomotor and affective learning. In the cognitive area, classroom instruction may be improved by offering online resources such as pre-reading assignments and audio-video clips during sessions. And students may be equipped with virtual resources such as audio-video clips, podcasts, videos, and web-links for self-directed learning designed to be used at home or as part of Flipped lectures. Psychomotor abilities, while better learned with actual experience, can also be improved by technology, at least up to the ‘know-how’ stage. Audio-visual illustration of treatments, diagnostics and therapies can be given. Students can read through the descriptions and display the procedural skills checklists before actually practicing the same under supervision in clinical posts or in specialist laboratories. In the affective domain, videos of scenarios depicting good and bad communication-skills, role-playing and counselling sessions, and self-recording - can be used to promote learning. Other modalities include multimedia case reports and patient records, health decision support services, interactive patients, medical video games, e-books, e-atlases, instructional libraries, and digital editions of online journals.

More and more colleges are now incorporating classroom training with online learning. Related methods have been applied: Blended learning ties together with online education and traditional classroom teaching. Both blended learning and e-learning in medical schools have developed over the past few years, taking various forms. It should be assured that students have gained a minimum of expertise before they reach the professional. This will significantly increase the efficiency of teaching.

Flipped classroom instruction is a situation where students research challenging data at home. The classroom is then used for problem-solving, analytical instruction and asking and response sessions. This teaching method has been seen to be very effective. Just in time teaching is another type of blended learning, where students study online, respond to MCQs and thus allow the educator to adapt the in-person teaching session to the needs of specific students.
Technology and applications play a vital role in the education sector during the lockdown:

1. Interaction enhancements:

Learning apps can improve a child’s relationship with their guardians. They seem to get more involved and to speak about their professions.

2. Good contact between parent and teacher:

These days, learning innovations are being introduced in different classrooms. This device also allows teachers to lecture from their homes and also review the student’s success with their parents. Teachers will take care of the parents’ questions at any time and wherever and make educated decisions about the child’s development.

3. Availability of resources online:

Online learning infrastructure allows students to browse a broad library of materials, including books, PDFs, test papers and more. These tools assist students in their learning process in order to access informative information.

4. Provides fun too:

According to research, smartphone applications facilitate entertainment. Learning is no longer passive practice, it is involved with apps. Lessons turned into games will change the face of education. The implementation of gamification of learning has helped to increase the level of engagement of children with creative and exciting strategies to play while studying.

5. Promotes distance learning:

Online learning has benefited from versatility in the time and place of study. Students have access to research materials and tools at all times. It also offers students the autonomy to study at their own pace.

6. Offers personalization:

In addition to so many other opportunities, E-learning often provides personalization. In order to address the needs of each student in compliance with their needs, e-learning platforms offer a customized way of teaching and learning that is specific to the individual. They stay involved in the course until they know what to study.

7. Cost-effectiveness:

E-learning technology is much more cost-effective than most other methods of education. With access to all students around the world, regardless of their educational and economic context, e-learning resources are accessible at a low price and provide them with better education.

8. Portability:

When studying online learning applications, you can study in a cozy and relaxing environment. And sure you’re checking it because you’re getting a decent internet connexion.

9. Sustainability:

The method of mobile learning is sustainable. Although millions of trees are being cut down to generate papers on the conventional learning process, smartphone applications in education need only a download. It means greener land for future generations.

10. Report on real-time performance:

E-learning helps students to assess their success in real-time. This input offers students a quicker and more thorough review of their success in school.

11. Live-streaming seminars on the solution of real-time doubts:

Online learning applications allow students to take part in live streaming lectures by instructors and professionals. Students may also benefit from real-time doubt-solving through the use of specialized technologies. This gives them a living knowledge of great and quality education at the comfort of their homes.

E learning during Covid 19

In India, students have access to their studies through e-learning due to a lockout. There are several platforms in place to facilitate online education in India. These networks are funded by the Ministry of Human Resources Development (MHRD), the National Council for Educational Research and Training (NCERT) and the Department of Technical Education. Many apps
have free access for online courses such as Gradeup, Unacademy, Vedantu, Byju’s. In the current situation, students have access to lessons across multiple applications and this lets students study for and complete their exams. Commonly, in India, since closing, most universities and colleges have requested faculty members and students to use the digital platform for academic purposes. Faculty members include PDF files, PPT, tasks, mock-tests to their WhatsApp and addresses, as well as online classrooms through Google Classroom, Zoom Cloud Meeting Software, WebEx App. This study of the students is not affected during this corona crisis. Health educators now face distinct obstacles than their predecessors in training physicians tomorrow. Over the last few decades, improvements in health care implementation and innovations in science have raised pressures on the college staff, resulting in less time for teaching than was historically the case. Changes in health care delivery environments, from acute care hospitals to community-based chronic care facilities, have prompted modifications in educational settings. Seeking time to educate “modern” subjects such as genomics, palliative care, geriatrics, and alternative medicine is challenging while medical school curricula are also being forced to include standard materials. Typical teacher-centered education gives way to a learner-centered paradigm that places learners in control of their own learning.

Benefits of e-learning

- It’s simply a web-based instruction.
- The easiest and most practical way to practice on your own.
- It’s the quickest way to read.
- 24x7 Easy to reach anytime.
- It helps to improve students’ skills when they have the option of choosing study content.
- It’s time-saving. Making education interactive Visualy impressive content to learn and retain better Convenient learning from comfort zones Personalized guidance and mentoring Multiple practice sessions Flexible study time.
- Convenience for participants in the learning process, – streamlining and maximizing the work of teachers.

- Simple, fast and reliable access to tools and deliverables for learning.
- Better data protection.
- More communication opportunities.
- More effective flow of knowledge.
- A highly efficient class organization.

- Some of the advantages of this digital platform are Screen Sharing Online Study-Whiteboard Online Mock Testing and Practice Testing File Sharing Registered and Live Classes Update and share analysis materials detailed scorecards and reviews Annotation Live discussions.

Limitations to e-learning

- It is not effective in rural regions where Internet access is not as high as it is focused solely on the Internet.
- It is not suitable for technical subjects such as mathematics and operational research.
- It is not important that the teacher is always available on request.
- It is not helpful for students who are not self-motivated to learn.
- The use of e-learning can make students feel alienated.

Conclusion

The Covid-19 outbreak makes us realize that no matter where the learning process takes place, schools should be ready to make the most of it. From this review paper we can conclude that e-learning is all about learning and taking a step that helps in moving toward higher education level. We have to be familiar with technology devices and use them to enhance the education system. This tool is very helpful in this pandemic as you will get knowledge without going outside to the home.

Herd Immunity: A Major Advantage or A Major Challenge to Achieve for the COVID-19 Pandemic

Parisha Subhash Walinjkar

Medical intern (M.B.B.S), Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Sawangi, Wardha, Maharashtra, India

Abstract

COVID-19 caused by the novel SARS-COV2 has been causing worldwide panic in recent times. Global epidemiological findings have shown numerous new cases being reported daily as well as drastic mortality rates. It is the need of the hour to plan out strategies to cope with this ongoing pandemic. Herd immunity has been used as an effective approach for years during epidemics and can prove to be a major advantage in controlling the spread of the disease. Various models have been studied using mathematical estimates to find out how herd immunity can be achieved as well as to predict risks involved in doing so. The current scenario where there are no efficient vaccines available has also been taken into consideration. It is important to take all these facts into consideration to come to a valid conclusion of whether achieving herd immunity can be beneficial or impractical.

Key Words: COVID-19, SARS-COV2, herd immunity, vaccination, pandemic

Introduction

The recently emerged COVID-19 or the so called coronavirus disease is caused by Severe Acute Respiratory Syndrome- Coronavirus 2 (SARS-COV2) and is a deadly disease of recent times that is of major health concern throughout the world. Globally, as of September 2020, there have been approximately 31,370,000 cases that are confirmed of COVID-19, including 966,000 deaths, reported to WHO. The rising number of new cases and the level of mortality across nations makes it a major concern to find suitable means to flatten the curve of the disease and reduce mortality significantly. Various methods to deal with this pandemic are under development, including finding new treatment measures to improve symptoms, isolation of infected individuals to prevent spread, promoting disinfection measures, promoting social distancing and vigorous research to create an effective vaccine.

“Herd immunity or community immunity is a type of immunity that occurs when a portion of the population is immune to a certain disease and provides protection to non-immune individuals in that population.” Herd immunity can be achieved by vaccination or by natural immunity being generated after being infected by the pathogen. It can play a significant role in preventing further spread of the disease in the society, which has also been achieved successfully in the past decades, especially during epidemics. But it is important to understand that achieving herd immunity without an effective vaccine against SARS-COV2 is a challenging task. Moreover, anticipating for target herd immunity to be achieved in a population naturally involves number of people being infected by the disease and may lead to unethical fatality rates. Hence, it is important to understand how herd immunity works to understand whether it is effective to aim at achieving target herd immunity threshold or if the idea itself has too many adverse effects to achieve in real life situations.

Material and Methods

Over the span of a few months the novel corona virus spread to several countries transforming an
epidemic quickly into the form of a pandemic. Various researches were done to find an effective way to control the pandemic. Many measures were implemented in all countries all over the world to prevent the spread of the disease. This included shutting down of schools, offices, public places, etc. Lockdowns were implemented which ranged from minor restrictions to locking down of entire countries. “However, while these harsh measures may have been extremely successful in averting catastrophic epidemic rise, they inflict major social and economic expenses on the society at the same time.”(4) Hence, all countries have been trying to find an effective and responsible way to waive off the lockdown gradually. It is possible to achieve this if there is adequate herd immunity being set up in the society. Herd immunity can prevent sudden rebound of new cases during the relaxation period of the lockdown. “The concept of herd immunity is based on the fact that direct effect of immunity in decreasing infectiousness in some individuals can reduce the risk of infection among those who still remain vulnerable in the given population.”(5)

There are two known effective methods to reach herd immunity. The most effective method is to successfully vaccinate individuals. The other method is to let natural immunity generate in individuals naturally infected with the said pathogen. Various mathematical models have been created using statistics of new cases, their recovery rate, overall case fatality rate, data obtained by screening tests, antibody testing in affected individuals, etc. which have helped to learn about the novel corona virus. Mathematical estimates are available which have been used to calculate how we can achieve herd immunity as well as to calculate the risk factors involved in achieving the goal. Studying the mathematical model has been helpful to weigh the pros and cons and to understand whether achieving herd immunity can turn out to be an advantage in this pandemic or prove to be just another unachievable challenge in an already critical situation.

Study Design:

Various mathematical models were studied to understand herd immunity and its significant effect in the COVID-19 pandemic and further observations were hence made. “Herd immunity refers to the indirect protection from a certain pathogen inherited by susceptible individuals when a adequately huge fraction of immune individuals exists in a population.”(6) The concept of classical herd immunity arose from mathematical models that were developed according to the impact of vaccination in a population. Depending on the amount of pre-existing immunity to a certain pathogen in the population at hand, probably due to successful vaccination, addition of a single infected individual to the same population will have varied outcomes. In an entirely susceptible population, the said pathogen will spread through non-immune hosts in a completely reckless manner after exposure of susceptible and infected individuals. However, if a large proportion of the given population is immune to the said pathogen, the odds of effective exposure of susceptible and infected individuals are greatly reduced. If the proportion of vulnerable or non-immune individuals in a population in comparison to infected individuals is too less, then the pathogen cannot spread effectively as the immune individuals prevent its spread and thus the prevalence of the disease will eventually decline. “The point at which the fraction of non-immune individuals falls below the threshold needed for transmission is known as the herd immunity threshold.”(6) It is important to calculate this herd immunity threshold to reach effective herd immunity. The herd immunity threshold, \( h_C \) is calculated as \( h_C = 1 - 1/R_0 \) \(^{(7)}\) \( R_0 \) is the basic reproduction number, defined as the average number of secondary infections caused by a single infectious individual during the early stage of an outbreak in a fully susceptible population.(6,7) Let’s take a pathogen whose value of \( R_0 \) is 5, this suggests that a single infected individual will further infect five other individuals following exposure, assuming a completely susceptible population at hand. The more transmissible the pathogen the greater is the value of \( R_0 \). “\( R_t \) is defined as the number of secondary infections caused by a single infectious individual during the infectious period in a partially immune population.”(6) \( R_t \) is considered a more practical form of \( R_0 \) which uses realistic figures to assess the reproductive number.\(^{(8)}\) “The value of \( R_t \) can be estimated by using the exponential growth method, using data gathered on a daily basis of new COVID-19 cases, or by multiplying \( R_0 \) with the fraction of non-immune population. We can use these estimated values of \( R_t \) to calculate the herd immunity threshold \( h_C \), to cease the spread of infection in the given population. For example, since \( h_C = 1 - 1/R_t \) if the value of \( R_t = 3 \) then, \( h_C = 0.67 \), i.e. at least
two-thirds of the population needs to be immune.”(8) It has been assumed that the value of $R_t$ should be brought down below 1. This can only happen when the immune fraction of the population surpasses the calculated herd immunity threshold level. When this point is reached, the transmission of the pathogen cannot be maintained effectively and there is a significant deterioration seen in the overall cases of infected individuals in the same population.

Although these mathematical models are helpful in making estimates, they majorly rely on assumptions made during creating the models. The model assumes the population to be homogenous in nature, which is far from reality. There are many heterogeneities in a real life population that influence the virulence and transmissibility of the virus. It is also assumed that all individuals in a society will develop absolute immunity to the pathogen and that the immunity developed will have lifelong protection against the pathogen.(6) “A possibility of partial immunity to SARS-COV2, even when it is a new coronavirus, may be present due to some antibody cross-reactivity and a form of partial immunity derived from former infections with the seasonal coronaviruses (OC43, 229E, NL63, HKU1) that have been present in the population for decades, which has already been seen for SARS-COV. A similar case could also be seen for SARS-CoV-2 and might explain the reason why some individuals have milder symptoms or even asymptomatic infections.”(8) This also proves that the virus that affects the population doesn’t have the same effect on all individuals, striking out the possibility of homogenous mixing of the population. A single pathogen will have not a single but numerous values of $R_0$ depending on the communicability dynamics of the virus and the population. To eliminate the assumption of homogeneity, we will have to consider different parameters like age, social activity level, population density, population structure, etc. Some models have been created wherein the population has been divided into different cohorts depending on these parameters to get more accurate values of herd immunity threshold.

Another problem that has emerged depends on the accuracy of screening tests for SARS-COV2 done across countries. If testing is done randomly and assuming that the test has very high sensitivity as well as specificity, we can obtain reasonably accurate estimates of the infected, the population attack rate, and the infection fatality rate. But the current worldwide situation does not bear a resemblance to this ideal condition.(9) If the estimates obtained by testing are low on accuracy, the calculated herd immunity threshold will also ultimately be less accurate. Therefore, it is important to get accurate statistics before making future policies and planning strategies in the ongoing pandemic.

There are various pathways that can be followed to achieve effective herd immunity levels. These pathways are made according to the value of $R_t$ in the given population. If the value of $R_t$ is more than 2, it indicates an uncontrolled epidemic spread of the disease. In this case the best solution would be to limit mortality rates and prevent an epidemic overshoot. A targeted lockdown implemented for a shorter duration once it is observed that we are on the verge of reaching threshold levels, could reduce mortality, and at the same time prevent socioeconomic losses caused by prolonged lockdown measures. If the value of $R_t$ is between 1 to 2, it indicates a controlled epidemic spread of the disease. In these situations, the population can be divided into two groups depending on the risk factors. A lesser degree of social distancing would be implemented to the group with less risk factors while strict measures of social distancing would be implemented to the group with high risk factors to make certain that only the groups with the least risk and least fatality become infected. If the value of $R_t$ is less than 1, it indicates that a local elimination of the disease can be carried out. With values less than 1, pathogen spread cannot be maintained effectively and the epidemic cannot sustain itself. Therefore, the epidemic and be controlled locally. This can be accomplished by early detection of active cases with extensive screening tests, along with strict isolation of primary cases and quarantine of all close contacts to inhibit further spread which will safeguard rapid elimination of the disease.(4)

Although once herd immunity threshold levels are reached by any of these measures, the actual efficiency of herd immunity is still greatly influenced by the strength and duration of the newly acquired immunity. “Recently shared research reports show that neutralizing antibodies were detected amongst patients with mild disease after roughly 10 days, but remarkably neutralizing antibodies were not detected in approximately 30% of patients.”(10) Thus, it can be said that we still do not have
enough research based evidence to find out the definite efficacy of the immunity induced by the pathogen. Herd immunity is extremely effective only when the pathogen induces lifelong immunity, for example measles vaccination. However, this is very rarely seen, as the immunity induced by many other pathogens is either less in strength or diminishes after a while. As a result, herd immunity is not adequately effective and sporadic outbreaks can possibly occur in the population. “Also, if immunity is distributed randomly and unevenly within a given population, masses of vulnerable individuals that habitually contact one another may remain. Even if the fraction of immune individuals in the population as a whole surpasses the threshold, these clusters of susceptible individuals still remain at risk for local spread of infection.”(6)

Most of the models that have been made over the years to learn about herd immunity have considered vaccination as the main source of achieving immunity. However in this case, SARS-COV2 being a new virus in the human population, enough studies have not been carried out yet to develop an effective vaccine. “Taking future research into development of a vaccine into mind, if we vaccinate a fraction $v$ of the population at hand, assuming the vaccine giving 100% immunity, and individuals being vaccinated being selected uniformly, then the reproduction number would now be $R_v = (1 – v) R_0$. Using this, we can derive the critical vaccination coverage $v_c = 1 – 1/R$. So, at the least if this fraction of the community is vaccinated the population will reach herd immunity, as $R_v \leq 1$, and the epidemic cannot sustain itself. However, if the vaccine is less than perfect but only reduces susceptibility by a fraction $E$ (so $E = 1$ corresponds to 100% efficacy), then the critical vaccination coverage is given by $v_c = E^{-1}(1 – 1/R_0)$, inferring that a larger proportion of the community needs to be vaccinated if the vaccine is not nearly perfect.”(7) These calculations may be helpful in testing the efficiency of a vaccine in the pandemic. However, since currently there are so such effective vaccines available for mass production, there is a huge gap that is too difficult to fill to achieve classical herd immunity. Merely naturally induced immunity cannot fulfill this adequately without having harmful consequences. If we rely only on natural immunity, for the herd immunity threshold that needs to be achieved, a large fraction of the population will have to be allowed to be infected by the virus. This can lead to severe rise in mortality rates.

While having the perspective of attaining herd immunity to SARS-COV2, it is mandatory to also keep in mind that there are only finite healthcare resources available throughout countries. As the approach of attaining herd immunity to limit the propagation of the disease has the major consequence of permitting a large portion of the community to be infected, if the healthcare resources are depleted, there would be an escalation in mortality rates not only due to coronavirus disease but also due to all other causes.(6) This would only make the current scenario worse and even more challenging to deal with.

**Results and Discussion**

After studying various models that have been made for achieving herd immunity in the COVID-19 pandemic, it can be said that we do not have enough data or sufficiently accurate data to estimate exactly how much duration it will take to establish adequate herd immunity in the society. It is also not practical to figure out exactly how effective herd immunity can be for this pathogen as we are still in the early phase of the pandemic where sufficient information is still not available to make a valid estimate. The development of a vaccine against the virus can drastically change the situation and may rapidly speed up the process of achieving target herd immunity threshold. But the idea of a 100% effective vaccine inducing 100% immunity in an individual seems too far-fetched. Also, the time taken to create a near perfect vaccine will take years and till then, waiting for herd immunity to be established based on only naturally induced immunity seems inadequate. Without an effective vaccine, there would be unnecessary mortality that accompanies reaching herd immunity which is an unethical compromise. “According to research, the case fatality rate of COVID-19 can be around 0.25–3.0% of the population, proving that the expected number of people who could possibly die from COVID-19, while the population reaches the herd immunity threshold, is too much to accept.”(8)

It is vital now to start planning policies and strategies guided with an end goal in mind. Until now individual countries have been driven by short term targets, such as flattening the curve. The longer term exit strategy should now be considered and should focus on better population
health outcomes as well as the economic outcomes of any action taken. While herd immunity is an approach that has helped in epidemics in previous years, it might not be the best method to follow in the ongoing COVID-19 pandemic considering the countless shortcomings that come along with it. Once we get acquainted better with this new virus and have better research results, as well as an effective vaccine at hand, there is a prospect that achieving herd immunity may perhaps become easier and more effective. But according to the current scenario, achieving herd immunity against the SARS-COV2 virus cannot be made the primary, global objective. Emphasis is given in primary prevention. So basic precautions like hand hygiene (11), avoiding undue public contact through movement and travel (12,13,14) can help a lot to prevent the spread of Covid-19. Also measures need to be taken to reduce depression, anxiety and stress among the general population(15). In its place, making strategies to protect the most vulnerable group of the population should be highlighted, assuming that herd immunity will sooner or later be attained as a consequence of such strategies, instead of waiting in anticipation for the target herd immunity to be achieved.

Abstract

Vaccination is the process by which a person is made immune to various preventable diseases. Most of the emphasis is given to childhood vaccination and very little focus goes on towards immunizing the adults. Health care services in India has very less contribution to adult vaccination. Hence a desperate need has emerged to develop strategies and schemes for adult vaccination. The disease burden in India is increasing for both communicable and non-communicable diseases. By vaccinating adults against a disease that are known to be life-threatening can reduce the mortality rates significantly. In a country like India with such a huge population, vaccination can be a major intervention in preventing morbidity, mortality, and disability due to many known and preventable diseases. There is no doubt that adult vaccination in India is negligible as protecting adults by vaccination has never been considered as a preventive strategy. Hence there is a need to sensitize the health care providers in our country regarding the same. By vaccinating adults along with children, the chain of spreading the diseases can be broken and quality of life can be improved in a disease-free world.

Keywords: Adult Vaccination, Indications to Use, Guidelines.

Introduction

Vaccination is the process by which a person is made immune to various preventable diseases. Vaccination starts at a very early age, right from birth till old age. However, most of the vaccines given are during childhood and adolescence. (1) Also, most of the emphasis is given to childhood vaccination and very little focus goes on towards immunizing the adults. Vaccinations are important to prevent mortality occurring due to infections that can potentially be prevented. (2-4)

Besides this, the schedule made by the Government of India and World Health Organization for immunization also covers the childhood vaccination with very less focus on adult vaccination. Health care services in India has very less contribution to adult vaccination. Hence a desperate need has emerged to develop strategies and schemes for adult vaccination. The disease burden in India is increasing for both communicable and non-communicable diseases. Framing policies for adult immunization needs infrastructure, strategy, funds, and massive awareness campaign. (5)

By vaccinating adults against a disease that are known to be life-threatening can reduce the mortality rates significantly. This primarily includes communicable diseases such as hepatitis A, hepatitis B, Measles, Mumps, Rubella, Tetanus, Diphtheria, Japanese Encephalitis, human papillomavirus, meningococcus, pneumococcus, typhoid, influenza and others. (5) Hospitalization for diseases as mentioned earlier can be prevented, thus preventing the economical constraints on the patient. The significance lies in the fact that more than 25% of mortality in India is due to infectious diseases. (6)
In a country like India with such a huge population, vaccination can be a major intervention in preventing morbidity, mortality, and disability due to the diseases mentioned above. The most common problems faced in vaccinating adults includes the cost of developing the vaccines for adults. (7) Also, the availability, efficacy, potency, and effectiveness plays a major role in inadequate vaccination. There is no doubt that adult vaccination in India is negligible as protecting adults by vaccination has never been considered as a preventive strategy. Hence there is a need to sensitize the health care providers in our country regarding the same. (5)

Vaccination depends on various factors such as previous vaccination, age, gender, occupation, location, lifestyle, and traveler. (6) Hence by educating an adult regarding the possible diseases he is at risk of developing, he can be motivated to get vaccinated for, preventing any major hospitalization and possible morbidity to the patient. (8)

**VACCINES CURRENTLY IN USE IN INDIA FOR ADULTS INCLUDE:**

Ø **HEPATITIS B:**

- Recombinant hepatitis B vaccine is recommended for all adults. (9)

- At risk population group includes health care workers, people living with HIV positive patients, iv drug abusers, multiple and recurrent blood transfusions, multiple sexual partners, chronic diseases of liver and kidney and sexually transmitted diseases.

- Doses: 1ml (20 mcg) i.m. at 0, 1, and 6 months (STANDARD REGIMEN). But for patients with immunocompromised state and CKD, 4 doses are given at 0, 1, 2 and 6 months as 2ml (40 mcg) i.m.

- The only contraindication includes Hypersensitivity to yeast.

- The effectiveness of vaccines can be assessed by measuring Anti-HBs level, which should be above 10 mIU/ml. if the levels are less than 10 in a normal healthy individual who had received 20 mcg doses, it is recommended to give 3 more doses of 20 mcg at least 1 month apart and retest the levels. If the levels are still suboptimal, then the dose is doubled, that is 40 mcg i.m injections are given at 0, 1, and 6 months.

  - Post-exposure prophylaxis can be given with hepatitis B immunoglobulin within 72 hours of exposure, to be followed by a full course of vaccination. (10-13)

Ø **HEPATITIS A:**

- Inactivated hepatitis A vaccine is available in India.

- A combination vaccine with Hepatitis B is also available.

- API does not recommend Hep A vaccination for all.

- This vaccine is only indicated in high-risk individuals; post-exposure prophylaxis, hemophiliacs and iv drug users.

- It is very important to vaccinate a patient of chronic liver disease, post liver transplant and those waiting for liver transplants as the infection is very severe in such individuals.

- Dose: 2 i.m. doses; the first dose followed by the second dose at 6-18 months. (9)

Ø **DIPHTHERIA, PERTUSSIS AND TETANUS VACCINES:**

- Vaccines available for adults are acellular pertussis (ap), tetanus toxoid (TT), reduced diphtheria with tetanus toxoid combinations (Td) and combination of acellular pertussis, reduced diphtheria and tetanus toxoid (Tdap).

- These are indicated in all adults who did not have any prior immunization.

- All adults up to 65 years can be vaccinated by Tdap (single dose) as per recommendations.

- It is contraindicated in individuals with a history of allergic reactions to these vaccines and also in patients with acute neurological deficits.

- The vaccine used for the pediatric population contains whole cell pertussis, which is contraindicated in adults, as the risk of neurological complications is very high with this vaccine. (14-15)
§ Post-exposure prophylaxis: For any major trauma, TT dose is recommended if the last dose given more than 5 years ago. But in case of minor trauma, TT may not be given if the last dose was within 10 years.

§ In pregnancy, the recommended dose is 3 doses of TT in the second or third trimester with a gap of at least 3 weeks in between. However, if TT or Td is received within 10 years, a single booster immediately after delivery must be given. If more than 10 years have passed, than a single dose is given in the second trimester. (9)

Ø MEASLES, MUMPS, and RUBELLA:

§ It is a live attenuated vaccine.

§ It is given in adults only if the vaccine is not received in childhood.

§ The recommended dose for adults is 2 doses of 0.5 ml s.c. 4 weeks apart.

§ In HIV patients, it can be given if the CD counts are >200 cells/cu.microlitre. (16)

§ Contraindications include fever, pregnancy, history of hypersensitivity and a severely immunocompromised state. (9)

§ Considering teratogenic risk rubella vaccine in particular is avoided in pregnant women and also in those planning a pregnancy should avoid pregnancy after receiving the vaccine for a minimum of 1 month.

§ Current recommendation for any girl ≥15 years is a 3-dose schedule (0, 1-2, 6 months) including younger than 15 years who are immunocompromised and also in HIV infected.

§ This schedule is applied to all types of vaccines (bivalent, quadrivalent, and monovalent vaccines).

§ Rubella is recommended in secondary target populations include females aged ≥15 years or males only if it is affordable and feasible.

Ø VARICELLA AND ZOSTER VACCINES:

§ Both are live attenuated vaccines.

§ It is observed that the incidence of herpes zoster and postherpetic neuralgia is tremendously reduced post vaccination.

§ Varicella vaccine is indicated in patients without prior varicella infections. It is highly recommended in patients of HIV with CD count of >200/cu.microlitre. (16)

§ It is also indicated in post-exposure prophylaxis in adults with no history of infection or immunization. Single dose within 3-5 days post exposure is recommended. (17)

§ Dose: 2 doses (0.5 ml) s.c. four to eight weeks apart.

§ Contraindications to vaccines include pregnancy, hypersensitivity, severe immune compromised host or recent history of blood transfusion.

§ Zoster vaccine is indicated in elderly (>60 years) and individuals with any chronic illnesses. (16)

§ Countries where the varicella infection is acquired in higher age group then average age group can consider alternative vaccination programme. Current recommendations includes a 2-dose schedule as mentioned above.

§ Use of zoster vaccine is not recommended in India as enough evidence are yet to be collected. (17)

Ø PNEUMOCOCCAL VACCINE:

§ It is of two times. One is a polysaccharide vaccine containing 23 serotypes (PPSV23) and another one is conjugate vaccine containing polysaccharide capsules from 13 serotypes (PCV13) bound to diphtheria toxoid.

§ PPSV23 has less immune response but lacks mucosal protection

§ PCV13 is more immunogenic, but also provides good life long immunity. It also protects the mucosal layer. (18-19)

§ CDC guidelines suggest vaccination of adults >65 years of age with single dose PCV13 following which single dose of PPSV23, one year apart.

§ PPSV23 is also recommended individuals aged
<65 years for chronic smokers, and patients suffering from chronic diseases of lung, heart, and liver. \(^{(16)}\)

§ Patients with Immunodeficiency or CSF leak, cochlear implants or asplenia (anatomical or functional) should be given a single dose of PCV13 followed by a single dose of PPSV23, 8 weeks apart.

§ In patients posted for elective splenectomy, a single dose of PCV13 must be given 2 weeks before surgery followed by single dose PPSV23 after 5 years. \(^{(16)}\)

Ø Meningococcal Vaccine:

§ Two types of vaccine are available – polysaccharide and conjugate vaccines.

§ Polysaccharide vaccines are of two types – bivalent and quadrivalent.

§ Conjugate vaccine is quadrivalent. In comparison to the polysaccharide, it is more immunogenic. Its protection starts 28 days post vaccination. It is not recommended for individuals above the age of 55 years.

§ Group B meningococci are not covered under any of the vaccines mentioned above. \(^{(20)}\)

§ This vaccine is indicated in health care workers, contact with cases, overcrowded places, immunodeficient patients and asplenia (anatomical or functional).

§ In the case of late complements (C8, C9) deficiency, the pneumococcal vaccine is recommended as these patients are at risk of developing an infection.

§ As per Indian national policy, MPSV4 vaccine is given to all Haj Pilgrims.

§ Dose: 0.5 ml s.c. a single dose of injections. For patients with asplenia, 2 doses are recommended 8 weeks apart.

§ Cautious use is advised in patients with a history of Guillain-Barre Syndrome. \(^{(9)}\)

Ø Hemophilus influenzae Vaccine:

§ Two types of vaccines are available.

§ One is trivalent (TIV), another one is a live attenuated virus (LAIV).

§ These vaccines protect after 2 weeks of injection.

§ It is indicated only for at-risk population, viz, old age (>50 years), chronic kidney and liver conditions, asplenia, diabetes mellitus, pregnancy, health care workers and immunocompromised host and transplant recipients.

§ It is contraindicated in patients with history of Guillain-Barre Syndrome and hypersensitivity.

Ø LAIV is not used in India. \(^{(17)}\)

§ Dose: TIV is used as a single dose of 0.5 ml i.m. \(^{(9)}\)

Ø Human Papillomavirus Vaccine:

§ Two types of vaccines are available – Gardasil (quadrivalent) and Cervarix (bivalent).

§ Gardasil is active against HPV 6, 11, 16 and 18 subtypes while Cervarix has its action on HPV 16 and 18.

§ It is indicated in all females of age between 13-26 years and males 13-21 years.

§ Dose: 3 doses at 0, 2 and 6 months. \(^{(16)}\)

§ It is contraindicated in pregnancy.

Ø Japanese Encephalitis:

§ It is a live attenuated vaccine.

§ Dose: it is given a single 0.5 ml s.c. dose. Followed by a booster dose after at least one year.

§ JE vaccine is currently not recommended for adults. \(^{(16)}\)

Ø Yellow Fever Vaccine:

§ It is indicated only in individuals traveling to endemic countries and under the age of 60 years.

§ Dose: 0.5 ml s.c. single dose. A booster dose is to be given every 10 years.

§ Such individuals are issued YELLOW CARD that is valid after 10 days of vaccination until 10 years after which booster dose is indicated. \(^{(17)}\)
Ø TYPHOID:

§ Two types of typhoid vaccines are available.

§ One is live oral Ty21a vaccine, an enteric coated capsule

§ Another one is an injectable Vi capsular polysaccharide antigen vaccine (Vi CPS). Efficacy is almost equal for both these vaccines. (21)

§ Typhoid vaccines are not recommended currently as a routine vaccination for adults.

§ It is indicated only in cases where individuals are in contact with known S. Typhi carriers.

§ Dose: Oral Ty21a is given in 3 doses, alternate day followed by booster dose every 3 years. Vi CPS is given a single dose of 0.5 ml i.m. with a booster given after every 3 years.

§ Contraindications include: immune compromised host, pregnancy and children (<6 years) for oral vaccine and <2 years age for Vi CPS.

Ø CHOLERA:

§ It is an oral vaccine.

§ It is not a recommended vaccine for adults. (16)

NEVER VACCINES:

· DENGUE:

o Dengvaxia (CYD-TDV), has been licensed and five additional dengue vaccines are in clinical development with 2 in Phase III trials. Dengvaxia is given in three doses of i.m. schedule at 0, 6 and 12 months.

o WHO-SAGE recommends that users should be limited to areas where the disease is common because vaccination may increase the risk of dengue fever in people who have not been previously infected with the dengue virus. (22)

· MALARIA:

o At present, there are no approved vaccines for malaria.

o Mosquirix (RTS, S/AS01) acts against P. Falciparum and is the most promising vaccine. It requires 4 doses with the efficacy of 26-50%. (23)

· HEPATITIS E:

o At present, WHO has made no recommendation on the use of this vaccine. (24)

· HIV/AIDS:

o VaxGen gp120 protein subunit vaccine is in phase III trial at present. No significant results are achieved till now. (25)

Apart from the forementioned vaccines, adult vaccination remains one of the most untouched modality of health care in India. There is no doubt that childhood vaccination has increased the longevity of life. But the quality of life deteriorates as the age progresses as the forehead mentioned diseases commonly manifest in adults and are one of the common infectious causes leading to mortality, morbidity and poor quality of life amongst old age people. (21)

Not only in India, but adult vaccination remains an untouched modality even in developed countries. But steps are now been taken towards it in developed countries. This is an alarm for a country like India, where poverty, overpopulation, unhygienic conditions prevail so much that communicable diseases spread very fast. (26)

CURRENT INDICATIONS AND GUIDELINES FOR USE OF VACCINATIONS IN ADULTS:

Vaccines received in childhood plays an important role in deciding the vaccinations required for an adult. The vaccinations in healthy adults differ from an individual to other.

Major guidelines followed in India are: (Details mentioned in the table given below; table 1)

· API (Association of Physician of India) – Expert panel guidelines.

· WHO (World Health Organization) guidelines.

Other guidelines include The Advisory Committee on Immunization Practices (ACIP) guidelines from Centers for Disease Control and Prevention.

**Conclusion**

By vaccinating adults along with children, the chain of spreading the diseases can be broken and quality of life can be improved. It is high time that government and other health service providers make a call regarding adult vaccination and frames new guidelines, keeping in mind the education level, the requirement of a particular vaccine in an individual, socioeconomic status of an adult and providing utmost immunization to the patient thereby preventing major diseases. The government needs to frame a proper guideline and implement it by promoting it and creating awareness among the general population.

Vaccinations Aren’t Just For Children.

Adults Need Them Too!

Correlation between Gestational Age and Abdominal Circumference in Second Trimester

Patond Swapnil¹, Chimurkar Vilas², Pande Varsha³
¹Associate Professor, Department of Forensic Medicine, ²Professor & Head, Department Anatomy, ³Assistant Professor, Department Anatomy, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Wardha, Maharashtra, India

Abstract

Gestational age is age of unborn baby, defined in weeks as beginning from first day of last menstrual period prior to conception. Estimation of gestational age and thereby forecasting Expected Date of Delivery is not only concern of the Individual but it is invaluable in the diagnosis of intrauterine growth retardation of fetus and obstetric planning. Determination of age of a fetus by using various methods is required for medico legal purposes in both civil and criminal matters. In present study we assesses Correlation between gestational age and abdominal circumference in second trimester, The study of Correlation between gestational age and abdominal circumference in second trimester by Ultrasonography was carried out and collected data was tabulated according to weeks of menstrual cycle and were taken in centimeters. Standard deviation of abdominal circumference for each week was calculated. We found that Abdominal Circumference is statistically highly significant and the regression equations derived for growth parameter for estimating gestational age in a normally developing fetus, increase with gestational age, showed good correlation with gestational age.

Keyword: Gestational age, abdominal circumference, age determination, Ultrasonography, Second trimester.

Introduction

Human development starts as oocyte from female which is fertilized by the sperm. Cell division, differentiation, growth transfigure the fertilized oocyte into a multicellular adult human being. Most of the changes occur during the early fetal and embryonic period, the development of which divided into pre and postnatal period. There are many changes that occur from the 3rd to 8th week called as embryonic development and changes occur from 9th week to birth into a recognizable human being called a fetus.¹ 

Gestational age is age of unborn baby, defined in weeks as beginning from first day of last menstrual period prior to conception. Trimester is period of three calendar months during a pregnancy. Radiologically the period of gestation is grossly divided into three trimesters. Estimation of gestational age and thereby forecasting Expected Date of Delivery (EDD) is not only concern of the Individual but it is invaluable in the diagnosis of intrauterine growth retardation of fetus and obstetric planning.² 

The parameters either singly or in combination useful in predicting the gestational age with fair degree of accuracy are Naegeles formula, Date of quickening, Palpation of fetal parts and Auscultation of fetal heart sound.³ 

The methods like physical examination, menstrual history, and laboratory methods have limitations in assessing fetal maturity, development and well being. At the same time Roentgenography like procedures having
hazards of invasive procedure or radiation compelled the research of safer, non-invasive and reliably predictive investigation modality, it was brought forth in the form of Ultrasonography.4

Determination of age of a fetus by using various methods is required for medico legal purposes in both civil and criminal matters.5, 6

Ultrasonography is non-ionising, non-invasive, safe and accurate method of objectively evaluating the fetal growth in uterus. In any obstetrics case correct assessment of gestational age is keystone. Measurements and fetal characteristics are helpful in estimating fetal age.

To determine the fetal age at the end of 1st trimester the crown rump length is method of choice because of negligible variation in the size of fetus during the period. In second and third trimester, fetus grows sufficiently in size; several structures can be identified and measured ultrasonographically.

Accurate knowledge of age is a keystone in the obstetrical and medicolegal Aspect legally also helpful in successfully managing the antepartum care of the patient and is critically important in the interpretation of antenatal test and successful planning of appropriate therapy and interventions.7, 8

Materials and Methods

The study Correlation between gestational age and abdominal circumference in second trimester was carried out at Govt. Medical College and Hospital, Nanded, between July 2011 to July 2013 period. The study included 150 females attending ANC clinic for Ultrasonography screening at Medical College and Hospital. Subjects of the study mainly include urban as well as rural areas in the vicinity.

Include Criteria

Women with known LMP

Women with regular menstrual cycle

Women with singleton and uncomplicated pregnancy

Women having age between 18 and 34 yrs.

Exclusion Criteria

Women with multiple pregnancies

Women with irregular menstrual cycles

Women having diabetes mellitus

Women with diseases like hypertension, chronic renal disease, heart diseases, iron deficiency anemia. Women having Fetus with congenital anomalies.

For collection of the data proper permission was obtained from ethical committee and radiology department. In this study various particulars of the subjects like age, menstrual and obstetric history had been recorded in the Proforma.

The American Institute of Ultrasound in Medicine recommendations were used for measurements of all the fetal parameters.9

The fetal Abdominal Circumference (AC) was measured at the skin line on a true transverse view at the level of the junction of the umbilical vein, portal sinus and fetal stomach. The fetal abdomen was identified with the help of digitaliser.

Date of Ultrasonography of subject is recorded and Gestational age of the fetus in terms of weeks was calculated from last menstrual period in the Proforma. The data so collected was then subjected to statistical analysis by expert statistician with the help of SYSTAT Crainsoft version 12 software. Standard statistical methods, parametric methods were used for the evaluation and significance.

Results

The study of Correlation between gestational age and abdominal circumference in second trimester by Ultrasonography was carried out at Govt. Medical College and Hospital Nanded.

The collected data was tabulated according to weeks of menstrual cycle and were taken in centimeters.

Standard deviation of abdominal circumference for each week was calculated. The mean of each parameter calculated statistical for each week. The completed week considered as the week of gestation. For e.g., 13th week refers to 13.00 to 13.86 weeks of menstrual age. 7 days =
1 week, hence 1 day = 0.14 weeks. Like this subsequently for each day.

Ultrasongraphic Abdominal Circumference was measured in a total of 150 subjects. The observations of week wise mean values and standard deviation of fetal Abdominal Circumference are shown in (Table 1).

Table 1: Mean and Standard deviations of fetal Abdominal Circumference (Week wise).

Regression output for 2nd trimester (13 to 28 weeks)

Regression equation:

$$G.A = 6.36 + 0.956 \times AC$$

From the above equation it is clear that during the second trimester, for every 1 cm increase in AC, the gestational age (G.A) increases by 0.956 weeks.

As the value of R is 0.9451 the variation in fetal growth on the basis of Abdominal Circumference during second trimester can be explained to the extent of 94.51%.
The value of R is highly significant (Student’s ‘t’ test value = 113.04, p<0.0001, very highly significant) showing that there is statistically highly positive or strong positive association between Gestational age and Abdominal Circumference.

Discussion

Ultrasonography is key imaging technique in the assessment of fetal growth because of its low cost, availability, and without any adverse effects. Ultrasonography can detect the fine observations of the chorionic sac and its contents during the various stages of fetal and embryonic period. Along with this technique can also detect anomalies abnormality various presentations related fetus at a very early stage. Therefore various advances in Ultrasonography have made this technique a crucial tool for prenatal diagnosis which is a most reliable method for the growth of the fetus.

It is observed that upper extremities almost reach to development by the end of 12th weeks, compare to lower extremities. Appearance of primary ossification centre for cranium and long bones develop by the end of 12 weeks. Various ossification centers can be observed during this period along with bones on Ultrasonography. Fetal abdominal, body and extremity measurements have been widely reported and found to be used in second and third trimester.10

After 10th week of gestational period one can differentiate soft and hard tissues after which measurement of various parameters like abdominal circumference other Parameter can be done by Ultrasonography which can be recommended.

The differentiation between hard and soft tissues of the embryo is possible after about 10th week of gestation when other parameters like Abdominal circumference, length of long bones can be measured and become more important than the crown rump length. Measurements of fetal parts during routine Ultrasonography screening have been recommended.11

Tamura RK et al found that fetal abdominal circumference added another dimension to the interpretation of cephalic growth particularly in indentifying macrosomic fetuses. The study also revealed that AC was significant in assessment of fetal size in those, who were for obstetric reason had to be delivered in the latter part of second trimester or early third trimester.12

Juozas K et al Found linear correlation of gestational age with abdominal circumference .13 Similarly Jain ND et al found that parameters increased progressively through the 2nd and 3rd trimester. These parameters were reliable indicators of menstrual age.14

Johsen SL et al Analysed that abdominal circumference at 10–24 Weeks of gestation. And the effect of fetal size at 10–24 weeks of gestation on pregnancy duration was assessed. Fetal size in the second trimester is a determinant of birth weight and pregnancy duration support a concept of individually assigned pregnancy duration according to growth.15

Bhusari PA et al found that Second trimester Abdominal Circumference Shows linear growth as gestational age advances and are strongly correlated with each other. The study was comparable to other studies carried out on aborted fetuses taking actual measurements. Thus accuracy and reliability of ultrasonographic measurements was established.16

Conclusion

Sonographically measured parameters during second trimesters of pregnancy were subjected to statistical analysis by simple linear regression. The regression was done separately for each parameter and for each week. Abdominal Circumference is found to be statistically highly significant. The regression equations derived for growth parameter for estimating gestational age in a normally developing fetus, increase with gestational age, showed good correlation with gestational age. Assessment of gestational age helped in calculating the EDD (expected date of delivery) in all patients, thus improving the antepartum management. Gestational ages are fairly accurate predictors of fetal growth. In Present study, in second trimester abdominal circumference is the sensitive parameter and results of present study was comparable with previous studies.

Abstract

Diabetic ketoacidosis (DKA) is a serious life threatening condition and it occurs when insulin production in our body is less. Diabetic ketoacidosis is a complication of diabetes mellitus and it mostly occur in hospitalized patients. Diabetic ketoacidosis condition mostly found in both type of diabetes such as Type 1 and Type 2 diabetes patients. In between 20-30% of cases of diabetic ketacidosis condition occur in newly diagnosed patient with diabetes. Almost till 20 years the mortality rate of diabetic ketoacidosis is 100 percent and till now there is no reduction in prevalence of diabetic ketoacidosis in younger patients due to that children are continuous suffering with death.

The mortality rate in Diabetic ketoacidosis is very important because it is a very serious life threatening condition so the prevalence of diabetes is very crucial. The younger are the foundation of future health care delivery system so the evaluation of their knowledge and continue development and upgrading regarding awareness and understanding the sign and symptoms of diabetic ketoacidosis it helps to reduce the mortality rate of Diabetic ketoacidosis.

It’s an emergency condition, so the health care professional becomes a vital part of managing diabetes-related hyperglycemic emergencies, rising health care costs and changing health care systems preventing signs and symptoms of diabetic ketoacidosis remains an essential requirement.

Effective management and prevention on diabetic ketoacidosis can reduced longer stay time in hospitalized patient.

Keywords: Nursing perspective, Knowledge, Prevention, Sign and symptoms, Diabetic ketoacidosis.

Introduction

Diabetic ketoacidosis is also called as diabetic acidosis and it is a serious life threatening complication of diabetes mellitus which causes a serious problem. Mostly the diabetic ketoacidosis condition affects to insulin dependent diabetes patients but it also affect to Non – insulin-dependent diabetes patients.¹ Diabetic ketoacidosis is a major diabetes complication in the United States and internationally.² Diabetic ketoacidosis is an metabolic emergency and it occurs with insulin deficiency, hyperglycemic, ketonemia and acidosis patients with diabetes mellitus.³

Diabetic ketoacidosis occurs when insulin production is less and severe insulin resistance in the hyperglycemic state. The crises occurs when there is problems with production and release of insulin. Dysfunction of beta cells results from inadequate glucose level stimulate to secrete amount of insulin and ultimately elevation of blood glucose level occur after a digestion of meal and with this formation of new glucose is suppressed. But in a hungar state, glucagon (counter-regulatory hormones) in which stored material are properly activated and formation of glucose is elevated.² Diabetic ketoacidosis disease was identified by Dreschfeld in 1886 until 1922 insulin was discovered. Since 20 years the mortality rate of diabetic ketoacidosis was 100 percent and there is no reduction in mortality rate till now.

The approximately 20 -30% cases of Diabetic ketoacidosis occur in recently diagnosed patients with diabetes. The mortality rate of diabetic ketoacidosis is
occur due to its complication such as one of the cerebral edema. The knowledge regarding diabetic ketoacidosis that helps to adult and youth for the adoption of good health-related practices. Youth and adults are the pillars of our future health care system and the evaluation and continuous improvement of their understanding is very necessary and understanding of signs and symptoms of Diabetic Ketoacidosis and help to reduce the high mortality rate.  

It is an emergency condition, and the health care provider is a critical part of handling Hyperglycemiasis. Similar diabetes emergencies, with higher health care charges and prevention of signs and symptoms of diabetic ketoacidosis remains an essential requirement for a changing healthcare managing and avoiding diabetic ketoacidosis in hospitals, admissions can be reduced and stay time shortened.

PREVALENCE OF DIABETIC KETOACIDOSIS

Prevalence and occurrence of diabetic ketoacidosis and its symptoms

Very few studies have examined the incidence or prevalence of diabetic ketoacidosis in patients with diabetes, the Danish National Patient Registry identified four thousand eight hundred and seven admissions in 1996–2002 and 137 deaths diagnosed with diabetic ketoacidosis in 1996–2000. The estimated annual incidence of diabetic ketoacidosis was 12.9 per 100,000, higher in males relative to females over the age of 40 years. And the prevalence of diabetic ketoacidosis over 50 years in type 2 diabetes is approximately 12 percent of all patients.

Compared to previous studies, the occurrence of incidence of diabetic ketoacidosis in children is decreasing with a high mortality rate recently and younger. Diabetic ketoacidosis is a type 1 diabetes metabolic syndrome typically characterized by acidosis, ketosis, and hyperglycemia. Diabetes symptoms that may cause DKA to develop include polyuria, polydipsia, polyphagia, weight loss, vomiting, abdominal pain and fatigue.

PRECIPITATING FACTORS IN DIABETIC KETOACIDOSIS

Precipitating factors such as infection, insulin omission or inadequate insulin administration, acute diseases include the cardiovascular system (myocardial infarction, stroke) and gastrointestinal tract (blindness, pancreatitis), including endocrine diseases (Cushing’s syndrome, acromegaly) and Stress due to recent surgical procedures may develop DKA which causes dehydration and may increase insulin hormones. Medicinal products such as corticosteroids, diuretics, beta-blockers, antipsychotics, and antiepileptics that influence carbohydrate metabolism and may, therefore, precipitate DKA. Many factors may also lead to DKA, such as eating disorders, psychiatric issues, insulin pump failure and illegal use of the drug.

SIGN AND SYMPTOMS OF DIABETIC KETOACIDOSIS

Diabetic ketoacidosis is buildup acid in blood it occurs when the blood sugar level rises it is life-threatening but it takes a long time to become serious so it can prevent or treat in early. It causes When the body isn’t producing enough insulin. And body cell doesn’t use sugar from the blood it uses fat as fuel energy and burn the fat and make acid called ketones.

Those who have type 1 diabetes can develop ketoacidosis and Diabetic ketoacidosis happens with type 2 diabetes also and it leads to severe dehydration. When the blood sugar level rises above 240mg /dl have symptoms like dry mouth, feeling of thirsty, so check for ketone.

LABORATORY INVESTIGATIONS AND DIAGNOSIS CRITERIA OF DIABETIC KETOACIDOSIS

Initial laboratory examination of patients includes Plasma glucose, blood urea nitrogen, creatinine, electrolytes, osmolality, serum and urinary ketones, and urinalysis, as well as initial blood gases and a full differential blood count. It should also be obtained an
electrocardiogram, X-ray in the chest, and samples of urine, sputum or blood. The DKA diagnosis includes Hyperglycemia (larger than 250 mg / dL), ketosis (anion gap greater than 12 mEq / L) and acidosis (arterial pH smaller than or equal to 7.3). The intensity of DKA is classified as mild, moderate, or extreme, depending on the magnitude of the decrease in levels of arterial pH, serum bicarbonate, and emotional, rather than hyperglycemic. Not all ketoacidosis patients do have DKA. Medical history and plasma glucose levels range from slightly elevated (rarely 200 mg / dl) to hypoglycemia, differentiate between malnutrition ketosis and alcohol ketoacidosis.  

**TREATMENT STRATEGIES**

The DKA treatment target involves the preservation of volume status, hyperglycemia and ketoadosis, metabolic abnormalities, electrolyte abnormalities, and precipitating factors. Before beginning a physical test, diabetic ketoacidosis care should be done first. Basic parameters should be obtained, and the final diagnosis should be made.

1. **Fluid therapy in DKA**: Replacement of fluid with normal saline also recommended to help expand interstitial, intracellular, intravascular and perfusion of kidney. Lacking cardiac compromise: First few hours of treatment 0.9 percent NaCl ie Isotonic saline should be administered intravenously at 15–20 ml / kg/1 h or 1–1.5 liter. But in general, if 0.45 percent NaCl infused at 250–500 ml / his elevated or normal at that time, serum sodium is. If the corrected Serum sodium is low, 0.9 percent NaCl should be intravenously administered at 250-500 ml / h. To know the successful progression with fluid replacement, blood pressure monitoring, and fluid deficiency are expected to correct within 24 hours of treatment. Measurement of the input/output fluid, laboratory values, should be carried out as required. To avoid iatrogenic fluid overload in renal or heart compromised patients, monitoring should have been updated for serum osmolality, frequent renal evaluation, assessment of cardiac status, evaluation of mental status. Fluid replacement administration depends on hemodynamic status, Status of hydration, serum electrolyte levels and urinal output. If the glucose level falls below 250 mg/dl, NaCl with DNS should administer and insulin administration continued until ketonemia is controlled.

2. **Insulin administration Therapy**

   The main objective of DKA treatment is to administer insulin on regular basis (0.1 units/kg) followed by (0.1 units/kg / h) by continue administration of intravenous infusion or repeated use of subcutaneous injection. If the glucose value in the first hour does not decrease by 50-75 mg, the dose of insulin infusion should increase for each hour until normal glucose levels are achieved.

3. **Potassium**

   Between mild to – moderate range of hyperkalemia is common in DKA patients. Acidosis correction, insulin administration therapy, volume expander helps to reduce the concentration of potassium in the serum. Replacement of Potassium should be initiated to prevent hypokalemia when the Serum rates fell below normal. Treatment purpose is to keep the serum potassium levels within the normal range of 4–5 mEq / l. In general, DKA patients can develop hypokalaemia. In these cases the treatment of potassium will start with fluid therapy replacement and insulin therapy should be put off until potassium restore concentration to > 3.3mEq / l to avoid arrhythmias and weakness in the respiratory muscle.

4. **Bicarbonate**

   The use of sodium bicarbonate at DKA is only recommended if the pH value is below 7. When the patient is pH<6.9 then inject 100mmol of sodium bicarbonate (two ampules) with 20mEq KCl in 400ml of sterile water (an isotonic solution) for 2 hours at a rate of 200ml / h until the venous pH is > 7.0. Repeat until pH reaches > 7.0 every 2 hours if pH remains < 7.0.

5. **Phosphate**

   If DKA’s total body phosphate deficiency is 1.0 mmol / kg body wt on average, serum phosphate levels are often normal or increased. For patients with heart disease, anemia or breathing disorder and with concentration of serum phosphate < 1.0 mg / dl, 20–30 mEq / l. Treatment of deficiency of potassium phosphate should be used to replace fluids at a rate of 4.5 mmol / h (K2 PO4 1.5 ml / h). The average replacement rate of phosphate considered safe is 4.5 mmol / h which helps to prevent hypophosphatemia-related heart and skeletal muscle weakness and respiratory failure.
Complication Associated with DKA

DKA presents the two most common complications, hypoglycemia and hypokalemia, but these complications occurred with the low-dose insulin therapy. In DKA Constant monitoring of blood glucose (every 1–2 h) is required because many patients may experience hypoglycemia during DKA treatment without sweating, nervousness, fatigue, nausea, and tachycardia manifestations. For adult patients, cerebral edema is particularly rare when being treated with DKA. Cerebral edema symptoms include headache onset, gradual awareness deterioration, seizures, looseness of sphincter muscle incontinence, pupillary changes, bradycardia, blood pressure elevation, and respiratory arrest. Other complications of DKA include Syndrome of an adult respiratory syndrome (ARDS), and hyperchloremic acidosis, non-anion gap acidosis in hyperchloremic. In DKA patient Rhabdomyolysis in the compartment that causes the syndrome can lead to acute renal failure, severe hyperkalemia, hypocalcemia and muscle swelling. Classical signs of rhabdomyolysis include myalgia, fatigue and dark urine. It is recommended that the creatine kinase concentrations be detected early every 2 to 3 hours.  

Preventive Strategies

Diabetic ketoacidosis in a patient who is newly diagnosed with diabetes can only be prevented if the general public and primary care physicians are aware of the symptoms and if doctors are alert to the possibility of developing diabetic ketoacidosis, particularly concerning young children. It is quick to do a urine test for glycosuria. Adequate education and support will prevent diabetic ketoacidosis in patients with proven diabetes (and for their families). Identification of children at risk for such behaviors and social and psychological support intervention can alleviate these issues. Given the risks and associated symptoms and complications of in patients with Diabetic ketoacidosis, strategies to prevent infections effectively are of paramount importance. Continued patient self-management awareness and support are vital for avoiding acute complications and reducing the risk of chronic complications. Patient care is the key to learning to fight illness.

The four important points are:

1. To explain the importance of insulin therapy during illness, and to emphasize that insulin should never be interrupted.
2. Regular interaction with health-care professionals is initiated.
4. Ensuring adequate intake of liquids

Preventive strategies include avoiding excessive hydration and rapid plasma osmolality reduction, decreasing serum glucose levels and maintaining serum glucose concentration from 250 to 300 mg / dl to normal serum osmolality and improving mental status. Cerebral edema care requires Mannitol injection, which should be recommended for mechanical ventilation.

Prognosis

Many studies suggest that the prognosis of properly treated diabetic ketoacidosis patients is excellent, particularly in the younger patients. The average mortality rate for DKA is 2 per cent or less. The indices of weak DKA prognosis are deep coma, hypothermia, and oliguria. The worst prognosis is typically seen in older patients with serious undercurrent diseases (e.g. myocardial infarction, sepsis, or pneumonia), particularly when these patients are treated outside an intensive care unit.

Discussion

The many studies revealed that the majority of participants exhibited average levels of knowledge about diabetic ketoacidosis. On the other hand, regarding awareness, there was minimum awareness concerning the causes, signs and symptoms and complications of DKA. However, this study revealed some gaps in the awareness concerning the prevention of sign and symptoms plan of management and complications of DKA. It has been concluded from the maximum study that the minimum of the individual has a basic knowledge of DKA and its management except in certain points; the importance of the collection of blood for a metabolic profile before initiation of therapy, stopping of insulin when the patient becomes hypokalemic, fluids infusion should be continuing for 24 hours, The importance of hourly blood glucose monitoring in patients and the use of sodium bicarbonate is controversial and recommended only when PH is below 7. There was a lack of DKA
awareness among participants concerning complications associated with DKA, diagnostic criteria and to some extent the precipitating factors. The overall knowledge and awareness related to the prevention of signs and symptoms were average among diabetes patients.  

**Conclusion**

With the combination of interdisciplinary collaboration and coordinated care, DKA’s mortality has decreased dramatically in recent decades. Current practitioners face problems including monitoring DKA patients at the correct level of treatment and educating patients to stop repeating DKA episodes. The potential cost savings in the medical floors associated with caring for less critical DKA patients must be balanced against staffing ratios. Prevention of DKA may require further research and cooperation among hospitalized and outpatient practitioners, as well as patient education.

Knowledge, Attitude, and Practice Regarding Child Abuse and Neglect among Dental Practitioners

Rachana . P. B1, Supriya H2, Seema M3, Vijaya Lakshmi G4, Meghashree Kerpala5, Charisma Thimmaiah6
1Reader, Department of Oral and Maxillofacial Surgery, 2Senior lecturer, Department of Oral Pathology and Microbiology, K.V.G. Abstract

Background: Child abuse and neglect (CAN) is a prevalent and growing public health problem. Dentists are in a strategic position to identify and report cases of CAN as common signs of child abuse are in the orofacial region. Proper knowledge and awareness are required for early identification and intervention to prevent untoward consequences.

Methodology: A cross-sectional observational study using a predesigned three parts questionnaire was conducted among general and specialty practitioners in branches of dentistry of Dakshina Kannada district, Karnataka to assess the knowledge, awareness, and behavioral practice towards child abuse and neglect. The data extracted were tabulated, statistically analyzed and results calculated based on percentages using SPSS.

Result: The participants in the current study demonstrated sufficient knowledge of the signs and symptoms of child physical abuse, actions that should be taken in suspected cases, circumstances in which to report such cases, and the legal authorities to which they should be reported. Most of the participants desired for further training such as courses or workshops on examining, diagnosing, and reporting cases of child abuse.

Conclusion: - The study suggests that dental practitioners need an effective education to increase their knowledge and awareness on CAN for its precocious identification and diagnosis as an assay for early intervention.

Keywords- Child abuse, child neglect, reporting, child maltreatment, knowledge.

Introduction

Child abuse and neglect is an augmenting element affecting the community in the present scenario. Since face and oral cavity are often the prime focus of child abuse it becomes the authority of dentists to acquire knowledge to diagnose and report child abuse and neglect cases. WHO estimates that nearly 3 in 4 children of age 2–4 years regularly suffer physical punishment and/or psychological violence at the hands of parents and caregivers. ¹

The short and long-term consequences of victims of CAN have been well documented. Well-established empirical evidence shows a ‘graded’ relationship between the number of unfavorable childhood maltreatment exposures and the occurrence of depression, poor academic performance, and even suicidal ideation among youth.²

Studies have reported that orofacial trauma is present in approximately 50 to 75 percent of all reported cases of physical child abuse.³ This high frequency of
orofacial lesions associated with child abuse place the dentist in the front line to individualize and to intercept an abused child.

As per the available literature, only 1% of child abuse cases were reported by dental professionals which draws attention to reasons behind underreporting. Analysis of research from different parts of the world has indicated that healthcare providers fail to report suspected cases of abuse, mainly due to a lack of knowledge. As Dentists are in a unique position that allows them to identify and report abuse cases, their knowledge and attitudes are essential factors in fulfilling this obligation. To the best of our knowledge, studies have not been conducted in this area to investigate the recognition and reporting of child abuse by dentists. Thus a questionnaire-based study was conducted among dentists practicing in Dakshina Kannada district to assess their knowledge, attitude, and practice regarding child abuse and neglect.

**Methodology**

The study was conducted among general dentists and specialty practitioners of Dakshina Kannada district, Karnataka, India to evaluate the knowledge, attitude, and practice regarding child abuse and neglect. Ethical approval was obtained from the Institutional Ethical Committee of KVG Dental College & Hospital, Sullia. (IECKVD/FR07/2019-20)

Validity and reproducibility test of the questionnaire were conducted with five faculty members of the institution to evaluate understanding, validate the content and attribute scores to each question accordingly:

- 0 (I did not understand anything),
- 1 (I understood just a little),
- 2 (I understood it in part),
- 3 (I understood almost everything, but had some doubts),
- 4 (I understood almost everything),
- 5 (I understood it perfectly and had no doubts).

Scores 0, 1, 2, and 3 were rated as insufficient understanding, and scores 4 and 5 as sufficient understanding, as suggested by Conti et al.\(^4\) One question was eliminated, two were corrected and the remaining were found to be appropriate. The finalized questionnaire written in English consisted of three sets of questions- the first set included 14 questions related to knowledge (table 1), the second set included 2 questions related to the attitude of the dentist (table 2) and third set included 5 questions related to practice they followed. (table 3). 20/21 questions in the study were dichotomous questions formulated as a statement using the yes-no format and 1 multiple-choice questions.

Demographic data including age, gender, clinical experience were also included. Written informed consent was obtained from the participants after explaining the nature and purpose of the study. Data were analyzed by descriptive analysis using percentages from responses to each question.

**Results**

A total of 125 responders participated in the study. Data collected from completely answered 105 proforma were subjected to analysis. The incompletely answered questionnaires (n=20) were excluded from the data [response rate was found to be 84%].

**Demographic characteristics:**

70% of the subjects were female, the most frequent age was 30-49 years (67%) with greater frequency in the working experience of 10 -15 years of dental practice (48%). Most of the respondents (72%) were general practitioners and the remaining 28% were divided between pediatric dentists (8%) and other specialties (20%).

**Knowledge on child abuse**

Results about the level of training and self-education regarding CAN and related items revealed adequacy. 94.28% of the participants agreed on the importance of the role of dentists in diagnosing and reporting child physical abuse cases. 70.47% agreed that craniofacial, head, face, and neck injuries make up more than half of child abuse cases. 87.61% agreed with documentation of CAN in patient record is mandatory. Regarding psychosomatic complaints by the child and physical appearance as poor nutritional status and growth, untidy appearance, untidy clothes a lower proportion of participants were able to correctly identify the signs.
(63.80%, 44.76%, & 11.42% respectively). On the signs (of child abuse 85.71% of the participants were able to recognize appropriately. A larger proportion of dentists (95.23%) knew that reporting physical abuse cases to legal authority is important and 63.80% were aware of the legal procedures involved in reporting of CAN.

**The attitude of dentists on CAN**

The attitudes of the participants are illustrated in Table 2. 36.19% thought that knowledge obtained on child physical abuse at the BDS curriculum was sufficient. 86.66% opinioned that further training is required on how to examine, diagnose, and to report suspected cases of child physical abuse.

**The practice followed by the dentists**

Only 8.57% of the practitioners had suspected physical abuse among patients. A higher proportion of dentists (82.25%) believed that children of employed mothers are more prone to get abused. A very low percentage (5.71%) reported cases of child abuse to Child protective services. Causes of underreporting were fear of legal involvement (25.25%) or lack of response from participants.

Discussion

The present study sought to assess the knowledge, attitudes, and practice of dentists in identifying and reporting cases of child physical abuse as part of an effort to propose and plan future programs and policies for undergraduates. Regarding knowledge about child physical abuse, participants in the present study correctly identified the signs and symptoms of it. Studies have quoted that head, face, and oral cavity are the areas of central focus for physical abuse, due to exposure and accessibility. In accordance, 70.47% of participants in our study were aware that craniofacial, head, face and neck injuries make up more than half of child abuse cases. Similar studies conducted by M. Mogaddam et al. (50%) in Saudi Arabia (73%) and Thomas et al. in the USA (56%, ) revealed that dentists' knowledge of the signs and symptoms of child physical abuse is insufficient in comparison.

In suspected cases of abuse, the actions to be followed by the practitioner were to ask the child and parents about the observed signs, document the signs and symptoms in the child’s file, and check the consistency of the parents’ and/or child’s explanations with the clinical finding. A substantial percentage of participants (87.61%) in our study were aware of the formalities. 76% of the participants in the study by M. Mogaddam et al.6 said that they would document the signs and symptoms and their suspicions in the child’s file.

To suspect a case of child abuse it is essential to have basic knowledge of signs and symptoms and how to diagnose them. The results in this study show that the knowledge of the respondents about the indicators of child abuse was satisfactory except for the untidy appearance and clothes of the child which showed a low percentage of 11.42%.

The majority of respondents knew signs of physical violence in form of bite-marks, swollen lips, ecchymosis, abrasions, or lacerations(85.71%). Awareness of reporting (95.23% ) was also found to be adequate. In another study conducted to assess the knowledge, attitude, and behavior of dentists nearly 76.8% correctly identified the indicators of child abuse.9 As per the response from the participants in our survey, though many of them were able to identify, the need for education on detecting physical signs is realized. It is important to realize that all dental professionals have a unique opportunity and a legal obligation to assist in the struggle against child abuse.2

Attitude

36.19% of dentists stated that the amount of knowledge obtained on child physical abuse at the BDS curriculum was not sufficient and 86.66% felt the need for further training to examine, diagnose and report suspected cases of child physical abuse (e.g. courses, workshops). When professional hygienists were provided post-educational training in identifying and reporting child abuse, post-test questioning indicated that 100% felt they would be able to make a report of child abuse if it was suspected and 96% reported that they knew how to make a report.10 These findings support the importance of courses and workshops to better understand the need to diagnose, document, and builds up the confidence to report cases of child abuse.

Practice:

Dental professionals have an ethical obligation to report suspected child abuse and neglect. Only 8.57% of dentists in our study had suspected physical child abuse cases in their clinical practice and 5.71% of them reported such cases.

The most common feature of emotional neglect is the absence of normal parent-child attachment and a subsequent inability to recognize and respond to an infant’s or child’s needs.2 Similarly participants of our study (82.25%) noticed CAN among children of employed mothers rather than homemakers. 59.04% of the respondents agreed that reports of child abuse is common in children studying in rural areas. In a 30-year follow-up on a prospective investigational study of physical health outcomes in abused and neglected children, it was found that childhood abuse increased the risk for several adult physical and psychosocial problems.10

When asked with the participants about whom to report the suspected child abuse cases, the majority of them answered to report it to the Child Protective Service(66.66%) followed by Law Enforcement Agency(33.3%).
91.43% of dentists didn’t report suspected cases and the greater response was in favor for the fear of legal involvement. Professionals in the field of child protection say that “it is better to over-report than under-report potential abuse”.\(^\text{10}\) Reports should be made to local protective services or law enforcement agencies, or through the National Child Abuse helpline, and should include the name, age, and address of the child, the nature and extent of his or her injury, the person believed to be responsible for the abuse or neglect, and any evidence of previous abuse or neglect. Although child safety protocols are vigilant by the government, this study has identified a definite need to address the subject of ignorance regarding the right authority to report CAN case in dental practitioners.

**Conclusion**

Child abuse and neglect is alarming and since the face and oral cavity are the central focuses of child abuse it is the responsibility of the dentist to acquire knowledge and diagnose such cases. Consequences of abusive behavior toward the child can lead to difficulties in the physical development of the child, health-related issues, psychological signs such as anxiety, depression, insomnia, and fear. Other effects could be a lack of interest in social activities, difficulty in building healthy relationships at work, and home. The magnitude of the problem is larger than estimated. Raising awareness of the warning signs of abuse and educating health care workers, especially dentists, on diagnosis and reporting cases of suspected abuse, would empower them to play an active role in the prevention of child abuse and the protection of vulnerable children.

Abstract

The on-going novel corona virus 2019 from the outbreak of china is affecting many more countries almost 213 have been reported. The highest number of cases till 10th of July 2020 is from the country united states. India is the 3rd most country which has been affected by novel corona virus 2019. The least country which is affected and recovered also is an islands of saint pierce and Miquelon. So for the measure of preventing the novel coronavirus the most of the government has declared complete lockdown especially in India there were complete lockdown from 23rd march 2020 and this whole pandemic thing has affected a lot of people, students, children’s, elders and all as all gyms and garden were closed people were not able to go out so then what about their fitness in this pandemic. New data has been come out that while doing exercise may reduce the risk of breathlessness like respiratory distress syndrome, which is one of the major causes of death with coronavirus 19. (covid19). Breathing disorder, a severe lung condition. Physical activity should not be confused with exercise. Physical activity means movement of body that uses energy. It can be moderate or vigorous intensity. Let’s be active everyone and every day. Regular physical activity reduces the risk of non-communicable diseases like blood pressure, ischemic heart disease, stroke, blood sugar level, colon and breast cancer. All conditions that increase the susceptibility to covid-19. And mainly in the lockdown the new things for people it will help you from to maintain your weight and from anxiety and depression.

Key words: Fitness and health come first proper diet and proper care will not lead to coved.

Introduction

At the beginning of lockdown people were enjoying the new change unhealthy lifestyle with a lots of home food and zero exercises. All progress take place outside the comfort zone. As we know good things come to people who sweats. Once you see the result it will make yourself happy and feel good. As health care provide, we need to considered that what can we do for the physical fitness by staying indoors and doing activities. From building up for proper routine to right from waking up till night. Rewarding yourself on reaching a milestone, giving proper time for exercise. Adopting various method to not get obsolete. In the form of running, walk at home, programs, weight training accompanied with proper diet, sleep and water intake.

Healthy health at home. This pandemic is not easy for anyone especially people who work out from the home because sitting at home doing the work without any movement may affect both physical and mental status of the person. But the time like this it’s very important for all ages of people to do activities at this point of time. By doing these 3 to 5 mins also it will not only ease your muscles but also blood circulations also.

It will affect both body and mind. Not only these it will also affect urn bone and muscle strength, flexibility and fitness.

It’s even harder for the people who don’t do all this activity but for time being its very much essential to do.

Indoor activities for physical fitness during lockdown

Ten boons of physical activities:

It will reduce your health risk. Change what you eat and when you eat. Stop smoking and control your blood pressure by eating healthy. So that way it’s helping your blood vessels to get clear. Which helps your heart strong and diseases free? As I already said stop smoking to
strengthens your lungs as smoking impairs lung function making it harder for the body to fight off coronaviruses and other diseases. Reducing the risk of diabetes mellitus as the patients who had diabetes more likely to have serious complications and patient may lead to death. Weight management not only for the fear of coronavirus but also for your own fitness as you know “health is wealth”. (1) So, weight management should be seen in the fitness list. It makes your bone strong and it also helps in preventing the cancer like colon and breast and many more. It regulates the hypertension the main reason is atherosclerosis. It also improves your enthusiasm level and it also builds up your stamina. And lastly and most importantly it enhances emotional wellbeing. And control in your delirium, anxiety and depression. (2)

**Getting started**

Fitness studio shutting and we are adjusting the new life. You are your own gym. To make health habitual in this pandemic we need to Thake this as an opportunity to promote the healthy lifestyle to prevent the diseases and for our mental health. Making new healthy habit. Deciding on a goal to achieve a new healthy habit. Plan when where and what will you be doing. (3) It will get easier with time and in about ten weeks you will find out that automatically you’re doing without any great initiations but you will feel good to do it and it will be a congratulations to you for making the healthy habit. Create a goal to have more wears and green vegetables not only that but to also have more proteins also. Not only this normal fluid intake in man per day is 3.7 liters and women is 2.7 liters.it will help you to lose your weight it will also boost your metabolic rate also. (4) It will also help you to relive the headache, constipation and kidney stones etc.

**Home fitness revolution**

As the covid19 is affecting people. As people are not going out due to the mode of transmission it’s better to have social distancing and take as much as precautions we can take. As government announces the complete lockdown in India and it includes all thing gymnasiums, pools, Zumba classes, dance classes and garden places also where people use to go every day for their fitness but now what as the things are being closed so here we come with the unique and the useful thing like home fitness mutiny. (5) In esteem to these issues, gyms and fitness centers like dance classes, yoga places are throughout in the India have been closed during the period to ensure the shielding of its citizens. (6) Before considering this covered 19 the people has actually had the apps for indoor cycling like Zwift, indoor cycling, cycle go indoor, full gas and many more. Hence know people are considering this more as there would be the new trend going in with social distancing norm of being self-distanced home workout. (7) Workout in simple language is it effective to do workout at home in short and simple = yes why not? You can complete a perfectly good fitness routine at home using nothing more than your body weight. (8)

*Triceps dips=* it’s one of the top most great and effective body weight exercise that not only builds but strengthen your arms and shoulders. It can be done anywhere and its simple to do.it is for upper body strengthen workout. Yeah, the muscles part which work for the triceps dips are anterior deltoid, the pectoralis muscles like sternal, clavicular and minor. And the rhomboid muscle of the back. (9)

**How to do triceps dips?**

1) while you use your hand grip the front edge of anything like chair, stool, table or stairs also you can use.

2) remain in one place in air with your buttocks region just off and make sure your feet flat, to make the bending of the legs so that the thighs are parallel to your floor where ever you are doing exercise. (10)

3) the starting position is to straighten your arm. It will help you to do triceps dips more evenly and flexibly.

4) bring your arm to 90 degrees make sure it is in comfortable position.

5) engaging your triceps and bringing back to first.

That’s one act!

Simultaneously do inhalation and exhalation also. Don’t do sinking of shoulders. There should be action of shoulder joint flexion and extension that would be engaging the triceps muscles. (11)
Figure 1: Pot rating how to do triceps dips.

_Disk exercise:_ - Plank don’t just work your core they work for your entire body. Plank is one of the most and the best calorie burning and beneficial exercises. A plank hold engages multiple muscle at once there by benefiting the core strength of your body. (12) Not just burning the fat around your abdomen area they also work by giving you good posture and flexibility. (13) The 2 vital components it will help you to keep your shoulder back and lower back in neutral position while sitting or standing. (14)

![Plank exercise instructions](image)

**THE 15-MINUTE PLANK WORKOUT**

Try this routine two or three days a week. Perform 10 to 15 reps of each exercise, moving from one to the next without resting. Rest for one minute, then repeat the circuit up to four times total.

1. **PLANK ROW AND KICKBACK**
   - Complete all reps, then switch sides

2. **PLANK WITH FRONT RAISE**
   - Complete all reps, then switch sides

3. **ROTATING T EXTENSION**

4. **MOBILITY EXTENSION**

![Plank exercise instructions](image)

Figure 2: How to do plank? (15)
Yoga and mental health

Yoga has all three things for health that are physical, mental and spiritual from prehistoric India. Freedom and flexibility to get on and do. It also helps in various form like to cure from depression, fatigue, stress and many more. Not only all this the positive vibes that people needed in this pandemic the yoga has that efficacy to do. It removes toxins from our body. Physically mentally fit is both important in today’s time as in this pandemic is something new for people.

There are some types of yoga you should do it to keep your mental health good. It will help you to have satisfaction.

1) Yoga Sana: - standing, sitting, prone and supine lying. Do it with breath awareness. Cardiac patient shall do it with care. It helps to improve chest expansion and cardio pulmonary functions.

Surya namaskar (the ultimate asana)

Strengthen your back as well as your muscles and bring down blood sugar level. Helps to improve metabolism.

Figure 3: Types of soya namaskar asana.

There are 12 asanas in this soya namaskar Ana the first one is namaskar asana. Second one is hastotanasana where hand stretching is the pose. thirdly it is podahastosana this is your feet to hand pose. Then fourthly you have ashwa sanchalanasana this is horse parading pose. Then come 4-point stick pose which is also called as chaturanga dandasana. Sixthly, it is downward facing dog pose adhomukha shewanasana. Then there is 8-point namasker which is also known as astanga namaskara. Bhujagasana that is cobra pose it’s the 8th position. In 9th position it is like baby pose also called as balasana. 10th position is horse parading pose which is ashwa sanchalanasana and second lastly there is foot to hand asana which is padahastasana and lastly your 12th position is hand stretching pose that is hastottanasana.

1) namaskarasana. Benefits= mental health is affecting this pandemic so this asana helps your calmness of mind and breathing regulation.

2) hastotanasana (hand stretching pose).

Benefits= infusing of the blood in Cerro-spinal column and it is helping on stretching of posture.

3) podahastosana (feet to hand pose).

Benefits= this asana helps you to reduce your adipose fat which also encourage you for the weight loss. As there is infusing of the blood in the cerebro-spinal system so the blood is also going in to abdominal organs which helps in functioning and healthy system of lifestyle.

4) ashwa sanchalanasana (horse parading pose).

Benefits= by this asana you’re getting strength and flexibility to your hip region, pelvic are and muscles and shoulders. Strengthening is benefited for your musculoskeletal system.

5) chaturanga dandasana (4- point stick pose).

Benefits= this asana helps you to maintain your straight and stiff posture of the back and abdominal muscles. It also helps in reduction of muscles by holding of your abdomen muscles like transverse abdominis and rectus abdominis.

6) adhomukha shewanasana (downward facing dog pose).

Benefits= this asana helps in flexibility, strengthen for your legs muscles sartorius, gastrocnemius muscle like and your thigh muscles like semimembranosus muscle, semitendinosus muscle, gracilize muscle.
7) astanga namaskara (8-point namasker).
Benefit= it’s an interim asana.
8) bhujangasana (cobra pose).
Benefit= it’s helps in stretching.
9) balasana (baby pose).
Benefit= it helps you to reduce your neck and back pain, simultaneously, it helps you to reduce your stress and fatigability and off course your weight.
10) ashwa sanchalanasana (horse parading pose).
Benefit= it is good for musculoskeleton system.
11) padahastasana (foot to hand asana).
Benefit= stretching and strengthen of the muscles.
12) hastottanasana (hand stretching pose).
Benefit= for calming of the mind.

There are some contraindications in which you should avoid surya namaskara (the ultimate asana) like the person who has went in recent surgery or who has severe back ache or vertigo don’t do it stop immediately.

Meditation

Meditation is like giving a hug to ourselves, getting in touch with that awesome reality in us. While meditating we feel a deep sense of intimacy of god, a love that is inexplicable. Meditation is a process of slowing down yourself, calming down yourself, don’t worry, don’t hurry…trust the process. Your goal is not to battle with mind, but to witness the mind. Not only for attention and awareness but also for mentally calm emotional state. It’s a part of self-realization and enlightens. meditation is under the effect of psychological, neurological and cardiovascular and many more other affects. Meditation helps in improvement in anxiety and depression and other effects also. The anxiety and depression are affecting more people in this pandemic of India. Mediation also help in irritable bowel syndrome(is), insomnia and post-traumatic stress disorder.

Why exercise?

· Improves the quality of life.
· It will help you in sleep.
· Reduces stress.
· Improve asthma control.
· You will happy.
· It will help your skin health.
· Relaxation.
· Builds aerobic power.
· Reduces the risk of arthritis.
· Maintain the immune system.
· Improves your mood.
· Lower dementia risk.
· Boost memory.
· It helps to not develop obesity.

This all we need in this pandemic to a better life and lifestyle.

Exercising while social distancing

As the time passing there are going to be unlocking to all the system as life don’t stop. As people will come out keeping in mind covid 19 is there wearing of mask and self-distancing is must. Getting some fresh air without coming in contact with people. You can do walking, cycling and jogging and all. Use the mask which is washable as there is allergy season going on. You should exercise alone. Not at all in the groups it
Exercise after covid19

Physical fitness is must in today’s time. Not only for just to be fit also for your mental health. It reduces so many things just buy doing exercise the non-communicable diseases like hypertension, diabetes, colon and breast cancer and many more. It makes you feel, good, happy, energetic. So why not to continue the exercise and say no to the diseases? Is it too much to ask for? For those who are doing it initially knows they are on the right track. Those who started doing in this pandemic here you go with starting game of your good health. The one thing in this pandemic you can say that health is your friend and you get happiness while doing so let’s make a promise to our self-healthy lifestyle say no to diseases. It’s for our selfcare. For beater future and healthy life style. Do it for today and for coming tomorrows. One last thing maintains a persistence, consistency and discipline.

From here where?

As we know food is a great friend of our human being. It has help in this pandemic also for many people but it had led to the cause also like obesity. Food in some amount is good not being overeaten. Weight gain it can encourage many people to start a new lifestyle a lifestyle of being fit and fresh mind and being not stressful. Being responsible and dutiful like sun, stay positive and being fit. Search a beauty in your lifestyle by doping exercise, work out. Or anything you called. Strive for progress not for perfection in your fitness. Physical fitness or exercise is not only one of the most important keys to a healthy body, it’s the basis of dynamics and creative intellectual activity. And remember the last thing the famous quote “health is wealth”. Take care of your body it’s the only place you have to live. Put the excuses aside.

Conclusion

Lockdown implemented in an attempt to contain the COVID 19 virus which is unpredictable for the countries and representing the major societal changes for people’s with mental health and physical health. Any health care professional should use this time as window opportunity to provide physical health and counselling to their patients. Healthy eating doing exercise sleeping on time making your own health good. Will conclude to “HEALTH IS WEALTH”.

Knowledge and Preventive Measures Adopted by Allied Health Care Professional Students to Control Transmission of COVID-19 Pandemic Infection During Lockdown

Sarika Dakhode¹, Swapnil Patond², Alka Rawekar³, Ajay Chaware⁴

¹Assistant Professor, Department of Community Medicine, Coordinator; ²Associate Professor, Department of Forensic Medicine & Toxicology, Vice-Dean, ³Professor, Department of Physiology, Dean, School of Allied Health Sciences, Jawaharlal Nehru Medical College, DMIMS, Wardha, Maharashtra, India; ⁴Associate Professor, Department of Applied Physics, Bapurao Deshmukh College of Engineering, Sevagram, Wardha, Maharashtra, India

Abstract

Introduction: After declaration of COVID-19 infection as pandemic by World Health Organisation (WHO), various preventive strategies have been intended to mitigate disease spread and control the infection rate such as isolation of patients, social distancing, hygienic practices; covering mouth and nose, restriction of mass gathering in society. Hence we planned this survey to assess the knowledge and preventive measures adopted by students to control COVID-19 infection during lockdown.

Methods: This cross sectional study was conducted among students of School of Allied Health Sciences, DMIMS, Wardha during April-May 2020. First year was selected randomly and all 168 students were approached by internet for sharing questionnaire after IEC approval. Received responses is analysed in the form of descriptive statistics.

Results: Total 139 students responded. 38.85% students understood the relationship between mass gathering and transmission of COVID-19 infection at community level. Only 34(24.46%) students were aware about safe social distance. Less than half of the students 66(47.48%) were aware about minimum 20 seconds needed to hand-rub by the alcohol based sanitizer. About 108(77.7%) students maintained the social distancing sincerely, only 74(52.5%) students always used to wear the mask and; 100(71.94%) participants always used to wash their hands.

Conclusions: Though some of the students adopted standards practices, others observed to be considering it as less important. Such survey can be conducted among in various institutions to assess the awareness and shortfall in practices. Awareness level can be raised through dedicated online awareness program.

Key words: Allied Health Sciences, COVID-19, Lockdown, Pandemic, Preventive measures, Students

Introduction

COVID-19 infection was declared as pandemic by the World Health Organisation (WHO) on 11th March 2020.[¹,²] Thereafter, it changes the world scenario and life of human being. In the present century, this infection causes global crisis for human species.[³]

Main source of this infection is patients with COVID-19 and most common routes of transmission are droplets and close contact. Patients are recovering by providing symptomatic and palliative care.[⁴,⁵] As no specific vaccines and treatment is available till date, only implementing and adopting preventive measures at individual and community level is the golden rule
to reduce the morbidity and mortality by COVID-19. Various preventive strategies are isolation of patients, social distancing, hygienic practices; covering mouth and nose, restriction of movements and mass gathering in society.\textsuperscript{[6,7]}

As virus is highly infectious; to date, COVID-19 has affected over 5,701,337 people worldwide, resulting in over 3,57,688 reported deaths.\textsuperscript{[8]} As of 1\textsuperscript{st} June 2020, confirmed cases of corona virus infection were noted as 1,93,473 in India; out of these 94,963 were active cases. Though 93,062 patients recovered, there were 5,437 deaths in the country.\textsuperscript{[9]} Mass gathering leads to close contacts of people and maintaining the social distance is the first one step to curtail the spreading of infection.\textsuperscript{[10]} Wearing of mask is the second essential action, if person has to go in society for the unavoidable task.\textsuperscript{[11]} As the virus may get inculcated, if infected hands come in contact with mucosal surface such as eyes, nose and mouth, so the importance of hand hygiene can’t be neglected.\textsuperscript{[12]} There is need to assess the preventive measures adopted in the community to ensure the control of spread of infection safety.

**Objectives:** To assess the knowledge and preventive measures adopted by Allied Health Care professional students to control the transmission of COVID-19 infection during the period of lockdown.

**Material and Methods**

This cross sectional study was conducted in School of Allied Health Science, DMIMS during April-May 2020. One of the graduation years i.e. first year was selected randomly and all 168 students were approached by internet. Questionnaire was prepared by referring guidelines from World Health Organization (WHO)\textsuperscript{[13,14,15]} and Ministry of Health and Family welfare, Government of India.\textsuperscript{[16,17]} Questionnaire was shared among students through internet after taking their informed consent. Received responses is analysed in the form of descriptive statistics frequency and percentage.

**Results**

Out of 168 students, 139 had responded to the shared questionnaire. Out of total responded, male participants were 60(43%) and 79(57%) were female students and; most of the students (33.09%) were of 18 to 19 years. Maximum participants i.e. 100(72.50%) students were residing in the green zone. Social media was observed to be the commonest source of information for 109(78.42%) students.[Table I]

In the present study we assessed the knowledge regarding the spread, preventive and control measures of COVID-19 infection. 91(65.47%) participants responded for coughing/sneezing, followed by 70(50.36%) participants responded for close contacts as a mode of spread of COVID-19 infection in the community. About similar pattern of distribution of responses was noted for route of transmission in a human i.e. 85(61.15%) for coughing/sneezing and for close contacts 71(51.08%).

Most of the students i.e. 104(74.82%) were found to be aware that most essential preventive measures can be taken by general public is social distancing. However, only 81(58.27%) of students believed that social distancing should be adopted by everybody as a preventive measure.

According to 23(16.55%) of the students, hand hygiene and; 27(19.42%) students, use of mask is the most essential measures that should be adopted by everybody.[Table II]

We also tried to uncover the basic and common knowledge about the corona virus among the participants. It is noted that, only 34(24.46%) students were aware about 3 feet (one meter) social distance should be maintained to prevent COVID-19 infection. Most of the students i.e. 41(29.50%) believed that social distance of more than four feet would be safe. Whereas, 37(26.62%) and 15(10.79%) students pointed for 1 foot and 2 feet as a safe social distance in these COVID pandemic. Minimal time take for alcohol-based hand rub to kill Cov-19 virus is 20 seconds and same time for soap rubbing.[14] Only 66(47.48%) responded this theme correctly, other 18(12.95%) and 39(28.06%) students ticked the 5 and 10 seconds required time to kill the virus respectively. 16(11.51%) students choose safer side for the same question i.e. time require to disinfect hands is more than 20 seconds.[Table III]

Table IV: Practices adopted by Allied students to prevent COVID-19 infection

</table>
In the present study, 108 (77.7%) students maintained the social distancing always and 24 (17.3%) students maintained it most of the time. Only 74 (52.5%) students always used to wear the mask for outdoor activity and 45 (32.4%) students followed this practice most of the time. After returning from outside at home, 100 (71.94%) participants always used to wash their hands and 26 (18.70%) students followed this practice most of the time. [Table IV]

![Methods of disposed off used mask by the students during COVID-19 pandemic](image)

About 48.92% students followed the practice of throwing the mask in dustbin and 27.34% students used to wash the mask for reuse. [Fig-2]

</table>

(*multiple response allowed)
When we asked the participants about frequency of going outside, it is noted that one third of them i.e. 46(33.1%) follows the rules of lockdown sincerely by remaining at the home. 41(29.5%) students moved out of home occasionally, whereas 27(19.4%) once in a week and only 14 (10.1%) students moved out daily. Common purpose of going outside was observed for purchasing vegetables/groceries/stationary/milk/fruits by 65(46.76%) and 38(27.34%) the students respectively. [Table V]

Discussion

We have received responses from almost all the participants in first half of the May 2020. Type of risk zone for Novel corona virus is observed to be very dynamic; it changes anytime during the week. Wardha district was declared green zone up to the 10th May 2020, where most of the students are residing during the lockdown. This may be the reason for maximum students responded for green zone during the data collection period. Social Media is playing the major role in making the community aware about the status of COVID-19.

Mass gathering is prohibited to avoid community transmission. This should be clear among the people. Only 38.85% students of Allied health sciences understood the relationship between mass gathering and transmission of infection at community level. It is equally important for a healthy individual to protect from droplets in the air by covering nose and mouth and, for the patient by adopting cough etiquettes. In present study, 61.15% participants responded correctly for coughing and sneezing main route of COVID-19 transmission at individual level. There is need to improve the specific awareness regarding mode of transmission among the students.

Social distancing is core strategy during this lockdown period. Important advice for general public by World Health Organization is to maintain the social distance at least three feet and so everybody should be aware of and follow it sincerely. [6,9] About three fourth (74.82%) of the participants believed that most essential preventive measures can be taken by general public is social distancing. However it is equally important to understand that everybody is involved in general public and it is the responsibility of each and every person to maintain the said social distance as a preventive measure. Students were observed to be not sure about personal level responsibility of social distancing and hence only 58.27% students could mark it correctly.

Less than half of the students (47%) were aware about the particular time needed to hand rub by the alcohol based sanitizer i.e. 20 seconds. Though very few students (11%) had chosen safer time i.e. 30 or >30 seconds for hand rub, still near about half of the students were unaware of it and might be practicing unsafe hand hygiene. Such unsafe practices may increase the chances of getting corona virus infection to an individual and community further. No specific vaccine is available for the COVID-19 infection till date. Most of the students were unaware the exact status of vaccine availability, so basic knowledge about COVID-19 disease needs to improve among students.

Various types of information are accessible on social media. However, not all students were accessing this information. Students have common tendency of following academic instructions sincerely. This may be the reason that, few students remain ignored from some of the facts published or shared through social media. In such situation, institution can plan the online session for these students to increase the particular knowledge.

Most of the students responded that, they were maintaining the social distancing. However, first of all one should know the standard or required distance to be maintained to avoid the catch of corona virus infection. As per the guidelines, minimum 3 feet social distance is to be maintained for prevention of corona virus infection. [10,18,19] More than 3 feet distance is safer, but less than 3 feet distance promotes the transmission of corona virus infection from person to person. In our study, 52(37.41%) were observed to be unaware of minimum social distance to be maintained in the society.

Hand hygiene and use of mask plays vital role in preventing of getting infection. As per WHO, wearing of mask is compulsory for the COVID-19 positive patient to control the diseases spread. [20] But it is equally important to protect our self from getting infection. One of the measures for it is wearing the mask by healthy or apparently healthy individual to cover nose and mouth. [21] In the present study only half of the participants were sincerely using mask every time for outdoor activity and about one third (32.4%) were trying to keep up
this practice by following it most of the time. But other students were taking it casually by allowing themselves going outside without covering their nose and mouth. This practice may be harmful for the individual and so for the community. However, students were following safe practice of mask disposal.

WHO recommended frequent hand washing not only at the home but also in outdoor settings.[22] However, about two-third of studied participants were following the practice of hand hygiene at home sincerely. Some of the students moved out during this lockdown and reason for outing was very rational i.e. for obtaining daily needs.

**Conclusion:** During this pandemic of COVID-19, it is important to follow some of the practices sincerely and always rather than missing any time. Students are needed to be aware of standard guidelines along with motivate the participants for adoption of safe practices. Our team has shared the important health awareness information which is published by WHO as an ‘Advice for Public’ among the students of Allied Health sciences.

Research in this area is observed very rare during literature search. It is recommended that, such survey can be conducted among the students of various institutions to assess the awareness and shortfall in practices adopted by them for prevention of COVID-19. So that gap in the knowledge, understanding and practices can be recognised and corrected further through academic learning session. Nowadays, teaching institutions are closed, still online academic teaching is going on. So, we can grab this opportunity to raise the awareness level among the students through dedicated online awareness program.

To Assess the Knowledge Regarding HIV/AIDS among New Entrant of the Nursing Institute in Wardha District

Savita Pohekar¹, Samruddhi Gujar², Arti Raut³, Sonali Tadas⁴
¹Associate Professor, ²Clinical Instructor, ³Assistant Professor, ⁴Bsc Nursing Student, Department of Medical-Surgical Nursing, Datta Meghe Institute of Medical Sciences(Deemed to be University), Smt.Radhiakabai Meghe Memorial College of Nursing, Sawangi (Meghe), Wardha, Maharashtra state, India

Abstract

Introduction: One of the world’s most significant public health issues has been HIV infections and AIDS (HIV / AIDS). The 1 percent of deaths worldwide are responsible for HIV / AIDS Knowledge of HIV / AIDS among students is crucial to the elimination of disease propagation. Besides, young adult university students may start their own families someday and some may be health care providers in the future. Data about Knowledge, regarding HIV/AIDS are needed to sensitize and create awareness among nursing students as they were becoming health care administrators and providers in the future. Aim: To determine the knowledge regarding HIV/AIDS among new entrants of the nursing institute. Materials and Methods: A cross-sectional study was carried out among new entrants of the nursing institute in Wardha district. The students were chosen randomly. This cross-sectional descriptive research was carried out by pre-designed, pre-tested, and semi-structured surveys of eligible 296 nursing students in their first year of life. First-year Basic Bsc nursing100 students, GNM100 students, ANM 96students in the age-group of 17-19 years on 1st, 4th, and 7th Oct’ 2016, respectively. After the study purpose was clarified, the students received 45 minutes without shared consultation under the supervision of the investigator, to obtain informed verbal consent and maintain confidentiality. Students have been given the right to withdraw without fear or obligation from the study at any time during their data collection, but none declined to take part. The research variables included demographic variables such as sex, professional education, the difference between HIV / AIDS, routes of transmission, prevention strategies, category of behavioral risk, and antiretroviral therapy, etc. Result: Out of 296 total students, 123 (51.9%) were women and 103 (44.0%) were rural native students. The mean knowledge score for the professional education of ANM was 17.35± 3.59, for GNM it was 13.00±3.61and for B.Sc. Nursing it was 17.37±4.31. The majority of the lot was aware of all four routes of infection transmission and methods of prevention. When the mean data score for the three new entrants is compared, no major statistical difference except ANM (P=.999) is noted.

Introduction

By 2030, the world has vowed to end the AIDS epidemic. Significant obstacles have yet to be met. The world’s number of new HIV infections, which amounted to 36.7 million (34.0 to 39.8 million), stood at about 2.1 million [1.8 million – 2.4 million] in 2015.¹

The latest HIV figures for India for 2015 are projected at 0.26% (0.22%–0.32%) by 2015 to include the number of adults (15–49 years), in India. In 2015, the prevalence of adult HIV among men is estimated at 0.30% and among women at 0.22%. In 2015, the most reported adult HIV prevalence of Manipur in the United States was 1.15%, followed by Mizoram (0.80%), Nagaland (0.78%), Andhra Pradesh & Telangana

India is the third-largest HIV outbreak in the world. In 2017, an additional 0.2% of adults were between 15 and 49 years of age. This number is small relative to most other middle-income nations, but 2.1 million are HIV sufferers due to the large population of India (1.3 billion people).

As most people in India are considered infection-free, education in information is one of those key policy items. Therefore, knowledge training will continue to regularly assess the level of awareness about HIV / AIDS to provide policymakers with insights on how education can be better improved. A survey was carried out in this context to assess the extent of the awareness of HIV / AIDS among first-year professional university students in India for the admission year 2016.

Materials and Methods: A descriptive cross-sectional study was conducted from 10th Oct 2016 to 15th Oct 2016 and the setting was selected under the ambit of Datta Meghe Institute of medical sciences, Smt. Radhikabai Meghe Memorial College of Nursing and Florence Nightingale College of Nursing in Sawangi Meghe Wardha after getting ethical permission (Ref. no: DMIMS(DU)/IEC/2016-17/6061). By using the purposive sampling technique, 296 students of new nursing entrants of all three courses of nursing i.e. Auxiliary nurse midwifery course duration two years, General nursing and midwifery three years, and four years degree course Basic B.Sc. Nursing. The nursing students were informed and explained the objective of the study. The written informed consent dully signed individually by them was obtained. The inclusion criteria were: students who are willing to participate in the study and senior students were excluded from the study. Demographic variables were collected in terms of Age, Gender, Stream of Education in 12th standard, Stream of professional education, a previous source of information about HIV/AIDS, and Family members in the medical profession.

A semi-structured questionnaire has 30 multiple choice questions and these were classified in different areas, such as (i) the meaning of HIV/AIDS and its mode of transmission (ii) Medical management and prevention. The questionnaire was prepared based on the extensive review of the literature and clinical experiences of handling HIV patients. Each correct answer carries one mark and the total score is 30. The prepared tool was validated by ten experts, out of the eight were from the nursing department, one was from the Department of medicine and one was from the physiology department. Reliability analysis was done by Guttman split-half coefficient and was 0.90, hence the tool found reliable, valid, and feasible. The interview technique was processed for 296 samples was planned to gather demographic information and the knowledge on HIV/AIDS including the meaning of HIV/AIDS and its mode of transmission, medical management, and prevention questionnaire was administered, each sample requires meantime 30 minutes to complete the questionnaire. As collected, the responses were arranged in tabular form to conduct statistical analyzes which are mentioned in the following sections.

Statistical Analysis

The collected data were coded, tabulated, and analyzed by using descriptive statistics (mean percentage, standard deviation) and inferential statistics. Association of knowledge with demographic variables was done by one way ANOVA test and independent t-test and for the multiple comparison Tukey test has been used.
## Results

Table 5 shows comparing mean knowledge score in all the three new entrants of nursing institute statistically significant difference was found among professional education of three new entrance of nursing institute. Except ANM (P=0.999) shows statistically no significant difference.
Discussion

A descriptive cross-sectional study has been conducted to evaluate newcomers to the health university in India’s knowledge of HIV / AIDS. The goal of the study was to evaluate knowledge of HIV / AIDS among students of newly established medical care and sensitivity among informers as well. The mean knowledge score for the professional education of ANM was 17.35± 3.59, for GNM it was 13.00± 3.61 and for B.Sc. Nursing it was 17.37±4.31. This score shows new entrants B.Sc students were well-known than students of ANM and GNM. By using one way ANOVA statistically significable variation was found in the knowledge score of three new entrances to the nursing institute in professional training as (F=42.308, p-value=0.000). Statistically significant differences between the professional training of three new entrants were found when the mean knowledge score was compared by using the Tukey test.

The National AIDS Control Organization’s (NACO) National Behavioral Surveillance Survey (BSSA) has also reported having higher rates of familiarizations of the terms AIDS (86 percent) than HIV (72 percent) for 78,916 Indian youth (15-24 years). The majority of young people who knew about HIV / AIDS were also aware of the possibilities of transmission of HIV / AIDS through non-protected sexual contacts (92%), infected blood transfusion (95%), and use / infected needles (94%). Over two-fifths of the young people could identify correctly three common misconceptions on HIV / AIDS transmission 6

Sadeghi M, Hakimi H (2008) studied the awareness and attitudes of Iranian dental students towards HIV / AIDS. This cross-sectional survey aimed to evaluate the knowledge and attitudes of Iranian dentists to patients with HIV / AIDS. All 750 dental students who participated in the 10th Dental Student Congress in Isfahan, Iran, were given a 53-point self-administration questionnaire. The total questionnaire response rate was 60.7%. While the majority of students had excellent knowledge (78.4%), only 1% held professional attitudes to treat HIV / AIDS patients 7

Oliveira E.R. et al carried out a related analysis of Brazilian dental students’ awareness and attitudes towards HIV infections. The dental students from the Federal University of Bahia (Brazil) treated patients in university clinics included 250 dental students. The tool consisted of 32 questions pre-coded and two open-ended questions. The findings showed that students’ awareness of HIV / AIDS generally increased as the program progressed, but that they were not compatible with the entire barrier technologies used to control infection and the clinical protocol. Therefore, the perceptions and attitudes of students towards the disease need to be discussed more explicitly. 8

Aggarwal A (2013) carried out an HIV / AIDS-related study between dentists. The purpose of this research, therefore, consisted of assessing the awareness and the actions of HIV / AIDS-related dentists among the 460 students of the Bareilly, Brazilian Institute (UP) of India. The students were conducted with a self-administered survey of 53 standardized questions. The results show that the awareness of students about HIV / AIDS has generally been improved with curricula progression; however, all barrier strategies for infection and clinical protocols have lost continuity and conformity. 9

Conclusion: Students on various professional courses pass a competitive examination to be admitted to the medical professional university. However, with students’ immediate educational background being similar (10+2), three professional streams in this study showed a clear difference in their level of knowledge. Ignorance and mistaken convictions can influence a person’s behavior and communication. However, there is a sufficient chance for thorough awareness, a positive attitude and behavioral improvement to be improved by students during their training time also required greater attention to GNM and ANM students. Although this research is dedicated to evaluating knowledge depth, it has not dealt with other important factors relating to attitude, actions, and practices.

Impact of COVID-19 on Women, Pregnancy and Psychologically

Sharleen Khan

Medical Intern, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Sawangi(M), Wardha, Maharashtra, India

Abstract

Background: Gender differences among the responses to the COVID-19 disease needs to be studied. As pandemic is growing and more and more cases are being registered, correlation between disease and gender response if any should be examined.

Summary: The pandemic of COVID-19 is evolving which reported its first case in Wuhan, PRC, considerable amount and efforts are only directed towards containment of the virus. The effect of the pandemic on pregnant women physiologically, psychologically and classification by socioeconomic status can give better trends to study. Further mortality rate between men and women and reason behind it can be evidently proved after through study. After all, one solution to different problems cannot be implemented. Middle East respiratory syndrome (MERS) and Severe Acute respiratory syndrome (SARS) also belonging to similar family of the coronavirus have more things to study regarding which strategy should be employed in containing the viral spread. Vertical transmission is not seen yet but occurrences of sporadic deaths of infants or still birth could be explained after research.

Conclusion: Gender based case fatality rate and its reasons can be extremely helpful in treating the patient with specific gender. Psychological state in the time of distress always been a cause of worry. It worries more when identified in pregnant state. All these aspects need to be studied thoroughly.

Keywords: COVID-19, OBSTRETICS, INFODEMIC, SARS, MERS, VERICAL TRANSMISSION

Introduction

The COVID-19 disease which first reported in Hubei province of People’s Republic of China in December 2019. Researchers then started studying the continuously evolving virus and found out that its shape resembles to the crown. Hence, they named it coronavirus. The disease caused by the coronavirus strain is known as coronavirus disease 2019 also known as COVID-19. Nearly 33 million cases have been reported and ever increasing. No downward trend has been recorded so far. Minor fluctuations can be seen. Nearly a, million people died of the disease. Symptoms include minor cough, cold and fever to asphyxiation and diarrhea. Various strategies are being implemented and rectified on daily basis. Previous outbreaks of the coronavirus family include severe acute respiratory syndrome (SARS) and middle east respiratory syndrome. World Health Organization (WHO) after seeing the severity and nature of quick spreading decided that it should be declared as pandemic in mid-march 2020. Since then Health authorities and governments are trying out various plans to contain the viral spread. Extreme non-pharmacological interventions like lockdown, movement restrictions, physical distancing, wearing mask were tried out. As time passed there is gradual lifting the ban on the movement restrictions. As consequence the cases of infected patients are increasing rapidly. The rising cases overwhelmed the health infrastructure and left them exposed. As the result of lockdown various persons were confined to homes and non-immediate surgeries were postponed. This includes elderly and pregnant women. Pregnant women need regular checkups between the trimesters. But as almost all the resources were diverted to the containment of COVID-19 other medical departments were left unattended. Due to movement...
restrictions and fear of contracting the disease, pregnant women and their families were refraining the hospital visit. This can create complications as regular checkups are necessary in pregnancy. In chalking out the plan to deal with this previous outbreaks of SARS and MERS can be studies. Vital data needs to be studied so that it can be used in drawing out the plan. Severe restrictions imposed should be studied and define their viability and employing local health care workers should be the part of the plan. Transmission vertically, from mother to offspring is also a crucial topic to be examined. Although the chances of contracting the disease of men and women are same, mortality rate is more in men than women. Women research needed more funding to do more fact-finding study. Habits and innate response to the virus is different in men and women. The neglected and one of the most important topics of psychological state of the pregnant women also be studied. Often it is neglected and leaves a scar on the mind of the patient. Neonatal and postpartum care is necessary in these times of pandemic. In this paper we will study all these aspects in light of the COVID-19. 

Pregnancy and Covid-19

Wuhan where first case reported of the COVID-19 is creating a global disorder in health care sector. Fever, cough and in some cases, diarrhea is reported. Oral route through sneeze and cough are the transmission factors of the disease. After testing the sludge from the residential areas, it is found out that feces of the human also contain the viral strain. As the case with comorbidities, pregnancy is also a vulnerable state with respective COVID-19 infection. While in pregnant state, women undergo immense transformation, mentally as well as physically. The already immunosuppressive state of the person is complemented by other physiological changes like change in hormone level, change in heart rate, respiration and breathing etc., which can be very dangerous if the person is contracted by COVID-19. Already maternal mortality rate (MMR) is highly debatable topic as scientific and health care community is striving hard to bring down the MMR rate. Now this deadly pandemic is only adding to the concerns of the associated professionals. Though there is considerable decline in the MMR, still theumber is far behind the set goal by various policies. In countries like India where there is huge population and population density it is decline to 113 per Hundred thousand live births. The sustainable development goals set by United Nations aims to reduce global mortality rate to 70 per hundred thousand births. At the starting phase of the pandemic, the obstetric patients were categorized as low risk. Then it was rectified as the data becoming available and more research was being done. It was seen from various studies that there was more need to shift the patient in intensive care unit (ICU) than non-obstetric women. However, the death rate remains low on paper until now. This can be attributed to underreporting than good healthcare facilities. The non-pharmacological interventions (NPI) like social distancing, prohibition on roaming and gatherings, persistent lockdowns made situation much worse as pregnant women’s and their families was finding it hard to access the health care facility. There is stark difference can be observed in between socio-economic groups. Poorer people were already experiencing job loss and the added cost of transportation only added to their woes. On authorities’ side, Major chunk of or rather say almost all the resources was being used to mitigate the spread of COVID-19. This creates artificial shortage of health care services for non-COVID-19 patients which also includes elderly who were having surgeries even which were postponed. The regular checkups between trimesters was completely halted. Further there is also a fear of large scale unwarranted births as people were finding it difficult to access the contraception’s and necessary medicines.

COMPARING WITH SARS AND MERS

The coronavirus disease 2019 also known as COVID-19 is caused due to the coronavirus family. The shape of the virus resembles with the crow so named as coronavirus. It belongs to the family whose other members caused the severe acute respiratory syndrome (SARS) and Middle Eastern respiratory syndrome (MERS) earlier in 2002 and 2012 respectively. Taking cue from that we can somehow predict the relation between pregnancy in females and the effects of COVID-19 on it. The new form of coronavirus popularly known as novel coronavirus (nCOV). The similarities observed are incubation period. All three of them have incubation period ranging from two days to fourteen days. Also, bat is the common animal hosts and almost all reported cases were from adults excepting very rare occurrence of child case report. Almost 95 percent patients’ symptoms
were fever and cough in all the three-virus infection. In addition to these symptoms some rare cases of diarrhea also have reported. Symptoms part can be considered dynamic because in some form or the other they had changed. \(^{(4)}\)

SARS which reported 8000 cases worldwide has similar symptoms. Also like in COVID-19 superspreading also caused widespread infection. Highest possibility of viral excretion was in the second week of the infection. Hong Kong was the place where largest number of pregnant infected cases were found. Out of 12 cases of SARS infection in pregnant women 3 died, making case fatality rate to 25 percent. Respiratory distress syndrome was prevalent among them. Abortion, premature or preterm delivery of infant was seen as the consequence of SARS infection. Half of the in first trimester and others were in second trimester. \(^{(7)}\) Two of the new born babies were suffering from respiratory distress syndrome. Two babies were having gastrointestinal infection. But the correlation between mother’s infection and infant’s disease was not established by the empirical evidence. Another interesting yet predictable conclusion was that forty percent of pregnant women was put on ventilator while this figure drops to thirteen in case of non-pregnant. Case fatality rate was also high among pregnant women’s than non-pregnant ones. Also, other non-pharmacological measures were at place to supplement the efforts. Some lessons can be learnt to tackle the COVID-19.\(^{(8)}\)

MERS also known as Middle East respiratory syndrome was first identified in the Persian Gulf countries. In 2012 when the outbreak reported there were almost two and half thousand cases reported of which around 900 deaths were reported. The case fatality rate stands at around 38 percent. Same initial symptoms of cough and fever were observed. Co-morbidity is also a factor in deciding the severity of the cases.\(^{(9)}\) Not much study has been done but there were thirteen cases of pregnant women who have been infected with MERS. Out of which 3 died. The case fatality rate in pregnant women stands at 23 percent. Contact tracing helps finding two women in asymptomatic state. Complications in the delivery is observed but no correlation is established with the infection.\(^{(2,10)}\)

**Non-pharmacological interventions and pregnant women.**

As the outbreak turned pandemic is wreaking havoc in the entire world little was known about the containment of the disease. After clarifying the WHO stated that the human to human transmission is highly relevant in this disease. Naturally various agencies and governments started to act. They put restrictions on movements of the people all of a sudden as this pandemic has not given enough time to strategize. So, government plans motive was to break the chain and identify the people who are already infected. Non-pharmacological interventions (NPI) such as physical distancing, wearing mask which is also called as social vaccine, lockdowns, movement restrictions etc. was imposed. This severely halted all other things except the COVID-19 containment. All the resources were targeted to serve the COVID-19 containment purpose. \(^{(11)}\) Naturally people avoided the health services due to fear. This also include the pregnant women which needs regular checkups and vaccination. This severely impacted the necessary interventions by the health care professionals which can lead to other complications other than the COVID-19 infection. The immediate family of the pregnant women were also in fear of attracting the disease of services are accessed. Ground and local health care workers need to look into the matter as soon as possible so the other disaster couldn’t unfold. A very sad impacts on women in general is that they are very prone to domestic violence due to forced close consistent proximity with their partner. Also, as part of NPI all shops including those who serves liquor etc. are also closed down. Addicted people release their anxiety either on their children’s or their spouse. According to the UN study there are chances of seven million unwanted pregnancies due to lack of access to contraceptives. Various programmed run by non-governmental organization has halted their programmers which was crucial in creating awareness in rural masses.\(^{(12,13)}\) Infodemic is also a serious issue to tackle. Only considering pregnant ladies, false information which turns into infodemic is creating fear about hospital visits and other fears of falsely showing positive with infection. \(^{(3)}\) This hinders the need of regular visit to the doctor.
TRANSMISSION FROM MOTHER TO OFFSPRING

There is not much empirical evidence whether the mother to offspring transmission of the disease takes place or not internally. Few positive cases of the mothers who delivered babies were found out that there was no prenatal transmission of the disease. But some instances of few days old babies testing positive for the novel coronavirus disease is concerning. But it can be attributed to the transmission outside the womb where symptomatic mother accidently sneezes or coughs and droplets inhaled by the baby. No infant death has been reported as far now.\(^\text{(9)}\) Transmission through breastfeeding is also a contentious topic but no evidence on this also found. But coughing or sneezing near the baby can be very dangerous and can cause infection. Proper masks to be wear at the time when baby is in near proximity. \(^\text{(8)}\)

LOW MORTALITY RATE AMONG WOMEN

Figures till date shows that men have more case fatality rate (CFR) than women in COVID-19. This means more men are dying than women after contracting the COVID-19. This is interesting to study as it indicates towards manifestation of disease in different way. Immune response can also be a reason among others. Also, women are less prone to engaging in risky behavior, less sin goods consumption and more sincere in following the non-pharmacological interventions such as wearing masks and physical distancing.\(^\text{(14)}\) More funding overall and more research needed in the women health research which is already underfunded. Correlation between how a disease behaves in men’s anatomy and women’s anatomy should be established. Then only we can conclude that one size fits all approach is not efficient in dealing with all the genders. Although men and women are equally prone to contracting the disease. \(^\text{(15)}\) Comorbidities are the main factor in confirming the severity of the disease. It is found in study that men have more heart ailment than women which is one of the prime reasons in deciding the case fatality rate. Diseases related to blood and liver caused by excessive consumption of alcohol also found in men mostly. Smoking is an activity which very few women subscribe to leading to their lungs being more efficient than men who are more in to that activity. Larger percentage of angiotensin-converting enzyme 2 (ACE2) in the blood of the men than women is also a cause of concern. Since ACE2 let the coronavirus infect the healthy cells it can be attributed to why more men are vulnerable than women. \(^\text{(2)}\)

PSYCHOLOGICAL IMPACT OF THE COVID-19

In the time of lockdown and movement restrictions due to fast spread of the COVID-19, there was distress everywhere. Slowly the anxiety built up and much needed events to vent out the anxiety like social gatherings and festivals were not happening. It creates a mental condition where you feel low and tired due to the monotonous life that just has started. The rising uncertainty accumulate overtime. It further worsens the situation because person do not know when this situation will end. And constant fear of catching the disease is there already. Home confinement also leads to less physical activity and more lethargy which then transforms into mental tiredness. If the family member is working on frontline to fight the disease then there is additional safety concern about the lover ones. It affects all age group and physiological condition. But among most vulnerable pregnant women are at the forefront. First, they are already bedridden and in later days they are unable to go out on their own. Second the loved ones visiting them are no more near them to bear the pain of the pregnancy. The hormonal imbalance which is common in the pregnancy aggravates the situation more.\(^\text{(5)}\) This leads to unnecessary thoughts of fetal deaths and vertical transmission worries the person more. Psychological interventions are as important as clinical intervention. Especially when there is the question of mental wellbeing of the pregnant women. It deeply affects the state of the neonates and affects their full development. Study showed that psychological impact of the COVID-19 is more in first trimester pregnant women than in second and third trimester pregnant women. Almost 70 percent women in pregnant state with infection showed more than normal anxiety. Around 50 percent women showed anxiety about vertical transmission of the disease from them to the offspring. Socioeconomic status of the pregnant women also matters in her pregnancy. Women from lower strata of the socioeconomic ladder has to work even if they are ill. Pregnancy in poor rural household already lacking the regular public health center forget
about the secondary and tertiary health service which almost all are concentrated in urban areas. NPI halted this access to. Domestic violence is on rise as lockdowns and movement restrictions are imposed. Addictive urge is not fulfilled so people are venting out their anger to the family members. Urban slums have bare minimum facilities with common sanitation and water facility. This create a huge challenge in the containment as there is congestion and therefore unable to implement the physical distancing measures (16,17,18). So far now, social distancing and isolation of suspected cases are the best prevention strategies for Covid-19(19,20).

**Conclusion**

With almost 33 million and increasing cases of the COVID-19 infection reported, governments are struggling to at least contain the virus spread. The highly uncertain behavior with changing viral strain and symptoms among the patients making it difficult for the scientists, researchers and health care professionals to chalk out the containment strategy. Among various of patients, pregnant women are one of the most vulnerable groups. Although some deaths are reported in pregnant women infected with COVID-19 and reports of still births, abortion, there is need conclusive study which clearly established the correlation between the COVID-19 infection and effects of it on pregnant women. Previous outbreaks of SARS and MERS can guide us on the plan to avoid any complications in pregnant women with the afore mention infection. The effects of non-pharmacological interventions like physical distancing and lockdown had severe impact in halting the access to healthcare service to the pregnant women. There is a need of local healthcare workers and professionals to reach out to the future mothers who needs medical intervention for vaccination and regular checkups. Also, no access to contraception’s will lead to many unwanted pregnancies which can be a challenge in upcoming days. Socioeconomic status plays a crucial role in any disaster as they are less resilient in terms of health and economic condition. Especially women where they are the victims of domestic violence and poor health and sanitation facilities. A common and widely seen factor was severe anxiety about the vertical transmission of the disease which is attributed to the innate response of the human beings toward the safety of their offspring. Proper guidance to the treating doctors or other health care professionals to counsel and give support to the future mothers. Designated and experienced doctors related to the psychological departments can be employed in the maternity ward. More comprehensive study needed with the empirical evidences to find and establish the correlation between pregnancy and COVID-19. Telemedicine option should be implemented wherever necessary. Also, pregnant women need not withhold the vital information of fever, cough due to fear of contracting the virus. Hygiene and sanitation should be assessed and rectified which helps in preventing the virus spread. Monitoring the mother and offspring in post-partum period is essential. Study by gender specific fatalities needed to establish or to undisclosed the reason behind high mortality rate among men than women. Gender specific habits needs to be monitored.

Assess the Prevalence of Hypercalcemia among Immobilized Patients

Sheetal Sakharkar¹, Mayuri Age², Ruchira Ankar³
¹Assistant Professor, Dept. Medical Surgical Nursing, ²Basic B.Sc Nursing Student, ³Asso. Professor, Dept. Medical Surgical Nursing, Smt. Radhikabai Meghe Memorial College of Nursing, Datta Meghe Institute of Medical Sciences Sawangi (Meghe), Wardha, Maharashtra, India

Abstract

Immobilization hypercalcemia is a diagnosis in which excessive bone metabolism abnormalities and conditions related to reduced movement such as medullar lesions or vascular cases. Investigation needs a more evaluation to find out other causes of hypercalcemia. Incidence rate of immobilization hypercalcemia is 11-22% in spinal cord injury group and 20-30% in immobilized patients secondary to fractures in 2 case series. Usually it occurs 4-6 weeks post trauma (1 week-16 weeks) may stay elevated for up to 12 months based on immobilization. Aim-To determine the prevalence of hypercalcemia among immobilized patients.

Materials and Methods-An analytical research approach and a cross-sectional research design were used. The study was conducted in Acharya Vinoba Bhave Rural Hospital; Sawangi Meghe Wardha. The samples were selected using purposive sampling technique, sample size was 30 and blood test done for screening after written informed consent. There were total 30 patients, blood samples which were carried out during study period, it was concluded that out of 30 immobilized patients 14 patients is having hypercalcemia in immobilized state. The study found that there was a person suffering from hypercalcemia in their immobilized state. Hence this study helps in treatment of hypercalcemia during their immobilized state of the patients. From this study it is concluded that 46.67% of the patients suffering from hypercalcemia.

Key Words: disabled patients, high level of calcium in the blood, pervasiveness.

Introduction

Hypercalcemia in immobilization was first discovered by Albright et al. in 1941 and thought that it may occurs due to excessive bone resorption. It is an under-recognized because of increased calcium level in the blood specially in hospitalized bedridden patients.¹ Immobilization hypercalcemia is a diagnosis in which excessive bone metabolism defects and conditions correlated with reduced mobility like lesions of the medulla or vascular injury. Investigation needs further study to find out certain sources of hypercalcemia.²

Incidence rate of immobilization hypercalcemia is 11-22% in spinal cord injury group and 20-30% in immobilized patients secondary to fractures in 2 case series. Usually it occurs 4-6 weeks post trauma (1 week-16 weeks) may stay elevated for up to 12 months depending upon mobilization.³

Diagnosis of immobilization hypercalcemia was verified by elevated urinary excretion of pyridinium cross-link’s-urine pyridinoline / creatinine ratio 386 nmol / mmol (NR 5-21.8). The hypercalcemia returned to health within one week with intravenous fluids and intravenous pamidronate (90 mg) and Normocalcaemia was sustained throughout the next several weeks until mobilization started. When analyzing the history and ignoring any factors, the elevated degree of hypercalcemia will seem to be linked with extreme trauma and sustained immobility.⁴

Hypercalcemia with immobilization induces a rise in the resorption of osteoclast bones. The cascade of events associating the lack of mechanical stress on the bone with increased resorption can include altered piezoelectric effects in the bone. The subsequent immobilization attributable to trauma, severe damage to the spinal cord or some other cause in this situation promotes the resorption of osteoclastic bone. Because of this condition increased
calcium in the urine and calcium loss from the bones may occur. Increased calcium level in the blood occurs whether calcium efflux becomes increase or the glomerular renal filtration volume becomes decreased. Muscle movement spreads a bone development signal through the osteocyte. With prolonged inactivity of the patients, the mechanical stimulation for bone development triggered by less muscle movement, leaving resorption unopposed. After immobilization the bone resorption occurs within 18 months, even after patients begin remobilization. Ultimately the resorption contributes to osteoporosis; particularly of the appendicular skeleton. The calcium produced by bone remodeling is excreted through the renal tubules. After injury hypercalciuria takes place within the first week and continues for 6-18 months. Calcium release cuts off parathyroid hormone development after few weeks of spinal cord injury. Decreased Parathroid hormone is related with excessive serum phosphate concentrations and decreased secretion of 1, 25-dihydroxyvitamin D. If the rate of calcium resorption increased the capacity of urinary excretion, hypercalcemia occurs. This problem is mostly common in children and young adolescence and patients with renal diseases. Hypercalcemia typically begins 4-8 weeks after immobilization but may start as early as 2 weeks or as late as 6 months after the injury. 

Immobilized hypercalcemia develop due loss of mechanical stress, it leads to excessive resorption of osteoclast bone and reduced the formation of osteoblast bone and then excessive calcium for normal regulatory mechanism of the body.

In symptomatic patients serum calcium level is more than 11.5-12 mg/dl. Clinical manifestation of hypercalcemia include tiredness, weakness, lethargy, pain in abdomen, difficulty to passing faeces, loss of appetite, vomiting, excessive thirst, excessive urination, and dryness. Patients may also show behavioral problems, tiredness, lethargy, misunderstanding or an acute psychosis. Early care has to be based on early mobilization, hydration with intravenous (IV) normal saline, rebuilding of the stability among calcium elimination and resorption and loop diuretics; zoledronic acid has to start if there is no progressive condition. If treatment not given, patients can develop dehydration, behavioral disorder, calcium oxalate nephrolithiasis, and chronic kidney diseases.

**Aim:** To determine the prevalence of hypercalcemia among immobilized patients.

**Materials and Methods**

An analytical research approach and a cross-sectional research design were used. The study was conducted during December 2019 and the setting was selected in Acharya Vinoba Bhave rural hospital Sawangi (M) Wardha city after getting ethical permission (Ref. no: DMIMS (DU)/IEC/Aug-2019/8206 ON DATED 03/10/2019, By using purposive sampling technique, 30 immobilized patients were selected from the Acharya Vinoba Bhave Rural Hospital Sawangi (M) Wardha based on the calculation.

**Statistical Analysis**

The demographic data, collected and descriptive analysis was done in terms of frequency and percentage. For statistical analysis SPSS version 16.0 was used.

**Method of data collection:**

**Section A:** Consist of demographic characteristics of sample such as age, gender, diagnosis, and calcium level.

**Section B:** blood test done for checking calcium level.

**Methodology**

Target population (Immobilized patients)

Accessible population (Immobilized patients in AVBRH Sawangi (M) wardha)

Purposive sampling technique used and sample size was 30

**Data collection**

**Result**

Table no. 1 showed that 3.33% of the patients were in the age range of 20-29 years, 13.33% of them were in the age range of 30-39 years, each 30% of the patients were in the age range of 40-49 years and 60-69 years, 13.33% were in the age range of 50-59 years and 10% of them were belonging to the age group of more than 70 years.
Table no.2 showed that 73.33% of the patients were males and 26.67% of them were females.

Table no.3 showed that each 6.67% of them patients had cellulites, ulcer over foot, and fracture of patella, 10% of patients had sub arachnoidshemorrhage and each 3.33% of the patients had brain tumor, traumatic cervical spine respectively.

Table no.4 showed that 53.33% of the immobilized patients were having normal calcium level and 46.67% of the immobilized patients were having abnormal calcium level.

**Discussion**

The following study supported the present study by Kyung Ae Lee and Wan He Yoo concluded one case report on Immobilization Hypercalcemia-Associated Acute Renal Failure in a Patient with Chronic Tophaceous Gout. They reported that hypercalcemia with immobilization is a uncommon source of severe kidney dysfunction in patients with immobilized state related to restricted motion. Researcher suggested that immobilization may be a probable source of hypercalcemia-prompted serious kidney problems in patients with chronic Tophaceous gout involving several large joints, and professional preparedness is necessary to avoid excessive evaluations and lethal problems.

Another research study concluded that excessive resorption of osteoclastic bone is the key incident for developing the immobilization hypercalcemia. The suggested pathophysiological cause is a loss of mechanical tension due to the absence of loading and muscle activity, low vascularity, metabolic changes in bone and bone denervation.

One case report showed that a 19-year-old elderly patient detected with hypercalcemia after investigation by a family doctor. The patient was suffering from quadriplegia because of spinal cord injury after falling into surface water. Patient had remained immobilized for 3 years. At the time presentation, the patient developed specific signs related to hypercalcemia like lethargy, sickness, quiescence, and loss of appetite, difficulty to passing the stool and thirst. After inspection, bed sore was present in the sacral bone. Reduced hemoglobin level was reported in laboratory workup. In comparison, calcium level was increased although intact parathyroid hormone and 25-OH vitamin D was lower than average. Calcium in urine was also elevated in 24 hours.

Another research study showed that a 48-year-old elderly patient experienced a pronounced and chronic hypercalcemia 3 months after admission for paraplegia arising from extreme peripheral neuropathy most possibly of alcoholic etiology. Serum ionized calcium was increased, and parathyroid hormone levels were low normal by the two separate radioimmunoassay. Urinary calcium excretion was markedly increased and serum 1, 25-dihydroxy vitamin D level was decreased. A comprehensive clinical review of potential occult
malignancy, myeloma, and sarcoidosis as a source of hypercalcemia did not show any promising outcomes. Calcitonin therapy started for the plasma calcium to be rapidly elevated, and its withdrawal culminated in reappearance of hypercalcemia. The patient started intensive physical rehabilitation for relief of the neuropathy and then the physician gradually decreased Calcitonin therapy, and the serum calcium of the patient stayed normal for the next 11 months.\(^9\)

Excessive resorption of the bone marks in hypercalciuria in days and hypercalcemia a few weeks later. If the ability of the renal to eliminate calcium is overdid. Hence kidney inadequacy raises the threat of prolonged inactivity due to hypercalcemia. Children and young adults are more common because of their increase bone turnover.\(^4\)

One study showed that a 79-year elderly patient with chronic kidney disease stage four was admitted with a limited-weight-bearing status after right-hip arthroplasty. Patient developed hypercalcemia (11.5 mg/dL) with serum albumin of 2.5 g/dL after four weeks. Despite IV fluids, hypercalcemia worsened (corrected serum calcium, 14.5 mg/dL), and she was rehospitalized.\(^10\)

Recommendation

1. Similar study can be conducted with more study participant to generalize the findings.

2. A study may be conducted on staff nurses to assess the knowledge regarding complication of immobilization.

Conclusion

Immobilization hypercalcemia more commonly impacts the teen age groups associated to the rapid bone turnover that accompanies development. Males are more commonly affected than females because of their more bone build. Immobilization hypercalcemia is common in tetraplegia patients than paraplegia. Immobilization hypercalcemia is a diagnosis in which excessive bone metabolism defects and conditions correlated with reduced mobility like lesions of the medulla or vascular injury. Investigation needs further study to find out certain sources of hypercalcemia. Present study findings will helpful for preventing the further complication and based on the above cited findings, it is concluded that it is effective method to determine the calcium levels in patients and reduces the risk for hypercalcemia among immobilized patients.

Acknowledgements: We would like to thank the authors whose works have cited and included in this study such as Gopal H, Sklar AH, Sherrard DJ, Gallacher SJ, Ralston SH, Dryburgh FJ, Kaul S, and Sockalosky JJ . We acknowledge the immense help received from the scholars whose articles are cited and included in references of this manuscript. We are also grateful to authors / editors / publishers of all those articles, journals and books from where the literature for this article has been reviewed and discussed.

Abstract

COVID-19 is a new type of corona virus that causes the disease. ‘CO’ is for corona, ‘VI’ for viruses, and ‘D’ for illness. This disease was previously referred to as ‘2019 novel corona virus’ or ‘2019-nCoV’. Corona virus is the contagious disease (COVID-19) is arising from newly discovered. The COVID-19 virus gets people of all ages infected. However, research to date shows that two classes of people are at greater risk of being strongly struck by COVID-19. The older people and others with existing health problems. WHO stresses that, in order to protect others, everyone must protect themselves from COVID-19. Old age people and individuals with underlying disabilities such as heart problems, asthma, chronic lung disease and cancer are more vulnerable to severe disease. Men is at a higher risk than females for COVID-19. **Conclusion** According to this short communication article, two groups of people are at higher risk of developing severe COVID-19 disease. Old age people and individuals with underlying disabilities such as heart problems, asthma, chronic lung disease and cancer are more vulnerable to severe disease. These peoples have to take more precaution to prevent covid-19 infections.

**Key words**- chronic respiratory disease, elderly people, greater risk people, heart disease, 2019 –novel corona virus

Introduction

COVID-19 is a new type of corona virus that causes the disease. ‘CO’ is for corona, ‘VI’ for viruses, and ‘D’ for illness. This disease was previously referred to as ‘2019 novel corona virus’ or ‘2019-nCoV’.¹ In more than 200 countries in the world, the Corona Virus Outbreak 2019 (COVID-19) pandemic is the latest epidemic.³⁶ The COVID-19 is a rapid succession pandemic. Fear has taken control of the whole planet. The number of those afflicted has risen and the death toll has reached a disturbing level. In this time of crisis, competent management of the afflicted, regular deaths, self-care and quarantines requires a lot of bravery to face the reality.³⁷

Corona virus is the contagious disease (COVID-19) is arising from newly discovered. The COVID-19 virus gets people of all ages infected. However, research to date shows that two classes of people are at greater risk of being strongly struck by COVID-19. The older people and others with existing health problems. WHO stresses that, in order to protect others, everyone must protect themselves from COVID-19. Old age people and individuals with underlying disabilities such as heart problems, asthma, chronic lung disease and cancer are more vulnerable to severe disease. Men is at a higher risk than females for COVID-19.²

Corona virus disease (COVID-19) is a newly discovered corona virus-related contagious disease. Many Individuals contaminated with COVID-19 may succeed mild to moderate respiratory problems and recover without having to take any special care. If a individual infected has cough or sneezes, virus COVID-19 diffused mainly by droplets of saliva or nasal flushing, so it is necessary to practice the respiratory good manners (such as coughing with a bend elbow).³

COVID-19 is a corona virus outbreak that originally occurred in Wuhan, Hubei Province, China in December 2019 but has now grown into a rapidly spreading pandemic across the world.⁴

As of 17 April 2020, more than 2 Mio. COVID-19 cases have now been recorded to WHO , and more than
135,000 people have lost their lives.  

13,835 confirmed cases in India with 452 deaths by the Ministry of Health and Family Welfare, there are 11,616 active cases with 1,766 cured/discharged cases. (Ministry of Health and Family Welfare 2020)

The COVID-19 virus gets people of all ages infected. However, research to date shows that two classes of people are at greater risk of being highly influenced by COVID-19. There are older people and others healthcare problems underlying them. WHO stresses that everyone must shield himself from COVID-19 to shield others.

The illness causes respiratory disease (such as flu) with symptoms like cough, nausea, and trouble breathing in more extreme cases. We should protect ourselves by constantly washing our hands, avoiding touching our face and eviting near touch with the unwell people (1 meter or 3 feet)

Elderly people and those with underlying medical problems such as heart disease, diabetic mellitus, chronic lung disease and cancer are more likely to develop serious diseases.

Italian data corroborate population groups previously identified at higher risk of serious illness and death. Such categories are elderly people over 70 years old and persons having medical conditions such as obesity, diabetic mellitus, chronic lung disease and cancer. Men is at a higher risk in certain classes than females. Chronic obstructive pulmonary disease.

There are different parts of our population that are most susceptible to COVID-19 secondary severe acute respiratory infection (SARI). Which include the following.

Old age people more than 65 years

An older adult, aged 65 and older people are at increased risk for severe COVID-19 disease and the capacity of their immune systems to combat infection declines and thus make us more susceptible. Coronavirus might affect any community the elderly people is the greater risk of serious illness. 8 out of 10 deaths recorded in the United States occurred in adult’s age of 65 years and older death threat is the highest for those ages of 85 years or older. Older adult Immunology are becoming weaker with age, making it more difficult to fend off infections. Older adults more often have chronic deaths which may raise the risk of serious diseases.

More than 95% deaths occurred in 60 years or older people. More than 50% deaths occurred in 80 years or older. One positive report showed that those people more than age of 100 years who were admitted to hospitals for COVID-19 and now they have completely recovered. It’s clearer that the healthier people were before the pandemic plays a crucial role. Those aged people who are healthily are less at risk.

Researcher concluded that with elderly people, the body has fewer T cells, which has the property for producing virus-fighting chemicals. By adolescence the thymus gland is producing tenfold fewer T cells than it did in childhood, by age 40 or 50, there is another tenfold drop.

Research study suggested that more than 60 years elderly people and specially those aged more than 65 years old are at significantly higher risk of severe disease, requiring respiratory support, and death from Covid-19 than younger age groups.

During the disease or when in quarantine, older adults, those who are in isolation who have the neurological disability may have anxious, afraid, worried, irritated, frustrated, angry who withdrawn. Using informal networks such as social services and health care providers to provide psychological assistance. Educate them about COVID-19 in a straightforward way and show them how elderly people with / without cognitive disability can reduce the risk of infection in their own words.

Aged people with heart disease are younger than 62 years of age or more than 80 years of age.

Individuals with underlying medical conditions:

Serious heart problems

Severe heart complications, like heart failure, coronary artery disease, cardiac parenthood disorder, cardiomyopathy and lung hypertension, can present a higher risk to people from COVID-19 for serious illness. Unlike other viral illnesses including flu, COVID-19 can disrupt the respiratory system and make it more difficult
for the heart to function. For people with cardiac insufficiency and other severe specifications.\textsuperscript{9}

Observations may clarify Older men, tobacco consumers / smokers and those with hypertension are vulnerable also illustrate the significance of recognizing smoking as a possible risk category for COVID-19. COVID-19 may develop serious heart problems including cardiac failure, myocardial infarction and embolism it’s may cause cerebro vascular accidents. They also caution that treatments with COVID-19 may interact with drugs used to manage existing heart conditions in patients.\textsuperscript{13}

Researcher point out that, some conflicting theories about antihypertensive medication making patients susceptible to the Novel Corona virus. Be assured that common antihypertensive medication not raise patients’ risk of infection. It is advised not to stop the antihypertensive medication, hence hypertension is a higher risk factor and it may lead to more complications in case of infection.”\textsuperscript{14}

Researcher evaluated that 45 recent reports pertaining to COVID-19 and cardiovascular complications and found that the corona virus can cause lasting heart impairments. Many patients who develop severe COVID-19 complications already have underlying heart issues. Researcher evaluated that over 72,000 patients with COVID-19 found that about 22 percent of patients who died had cardiovascular co morbidities.\textsuperscript{15}

Research study showed that those patients who were suffering from cardiovascular problems and/or development of acute myocardial injury are associated with significantly worse outcome in covid 19 patients.\textsuperscript{16}

**Lung diseases** – Chronic respiratory obstructive disease (COPD), asthma, lung fibrosis and cystic fibrosis. People has chronic lung disorders are suffering from inadequate ventilation due to a number of conditions which include inflammation, blocked or airways clogged, alveolar defects and other structural problems. Viral diseases exasperate the lung disease at the root and can cause breathing failure, septicemia, and acute respiratory distress syndrome (ARDS). \textsuperscript{9}

Meta-analysis concluded that those patients who having a history of COPD, they are more prone to get covid -19 infection. Encouraged to patients for adopting more restrictive measures for minimizing potential exposure to SARS-CoV-2 and contact with suspected or confirmed cases of COVID-19. \textsuperscript{17}

American Lung Association concluded that above 35 million Americans suffering from chronic lung disease, and researcher said that these patients having greater risk for severe implications if they were to contact the virus.\textsuperscript{18}

Corona virus disease 2019 (COVID-19) can cause respiratory, physical, and mental dysfunction in patients. Hence, pulmonary rehabilitation is important for both admitted and discharged patients of COVID-19.\textsuperscript{19}

Researcher said that those patients who having chronic respiratory problems these patients has to take extra precaution during the middle of COVID-19. “Because the virus attacks the lungs, patients with chronic lung disease such as asthma, COPD, and pulmonary fibrosis are more susceptible to the COVID-19 infection,”\textsuperscript{18}

**Diabetes**

Diabetes, in that dependent, independent diabetic mellitus or diabetic in pregnancy may put people at increased risk of COVID-19 serious illness. Hyperglycemia, or impaired blood glucose regulation, is affecting the immune system. Vascular failure may impede inflammatory reaction locally and antibiotic supersorption.\textsuperscript{9}

Those patients who are suffering from diabetes are among those greater-risk categories that, when they get the virus, can become seriously ill. \textsuperscript{20}

Infection with COVID-19 is a double challenge for diabetes patients.\textsuperscript{21}

Hospitalization and mortality rate of the COVID-19 infection is increased due to diabetes.\textsuperscript{22} comparative study concluded that ICU and non ICU patients with COVID-19 The incidence of intensive care patients with diabetes appears to be double increasing.\textsuperscript{23} Mortality in people with diabetes seems to be about threefold higher compared to the general COVID-19 mortality in China.\textsuperscript{22,23}
Those patients who having diabetes are indeed a greater-risk group of serious illnesses. In the previous SARS, diabetic mellitus was also a causative factor for serious illness and death.  

Statistics indicate that India has the second largest number of people with Diabetes globally. In the current scenario of lockdown, while we all are taking necessary precautions like social distancing and staying home to prevent the rapid spread of COVID-19, managing Diabetes may seem quite challenging.

People with Diabetes are not more likely to get COVID-19 than the general population. However, COVID-19 can cause more severe symptoms and complications in some people living with Diabetes.

**Immunocompromised**

Some conditions and treatments can lead to a person’s immune system weakened, including treatment for cancer, bone marrow or liver transplants, HIV immune deficiencies with or without small cell count CD4, and excessive usage of corticosteroids and other immunodeficiency’s drugs. People with compromised immune systems have reduced their ability to fight infectious diseases.

**Who is immunocompromised is at greater risk of respiratory infections than the average person.**

Research concluded that elderly people with certain co-morbidities and those with immunocompromised may be at greater risk of succeeding severe illness. An immune system helps the body to fight off infections. Hence it is important that the immune system is working efficiently to fight infection such as that given by the SARS-CoV-2.

One case report concluded that COVID-19 affecting an immunocompromised women. A 60 yrs women was admitted to the emergency department on 10 March 2020 due to breathing difficulty and high grade fever, consistent with COVID-19.

**Chronic renal disease treated with dialysis**

Chronic dialysis-treated renal disease can increase a person’s risk for serious COVID-19 illness. Patients with dialysis are more vulnerable to infection and serious illness due to compromised immune systems; medications and kidney failure control procedures; and conditions which coexist like diabetes. Those patients who were suffering from renal disease and other severe associated conditions are at greater risk for more severe illness.

Dialysis patients and those patients who are on immunosuppressive medicines may have weaker immune systems, making it harder to fight infections.

**High Obesity**

Extreme adiposity identified as 40 Body Mass Index (BMI) or higher, puts people at greater risk of COVID-19 complications.

Extreme obesity raises the likelihood of a severe respiration condition called Acute Respiratory Failure Syndrome (ARDS), which is a significant complication of COVID-19 and may cause problems with the ability of a doctor to provide critically ill patients with respiratory assistance. Individuals with extreme adiposity can have several serious chronic conditions and underlying health problems which may increase. A study of 3,615 COVID-19 patients who visited an academic hospital in New York shows that obesity even among relatively younger patients has increased the risk of severity. For example, patients who were extremely obese (BMI > 34 kg / m2) and were under 60 years of age were 3.6 times more likely to be admitted to ICU than patients in the same age group who had less than 30 years of BMI.

In China, data showed from 383 patients having obesity was associated with a 142% greater risk of succeeding severe pneumonia associated with COVID-19. One study showed that more than 4,000 patients with COVID-19 in New York City found that severe obesity was a higher risk factor for hospitalization, 85% of obesity patient’s required mechanical ventilation, compared with 64% of patients without the disease. In addition, 62% of obesity patients died from COVID-19 compared to 36% of those without obesity. Evidence to date suggests that obesity is associated with a greater risk of succeeding severe corona virus disease symptoms and complications independent of other diseases such as heart disease.
Liver Diseases

People with liver disease may have a higher risk of COVID-19 severe disease. Chronic hepatitis like cirrhosis of liver may cause increase the risk of serious COVID-19 disease.9

A recent publication concluded that 54 percent of patients in a single center in China hospitalized for COVID-19 had elevated gamma-glutamyl transferase (GGT). The expression ACE2 is enriched in cholangiocytes, indicating that COVID-19 may potentially cause a higher risk of biliary injury over hepatocyte injury, as evidenced by these elevations of the GGT.33

Cohort study concluded that 1,099 cases of COVID-19 in China showed that 21 (2.1%) had pre-existing hepatitis B. The overall ALT rise was 21.3 per cent (158/741) and the AST rise 22.2 per cent (168/757) respectively. Extreme patients have a higher likelihood of elevation of ALT relative to non-serious patients (28.1% vs. 19.8%) and elevation of AST (39.4% vs. 18.2%). 10.5 per cent (76/722) of patients in total 50.34

Pregnancy – – There is insufficient information about risk and transmission during pregnancy and breast feeding at the time of this writing.9

One research study found that a sign of placental damage in pregnant women with COVID-19, this damage actually affects birth outcomes. Most women with the novel corona virus who had these abnormalities gave birth to healthy babies’ at-term. Pregnant women those who were more than 35 years old , obesity and those who having pre-existing medical conditions , like hypertension and diabetic mellitus, were also at higher risk of occurring serious illness.35

Conclusion

According to the short communication, two groups of people are at higher risk of developing severe COVID-19 disease. Old age people and individuals with underlying disabilities such as heart problems, asthma, chronic lung disease and cancer are more vulnerable to severe disease. These peoples have to take more precaution to prevent covid-19 infections.

Efficacy of Manual and Digital Contact tracing of COVID-19

Shradha Agrawal
Medical Intern, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Wardha, Sawangi(M),Maharashtra, India

Abstract

Background: The unprecedented situation unfolded by the COVID-19 pandemic needs tools and measures of varying degrees. Contact tracing is one of them. Contact tracing has become buzz word these days. Along with non-pharmacological interventions (NPI) this is one of the major tools employed by the local health care authorities.

Summary: The contact tracing measure is major part of the response against COVID-19 pandemic. Methods of contact tracing and its efficient way to carry them out needs to be studied. The efficacy of the contact tracing mechanism needs strong backing of empirical data upon which research is ongoing. Further combining the manual and digital contact tracing is the option authorities needs to check out. Health care human resource crunch can be addressed by creating civilian vigilantes to inform the health authorities about the possible suspected case. In case of digital tracing the data minimization and anonymizing the data in which there is no name attached with the particular data can used so that doubts about data privacy should get vanished. Balancing between controlling case fatality rate and infection rate with the help of proper and adequate resourceful data is the key to effectively control the spread along with easing of restriction and step towards normalization of lives.

Conclusion: More thorough study is needed with numerical data backing to establish the efficacy and the relation between controlling the case count and contact tracing.

Key Words: - Contact Tracing, Covid-19, Infodemic, Primary Tracing, Secondary Tracing, High Risk

Introduction

The coronavirus disease 2019 shortly named as COVID-19 is wreaking havoc in all parts of the world. Started from the Hubei province of Wuhan in Peoples Republic OF China, the spread and reach of the virus has reached every nook and corner of the world. Nearly 1 million deaths and 32 million cases worldwide it effectively put pressure on already crumbling health infrastructure. Named after its shape of crown the coronavirus is hitting harder and like never before to all the humanity. As vaccine is under trial and will need some more time and cannot be expected in near future, it is essential to innovate various methods to be employed in the containment of the deadly virus which has been employed and being rectified according to the feedback. Initially the ambiguity of whether this disease spread through human to human contact or not was there but later World Health Organization (WHO) clarified that this can be transmitted from human to human. This triggered the need of identifying the persons carrying the load of coronavirus. First the authorities tried to treat them but later found out that before treatment the infected person might have contacted with other peoples steadily increasing the patients count. Then the need of contact tracing was really felt and authorities started to chalk out the plan to contain the spread of the deadly disease. The test, trace and treat model immensely helped in containing the cases during early period. Initially only family members were isolated and quarantined but on the course of the time other immediate contacts such as neighbors and house help also got isolated. This prove out to be a great strategy for containment as where resources are lacking and where there is low doctor to population ratio. Densely populated countries where health infrastructure is already burdened now experiencing the crushing effect of added pandemic. In such situation this strategy of policy making to contain the spread is
really helping to avoid the unfortunate scenario. As the test, trace, treat model evolves, testing eventually becomes an essential part in success of the contact tracing methodology. Proper rules and regulations and training should be undertaken by swab takers which are in turn health care professionals to properly take the swab which can correctly decide the infection level.\(^{(3)}\)

Efficacy of the contact tracing is also under scanner as more study is needed to establish the correlation between number of cases and tools employed. Which should be employed and where is a crucial factor in containing the viral spread. Various methods according to the ground reality are being employed and rectified every day to get on the nerves of this unprecedented situation. The role of technology is also crucial in contact tracing in particular as the penetration of the network of the cellular phones with internet is ever increasing and on the level that was not seen before. Also, ethical dilemmas such as right to privacy should be given thought while formulating any guidelines on the digital contact tracing. This article unfolds some aspects involving the contact tracing strategy to effectively contain the viral spread.\(^{(4)}\)

**What is contact tracing?**

Contact tracing has become buzz word these days. People who were in close contact of a person whose report is positive for contagious virus such as coronavirus and are at higher risk of becoming infected with the said infection and who has potential to further infect others are called close contacts of the infected person. Tracing and isolating such people if necessary are known as contact tracing. Contact tracing becomes extremely important in such scenario where spreading rate of contagious virus is high such as novel coronavirus.\(^{(5)}\)

Contact tracing can be broadly divided into three basic steps. In which first one is contact identification. Once some people confirmed with such virus, such person is asked about his recent activities where the person possibly came in contact with another people. These contacts can be anyone from family members to house keepers. Second steps are called as contact listing. All the persons listed by the above infected person should be listed as contacts. It can be further classified into high risk category and low risk category. As receiving early care is of utmost importance, these contacts should be identified and conveyed the necessary message and acquaint them of further procedure. The third and the last step in the contact tracing procedure is called as contact follow up. Regular and in appropriate time the contacts should be checked and monitored by the health authorities for symptoms. Asymptomatic contacts can be kept at home with proper medical interventions. But even mild symptoms contact should be admitted to the hospital as soon as possible otherwise his health would worsen and risk of transmitting the virus is maximized which is low in the asymptomatic cases hence quarantined at home.\(^{(6)}\)

Further contacts can be further divided into primary and secondary contact. Primary contacts are those who were within close proximity of six feet for at least two days prior of the confirmed positive report. These can also call as close contact. Secondary contacts are those contacts whose proximity with the confirmed positive patient were less than the primary contact. In case of lack of healthcare infrastructure and overwhelming scenario secondary contacts can be quarantined at home with appropriate care provided they are asymptomatic and having less comorbidities. While primary contacts should be monitored closely and hospitalized even if minor symptoms are shown. High risk contacts are those contacts whose age is above 50 years and having different comorbidities. Research showed that the virus affects more comorbid patients than healthy ones.\(^{(7)}\)

**Methods of contact tracing**

World Health Organization has issued guidelines that must be adopted with necessary changes to effectively counter the viral spread. Depending on the epidemiological scenarios there are some case by case basis response level. For example, what should one do when there are zero cases, when there are sporadic cases here and there, when there is cluster outbreak and finally when there is community transmission where one does not know from where he or she got the infection? [WHO INTERIM] In first two scenarios where cases are zero or sporadic occurrences, health infrastructure can be strengthen and necessary medicines can told to manufacture as lot and equipment’s should be strengthen. In second and third scenario cluster outbreak, needs intensive contact tracing to avoid upgradation into community transmission. Finally, when community transmission takes place then it is extremely difficult to effectively employ the contact tracing strategy especially in the countries with huge population and population density. It is hard to completely defenestrate the virus at
one go but due diligence is essentially required. Contact tracing can reduce the further infection by up to 15 percent which is remarkable feat.(8) Self-reporting is also an effective way to counter the disease spread. But that needs proper dissemination of information by authorized agencies. The preference level for isolation of the suspected patient whose report is under progress should also be decided by the authorities. The prime importance should be given to the health care professionals who are the frontline workers in this pandemic then according to the comorbidities and risk factor associated the next in line should be decided according to the ground condition. The Pandemic also parallel accompanied by Infodemic which is lot deadlier than previous. In some cases it even prevented from reporting the patient by creating a hoax.(1) As the person having the infection is not able to disclose its identity publicly which would have been a best option, due to attached taboo, the healthcare professionals manually trace the nearest past contact of the infected patients. People’s participation is extremely necessary in this complicated task. The right information would eventually bring down the casualties due to late reporting of the cases.(9) Efficiency of contact tracing Contact tracing is the main response on which local health authorities can rely upon to control the spread. An average individual has on an average has 36 contacts and among all people around 9 percent of them have around 100 contacts.(11) To sharpen the contact tracing strategy maximum number of secondary contacts needs to be traced so that they are identified before they get infected and spreader. Longer time would eventually increase the case count day by day exponentially. All the contacts need to be monitored as not all the contacts are symptomatic and will render test negative. They possible can became infectious after some days. The efficacy of the contact tracing is also depending on the nature of primary and secondary contacts. The comorbidity plays a very vital role in case fatality rate (CFR). The more medical conditions one is suffering from more is the chance of one to be turn out a severe case. As more and more governments are turning towards easing up the social restrictions norms, their strategy focuses on reducing the case fatality rate (CFR) than reducing the number of infections. So, it would be disaster if more comorbid which are also known as high risk patients or contacts exposed to the virus. There is a need of correcting the definition and criteria of close contact and secondary contacts. Almost every government have their different perception of close contact. Contact tracing can go hand in hand with other non-pharmacological interventions (NPI) like physical distancing, wearing of masks, and sanitization on regular intervals to lessen the
burden of the health authorities. Apart from what is being discussed the major tool for the local health authorities is definitely the contact tracing strategy. It is efficient so far and its importance is increasing as the case count is surging on daily basis.\textsuperscript{(12,13)}

\textbf{A case for digitally tracing the high-risk contact}

Authorities are relying on the manual tracing of the contacts of the detected COVID-19 patients. As the exponentially of the pandemic is ever increasing it is necessary for the authorities to trace as soon as possible. Taking the help of the technologies will surely help as we experiencing technological revolution. The penetration of the internet connectivity will only help in tracing the contacts.\textsuperscript{(14)} In India the government has launched Arogya setu application which can be downloaded on the cellular phones of the peoples. It uses Bluetooth as well as location data to alert the folks about nearby positive cases so that it can secure itself from that particular area. Further it is also helpful in crowded places such as transport and various congregations where large gatherings are expected. Close circuit television camera’s (CCTV) can be used with thermal gun to monitor the temperature and isolate the suspected patients. It is far rapid than the manual method where the chance of the infection of health care processional is also high. The confirmed positive report of a patient should automatically trigger the authorities to trace its digital contact in near past and alert them as they also can be potent infection spreader.\textsuperscript{(15)} These days cellular phones popularly known as mobile is the nearest possible thing of a person so further process becomes easy. The asymptomatic patients can be isolated under supervision in their respective homes as chances of early detection reduces the spreading capacity of a patient. There is a direct relation between population adopting digital contact tracing application and decrease in number of infections. Both are in direct proportion. Means as the download and usage count of the tracing application increases it further facilitates in identifying the contacts rapidly and quarantine or isolate them further to reduce their exposure to the masses. In country like India where there is already lack of manpower and infrastructure this methodology will immensely help in getting off some of the health professionals’ burden. Even if it covers small number of our population it is very rapid and can further prevent the spread by identifying the risky contacts rapidly. The pandemic already wreaking havoc and any possible and innovative solution should be tried to check its feasibility. But the efficiency of the application-based contact tracing increases with the large cross section of the population uses it. Otherwise it will render ineffective tool. Also users should use the application in a continuous manner then and only then it will show some intended results.\textsuperscript{(15)}

But the other side of the coin also has strong point to make. As this pandemic unfolds the power wielding nature of the various governmental authorities, handing over information of citizens which they are hesitate to share is also a big concern. Too much information at the disposal of the authorities can crush the opposition’s voice. WHO In its interim guidelines suggested for rational usage of the technology in digitally contact tracing. It suggested measures like data minimization, limited retention of data, independent oversight, and accountability to be in regular use while employing the digital tracing method.\textsuperscript{(15)} In addition, the non-state actors can unethically exploit the loopholes in the governmental data storage and possible leakage of the information such as whereabouts of the peoples is also detrimental to the overall wellbeing of the people. Further proper usage from the user’s side is also necessary as selective usage will only create false sense of security.\textsuperscript{(4)}

A wider and quick consultation with all the stake holders about the digital tracing and proper, unambiguous guidelines should be issued by the authorities. Anonymizing the data is one way out as it will not disclose the person’s identity and will also serve the purpose of faster tracing. Using technology is the need of the hour but concerns of the people are also legitimate. Judicious and ethical usage is the only way out to conquer the unleashed dragon like COVID-19 pandemic.\textsuperscript{(16)}

\textbf{Conclusion}

As there is rapid surge in COVID-19 cases worldwide, almost 32 million cases registered so far, various schemes are being chalked out and tested continuously. Contact tracing is one of the efficient and reliable method to counter the spread of the virus. Definition and criteria of the contact tracing needs periodic rectification. High risk patients or patients having co-morbidities should be
on top in priority list. Protocol on asymptomatic patient as they are undetected and possible spreaders should be monitored regularly. As far as manual tracing is concerned it can be supplemented with digital tracing which is more rapid and the fast. Government can try out hybrid model engaging both, manual as well as digital tracing, to make policies regarding the containment of COVID-19. As governments are turning towards lowering case fatality rate than lowering the number of infections a delicate balance should be established as most of the governments lack resources even after dedicating sizable amount of resources toward dealing with COVID-19 pandemic. Tracing should cover large spectrum of the population and the testing result delivery should be as fast as possible to avoid more spreading. Lack of human resource in health care system is road block in contact tracing like strategies. Self-reporting by people on their own after creating awareness could be effective. Efficacy of the scheme of contact tracing needs more empirical study to prove its profitability. It can act as guiding light in upcoming such unfortunate scenarios. Study on spreading capacity of seconaey patients must be studied as it will also adds up to the containment of the pandemic. Infodemic is also parallely spiraling upward as technology can be misused too. Hesitancy in testing by people because of fake messages world end up creating a whole new disaster. Case for digital tracing is strong as these unprecedented situations requires utmost solutions. Technical glitches are hindrance in employing the application-based tracing which can be removed by strengthening the back-end support system of the application. Although manual tracing is rendering more result the digital one is faster. Limited reach of the technology is a cause of concern in employing it. Proper guidelines regarding how to use the application should be popularize thorough various platforms so that the masses can use them with ease. But also, the ethical concerns of the users about privacy and data usage should be addressed so that we can effectively use the technological advancements.

Survey on Parental Attitude Towards Ethical Considerations of Involving their Children in Physiotherapy Care

Sivasankari.A¹, Malarvizhi.D ²
¹PG 1st Year, ²Professor, Dean of SRM College of Physiotherapy, SRM Institute of Science and Technology, Kattankulathur, Tamil Nadu, India

Abstract

BACKGROUND: Ethical considerations around Physiotherapy treatment on Children are more complex than discussions about adult involvement. The interrelation between the ethical values and its involvement in practice is a challenging one. The accountability of clinical decision making by the therapists differ for children and adults. The implications of ethical values in practice provide quality good care for the patient. The purpose of this study was to explore the parental attitudes towards ethical considerations of involving their children in Physiotherapy care.

METHODS: Total of 38 parents whose children undergoing Physiotherapy session at present were participated in the survey. Participants were chosen using convenient sampling technique. The instrument used in the study was a self-descriptive questionnaire. The data were analysed using descriptive statistics.

CONCLUSION: The result revealed that there is no marked evidence of ethical misconduct seen among Physiotherapists handling the Children and it was found that there is a bias in some of the ethical norms like getting written informed consent before treatment, documentation of the records. Efforts to focus on the elements which has a bias and if rectified will have a positive effect on quality Physiotherapy treatment for the children.

Keywords: Ethical considerations, Parental attitude, Parental care, Physiotherapy care, Quality of treatment.

Introduction

Quality of care combines both the care provided as well as the criteria for what constitutes good care. Patient satisfaction is an indicator of quality of care (¹). Number of studies is been evolving which says about patient satisfaction with the medical care of their children (²,⁴,¹⁶).

Every child is special to a parent. Parental care and treatment services are determined based on the special needs of some children (³). In the Physiotherapy care for children, Physiotherapists normally view Children and their families in intervention services and treatment plan and set goals to provide the Child with better quality of life to be best extent and with more opportunities to acquire motor abilities and longevity.

Ethical considerations around Physiotherapy treatment on Children are more complex than discussions about adult involvement (⁵).

Children are the highly susceptible population as they depend on their parents or caregivers for care and protection. The liability for autonomy in decision making for this group of population is always influenced by their authority figures (⁷).

Professional competencies which include ethical knowledge, ethical problems and the skills to handle the problems play a major role and are much needed in the modern healthcare area. To develop the betterment of quality of care for the child, there is a need to determine how widespread the use of ethical guidelines in the practice of Physiotherapy was.

The purpose of this study was to rule out the parental attitude towards the use of ethical guidelines in Physiotherapy session where their Children are being rehabilitated.

As parental care is an important aspect in the Physiotherapy rehabilitation, their attitude towards the knowledge of ethical guidelines to be followed
by the physiotherapists handling their child must be encountered. This set the base to know how quality Physiotherapy is been achieved for their child.

**Materials and Methods**

This was a study conducted in order to explore the attitude of parents towards quality treatment taken by their children in Physiotherapy care. This study was carried out in two rehabilitation centers in Chennai, Tamil nadu. Participants were selected through convenient sampling. Questionnaires were administered to 38 parents who had brought their children for Physiotherapy treatment. There were four non respondents. Data analyses were therefore based on 38 questionnaires.

The questionnaire used in this study was a self-descriptive questionnaire for which content validity and reliability was taken.

1. Demographic data survey instrument:

The demographic data form consists of items to elicit information regarding age, gender, education and presence of the children undergoing Physiotherapy at present. Also it consists of details of parents.

2. Questionnaire:

The questionnaire comprised of a 19 questions of a likert-type scale which serves as a measuring tool for this study. This questionnaire was developed using statements from ethical principles stated by World Confederation of Physical therapy. Questions were designed to provide information on parent attitude towards quality Physiotherapy care for their children, respect, level of remuneration, etc. parents has to indicate to which degree they agree (or not) with each statement by encircling the statement corresponding to one of four statement categories varying from “strongly agree” to “strongly disagree”. Content validity was found for the questionnaire and has been established. It was found out through examination of the questionnaire by health care staffs.

Data was collected by explaining briefly about the aims and method of the study to all the parents participating in the study. Parents who were willing to participate were asked to complete the questionnaire. Table 1 shows the demographic data of the parents who participated in the study and it also shows the characteristics of the children who are involved in physiotherapy care. The time taken to complete the questionnaire was 15 to 20 minutes. Participants were assured that the information given by them will be protected and remain confidential. Study participant was chosen as parents to complete the questionnaire since in the pyramid of Child rehabilitation, Physiotherapist and the parent accompanying the Child, only the parent can be able provide the absolute and correct information on how ethically was the treatment carrying during the session. And the misconducts in the Physiotherapy session can also be identified from the data obtained from the parents.

Results and Discussion

The result of this study shows that, according to parent’s attitude, there is no marked evidence of ethical misconduct seen among Physiotherapist during the Physiotherapy session. From the data available, it was shown that the physiotherapists handling the Children are highly following all the ethical guidelines except some one or two considerations. As per the guidelines given by World Confederation for Physical therapy (WCPT), it expects Physiotherapists to Respect the rights and dignity of all individual, the physical therapist should act in accordance with the laws and regulations ruling the practice of physical therapy in the country in which they practice, Physical therapists must have a knowledge to make independent judgement, Physical therapist should provide honest, competent and quality services, physical therapist must give a legal right to a just and fair level of remuneration for their services, Physical therapists must provide accurate information to patients/clients about physical therapy treatment. Based on these ethical principles, the questionnaire was made and data were collected from the parents.

The main aim of this study is to find out how quality physiotherapy treatment is given to the child involved in physiotherapy care. The connection between the ethical values and its involvement in practice is a challenging one and every physiotherapist must pay attention to the implication of ethics in their practice to provide quality good care. This saying goes in hand with one study by Kati kulju et al, where the authors in that study found the ethical problems faced by the therapist in their practice and there is a state that with moral conduct and moral sensitivity by the physiotherapist, the quality good care can be achieved (11).

The professional relationship between therapist and patient plays a major role to carry out goal directed treatment approach where both the need of the patient and the goal of the therapists should be achieved without any conflicts. In a study by Andrew A. Guiccione stated and found this issue of conflicts arising in professional practice with regards to professional relationship between therapist and patient (9). In case of paediatric treatment approach, the goal directed treatment by the therapist is as important as achieving the needs of the patient (both parent and child). This conflict can be solved out when the therapist handling children educate the parents about the diagnosis and prognosis of the child and if the treatment goal is carried out by giving opportunity to the parents to tell their opinion regarding their needs for their children. This study focused these issues and questions were asked to the parents accordingly. It shows positive response that physiotherapists handling the children are educating the parents about their child’s condition and prognosis and they are following a goal directed treatment by keeping parents view on the need for the child.

From the obtained data (Table 2), there was a positive response from the parents for most ethical considerations like respecting the Child’s needs, about satisfactory Physiotherapy care based on the money paid and time spent. There was 97.1% positive response towards domains like confidentiality, setting the treatment goals with parents. 94.1% of positive response was found for parent’s opportunity to participate in discussions concerning Child’s condition and treatment. Also, it was found that there is a bias only in the domain like maintaining documentation of records which showed 88.2% of positive response and getting written informed consent which only showed 55.9% of positive response. Getting written informed consent should be followed by physiotherapist handling children before starting the treatment and it will have a positive impact and confidence in the therapist skills by the parents and it also ensures therapists safety and precautious measures before handling the patient. Next point to focus is, documentation of records in the Physiotherapy session should be an important one which should be focused and followed in future as that would provide the information of prognosis of the child.

Conclusion

The study shows that the physiotherapists handling the children are highly following all the ethical guidelines during the Physiotherapy session. Hence the study concludes that there is no marked evidence of ethical misconduct seen among the physiotherapists handling the children in Physiotherapy care. In order to make betterment in the quality of Physiotherapy care for children and for the development of the profession, the practicing physiotherapists must follow all the ethical guidelines in their practice.

Acknowledgment: A hearty appreciation and thanks to all those parents who accepted to participate in this study.

Abstract

Loss of facial organs in an individual may be developmental anomalies or acquired. The missing parts of the face ear, eyes and nose are considered as maxillofacial defects which can be rehabilitated by the prosthesis and/or cosmetic surgeries. This art of science has developed into a more reliable and predictable process due to ever increasing development of materials and equipment used in the procedure. This article describes a simple technique to rehabilitate patients with auricular defects which are both aesthetically acceptable and economical for the individual.

Keywords: Maxillofacial defects, Auricular prosthesis, Facial rehabilitation, Spectacle retention

“Disfigurement is the sign telling the world that you have survived from what tried to kill you, well they will tell you all those sorts of solace, deep down humans are still run by societal laws and these laws are brutal they coerce you into adapting into their image of superficial beauty which rather controls your own understanding of self-esteem, so until the time the society acts on what it speaks we embrace the fact that satisfaction lies not in content but validation”

Introduction:

“The love of life is next to the love of our own face. And thus the mutilated cry for help.”

Sushruta Samhita, India, 600 B.C.

The face is an extremely important symbol of man although not the only one. Facial deformities are concealed with great difficulty and jeopardize the appearance of a person more seriously than do similar defects in other parts of the body. Because of this fact they are the most common disfigurements which produce psychic distress. A slight facial deformity frequently produces a psychological effect out of all proportion to the extent or appearance of the disfigurement¹. Microtia is quite often categorised as congenital deformity where the external ear is underdeveloped. A completely undeveloped pinna is referred to as Anotia. Because microtia and anotia have the same origin, it can be referred to as Microtia-Anotia². Microtia can be unilateral (one side only) or bilateral (affecting both sides). Microtia occurs in 1 out of about 8,000–10,000 births. In unilateral microtia, the right ear is most commonly affected.

The aetiology of microtia remains undefined but there are few cases that associate the cause with genetic disorders or with gestational diabetes³. Genetic inheritance has not been fully studied but in the few studies available, it has shown to occur during the early stages of pregnancy³.

Despite remarkable advances in surgical management of oral and maxillofacial defects, many such defects, especially those involving eyes and ears cannot be satisfactorily repaired by plastic surgery alone. Maxillofacial Prosthodontists are highly skilled prosthodontist who have advanced training in complex oral rehabilitation. They carry these treatments of managing these facial defects or other in a multidisciplinary team comprising of maxillofacial surgeons, ENT surgeons, Plastic surgeons, neurosurgeons, speech therapists and clinical oncologists. The principle being enhancement of quality of life of the patient.
According to Chalian (1970) objectives of maxillofacial prosthetics include, 1) Restoration of aesthetic appearance, function 2) Protection of tissue 3) Therapeutic healing affects 4) Healing the Psyche. Prostheses are made to replace hard tissues like bone and teeth, or soft tissue to restore oral function and form. Prosthetics also include devices which protect and shield the soft tissue from radiation during the procedure. On account of all the services that a prosthodontist provides, maxillofacial Prosthodontists (MFP) are trained in working with a multidisciplinary setting together with maxillofacial surgeons; otolaryngologists; cosmetic surgeons; speech pathologists; etc. The rationale stated above clearly qualifies the maxillofacial prosthodontist to rehabilitate deformities. Maxillofacial prosthetic rehabilitation is a justified alternative when surgical reconstruction is not feasible or desirable. The success of extra-oral prosthesis are dependent on the modes of retention, which may be using biological adhesive, utilization of undercuts, retention by other customized devices (e.g- spectacles), magnets, endosseous implants. The following case series is regarding rehabilitation of lost ear with maxillofacial prosthetics which are retained by various modes of retention, providing an insight into the options the prostheticians have.

Case Series:

The artificial ear must be a mirror image of the natural ear, the impression of the natural ear must be made along with that of the defect to fulfil this criterion. Guide lines must also be drawn on the face of the patient to establish proper positioning of the prosthesis coinciding with the natural ear, also anatomical landmarks can be used as a stable guide. A set of three cases will be discussed simultaneously under the general headings of steps to be followed for fabrication. Informed written consent for case recording and photographs were obtained from the patient before the beginning of the procedure.

Step 1: Case evaluation and Planning (Figure 1)

Figure 1 A, B: Preoperative photograph of the patient with missing ear defect.

Figure 1 C-Preoperative photograph with right ear missing; D- Endo-osseous implants placed as a retentive aid planned for the prosthesis.

Figure 1 E; preoperative photograph of the defect area; F- 2 implants were placed in the temporal region for bar attachment as a retentive aid planned for the prosthesis.

Case 1:

A 28-year-old Female Reported to the department of Prosthodontics and maxillofacial prosthetics, with a chief compliant of missing ear (Figure 1 A,B). On careful history recording and clinical examination it was deduced that the patient had a congenitally missing ear with a rudimentary lobe which consisted of cartilage. After all the option were explained to the patient, the patient opted for an auricular prosthesis which would be supported by customized silver attachments.

Case 2:

A 19-year-old male reported to the department of prosthodontics and maxillofacial prosthetics with a chief complaint of missing ear. The patient had a congenitally missing ear with the external auditory meatus opening near the angle of the mandible on the right side (Figure 1 C). Implant supported auricular prosthesis was planned keeping in view the young age of the patient. Using guide lines the new position of the ear was determined coinciding the natural ear. After radiographic examination
the positions of the implants were decided. Three 4mm EO implants (Straumann, AG, and Switzerland) were placed in the temporal region (Figure 1 D). After Osseo integration and healing, ball and socket attachments were placed before impression making. The prosthesis was to be supported by a customized acrylic scaffold which would retain on the implant by means of socket type attachments.

Case 3:

A 33-year-old female reported to the department of prosthodontics and maxillofacial prosthetics with a chief complain of missing ear(Figure 1 E). The ear was congenitally absent with the external auditory meatus opening near the posterior border of the mandible. An implant supported prosthesis was planned after radiographic examination of the prospective site of the ear. Two 4mm EO implants (Straumann, AG, Switzerland) were placed in the temporal region. Castable abutments were used and were connected using inlay wax, later the entire assembly was casted and checked for fit over the implant. The prosthesis was to be retained on the implant with the help of bar-sleeve attachments connecting the two implants(Figure 1 F). The sleeves were embedded in an acrylic frame work to assist the retention.

Step 2: Impression Making:

The primary goal of impression is to record the defect site with maximum peripheral tissue coverage, if it is possible a facial moulage must be taken as it helps in reference for ease of sculpting for mirror image of the natural ear. Impression of a suitable donor ear is also taken, if donor ear is not available. The decision of the retention areas are then made whether to choose implant supported or mechanically retained prosthesis. For implant supported prosthesis, impressions were recorded after placement of implants and the abutments. The ear canals are blocked with cotton and petroleum jelly is applied around the hairy areas. The area to be recorded is boxed using cardboard scaffold. Irreversible hydrocolloid material (Zelgan, Dentsply) was used in a thin consistency and poured in the area, the impression was reinforced by pouring a layer of fast setting plaster on the impression. After careful inspection of the impression it was poured in dental stone (kalstone, kalabhai)

Modes of Retention:

The Methods of Retention and their peculiarities are presented in table 1 with photographs below:

Figure 3-(Case 1), A-illustrates the customised silver struts and wire attachments used as a retentive aid; Acrylic mock trail substructure for evaluation of the efficacy of the retentive aids used. Definitive silicone prosthesis attached through the struts and customised silver wires as retentive aid.

</tr>
</tbody>
</table>

**Step 3: Wax Pattern Fabrication and Trial**

Trial pattern can be fabricated using modelling clay or wax. Modelling waxes are preferred. A wax pattern was carved by using the remaining natural ear as reference using modelling wax. A wax trial was performed to ascertain the appearance of the ear. For case 1 two wax pattern trials were made to mark areas of the remaining lobe for making channels for the silver struts and check for the ability of the customized retainers to hold the prosthesis in place. In Case 2 & 3 the acrylic substructure is fabricated with wax and fabricated separately with attachments embedded in them. Wax patterns were retained on these substructures using boxing wax during wax trial.
Step 4: Flasking, Coloration, Fabrication & Finishing of Prosthesis

Fabrication of mould for auricular prosthesis differs from fabrication of prosthesis for other defects. A three-piece mould is fabricated using dental stone (kalstone, kalabhai) and plaster (Neelkanth plaster) for packing of silicones. Shade matching is done and intrinsic stains (Functional Intrinsic II) are added to the room temperature vulcanizing silicone (RTV, Technovent). The mix is thoroughly spatulated to uniformity and packed into the moulds. After 12 hours of setting time, the prosthesis is retrieved. The excess is trimmed and the irregularities are grinded with a fine acrylic bur. The prosthesis is cleaned and a trial is carried out to check the fit of the prosthesis. Extrinsic shading (Technovent Extrinsic colours) is applied by dissolving shades in the RTV-silicone, the prosthesis is left to dry.

Step 5: Prosthesis Delivery

Case 1: (Figure 5 A)

Three holes were made corresponding to the ones made in the trail appointment in the prosthesis and the silver struts were inserted and closed through these holes, the rest of the margins were adapted to the adjacent skin and biological adhesive was used to blend the prosthesis with the surrounding skin.

Case 2 & 3: (Figure 5 B,C)

The acrylic substructure was glued to the prosthesis using cyanoacrylate adhesive and adapted on the implant.
Step 6: Prosthesis Post-Operative Care

The patients were taught how to handle the prosthesis and how to wear it. Use of mild soap was advised to clean the prosthesis. Instructions regarding follow-up and shelf life of the prosthesis were given to the patient.

Discussion

Cosmetic re-construction is one sure way to restore the original tissue, but many times the facial defects are extensive and surgery does not yield good result. Maxillofacial prosthesis is an effective and economic way of rehabilitating facial defects. Maxillofacial silicone is an aesthetic material which can be coloured or stained according to the complexion of the patient, it is easy to manipulate and has a close-to-natural texture. Intrinsic colouration is more stable than extrinsic but they are un-aesthetic as they are homogenous, humans have skin tone differences due to thickness of mucosa, vascularity, presence of cartilage. These are the rationales on which the decision to use RTV-Silicone and extrinsic coloration are based.

Facial defects cripple the patient in a psychologically more than any other aspect. The acceptance of the prosthesis plays a major role. Retention provides psychological comfort to the patient and thus by relation is one of the most important necessity. Literature has discussed numerous ways to retain extra-oral prosthesis.

Adhesives are one of the most popular retentive aid in maxillofacial prosthesis retention. Silicone adhesives are basically RTV-Silicones which are diluted in volatile solvents. On the evaporation of these solvents the set adherent silicone is left which helps in retention. In case 1 there has been use of custom-made silver attachments along with adhesives, the adhesives blend in the thin margins of the prosthesis while the attachments provide the major share of retention. It was a less invasive and economic method for rehabilitation.

Craniofacial implants are used for retention of extra-oral maxillofacial prosthesis as they provide excellent support and retention, this leads up to the improvement in patients appearance and quality of life. According to clinical studies, a minimum of two implants are required to retain an auricular prosthesis.

Ball and socket type of attachment are also effective way of retaining the prosthesis, it is easy for the patient to wear such a prosthesis. the ball and socket type of assembly require the abutments to maintain parallelism so as to facilitate single path of insertion for the prosthesis without shear stress on the implant.

Bar-clip retention is one of the forms of retention used in the auricular region. The limitations of such attachments are that they limit access for cleaning the implant area and patient faces difficulty in insertion and removal of prosthesis. Thus this case series of rare defects found gives us the insight about the multidisciplinary team involved and pivotal role of each member. Role of a Psychiatrist post rehabilitation also contributes to a major extent, the patient is counselled for the same. Rehabilitation of these defects boosts the confidence in the patients and thereby developing a feeling of completeness. Patients become socially active gradually and carry out their routine effectively without denial, hesitation or self-doubt. Thus, the prosthesis not only restores the anatomical defect but also relieves psychological distress.

Conclusion

Facial defects are psychologically traumatising, it is a social stigma. Rehabilitation is not the only treatment which solves these problems. The inflictions of this trauma are deeper than the defects itself. Communication is the key to alleviate this issue. A good quality of life does not stem from treating the problem but helping the patients to recognise that life is beyond the defect. Comprehensive care is deliverable by the dentist as it is him/her who the patient has opened up to.

Prosthetic Rehabilitation of a Patient with Symptoms of Iron Deficiency Anaemia in association with Fraser’s Syndrome – A Case Report

Sweta Kale Pisulkar1, Chinmayee Dahihandekar2, Seema Sathe3, Surekha Godbole4, Gajanan Pisulkar5
1Associate Professor, 2PG Student, 3Professor & Head Of Department, 4Professor, 5MS (Orthopedics), Department of Prosthodontics, Sharad Pawar Dental College and Hospital DMIMS, Sawangi, Maharashtra

Abstract

About a quarter of the population in the world is affected with Anaemia and deficiency of iron is one of the major causes. Associated symptoms are long term fatigue, cognitive function which shows impairment, and decreased well-being. “Fraser syndrome” can be described as rare, genetically inherited disorder. It is manifested as Cryptophthalmos, Syndactyly along with Enamel Hypoplasia because of which the patient is referred to a dentist. The following report presents the report of a male patient who had symptoms of iron deficiency anaemia and also showed signs & symptoms of Fraser’s Syndrome. Proper knowledge regarding Fraser’s syndrome and iron deficiency anaemia is imperative to plan an oral rehabilitation treatment protocol for such patients.

Keywords: Iron Deficiency Anaemia, Fraser’s syndrome, Enamel Hypoplasia, Ocular Prosthesis.

Introduction

The main objective for the patients with Iron deficiency Anaemia is facilitation of the understanding and curing measures of the primary causative condition and avoidance of the treatment measures which are invasive and the risks with come along with it.1

The World Health Organization(WHO) has defined iron deficiency anaemia as the one which has haemoglobin values “Less than 7.7 mmol/l (13 g/dl) in men and 7.4 mmol/l (12 g/dl) in women”. Iron deficiency anaemia is characterized by microcytic, hypochromatic erythrocytes and depleted stores of iron in the body. The oral signs and symptoms include sensation of burning of the oral mucosa, lingual varicosity, xerostomia, Oral Lichen Planus, reduced sensory sensations of the oral mucosa and taste dysfunction.2

“Fraser syndrome” was first illustrated in the year of 1962 characterised by Syndactyly, Cryptophthalmos, oral clefting, genitor-urinary malformations, and laryngeal stenosis. The main cause is said to be mutations in “FRAS1”, “FREM2”, or “GRIP1” genes.3

The guidelines for diagnosis of the “Fraser’s syndrome” is given by Thomas et al(1986) which states that the diagnosis meets in those patients which contains at least of two of the major criteria and minimum of one minor criterion or one of the major criterion and four of the minor criteria.4

Oral Manifestations for the syndrome include facial asymmetry, cleft palate along with conditions like Enamel Hypoplasia. Most common signs and symptoms which the patient presents are cryptophthalmos and, syndactyly.  

**Case Report**

A 24 year old Male patient reported to the private dental clinic with the chief complaint of missing teeth, caries and poor aesthetics. He was born second to the consanguineous parents. During his childhood he went multiple surgeries to correct genitalia abnormalities. The patient was born without one kidney and has not undergone any treatment for the same. His intellectual level was normal and no history of any medical disease or disorder was seen in the family.

Ophthalmologic examination showed cryptophthalmos with loss of vision. Head, Face and Neck check up demonstrated hypertelorism which was mild, slight facial-asymmetry and slight reduction in lower facial height. (Figure Nos. 1)

Oral examination indicated microdontia which was generalized in nature and involved dentitions of arches with reduction in their size. He had poorly developed teeth with oral hygiene which was diagnosed with gingivitis and Hypoplasia of the enamel. Patient had reduced taste sensations and burning in oral mucosa which further hinted for diagnostic tests for Iron deficiency anaemia. Teeth present were 11-18, 21-28, 31-37 and 41-47 with grade II mobility seen with 11, 21, 31, 41 and 42. Radiographic examination showed teeth with short roots. (Figure No. 2)

**Management of Anaemia due to Iron Deficiency:**

Blood tests were done to estimate the Haemoglobin level which revealed 11g/dl value. The peripheral smear showed hypochromic, microcytic, erythrocytes and low iron stores. (Figure No. 3)

Invasive tests like anti-parietal cell antibody, celiac serology, Stool sample was tested for H. pylori infection & faecal occult blood test were carried out. Iron replacement therapy was initiated to check the response for a span of 4 to 8 weeks. There was considerable improvement in the haemoglobin level of the patient (14g/dl) and follow up was carried out after 3 to 6 months.

**Dental Rehabilitation:**

To meet the requirements of the patient, a complete tooth supported overdenture was considered. A proper sequential treatment protocol was planned. Teeth with compromised periodontal support were extracted and Elective Endodontics was implemented in the remaining teeth and the preparation was done in a dome shaped contour which could receive copings.

Custom post patterns were fabricated and an impression was made. The copings were finished and polished and luted to the abutment teeth with the help of GIC luting cement (Figure No. 4).

After primary impression, border moulding was done and secondary impression was made. After Jaw Relation and a successful try in, processing was done using heat-cure acrylic resin. The denture was well accepted by the patient and had satisfactory results in terms of aesthetics and function.

**Occular Rehabilitation:**

An acrylic special tray with holes and a syringe tip was made for impression procedure (Figure No. 5). Impression was made using light body elastomeric material. Indentations were marked for proper orientation of the cast which was obtained with respect to fabrication of further wax pattern. The wax pattern was fabricated so as to resemble and simulate the eye which was lost. The stock scleral eye was opted after comparing with the normal eye of the patient. That iris from the stock eye shell was embedded in the pattern. (Figure No. 6).

Flasking and Dewaxing was carried out for the adapted wax pattern. Packing was done with Self-cure tooth colour acrylic Polymerizing resin. After finishing and polishing spectacles were used to make the borders of the ocular prosthesis inconspicuous. Necessary instructions for placement, cleaning, and prosthesis removal were given to the patient. Regular follow up appointments were scheduled (Figure No. 6).
(Figure No. 1 Extraoral Examination of the patient showing reduced lower face height)

(Figure No. 2 Radiographic examination showed teeth with reduced face height)

(Figure No. 3 Peripheral Smear showing Microcytic, Hypochromic anaemia)

(Figure No. 4 The Metal copings Finished, Polished and Luted)

(Figure No. 5 An acrylic special tray with holes and a syringe tip was made for impression procedure)
Discussion

There are several studies which state the importance of immediate and prompt care for the patients with anaemia associated with iron deficiency. It not only eradicates fatigue related symptoms but also elevated the level of quality of life. The treatment of iron deficiency anaemia associated with certain specific syndromes should be undertaken according to the guidelines of the specialist.

The oral supplemental therapy of iron deficiency anaemia may be limited to the patients which do not manifest gastrointestinal signs and symptoms such as cramps in the abdominal region and nausea along with vomiting. Intravenous iron therapy is another alternative for oral iron replacements that is indicated for the patients with blood loss more than 10 ml/ per day.

Fraser’s Syndrome is an autosomal dominant but a rare disorder. Oral manifestations which were met by the patient were as described earlier which included short roots, retained deciduous teeth including Enamel Hypoplasia. After diagnosis of anaemia caused by iron deficiency, identification of the cause should be done or else it will lead to recurrence even after proper treatment protocol.

Cardiovascular abnormalities which are seen in patients with Fraser’s Syndrome include coarctation of aorta, valvular stenosis, ventricular septal defect, atrial septal defect, and cardiomyopathies. If any involvement of cardiovascular system is seen, the protocol regarding infective endocarditis to decrease the microbial load should be carried out. When any sort of Renal Involvement is seen nephrotoxic drugs should be avoided.

Conclusion

Anaemia due Iron deficiency is the major cause of fatigue and impairment in the cognitive function and diminishes the quality of life which is all the aspects of “Health status”, “Lifestyle”, “Life satisfaction”, “Mental health” and “Well-being” reflecting together in an individual. It is an important health outcome and hence Iron deficiency anaemia should be treated upon diagnosis.

Proper knowledge of oral and dental features is definitely going to help with identifying the Fraser Syndrome. Dentistry should reconsider the recent aesthetic approach keeping in account of previous data working its way for successful prosthetic rehabilitation.

Increased Demand of Emergency Medical Services in Covid-19

Vaibhav Vikas Bisne

Medical Intern, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Sawangi (Meghe), Wardha, Maharashtra, India

Abstract

The World is going through a tough situation and that is a pandemic caused by the Novel Corona virus which originated in the Wuhan Province of China in December 2019. During this tough and critical situation, the only saviors of humanity are our health care professionals, who restore the faith and trust in humanity and ensure the safety of each individual suffering from this COVID-19 disease. The cherry on the cake is the additional health support provided by the staff of Emergency Medical Services who help the health care workers in treating the patients in hospital, by giving the pre-requisite or the initial treatment during this emergency situation. So to tackle this pandemic, it is important to meet up to the increasing demand of Emergency Medical Services so that the situation remains under control and there is a decrease in mortality. The fragile and fragmented healthcare system of India needs to be upgraded and emphasis needs to be put on developing the Emergency Medical Services so as to strengthen the healthcare system as a whole and to make living better.

Keywords: fragile, proactive protocol, episodic care, emergency medical services, increased demand

Introduction

No one can deny the fact that the world has changed dramatically in just a matter of few months due to spread of Novel Corona Virus, COVID–19. This COVID-19 is a member of SARS family CoV- 2 Virus and was identified in Wuhan, China in December 2019 and has rapidly spread across the world. India being the second most populous country after China, the presence of this virus in a patient was first detected on 30 January 2020 in Kerala. Being an agronomical (agricultural-based economy) country, the majority of population stays in rural areas and access to health care facilities is difficult. To restrict the spread of the virus in India, a series of lockdown were instituted and as on 8 July 2020 there are 7,46,506 cases and India is ranked 3rd in the world as far as the number of cases are concerned. As the number suggests a diffuse spread of this disease in India, Maharashtra and Tamil Nadu are amongst the worst affected states with both of them nearly contributing around 50% of total cases.

India’s healthcare system is fragile and fragmented. Considering this type of healthcare system during the pandemic caused by Corona Virus, there is immense requirement if Emergency Services at utmost priority.

Emergency Departments are medical treatment facilities which cater to provide episodic care to patients suffering from acute injuries and illness as well as patients who are experiencing sporadic flare ups of underlying chronic medical conditions which require immediate attention. Hence to tackle this pandemic, there is increased demand of Emergency Services and it also highlights the importance of Emergency Medical Services, its education training in a developing country like India.

Reviews

Public health emergencies like pandemic put enormous burden on healthcare systems while revealing deep structural and functional problems in organization care. These difficult times require ones healthcare system to press on acceleration lever and to increase the efficiency of emergency healthcare services and at the same time taking utmost precautions so as to prevent the spread while giving the treatment. (1)

One to this pandemic, there has been an increased need of re-organizing our healthcare system. There has been a complete saturation of healthcare capacities and service. Emergency Medical Services play an important role during this pandemic. (2)
There has been a consistent rise in the number of cases day-by-day. This COVID-19 being an infectious disease, known to be spread by aerosol transmission and affecting mainly the respiratory system of humans, has caused many mortalities especially affecting the older age groups. The increased mortality in older age groups (more than 60 years) is also due to other related comorbidities like Diabetes Mellitus, Hypertension, Bronchial Asthma, Tuberculosis, Immunocompromised patients, cancer patients. Considering these group of patients with underlying comorbidities, most of them are bound to arrive in casualties requiring medical attention at priority in the form of Emergency Medical Services. Emergency Medical Services take into consideration all cases related to any system or organ involved in human body.

During this pandemic caused by COVID-19, the healthcare professionals posted in Emergency Medical Services Department need to wear PPE (Personal Protective Equipment) for their protection. A COVID-19 positive patient with underlying comorbidities may present with attack of asthma, respiratory distress, attack of stroke, Myocardial Ischemia or heart attack, and in such cases immediate medical attention is required. Due to these underlying comorbidities, there have been rise in deaths in India, so somewhere in order to save lives, there is the need of Emergency Medical Services during COVID-19.

To save the lives of these patients EMS professionals have to follow a proactive protocol, just like that followed in a natural disaster “Triage”. There needs to be increase in the amount of medical equipment required in healthcare facilities. Proper PPE (Personal Protective Equipment), ventilators, emergency drugs, ambulances need to be made available and hence their production needs to be increased. These Emergency Medical Services provide urgent pre-hospital treatment and stabilization for severe illness and injuries. It plays an important role in saving life of patients as they carry the patient to healthcare facility and treat them during the transportation time.

So as to enhance the effectiveness of the Emergency Medical Services in India during this pandemic, a proper hotline number should be created so that people have easy access to these Emergency Medical Services as soon as possible. As the spread of COVID-19 is rising exponentially, there should be deployment of ambulances in these zones where there is increase in number of cases, so that during any emergency to a patient, there is easy access to Emergency Medical Services and patient reaches the nearest healthcare facility as soon as possible. As there is increased demand during this pandemic, there should be increased emphasis in training of health professionals in field of Emergency Medical Services. Basic courses like first aid training, Advanced Cardiac Life Support, Basic Life Support, suturing, catheterization should be instituted and made sure health professionals are qualified enough to provide these to patients during emergency. Availability of air-ambulance wherever necessary and required.

As major population of India lives in rural areas, establishment of Emergency Medical Services during COVID-19 pandemic is of utmost importance. Posting of health professionals in rural Primary Health Centre along with availability and access to Telemedicine care will help provide Emergency Healthcare Services to the poor people living in remote areas and help save their life and decrease mortality rate. To make use of the potential of the youth population (especially in the rural areas) and training them to provide basic emergency services during this pandemic will provide aid in decreasing the burden on healthcare professionals. Timely healthcare provided in Emergency Medical Services during this pandemic will help save life of many people and hence justify the statement “Doctors are equal to God” and will help to bring back the faith and trust of people on Doctors. During this pandemic of COVID-19 a major role has been played by Emergency Medical Services efficiently so as to reduce the mortality rate in our country. But as there has been an increased demand of Emergency Medical Services the call volume has explicitly increased on the emergency medical number, thereby leading to unavailability of Emergency Medical Services in remote locations. Hence, a separate Coronavirus Helpline Number should be created so as to streamline the process and help in timely availability of Emergency Medical Services in such localities.

Accessibility and availability of Emergency Medical Services through the use of technology i.e. Tele-Health
for places which are remote and difficult to access. It can be a useful and an efficient option. This portal of technology will help in providing immediate care to patients without the need for any medical professional to go and visit personally. A team of Emergency Medical Services should be made which will cater to needs of people through Tele-Health. (19)

Emergency Medical Services play a major role in trauma and Department of Orthopedics, (20) and during this pandemic there are incidents occurring that have caused disruption and affected the efficiency of Emergency Medical Services. This pandemic is similar to disaster and hence to bring out the maximal (21) output of our Emergency Medical Services is of utmost importance. It is a challenging task to provide adequate Healthcare during this pandemic so there is a need to expand on our Emergency Medical Services so as to make things easier. This Coronavirus outbreak has led us to utilize our resources of medical importance and cater to need of patients and even the Healthcare Professionals. It has led to paying heed to strategizing the need to provide urgent medical healthcare through our Emergency Medical Services. (22)

So as to provide Emergency Medical Services efficiently, the staff working needs to have access to proper N95 respirators, Personal Protective Equipment (PPEs) (23), sanitation practices, and other established safety protocols during COVID-19. Early identification (24) of cases in Emergency Department, which present with symptoms similar to COVID-19, can help restrict the spread of this disease and hence Emergency Medical Services Healthcare Professionals play an important role in this situation of the Coronavirus pandemic across the globe. (25)

**Discussion**

Emergency Medical Services are an integral and important part of health care system and hence are needed during this pandemic. SARS (Severe acute respiratory syndrome)- Corona virus-2, causes COVID-19 disease, is highly contagious and is the causative agent behind this pandemic. (26)

To bring about the effective output of Emergency Medical Services during this pandemic, the fragile and fragmented healthcare system of India needs to form a bridge so as to connect all the aspects of healthcare and to ensure the increased demand. Financial support should be provided by The Government which would be of immense help to meet the rising demand of Emergency Medical Services during this pandemic. (27) The constituents of healthcare which includes Doctors, nurses, Emergency Medical Services staff, ward boys, ambulance drivers and pharmaceutical professionals need to come along together to execute a proactive plan so as to bring about maximum and effective output and help save lives of patients. (28)

Pharmaceutical professionals have important and significant role to play in Emergency Medical Services. Timely availability of emergency medications to the Emergency Medical Services provider staff will help save lives of the patients who are having underlying comorbidities and are also suffering from Corona virus infection. The onus of clinical decision making is less in hands of pharmaceutical professionals in India, so this responsibility of decision making needs to be given to professionals to some extent, so as to bring about rapid response in case of emergencies (29)

Due to this pandemic, there has been an undue pressure on healthcare system of our country and hence so as to release the pressure on the health care system, it is time we require efficient tools for smart governance and resource allocation. To cater this need, we need to stabilize and improve the Emergency Medical Services so that the life of patients is saved. The increased demand of Emergency Medical Services along with their timely action would help to ease out the pressure and decrease the burden on healthcare facility and prevent it’s saturation. (30)

Emergency Medical Services usually include fundamental principles of managing airway, emergency tracheal intubation, cardiac arrest, stroke patients, anesthetic care , Basic Life Support training and hence to meet the increased demand during pandemic, we need to increase the efficiency of the working staff so as to bring about a better output. As a safety measure, prevention is better than cure. So basic precautions like hand hygiene (31): avoiding undue movement and travel (32,33,34) can help a lot to prevent the spread of Covid-19. Also measures need to be taken to reduce depression, anxiety and stress among the general population(35).
Conclusion

During this pandemic, it is of utmost importance to be safe, stay indoors and follow healthy sanitary practices. The improvement in healthcare facilities of our country has led to an additional support in treating these patients suffering from COVID-19. The need of the hour is increased qualitative and quantitative efficacy of Emergency Medical Services so as to meet the increasing demand and also put an emphasis on the development and improvement of Emergency Medical Services so as to help tackle any situation in near future with great ease.

Effect of Fluoride Contaminated Groundwater on Human Health in Fluorosis Endemic Areas

Abhyuday D Meghe¹, Deepak B. Malpe², Dhananjay C. Meshram³
¹Chief Executive Officer, Acharya Vinoba Bhave Hospital, Datta Meghe Institute of Medical Sciences, ²Professor, P.G. Department of Geology, R.T.M. Nagpur University, Nagpur, ³Professor and Head, Department of Geology, Savitribai Fule Pune University, Pune

Abstract

Background: Fluorosis is an endemic health problem in twenty-five nations around the globe. Objectives: To correlate fluoride content of groundwater and health status of affected population and suggest remedial measures. Methodology: A cross-sectional research design is followed because people from different age groups were sampled, observations were made and skeletal examinations were conducted at a specified point of time. The study is conducted in Yavatmal and Chandrapur districts of Vidarbha region of Maharashtra State. Health related surveys were carried out in 54 villages from study area selected on the basis of high fluoride level in groundwater. Result: Out of these, 32 villages are selected from Yavatmal district having a population of 30320 and 22 villages from Chandrapur district with a population of 21581. Out of the total population of 51901 total 3268 subjects have been examined. Amongst these subjects 1760 were male (53.86%) and 1508 were female (46.14%). Out of the total 3268 subjects 2445 subjects included in the ‘normal’ grade, which does not show indications of skeletal fluorosis. It has been observed that as the concentration of fluoride increases the cases of ‘normal’ grade decreases. Out of the 360 subjects studied, about 102 (28.33%) subjects show radiological evidences of skeletal fluorosis. Mild radiological fluorosis was seen in 55, moderate in 21, severe in 17 and very severe radiological fluorosis in 9 subjects. Conclusion: Based on the outcome of the research work carried out in the study area, it is recommended that awareness among the people residing in the area about the protection & prevention of groundwater contamination from different sources, groundwater quality, its impacts on health, soil and plants should be created on priority basis.

Keywords: Fluoride Contaminated Groundwater, Human Health, Fluorosis, Endemic Areas

Background

Groundwater has become the major source of water supply for domestic, industrial and irrigation sectors of many countries. Fluorosis is an endemic health problem in twenty-five nations around the globe (¹,²,³) It is a conclusive fact that concentration of fluoride between 0.6 to 1.0 mg/L is essential in potable water to protect teeth decay and enhance bone development, while their higher concentration may lead to fluorosis (³). Central Ground Water Board (⁴) and Groundwater Survey and Development Agency (⁵) carried out studies on occurrences of fluoride in groundwater in Maharashtra state which falls under second category, where 40 to 70 % of the districts are affected. The endemic districts are Bhandara, Chandrapur, Nanded, Aurangabad and Yavatmal, where up to 13.4 mg/L fluoride has been reported (⁴). Though work pertaining to groundwater quality, hydrogeology, groundwater resource estimation, development and management have been carried out in parts of study area, detailed health related studies including effect of high concentration of fluoride in groundwater on human health have not so far been carried out in the present area. Therefore, objectives of

Datta Meghe Institute of Medical Sciences
the present investigations to correlate fluoride content of groundwater and health status of affected population and suggest remedial measures.

Methodology

In the present study, effect of fluoride on human health is studied and relationship with skeletal and radiological findings is explored. A cross-sectional research design is followed because people from different age groups were sampled, observations were made and skeletal examinations were conducted at a specified point of time.

**Study Setting and Location:** The study is conducted in Yavatmal and Chandrapur districts of Vidarba region of Maharashtra State. The study includes Ghatanji, Kelapur, Maregaon, Wani talukas from Yavatmal District and Warora, Bhadrawati and Chandrapur talukas from Chandrapur district. Prior to the commencement of the study, permission to conduct the research investigations was sought from the Institutional Ethical Committee, Datta Meghe Institute of Medical Sciences (Deemed to be University). Following considerations were taken into account during the planning and execution of the study. The data of fluoride level in groundwater received from Groundwater Survey and Development Agency (GSDA) for study area have been used.

In the present work, BIS recommendations have been used for the desirable level of fluoride in groundwater (1mg/L) as the study area comes under semi-arid climate and surveys have been carried out in rural and tribal part of Yavatmal and Chandrapur districts where most of the population is farm laborers or working laborers in quarries or mines and their per day consumption of water is 3 to 4 liters/day/person. In view of this fluoride level in groundwater has been divided into four groups namely ≤1mg/L, 1.01 - 2.00mg/L, 2.01 - 4.00mg/L, >4.01 mg/L. Safe level of fluoride in the potable drinking water has been considered as 0.5mg/L desirable and 1.0 mg/L as maximum allowable concentration (6).

In the present work, BIS recommendations have been used for the desirable level of fluoride in groundwater (1mg/L) as the study area comes under semi-arid climate and surveys have been carried out in rural and tribal part of Yavatmal and Chandrapur districts where most of the population is farm laborers or working laborers in quarries or mines and their per day consumption of water is 3 to 4 liters/day/person. In view of this fluoride level in groundwater has been divided into four groups namely ≤1mg/L, 1.01 - 2.00mg/L, 2.01 - 4.00mg/L, >4.01 mg/L. Safe level of fluoride in the potable drinking water has been considered as 0.5mg/L desirable and 1.0 mg/L as maximum allowable concentration (6).

Health related surveys were carried out in 54 villages from study area selected on the basis of high fluoride level in groundwater. Out of these 32 villages are selected from Yavatmal district having a population of 30320 and 22 villages from Chandrapur district with a population of 21581. Out of the total population of 51901 total 3268 subjects have been examined. These

54 villages are selected Primary Health Centre (PHC) wise and total 2 villages are selected from 26 PHC, while from Durgapur and Guggus PHC of Chandrapur taluka, one village each is selected. From each taluka two villages are selected having fluoride level ≤1mg/L, 1.01 - 2.00mg/L, 2.01 - 4.00mg/L, >4.01 mg/L. In Chandrapur taluka >4 mg/L fluoride level is not present in the groundwater and therefore two villages from this category have not been selected.

**RECRUITMENT AND SAMPLING PROCEDURE**

A nonprobability convenience sampling technique was used in the study, as the samples were restricted to a part of the population that was readily available and true random sampling would have been difficult to achieve due to time, cost, and transportation limitations. To start with, 3602 potentially eligible subjects were identified which were examined for eligibility. Out of this, 3268 subjects were confirmed eligible and were included in the study. All these 3268 subjects gave consent to participate in the study and so were investigated and their data was analysed. 334 subjects were excluded from the study because they either met exclusion criteria or were not willing to participate in the study because of social reasons or lack of availability of time.

**Data Collection Procedures**

The participants were evaluated according to pre-designed protocol. They were explained the purpose of the study and were requested to participate in it. Each participant was interviewed and examined. The purpose of the questions was to extract a brief medical history and to identify pre-existing risk factors for skeletal deformity. The formulation of the questions was same for all the participants to ensure reliability.

**SKELETAL INVESTIGATIONS**

In the present work, during the clinical examination, base line data was collected using the proforma, while incidence of skeletal fluorosis has been assessed on the basis of physical tests designed for assessing the pain in the joints (2). Classification of skeletal fluorosis based on the clinical and radiological examinations given by Teotia, M. and Singh, K.P. (6) has been used. Out of the
Results and Discussion

In the present work health related surveys were carried out in 54 villages selected on the basis of fluoride level in groundwater. The villages surveyed are 32 from Yavatmal district and 22 from Chandrapur district. Out of the total population of 51901 from these 54 villages, total 3268 subjects have been finally selected and examined. Amongst these subjects 1760 were male (53.86%) and 1508 were female (46.14%).

The fluoride level in groundwater has been divided into four groups namely first ≤1mg/L, second 1.01-2.00mg/L, third 2.01-4.00mg/L and fourth >4.0 mg/L. The participants are also distributed into three age groups. In the first group (≤18years) the subjects included are 1099 (33.63%). In the second age group (19 - 60 years) 1075 (32.89%) subjects and in the third age group (>60 years) total subjects included are 1094 (33.48%) (Table 1.1).

| Table 1.1 Distribution of studied subjects as per age group and F⁻ level in groundwater |
|---------------------------------|----------------|----------------|----------------|----------------|
| F⁻ level in groundwater         | Σ≤1.00 mg/L   | 1.01 - 2.00 mg/L | 2.01 - 4.00 mg/L | > 4.00 mg/L |
| Age Group                      | M  | F  | Total | M  | F  | Total | M  | F  | Total | M  | F  | Total |

|                                |          |          |       |      |      |        |      |      |        |      |      |        |
|                                |          |          |       |      |      |        |      |      |        |      |      | 100.0  |

Relationship of Skeletal Fluorosis with fluoride Level in Groundwater

Relationship of skeletal fluorosis with fluoride level in groundwater used for drinking purpose has also been studied and their details are given in table 1.2. The concentration of F in drinking water has been divided into 4 groups namely first (≤1 mg/L), second (1.01-2.00 mg/L); third (2.01-4.00 mg/L) and fourth (>4.0 mg/L).

As discussed earlier, out of the total 3268 subjects 2445 subjects included in the ‘normal’ grade, which does not show indications of skeletal fluorosis. It has been observed that as the concentration of fluoride increases the cases of ‘normal’ grade decreases. The remaining 823 subjects show symptoms of skeletal fluorosis. Present study showed that out of the total 823 subjects, 431 show the symptoms of ‘mild’ grade, where 60 subjects are from ≤1mg/L group. This could be due to long time of exposure to F⁻ intoxication and change in source of drinking water. Earlier they were using the drinking water with high concentration of fluoride and now shifted to the drinking water source having low concentration of fluoride.
Study by Teotia, M. and Singh, K.P.\(^{(6)}\) has shown that the clinical recovery of skeletal fluorosis is partially possible with supplementation of vitamin D and calcium. But in the present case as the subjects are from the rural and backward area where the food is habitually deficient in vitamin D and calcium no clinical recovery has been observed. Perusal of table 1.2 shows that as the fluoride concentration in the drinking water source increases, the cases of skeletal fluorosis increases. In the present case in all the grades (mild, moderate, severe and very severe) there is an increase in the number of cases of skeletal fluorosis from ‘mild’ to ‘very severe’ as the fluoride concentration in drinking water source increases. This has also been observed by Nirgude et al\(^{(7)}\) during their studies in Gadag and Bagalkot districts of Karnataka, Punjab, Nalgonda and Rajasthan areas respectively.

Surprisingly, in the areas where fluoride levels of drinking water is not very high and is in the range of 1-2 mg/L, the cases of skeletal fluorosis have been observed. The proposed possible mechanisms for such severe manifestations may be: (a) high atmospheric temperatures (115-116°F) during summer months, (b) hard physical labor activity, (c) poor nutrition, deficient in calories and vitamin C. Similarly, it is now established that diseased kidneys cannot handle fluoride excretion leading to F- toxicity and development of skeletal fluorosis even while consuming low levels of F- in drinking water supplies \(^{(8)}\).

### Radiological Studies

In the present work, classification of skeletal fluorosis based on the radiological examinations given by Teotia, M. and Singh, K.P. \(^{(6)}\) has been used (Table 6.5). On the basis of radiological studies they suggested mild, moderate, severe and very severe grades depending on the basis of intensity of the fluorosis.

Out of the total 3268 subjects studied, 360 subjects are subjected to radiological investigations at Acharya Vinoba Bhave Rural Hospital, Sawangi Meghe, Wardha. Out of the 360 subjects studied, about 102 (28.33\%) subjects show radiological evidences of skeletal fluorosis. Mild radiological fluorosis was seen in 55, moderate in 21, severe in 17 and very severe radiological fluorosis in 9 subjects. In general, in male
the radiological fluorosis is more as compared to female. In ‘moderate’ and ‘very severe’ grades the radiological fluorosis in female is marginally more as compared to the male subjects (Table 1.3).

**Conclusion**

Based on the outcome of the research work carried out in the study area, it is recommended that awareness among the people residing in the area about the protection & prevention of groundwater contamination from different sources, groundwater quality, its impacts on health, soil and plants should be created on priority basis.

Creating environmental awareness among the people about the habit of safe drinking water, side effects of drinking high fluoride rich groundwater, improving oral hygiene conditions and handling of defluoridation instruments is essential in effective mitigation of fluorosis.

Regular health surveys and Periodic monitoring should be conducted in the affected areas to assess the health impacts of high concentration of fluoride and NO$_3^-$ present in groundwater, especially in infants and children residing in the area.

More emphasis may be given to intake of calcium and phosphorous rich food as it helps in reducing the absorption of fluoride by intestine and also reduces the rate of accumulation of fluoride in human body.

As abundance of fluoride is more in deep aquifers (bore wells) compared to shallow aquifers (dug wells), the groundwater from shallow aquifers are safer and should be preferred for drinking purpose, if nitrate and other contaminants are within the safe limits.

Water quality management in the area should be carried out considering the hydro-geochemical conditions existing in the area and influence of geogenic and anthropogenic factors on physico-chemical characteristics of groundwater.

Defluoridation technique like Nalgonda, reverse osmosis, activated alumina and other techniques may be adopted in areas where no alternative source is available with the involvement of community in operation and maintenance. Recharging centres for the household activated alumina filters for defluoridation of groundwater shall be set up at each affected village.

The planners, policy-makers and public should become more aware of programme concerned with the
sustainable management of groundwater quality.

Integrated fluorosis mitigation approach in the form of dilution of groundwater through artificial recharge, nutritional supplement through food intake and use of cost-effective and environmentally friendly adsorption based defluoridation techniques should be adopted in dealing with fluorosis problems existing in the area.

Abstract

Objective: This paper aims to describe the findings on quality, health, and safety guarantee of fish catch and the related regulations in the Governmental Decree No. 57 of 2015. Method: This research uses the juridical sociologic research method, with the descriptive qualitative approach, which describes the guarantee of quality, health, and safety of fish catch based on the Governmental Decree No. 57 of 2015. Results: It is found that there are violations in the form of an unhygienic method in processing the fish catch. In the Fish Auction Center, the processing uses chemical substances which are prohibited for food. Conclusion: The government should make a policy which support the fishermen, so that they may use a safer and a healthier method in processing fish.

Keywords: Quality Guarantee, Health, Fish, Seafood, Regulations

Background

The handling of the various problems which are the cause of food safety hazard regarding the fish-catching activity started from the activity in catching fish to the end consumers. The food safety system in the fish agroindustry include Good Manufacturing Practices (GMP), Standard Sanitation Operational Procedure (SSOP) and Hazard Analysis and Critical Control Point (HACCP).¹ For the sales of domestic fish commodities or products, the fish catch of the fishermen are directly brought to the distributors to fulfill the demand of fresh seafood or to fulfill the demand of primary or secondary fish-processing industries.

Food quality and safety cannot be separated when discussing about seafood products. This is based on the fact that fish is included as highly perishable food. Thus, there must be high attention to the efforts to maintain the quality and safety of the products. Food products such as fish and its produces must be required to fulfill some food health and safety standards before being consumed.²

The fishermen have a crucial role in maintaining the health and safety standards of those fish. In the food industry, it is a must for the businessowners to pay attention to the safety of the food products so that the products may be accepted with superior quality.³

To guarantee the fish catch quality of health and safety, the Fishery and Sea Service of North Maluku worked together with the Fishery and Health Service of Ternate City to establish the fish catch guarantee of quality monitoring in the fish ports in the Fish Auction Center which was participated by fishermen, processing,
and marketing representatives.

In this activity, the head of the Fishery and Sea Service of North Maluku, M. Buyung Rajiloen, S.H., M.H. (personal communication, June 2020) stated that, “It is crucial to guarantee the health quality of the fish products in this fishery port to increase the fish catch health and safety quality for the people to consume. The increase of fish catch quality by the fishermen, the processors, and the marketers in Madya Ternate city may increase its price, which will surely increase the income of the fishermen.”

The increase of health safety and quality on the fish for consumption may be carried out after the fish caught by the fishermen by using the cold chain system. This system is crucial as fish have a high level of water and protein, which makes them prone to rot. The most effective method is by maintaining the fish’s temperature in a fresh condition when arriving at the port.4

Research Methods

This study used a sociological juridical research method with a qualitative descriptive approach, to describe the quality assurance, health and safety of fish catch based on Government Regulation No. 57 of 2015. Descriptive method is used to describe and explain the factual conditions during the research, examining how the Quality Assurance, Health and Safety of Fishing Products in North Maluku.

Discussion

The government actually has often socialized to fishermen, managers and the marketing department to not cheat in using additional materials which are prohibited by the government such as formaldehyde, rhodamine, and others. This needs to be conveyed in order to maintain the positive aspirations of processed fishery products from North Maluku province, such as Fufu (smoked fish), tore (roasted fish), salt (salted fish), ngafi (anchovies) and balacan (shrimp paste).

Mrs. Ivon as the head of quality development and verification from the Marine and Fisheries Office of North Maluku province conveyed the processing (SKP) from the Health Office of the Madya Ternate city, the head of the Drug and Food Monitoring Ternate Post, Drs. Karim Latu Consina Apt, M. Kes as the head of drug and food control delivered material about the assurance of safety and quality of food quality that will be marketed to the community.

Poor handling practices may lead to microbial contamination and may accelerate the rate of spoilage of fish5. Food safety, especially seafood, continues to be a problem for people around the world. Inappropriate food handling is caused by a lack of knowledge about food safety6. The fish catch requires special handling to keep the fish fresh. Handling of fish on board includes all actions against catches on board, from initial action to storage. This aims to maintain the quality or quality of fish according to the certain standard7.

The fishing method (a type of fishing gear) is directly related to the way the fish die and the way the fish die is related to the physical and chemical processes that the fish body experiences in post-fishing. The government’s concern for quality assurance of fishery products is quite high, it can be seen from the laws and regulations or policies that have been established, namely where these processes have a direct effect on fish quality.8 The poor quality of fish can cause the sales price of the fish to decrease9 as this has been regulated in the Government Regulation of the Republic of Indonesia Number 57 of 2015 concerning the System of Quality Assurance and Safety of Fishery Products and Increasing the Added Value of Fishery Products.10 The cleanliness of the tools, the deck of the ship, the containers used are an effort to reduce contaminants in fish11.

The absence of a clean seawater-cooler machine renders the facility regarded as inadequate or not fulfilling the standard. According to Nurani et al.12, Ships with a refrigerated seawater system or RSW is better in implementing the quality standard compared to ships with a cooling system using ice blocks.

The fish-catching equipment which must be fulfilled by the fish-catching ships are as follows: 1) The tools and equipment must be kept clean; they must be kept in a good condition and must be ready to use. 2) There must be tarpaulin to protect the fish from the heat of the sun. 3) There must be a seawater pump. 4) There must be an adequate supply of ice to fulfill the need in sailing and in handling the fish after being caught. 5) The tools used to handle the caught fish must be maintained well. 6) There must be water/ice used to cool and to refrigerate.13
The requirements which must be met by the fish-catching ships regarding the role of the sailors are as follows: 1) the sailors must have the knowledge and the skills to catch fish, 2) the sailors have the responsibility to maintain personal hygiene and to maintain the ship’s facilities including the tools and equipment, 3) The ship’s crew who handle the fish must be in a healthy condition. s, 4) The ship’s crew must undergo a periodic health examination at least once a year.\(^{13}\)

The handling of the fresh fish by the North Maluku fishermen usually starts as the fish are brought up from their habitat in the sea. They are treated with low temperature. Sometimes, there is a lack of care regarding the factors of hygiene and health, even though the treatment, hygiene, and cooling process are the keys to produce fish catch of good quality. Only a small percent of motor boats bring ice to the sea. The fish hold used for it is usually far from perfect. There is a lack of sanitation and health factors when handling the fish on the boats. They do not keep the fish in a perfect condition, as some do not use chests or bulkheads, which makes the quality of the fish not good as they arrive on land.

Nasran\(^{14}\) states that, “The process of cooling the sea catch is included as a post-harvesting activity. The fishing ships are completed with holds, tanks, and fish containers (chests, drum). But none of those equipment are insulated. They bring some supply of ice and other supporting materials, such as salt, fish-packing materials, etc.”

The technical sampling analysis was carried out at six research locations in North Maluku. It was shown that dangerous additional chemical materials to preserve the fish in the form of formalin was found in three locations. Meanwhile, the rest of the three locations show a negative result. This shows that there are cases where dangerous additional chemicals were found in fresh fish, as concerned by the writer.

As we know, the fish catch products such as shrimp or fish which use the formalin preserving material have some characteristics. The characteristics include having a clean white color, springy texture, the gills are dark red instead of bright red, and the durability increases. Apart from that, the illegal additional chemical material in the form of formalin was also found on dried fish in four locations, meanwhile the other locations show negative results. Meanwhile, there is no proof of the presence of other illegal food additives such as borax and rhodamine B.

As described above, the evidences on those cases have been obtained from the survey results in the visited venues of fish-processing. Usually, the formalin chemical preservative is used on fresh fish or dried fish by the processor to fulfill certain market segments which demand springy and durable fish\(^{15}\).

Technically, the processors consider the effectiveness and the quality of a better preservative, which is usually present in non-food preservatives. For that reason, many of the fish processors use formalin as fresh fish or dried fish preservatives. Apart from that, the use of formalin in food cannot be separated from macro policies which are implemented by the government.

The increase of the gas price which happened also influenced the income of the fishermen. The impact of that policy is seen from the increase of the production price. This makes the solar gas rarer and more expensive. The materials which must be brought to the sea become more expensive, including the ice blocks which are usually used to preserve fish by the fishermen.

Regarding the issue of formalin usage by the fishermen, marketers, or processors in the research venues, most have real impact to the fish demand. The people do not care about the fish they consume. The perception formed is that all fish marketed contain formalin. The impact is that the consumers will be scared or will have antipathy towards fish. Even though not all fish industries will be impacted, but this will make the people concerned as this will have direct impacts towards the income of the fishermen, the processors, or the sellers.

The government needs to formulate policies which support the fishermen, so that they may have the capability to use a healthier and a safer method. Without a pro-fishermen policy, thus the Republic of Indonesia Governmental Decree No. 57 of 2015 on the Quality and Safety Assurance System of Fish Produce and also the Increase of the Fish Produce Value becomes useless.

A one-sided decisive policy which is unbalanced by a pro-fishermen policy will be useless. The fishermen do
not have many choices in maintaining the fish products’ safety and health standard if there is no incentive nor protection in the form of policies which bring advantage to the fishermen.

The sociosphere (the social environment) of the fishermen in North Maluku actually encourage them to use the method which produces an unhealthy and an unsafe sea produce from time to time. They are influenced by a non-populist policy which makes the sailing cost higher and higher. They lost competition to the illegal fishing perpetrators who have better ships and equipment. The healthy method of processing fish becomes less and less affordable.

The sociosphere is the most important environment in determining the health of the environment. The sociosphere is an environment which is formed due to a rational relation between human beings to fulfill the needs or to seek solutions towards the many challenges and difficulties together.

There are some socio-cultural problems which cause the continual malpractice in using illegal chemical products as the additives to the seafood caught in North Maluku. There is a lack of the official authorities. There is a lack of socialization, coaching, and trainings on food safety. There is a low awareness of the processors and the society on the food produce safety and there is a lack of long-term thinking. The society has an eating habit which lacks attention to the safety of the consumed food to their health.

In the institutional aspect, there is a weak coordination, job delegation, authority, implementation, and technical realization in the field regarding the sales and the processing of the food with safety and quality assurance. This is stated by the Minister of Health, Siti Fadilah Supari which suggests that there is a lack of coordination in the National Agency of Drug and Food Control which causes the issue of seafood being preserved with formalin. She suggests that the National Agency of Drug and Food Control have neglected its duty and its authority in monitoring the food and drugs, which may endanger the health of the people.

### Conclusion

The handling of fish on the ship includes all treatments towards the fish catch on the ship, starting from the initial treatment to the storing. This aims to maintain the quality of the fish to match the desired standard. The indicator of a good treatment is that the fish catch has a good quality and is safe to be consumed. A bad quality of fish may cause the low price of the product in the market.

The government needs to formulate more policies which is pro-fishermen, so that they may use a safer and healthier method. The fishermen do not have many choices in maintaining the health and safety standard of the fish and its products if they do not receive incentives and if they do not have protection in the form of policies which put them on the upper hand.

The sociosphere of the fishermen in North Maluku actually encourages the fishermen to use unsafe and unhealthy methods in processing the sea produce. They are influenced by non-populist policies, which inflate the sailing cost. They also lost competition to the illegal fishing perpetrators who own ships and better equipment in treating the sea produce. The healthy processing method of sea produce becomes less and less affordable.

Abstract

Background: Autologous bone marrow transplantation is a curative procedure for hematological diseases and immune deficiencies. The unique and intensive nature of this treatment requires distinctive care during and post the entire transplant course. Nursing intervention for caregivers post autologous bone marrow transplantation patients at home is an important component of the care that improves and develops knowledge and practice of the caregivers, to take care of the patients in order to help them follow the demanding treatment plan to reach recovery. Aim to evaluate the effect of nursing intervention for caregivers of post-autologous bone marrow transplantation patients at home. Material and Method: A Quasi-experimental study was carried out among convenient sample of 143 patients and their caregivers who attended the follow up clinic during the first six months post autologous bone marrow transplantation. The study was conducted among patients and their caregivers in three different hospitals Sheikh Zayed Specialized Hospital, National oncology institute, and Nasser institute at outpatient’s follow-up clinics. A self-administered questionnaire of patients and their caregivers’ demographic data, and reported checklist of caregivers’ knowledge and practices toward post-autologous bone marrow transplantation patients at home. Results: there was a statistically significant difference between pre and post nursing intervention, which indicate improvement in caregivers’ knowledge and practice post implementation of the nursing intervention program, and positive correlation between their knowledge and practice. Conclusion and Recommendations: Although caregivers had adequate knowledge, practice on some aspects, gaps were identified. There is a need for educational interventions and discharge plan to upgrade knowledge and practices of the caregivers of post autologous bone marrow transplantation patient at home.

Keywords: Autologous bone marrow transplantation, caregivers, nursing intervention, home.

Introduction

Since the onset and progression of bone marrow transplantation it was evident from the 1950s to early 1960s that nurses play an important role within the multi professional team caring for patients and their families go through this treatment.¹ Bone marrow transplant is an umbrella term for the grouping of a variety of procedures. These transplants use stem cells from bone marrow, peripheral blood or cord blood and more recently the procedure has been called haemopoietic stem cell transplantation (HSCT) The type of treatment is then classified based on the origin of the stem cells, autologous being derived from the recipient himself. ² The family does need support, and need pre- and post-HSCT education and psychosocial intervention,. All stages of the transplant process will affect family members. The effect of this severe medical procedure will clearly extend beyond the person concerned to the entire family network. ³ In the post-transplant duration, it is important to have a distinct pattern of evaluation to assess disease condition and for any post-transplant complications.⁴ Increasing caregivers’ confidence and competence require training in the skills they need to provide care to the patient. Past studies have repetitively shown that caregivers often express attentiveness in, and have a need for education and support programs.⁵
The population of Egypt exceeded 100 million in 2020. There are fifteen transplant centers and the transplant rate is 8.4 million. Bone marrow transplantation in Egypt began on a restricted scale in 1989. In 1997, the rate of transplantation increased significantly. Specific attention has developed towards educating the long-term survivors and their caregivers in which nursing intervention plays a significant role because medical treatment activities are more in the background and day-to-day questions have to be dealt with.

Research Hypothesis:

The nursing intervention program will improve the caregivers’ level of knowledge and practices in caring of post Autologous Bone Marrow Transplantation Patients at Home.

Materials and Methods

A quasi-experimental study was carried out among 143 patients and their caregivers at outpatient follow-up clinics in three biggest hospitals in Cairo, Egypt for autologous bone marrow transplantation patients, Sheikh Zayed Specialized Hospital, National Oncology Institute, and Nasser Institute. An official written letter including the title and purpose of the study obtained from the dean of Faculty of Nursing, Ain Shams University to the get the approval form directors of the mention hospitals to conduct the study. A consent was obtained from each participant (patient and caregiver).

The 143 (patients and caregivers) were divided into 6 groups The actual process of data collection was carried out in the period from February 2019 to July 2019 The intervention program consisted of 17 hours (5 hours theoretical, 12 hours practical). Educational media were used such as poster, PowerPoint, laptop, handout Arabic booklet, videos.

The tool was developed by the researcher, based on reviewing related literatures and experts’ opinions, written in Arabic language, and Completed under supervision of the researcher through group interview. A self-administered questionnaire of patients and their caregivers’ demographic data includes 10 questions. Self-Reported checklist of caregivers’ practices and knowledge toward post autologous bone marrow transplantation patients at home. Caregivers’ Knowledge consisted of 15 questions with Cronbach’s value 0.78.

Answers was coded as follow: poor=1, good =2. Caregivers’ practices consisted of 90 questions including:- patient transfer, Central venous catheter care, Meals preparation and diet restrictions, Personal hygiene, Medication administration, and Following Infection control. With Cronbach’s value 0.76.

The total score was divided into two scale: Poor > 60% Good ≥ 60%.

The collected data were organized; tabulated and analyzed using software, the appropriate statistical tests was the Statistical Package for Social Science SPSS (version 25). The statistical analysis includes; percentage (%), Chi-Square test (X^2), Proportion probability P value.

Significance of results was described as follows:

· Not-significant difference obtained at p> 0.05.
· Significant difference obtained at p< 0.0 5.

Evaluation the level of improvement in caregivers’ knowledge, practice, was done by giving post-test similar to pre-test. Evaluation was administered to the caregivers after completion of the program in order to estimate the effect of the program on the caregivers, and recognize the benefit of the program and what are the ways of obstacles to lack of implementation.

Results

Table (1) Shows that, the median and range of age of the studied patients was 48 (21-50) years, in relation to gender, 53.1% were males, and 67.1% were married, while 58% had 3-4 children, as regards educational level 42% of them had university education. Concerning occupation, 37.8% were employees, with 70.6% had sufficient monthly income.

Regarding the caregivers Illustrates that, the median and range of age of the studied caregivers was 47 (18-60) years. 68.5% of the caregivers were females. Regarding Kin-relation with the patient 30.8% were spouse. Related to educational level 41.9 % of the studied sample were secondary education. In relation to the marital status, 41.9% were married, Concerning of job 34.3% were employees, and 76.9% of time of care
were full time.

Figure (1) displays that, pre interventional program good knowledge and practice was 27.2%, 36.4%, respectively, while post implementation of an interventional program good knowledge and practice was 87.5%, 89.3% respectively.

Table (2) Clarifies there was statistical significant relation between pre and post of total caregivers’ demographic characteristics (age, gender, educational level, occupation, time of care) and total caregivers’ knowledge and practice score. However marital status, kin-relation, shows no significant effects on caregivers’ knowledge and practice.

Table (3) Illustrates that there was statistical significant positive correlation between pre & post-test of total caregivers’ knowledge and practices at P < 0.001.

Discussion

The current study illustrated that Table (1) the median and range of age of the studied patients was 48 (21-50) years, in relation to gender, around half of the patients were males, and about two third were married, while more than half had 3-4 children, as regards educational level less than half of them had university education. Concerning occupation, almost one third were employees, with more than two third had sufficient monthly income. This study was in agreement with previous studies. 7,8

Regarding the caregivers Illustrates that, the median and range of age of the studied caregivers was 47 (18-60) years. More than two third of the caregivers were females. Regarding Kin-relation with the patient less than one third were spouse. Related to educational level below than half of the studied sample were secondary education. In relation to the marital status, less than half were married, Concerning of job almost one third were employees, and more than three quarter of time of care were full time. This study was in the consistent with previous studies. 7,9,10 Similar findings also were reported in the studies conducted in USA. Becoming a caregiver was a second full-time occupation, as caregiving had become the priority in their lifetime. 11 But another earlier study was in contrast to the current study, claiming that young caregivers typically have to juggle jobs, their own family commitments, middle-aged caregivers usually worry about missing workdays. Interruptions in work absence leave and reduced productivity. In addition to, limited income can place families at risk of care for non-compliance or of treatment related decision on the basis of income. 12

Concerning caregivers’ demography Table (2) Clarifies there was statistical significant relation between pre and post of total caregivers’ demographic characteristics (age, gender, educational level, occupation, time of care) and total caregivers’ knowledge and practice score level. However marital status, kin-relation, shows no significant effects on caregivers’ knowledge and practice. The finding was supported by other study conducted in USA Indicating that the caregiver does not necessarily discuss the gender position of the participants. This can be explained at least in part by the fact that the majority of caregivers are women, that caregivers themselves are viewed as a woman’s position, and that male caregivers make less use of resources, including support groups, than women do. 5

The same results were observed in early studies that educational and training needs would flow over time, driven by complex processes that characterize adult and family life trajectories. Only a few States provide financial aid to family members who perform the position of caregivers. Therefore, to give full-time care, caregiver has to leave the workforce to support the loved ones. Currently, the Health Care Management System offers some assistance to spouses who perform the function of caregivers. 5,13 With regard to time of treatment. In addition, there were statistically significant differences between the pre-and post-intervention programme, the

Figure (1) displays that, most of the caregivers had good knowledge, and majority of them had good practice post-interventional program, indicating that the caregivers improved in their knowledge and practice after application of nursing interventional program. This could be because they got benefit of the program, and education outcomes. The level of good knowledge and practice were lower in pre-interventional program as mentioned in early study that Family caregivers often feel unprepared, have inadequate knowledge, and receive little guidance from the transplant team. Beside education should pass expertise, skills and details. Successful delivery of education is a dynamic process that depends on sufficient timing. The primary outcome identified in the majority of health education. Respondents show increased health awareness and make healthier decisions about their patients’ health following intervention. So good education also increases patient/ caregiver self-efficacy, reduces anxiety by planning for transplantation, and increase the satisfaction of the patient. More long-term education results might include improvement in survival and transplantation morbidity, accessibility of health care, willingness of patients / caregivers to return to work, and quality of life. 12,13 other study revealed that the preparation of family caregivers for their position must include clear education, including skills training. Preparing caregivers should be an ongoing process such that benefits are maintained and education programmes develop as required. 14
current research in the same line of the previous study showed that full-time caregivers offer more support and can apply the information acquired by the caregiver from the programme.  

There were no major variations in marital status, the relationship of caregivers and their expertise and experience in the current research. The findings show that, in accordance with the previous studies it reported that there was no significant relation between marital status, and kin-relation of caregivers and their knowledge and practice. This may be due to the nature of the intimate relationship between the caregiver and the patient. It did not rely on the relationship. However, depending on the nature of the relationship between the patient and the caregiver, it could possibly lead to a complicated situation of caregiving that could affect the delivery of care, but did not influence awareness.  

Finally Table (3) Illustrates that there was strong positive correlation between pre & post-test of total caregivers’ knowledge and practices, the caregivers’ total knowledge score was positively associated with the total practice score toward post autologous bone marrow transplantation patients at home. The higher the knowledge, the higher the practice, in which this shows that caregivers’ practice is directly related to their knowledge as reported in the previous study. In the most recent sense, a similar study was performed in the United States, which determined that there is a substantial association between the degree of education of caregivers and their practice in post-autologous bone marrow transplantation patients. Improved awareness and/or willingness to offer treatment to United States.  

In other previous study mentioned that Role preparedness has been studied in terms of how the development of knowledge and skills might protect the caregiver from role distress when the difficulty of care or the need for care is high.  

**Conclusion**

Based on the results of the current study and research hypothesis; implementation of nursing intervention program improved the knowledge and practices of the caregivers of post autologous bone marrow transplantation patients at home, there was statistically significant differences between pre/post-nursing intervention post autologous bone marrow transplantation regarding caregivers’ knowledge, practice. In addition, there was statistically significant relations between caregivers’ demographic characteristics and total score level of caregivers’ knowledge and practice in some parts, beside there was positive correlation between pre & post-test of total caregivers’ knowledge and practices score level. Further research with a larger sample of caregivers from other governorates in Egypt are required in order to have a better understanding the needs of caregivers’ knowledge and practices post autologous bone marrow transplantation patient at home.

Chronic Kidney Disease: A Case Report

Sonal Dhobe1, Vaishali Tembhare2, Ruchira Ankar3, Savita Pohekar4, Samruddhi Gujar5

1M.Sc Nursing 1st year, 21st year, Lecturer, 3Associate Prof. 4Associate Prof., 5Clinical Instructor, Department of Medical-Surgical Nursing, Smt. Radhikabai Meghe Memorial College of Nursing, Datta Meghe Institute of Medical Science, (Deemed to be University) Sawangi (M), Wardha

Abstract

Chronic kidney disease can occur in mostly those patient which having a history of hypertension and diabetes, this disease also known as a chronic renal failure. In this disease condition kidney can decreasing the rate of filteration or kidney function since month or a year. In the beginning period of Chronic Kidney Disease the person not showing any sign and symptoms about disease condition, after the months and year patient showing symptoms like nausea, vomiting, lethargy edema, confusion and loss of appetite. If the early detection and treatment is not getting so the patient can goes in complication such as heart disease, hypertension, bone disease and anemia.1 Case Report: The female patient name is Rashida khan 63 year old religion by Muslim lived in the yawatmal. She was admitted in the AVBRH with the chief complaint of breathing difficulty, fever, nausea and vomiting, swelling on both legs, lethargy weakness since 10 days. She having a history of HTN since 5 year and freshly diagnosed as DM2. Conclusion: This case presented how the prolong history of HTN which is uncontrollable causing the DM2 and it can leads to CKD. The firstly clinical presentation of the patient providing information about the history of HTN and DM2 and the laboratory studies suggested a reducing function of kidney. So the patient sign, symptoms and the laboratory values showing the condition of patient kidney with increasing volume of kidney, breathing difficulty, moderate anemia and uremia. Early detection of the HTN and DM2 and their management in early stage, also the modification in lifestyle and diet can help to reduce the chances of occurring Chronic Kidney Disease. Patient also have to complete the given treatment and counseling about the disease condition, and the problem get solved by taking proper treatment.

Key word: chronic kidney disease, Diabetes Mellitus type 2, Hypertension.

Introduction

Chronic kidney disease can occur in mostly those patient which having a history of hypertension and diabetes, this disease also known as a chronic renal failure. In this disease condition kidney can decreasing the rate of filteration or kidney function since month or a year.1 In the beginning period of Chronic Kidney Disease the person not showing any sign and symptoms about disease condition, after the months and year patient showing symptoms like nausea, vomiting, lethargy edema, confusion and loss of appetite.2 If the early detection and treatment is not getting so the patient can goes in complication such as heart disease, hypertension, bone disease and anemia. If there is not given proper treatment for the Chronic Kidney Disease so it leads to total damage of the kidney.3 As ageing the person get older the chances of kidney diseases is increased and it very common in elder people. The prevalence shows the disease can occure in one men in five men and one women in four women, and mostly occure in age between 65 to 74 years.4 Hypertension, chronic diseases and diabetes mellitus 2 that is the main cause behind the occurrence of Chronic Kidney Disease.

The high prevalence of hypertension in such contries like African and Diabetes Mellitus mostly seen in the South Asian People that is the main reason behind the Chronic Kidney Disease. This condition most commonly seen in the Pakistan, India, Bangladesh and people belong to the black population.5
Treatments may include: Symptomatic treatment like if the person suffering from high blood pressure and DM2 so the providing the antihypertensive medicine and insulin therapy to reducing the complication and deal with Chronic Renal Failure to help in preserving the function of the kidney. Treatment for the chronic renal failure depend on the degree of kidney damage if the kidney in their third degree and more than that so dialysis are the best treatment for preserving the kidney function but when the kidney not showing any response on dialysis so we consider that kidney in very poor condition that time only option that in kidney transplantation. In kidney transplant the receiver get the healthy kidney from the donor into patient body, this kidney can take by living or brain dead donor.

**Case History**

Female patient name is Rashida khan 63 year old religion by Muslim lived in the yawatmal. She is a house wife but she used to do work in her own farm and lived in joined family her husband and son is the breadwinner of the family, rashida done her education in class 8 Th and her monthly family income is around 8000 per month. The source of health care that is government hospital in yawatmal.

She was admitted in the AVBRH with the chief complaint of breathing difficulty, uremia, fever, nausea and vomiting, swelling on both legs, lethargy weakness since 10 days before she came to the hospital she is admitted in yawatmal, she can suddenly unconscious in the house so her relative take her in yawatmal hospital then doctor freshly diagnose as aDM 2 and she also having the past history of HTN. She doesn’t have any other medical history in past and she done her family planning (tubal ligation) other than she not having any type of surgical history.

**Nursing Assessment**

In physical examination the patient showing a poor condition, presence of distress, undernourished, body build thin, activity is dull, conscious and oriented to things. Showing vitals like heart rate of 94 beats per minute, breathing rate of 16 breaths per minute, saturation of 96%, blood pressure that is increase, 140/90 mmHg and she having a fever- 100 F and her body is warm. She having pain in both the lower leg, swelling present on both leg, she had a hemodialysis catheter present over neck. The other physical examination not showing any abnormalities.

Thesome raising and decrease laboratory finding showing below:

- HB% - 10.0 g/dl
- WBC - 15000cu/mm
- Blood Urea - 56.0mgdl
- Bun-26.17 mg/dl
- Creatinine- 5.0 mg/dl
- Sodium – 132 mmo/l
- Potassium – 4.0 mmo/l

**CASE:**

Pantoprazole 40mg- IV-OD
Piperacillin /tazobactam 4.5g - IV - BID
Furosemide - 50mg -IV -TID
Ondansetron - 4g- IV -BD
Insulin - 15mg P/O -BD
Cyanocobalamin - 1amp IV -OD
Nitrofurantoin - 100mg P/O –BD

**Hemodialysis:** she started her heamodialysis cycle as came to hospital,

**Discussion**

Present case report showing that the patient those having the history HTN and it could not control because of not aware about disease condition, adherence of medication, not control over diet and sedentary life style which lead to the DM 2 and this Chronic Kidney Disease of the patient. Then treatment include the drug therapies, control sign and symptoms, Hemodialysis, kidney transplant, patient counseling, prevent complication, life style modification and taking regular follow up. With the help of drug patient need to hemodialysis for recovering the condition of kidney and managing the sigh and symptoms in this disease condition, also reducing the complication which may lead to further. There is need to patient education about her condition and treatment modalities.
All over the world the people present with some degree of kidney disease that is 1 in 10 people. The CKD can develop mostly in elder people but it can develop at any age and there so many condition leads to develop CKD. It can be very common with people increasing their age, nearby 1 % function of the kidney can affect by the age over the 40 year. Such as condition like hypertension, diabetes mellitus type 2, heart diseases can start affecting on the kidney after ageing as compare to young people. In developing countries over the 600 million population they do not afford the surgeries like renal replacement so it can be leads to increase the mortality rate in kidney patients. Although 80 % of people who get the renal replacement therapy can be alive in some developed countries. As we see in our country there is less than 10 % of people we get to need the renal replacement therapy and they live with the get new kidney, the WKD can spreading massage about the importance of the health of kidney.8

Studies shown that there is the one in five men and one in four women that age of 65-75 year, the elder people come in risk factor to getting the kidney injury as compare to younger people. The health of kidney is very necessary because if the kidney is damaged so it can lead to heart attack, stroke and other life threatening condition. In treatment of CKD some cases are required dialysis and renal replacement therapy. The reducing the risk factor and life modification and early detection and treatment that is the way to reducing the mortality and morbidity rate in kidney diseases.

Conclusion

This case presented how the prolong history of HTN which is uncontrollable causing the DM2 and it can leads to CKD. The firstly clinical presentation of the patient providing information about the history of HTN and DM2 and the laboratory studies suggested a reducing function of kidney. So the patient sign, symptoms and the laboratory values showing the condition of patient kidney with increasing volume of kidney, breathing difficulty, moderate anemia and uremia. Early detection of the HTN and DM2 and their management in early stage, also the modification in lifestyle and diet can help to reduce the chances of occurring Chronic Kidney Disease. Patient also have to complete the given treatment and counseling about the disease condition, and the problem get solved by taking proper treatment.

Physiotherapy Students Willingness To Report Misconduct To Protect The Patient’s Interests In Chennai

Malarvizhi1, Bhagya Lakshmi K2, Hariharan S3
1Dean, 2BPT IV YEAR Student, 3BPT IV YEAR Student, SRM College of Physiotherapy, SRM Institute of Science and Technology, Kattankulathur, Chengalpattu, Tamil Nadu, India

Abstract

Background: Applying the ethics in practice is more essential than just learning it. Any sought of misconduct to the patient is not just an ethical issue but it will also degrade the professionalism and it brings a sense of insecurity in patients and this will slow down the progress of treatment. So it is not only important to avoid the ethical issues and misconduct but it is also necessary to stand against ethical issues that happen within the organization that may done by colleagues or higher authorities without any dilemma. Objective: This study aims to find out the difficulties and dilemmas of the physiotherapist in ethical decision making and disclosing the misconduct of their colleagues without any hesitation. Methodology: A close ended questionnaire was used to assess the willingness of the student physiotherapist to expose the misconduct which might be an internal or external disclosure. The questionnaire consisted of two clinical scenarios which were most likely to arise in a work place. Each scenario consisted of 5 questions that rated the severity, likelihood of confronting, internal disclosure, external disclosure to the association and external disclosure to media. The scoring was based on five point likert scale. It was a study that was done with convenient sampling method. The questionnaire was given to 100 Physiotherapy students in Chennai of both the sexes who were willing to participate in the study. Result: From the statistical analysis, there is a significant difference obtained for the likelihood of reporting the manager’s misconduct than colleague’s misconduct. Also their willingness to report internally within the organization is greater than that of reporting externally to the association and to the media. Conclusion: Ethics being a part of Physiotherapy curriculum, these students have well understood the ethical and professional behavior and have good ethical acceptance. Hence we conclude that the students do understand the seriousness of any misconduct of a therapist to the patient and are willing to expose any misconduct they encounter to the internal or external environment.

Key words: Ethics, Students, Physiotherapy, Misconduct, Ethical dilemma

Introduction

Whistle blowing is usually defined as the reporting “by organization members (former or current) of illegal, immoral, or illegitimate practices under the control of their employers to persons or organizations that may be able to effect action” 1. Reporting any sought of unethical behaviour is more inevitable and essential in the field of health sciences as it is concerned with human lives. Whistle blowing largely helps in the reducing the rates of misconduct in future 2,3. But still blowing a whistle against the organisation or colleague or a superior is a major dilemma faced by an individual because when blowing a whistle, it not only involves the whistle blower and the organisation but it also involves the patient who is actually affected, this will lead to deterioration of the hospital’s fame. This will put the whistle blower at risk 1. All though whistle blowing is a moral behaviour, it will risk the life of the one who reports the misconduct. The person who voluntarily reports the misconduct might be exploited and might end up in losing his livelihood 1, 4. Despite these consequences it is to be noted that those who are with high self-ideals are the one to report the misconduct as they are ones intolerable to the unethical behaviour 4. It must also be noted that a person will hesitate to report his friend if found guilty because of their bond or because of the fear that they might get caught one day 5.
When a person is dishonest or unethical during his student life then there are high chances that he will be more deviant during his professional life\(^5\). Any unethical behaviour as a professional will lead to distrust of patients and a sense of insecurity which in turn reduces the progress in the patient condition that will lead to ending up of the professional’s career\(^6\). This is the reason why any sought of unprofessional behaviour has to reported and stopped immediately. Since ethical acceptance begins at the college level\(^7\), it is important to know level of ethical knowledge and their willingness to follow ethics and their ability to make decisions in critical cases and their willingness to report the unethical behaviour that is either conducted by their superior or their colleague. Though this subject is of high importance there are not enough researches done in India to find out about the ethical dilemmas and decision making related to physiotherapy. Our study aims to find out how well the students are able to understand the seriousness of the misconduct of the therapist to the patient and how willing are they to expose any misconduct they encounter to the internal or external environment. Internal disclosure implies reporting misconduct to an higher authority within the organization. External disclosure implies reporting misconduct outside the organization such as law enforcement or media.

### Materials and Methodology

Based on the selection criteria only physiotherapy students of UG final year, PG first and second year and interns those who were pursuing their degree in Chennai were selected as participants. Departmental ethical committee approval was obtained. A total of 100 participants were aimed and a closed ended questionnaire was sent as google forms. Students from colleges without ethics as a part of curriculum were excluded. Initially the participants were asked to fill the demographic data that included the name, age, college they belonged to, and the year they were studying. The questionnaire consisted of 2 clinical scenarios and 5 set of questions were asked under each scenario. The first scenario was related to colleague’s misconduct and the second one was concerned with the misconduct by the higher official. The first question dealt with how far the students were able to understand the seriousness of the situation while the second question dealt with the student’s willingness to confront the misbehaviour to the one who committed it and insisting him to correct what he did. Question 3 and 4 dealt with blowing whistle to the internal environment. Question 5 is related to the blowing of whistle to the external environment. All the questions were rated according to 5-point likert scale. The answer for the first question ranged from “very serious” to “not serious at all”. The answers for the remaining four questions ranged from “strongly agree” to “strongly disagree”.

### Results

The mean differences between the groups were assessed using the paired sample’s test. The data were analyzed using SPSS statistical software, PC version 20.0.

**TABLE 2: Paired sample test**
Table 1 shows the comparison between the respondents’ scores for the two case stories regarding the severity of the misconduct, the likelihood of taking action to change the situation and the indices of internal and external whistle blowing. From the scores obtained, the likelihood of reporting director’s misconduct is higher than that of colleague’s misconduct.

Table 2 shows the comparison between the scores of the internal and external whistle blowing to the association and to media. From the scores obtained, the likelihood for internal whistle blowing is higher than that of external whistle blowing. There is a significant difference (0.010) between the internal whistle blowing for colleague and director misconduct. There is a significant difference (0.016) between the external whistle blowing for colleague and director misconduct in reporting to the physical therapy association. There is a non-significant difference (0.056) between the external whistle blowing for colleague and director misconduct in reporting to the media.

Discussion

The purpose of this study is to find out how well the students are able to understand the seriousness of the misconduct of the therapist to the patient and how willing are they to expose any misconduct they encounter to the internal or external environment. Totally 100 physiotherapy students with ethics as a part of curriculum were taken into consideration out of which 58 female and 42 male students have participated. From the study it is found that the physiotherapy students witnessed the situations that are harmful to the patients to be very serious. In such situations, they are likely to report to the higher authorities in both cases of misconduct by their colleague as well as manager. However the rate of likelihood to report varied between both the case stories. Hence there was a significant difference obtained by the statistical analysis of the obtained data. From the scores obtained the likelihood of considering the severity of misconduct, confronting the person responsible for the wrongdoing, reporting the misconduct to someone in workplace, to the association...
or to the media for the director’s misconduct was higher than that of colleague’s misconduct. This shows that the students give more importance to the interest of patient rather than supporting the misconduct of colleague or manager. In situations where such misconduct arises their willingness to report seems to be expressed rather than supporting the misconduct. Similarly the scores obtained for internal whistle blowing was higher than that of external whistle blowing. The reason for this might be because the students prioritize to report to the superior authority within the organization than disclosing it outside the organization. Also Abraham Mansbach et al., (2011) has stated that the students prefers and follows a pattern of internal whistle blowing after which the external whistle blowing is being is approached rarely. Anna Myers, (2008) has also stated that it is wiser to whistle blow first internally and then externally outside the organization. It is more ethical and also being loyal to the organization. While also expresses that whistle blowing to an unethical or a deviant act is a core component of an employee and that at all costs whistle blowing to root out a criminal activity which is possibly harmful to the client or the reputation of the institution must be encouraged.

**Conclusion**

Ethics being a part of Physiotherapy curriculum, these students have well understood the ethical and professional behavior and have good ethical acceptance. Hence we conclude that the students do understand the seriousness of any misconduct of a therapist to the patient and are willing to expose any misconduct they encounter to the internal or external environment.

The limitation and recommendation of the study are The answer that was recorded by the participants was just their interest and opinion towards whistle blowing as a student. But the actual response that they give when they are into the situations might vary. In future studies can be done with a comparison between physiotherapy students with and without ethics as a part of curriculum. In future studies can be done with a comparison between physiotherapy students and practitioners.

Cognitive Impairment and Its Impact on Quality of Life in Rural Indian Female after Stroke: A Cross Sectional Study Protocol

Nikita S. Deshmukh1, Ashish Bele2

1Final Year Student, Ravi Nair Physiotherapy College, Datta Meghe Institute of Medical Sciences, Wardha, Maharashtra, India, 2HOD, Department of electrotherapy and Associate Professor, Department of Community Health Sciences, Ravi Nair Physiotherapy College, Datta Meghe Institute of Medical Sciences, Wardha, Maharashtra, India

Abstract

Introduction: Stroke represented growing social, health care and economic problems. In 2005 vascular cognitive impairment a condition that can be found in 20-30% of stroke patient. Now in 2018-19 over 50 percent of stroke survivors have reported cognitive impairment 6 months after stroke and are associated with poorer quality of life which increase disability. Cognitive functions is identified as a top priority for stroke research. Cognitive impairment affects inadequate ability to focus on the job, recall, understand, prepare, use knowledge, initiate and stop the operation and solve problem. a stroke impaired cognitive function including focus, memory, vocabulary, executive function, perception and orientation of space. Because of abnormality in functional independence and other abnormalities in higher function, cognitive impairment may lead to affect independence. it increases the death ratio, abnormality. Stroke impacts wellbeing dramatically on health system resulting in high costs, and is also considered a global public health problem due to severe disabilities, functional deficiencies and reduced quality of life.

Method: The corrective study is assessing the cognitive impairment and the quality of life. The cognitive impairment will be measured with the use of the MoCA and QoL will be measured by stroke specific quality of life questionnaire. Female stroke patient with age in between 45-65 year who was diagnosed by the physician is included in the study.

Discussion: Stroke is a prevalent condition which affects most of the Indian population. Most studies are done on stroke including male and females both. Many studies have concentrated on cognitive disability after stroke and quality of life in males but no research is available in rural Indian females. The need for the research is therefore to establish the prevalence of cognitive disability in females and their effect on quality of life after stroke.

Key Words: Rural Indian females, Stroke, Cognitive impairment, Quality of life, MoCA , and SS-QoL scale.

Introduction

Stroke is a leading cause of death and disability in India. It represented growing social, health care and economic problems. In 2005 vascular cognitive impairment a condition that can be found in 20-30% of stroke patient. Now in 2018-19 over 50 percent of stroke survivors have reported cognitive impairment 6 months after stroke and are associated with poorer...
quality of life which increase disability.

The cognitive impairment after stroke is disturbed in any cognitive domain after stroke, executive function, memory, language, visuo-spatial function, visual-construction ability or global cognitive function. Hence, cognitive function is identified as a top priority for stroke research. Cognitive impairment affects inadequate ability to focus on the job, recall, understand, prepare, use knowledge, initiate and stop the operation and solve problem. A stroke impaired cognitive function including focus, memory, vocabulary, executive function, perception and orientation of space. The word cognitive impairment post-stroke is used to describe both mild cognitive impairment and dementia that either occurs 3-6 months after stroke incident. In addition, An approximate 16.9 million stroke cases occurred globally in 2010.

We do not know how many patients with strokes display deterioration or worsening of their cognitive impairment over a period of several years, and we do not have clear prognostic clues to classify those more likely to deteriorate. The estimates modified stroke prevalence range 84-262/100000 in rural areas, and 334-424/100000 in urban areas.

The definition of post-stroke cognitive impairment usually refers to disorders that arise after neuro-radiological examination after symptomatic stroke with associated ischemic finding. The post-stroke depression was found to be cognitive impairment related. It is believed to be linked mortality, reducing functional outcome and quality of life, and may be correlated with multiple factors and psychological mechanisms. Cognitive deficits are a negative prognostic factor that affects behavior and personality. The method such as Montreal Cognitive Assessment is commonly used clinically for examining cognitive disorder. Because of abnormality in functional independence and other abnormalities in higher function, cognitive impairment may lead to affect independence. It increases the death ratio, abnormality.

The physical, social and psychological effects of this disease are severe – approximately 90% of survivors have some kind of impairment. Quality of life in relation to health refers to all types of quality of life affected by diseases. Stroke impacts wellbeing dramatically on health system resulting in high costs, and is also considered a global public health problem due to severe disabilities, functional deficiencies and reduced quality of life.

**Need of The Study/ Rationale**

Stroke is a prevalent condition which affects most of the Indian population. Most studies are done on stroke including male and females both. Many studies have concentrated on cognitive disability after stroke and quality of life in males but no research is available in rural Indian females. The need for the research is therefore to establish the prevalence of cognitive disability in females and their effect on quality of life after stroke.

**Aim and Objective**

**Aim:** To assess the effect of Cognitive Impairment on quality of life in Rural Indian women after stroke.

**Objective:**

3) To find out the Cognitive Impairment in females after Stroke.

4) To find out the impact of cognitive impairment on the Quality Of Life of rural females after stroke.

**Material and Methodology**

Ethical approval will be obtained from the Institutional ethical committee. 40 participants will be selected randomly specially females and assessed for cognitive impairment and quality of life after obtaining consent form.

**Material-**

4) Couch

5) Chair with hand support

6) Immobilizer belt

7) Table

8) Pen

**Method:**

The research project will be conducted in Ravi Nair College of physiotherapy with rural population. It is cross-sectional observational study. All female patients.
who were diagnosed as having stroke and who fulfilled the inclusion and exclusion criteria included in the study.

The corrective study is assessing the cognitive impairment and the quality of life. The cognitive impairment will be measured with the use of the MoCA and QoL will be measured by stroke specific quality of life questionnaire.

Mixed etiologies subject is excluded from the study.

**Instrumentation:**

MoCA, and SS-QoL scale is use as instrument.

The study selected because:

2. It is simple and convenient
3. Does not involve expensive technology or not to costly
4. It is time efficient to perform
5. Easy to understand
6. Reliability of MoCA is 0.75-0.96 , and SS-QoL is 0.65-0.99

**STUDY DESIGN:** Observational study.

**STUDY SETTING:** Ravi Nair College of Physiotherapy, Sawangi(M), Wardha

**PARTICIPANTS:**

**Inclusion and Exclusion Criteria:**

Inclusion criteria:

1. Female stroke patient
2. Age in between 45-65 year who was diagnosed by the physician is included in the study.

Exclusion criteria:

5) The patient having mix – etiologies
6) Elderly female above 67 year
7) Any other psychological disorder is excluded from the study.

**Variables:**

1. MoCA Scale
2. SS-QoL Questionnaire.

**Data Sources/ Measurement:**

Ethical clearance will be obtained from institutional ethical committee (IEC). Participant will be selected by simple random technique. Inclusion and exclusion criteria will be implemented assessment during the hospital stay or within 3 month of stroke. To assess the different aspect of cognitive functions each participant tested approximately 1 and ½ hours session.

MoCA is commonly used method for cognitive evaluation. Eventually the MoCA returns a judgment-based score. The first only requires verbal input and involves orientation, memory and attention assessment. The second portion assesses the naming skills to obey verbal and written orders, writes a sentence randomly and copies a complex polygon. Since the MoCA includes divisions there is no limit of sub-domains. Total total score is 30 and total administration time is around 10-15 min. A cutoff <24 is used to define cognitive impairment.

With the SS-QoL we assessed Life Value

We applied the stroke Specific quality of life scale this method to measure the Quality of Life. The SS-QoL is a particular instrument used to measure health-related quality of life among individuals suffering stroke. It holds 49 objects in 12 domains. Higher values suggest a better quality of life linked to health.

**Data Analysis:**

Data analyzes are carried out using concise and infererse statistics, using unpaired chesquare research students. The program used in the study will be the SPSS 24.0 version, the praphade prism 7.0 version and the degree of significance < 0.005 (p=0.005 m) is considered.

**STUDY SIZE:** 40

**STATISTICAL METHOD:** Simple Random Sampling

**Result**

Upon completion of the study results, statistical
analysis will be estimated.

The result could show the impact on cognitive impairment and quality of life of post stroke patients in rural Indian females. or

The result could not show the impact on cognitive impairment and quality of life of post stroke patients in rural Indian females.

Discussion

Stroke is a prevalent condition which affects most of the Indian population. Most studies are done on stroke including male and females both. Many studies have concentrated on cognitive disability after stroke and quality of life in males but no research is available in rural Indian females. The need for the research is therefore to establish the prevalence of cognitive disability in females and their effect on quality of life after stroke.

Limitations:

It might be difficult to get convince patient for being a part of this study.

Implication:

Outcome of the study shall help the geriatric population to get aware about their condition and health the researcher to plan the treatment protocol.

Generalizability:

study not yet done.

Ethics and Dissemination:

The approval of the Committee on Institutional Ethics must be obtained prior to the start of the study. Patients must be treated with respect first. Upon meeting the requirements of inclusion and exclusion criteria, the patients are taken for review

Source of Funding: There will be no direct support for this research from public and private organization. The department of physiotherapy, at Datta Meghe institute of Medical Science, Deemed to be university will provide material needed for research.

Conflict of Interest: Nil

Knowledge, Awareness and Attitude about Breast Lump among Females Attending Mahatma Gandhi Ayurved Hospital

Ishwari Gaikwad¹, Pradnya Dandekar²

¹UG Scholar 2nd BAMS Student, MGACH & RC, Salod(H), Wardha, Datta Meghe Institute of Medical Sciences, Wardha, ²Professor & HOD, Dept. of Kriya Sharir, Mahatma Gandhi ayurved College, Hospital and Research Centre, Salod (H), Wardha, Datta Meghe Institute of Medical Sciences, Wardha

Abstract

Background: Breast lump is considered as carcinogenic unless it is tested and diagnosed as other than this. Today in India, it is one of the main causes of cancer deaths among women. Only early detection and early medical intervention could decrease its mortality rate. Knowledge and awareness of palpation of breast lumps and attitude to get diagnosed at earliest is extremely crucial. Aims & Objectives: Aim is to assess knowledge, awareness and attitude about breast lumps in women attending Hospital OPD. Objectives are to assess the existing knowledge and awareness and to study the attitude about breast lump examination for prevention & early diagnostic measures. Methodology: The proposed cross sectional observational study will be carried out in in Mahatma Gandhi Ayurved Hospital, Salod (H), Wardha. The women visiting OPD will be randomly selected and with their consent will be interviewed personally by a structured and validated questioner. Result: Result will be interpreted on the basis of statistical analysed data. Conclusion: Conclusion will be drawn from the observations and analysis.

Key words: Breast lump, Breast self examination, Clinical Breast examination.

Background and Rationale

In India, the diseases related to palpable mass in breast are the very common. These palpable lumps may include inflammatory conditions, may congenital or may be related to hormonal mastopathy, having traumatic history, benign and malignant neoplastic conditions. Breast lump is the most source of anxiety to a female when it is discovered. Annually, in an average 20,000 of cases of breast diseases are diagnosed.¹ A mass is cancerous until proven otherwise and have to manage by the usual management of a breast mass.

There has been an increase in the cases of breast cancer over the years and it continues to raise steadily². Breast cancer related mortality is seen at an increasing rate. It is the fifth highest due to cancer. It is the most common cause of death among women suffering from cancer.³ In India, interventions need to be done to guide and educate people about the risk factors, importance of screening and management of Breast lumps.

Awareness about the breast cancer and substantial support for the advancement in the diagnosis technology and treatment care for breast cancer is required. Day by day because of available management and early detection strategies the breast cancer survival rate is increased and death rate is going on declining. Benign breast diseases are more seen as compared to malignant and inflammatory⁴. In benign diseases fibro adenoma are more in frequency as found to be almost half of the case in population⁵. Mammography is the diagnostic tool in early stages before the lump can be felt. It is effective technique to diagnose breast cancer in early stages but
not 100 percent in all the time. The reason behind it as there the changes and symptoms might or might not occur. That is why regular screening is so important.

45% of all cancer in females is breast cancer. Breast cancer is very rare in younger group age & it is very aggressive in this category. Survival rate is very low in this category. A survey study at an international level in 23 countries showed that the awareness in younger age is very low as compare to older women. This emphasizes the importance of promoting awareness among young women about not only breast cancer but any palpable mass in breast and strategies available for its screening are very much essential. Early detection plays a pivotal role in the prevention of breast cancer. The techniques which are recommended for precautions to reduce breast cancer and ultimately morbidity and mortality include easily available method as breast self-examination (BSE), Clinical breast-examination (CSE) and mammography. It is need to promote awareness in society not only about breast cancer but any palpable mass find in breast and different techniques available for its screening. Early detection is one good way to prevent breast cancer. WHO has recommended clinical breast examination for the women who are attending the primary health centres for other health problems. There is an urgent need of intervention as to explore the need & way of different ways to detect breast cancer at earliest. So that incidence & mortality can be prevented.

Objective of the study.

1. To assess the level of knowledge and awareness of breast lumps and its early detection strategies in females.

2. To determine the attitude of females towards screening.

Material and Methods

Study design – It will be a Cross sectional observational study. The sample selection will be randomized. A structured and validated questioner will be prepared to assess knowledge and attitude about Breast lumps among women attending OPD of Mahatma Gandhi Hospital will be interviewed personally. Questionnaire administered by an interviewer will be used to survey socio demographic factors, knowledge, attitude and awareness regarding any palpable mass of breast. Before interviewing the verbal consent of the subject will be taken.

Study place: Study conducted in Mahatma Gandhi Ayurved Hospital, Salod (H), Wardha, which is NABH accredited learning Institute under the ambit of Datta Meghe Institute of Medical Sciences University, Wardha, Maharashtra.

Study Population: All the females above age of 14 years attending the hospital were interviewed.

Methodology

The Participants will be explained about the nature and purpose of study. Consent will be obtained from the participants prior to their recruitment in the study. A self-structured questionnaire will be prepared and validated by the subject expert. All the subjects will be personally interviewed on the basis of questionnaire. The study will be conducted from October 2019 to November 2019. In this period, the females above the age of 14 years attending the hospital in the OPD hours 10 am to 1 pm will be interviewed. The non-probability convenient sampling method will be used to collect data. Their data will be collected and analysed statistically.

Inclusion Criteria

Females above the age of 14 years who are willing to give their consent will be selected for study.

Exclusion Criteria

Pregnant and lactating women will be excluded from the study.

Recruitment

Women willing to participate in this study will be provided details regarding the study by verbal explanation. Those who will agree will be provided information and the questionnaire.

Recruited participant must include in eligibility criteria.

Ethical Consideration

The approval of research protocol has been obtained from Institutional Ethical Committee, MGACH & RC, Salod(H), Wardha with letter no. DMIMS (DU)/IEC/
Expected Results

Promoting awareness in women regarding breast lumps and other various health issues will be the main focus. Even though many more programmes are taking care of these issues at government level, this study will focus on the level of knowledge, awareness & attitude about breast lump among women. Result will be interpreted on the basis of statistical analysis.

Discussion

Education that may be formal or informal way plays an important role in this condition. It helps to understand health related issues. The knowledge about importance of Self Breast Examination, Clinical Breast Examination & mammography will helps the society a lot. Discussion will be derived on all these parameters.

Strengths and Limitations - Strength of the study is that this assessment and then planning of intervention is at rural hospital area. This will provide a big advantage to the community.

Ethical Issues at the Interface of Physiotherapy Care and Research Practice in Pediatric Oncology—Descriptive Study

Malarvizhi D1, Metha K S2

1Dean, 2BPT IV YEAR, SRM College of Physiotherapy, SRM Institute of Science and Technology, Kattankulathur, Chennai, Tamil Nadu, India

Abstract

Pediatric oncology has a major role in research. This paper discusses about the ethical consequences of physiotherapy care and research in Pediatric Oncology. Empirical ethics is a broad division, grasping, difference in indicating ethics and empirical research. A major Australian tertiary teaching hospital reveals that 65% of patients present with specific indication for physiotherapy, in that only 12.8% are receiving physiotherapy. Indications include in physiotherapy care are pain, lymph-oedema, incontinence, respiratory and musculoskeletal problems also it includes hard to move. Physiotherapy has extensive role in palliative oncology, it also has large preventative, educative and supportive roles to play and provides independent and complementary therapies for physical debility and pain. Pain from reflex spasm and contracture are dealt with Physiotherapists. Founded that no reference based on standard of life and quality-adjusted life years in terms of preventing dependance and avoid hospitalisation. Treatment of pediatric oncology often has physically, socially and psychologically demands. Always there must be some ethical reason for all the decision on treatment and care for a patient with cancer. It is a fact that ethics needs not only all the stakeholders to do the right things but also it needs the one who do it in the right way. Research practice has led us to great advances in pediatric oncology and the proportion is greater in children than adults. Obtaining the informed consent and assent was the most important ethical challenges faced during the research.

Key words: Ethical issues, Pediatric oncology, Empirical research, Physiotherapy care, consent, assent

Introduction

In Pediatric oncology, children were treated for cancer to increase survival rate. Pediatric with oncology overall survival rate has improved to 25% - 75% in last 5-years compare to past 30 years due to improvement in supportive care.1 Pediatric oncology has a major role in research ideas. As a consequences, many Physiotherapist are indulged in both physiotherapy care and research. The national and international protocols, explained the information of treatment procedure for each type of cancer. In research 70% of children present with cancer are enrolled in study they were from developed country and enroll even during their cancer treatment.1 The process of research and Physiotherapy in the Pediatric oncology has more ethical challenges. Aim of this paper to differentiate between the Physiotherapy care and research practice on children with cancer.1 A major Australian teaching hospital reveals that 65% of children presents with particular indication in physiotherapy, in that only 12.8% are getting physiotherapy.2 Indications includes in physiotherapy care are pain, lymph-oedema, incontinence, respiratory and musculoskeletal problems also it includes hard to move.2

Today, the involvement of physiotherapy on Pediatric oncology has specific roles which are evidence based: Prevention - target specific exercise and education programs, Acute and post acute – bio psychosocial to pain management, Institutional and community based rehabilitation - Easy measure (e.g. wheel chair training after spinal cord compression, gait training for neurological dysfunction and Palliative care - Physiotherapy specific skills such as TENS used for relief pain, lymph-oedema and incontinence programs, laser therapy for wounds and ulcer management and maintenance of free movements and physical function.2

The health-care professionals described many ethical issues facing on physiotherapy and research on...
piediatric oncology based systematic literature.

**Methodology**

A study design was descriptive study. Empirical evidence was more popular and most important from a applied ethics, especially in bioethics. It also has broad category grasping different explanation about the content in ethics and empirical research. To gain empirical information, we collected an article based on descriptive study on observation of parents, children and physiotherapist in physiotherapy care and research practice. The experiences about the ethical issue on pediatric oncology research has the goals. The goals are such as research, informed consent, interests and therapeutic misconception. The knowledge of children, parents and physiotherapists in research gives deep understanding in research and the ethical role in research practice. There are different type of empirical research and ethical reflection: firstly - empirical ethics states that the study of people's belief, intuitions, behaviour and information is meaningful in ethics and it has the emerge ethical points; secondly - empirical ethics accept that the methodology (with descriptive methods such as collecting article related experiments, interviews and observation); thirdly - empirical ethics states that the contrast across descriptive and prescriptive study.

**Discussion**

Analysis of 10 studies were reviewed, it has the contrast between research and physiotherapy care in pediatric oncology. It has problem with informed consent and learn about research setting. Its has the consequence of disappear boundary between research and physiotherapy care. Also ethical view has different in treatment and research goals.

Martine C de Vries et al. 2011 described in term of research, the researchers find the information about what would be the best treatment for children with oncology and improve the interest in research in academic merit. Pediatric oncology child therefore undergo the procedure like blood sample, spinal taps and PET scans not related to treatment goals. Ethics has different two-dimensional treatment and research were provide by the various types of ethical principles. Normally parents and physiotherapist will discuss the idea on what the child interest and make it to use concept on consent. And the treatment should given on the interest of the individual child. Respect given for rights incorporates two ethical decision: 1) The individuals were willing to participate in study 2) the person with smaller or less rights entitled to protection. Respect to rights of the individuals they were voluntarily to participate in the research with basic information about the research and the consent. The research and physiotherapy care has the different in methods simultaneously applied to everyday practice of pediatric oncology. It have the consequence for the informed consent and the child with interest are difficulty to identify by the parents and physiotherapists. Pediatric oncology has many difficulty to get an good informed consent process, specially regarding diagnosis and treatment. Informed consent of participation has there own decision making after understanding the treatment protocols and research and make the participant to participate in the both research and physiotherapy care. The consent form has the following: explaining concept and method it has difficult to understand about it. Although the parent has difficulty in understanding about the informed consent in research such as the risk factors, the procedure, the alternate treatment, the duration of study, the right to dropout and the voluntaries to participate. The duty of parents to care the child, the parents are enrolling their children in clinical care and some will take interest to make their child to participate in research. Motivate and support the research to prevent the future generation from the occurrence. The misunderstanding were happen in between research and clinical care of physiotherapy, parents were mix up the research and clinical (treatment protocol) its has the major disadvantage. The study has revealed that 40 - 80% of subjects has misunderstanding of the research. Not only parents are confusion but also the physiotherapist has confusion while conducting both research and clinical session simultaneously.

Liisa Laakso et al. 2006 stated that palliative care provide both positively team based and community based activity. Approaching the advice and care of a therapist has the effectively utilizes and experience the health care and benefit.

Jean-Claude K Dupont et al. 2016 concluded that the wide spread of ethical issues founded in pediatric oncology. It shows the therapists, parents and child take interest to participate in the research. The evidence of
positive and negative effect of participants were offering research in pediatric oncology. Ethical reflection were need to develop in pediatric oncology community among a person with an interest and have the knowledge about it. Empirical ethics has the difficulty to find out the result with individuals studies. Difficulty to document the informed consent because of the misleading communication or misunderstanding about the research. It has the categories such as (misconception, misestimating or misunderstanding).

Cecilia Bartholdson et al 2014 described based on this study finding it has divided into two domains, which has the objectives of study: ethical related and dealing with ethical related concept. Ethical related issues has dealing with truth about the children diagnosis, treatment and prognosis are unknown to children and the parents prevents the truth-telling to the children. Preventing Truth-telling has the ethical issues and stress to the parents. parents and therapists has protect and preserve the truth-telling still the end of the life. The many results of the study has shown the goals achieved by the child were interest to participate in the study. On major, the pediatric with cancer will affect the family, relatives and caregiver. Because the pediatric is present with cancer. The current study has pain relief as the major goals.

lynette Rashleigh et al 1996 stated that the physical dangers occurs in end stage of cancer and that are managed by the trained professional to deal with it, as a part of physiotherapy. In physiotherapy, the main aim is to reduced the pain in cancer patient. To avoid unnecessary and expensive drug intake by cancer people and involve the people in community level physiotherapy by the patients and care givers.

Stacey L et al 2007 concluded that clinical research has been necessary to improve mortality rate and reduce disorder and improve treatment related to the disease in children with cancer. Before that obtaining informed consent and assent from the child participants. It has the major Challenges on pediatric oncology, children and parents to understands about it.

Conclusion

Research will be continued to improve survival rate and decreasing disease morbidity rate in pediatric oncology. Above all studies found difficult in obtaining informed consent and assent from both parents and children to participate. Researcher and therapist found difficulty to make the parents and children understanding about the procedure and the protocol. Major ethical issues founded were parents were confused with treatment protocol in both research and clinical care practice.

Ethical Clearance: Departmental Ethical clearance was obtained.

Conflict of Interest: Nil

Age Estimation from Fusion of Manubrium & Xiphoid Process with Sternal Body: A Radiological Study in Living Individuals from Central India

Ninad Nagrale1, Swapnil Patond2, Prakash Mohite3
1Associate Professor, Department of Forensic Medicine, Datta Meghe Institute of Medical Sciences, Nagpur, , Maharashtra, India (MS), 2Associate Professor, Department of Forensic Medicine, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Wardha, Maharashtra, India. (MS), 3Professor, Department of Forensic Medicine, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Wardha, Maharashtra, India (MS)

Abstract

Forensic Age Estimation is an expertise in Forensic Medicine which aims to find out the most accurate way of determining the chronological age of the unknown person involved in judicial or legal proceedings. This study aims to investigate the relationship between the stage of union at Manubrium, Sternum & Xiphoid Process and biological age in Chhattisgarh population. The study was carried out in 270 healthy subjects (135 males and 135 females) aging from 25 to 70 years. The obtained results from the radiographs revealed that the complete fusion of Xiphoid process & Manubrium with the body of sternum is seen in more than & 70% of individuals in the age group of 50-55 years. Females were consistently developing union at a younger age than their male counterparts. Results also suggest that the age of union is found to vary greatly all over the India indicating the need for separate standards of age of epiphyseal union for separate regions.

Key Words: Manubrium, Sternum, Xiphoid, Union, Central India.

Introduction

Age Estimation is necessary in the identification and creation of biological profiles, which can then be compared with suspects, victims or missing persons. Human identification whether living or dead is one of the most crucial tasks in medico-legal practice. The services of Forensic Medicine experts are sought in establishing the identity of the dead, especially in mass disasters. Extreme mutilation, advanced decomposition, skeletal and fragmentary remains, makes the process more complicated. Most of the time, Forensic Medicine specialists have to mainly depend upon bones for establishing the identity. Estimation of age in elderly person is comparatively more difficult than in young persons. The young individual has various factors for age estimation such as physical and morphological features, eruption of teeth, ossification activities and growth of bones which help in establishing the age with utmost accuracy. On the contrary, the elderly persons have very few identifying factors like fusion of sternal bones, fusion of skull sutures, changes that occur in the pubic symphysis, degenerative changes and application of Gustafson’s formula. Age estimation in elderly person has limitations due to paucity of anatomical factors. The present study is an attempt to assess the age of an individual from sternum which is one of the superficial bones, and is spared even in a highly decomposed body. Moreover, it is a bone which can be easily procured from cadavers, without the slightest damage during a routine autopsy procedure.
Aims & Objectives

1. To estimate age from union of manubrium sterni & xiphoid process with sternum.

2. To compare bisexual difference in union of manubrium sterni & xiphoid process with sternum.

3. To compare the findings of union of manubrium sterni & xiphoid process with sternum in Central Indian population with other parts of India on the basis of previous studies.

Material & Methods

The present study was carried out in the Department of Forensic Medicine & Department of Radiology, SSIMS, Bilai, Chhattisgarh (Central India). A total of 270 individuals participated in this study. The subjects included were individuals of 25-70 years of age from Bilai city. They are born to parents living in Central India and have lived here since birth. The subjects do not have any disease/deformity pertaining to bones or chronic disease affecting the general health. Only those cases were considered whose records for date of birth were available. The X-Ray Sternum Lateral View was taken of study cases after obtaining their written informed consent. In this study only bonafide residents, who do not show any disease in respect to anterior chest wall were considered. The female cases were taken less because of poor quality of X–Ray film due to over shadowing of the breast tissue. The status of Fusion of Xiphisternum and Manubrium with the body of sternum was studied. At the end conclusions were drawn, which were compared with available results of various previous studies.

Summary and Conclusion

1. This study was conducted exclusively on the young indigenous population of Central India (Chhattisgarh).

2. The union of Xiphoid process with sternum in 80% males is seen in the age group of 50-55 years.

3. The union of Xiphoid process with sternum in >70% females is seen in the age group of 50-55 years.

4. The union of manubrium with sternum in 80% males & females is seen in the age group of 50-55 years.

5. Females were consistently developing union at a younger age than their male counterparts.

6. Fusion was delayed by 5-10 years in this study (Central India) as compared to population of South India but is in agreement with some studies done in Gujarat.

7. Central Indian population is of mixed type comprising of various religions and castes. The opinion about age should always be given in the range.

8. For age estimation, relevant joints should be radiologically examined for different centres and opinion should be arrived considering the status of multiple centres.

Ethical Clearance: Taken from institutional ethical committee.

Funding: Article did not receive any specific grant from funding agency

Conflict of interest: Author declares that there is no conflict of interest

Assessment of Knowledge and attitude about Medicolegal Aspect of Organ Donation amongst Medical Students

Pande Varsha1, Nagrale Ninad2, Patond Swapnil3

1Assistant Professor, Department of Anatomy, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Wardha, Maharashtra, India, 2Associate Professor, Department of Forensic Medicine, Datta Meghe Institute of Medical Sciences, Nagpur, Maharashtra, India (MS), 3Associate Professor, Department of Forensic Medicine, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Wardha, Maharashtra, India

Abstract

Organ Donation is one the lifesaving procedure for many critically ill patients with organ failure. Even if the various advanced and modern medical science and technology, there is Scarcity of organs led to big gap between the demand and Supply of organs with number of donors. Present study was conducted At Jawaharlal Nehru medical college DMIMS, Wardha. It was a cross sectional study and second year medical students who were willing to participate included in the study. After taking their informed consent total of 100 students, brief introduction about the scope of our study, general demographic data was collected. Most of the students answered correctly the knowledge based questions on Organ Donation Appropriate knowledge and a positive attitude by health science students could play a crucial role in shaping public perspective.

Keywords: Organ donation, Knowledge, Attitude, Medical students, Donor

Introduction

Health care professionals are the first person to build the a relationship with the family of donor and health care providers have an opportunity to up thrust the option of organ donation. It has been suggested that a positive attitude of health professionals toward organ donation can influence a potential donor family’s decision to consent2

Main reasons for a shortfall in transplantable organs in all countries are Lack of awareness amongst healthcare professionals to identify brain-dead patients as a potential donor is one reason. Organ donation from brain-dead patients is a particularly contentious, following recent legal recognition of brain death within the cultural context of Confucian beliefs3

Nurses, physicians and health care professionals also responsible for requesting organ donation from the family of a brain-dead patient. Since they are in direct contact with patient care and relative’s. Health care professional hypothesized that staff support, knowledge, and training levels would be significantly associated
with organ donation rates.  

The knowledge, skills, and attitudes necessary for physicians and nurses to promote good end-of-life decision-making are widely variable. Active Participation require for those making requests of families for organ donation and should receive training related to procedure.  

**Material and Methods**

This study was conducted At Jawaharlal Nehru medical college DMIMS, Wardha. It was a cross sectional study and second year students who were willing to participate included in the study. After taking their informed consent total of 100 students, brief introduction about the scope of our study, general demographic data was collected.

Complete procedures involved in the study was explained to them and the assurance of confidentiality of the data collected was given. Structured questionnaire on knowledge and attitude was sent by internet to every participant.

**Results:** All 100 students had replied positively, out of these 53% were female and 47% male as depicted in Table 1

**Table 1:** Gender wise distribution of Allied Health Care Professional students

Attitude of students about organ donation, almost all respondents agreed on discussing organ donation with family member and most of the participant response positively about donation of organ 88 % and 68 % respectively And also agrees that its duty of health care professionals to give information regarding organ donation to Patient and relatives.

**Discussion**

In modern era, India witnessed its first successful corneal, kidney and cardiac transplant in the year 1960, 1967 and 1994 though the reverberations for organ donation and transplantation. The legislation called the Transplantation of Human Organ Act was passed in India in 1994 to streamline organ donation and transplantation activities. Broadly, the act accepted brain death as a form of death and made the sale of organs a punishable offence.

Pathi et al reveals that there was significant knowledge gap exists amongst the undergraduates and the general population for organ donation. The positive influence of educational intervention emphasizes the need of an intervention to bring positive changes thereby highlighting the significance of health education.

Sucharitha et al found that there is a positive attitude of medical students towards organ donation but there is lack of sufficient knowledge on the topic. Improving their knowledge by including organ donation topic in medical curriculum can help to reduce this gap.

Schaeffner et al found that knowledge and positive attitude in medical education is toward organ donation are more likely to hold an organ donor card and also feel more comfortable in approaching relatives of potential organ donors.

Similarly Marquès-Lespier found in his study that the students of health sciences professions have an
Optimistic attitude towards organ donation. Although a considerable shortfall of knowledge of organ donation amongst is a barrier to their taking the necessary measures to become active donors.

**Conclusion**

A positive attitude and relevant knowledge of health science students could play a crucial part in shaping public outlook. The CBME and Integrated teaching in medical curriculum must highlight and focus on the importance of organ donation, concept of brainstem death. This significantly associated with organ donation rates.

Prevalence of Associated Factors of Depressive Symptoms among School Going Children’s

Sonal B. Dhobe¹, Samruddhi Gujar²
¹Student, Medical Surgical Nursing, Smt. Radhikabai Meghe Memorial College of Nursing, Datta Meghe Institute of Medical Sciences, (Deemed to be University), Sawangi (Meghe), ²Clinical Instructor, Smt. Radhikabai Meghe Memorial College of Nursing, Sawangi (M), Wardha

Abstract
Depression is the most often encountered in the world of mental illness. In adulthood these mental disorders do not understand as people do not want to share their mental illness with health care providers, they are fearful of receiving approval from the physician. The community people in the last century did not accept the existence of mental illness to the children. Nowadays some studies can provide evidence of mental illness and treatment, or the medical field is also evolving so that people believe disease and death rates. Earlier studies show that depression is prevalent in adolescents (10% to 60%). The mood disorder (depressive mood) may inform lows all around, people may go to sadness in this condition, and in a severe case, people may end their lives. A person may suffer for a long period in a situation in which he or she feels sad and does not participate in social, personal, professional life. In all life situations, the person feels low and does not feel pleasure in everyday life, so if the individual can feel these things in their life so that they consider depression. Influence of depression mood which is unusual at a particular age. This can lead to negative effects on a friend, social, and family relationship. Most suicide and suicidal behavior can lead to major depressive disorders. Younger depression can lead to chronic waxing and increased risk of major depression in adulthood. Some studies can indicate that depression may occur early in adulthood as opposed to people’s past lives.

Keywords: prevalence, depression, mental illness, suicidal behavior.

Introduction
Depression (major depressive disorder) is a commonly diagnosed health problem that has a negative impact on how you feel, perceive and act. Fortunately this is always treatable. Sadness leads to the feeling of depression and/or lack of enthusiasm for once loved activities. It can contribute to many emotional and physical challenges which can impair an individual’s capacity to act at home and at work Important events in life, such as poverty or job loss, could cause depression. But doctors only see feelings of distress as part of depression if they carry on. Depression is a persistent and not a passing problem. This is made up of episodes where symptoms last for a minimum of 2 weeks. Depression can take several weeks, months, or years to last.

The mood disorder (depressive mood) will explain the emotional lows all around, people with this condition can go through depression, and people in a serious situation can end their lives. In certain cases a person may suffer for an extended period of time because he feels depressed and is not involved in social, family, or professional life. The person who feels low in every situation of life and does not feel joy in everyday life and if the individual can feel these things in their life then...
he / she considers depression. In this particular period the influence of depressed mood is extraordinary. It will have a negative impact on relationships with friends, the social, and family. A major depressive disorder can cause most depression and suicidal actions. The greatest depressive disorder also affects the most suicide and suicidal behaviour. Younger depression can lead to constant waxing and an increased risk of serious adult depression. Some research may indicate that depression can lead to early adulthood as opposed to previous lives.

**Definition**

Depression is a mood condition which implies a lasting sense of depression and lack of interest. This is different from the mood swings that people regularly experience as part of life.

**Prevalence**

Data available show that the point prevalence of depression / affective disorders varies from 1.2% to 21% in clinical-based studies; 3%-68% in school-based studies, and 0.1%-6.94% in community-based studies. India has only performed one incidence analysis estimating the incidence to be 1.6 percent.

**Risk Factors**

Genetics: A family history of depression can increase chances of having a depression. The disease may be passed on, it’s believed. The precise manner in which this occurs is not clear though.

Death or loss: Sadness and sorrow are natural reactions. Nevertheless, these great pressures can often carry with them severe signs of depression, such as thoughts of suicide or feelings of worthlessness.

Conflict: Personal disputes or disagreements between family and friends may lead to depression.

Abuse: It may also be brought about by physical, sexual, or emotional violence.

Events in life: Even good things could make you depressed, like moving or graduating.

Different diseases: Depression often pairs with another disorder, or can be a reaction to it.

Medicines: Depression can be a side effect of medication that patients taking for a particular illness.

Abuse of substances: Up to 30 percent of people who use drugs or alcohol also have depression. Some people misuse drugs when they’re feeling down. In others, heavy alcohol or drug use may cause depressive symptoms.

Other issues: Issues such as social isolation from another illness or family or social group alienation may lead to depression.

**Causes**

Although don’t know exactly what is the causes depression, several factors often correlate with its development. Depression is usually the result of combining recent events with other long-term or personal triggers, instead of an immediate crisis or accident.

Life events: Evidence suggests that chronic long-term unemployment problems, living in an abusive or dysfunctional relationship, long-term alienation or loneliness, constant work-related stress – are more likely to cause depression than recent life stress. However if the person is at risk due to past bad experiences or personal factors, recent events (such as losing person job) or a combination of events may cause depression. Evidence suggests that persistent long-term unemployment issues, living in an abusive or carefree relationship, long-term loneliness or isolation, excessive tension at work – are more likely to trigger depression than recent life stress. However, if the previous negative experiences or personal factors, the patient is still at risk.

**Person factors:**

- The history of a family
- Full personality
- Serious medical condition
- Alcohol and drug use

**Sign and Symptoms**

Depression symptoms typically progress over days or weeks but person can experience an anxiety or moderate depression period that persists for weeks or months in advance. Not everyone who has depression should be complaining about misery or constant low
mood. A person can experience other symptoms of depression, for example, sleep issues. Some would mourn the ambiguous physical signs.

Signs to feel a person include:

$\quad$ A person can experience other symptoms of depression, for example, sleep issues. Some would mourn the ambiguous physical signs.

$\quad$ Lack of interest in daily hobbies and enjoyment. That is a reduced enjoyment performance. This comes with a lack of sexual desire.

$\quad$ It’s a mood irritable. This may be the main change in mood, especially among young people, and among men (For Maori and Pacific minority groups in particular).

$\quad$ Changes in Sleep habits. Sleep deteriorated more often, with difficulty sleeping, sleep disrupted and/or early waking and unable to sleep again. Several men are oversleeping.

$\quad$ Shift in famine. Too many people don’t feel like eating, and may have lost weight as a result. Many people feel hungrier, even after having fun. For those who do more sleep this is also seen.

$\quad$ Less strength, less exhaustion and less exhaustion. Such feelings can be so serious that it seems too difficult to finish even the smallest task.

$\quad$ Physical slowing or restlessness also leads to extreme depression. For periods, the person may sit in one place, and turn, react, and talk very slowly; or maybe they can’t sit still, but hold pace and wring their hands. The same person can experience alternations which are slowing and agitating.

$\quad$ Truth or shame feelings. Thoughts of guilt or worthlessness. People may withdraw from doing things and contact others because they feel bad about themselves.

$\quad$ Hopelessness, and feelings of death. No hope in life can be felt by the individual, the wish that they were dead or feel suicidal.

$\quad$ Talk of danger. People can consider concentrating hard. Person can not read the paper or watch a TV. We can find it very difficult even to make easy daily decisions.

**Anxiety symptoms**

These are very common as a part of depression but these signs usually stop as depression is treated. Signs of fear include:

$\quad$ Excessive restlessness or anxiety associated with physical signs such as stress in the body, dry mouth and heart attack.

$\quad$ Attacks over panic. Sudden bouts of intense panic and anxiety, including signs of physical cravings.

$\quad$ Falun Gong. Concerns unique to circumstances, items or creatures

$\quad$ The physical wellbeing issues are severe.

Symptoms include depressed mood, diminished participation in play activities, attention issues, anger and behavioral problems such as aggression, pessimism, decreased appetite, reduced sleep, anhedonia, and somatic symptoms should include. 8

**Treatment**

Depression can’t go anywhere, by itself. However, if left untreated and ignored, depression can continue for months, even years, and can have many negative effects on a person’s life.

Each one has to find the care they need. Finding a workable cure will take time and patience.

Various forms of depression demand different treatment. Mild symptoms can be soothed by:

---->Knowing the Condition

$>Changes$ $in$ $lifestyle$ $(for$ $example$ $regular$ $physical$ $exercise)$

$>Psychiatric$ $care$ $offered$ $by$ $a$ $mental$ $health$ $professional$ $or$ $by$ $online$ $e$-therapy.

Medical treatments, in combination with these other treatments, are likely to be needed for moderate to more severe depression.

Depression treatment should start with a patient’s condition. Book an extended consultation to give time
to discuss symptoms and options for treatment. The doctor may ask to complete a screening questionnaire or perform certain tests to rule out other conditions.

Patients should be referred to a psychologist, social worker, counselor or psychiatrist by a doctor. Access a rebate through Medicare to see most of those professionals. This requires that physicians write a patient GP Mental Health Plan.

- Local community health center-get in touch with someone at your local council for details
- Local triage mental health service – they can give you advice about your nearest major hospital with a psychiatric department with mental health assessment staff available.

**Psychological treatments for depression**

Psychological therapy (also called speech therapy) have been shown to be an successful way to combat depression. We will help people adjust thought habits and develop their coping skills, so that you are better able to cope with life’s pressures and conflicts.

Through understanding and modifying unhelpful thoughts and behaviors, psychological therapy will help you remain well.

Several types of psychiatric therapies exist including:

- Cognitive behavior therapy ( CBT)
- Interpersonal (IPT) therapy;
- Comportemental therapy
- Cognitive therapy (MBCT) focused on alertness.

CBT is among therapies that are most widely used. This helps people with depression monitor and change negative thought patterns, and increases their ability to cope better with life’s stresses and conflicts.

A large variety of appropriate treatments are available for the major depressive disorder. Relevant medications (see Medication) and brief psychotherapy (e.g. cognitive-behavioral therapy, interpersonal counseling) can be used to relieve depressive symptoms. Scientific evidence also accounts for the ability of brief psychotherapy (CBT) to prevent relapse.

However, pharmacotherapy by itself is ineffective care in children and adolescents. Nevertheless, the combination of medication and psychotherapy typically provides the quickest and most effective solution in all patient groups.  

**Complementary therapies**

The word alternative therapy is widely used to describe methods and therapies that vary from conventional Western medicine, and can be used to support and maintain it. Some natural therapies will improve your life, and help patients stay healthy. It has been shown in general that attentiveness, hypnotherapy, meditation, exercise, relaxation, massage, mirimiri and aromatherapy all have some effect in alleviating mental distress.

**Complications**

Depression can get worse if left untreated and can lead to problems affecting any part of your life such as social, mental, behavioral, and physical.

- Panic assaults
- Social anxiety or a phobia that results in social isolation
- Weight loss or excessive weight gain
- Physical disorders and illnesses
- Attempts and suicidal thoughts
- Substance misuses like alcohol and medications
- Can affect the immune system

**Prevention**

Even if evidence-based care could be given to all individuals afflicted by a depressive illness due to the constant influx of new patients and the limited efficacy of medications currently available, the effect on averting disabled years will be marginal.

Prevention will offer new ways of reducing the burden of depressive disorders on the disease. Research by the Institute of Medicine described prevention as an initiative aimed at preventing new cases of mental
disorders that occur in individuals that are not yet meeting the criteria for such disorders. 13

**Conclusion**

Depression is the commonest condition in primary care, but it mostly undiagnosed, unrecognized and undiagnosed because of that prevalence will be an increase in the mental disorders. Depression having a high rate of mortality and morbidity when it was untreated. Most of the patient those who are suffering from depression never accept the condition and they feel afraid to get treated, but when the condition goes worse that time it will showing the sigh and symptoms that under controlled by the person. Psychotherapy that is the first line and effective treatment for the depression in mild and moderate phase but when a severe case is their so give treatment along with psychotherapy and medications. Those patients are live with depression along with their family and friends.

Bibliometric Analysis of Publications on Dental Caries and Dental Fluorosis from India

Rutuj Waghmare¹, Roshan Umate², Shobha Joshi³, Manoj Patil⁴

¹Post Graduate Student, Department of Community Medicine, Datta Meghe Institute of Medical Sciences Sawangi (M), Wardha, Maharashtra, India, ²Research Consultant, Department of Research and Development, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Wardha, Maharashtra, India, ³Post Graduate Student, Department of Community Medicine, Datta Meghe Institute of Medical Sciences Sawangi (M), Wardha, Maharashtra, India, ⁴Research Consultant, Department of Research and Development, School of Epidemiology and Public Health, Datta Meghe Institute of Medical Sciences, Sawangi (M), Wardha, Maharashtra, India.

Abstract

Introduction- Dentistry goes back to about 5000 BC when a “tooth worm” was believed to be the source of dental caries. Repeated processes of acid generation lead to the superficial degradation of calcified tissue in the tooth, and consequently cavitation. Work has shown that enamel demineralisation happens at a pH of 5.5 and below. World Health Organization (WHO) mission is Health for all. Fluoride containing drinking water and supplements such as tablets, gums, gel, and toothpastes are the major sources that could be responsible for increased fluoride consumption. At various periods of tooth growth, the ingestion of unnecessary fluoride may have a number of consequences on teeth, including the presence of white lines or streaks on enamel, yellow or brown streaks on enamel, and the general participation of enamel with white or dark chalky stains.

Material and Method- A systematic Search Strategy was framed using the specific keywords related to Dental Caries and Dental Fluorosis. The Web of Science Database was accessed and Search Query was input as “KP= (“Dental Caries*” OR “dental fluorosis*” OR “school children 8-13 Years*” OR DMFT* OR “Dean’s fluorosis Index*”)

Result- Search output generated total 210 documents from 111 Sources (Journals, Books, etc.) Over the period from 1999 – 2020. Total Author’s Keywords (DE) were 664

Conclusion- Dental caries is genuinely a neurological disease whose nature primarily depends on the existence of fermentable sugar, host factors, cariogenic microbial flora and other related environmental conditions. Researchers have proposed numerous theories within the context of dental caries. Fluoride is among the relatively few contaminants that may cause significant public safety impacts in drinking water. Various types of exposure to fluoride have been found to influence systemic F material, thereby raising the likelihood of fluoride sensitive diseases.

Keyword- Dental Caries, Dental fluorosis, Publications

Introduction

Dentistry goes back to about 5000 BC when a “tooth worm” was believed to be the source of dental caries. Around 1634 the expression “dental caries” first appears in the literature, which came from the Latin word “caries,” which stands for decay. Originally, the word was used to identify the gaps between the teeth. Dental caries have been reported to be among the earliest and
most common diseases that exist in humans. Dental caries is a common, chronic, transmissible disease that develops from specific bacteria that attach to the tooth, namely Streptococcus mutans that metabolize sugars to produce acid that demineralizes the tooth’s surface.

Dental caries is genuinely a neurological disease whose nature primarily depends on the existence of fermentable sugar, host factors, cariogenic microbial flora and other related environmental conditions. Researchers have proposed numerous theories within the context of dental caries. Another such hypothesis, suggested by W.D. in 1881. Miller is “chemo-parasitic theory,” which explains the cumulative impact of bacteria that create acids and acids in the oral cavity, and is universally accepted with modification. Using this hypothesis as the basis, many models have been suggested to address the theoretical aetiology of dental caries, such as J.L Williams, Keyes and Fitzgerald’s idea of plaque-causing dental caries to clarify the likely causal association of the involvement of different microorganisms such as lactobacilli, streptococci in dental plaque, and incidence of dental caries. A basic Venn diagram which consists of three circles and the motion of these circles will clarify the aetiology of dental caries. Two circles reflect fruit, plaque, or microbial charge, and in the sixth, the host takes position. Those three circles are intersected by caries. Recently a fourth “time” circle was added which determines the duration of the above circles’ interaction. Plaque and nutritional influences interdepend with one another in the development of dental caries. Through contrast, the third circle, which represents the host, acts as a mechanism for transmitting these variables.¹ The initiation and progression of dental caries involve specific microorganisms. Streptococcus mutations (S. mutans) have main connections with the initiation of dental caries, and Lactobacilli has connections with the development of dental caries. The polymers for these microbes are fermentable sugars, as well as the reserve of biofilm carbohydrates generated by bacteria. When the bacteria metabolize these substrates they create the lactic acids and other acids. In accordance with host factors, lactic acid synthesis reduces the oxygen coefficient locally, which facilitates the occurrence and growth of dental caries. Repeated processes of acid generation lead to the superficial degradation of calcified tissue in the tooth, and consequently cavitation. Work has shown that enamel demineralisation happens at a pH of 5.5 and below. World Health Organization (WHO) mission is Health for all. Universal Declaration (1998), recognizes that all members of the human family have ‘equal and inalienable rights.’² Dental caries is one of the common and most widespread illnesses of humans. While continuous efforts have been made to reduce its prevalence, it is still prevalent, especially in the lower socioeconomic groups. Globally, dental caries is a widespread problem of the disease. The prevalence of dental caries ranges from 49% to 83%, according to a recent survey by the Global Oral Health Data Bank. Regardless of age, almost all age groups are negatively impacted by dental caries. Data from different studies found that teenagers between the ages of 12 and 19 had the largest amount of dental caries accompanied by babies, and then adults. Kids are vulnerable to “rampant caries” or “nursing bottle caries” that mainly involve one or more decayed teeth in every primary dent between the birth date and 71 months of age.³ ⁴ While dental caries is in decreasing patterns in many sections of the developed world, in most developing countries it is still a major public health concern, affecting 60-90 % of school children claim a World Health Organization (WHO) study. In a transition from norm to a more westernized lifestyle, cultural, social and political developments in the developed world have had a major effect on food and wellness. Instead, services are shown to be insufficient for some key prevention initiatives. In fact, lack of knowledge and enthusiasm in the area of public health appears to be significant contributors to the rise in dental caries.⁵ India ranks among the world’s 25 nations, with ever-increasing increases in dental caries. There, dental caries continues as a charred disease that really has spread its tentacles widely into many regions where there have been insufficient dental care facilities, lack of public health awareness, motivation and increased usage of processed carbs.⁶ Dental caries is also a smoldering disease in developing countries such as India, which has extended its tentacles deep into regions where resources are inadequate for dental treatment, lack of medical awareness and incentive for increased consumption of carbohydrates.⁷ ⁸ Low wages, weak oral hygiene, schooling for mothers, fluorosis, enamel deficiency, multiple low socioeconomic interventions, low level of parental education and cariogenic diet all influence caries risk.⁹ ¹⁰ Approximately 60-65 % of the present...
incidence of dental caries in India is rising day by day. Geographical area plays an important role in caries prevalence; this fluctuates with changing location. Caries incidence in India was 51.9 percent, 53.8 percent, and 63.1 percent, respectively, at 5, 12, and 15 years, according to the 2004 National Oral Health Survey. Present, in various regions of India. A varied image shows the frequency of dental caries in India including its accessible literature from 1940 to 1960. Notwithstanding contradictory estimates, the incidence of dental caries was reported to be 55.5 per cent in India in 1940, and 68.4 per cent in 1960. Dental caries and dental fluorosis are double problems for school children in India, “fluoride is sometimes referred to as a double-edged weapon” – the effective and judicious usage of which provides optimum safety for caries, while unfair and unnecessary systemic intake will contribute to lingering fluoride toxicity. That manifests as dental fluorosis and skeletal fluorosis. In the literature, dental fluorosis was defined as a “developmental disruption caused by sustained exposure to high levels of fluoride during teeth development, resulting in the formation of enamel with reduced mineral content and increased porosity.” Fluoride (F-) is among the relatively few contaminants that may cause significant public safety impacts in drinking water. Various types of exposure to fluoride have been found to influence systemic F material, thereby raising the likelihood of fluoride sensitive diseases. Consumption of Fluoride has beneficial effects on small doses of teeth (< 1.0 mg / L), such as avoiding or reducing the likelihood of dental caries, which is one of the main worries among dentists. Such ion may deter new caries from developing, and could even cause some minor cavities to be retrieved. Increased ingestion of fluoride during enamel forming helps in enamel mottling this mottle enamel is also known as dental fluorosis. It causes visible differences in enamel (intrinsic tooth discoloration), which often contributes to actual injury to the teeth. The effect of the condition will vary according to the dosage, duration range and age of the individual during exposure. The esthetic portion of mild to extreme fluorosis is of significance as it allows the teeth to experience physical harm. Fluoride affects the dental caries forming cycle by three ways: enhancing the chemical enamel structure throughout its production and rendering it more immune to acid attack; promoting mineralization with increased enamel crystal quality; and the plaque microorganisms’ capacity to generate acid. However, too much fluoride absorbed for longer times (higher than 1.5–2 mg / l) may induce dental fluorosis. Fluoride containing drinking water and supplements such as tablets, gums, gel, and toothpastes are the major sources that could be responsible for increased fluoride consumption. At various periods of tooth growth, the ingestion of unnecessary fluoride may have a number of consequences on teeth, including the presence of white lines or streaks on enamel, yellow or brown streaks on enamel, and the general participation of enamel with white or dark chalky stains. Children below the age of 13 have oral health as the object of several epidemiological studies carried out around the world. According to the World Health Organization (WHO, 2013), the importance attributed to this age group is that it is the time that children leave primary school.

Methodology

A systematic Search Strategy was framed using the specific keywords related to Dental Caries and Dental Fluorosis. The Web of Science Database was accessed and Search Query was input as “KP=(“Dental Caries*” OR “dental fluorosis*” OR “school children 8-13 Years*” OR DMFT* OR “Dean’s fluorosis Index*”)”. The results were refined by Countries/Regions for India. A list of total 210 articles was retrieved which was imported R-Studio application and analyzed for various categories as outlined in the results.

Results

Search output generated total 210 documents from 111 Sources (Journals, Books, etc.) over the period from 1999 – 2020. Total Author’s Keywords (DE) were 664. Main data revealed following details-
The types of published documents obtained from Web of Science Database were as follows:

- Journal ARTICLE - 161
- ARTICLE, BOOK CHAPTER - 5
- ARTICLE, EARLY ACCESS - 3
- EDITORIAL MATERIAL - 2
- PROCEEDINGS PAPER - 1
- REVIEW - 37
- REVIEW, BOOK CHAPTER - 1

Discussion

The published materials of Health Sciences University show an increase in the year 2019 whereas the sum of total citations of published materials show a prominent rise in the year 2018. The sum of total citations of materials published in 2019 is expected to show sharp rise in the year 2020. Among all the publish mater Indian authors shows highest number of publication on the topic.

Conclusion

Dental caries is genuinely a neurological disease whose nature primarily depends on the existence of fermentable sugar, host factors, cariogenic microbial flora and other related environmental conditions. Researchers have proposed numerous theories within the context of dental caries. Fluoride is among the relatively few contaminants that may cause significant public safety impacts in drinking water. Various types of exposure to fluoride have been found to influence systemic F material, thereby raising the likelihood of fluoride sensitive diseases. Consumption of Fluoride has beneficial effects on small doses of teeth (< 1.0 mg / L), such as avoiding or reducing the likelihood of dental caries, which is one of the main worries among dentists.

Conflict of Interest - None

Source of Funding – None

Effect of Finger and Hand Exercises among Amateur Pianist

S.F. Mariyam Farzana¹, Ashish Mathew A²

¹Assistant Professor, Srm College of Physiotherapy, Srm Institute of Science And Technology, Kattankulathur Chennai 603 203, Tamilnadu, India, ²Final Year Student, SRM Institute of Science And Technology, Kattankulathur Chennai, Tamilnadu, India

Abstract

BACKGROUND: Now days the number of students studying piano in tertiary institution is being increasing. The piano player is similar to athletic activity to play the notes accurately. Posture plays a vital role in piano. Musicians are prone to injuries due to the nature of musical practice, inappropriate body postures and potentially harmful playing techniques. Majority of amateur players are prone to injuries .Amateur piano player experience pain in hands and fingers. The main objective of the study was to strengthen the finger and hand muscles to reduce the level of pain.

Methodology: Quasi Experimental study and convenient sampling. 20 amateur piano players, were selected according to inclusion and exclusion criteria. Pre test was done to the participants using V AS score, hand grip dynamometer and cornell musculoskeletal discomfort questionnaire. Finger and hand Exercise were given to the participants for 4 weeks . After 4 weeks of study to analyze their level of pain, a hand held cornell musculoskeletal discomfort questionnaire, V AS score and hand grip dynamometer were used to find the effect of finger and hand exercise exercise.

Outcome Measure: CORNELL MUSCULOSKELETAL DISCOMFORT QUESTIONNIARE, V AS SCORE,HAND GRIP DYNAMOMETER

Result & Conclusion: The study concludes that there was significant reduction in the level of pain and also the hand grip was significantly improved

Keywords: Amateur Piano player, harmful playing techniques, finger and hand pain,

Introduction

Piano is a classical and fascinating instrument. In 18th century Bartolomeo Christofori invented first generation of piano and twentieth century piano was highly developed and its quality , both in mechanism and sound reached its peak .Playing Piano notes accurately is similar to the athletic activity. The touch of each key weights around 52g for present day acoustic piano. Piano needs an application of greater muscle effort to stabilize the finger joints¹.

Most of the public music is often perceived as fun and safe job without posing any harm to the body . There is a possibility for musicians to suffer from injuries. Pianist are prone injuries due to nature of musical practice.

The occurrence of “Playing related musculoskeletal disorders” is almost unavoidable when a given motion is highly repetitive when combined with the prolonged use of body segments and without a proper understanding of the anatomical limits and motion ranges of the Human body.

From the history of piano playing, some experience regarding injuries was recorded such as Robert and Clara Schumann and Sergei Rachmaninov. In twentieth century when piano was highly developed and its quality both in mechanism and sound reached at its peak, many contemporary pianists reported their symptoms and their horrible experience after injuries were developed such as Glenn Gould, and Leon Fleisher (Mark, 1999). In most of cases, injuries can be so severe that they cannot even perform and play some kind of repertoire³.

The present research has shown that Prevalence of PRMD has been reported in the range of 25%to 93%.

Now days students learning music in tertiary institution
has been increasing. The students require extreme mental and physical endurance strength to perform. Although piano techniques vary in different genres of music, examples of faulty piano techniques that could put pianists at risk of PRMD include fingers pressing too hard on the keyboard, head deviating from the central position, elevated shoulder, curving of the wrist which should be in a straight line with the fifth finger, forearm raised until it is not parallel with the floor, elbow too close or too far from the body, and locked wrist.

A regular practice session on daily basis is required for a pianist to reach the required standard. Some piano pieces require more grip and strength in fingers, for example pieces like “MODERATO” AND ALLEGRO. So to play the notes accurately the students practice a lot. A sudden increase of practice time before examination and performance is one such cause of PRMD. Lack of finger exercise prior to and after piano playing is also a risk factor of PRMD. As well, a lack of warm-up and cool-down exercises prior to and after piano playing is also a risk factor for PRMD. The main objective of the study is to strengthen the finger and hand muscles and to reduce the level of pain.

Materials and Methods

The study is an Quazi Experimental study which was conducted in 2020 at Kingsway Music Academy. In this study twenty amateur piano students of both men and women between the age 18 -21 were recruited. The Grade exam appearing students who practice for 60 mins a day and who had Playing related musculoskeletal disorder in Hand and wrist were recruited. The students who learn other instrument along with piano were excluded. Initially the level of pain and hand grip was measure using Vas Score and Hand grip Dynamometer and Cornell musculoskeletal discomfort questionnaire was given to disclose the discomfort in the hand among the participants.

The exercise protocol had been charted out, for 4 weeks duration, twice a day, weekly thrice, 3sets,10 times repetition. Stretching exercise for forearm and finger flexors, lumbricals and thumb extensors with 5 seconds hold. Free exercises such as finger opening and closing, finger taps and thumb bending exercises were charted for the participants. Elastic band resistance was used to strengthen the finger and thumb abductors. Digi flex finger strenghtener was used for strengthening MCP and interphalangeal joint flexor.

Then after 4 weeks of exercise, the Vas score was measured to analyze the level of pain and Hand grip dynamometer to measure the hand grip. Cornell musculoskeletal discomfort questionnaire was given to disclose the discomfort in the hand among the participants.

Result

A total 20 participants were selected in which 11 were women and 9 were men. Out of 20 students 25% were 18 years of age ,25 % were 19 years of age ,25% of them 20 years of age and 25% of them were 21 years of age.

From Table III the pre and post test value, analyzed according to Cornell musculoskeletal discomfort questionnaire. In Area A the mean value of pre test was 5.05 and post test was 2.750. In Area B mean value of pre test was 9.05 and post test was 4.925. In Area C mean value of pre test value was 2.55 and post test value was 2.125. In Area D the mean value of pre test value was 0.50 and post test value was 0.250. In Area E the mean value of pre test value was 3.20 and post test value was 1.8255. In Area F the mean value of pre test value was 4.50 and post test value was 2.050. The pre and post test values analyzed using questionnaire show that pain has been significantly decreased.

From Table IV the level of pain and hand grip was analyzed. The mean value of vas score in pre test was 5.15 and post test was 3.750 in which the level of pain had been significantly decreased. The mean value of hand grip in pre test was 10.25 and post test was 12.500 in which hand grip has been increased.

Discussion

Piano, the hammer incorporated in it strikes the strings and reproduces the sound of musical note, when the key pressed stronger, the velocity of the hammer striking the strings is increased and more sound will be produced(1) this 20th century many young population particularly school going students are interested to learn playing piano as an recreational activity and as an passion on music.
The musculoskeletal injuries in work and recreational activities like sports are common, similarly playing musical instruments is also prone to cause musculoskeletal injuries called Playing-Related Musculoskeletal Disorders (PRMDs).

This PRMDs is common among amateur piano players, mainly due to the posture which assumed and maintained during playing the piano, the wrist and hand symptoms are common among them. There are three types of wrist posture commonly assumed during playing piano, one is high wrist, neutral wrist and weight piano playing. The first one high wrist is preferred by few piano players which is traditional, in this wrist will be higher than the keyboard, the second one is neutral wrist in this the piano player assumes the wrist in neutral posture, the wrist corresponds appropriately to the level of keyboard, the third one weight on piano in this wrist rotates while playing and weight of the hand and wrist will be on the fingers. While playing piano along with wrist and fingers, the elbow and shoulder joints is also involved. While playing piano the posture assumed by the fingers can be flat or rounded, posture of elbow can be straight or bent and posture of shoulder can be elevated or non-elevated. The motion of the fingers can horizontal or vertical while playing piano. Apart from the joints of upper extremities, there will be involvement of motion of neck and torso while playing piano(2).

The wrist joint connects the hand an sensory organ to upper extremity. Numerous muscles, tendons, nerves and vascular structures of hand transverses wrist joint. The neutral wrist joint posture plays a crucial role for normal functioning of these structures, which transversing it and in preventing injuries to these structures from mechanical origin.

The commonly assumed wrist postures during playing the piano are high wrist, neutral wrist and weight of piano. These postures are not an neutral posture for wrist joint, the neutral posture of wrist is forearm in mid prone position, wrist joint neutral with out any flexion, extension, radial and ulnar deviation(5).

In all the three postures which commonly assumed during playing piano, the forearm will be in a fully pronated position, in which radius shaft will be twisted on ulna and with arthro kinematic changes in the inferior radio-ulnar joint such as radius will be migrates medially and superiorly on ulna and ulna abducts and migrates posteriorly(4).

In high wrist posture and weight on piano playing the wrist will be in flexion, the proximal carpal row of wrist will moves volarly and distal row palmarly(4).

In all the three postures of wrist while playing piano, in the MCP joints of fingers, the proximal phalanx will slides and rolls palmarly on flexion and volarly on extension, the proximal phalanx and slides and rolls laterally during abduction, in the corresponding metacarpals. In the interphalangeal joints of fingers, the phalanx will be rolling and sliding palmarly and volarly on finger flexion and extension movements. The first metacarpal of thumb slides and rolls on trapezium palmarly on abduction, medially on flexion, laterally on extension.(3)(6)

The repetitive motion and sustained posture of wrist while playing piano and the arthro-kinematic changes due to it, in inferior radio-ulna joint, carpal joints, MCP joints and interphalangeal joints interfere with structures transversing the joint, commonly there will be length-tension changes in the musculo-tendinous structures and it is prone to cause muscle fatigue, myofascial trigger points, tendinitis and etc. Most commonly the long flexors and extensors of wrist and fingers, thenar muscles, lumbricals, palmar and dorsal introssei muscles are involved. At times the neural structures adjacent to these musculo-skeletal structures is also involved in causing pain and numbness.

The wrist posture other than the neutral will over tax the musculo-tendinous structures and it is prone to cause PRMDs and loss of grip strength(7). Same time the repetitive motion of the fingers and thumb are prone to PRMDs. The long flexors and extensors of wrist and fingers are affected by non-neutral wrist posture and repetitive motions, the intrinsic musculature are affected by sustained finger flexion and abduction and repetitive motions.

The muscular structures of wrist and hand are primarily involved in causing PRMDs among piano players. The PRMDs is more prevalent among adult and children amateur piano players. The common cause of the PRMDs among the amateur players are improper posture of wrist assumed during practice and playing.
lack of strength and flexibility in wrist and finger muscles.

In this study 20 amateur piano player, both male and female genders, between the age group of 18 to 21 years, who had PRMDs in wrist and hand due to playing piano had been selected in and around chennai. In this study on pre-test The pain had been measured with VAS scale, the hand grip strength were measured with hand held dynamometer and cornell musculoskeletal discomfort questionnaire was given to disclose the discomfort in the hand among the participants.

The exercise protocol had been charted out for this 20 participants, for 4 weeks duration, twice a day, weekly thrice, 3 sets, 10 times repetition. Stretching exercise for forearm and finger flexors, lumbricals and thumb extensors with 5 seconds hold. Free exercises such as finger opening and closing, finger taps and thumb bending. Exercise with elastic resistance band to strengthen finger and thumb abductors and finger play strengthener for strengthening MCP and interhalangeal joint flexors. After 4 weeks charted exercise protocol, there was significant improvement among this 20 piano players pain and discomfort in wrist and hand.

**Conclusion**

The study concludes that lack of warm up and cool down exercise among amateur pianist is the cause of PRMD. The study also concludes that Correct positioning at the piano can play a large role in achieving correct balance and posture creating tension free playing. The possible prevention of future occurrence of playing related musculoskeletal disorder is to seek a set of suitable playing technique that is user friendly. Along with posture warm up and cool down exercise can be charted for the amateur piano players so that level finger pain, and fatigue can be minimized.

**Limitation**

Sample size is less.

Limited age group was included.

Protocol Duration was lesser.

**Recommendation**

Interference with large sample.

Exercise Duration could be increased.

Motion capture analysis camera can be used

Appropriate Questionnaire can be designed

**Conflict of Interest:** Nil

**Source of Funding:** Self Funding

**Ethical Clearance:** Institutional Ethical Committe

Analysis of Posture Using Posture Screening Mobile Application among Collegiates

S.F. Mariyam Farzana¹, Pooja²,
¹Assistant Professor, ²Student, SRM College of Physiotherapy, SRM Institute of Science and Technology, Kattankulathur Chennai 603 203, Tamilnadu, India

Abstract

BACKGROUND: A posture is a position of the body which is maintained by the balanced muscular forces on the skeletal system. The posture is affected by the imbalance between the muscle force and also by reduction or increase in the muscle length. OBJECTIVE: To analyze the posture using posture screening mobile application among collegiates. METHODOLOGY: It is a non-experimental, observational study, sample size 200 subjects both genders between 19 to 23 years, more than 18.5 to 25 ratios of BMI were conveniently included in the study. The exclusion criteria was any congenital or acquired musculoskeletal problems and recent surgeries fractures and injuries. METHOD: A written informed consent was taken from the subjects. The posture assessment was taken using posture screening mobile application and was documented. RESULTS: The result shows the percentage of abnormal posture deviation among normal BMI collegiates. CONCLUSION: The study concluded that the prevention of musculoskeletal disorders among young individuals with normal BMI is one of the challenging issues among health care professionals.

Keywords: posture, musculoskeletal disorder, posture screening mobile application

Introduction

Musculoskeletal disorders describe the conditions that affect the muscle bones and joints. Many studies and literatures quotes that the prevalence of musculoskeletal disorder among students are increasing. The factors that contribute to musculoskeletal disorder are imbalance in biomechanics of body, improper posture, weak muscles and endurance¹.

A posture is defined as position of the body or the arrangements of the body segments relative to one another². The posture can be either static or dynamic.

During static posture, in certain positions such as standing, sitting, lying and kneeling, the body and its segments are balanced and maintained. Dynamic posture refers to the posture in which the body or its segments are capable of arranging and rearranging body segments to shape a wide variety of postures, but keeping an upright bipedal position which is ideal for humans, including movements such as walking, running, punching, jumping and lifting. Every specific posture research includes kinetic and kinematic analysis of all body segments³.

Classical method of assessing the posture, in order to understand the optimal posture, it is necessary to understand the optimal alignment of the spine and other joints at rest. This is usually done by analyzing or using plumb line, the gravity should pass through specific points of the body⁴.

On examination, the body should be viewed from three aspects anterior, posterior, lateral. The standard erect posture is where the gravity of the vertical line drawn through the center of gravity of the body is viewed from each side. The gravity line passes through the inner auditory meatus through the shoulder joint and approximately halfway via the cervical and lumbar vertebral bodies. At hip, it passes through the hip joint at the level of greater trochanter of femur. Then it

Corresponding Author:
Mrs. S.F. Mariyam Farzana
Assistant Professor
Email id: mariyamf@srmist.edu.in
continuously passes through anterior to the knee joint and anterior to the lateral malleolus.

When it is viewed from either the front or back, the vertical line passing through the center of gravity should theoretically bisects the body into two halves, the body weights distributed evenly between the legs.

Erect spine must be kept in a position by active forces, counteracting the pull of gravity and the other forces, acting on it. The abdominal muscles remain quiescent although the lower fibers of the internal obliques are active in order to protect inguinal canal.

To maintain an ideal posture, one should possess a good stability and balance with minimal stress. Posture such as lordosis, kyphosis, swayback, straight back, flat back and increased kyphosis with forward head, flat upper back and neck posture, scoliosis are some examples of faulty postures. A forward head posture or poking chin are more common among collegiate students and this may result in craniofacial pain, headache, neck ache and shoulder pain together with decreased range of cervical motion, muscles stiffness and tenderness.

The importance of adapting to an ideal posture in the young age prevents the occurrence of musculoskeletal disorder among collegiate students. A study done has proved 48.6% and 66.8% of students has prevalence of upper cross syndrome and lower cross syndrome. This is an alarming sign which may affect the student’s performance and quality of life. The method of assessing or evaluating the posture among the students are concerned with limited quality. The classical method could help identifying the postural abnormalities but exact degree of deviations are not known.

By assessing the exact degree of deviations, it could help us to work on educating the ideal posture. Each individual may vary with their postural deviation. Thus, applying the standard protocol results in identifying these deviations, it could provide a better outcome.

The technological improvement over a decade has made it possible. The POSTURE SCREENING MOBILE application tool in the mobile is used because of its simplicity, low cost and non-invasive technique applicable in both clinical and community interventions. There are many studies related to postural changes in obese students but there are few studies reported on college students with normal Body Mass Index. Thus, this study will be more useful to assess the posture by using posture screening application. To analyze the posture using the posture screening app among collegiates.

**Methodology**

The ethical clearance for the study was obtained from the institutional ethical committee. It is an non experimental study which was conducted in the year 2019 at SRM Institute Of Science And Technology. In which 200 healthy subjects of both gender, between 19-23 years of age were who were not affected by any physical and mental disorder and who came under the normal bmi range of 18.5 to 25 were recruited for the study. The participants were explained about the procedure and informed consent was obtained. The Posture Assessment was carried out using an Android mobile phone with an Android application “Posture Screening Mobile Application. This posture mobile application has shown high reliability and validity. For postural assessment and photographic documentation, the subjects were requested to stand and the posture was analyzed by using the anatomical landmarks as given in the application. Head posture, shoulder posture, hip posture, and knee posture was assess. A photographic record was taken in both anterior and lateral view. The data collected from the students were tabulated and entered in MS-Excel spread sheet. The data was analyzed using descriptive statistics.

**Aim and Objectives**

To analyze the posture using the posture screening app among collegiates.

During the early adult hood usually, students are neglecting their posture and they are not much aware of its consequences which leads to the muscular imbalance and pain.

There are many studies related to postural changes in obese students but there are few studies reported on college students with normal Body Mass Index. Thus, this study will be more useful to assess the posture by using posture screening application.
Results

A total of 200 participants were selected in which 61.5% were men and 38.5% were women, about 30% of total population were 23 years of age, 20% each at the age of 22 & 21 years and 15% each at the age of 20 & 19 years.

From the anterior view aspect out of 200 participants, In Head 31% had normal deviation and 69% of them had abnormal deviation. In shoulder 12.5% had normal deviation and 87.5% had abnormal deviation. In Hip 25% had normal deviation and 75% had abnormal deviation.

From the lateral view aspect, In Head 12.5% had normal deviation and 87.5% of them had abnormal deviation. In shoulder 75% had normal deviation and 92.5% had abnormal deviation. In Hip 16% had normal deviation and 84% had abnormal deviation. In knee 3% had normal deviation and 97% had abnormal deviation.

Discussion

The current study explores the postural deviation of the collegiate students with the mean age of 23. To identify the risks of developing musculoskeletal disorders using POSTURE SCREENING MOBILE APPLICATION.

Generally postural deviation is related to the spine and also involves its malalignment. If the body parts are out of the alignment for longer duration, this results in the two ways that one muscle group get shortened and other lengthen in position, this affects efficiency of muscular system and results in musculoskeletal problems.

Many efforts have been taken to educate people about the postural abnormalities and the effects of poor posture, that still remains a major problem among students populations14.

The current findings demonstrate, about 69% of subjects have abnormal posture of head in anterior view 87.5% have abnormal posture in lateral, 87.5% of subjects have abnormal posture of shoulder in anterior view and 92.5% have abnormal in lateral view. 25% of subjects have abnormal posture of hip in anterior view and 75% of subjects have abnormal in lateral view. 97% of the subjects have abnormal posture of knee in lateral view among 200 collegiate students with normal BMI.

On analyzing the posture previous studies reported certain factors in posture modifications among collegiates due to overuse of smart phone gadgets, high heels, sitting or standing, with heavy back packs for a long duration, adopting posture while watching televisions, working in
computers, motorcycles accidents.

Carrying bags in asymmetric positions causes shifts in upper back and shoulder, increase in the cervical lordosis and these factors also contribute to pain and abnormal posture in students\textsuperscript{15}.

The incidence for development of musculoskeletal discomforts are higher in knee region, followed by shoulder region with rounded shoulder. The participants are also at the risk of developing forward head posture.

To compensate these discomforts the students further adapt some abnormal postures which may lead to serious problems.

The poor postural habits are the results in the era of technology which has become a part of the current lifestyle. Engaging the peoples on more of physical activities, exercises and sports could only be alternative ways of maintaining an ideal position.

The methodology of assessing the posture using POSTURE SCREENING MOBILE application really worked well to identify the problems of each individuals.

**Conclusion**

This study find out the prevalence of musculoskeletal disorder among collegiates with normal Body Mass Index. The study concludes that there is increases in risk of postural changes in targeted population. Hence the musculoskeletal pain in young people should not be ignored, as it can help to evaluate pain in adulthood. This study results hold higher risk of postural changes in normal BMI collegiates.

Thus, assessing posture using mobile application paves way to simple, cost-effective and evidence based diagnostic tool. Application of such tool helps health care professionals to design individual intervention protocols.

**Limitations**

- Study is based only on normal Body Mass Index.
- Equal number of gender populations are not taken.

**Recommendations:**

- Utilization of the mobile application in the clinical practice.
- Applicable for research with larger samples.
- Posture screening mobile application can be used as prognostic tool in the field of physiotherapy interventions.
- Awareness among young students about increasing musculoskeletal disorder is more essential.
- Further study are suggested with large number of equal gender populations of the same age is recommended.

Knowledge of health education about occurrence of musculoskeletal disorder among adulthood is important.

Cognizance Among Physiotherapy Clinicians and Students in Pelvic Girdle Dysfunction- Qualitative Analysis

S.F. Mariyam Farzana1, M.S. Pawan Kumar2, D. Malarvizhi3

1. Assistant Professor, SRM College of Physiotherapy, SRM Institute of Science and Technology, 2. Director, International Institute of Digital Teachings, Consultant Raa Physiotherapy Clinic, 3. Dean, SRM College of Physiotherapy, SRM Institute of Science and Technology

Abstract

Low back pain of pelvic girdle dysfunction origin is most prevalent among all age group, hence there is constant need of updates in diagnosis and therapeutic approaches, manual physiotherapy gained an adequate importance in addressing pelvic girdle dysfunctions, with an objective of understanding the awareness of pelvic girdle dysfunctions among the clinicians and students, a self-administered questionnaire was designed and administered in pre-conference workshop pelvic girdle dysfunction dogmas in diagnosis and approach at SRM college of physiotherapy SRM Institute of Science and Technology Chennai India, based on the response and through the statistical analysis it was found that the awareness was lacking and there was also need to focus on the clinicians and student community towards pelvic girdle dysfunctions and its basics, this may be beneficial in enhancing better patient care services and evidence in framing up clinical practice.

Keywords: Manual Physiotherapy; Pelvic biomechanical models; Pelvic girdle dysfunction; Physiotherapy curriculum; Structural diagnosis; Workshop survey

Introduction

The pain and motions in the pelvic girdle structures, had been controversial and still being debatable, particularly from sacroiliac joint and its different types of motion, after several researches and world congress on low back and pelvic pain(1,2), the healthcare community accepted, that sacroiliac joint is prone to cause pain and the joints of pelvic girdle structures poses minimal motions. Researches till date had more emphasized on stability and mobility of these joints, when coming to mobility of sacroiliac joint it is still debatable and the enigma still persists.

The pelvic girdle structures are composed of three bones namely two innominates and one sacrum, the sacrum is invertedly pyramidal in shape base on above and apex on the bottom, superiorly articulate with L5 and inferiorly articulate with coccyx through sacro-coccygeal joint, sacrum has paired articular surfaces for articulating with ilium called auricular surface it is in L-shape with long and short arms, the articulation of sacrum with the ilium through sacro-iliac joint(1). The innominate bone is embryologically divided into three distinct parts ilium, ischium and pubis, ilial part of innominate will articulate with sacrum through ilio-sacral joint(1), the pubis bone articulates with another pubis bone through symphyseal pubic joint, fibrocartilage disc is interposed between the symphyseal pubic joint(21). The three bones and it’s three articulation are clinically significant.

The pelvic girdle structures plays vital role in transferring weight of upper half of the body to the lower extremities and it is an house of abdomino-pelvic visceral contents. The pelvic girdle structures are transversed by various muscles, fascia’s, ligaments and neurovascular structures(3). The dysfunctions of pelvic girdle structure are prone to cause locomotory dysfunctions as well as uro-gynaecological problems(1,3,4).
physiotherapy discipline which predominantly deals with the human pathokinesiological problems has an pivotal role in addressing the Pelvic Girdle Dysfunctions (PGD). The physiotherapy specialities in Orthopaedics, Obstetrics & Gynaecology, Sports and Biomechanics has wider scope in evaluating and addressing the pelvic girdle dysfunctions.

In India only few physiotherapy clinicians are evaluating and addressing PGD with manual therapy approach appropriately. Most of the physiotherapy clinicians either misdiagnose this dysfunction or address PGD symptomatically with conventional electrotherapy modalities. Ignoring these structures dysfunctions or addressing with electrotherapeutic modalities will not give long term results. Consequences of unaddressed malaligned structures can lead to orthopaedical problems such as wear and tear of hip, pes-anserinustendinitis, foot problems and etc (1,3,4,5,6). These malaligned unaddressed structures can cause range of uro-gynaecological problems such as interstitial cystitis, dysuria (3), over active pelvic floor, pudendal neuropathy (5), dyspareunia, pre menstrual syndrome, dysmenorrhoea (4) and etc. Visceral reflex’s play a significant role in causing uro-gynaecological problems (7). Addressing these malaligned structures are essential for restoring the locomotory system to normal and to intervene with uro-gynaecological problems.

The knowledge in anatomy, biomechanics, pathomechanics, structural diagnosis, provoking special tests and appropriate manual therapy technique is essential for diagnosing and addressing PGD. In India diagnosis and manual physiotherapy intervention in pelvic girdle dysfunction is not taught in most of the educational institutions, most of the physiotherapy clinicians and students learning appropriate diagnosis and manual therapy interventions through manual therapy courses and workshops. The clinicians and students attending the courses and workshops are less in number.

The PGD among the Indian population is prevalent. The conservative management with medications and conventional physiotherapy with electrotherapy modalities, lumbo-sacral belts and exercises are not giving long term results. The pelvic girdle dysfunction need to be addressed by manual therapy to realign the malaligned structures, it should be followed by motor control and sensory motor retraining programme appropriately. Failing to realign themalaligned pelvic girdle structures with manual therapy approach can cause the “Dirty Half Dozen” in failed lower back syndrome as described by Greenman (1).

**Methodology & Materials**

To know about the knowledge of diagnosis and management in PGD among physiotherapy clinicians and students, self administered questionnaire had been designed and distributed to the participants who participated in the one day pre-conference workshop in Pelvic Girdle Dysfunction dogmas in diagnosis and approach on EYAN international conference in recent physiotherapy updates at SRM college of physiotherapy SRM institute of science and technology on 12th December 2018. Totally 36 participants attended the workshop and the survey using the self-administered questionnaire was conducted among this 36 participants. The questionnaire consisted 12 questions in 6 categories like 1) Willingness to update in PGD, 2) Knowledge of physiotherapy’s scope in PGD, 3) Knowledge about radio-diagnosis in PGD, 4) Knowledge about PGD, 5) Clinical decision making in PGD, 6) Knowledge about manual therapy in PGD. The questionnaire was given to the participants of workshop before the commencement of workshop and the participants were requested to fill it.
Analysis

1) Willingness to update in PGD

This category of question, is about the willingness to update their knowledge in PGD diagnosis and approach, for this 100% of participants had answered that they are willing to update their knowledge in PGD.

2) Knowledge of Physiotherapy’s scope in PGD

This category of question, is about the knowledge of the scope of physiotherapy in diagnosis and approach in PGD, for this 94% of participants answered that there is an scope for physiotherapy and 6% of participants answered there is no scope for physiotherapy in diagnosis and approach in PGD.
3) Knowledge about radio-diagnosis in PGD

This category of question is about the radiodiagnosis in PGD, for this 92% of participants answered radio-diagnosis is needed for diagnosing PGD and 8% of participants answered radio-diagnosis is not needed for diagnosing PGD.

4) Knowledge about PGD

This category of question is about the fundamental knowledge about the PGD, in this 28% of participants is having fundamental knowledge about PGD and 72% of participants is not having fundamental knowledge about PGD.
5) Clinical decision making in PGD

This category of question is about the knowledge of clinical decision making in PGD. In this 28% of participants is having knowledge of clinical decision making in PGD and 72% of participants is not having knowledge of clinical decision making in PGD.

6) Knowledge about manual therapy in PGD

This category of question is about the knowledge of manual therapy in addressing PGD among the participants. In this 6% of participants is having knowledge of manual therapy in PGD and 94% of the participants is not having knowledge of manual therapy in PGD.

Results

From the data obtained from the survey using the self-administered questionnaire. It was evident that most of the participants except those who attended previous manual therapy workshops or courses was not familiar with the concepts of PGD diagnosis and management approach. The results of the survey are 1) Willingness to update in PGD in this category 100% of participants are willing to update their knowledge in PGD, 2) Knowledge of PT scope in PGD in this 94% of participants is revealed there is a scope for PT in PGD and 6% of participants is revealed there is no scope for PT, 3) Knowledge about radio-diagnosis in PGD in this 92% of participants is
revealed radio-diagnosis is not needed to diagnose PGD remaining 8% is revealed radio-diagnosis is needed,4) Knowledge about PGD in this 28% of participants is having fundamental knowledge about PGD and 72% is not having it,5) Clinical decision making in PGD in this 28% of participants is having knowledge of clinical decision making remaining 72% is not having it,6) Knowledge about manual therapy in PGD in this 6% of participants is having manual therapy knowledge to address PGD and remaining 94% participants is not having it.

Discussion

The fundamental knowledge in PGD, clinical decision making and manual therapy knowledge in PGD, knowledge in these three categories among physiotherapy clinicians and students are lacking. There as an lack of knowledge in structural diagnosis of malaligned pelvic girdle structures, cluster of laslett to rule in sacroiliac joint dysfunction(9) and sacroiliac pain pattern. The lack of knowledge in Clinical Prediction Rule (CPR), sclerotomal pain pattern of sacroiliac joint, structural diagnosis of malaligned structures and in manual therapy is due to the comprehensive anatomy, complex biomechanics, less prevalence of evidence based practice. The orthopaedic manual physiotherapy is budding in India since past one decade. The orthopaedic manual physiotherapy practice is prevalent across the globe, but in India it is in infantile stage in grounds of practice, only few clinicians qualified in it and practising it as their full time clinical practice. The population of orthopaedic manual physiotherapist in India is scarce and very few institutions across India offering orthopaedic manual therapy education because of lack of adequate number of teachers in manual therapy, hence Indian physiotherapy clinician are not much into the practise of orthopaedic manual physiotherapy and for the same reason the physiotherapy students community are not much exposed to the orthopaedic manual physiotherapy. Moreover somatic dysfunctions is new to the Indian physiotherapy clinicians as well as students, this somatic model belongs to osteopathic medicine, Somatic dysfunction is impaired or altered function of related components of the body framework such as skeletal, arthrodial, and myofascial structures, and the related neurovascular and lymphatic elements(1). Structural diagnosis is evaluation of the musculoskeletal component with the objective of identifying the presence of somatic dysfunctions, it is an part of the physical examination. Most of the manual therapy techniques are borrowed from osteopathy (16). The one of the pioneer in Orthopedic Manual Therapy (OMT) FreddyM. Kaltenborn an physiotherapist, he was one of the founder of International federation of Manipulative Therapist (IFOMT) and now it was renamed as International Federation of Orthopaedic Manipulative Physicaltherapists (IFOMPT)(23) it is an sub group of World confederation of Physical Therapist (WCPT), he was the first clinician to integrate the theory and practice of orthopaedic manual medicine with osteopathy, his method of manual therapy techniques was from orthopedic medicine, osteopathy and his own techniques (19). The orthopaedic manual physiotherapist ‘deepak sebastian’(5), Timothy Flynn(20) and Christopher H. wise(6) had integrated somatic dysfunction models with physical therapy in their authored books. The physiotherapy clinician and students in US, Canada & Europe who learned osteopathic school of thought in manual therapy or mixture of traditional orthopaedic manual physiotherapy and osteopathy thoughts will be familiar with this somatic dysfunctions and structural diagnosis, for the physiotherapy clinicians and students in India it is new, Indian physiotherapy clinicians those who completed post graduation degree in physiotherapy and postgraduate physiotherapy students are familiar with Fryette’s law of spinal motion but they are not familiar with pelvic biomechanical models of Mitchels, Chicago and Stills(22). The American osteopathic text books advocates Mitchels biomechanical pelvic model, this model is commonly used by osteopathic practitioners in USA and Australia (24). These pelvic models are essential to address pelvic girdle dysfunctions, so it is necessary to include these models in physiotherapy curriculum along with the Fryette’s law which already exist in Indian physiotherapy postgraduate curriculum. Structural diagnosis based on somatic dysfunctions have to be introduced to Indian physiotherapy student community, especially when coming to pelvic girdle, because somatic dysfunctional model entails these structures dysfunctions detailedly than other school of manual therapy thoughts. Emphasis on sclerotomal pain patterns in physiotherapy curriculum from undergraduate level have to be made mandatory to make understand the pain patterns of facet joints and sacroiliac joint(18). Introduction of
orthopaedic cluster tests\(^9,11\) and decision making tools such as Clinical Prediction Rule (CPR)\(^{10,11}\) to the indian physiotherapy clinicians and students must be made to inculcate the evidence based practice. More over including the concepts of diagnosis and manual therapy management of PGD in the books of orthopaedics,obstretrics& gynaecology ,sports physiotherapy are essential it will benefit the indian clinicians and student community.

**Conclusion**

Introducing the concepts in diagnosis and management of pelvic girdle dysfunction to the indian physiotherapy clinicians and students is essential to serve the patient community. Thefundamental knowledge of pelvic musculoskeletal structures and its mechanics is mandatory. The pelvic girdle dysfunctions are precursors of various orthopaedic and uro-gynaecological problem, The pelvic girdle dysfunctions causes the affected person to cripple and it create annoyance. The diagnosis and management of pelvic girdle dysfunction is not confined to orthopaedic manual physiotherapy speciality alone, the orthopaedic manual physiotherapy is tailored with the obstretics and gynaecological physiotherapy,sports physiotherapy and biomechanics specialization in physiotherapy. The pelvic girdle dysfunction is predominantly an orthopaedic problem, but other physiotherapy specialities has a equal scope in diagnosing and addressing the dysfunction , for an instance obstretics and gynaecological physiotherapist is having spectrum of scope in addressing Pregnancy-related Pelvic Girdle Pain (PPGP)\(^17\), this PPGP can be addressed by realigning the malaligned pelvic girdle structures withimplusive techniques (thrust techniques) and non-impulsive techniques (non-thrust techniques) such as articular technique and muscle energy technique\(^7,12,13,14\) and range of urogynaecological problem can be addressed with manual approach to pelvic girdle structures, the articular dysfunction (malalignment) in sacroiliac joint may aggravate the source of myofascial trigger points in pelvic floor muscles\(^15\). In sports physiotherapy ranging from groin pains,gluteul muscle inhibition\(^1\) and etc can be addressed.In biomechanics there is lot of scope in biomechanically analysis of pelvic girdle structures. There is a spectrum of scope in these physiotherapy specialities in diagnosing, addressing and researching in pelvic girdle structures. Includingrecent evidence based concepts in diagnosis and management of pelvic girdle structures in physiotherapy curriculum will help the student community as well as clinicians and it increases the cognizance of pelvic girdle dysfunctionsamong them to serve the patient population.

Patient Safety Program in a Hospital with Reference to Costs Associated with Patient Falls

Renu Mirchandani, 1 P. Naveen Kumar2, Vikram Palimar3

1Trainee, Department of Health Innovation, Prasanna School of Public Health, Manipal Academy of Higher Education, Manipal, 2Professor & Head, Department of Hospital Administration, 3Professor, Department of Forensic Medicine, Kasturba Medical College, Manipal, Manipal Academy of Higher Education, Manipal.

Abstract

Background: Patient safety is an emerging field in healthcare that has indirectly or directly affected all stakeholders of healthcare delivery system in the last decade. World Health Organization guidelines for adverse event reporting and learning systems, 2005 describes adverse events as “an injury related to medical management in contrast to complications of disease.” These adverse events can be preventable or non-preventable. Inpatient falls presents a serious challenge to the safety and quality of patients in hospitals. Falls are not harmless, they delays in functional recovery and prolonged hospitalization that can cause patients to suffer. The study was conducted to estimate the incidence and major reasons for falls.

Methods: Retrospectively, case records from January 2016 to September 2018 of all the inpatients were researched for patient fall incidents, reported to the committee. The committee findings noted and the costs were estimated in terms of cost to the patients, and costs to the hospital.

Results: 118 incidents of patient fall happened in study period. 3(2.6%) of them experienced two or more falls during stay, 115 (97.4%) fell once. 5 patients were morbidly obese. Costs to the hospital on each patient was Rs. 5412/-, not levied on patients.

Conclusion: The number of fall incidents and falls reporting system have been improved by early detection of reasons by conducting root cause analysis.

Keywords: Patient safety, Indian Patient falls, Obesity, Consciousness, Facilities Management.

Introduction

The healthcare organizations in developed world have been swaying under the effect of the adverse public opinion generated as a result of a number of studies on medical errors. Patient safety is an emerging field in healthcare that has indirectly or directly affected all stakeholders of healthcare delivery system in the last decade. Inpatient falls presents a serious challenge to the safety and quality of patients in hospitals. 6.63 falls per 1000 occupied patient days on an average equates to more than 1700 falls every year in an 800 bedded hospital general hospital in recent audited data. The estimated falls rate per 1,000 bed days, a provider with 800 beds will have approximately 1,500 falls at a cost of £3.9 million. “Patient safety is the absence of preventable harm to a patient during the process of healthcare and reduction of risk of unnecessary harm associated with health care to an acceptable minimum. More than 250,000 are recorded annually as well as they are the most frequently reported safety incident. “An average of 6.63 falls per 1,000 occupied bed days (OBDs), which equates to more than 1,700 falls every year in an 800-bed general hospital at current bed occupancy rates, has been exhibited by recent audit data”. Physical injury and fractures occur in 1–3% as a result of some 30-50% of falls. The estimated falls rate per 1,000 bed days, a provider with 800 beds will have approximately 1,500 falls at a cost of £3.9 million. “A patient fall is an unplanned descent to the floor (or extension of the floor, e.g., trash can or other equipment) with or without injury to the patient, and occurs on an eligible reporting nursing
unit”. Patient falls are designated as one of the “National Patient Safety Goals” by “The Joint Commission on accreditation of Healthcare Organizations.”

The causes of falls can be classified under: 1) Staff Factors: Incomplete assessment of patient and failure to elicit the history of falls. One of the strongest predictor of falls is - Inadequate staff, Insufficient training. 2) Patient Factors: Lack of communication regarding previous history of falls by patient or relatives, Morbid conditions of patient like poor vision, obesity, diabetes, hypertension, severe anaemia etc., Type of medications, Patients on sedatives, Anti- Diabetic medications, 3) Organizational: Lack of policy to avoid falls.

“Quality Indicators (QIs) are standardized, evidence-based measures of health care quality that can be used with readily available hospital inpatient administrative data to measure and track clinical performance and outcomes”, which highlight potential quality improvement areas and help in track changes over time. According to Continuous Quality Improvement chapter of National Accreditation Board for Hospitals and Healthcare providers, a CQI standard 4 and objective element b says, Monitoring includes risk management; incidence of falls is one of the key performance indicators which the organization should monitor.

Through this study, we found out the incidence and major reasons for falls along with it estimating an approximate cost incurred due to each patient fall using different statistical methods. The hospital has a total of 10 blocks.

**Aim:** To assess patient falls and the cost associated with it in tertiary care teaching hospital, with Objectives of: Estimating the incidence and the reasons of patient falls, estimating the cost involved and potential savings to the hospital from reducing those falls, suggesting recommendations for downgrading such falls

**Methodology**

A cross sectional, prospective and retrospective study was performed, wherein case records were reviewed from January 2016 to September 2018 of all the inpatients who were admitted in the hospital. Costing estimation was done. The hospital uses incident reporting software where all incidents are uploaded and reported.

**Study design:** After obtaining the clearance from Institutional Ethical Committee, the Details of In-patients admitted in casualty, Operation Theatre, Intensive Care Units and Surgical Wards having incidence of falls, reporting to Safety & Sentinel Committee of the hospital, were collected. The details of patients like UHID (Universal Hospital Identity number), Time, Location, where the incident happened, Reasons of fall, fall risk assessment score, dependency of the patient on nursing staff all these parameters were obtained through the incident management software and medical records of patients. All patients with incidence of fall have been included, patients without falls have been excluded for the study. **Study period:** Six months durations, November 2018 to April 2019. **Study population:** In patients falls reported and documented in a tertiary care hospital from January 2016 to September 2018. **Study tool:** A checklist for data collection was framed and records from incident management software and medical records were obtained. The incidence of falls was collected and calculated by a formula given by National Accreditation Board of Hospitals and Healthcare Providers. The formula used was: (Number of patient fall reported in a period / Total patient days in that period) x 1000.

**Study Setting:** The hospital is a tertiary care teaching hospital with 2000 beds with all clinical and non-clinical departments. The average bed occupancy of the hospital is 85%, with 80,000 people getting admitted per year. The hospital had admitted 200,000 patients during the January 2016 to September 2018. The wards are divided into 400 beds of single rooms with attached bathrooms, 800 semi-private rooms with sharing bathrooms, 800 of general ward beds with common bathrooms. All the floors in corridors, ramps, bathrooms have non-skidding tiles, mosaic tiles etc. The hospital is certified with National accreditation board for hospitals and Healthcare providers (NABH).

**Results**

A total of 118 patients experienced fall during the study period. These patients accounted for 121 incidents of falls, as 3 (2.6%) of them experienced two or more falls during their admission period of single admission, while rest 115 (97.4%) fell once during single admission
episode. 40 patients were obese, with 10 people mild obese, 25 with moderate obesity and 5 people were morbid obese. For our estimation of costing purpose, the first falls of the patients was only accounted as second and third fall may become a bias for patient attributions as multiple fallers tend to repeat the location and type of fall on subsequential falls. The eldest patient who fell had an age of 52, years 2 months and the average age of patients ranging around 40-60 years. Incidence of falls was 0.034, 0.06 and 0.13 for the years 2016, 2017 and September 2018 respectively, which is depicted in Chart 1. The maximum falls happened during March (n=13) month of 2018, and the rate was 0.27 per 1000 patient days and next in August (n=12) 2018. The frequency of falls range from 13 a month to zero falls reported during February, June, July, December 2016, and April 2017.

The reasons identified by the floor nursing staff were, falling from bed while raising was the reason in 25 incidents (21% of cases), as they were not using side railings which were provided. Chart 2 describes all the reasons. A pamphlet is given to all inpatients regarding do’s and don’ts to avoid falls. The patients with hypoglycaemia was the common reason for giddiness and blackout. The patients slipping in bathroom was next common reason. Side railings have been provided next to shower, western toilets. About (20/118; 16%) falls happened while the patient was using the bathroom. Generally, falling in bathrooms have been reported in early morning timings between 4 AM to 7 AM, when patients do not wake up their attendant. 42.5% of falls were seen during Nursing night shift timings, 38% were during the morning shifts (7 AM to 2 PM), 20% were in evening shifts (2 PM to 9 PM). The floor was wet for 3 (2.54%) of the falls, we started making it mandatory for environmental health workers to use yellow sign boards to indicate, people walking around that area, that cleaning is in progress. Issues with chairs and stools or furniture malfunction contributed to 12.7 % and 8.47% respectively. 2 patients had fallen in acute areas, rest of all patients the incidents were reported from long stay ward areas. Block 2 of the hospital where general medicine and surgery wards are located reported more number of falls whereas block 4 with special category had least.
Chart 2: Environmental Circumstances of patient falls in this hospital:

Overall, 80% of the 118 falls resulted in certain type of injury, as shown in Chart 3. 4 (3.2%) of them had stroke or cardiac event leading to fall and subsequent death and 24 of the 122 incidents (20.3%) had fractures while many of them suffered moderate injury like wound and laceration (15.25%), bruise (5.9%) while few cases had sprain (3.38%), and dislocations.

Chart 3: Type of injuries recorded after the fall incident:
Every fall was associated with additional hospital costs which included investigation and consultation charges while few had to undergo intervention procedure and medication costs. For the purpose of study, as shown in Chart 4, a box and whisker’s plot was created as the data for the cost was highly skewed. Therefore, Procedural and medication costs were calculated together which estimated to be around Rs. 4407 (Chart 4 B), while the Investigation and consultation costs were Rs. 4140 (Chart 4 A). Approximately Rs. 5412.3 was the total cost incurred from each patient fall (4 C). Whenever a patient fall happens the care given to patient may vary according to the seriousness of fall. In cases of No harm; vitals were checked by the duty postgraduate doctor, simple first aid was given and in cases of requirement, analgesics were given. The common analgesics given in the study hospital were Voveron gel and tablets, Hifenac - P were given while in Moderate injury cases: orthopaedics, physiotherapy or according to disease ailment consultation was provided to the patient. Common investigations done were X-Ray, MRI and CT-Scan for head or limb injury cases. In cases of sprain and fracture (n=22) arm sling and splint were provided to the patient.

Needed cases open reduction and internal fixation, close reduction and Tension band wiring and K-wire fixation was also done and patient had to stay for 5 days more.

Discussion
“Falls are not harmless, along with psychological sequelae that lead to loss of trust, delays in functional recovery and prolonged hospitalization that can cause long-term patients to suffer. Falls are not true accidents, however, and there is attestation that a coordinated multidisciplinary clinical team approach can reduce their incidence”. The nurse patient ratio for general wards can be optimised as critical falls were happening in these wards. The current ratio being 1:3 per 24 hours duration, 1:7 beds per shift, it can be brought down to 1:5 beds per shit. This would improve public relations, constant communication to the patient attendants and the
patients about precautions to be taken while raising from the beds, using washrooms. In one study done in similar setting, overcrowding in wards is seen as single most individual factor perceived by all study participants potentially leading to violence and injuries to patients. The injuries sustained range from head to limb injuries.\textsuperscript{9} Bed alarms and other protective measures in special wards can be provided. Inpatients should have an easy access to call bells and bed alarms can be provided as simple safety measure. Use of lower size beds and bed rails. For the morbid and moderate obese patients, this change will lead to reduction in number of falls. Staff orientation: Awareness and training sessions were taken for nurses to follow extra precautionary measures (there should be standardisation of practice and application of interventions). Low back injuries are the leading occupational health problems affecting healthcare workers and are increasing among nurses and nurses’ assistants. The primary risk factor for low back disorders among nursing personnel is lifting and transferring of patients. During the transfer of patients, nurses of origin ward and receiving wards should make ward helpers to reduce the risks of patient falling from stretchers.\textsuperscript{10} Risk analysis at the time of hospitalisation: Fall Risk Assessment score is noted for all the in-patients during the time of admission can be improvised as in many medical records it’s not filled completely. As part of building management, usage of non-skid tiles and installation of grab bars at two different levels for wheel chair bound people and normal patients, where appropriate and use of well illuminated lighting in the sanitary areas has been implemented through patient safety committee. The patients should be constantly accompanied by either patient attendant or the nursing assistants. None of the patients who fell in this hospital, required any further rehabilitative services. No physiotherapy requirements were noted during the study, hence, they are not included in the costs. We included movement analysis tests as part of training program to Nurses, who will in turn make patients aware of the situations and symptoms which will aggravate the fall incident. Once patients are aware, their fall rates at home surroundings will get mitigated and re-admission rates will reduce to hospital and burden on healthcare delivery system gets reduced.

**Conclusion**

The influence of falls on Hospitalized patients should be defined as well as the areas where hospital administrators need to keep an eye are potentially effective interventions. Once a problem is suspected, one may be tempted to move directly to intervene. Initiative from the leadership to motivate hospital staff to reduce/prevent the falls from happening can be implemented. Multifaceted and multidisciplinary approach is required for prevention of falls inpatient settings. Single definitive factor is not silver bulleted in preventing falls.

Physical Therapy Rehabilitation and Care in Post Operative Trans-Tibial Amputation Patient

Renuka Dhole¹, Simran Jaiswal ¹, Waqar M. Naqvi², Arti Sahu¹

¹Student, Ravi Nair Physiotherapy College, Datta Meghe Institute of Medical Sciences, Wardha, Maharashtra, India, ²Professor and Head of Department, Community Health Physiotherapy, Ravi Nair Physiotherapy College, Wardha, Maharashtra, India

Abstract

Introduction: The case study is focused on the treatment of an individual with a residual limb after a transtibial amputation. The main goal is to help provide a greater understanding of how to treat the residual limb after transtibial amputation.

Case Description: The case study focuses on a 65 year old female who recently underwent a transtibial amputation of the left lower extremity because of chondrosarcoma of distal tibia. The patient was mesomorphic and had a history of tumor. Physical therapy provided care in ways including wound care, therapeutic exercise, gait training and prosthetic fitting and training.

Conclusion: The patient progressed well because of her motivation to continue physical therapy and the proper management. After much hard work, by both the patient and the therapist, the patient was able to ambulate house distances without assistance. For the patient’s age, it was remarkable to be able to progress to the current functional status which she attained.

Key words: Transtibial, amputation, treatment, rehabilitation.

Introduction

The case of a 65 year old female is reported, who underwent below knee amputation following the diagnosis of chondrosarcoma in lateral malleolus of left fibula. Patients that need care after amputation have been a main stay of the medical community for many years, but new research and treatment methods need to be pioneered for the comfort and functionality of amputees. A lot of research has been done recently with the use of 3D printers and their application to the amputee treatment process but there are still many areas of treatment that need improvement, especially surgical procedure, wound healing, prosthetic fitting and prosthetic gait training. The primary aim of the physiotherapy rehabilitation in case of amputation is to improve the community mobility of amputees. To attain this goal, it is necessary to design individual rehabilitation protocols specifically for each patient depending upon his or her functional ability, societal requirements, and motivation. Initially when transtibial prosthesis is fit, the patient finds it difficult to regain his function and mobility.

Maintenance of ambulation with the use of a prosthetic limb is seen as an important factor associated with preserving independence. Normally, patients who require a transtibial amputation are older in age and there is a high chance for them to suffer from clinically depressed after the surgical procedure. So, it is necessary for the physical therapist to be caring, competent, and have an understanding of the patient’s emotions. Also critical are the knowledge and skills for providing the patient with the best treatment possible.(1)

The patient normally starts pre-prosthetic physical therapy immediately after the transtibial amputation. Pre-prosthetic rehabilitation includes upper and lower body strengthening exercises while maintaining range of motion in the lower extremity. This can be difficult as a result of changes in the leg musculature during the amputation surgery, which can either be from being cleaved or atrophied from inactivity. The physical therapist will perform desensitizing the patient’s residual limb by using skin rolling, tapotement, and soft tissue mobilizations.\(^{(2)}\)

**Patient Information:** A 65 years old female farmer with normal body mass index and right hand dominance complained of pain and burning sensation and swelling at the lateral malleolus which later spread to the whole foot. With these complaints, she visited AVBRH where radiological investigations were done along with other investigations. She was diagnosed with chondrosarcoma and planned for below knee amputation, i.e., transtibial amputation so as to control the spread of the pain and swelling due to the tumor. She had a history of tobacco chewing since 20 years with no other addictions. She had a past history of hospitalization for the same complaint 1 year earlier to the surgery. At that time, excision biopsy was performed but the patient and her family refused to undergo operative treatment. She lives in the ground floor of her 2 storey house, so that she isn’t required to climb stairs. She has her 2 sons and 2 daughter-in-laws to take care of her. Transtibial amputation was performed on 22\(^{nd}\) September 2019. Post-operatively, she was referred to physiotherapy department with the complaint of pain at the suturing site and difficulty in performing functional activities.

**Clinical findings:**

On post-operative day 1 after the amputation, the patient’s heart rate was 74 bpm, respiratory rate was 18 breaths per minute, blood pressure was 110/70 mmHg. The patient was alert and oriented with time, place and person. The patient’s overall posture was assessed and no abnormalities were detected besides loss of her left leg. Her residual limb was warm to the touch and swollen, showing cardinal signs of inflammation. The residual limb measured 34 centimeters in girth at the level of 15 centimeters below the patella and her wound was closed with sutures. Since it takes time to know how the incision site will seal or if it will seal completely at all, hence monitoring was done regularly. Pain stated by the patient was 4/10 on NPRS scale. Measurements of the active range of motion (ROM) using goniometer at the hip joint were: 100\(^{\circ}\) of hip flexion, 30\(^{\circ}\) of hip extension, 25\(^{\circ}\) of hip adduction and 40\(^{\circ}\) of hip abduction. She showed an extension lag of 15\(^{\circ}\). The patient was unable to perform flexion beyond 110\(^{\circ}\).

Manual muscle tests for right lower extremity were performed. Her strength was 3+/5 for hip flexion, 4+/5 for knee extension, 5/5 for knee flexion, 3/5 for dorsiflexion and 4/5 for plantar flexion. Manual muscle tests of the left lower extremity were deferred due to pain. The Functional Independence Measure (FIM) was the primary tool used to evaluate changes in areas such as ambulation, bed mobility and balance for the patient because of its reliability and validity. The patient was unable to go from sit to stand independently. She required max assist of 1 or a moderated assist of 2 to stand, making her a FIM Level 2. The patient required minimal assistance with all bed mobility skills making her a FIM Level 4. Her balance in the seated position was reduced; however, she did not require assist to maintain an upright sitting posture. She needed supervision for safety while sitting, making her a FIM Level 5. Balance in standing was not tested.

The patient’s upper extremity strength and range of motion were adequate to carry out the activities of daily living. Her lower extremity strength in her uninvolved limb was functional as evaluated by MMT and she had no previous history of weakness in the same. The main problems as per standard International Classification of Functioning, Disability and Health (ICF) model were: decreased strength of both involved and uninvolved lower extremity, decreased ROM in extension of involved hip and bilateral upper extremity, decreased balance/postural control in both sitting and standing, decreased endurance because of bed rest and loss of limb, loss of ankle joint which makes ambulation with prosthesis difficult.

**Therapeutic intervention:**

Intervention consisted of two phases.

In the first phase, pre-prosthetic training and emphasized range of motion stretching, especially
hip and knee flexion stretching were done. Strength training was performed for her residual limb and sound limb, particularly strengthening the hip abductors of her residual limb to assist with maintaining proper stability in gait. Scar and soft tissue mobility were performed on the patient’s residual limb for gait training and weight bearing in the prosthesis, ensuring proper mobility of the skin on the residual limb stump and reducing pain. In addition, transfer training, wheelchair negotiation training and standing balance training were performed. (3)

In the second phase of therapy, donning and doffing training of the patient’s lower extremity prosthesis was performed along with application of socks. Weight shift training was practiced while standing in the prosthesis in a lateral and diagonal fashion. More challenging exercises were added progressively to increase the patient’s single leg stance ability. (4)

Gait training was initiated within the parallel bars, progressing to walker and then cane as an assistive device. Stairs, ramps, outdoor gait and functional training such as lifting heavy items off the floor, reaching for higher shelves, etc were also performed. (5)

Follow up and outcome:

By the end of the sessions, she was able to walk without any assistance and was independent in mobility. The patient came for physical therapy with motivation and was readily willing to do whatever she was asked. She was taught home exercise programmes, which she performed sincerely and came for follow up weekly. She started with her full Functional activities and activities of daily living within 4 months. The patient’s psychological well being was also a positive factor which helped the treatment plan to work with the time of recovery estimated for her.

Discussion and Conclusion

This patient is a great example of what the prognosis after an amputation should look like. Motivation plays a huge role in the improving the outcomes of any treatment. This patient’s family’s and her own will to recover faster helped play a big part. As the patient suffered for a year prior to the elective procedure to ampute, she was mentally ready to face all the challenges in the path of recovery. She complied with the physiotherapist better due to her past references with pain. All these factors counteracted the barrier of age and easy accessibility of the physiotherapy. (6)

The patient opted for no prosthetic fitting due to her poor economic condition. This did not hamper much of her life as she was a home maker with her daughter-in-laws for support. But would that be a case where the social life and economic necessity in reference to job would have come, then counseling for a proper prosthetic fitting and budgeting the cost of the prosthetics be the agendas in the therapist goals. That would lead to prosthetic training and ergonomic transformations in home and workplace. Transportation facilities and daily commute with public transport would also be important (7)

Impact of Workstation Exercise and Ergonomic Exercise on Nursing Population – A Randomized Clinical Trial Research Protocol

Renuka Dhole¹, Deepali Patil², Angela Kapoor³
¹Final Year Student, ²Associate Professor, Ravi Nair Physiotherapy College, Datta Meghe Institute of Medical Sciences, Wardha, Maharashtra, India, ³Assistant Professor, Department of Cardio-respiratory Physiotherapy, Ravi Nair Physiotherapy College, Datta Meghe Institute of Medical Sciences, Wardha, Maharashtra, India

Abstract

Nursing workers represent a significant proportion of the hospital workforce. In recent times, focus is put on increasing efficacy with reducing the concurrent risks in this population. Many researches imply on including workplace modifications and various exercises to reduce the number of absenteeism and heighten the quality in work. As low back ache is the most prevalent, this study targets on determining the effects of workstation exercise and ergonomic intervention on it.

Purpose - Nursing staff is the base of primary healthcare provision in the Indian background. The most common reason for early retirement, sickness absenteeism, and decline in working population in nurses is low back pain. With proper evidence, the efficacy of workstation activities in nursing staff will mitigate or eliminate this issue in the area of healthcare.

Methods: There will be 3 groups, workstation exercise group, ergonomic modification group and a control group each consisting of 40 patients selected from a fixed criterion. They will be graded with a QOL scale and a pain scale during the start of treatment and after 2 months to compare the results and determine which therapy gets better results.

Results: Statistical analysis will be done after the study’s completed by use of concise and inferential tests use Student’s distribution t test on single and combined analysis, one-way Analysis of Variance (F) ANOVA test and Multiple Comparison: Turkey Test and analytical tools is SPSS24.0 version and Graph Pad Prism 6.0 version and p<0.05 is known as value point.

Conclusions: Both the ergonomic training and workstation exercises will result in reduction of low back pain with workstation exercises proving more effective. The Publication will be done after conducting the study and obtaining the results through the statistical analysis.

Key Words: Workstation Exercises, Ergonomic Intervention, Quality of Life, Low Back Pain, Nursing Staff, Physiotherapy Approach.

Background

Musculo skeletal conditions are the utmost public wellness issue.¹Those that requires medical condition attention, a difficult issue to tackle with many professional groups, such as the nursing staff. Even though the nurses are trained to administer to such health issues of others, they neglect their own well being for the
sake of reduction of taking leaves and better job caliber. Historically, back pain has become a more common complaint, and most of the health care practitioners are at the greatest risk. Many researchers have become a witness to this condition in their trials.2

Community of low back pain (LBP) is highly prevalent, and it has been explored in much research.3 Findings put it on record that perhaps a multitude of factors relate toward low back pain globally. Some factors include age, genes, body mass index, comportment, style of living, vocational jeopardy, and many others or idiopathic in nature. However the etiology has not yet been known. Thus, intervention as well as preventive strategies was found to lack of documented feasibility on the basis of etiology.4

The ergonomic changes to counter act or reduce the pain from low back pain are prominent. The hospital attendants are thoroughly well versed with these. Even though ergonomic modifications have been shown in certain research to also be moderately successful in reducing musculo skeletal disorders, they are very expensive which would be an important factor particularly in developing and undeveloped countries. In such times, the work place training comes in handy. It is relevantly cost effective and also helps to save time and money in recurrent process of modulating and refurbishing of the wards or clinics. It can be worked as it is, to build more support by cost efficiency. In other words, work place work outs save the time and money to start or initiate the treatment program to relieve low back ache.

When determining progression of the disease, the diagnosis, as well as the control of any of the musculo skeletal disorders, Q O L scales are now being used. As widely relevant Q O L is defined as a term that reflects individual responses to different effects of disease on everyday life, affecting to what level real fulfillment should be attained. Measurement of Q O L is detected in recent clinical trials as a significant add-on to achieving therapeutic effectiveness for the beneficial change. Low back discomfort is actually a major deterrent to Q O L and the Q O L scores co related with low back pain and other disabilities.6

Visual Analog Scale is a validated and utmost used in all the musculoskeletal, neurological or other conditions. It does not diversify pain in various components and hence is reliable in pre tests, post tests and follow ups. Language barrier or educational intelligence and other factors do not hamper the outcomes of this pain rating scale.

Through this research, we aim at estimating and contrasting the influence of ergonomic alteration and work place exercises on low back pain in a crowd of nursing health care providers.

**Objective**

1. Assessment of low back pain
2. Analysis of effectiveness of ergonomic changes in low back pain
3. Analysis of effectiveness of workstation exercises in low back pain
4. Comparison of the effects to analyze superior treatment method

**Material and Method**

The study is set at Datta Meghe Institute of Medical Sciences, Sawangi (Meghe).

The Study design is randomized clinical trial in an intervention group of nursing personnel. Participants will be assigned their groups randomly or by chance.

Study setting - Ravi Nair Physiotherapy College, A V B R H

Sample type – randomized sampling

Sample size – 120

The sample size formulae used are as follows

\[ n_i = \left( \frac{\sigma_i^2 + \sigma_2^2}{\kappa} \right) \left( Z_{1-\alpha/2} + Z_{1-\beta} \right)^2 / \Delta^2 \]

The notations of formulae are

- \( n_i \) = sample size of Group 1
- \( n_2 \) = sample size of Group 2
- \( \sigma_i \) = standard deviation of Group 1
- \( \sigma_2 \) = standard deviation of Group 2
- \( \Delta \) = difference in group means
Indian Journal of Forensic Medicine & Toxicology, January-March 2021, Vol. 15, No. 1

\[ K = \text{ratio of } \frac{n_2}{n_1} \]

\[ Z_{1-\alpha/2} = \text{two sided Z value (e.g. } Z = 1.96 \text{ for 95\% confidence interval)} \]

\[ Z_{1-\beta} = \text{power} \]

- Group A with 40 participants under ergonomic intervention group.
- Group B with 40 participants under workstation exercise group.
- Group C with 40 participants under control group.

Sampling will be allotted randomly. The division of the groups would be on the basis of the time and number of subjects received. The first subject will be allotted Group A, the second subject will be allotted Group B, the third subject will be allotted Group C. the Fourth with Group A and continued henceforth. The chronology of the patient list will be solely dependent upon the time and date of assessment rather than the Alphabetical order or age or other criterions.

Study duration - 6 months

**INCLUSION CRITERIA**

- Patients willing to participate.
- Permanent nursing staff.
- Age group 18-50 years.
- Diagnosed with low back pain.
- Pain persists more than 1 month.
- Both genders.

**EXCLUSION CRITERIA**

- Patients not willing to participate.
- Patients not willing to continue treatment for long duration
- Individuals with other musculoskeletal and neurological issues.
- Age group above 50 years.
- Individuals with chronic low back pain.
- Interns and temporary job nurses
- Recent parents with infants and children
- Other chronic conditions.
- Chief cause of pain irrelevant to the nursing chores

**MATERIALS**

- Printed consent forms for participants.
- Printed sheet of Visual analog scale.
- Printed sheet of WHOQOL BREF scale.
- Ergonomic advice charts.
- Thera bands.
- Lumbar corsets.

**DEPENDENT VARIABLES**

- Visual Analog scale
- WHOQOL BREF

**INDEPENDENT VARIABLES**

- Workstation exercises.
- Ergonomic intervention.
- Lumbar corset.

**PARAMETERS/ OUTCOME MEASURES:**

- Visual analogue scale for intensity of pain measurement
  - Reliability: 90\%, Validity: 76\%-84\%
- WHOQOL BREF scale for functional disability and quality of life assessment
  - Reliability: 76\%-80\%
  - Validity: physical domain- 67\% , Psychological domain- 78\% , Social domain- 74\% , Environmental domain- 86\%

**PROCEDURE**

The institution ethics committee clearance will be obtained 120 participants will be selected, nurses
who are diagnosed with low Back pain from AVBRH hospital as per the criteria. The informed consent will be obtained. The participants will be explained about the type of study in their own language. They will be divided into 3 groups and each group would be explained the steps of intervention. They will be provided with visual analog scale and WHOQOL BREF scale. Pre-treatment pain and overall quality of life would be calculated. Group A will be educated and facilitated with ergonomic interventions and charts will be given depicting the same. Group B will be taught stretching and strengthening exercises to be done within scheduled breaks during the work hours. Group C will be the control group that will be given lumbar corsets to use. This group will serve as the standard for comparison for Group A and Group B. After two months of treatment, follow up of all the groups will be taken with the same scales and thus will be compared. The data collected will then be analyzed statically.

Hypothesis: The Group A of ergonomic interventions will yield positive results wherein the mean of observations of the Group B of workstations exercises will be more inclined to the value of 1.00 levels. Group C will be inclined to 0.05 re 0.01 level of null hypothesis.

The independent variables of this study will not have co relational analysis with the dependent variables. This will help the study to move forward to the rank order co relation in the specific statistical analysis.

**Data Analysis**

Statistical analysis will be done after the study is completed by use of concise and inferential tests use Student’s distribution t test on single and combined analysis, one-way ANOVA and Multiple

Comparison: Turkey Test and analytical tools is SPSS24.0 version and Graph Pad Prism 6.0 version and p<0.05 is known as value point.

The t test is used to determine the statistical significance in small sample observations for near correct conclusions. It rectifies the difference in the curve of small sample distribution when referred to the reliable large sample distribution curve. Many t table list values at various degrees of freedom of rejection of the null hypothesis are at 0.05 and the 0.01 level of significance.

Analysis of Variance (F) ANOVA test is a useful method to pinpoint if the sources of more than the two simple random samplings are sufficiently close for sampling measurement variances and errors to be related. It raises the question if the sample means differ from their own sample means (under variability of the category selected). The significance of the ‘F’ - ratio is found in ‘F’ - tables which indicate the values necessary to reject the null hypothesis at the 0.05 or the 0.01 levels.

If the global null hypothesis Ho is dismissed, the researcher’s greatest interest is to know how the meaning of t treatments varies. If the global null hypothesis Ho is denied, the researcher’s greatest interest is to know how the meaning of t treatments varies.

For each pair of means the Turkey test decides if they are substantially different and is based on a family error rate for comparisons k = t (t-1)/2. The procedure is to test the hypotheses: Ho: μi = μi, vs. Ho: μi = μi, I = 1, t, and Ho are rejected at a meaning level if

\[ m_i - m_{i'} > q s \sqrt{1/r_i} \] or \[ m_i - m_{i'} > q s \sqrt{1/2(1/r_i + 1/r_{i'})} \]

Where mi and mi’ are estimates of the means and ri and ri’ are the number of replicates of the treatments I and i’ and q = qt, a is the value of the student range with t means, n degrees of freedom associated with s2, the Residual Mean Square.

Prism is a versatile blend of biostatistics, curve fitting (nonlinear and empirical regression) grappling with a robust plan. It may report on intervals of confidence of best-fit parameters as asymmetric ranges (likelihood of profiles), which are far more precise than normal intervals symmetrical. Even it will automatically interpolate unknown values from default curves (I.e., the analysis of RIA data), the comparison of two fits equations using or the Knowledge Criteria for Akaike (AIC), plot residuals, differentially classify outliers weight data points, the normality test residuals and lots more.

As the Sample size is significantly smaller and there are more than two samples, the sampling error will be larger with concerns of the graph of distribution of the means. Altogether in random sampling methods, the
window of error is more than systematic, cluster or convenience sampling. Thus for precise analysis and conclusion of the study, we will use more than one statistical tool. The values generated will justifiably be helpful in rejection of the null hypothesis.

**Expected Result**

After completing study, result will be calculated by statistical analysis and will be prepared and published in the form of a research paper.

**Discussion**

At the end of the study duration, both the groups’ observations would manifest a cogent that both the work place exercises and the convenient ergonomic mediation work wonders on the nurses suffering from low back ache.

The consistency of results after follow up in four domains of the Q O L scale is not pinned down in all the three groups. The physical and psychological domains show highest average in satisfaction whereas the social and environmental domains don’t show much equivalency. This might be due to the level of work stress which was not well accounted for during the period when study was conducted. The longer version of the Q O L can also be applied in further studies for precision.

Difference of findings with the help of Numerical Pain Rating Scale and Visual Analog Scale is almost negligible. Although the Numerical Pain Rating Scale might have more precise value in follow ups. Other new found Pain Rating Scales might also be verified and used for the purpose of fulfillment of the agenda. Although the researches on the more modern approaches to narrow down the pain criterions and denounce its measurement are continuously advancing.

In this study, effects of ergonomic training and work place exercises were evaluated separately. Sahu A, Naqvi WM explained thoroughly the effects and influence exercising does on the human body. It covers all the physical, psychological, pathological, social and moreover importantly environmental and mental aspects in which the exercises help our body. The impact would increase with both the manipulations combined for low back pain. Further studies may involve another group with this type of an intervention. Both the exercises and the ergonomic rules would be compared with a more convenient control group to estimate the amount of recovery from the pain.

The stretching and strengthening exercises both fall under the work station exercises. They both have different effects on the muscles of the lower back. At such times, clinical reasoning for the etiology should be considered before chalking the plan of treatment. This can be achieved with the help of a thorough study of the biomechanics of the lower thoracic, lumbar, sacral and sacroiliac joints.

The inclusion criteria and the exclusion criteria are more precise regarding this study setting. Although every study setting might include more exclusion criteria based on the demographical aspects, geographical aspects, medical characteristics and / or any other external characteristics. With the changes in the goals and objectives of the study, the inclusion and exclusion criteria will change drastically. After the completion of sampling process, additional data of the participant can also compromise the analysis and make it inaccurate or misleading or biased.

Intervention control in all the trials proves as a facilitator to provide and also to compare the statistical analysis. The control groups have a tendency of placebo effects degrading the reliability and validity of the experiment. Thus, cautious selection of the control group and activity allotment is requisite. Pharmacological drugs, yoga, hydro collator pack are some of the activities applicable in control groups for such practice.

**Conclusion**

The Publication will be done after conducting the study and obtaining the results through the statistical analysis. Both the ergonomic training and workstation exercises will result in reduction of low back pain with workstation exercises proving more effective.

Null hypothesis - Follow up results of low back pain will be same for all 3 groups.

**Ethical Clearance**: Clearance will be sought from the institutional ethics committee.

Correlation of Matrix Metalloproteinase-2 and p21 Expressions with Capsular Invasion of Thymoma AB

Santi Maulina1,2, Etty Hary Kusumastuti3,4, Nila Kurniasari3,4
1 Resident, Department of Anatomical Pathology, Faculty of Medicine, Universitas Airlangga, Surabaya, Indonesia, 2 Resident, Dr. Soetomo General Academic Hospital, Surabaya, Indonesia, 3 Lecturer, Department of Anatomical Pathology, Faculty of Medicine, Universitas Airlangga, Surabaya, Indonesia, 4 Lecturer, Dr. Soetomo General Academic Hospital, Surabaya, Indonesia

Abstract

Thymomas are the common neoplasms of mediastinum, and type AB is the most frequent case. All thymomas are potential for invasion to adjacent tissues and considered malignant. Capsular invasion is one of its prognostic indicators. Matrix metalloproteinase-2 (MMP-2) is a family of proteinases that has the ability to degrade a component of extracellular matrix and affect tumor invasion and or metastasis. Cytoplasmic expression of p21 protein can be significantly correlated with invasion and metastasis. The correlation of these two proteins in thymoma has not been widely studied, hence we aimed to analyze the expression of MMP-2 and p21 and investigate their correlation with capsular invasion of thymoma AB. This cross-sectional study was performed on the 24 paraffin-embedded samples of thymomectomy during January 2013-Desember 2019 at Anatomical Pathology Laboratory of Dr. Soetomo General Hospital Surabaya. The samples were divided based on capsular invasion into 2 groups. Immunohistochemical staining was performed to detect expression of p21 and MMP-2. The correlation was statistically analyzed using Spearman test. There was no significant difference of MMP-2 expression between thymoma with capsular invasion and without capsular invasion (p=0.839), and also no significant difference of p21 expression between thymoma with capsular invasion and without capsular invasion (p=0.816). No correlation of MMP-2 and p21 expressions in thymoma AB was revealed (p=0.255). In thymoma AB, the expression of MMP-2 and p21 were not correlate with capsular invasion. These results may contribute to the development of thymoma research.

Keywords: Thymoma, MMP-2, p21, capsular invasion

Introduction

Thymoma is the most common neoplasm in the mediastinum, origin from the epithelial cells of the thymus gland, and the cause has not been determined until now[1]. The incidence of thymoma is approximately 1.3-3.2 cases per 1 million world population[2]. Their management strategies have not been standardized yet and because of the rarity case[1]. Thymoma is generally an indolent neoplasm, however, all subtypes of thymoma can appear at an advanced stage and show malignant behavior[3].

World Health Organization (WHO) 2015 divides thymoma into five subtypes which type A is reported to be about 4-7% of all types of thymoma, type AB 28-34%, type B1 9-20%, type B2 20-36%, and type B3 10-14%[4]. Tumor invasion and metastasis are also thought to be more related to prognosis than with tumor histology[5]. All thymoma subtypes have the potential to invade adjacent tissue with the rate of invasion increases according to tumor type in the order of types A, AB, B1, B2, B3. In thymoma A there were no invasion cases, in thymoma AB there were 5.9% cases, B1 18.5%, B2 20.5%, and B3 41.7% cases[6]. Many researches investigate about invasion in thymoma B2 and B3 but...
The most important part of the metastatic process is the degradation of the basement membrane and extracellular matrix. Basement membrane damage is the main predictor of tumor metastasis. Type IV collagen is the main component of the basement membrane. MMP-2 has a role in cell invasion because of its ability to degrade type IV collagen. Immunohistochemical examination of MMP-2 is also useful for showing a correlation with tumor stage, predicting aggressiveness (invasion) and the potential for malignancy of thymoma.

The p21 protein, also known as a cyclin-dependent kinase (CDK) 1 or protein-interacting 1 inhibitor, is an identified potent inhibitor of the cyclin/CDK complex. p21 in the cytoplasm has the function of promoting tumor proliferation and metastasis and in one study, it had a negative effect on thymoma survival rates, and was significantly correlated with WHO subtype, Masaoka stage and with thymoma invasion.

The correlation of these two proteins in thymoma, especially in thymoma AB has not been widely studied. This research aimed to analyze the expression of MMP-2 and p21 and investigate their correlation with capsular invasion of thymoma AB and get the prospect of providing prognosis of thymoma in general and thymoma AB specifically.

**Materials and Methods**

This study had been approved by the Health Research Ethic Committee of Dr. Soetomo General Hospital, Surabaya, Indonesia (2015/KEPK/VI/2020). This was analytic observational research with a cross-sectional approach that was performed on the 24 paraffin-embedded samples of thymectomy during January 2013-Desember 2019 at Anatomical Pathology Laboratory of Dr. Soetomo General Hospital Surabaya. The samples were grouped based on capsular invasion into two groups. Thymoma AB with capsular invasion were 13 samples and thymoma AB with no capsular invasion were 11 samples.

Immunohistochemistry staining was performed to detect expression of p21 and MMP-2. The tissues were cut into four mm sections, deparaffinized three times with xylol for five minutes each, and rehydrated through graded alcohol. Antigen retrieval was achieved by microwave treatment in sodium citrate buffer (pH 6.0) for ten minutes. The tissue sections were then incubated with monoclonal antibodies for MMP-2 (8B4: sc-13595; dilution 1:200; Santa Cruz Biotechnology) and p21 (0.N.488: sc-71811; dilution 1:200; Santa Cruz Biotechnology) overnight, followed by secondary antibody for 10 minutes at room temperature. Sections were then counterstained with hematoxylin and dehydrated with alcohol.

Cytoplasmic staining for MMP-2 and p21 were evaluated in tumour cells. MMP-2 is considered positive if expressed in the cytoplasm >1% of tumor cells. p21 is considered positive if expressed in the cytoplasm >1% of tumour cells. All samples were evaluated by two pathologists in the blinded fashion. Any discordant was solved by interobserver agreement. The comparison of MMP-2 and p21 expression in thymoma AB with and without capsular invasion was tested using Mann-Whitney U test. The correlation was analyzed using Spearman test, a p-value of less than 0.05 was considered statistically significant.

**Results and Discussion**

The majority of patients in this research were aged 40-49 years (29.2%) and average age of all patients was 52.21 years. Clinicopathological characteristics of the patients are shown in Table 1. MMP-2 was expressed at cytoplasm (Figure 1). Mann-Whitney U test showed no difference in thymoma AB with and without capsular invasion (p = 0.839) (Table 2). p21 was expressed at cytoplasm (Figure 2). Mann Whitney U test showed no difference in thymoma AB with and without capsular invasion (p = 0.816) (Table 3). Spearman correlation test showed no correlation between MMP-2 and p21 in thymoma AB (r = 0.242, p = 0.255) (Table 4).

The metastatic process is undoubtedly an important phase of neoplastic disease and develops when tumor cells acquire the specific ability to leave the primary tumor, invading the surrounding matrix\textsuperscript{[11]}. Matrix metalloproteinases (MMPs) and tissue metalloproteinase inhibitors (TIMPs) represented a critical role in tumor invasion and metastasis. In particular, gelatinase including gelatinase A (MMP2) can degrade the extracellular matrix (ECM) and basement membrane. Very few studies have been conducted on thymoma, and fewer papers have discussed the expression of the MMP molecule and its significance for predicting biological behavior in thymoma. It is known that the gelatinolytic activity of MMP2, known as gelatin zymography, is associated with thymoma invasion and is thought to have the potential for malignancy\textsuperscript{[12]}. Capsule invasion is a factor that can affect the prognosis of thymoma\textsuperscript{[13]}. The age of the patients observed in this study ranged from the age of 34-75 years (mean 52.21). Most belonged to a group of the 40-49 years (29.2%) and the majority occur in women (70.8%). This is consistent with a study stated that type A and AB patients were significantly older than patients B1-3 by a median of 60 versus 52\textsuperscript{[14]} and the majority patients are women with an overall mean age of 51.0 ± 14.3 years\textsuperscript{[15]}. The results of this study indicated that there was no significant difference between the expression of MMP-2 and capsular invasion in AB thymoma. According to another research conducted by Takahashi, the expression of MMP-2 showed varying results, namely in type A thymoma, expression 20%, type AB 8.3%, type B1 18.2%, type B2 27.3%, type B3 77.8%, type C 55.6%. Researchers also conducted research on TIMP-2 which the results were positive in 40%, 58%, 73%, 82%, 78%, and 67% respectively of types A, AB, B1, B2, B3, and C thymoma. The MMP-2 expression showed a weak correlation with TIMP-2 where the Spearman correlation coefficient is 0.362\textsuperscript{[5]}. While other studies mentioned, all thymomas A expressed MMP-2, 67% expressed TIMP-2, and about 66% of thymomas expressed both. About 60% of thymoma B1 and 25% of thymoma AB expressed TIMP-2 and MMP-2, and 50% both expressed strongly. Most of thymomas B2, B3, and C (83-100%) expressed MMP-2 and TIMP-2. The result of the study, in non-invasive (stage I) thymoma the positive staining rates for MMP-2 and TIMP-2 were very low (10% and 0%, respectively), and in invasive (stage II-IV) tumors, the positive staining rates for MMP-2 and TIMP-2 were very high (91% and 97%, respectively). There was a significant difference in the expression levels of MMP-2 and TIMP-2 between
non-invasive and invasive thymoma (Fisher exact test; P = 0.0001)\(^{[16]}\).

MMP activity is a balance between MMPs/TIMPs and is a determining factor for maintaining the stability and integrity of the extracellular matrix. The roles of MMPs in tumor metastasis were not relied on the exact concentration of MMPs in the local area, but on the ratio of MMPs/TIMPs\(^{[17]}\). TIMP is a specific regulator of MMP. Decreased TIMP production can also result in more effective enzyme activity and is potentially invasive. Overexpression TIMP in tumor cells can inhibited tumor invasion and metastasis\(^{[18]}\). MMP-2 and TIMP-2 imbalance is very important for tumor cells to have a strong invasive potential. Thus, exact concentration of MMPs in the local area has no significance and cannot reflect tumor potential. MMPs/TIMPs can act as a prognostic factor indicating invasiveness and metastasis\(^{[17]}\). The unexpressed MMP-2 in this study could be due to the inhibitory activity of TIMP-2, but the previous MMP-2/TIMP-2 ratio data were not known.

Regarding p21 expression, there was also no significant difference between the expression of p21 and capsular invasion in AB thymoma. This result is in accordance with study by Kuhn and Wistuba that stated the expression of p21 was minimally increased (16%) in the 31 examined thymomas\(^{[19]}\) and according to Omatsu, there was no cytoplasmic p21 expression in normal thymic epithelial, thymoma, and thymic carcinoma\(^{[20]}\). Also, p21 expression was detected in small amounts in thymoma and it has been reported that p21 expression is increased in thymic carcinoma than in thymoma B3. The combination of high p53, low p21 and p27 low expression has the potential to predict the biologically aggressive behavior of thymoma\(^{[21]}\) and it is found more frequently in invasive than non-invasive thymomas\(^{[22]}\).

The results of this study indicate that there is no relationship between MMP-2 and p21 expression in thymoma AB. A research suggests the expression of TIMP2 at p21 reduction, while TIMP2 is described as the component responsible for removing MMP. Taken together, reduction of p21 leads to attenuated cell motility and invasiveness of the different cell lines, possibly by ERK3 scattering which in turn results in decreased levels of the MMP2 and TIMP2 genes. In summary, the data suggest that p21 reduction has a negative impact on cell motility and invasion that is mediated, at least in part, by the ERK3 / MMP2 / TIMP2 pathway\(^{[23]}\).

**Conclusion**

In thymoma AB, the expression of MMP-2 and p21 were not correlate with capsular invasion. These findings can contribute to an improvement of thymoma research.

Effect of Graded Theraband Exercise on Myofascial Dysfunctions in Breast Cancer Survivors

Sapana Namdev Jare¹, Mandar Malawade²

¹Faculty of Physiotherapy, Krishna Institute of Medical Sciences “Deemed to be University” Karad-415110, Maharashtra, India, ²Department of Pediatrics, Krishna Institute of Medical Sciences “Deemed to be University” Karad ‘India

Abstract

Background: Cancer is the leading cause of morbidity and mortality. Breast cancer is the most common form of cancer among women. Many breast cancer surgeries lead to dissection of muscles and soft tissue structures. After the breast cancer treatment, many complications are seen in breast cancer survivors. In that myofascial dysfunctions are common. These dysfunctions are one of the common sources of pain and discomfort. Not only pain but this dysfunction also leads to decreased range of motion, decreased strength, and altered posture. Because of dysfunctions, an upper body function decreases and affects the activity of daily living. Graded theraband exercises are effective in improving muscle strength and shoulder range of motion in breast cancer survivors. And also helps to enhance functional capacity. Early rehabilitation can be implanted to reduce pain, improve strength and flexibility which will be helpful in minimize restrictions in daily living activities and improve quality of life. This effectiveness study will help to enlighten the status of myofascial dysfunctions in breast cancer survivors. The objectives of the study were as follows: To find out the effect of graded theraband exercise on myofascial dysfunctions in breast cancer survivors.

Methods: A total 40 females who underwent breast cancer surgeries along with chemotherapy or radiotherapy or hormone therapy, were included based on inclusion criteria. All the females received theraband exercises along with medications for five days per week and pre and post assessment was done with manual muscle testing (MMT), shoulder range of motion (ROM), and Shoulder Pain and Disability Index (SPADI) questionnaire.

Result: The result concluded that strengthening with thera-band showed better effect in the breast cancer survivors. Strengthening exercise program with resistance band showed significant improvement in the shoulder strength, ROM and activities of daily life.

Keywords: SPADI, MMT, Thera-band, myofascial dysfunctions, Breast cancer survivors (BCS)

Introduction

Breast cancer refers to cancers originating from breast tissue, most commonly from the inner lining of milk ducts or lobules that supply ducts with milk¹. Prevalence of breast cancer in India is 25.8 per 100000². When cancer cells metastasize to nearby tissues or to distant areas of the body it is known as malignant tumor³. When cancer cell grows but does not spread it is known as benign tumor. There are many risk factors such as sex, aging, estrogen, family history, gene, unhealthy lifestyle which increases the risk of developing breast cancer⁴. Since from few years, awareness is increased about breast cancer. Many surgeries are performed to remove the lump. Recently more selective and less invasive methods of treatments are available⁵. Breast cancer treatment includes surgery, chemotherapy,
radiation, hormone therapy, it can be used alone or with combination. This increases life expectancy for women in breast cancer and they have given special importance to improve quality of life. After the surgeries many complications are seen in that pain, reduced total loss of movements, muscle strength, reduce flexibility, postural changes, scarring complications, sensitivity alterations. Many breast cancer survivors reported significant limitations in upper body strength which is important for daily life activities such as pushing, lifting and reaching to an object especially problematic for the Indian women. Patients having difficulty to completing task. Also it affects on patients quality of life. Breast cancer survivors have muscle weakness of upper limb. Chemotherapy shows a loss of muscle mass. The muscle weakness can also progress and lead to loss hand function. Mainly in the breast cancer management muscles of shoulder complex are involved which causes difficulty in moving hand.in breast cancer management pectoral muscles, rhomboid, serratus ant, trapezius are important which causes difficulty in flexion, abduction, internal rotation of the shoulder joint. Graded theraband exercises have shown interesting effects in reducing fatigue levels, improve functional capacity, and muscle strength and inducing positive changes in body composition which shows direct effect on patients quality of life. This graded theraband exercises is useful in improving functional capacity, muscle strength and hand mobility. Thera-bands are cost effective, easy to handle, portable, and versatile. Theraband exercises are very easy and simple, hence patient can do easily at home also.

**Materials and Method**

It was an interventional study which was carried out in Krishna hospital, karad. The study duration was the 6 months. The study was conducted in Krishna Hospital, Karad. An informed consent was taken from the subjects who were included in the study. Total numbers of subjects included in the study were 40, this sample size was calculated using formula \( n = \frac{4pq}{L^2} \). Subjects were taken by using simple random sampling techniques. The duration of the study was 6 months, and the treatment was given for 30 minutes per day and 5 days / week. All the subjects were included in this study based on inclusion criteria. An inclusion criterion includes breast cancer survivors, stage I and stage II A. Histological confirmed breast cancer survivors with no evidence of recurrent or progressive disease since last six months. Completed surgery, radiotherapy and or chemotherapy. Females with age between 40 to 55 years. Breast cancer survivors receiving hormone therapy. An exclusion criteria includes breast cancer survivors with known case of fracture dislocation, stroke, peripheral neuropathy, skin diseases. Infections in the axillary area. Materials used in this study are Thera-band, SPADI Questionnaire and Goniometer.

All the exercises are started with 2-3 sets of 10-15 repetitions. Gradual progression to next colour when breast cancer survivors is able to easily complete 3 sets of 10-15 repetitions.

1. The Shoulder Pain and Disability Index (SPADI) is the self-administered questionnaire that consists of two dimensions, one for pain and the other for functional activities. The pain dimension consists of five questions related to severity of pain. Functional activities are assessed with eight questions design to measure the difficulty an individual has with various activities of daily living that require upper extremity use.
2. Manual Muscle Testing (MMT): It is the method of diagnostic evaluation used by physiotherapist. It is the important part of physical therapy examination which is useful in differential diagnosis and treatment of musculoskeletal and neuromuscular disorders. It is graded from 0-5 which is determined by the patients capability to move tested body part depending upon muscle contractility, gravity assisting and antigravity positions.

Procedure

The study was conducted to find out the effect of graded theraband exercises on myofascial dysfunctions in breast cancer survivors. After getting ethical approval from the institutional ethical committee of Krishna institute of medical sciences “Deemed To Be University”, Karad. The total 40 subjects were selected as per inclusion and exclusion criteria. All the subjects were assessed for disabilities of the shoulder function and strength, mobility of the shoulder complex before intervening with the treatment. Subjects were explained about the procedure and importance of the study. The subjects received exercises of shoulder flexion, extension, abduction, adduction, internal rotation, external rotation by using theraband. All the exercise started with 2-3sets of 10-15 repetitions. The exercise started with the yellow colour theraband and progressed to red and then green colour. Progression to next colour considered when individual was able to easily complete 3 sets of 10-15 repetitions. The study was done 5times per week for 8 week. After the 8 weeks the post treatment assessment for shoulder range of motion, disability and strength by using SPADI Questionnaire, goniometer, MMT. After that the subjects taken for statistical analysis and the result of the study was done on the basis of comparing pre and post-test assessment. The study resulted by statistical analysis of the entire outcome measures.

Statistical Analysis

Statistical analysis was done manually and by using instat software to verify the result. The statistical analysis was done by using paired T-test. P and T test was calculated by using instat software. Effect of graded theraband exercises on myofascial dysfunctions in breast cancer survivors was analysed.

Discussion

Many studies are undertaken to find out the prevalence rate of myofascial dysfunctions but there was not awareness about the rehabilitation programme. This dysfunction have direct relation with the QOL of breast cancer survivors that’s why it was necessary to put some light on rehabilitation programme. It will help to improve QOL and functional mobility in breast cancer survivors. Knowing about the importance of the research, this topic has been approved by institutional ethical committee and there after research began. Sample size included in this study was 40 females which was selected by simple random sampling techniques who are undergone breast cancer management. After that the protocol is given to each patient and explain about all the information and importance of the study. This study is on “effect of graded thera-band exercises on myofascial dysfunctions in breast cancer survivors” was conducted to find out the effect of strengthening with thera-band and find the effect on muscles strength and arm mobility. Breast cancer survivors have shown interesting effect to decrease fatigue level, improve functional capacity and muscle strength. Graded thera-band exercises showed improvement in SPADI scores with prevalence rate <0.0001 and showed improvement in shoulder movements. The result showing that strengthening with thera-band showed better effect compared to previous status of breast cancer survivors. Also graded thera-band exercises helps to improve patients quality of life. Thera-band strengthening exercises have been shown to be practicable alternative to weight cuffs and other strength training methods. Thera-bands are easily available in hospitals and physiotherapy clinics. This thera-band easy to use, breast cancer survivors can also do all the exercises at home also. When comparing this research with previous studies, Ausanee Wanchai (2018) concluded that resistance exercises is beneficial for effective lymphedema management. Where in our study exercise programme is focused on myofascial dysfunctions related to upper body which shows better effect and progression in health status of breast cancer survivors. Roger T. Anderson showed that many of the studies used manual resistance exercises. In which the resistance is applied by the therapist, where in our study resistance force is applied by the thera-bands which are easy to handle and more convenient. Cornie et al. concluded that progressive resistance exercises significantly improved muscle strength, muscle endurance and quality of life in women with breast cancer related lymphedema. In present study thera-band exercises started earlier in breast cancer survivors. When the body system are started exposed to a greater than usual but proper level of resistance, they react with a number of acute physiological response and later adapt to the newly imposed physical demands. In thera-band exercises, the speedy get to in tension producing capacity of skeletal muscles is largely attributed to neural responses not adaptive muscle changes itself. All of this response might have contributed in improvement in SPADI questionnaire. Comparably high levels of muscle activation during exercises are achieved resistance training with elastic products than weights and it is feasible alternative to training with machines and heavy weights. Also, resistance training with thera-band is subjective force as the subject might stretch minimally or as tolerated the initial few days and as neural and muscle adaptation occurs may more stretch more to experience more resistance. Which will eventually add to increase in flexibility and strength, which isn’t the case in traditional weights as the resistance cannot be altered. Although it is known that regular exercises and physical activity can improve health related status of the breast cancer survivors. There is a critical need for developing correct treatment and early rehabilitation protocols related to myofascial dysfunctions which causes negative effect on patients health status. To improve activity of daily and quality of life graded theraband exercises are needed.

Conclusion

The present study concluded that the thera-band exercises improved better strength than the previous status of breast cancer survivors. All the activities of daily living also improved and that is confirmed again with the SPADI questionnaire.

Morphometric study of Macewan’s Triangle in Relation to Depth of the Sigmoid Sinus Plate

Senthil Kumar. B
Assistant Professor in Anatomy / Head – Central Research Laboratory for Biomedical Research, Vinayaka Mission’s Kirupananda Variyar Medical College and Hospital, Vinayaka Mission’s Research Foundation (Deemed to be University) Salem, TamilNadu, India

Abstract

Background: The suprameatal triangle is used for approaching the tympanic cavity and also it is an important landmark for otologic surgeons during mastoidectomy.

Aim: To determine the depth of sigmoid sinus plate over the Macewan’s triangle by morphometry of various anatomical landmarks.

Materials & Methods: The study was carried out in the Department of Anatomy, Penang International Dental College & VMKV Medical College, Salem on 30 dry human adult skulls. Five landmarks (D1, D2, D3, D4, D5 and D6) were taken on the left and right sides of the skulls and the imaginary lines were constructed and measured by Vernier caliper between the landmarks.

Results: The measurement of D2 showed statistically significant differences. The correlations of D1, D3, D4, D5 and D6 on both sides do not show any significant differences. The linear correlation equations were derived using the measurements for predicting D6.

Conclusion: The depth of sigmoid sinus plate (D6) can be assessed using D1, D2, D3, D4, D5 on lateral view of head & neck X-rays which can be used by Otologist during mastoidectomy to avoid severe bleeding complications from sigmois sinus.

Keywords - Henle’s spine, Suprameatal triangle, Mastoidectomy, Sigmoid sinus,

Introduction

The Macewan’s triangle or suprameatal triangle is an important surgical landmark for mastoidectomy. It is used by surgeons as an anatomical landmark to locate the mastoid antrum of the mastoid process. Suprameatal triangle is present above external acoustic meatus of the temporal bone. The triangle is related to the Henle’s spine or suprameatal spine. The suprameatal spine is crest shape in female and suprameatal depression is deeper in males than in females. The mastoid antrum of the mastoid process is located 15 mm deeper to the suprameatal triangle of the skull. The suprameatal triangle is bounded anteriorly by the post-superior border of the external auditory canal, superiorly by the supramastoid crest and posteriorly by a vertical line drawn tangential to the posterior margin of the external canal.

The supramastoid crest corresponds to the floor of middle cranial fossa. The posterosuperior margin of the...
external acoustic meatus, lies over the descending part of the facial nerve canal. The suprameatal approach can avoid the process of mastoidectomy and posterior tympanotomy. The suprameatal approach is done by entering through retroauricular tympanotomy flap, by introducing an electrode through the tunnel drilled in the suprameatal triangle above the Henle’s spine. Thus the approach is of great importance to otologic surgeons during mastoidectomy.

The sigmoid venous sinus commences immediately below the temporal bone on both sides of the head, following a complex course by passing through sigmoid sulcus and enters the jugular foramen and continues down as the internal jugular vein. In mastoid clearance two main surgical procedures were followed that includes canal wall up and canal wall down. The sigmoid sinus acts as an anatomical marker during mastoidectomy. The anatomy of sigmoid sinus and its extent along with the depth of it from suprameatal triangle will help to prevent unwanted bleeding during surgery.

**Aim:** To determine the depth of sigmoid sinus plate over the Macewen’s triangle by morphometry of various anatomical landmarks.

**Objectives**

1. To correlate the surgical landmarks on the lateral surface of the mastoid bone to the sigmoid sinus plate depth.

2. To trace out the depth between the Macewen’s triangle and the sigmoid sinus plate using various surgical landmarks.

**Materials and Methods**

The study was carried out in the Department of Anatomy, Penang International Dental College & VMKV Medical College, Salem on 30 dry human adult skulls. The study was approved by IEC of VMKV Medical College (Reference - VMKVMC/IEC/18/52). Five landmarks were used on the left and right sides of the skulls which includes the tip of the mastoid process, the asterion, and the midpoint of the suprameatal triangle, suprameatal spine/Henle’s spine and porion. Five imaginary lines, D1: Distance between asterion and tip of mastoid process, D2: Distance between asterion and midpoint of Macewen’s Triangle, D3: Distance between tip of mastoid to midpoint of Macewen’s Triangle, D4: Distance between Henle’s spine and midpoint of Macewen’s Triangle, D5: Distance between porion and midpoint of Macewen’s Triangle D6: Depth of Macewen’s Triangle. To measure the depth of sigmoid sinus plate from the surface of suprameatal triangle (D6), the skull was oriented in the anatomical position (Frankfurt plane) and the drilling was done using electrical driller between surface of suprameatal triangle and the sigmoid sinus plate towards the direction of maxillary process of temporal bone along its upper border. Skulls without any damage of Macewen’s triangle, prominent suprameatal spine/ Henle’s spine were included for the study.

**Results**

D1, D2, D3, D4, D5 and D6 of adult skulls were measured on both right and left side and the average was calculated among the sides and tabulated as below.
(Table1). The average of D1 (5.14±0.45 cm), D2 (3.87±0.18 cm), D3 (3.35±0.38 cm), D4 (3.27±0.14 cm), D5 (1.22±0.19 cm) and D6 (0.93±0.043 cm) of all 30 skulls on both sides (Table1).

**Discussion**

The morphology and anatomy of the suprameatal triangle has more surgical importance. The knowledge is very much essential for otologic surgeons to approach the mastoid antrum. Sigmoid sinus is a dural venous sinus draining the brain structures. Emissary vein drains into the sigmoid sinus through the posterior condylar canal. The sigmoid sinus is related to the occipital emissary foramen which transmits a vein that connects sigmoid sinus with the suboccipital venous plexus of veins. During mastoidectomy, there is a complication of perforating the sigmoid sinus. The perforation of sigmoid venous sinus during mastoidectomy can be prevented by calculating the depth of the sinus plate preoperatively using the equation derived. It is very important to know the exact depth and site of sigmoid sinus. In radical mastoidectomy chances are more for damage of the sinus plate accidentally which can result in severe venous bleeding. If the depth (D6) can be calculated from D1, D2, D3 and D5 on the lateral view of plain X-rays, the dangerous complication of severe venous bleeding can be avoided. The statistical analysis of the variants suggested that their exists correlation between the depth of the sinus plate (D6) with other five parameters namely D1, D2, D3, D4 and D5.

The depth of the sigmoid sinus plate can be calculated using various measurements of D1 to D5 using X-rays with Macewen’s triangle as a surgical landmark. Many morphometric measurements were performed and reported between various surgical landmarks for the mastoideotomy. The suprameatal approach was proved to be safer technique as it does not endanger either facial nerve or the chorda tympani nerve.

Mohammad et al., 2011 were using D1 and D2 to estimate D3 (depth of sigmoid sinus plate), in their study and stated a hypothesis that measuring the first two lines D1 and D2 might be an indicator to the third line D3. Earlier studies were done only on the topographic anatomy and surgical importance of the suprernal triangle but no further studies had mentioned the use of various landmarks of Macewen’s triangle to know the depth of sigmoid sinus plate. The equation derived are as follows, D6 = 0.0056 D1 + 0.9056, D6 = -0.0257 D2 + 1.0341, D6 = -0.0115 D3 + 0.9731, D6 = -0.0408 D4 + 1.0681, D6 = -0.002 D5 + 0.938 (Table 3).

In the present study D2 (p value - 0.002) showed statistical significant differences (Table 2). By finding D1, D2, D3 and D5 radiologically, the approximate depth of sigmoid plate (D6) value can be calculated. D4 cannot be used as a reliable landmark as the spine may be absent or not able to trace out in X-ray image.

**Conclusion**

The depth of sigmoid sinus plate (D6) can be calculated using the measurements of D1, D2, D3, D4, D5 on lateral view of head & neck X-rays which can be used by Otologist during mastoidectomy to avoid severe bleeding complications from sigmois sinus. The pre-operative measurement can be taken well in advance using the radiographic images like X-rays and the surgery can be planned accordingly.

**Ethical Committee Approval:**

The study was approved by IEC of VMKV Medical College (Reference - VMKVMC/IEC/18/52).

A Comparative study on Prevalence of Diastasis Recti in Primipara and Multipara Undergone Full Term Normal Delivery - A Research Protocol

Simran Jaiswal¹, Shalaka Dhankar¹
¹Final year B.PT, Ravi Nair Physiotherapy College, DMIMS(DU) Wardha, Maharashtra

Abstract

Background: Diastasis Recti is very common in women after pregnancy. Diastasis recti among women should be treated as soon as possible as it may cause various musculoskeletal dysfunctions. A digital caliper is a tool for assessing diastasis recti in postpartum women. It is a simple, fast, and reliable assessment tool for assessing diastasis recti. Objective: The objective of the study is to find the prevalence of Diastasis Recti in Primipara and Multipara undergone full-term normal delivery and to compare the prevalence of diastasis recti in the both of the groups Method: This study will be carried out in Physiotherapy OPD, Ravi Nair Physiotherapy College and AVBRH, Sawangi (Meghe), Wardha. Diastasis recti will be evaluated in full-term normal delivery females. Diastasis recti will be compared in primipara and multipara using a digital caliper. Results: The result of the study will be estimated by the statistical analysis of the data and will be discussed after the study is completed. Conclusion: After going through various studies, many studies have indicated that the prevalence of diastasis recti abdominis is commonly seen in multipara undergone cesarean section delivery. Very few studies indicate the prevalence of diastasis recti abdominis in primipara and also women underwent full-term normal delivery. Therefore, the current study is carried outreach a conclusion to find whether there is any discrepancy of the prevalence of diastasis recti abdominis between primipara and multipara in females undergone full-term normal delivery.

Keywords: Diastasis recti, Primipara, Multipara, Full term normal delivery (FTND)

Introduction

Diastasis of recti is one of the commonest consequences of pregnancy. Diastasis recti is caused by the separation of the two bellies the rectus abdominis along the linea alba and widening of the linea alba. There are certain factors which cause diastasis recti which is mechanical effect of pregnancy on the abdominal musculature or hormonal factors. Weakening of the linea alba results because of the softening of the connective tissue as there is increased level of relaxin, progesterone, and estrogen during pregnancy. Diastasis recti abdominis also causes low back pain which can be treated surgically. Exercises are recommended to the pregnant women which has many benefits which includes maintaining strength, muscle tone, and endurance. Exercises also helps to improve well-being of the patient, reduces labor pain and also low back pain. Multiparous women have an increased risk of development of diastasis recti because there is repeated and prolonged stretch on abdominal musculature. Pregnant women have weaker abdominals than non-pregnant women. Exercises are helpful in improving the strength and tone of the musculature. It helps to decrease and reduce the size of diastasis recti abdominis. There is weakening of the anterior abdominal wall because of strain placed by the enlarging uterus which results in diastasis recti. The rectus abdominis muscle becomes stretched and elongated around the enlarging uterus as the pregnancy advances. The main role of the abdominal

Musculature is trunk control. The functions which result in diminished trunk stability, abnormal posture. (1) There are various methods for the assessment of diastasis recti abdominis which include the finger-width method, ultrasonography, magnetic resonance imaging (MRI), Computed tomography (CT) scan, calipers, and tape measurement. Diastasis recti abdominis can be treated conservatively focusing on postnatal exercises which limits the progression of diastasis recti abdominis, increases well-being of the patient, promotes weight loss, and also improves the cardiovascular endurance of the patient. Surgical management is needed which is (abdominoplasty) if a woman is unable to perform optimal functions like transfer of weight through the pelvic girdle. Parity increases the prevalence of diastasis recti. Diastasis recti abdominis is found both in primipara and multipara but prevalence of diastasis recti below the umbilicus is more in multiparous women and diastasis recti abdominis at the level of umbilicus is same in primipara and multipara. Diastasis recti is found more in multipara than in primipara. There is a link of diastasis recti abdominis with other conditions like urinary incontinence, fecal incontinence, uterus prolapse, myofascial pelvic pain, rectal prolapse, bladder prolapse. Diastasis recti abdominis also has an association with lumbopelvic pain. Tape measurement and finger-width method are used to measure diastasis recti abdominis because of its cost-effectiveness and accessibility. Digital caliper is used in the assessment of diastasis recti which shows a widening of inter rectal distance more than 2.5 cm at one or more assessment points (2) Diastasis recti is seen comparatively more in multipara than in primipara (3) Diastasis recti abdominis is found more in obese, multiparous, and multiple pregnancies. Including multiparous and multiple births diastasis recti abdominis is also found in women who have narrow pelvis because in pregnancy location of the baby will be more anteriorly. Diastasis recti abdominis can be umbilicus or can be extended above and below the umbilicus or even include the linea alba (4) There is little understanding of diastasis rectus abdominis in society. Majority of women are unaware of diastasis recti abdominis and do not know if they even have this problem. These women also are not aware of the possible exercises which can be performed. The exercises focus on the abdominal muscles and the exercises could be performed during pregnancy. Pregnancy without complications may be an encouragement for women who had a sedentary lifestyle before pregnancy. Women with sedentary lifestyle should be encouraged to add appropriate aerobic exercises and strengthening workout to their routine. Women who are physically active even before pregnancy should continue their lifestyle which includes working out daily, performing aerobic exercises, strengthening exercises. Exercises help in improving physical pain response, it also enhances proper body posture, if exercises are properly chosen then it also reduces pain in the lumbar spine area. This helps after delivery and also taking care of the newborn. Every other woman may have diastasis rectus abdominis after pregnancy but appropriate treatment may reduce the inter recti distance. It is necessary to raise awareness among women about the nature of diastasis rectus abdominis, its predisposing factors, its implications, and physiotherapy treatment. There are two groups of women with diastasis rectus abdominis after pregnancy. The first group in which women are able to regain proper load transfer through the abdominal wall with diastasis recti or without diastasis recti. In the second group of women diastasis, rectus abdominis is larger than the normal ones but they are unable to transfer load through the abdominal wall. In this group women are not able to perform activities like squatting, standing on one leg, changing positions for example sitting to standing, climbing stairs, walking. In this case, a woman requires abdominal surgery which is abdominoplasty which is done after delivery because there is long term damage to the abdominal muscles and the central fascia structures which means that the proper functioning cannot be obtained. Strengthening of the abdominals before pregnancy often decreases the risk of diastasis rectus abdominis, and if it happens then the size of the diastasis is small. It is also said that performing strengthening exercises of abdominals before pregnancy and continuing the exercise in the period of pregnancy can reduce the chances of having a Caesarean section delivery and also influence more effective delivery. (5) Most women experience an increase in inter-recti distance in the abdominal muscle during pregnancy or after pregnancy which occurs because of stretch in the linea alba or due to thinning of the linea alba. Diastasis of the abdominal muscle is considered to be pathologically positive if there is >2.7 cm widening of diastasis recti above the umbilical level. Diastasis of rectus abdominis occurs in
the second trimester of pregnancy and most frequently diastasis is seen in the third trimester of pregnancy. Few studies have been conducted which shows that there is an increase in the inter-recti distance at the 14th week of pregnancy and it continues to increase until delivery. Recovery of the diastasis of the rectus abdominis occurs between 1 day and 8 weeks after delivery. Diastasis of the rectus abdominis ranges from 66% to 100% in the third trimester of the pregnancy and then 53% after delivery. Diastasis recti can be treated surgically which can reduce the effect of the diastasis recti such as back pain. If regular exercises are done before and during the antenatal period such as the strengthening of the core muscles, then there is a reduced risk of developing diastasis recti and also if diastasis recti occur then to reduce the size of diastasis recti. Abdominal exercises are prescribed to the women after delivery who have diastasis of rectus abdominis. Other non-surgical interventions to treat diastasis recti include back care and postural education, aerobic exercises, and external support such as corsets and Tubigrip. Tone, control, and strength of the abdominal muscle can be maintained if the exercises are done, as exercise reduces the stress on the linea alba. Women who exercise regularly in their pregnancy have a less and reduced risk of developing diastasis recti than the women who have a sedentary lifestyle and who do not exercise regularly. Exercises performed in the antenatal period have faster recovery of diastasis recti abdominis. Ultrasound and digital calipers are used to measure the diastasis recti abdominal width and these are the reliable ones. Palpation and finger-width methods are also used to measure the diastasis recti abdominal width but they are not much reliable and not considered to be valid to measure the exact inter-recti distance. (6)

RATIONALE:

Various studies have been carried out to find prevalence of diastasis recti in multipara but very few studies indicate the presence of diastasis recti in primipara and in females with full-term normal delivery. Therefore, current study is carried out to find the prevalence of diastasis recti in females with full-term normal delivery and also to compare it among primipara and multipara.

Objectives

1. To Evaluate Diastasis recti in Full Term Normal Delivery Females
2. To Compare Diastasis Recti in Primipara and Multipara

Methodology

The study will be conducted in OPD of Community Health Science in Ravi Nair Physiotherapy College, Sawangi, (Meghe) Wardha. Prerequisite permission and IEC approval will be taken subjects will be consented and selected as per the inclusion criteria those who are willing to participate will be selected as samples. Assessment of diastasis recti will be done using dial caliper. Outcome measure calibration will be done as per width of diastasis recti in inches. Reading will be spread on a master sheet. Data will be analyzed statistically.

OUTCOME MEASURES: Width of Diastasis Recti using a dial caliper

METHODS:

Study design: Observational study
Study setting: Ravi Nair Physiotherapy College and AVBRH hospital Sawangi (M), Wardha

PARTICIPANTS:

Inclusion criteria:
1. Primipara with FTND
2. Multipara with FTND
3. Up to 6 months postpartum
4. Age 20 to 35 years

Exclusion criteria:
1. Female undergone C – section
2. Female with a previous history of abdominal surgeries
3. Female with BMI > 40 kg/m2

VARIABLE:

1. Width of diastasis recti
DATA SOURCE/MEASUREMENT:

For Diastasis recti – width of the gap between the two bellies of diastasis recti will be measured using a digital caliper

Bias: Age and other Anthropometric factors between the two groups will be matched and subjection not fulfilling the selection criteria will be excluded to prevent bias

Study size: 175

Statistical method: Simple random sampling

Result: Upon completion of the study results, statistical analysis will be estimated.

Discussion

The current study will be carried out to compare prevalence of diastasis recti in primipara and multipara. Various studies have reported a prevalence of diastasis recti in females undergone c- section whether may be primipara or multipara due to separation of rectus abdominis muscle during surgery. However, diastasis also occur due separation of two bellies of recti muscle to accommodate the growing size of uterus but after delivery in postpartum period when the structures of abdomen and pelvic come to their normal position eventually the gap is reduced but diastasis may still persist may show different feature in a female with single delivery compared to females under multiple deliveries. Therefore, the current study aims to compare the prevalence and severity of diastasis recti in primipara and multipara with FTND

Key results: Diastasis recti, Pregnancy, Full term normal delivery, Primipara, Multipara, Full term normal delivery

Limitation: It might be difficult to convince patient for being a part of this study.

Generalisability: Study not done yet.

Conflict of Interest: There is no conflict of interest

Source of Funding: No funding needed

Ethical Clearance: Being an observational study institutional ethical committee permission was taken.

Does Dermatoglyphics An Essential Tool for Predicting Dental Caries? - A Systematic Review

Suganya P1, Lubna Fathima1, Prabu D2, Raj Mohan3, Bharathwaj4, M.R. Prashanthy1

1Post Graduate Student (MDS), 2Professor, 3Reader, 4Lecturer, Department of Public Health Dentistry, SRM Dental College, Ramapuram, Chennai, India

Abstract

Background: Dermatoglyphics is one the vital tool which helps to predict many systemic diseases including oral problems. Dental caries seems to be a major problem overall the globe. The best way to manage this condition is only early diagnosis.

Aim: This study aims to assess whether dermatoglyphics effective in predicting dental caries.

Materials and Method: A systematic review of controlled trials was performed. The data were hand searched using electronic databases and the 328 number of articles were screened. The intervention and outcomes were assessed in the study included for systematic review. The bias assessment of the articles was done by using Newcastle Ottowa scale.

Results: Seventeen cross-sectional studies were included in our systematic reviews. Of that sixteen articles were found to be statistically significant, but further studies should be done in other countries to prove the association between dermatoglyphic pattern and dental caries.

Conclusion: The pattern of dermatoglyphics was found to be very effective in predicting dental caries and thereby prevent the caries formation at an incipient stage.

Key Words: Dermatoglyphics, Finger print, Dental caries, Streptococcus mutans.

Introduction

Dermatoglyphics or palmistry is the study of the permanent dermal ridges of the hand and feet. The term dermatoglyphics is procured from Greek word which means skin carving. It is the pattern of imprints of the epidermal ridges of the plantar and palmer surfaces of both feet and hands. In simple term, it is considered as the study of finger prints. The finger print of human beings always remains unique throughout their life time and it will not change. It is a very essential tool for the preliminary investigations such as the cases with suspected or doubtful genetic basis [1,2]

In the recent times, the dermatoglyphics plays a crucial role in determining the future incidences of mystery to a perfect application on a scientific basis. Hence it is very useful for the health care professionals in detecting the diseases at an earlier stage [3].

The dermatoglyphics have been correlated with many systemic diseases due to the coexistence in the morphology of organogenesis and the structure of dermatoglyphics by their interlinked genetic countenance. The dermatoglyphics study is based on the finger ridges which was under the jurisdiction of genetic and environmental factors; hence they act as a reservoir of the early genetic and developmental anomalies [2,3].

Currently, the dermatoglyphics have been used to predict many oral diseases such as precancerous lesions, oral clefs, dental caries and many other conditions. Of these dental caries is one of the most predominant disease that exists globally and affects all age groups in
general. Though many recent advanced materials and technologies have development to determine and treat dental caries but the problem still persists [2].

Dermatoglyphic pattern is considered as a genetic marker to predict dental caries due to the similarity in the ectodermal origin of the epithelium of finger buds, enamel and the primary palate which was development during the same intrauterine period [3].

Various studies have been conducted regarding the association of dermatoglyphic patterns and dental caries. To clarify this in an appropriate manner, this present study aims to evaluate the association of dermatoglyphics and dental caries by conducting a systematic review.

**Materials and Methods**

In this study the systematic review of trials was carried out to evaluate the association between dermatoglyphic pattern and dental caries.

**SEARCH STRATEGY:** The articles related to the correlation between dermatoglyphics and dental caries were hand searched using electronic databases such as Prospero, Web of science, Cochrane library, Wiley online library, Grey literature, Science direct and PubMed. The articles were retrieved from each database based on the mesh representation.

**INCLUSION CRITERIA:**

1. Original articles
2. Articles with full text are included
3. Only cross sectional studies
4. In vivo studies

**EXCLUSION CRITERIA:**

1. Articles other than English language
2. Review articles, case control
3. In vitro and animal studies are excluded.

**Search engine:**

- Cochrane library
- Wiley online library
- Prospero
- Pubmed
- Science direct
- Grey literature
- Web of science

**Results**

The figure 1 shows about the articles eligibility for the study. Totally 328 number of articles related to the correlation of dermatoglyphics and dental caries were retrieved. 206 articles which outfit the eligibility criteria were excluded from the study. Out of that 122 articles with full text were assessed for eligibility of the study. Finally 16 articles with full text were qualified for the study.

</table>
The 200 subjects of aged 6-13 years were selected and divided into two groups 100 children with caries active and 100 with no caries. Their hands prints were obtained and their dental caries were recorded using DMFT index. The caries active children had more number of whorl pattern whereas the number of loop pattern was found to be highest among caries free children <0.05

Samples of 300 children of aged 6-12 years were selected in Vadodara city, Gujarat and their hand prints were obtained. Their dental caries and malocclusion were recorded. There was a statistically significant difference between dermatoglyphics and dental caries < 0.03

A 276 number of children of aged 12-15 years were randomly selected from 6 private schools in Kanpur city and their finger prints were recorded using blue ink. Then their dental caries were assessed using DMFT index. The children with whorl pattern had more number of dental caries whereas the children with loop pattern are caries free <0.05

512 children of aged 2-6 years were selected randomly from schools in Lucknow and are divided into three groups based on the dmft score which was assessed using WHO Proforma, 1997 and their finger prints were obtained using stamp pad. Children with whorl pattern are more prone to dental caries <0.05

100 school children of aged 5-12 years were obtained and are divided into caries free and caries active groups with equal number of males and females in both groups. There was a strong association was found between dental caries and dermatoglyphics. Dental caries was found to be more common among children with whorl pattern especially among females Not specified

200 children of aged 3-6 years were selected from two kindergarten in Egypt and were divided into two groups based on the presence of dental caries using dmft index then their finger prints were recorded using stamp pad method. Caries active children had more of whorl pattern finger prints. The children with loop pattern have lower dental caries 0.000

Discussion

Dental caries is one the complex microbial disease that predominantly spreads throughout the world. The dental caries was caused by many factors but the exact reason is unknown. Even though many advanced materials have been developed for the treatment of dental caries, the best approach for the dental caries is prevention. To prevent the disease, the early detection of the root cause or the risk factor of disease is most important. Dermatoglyphics plays a very crucial role in
detecting many systemic diseases such as dental caries.

The study conducted by Sanghani et al in the year 2016 had discussed about the correlation of dermatoglyphic pattern among 200 school children of aged 6-13 years in India and they were divided into two groups equally based on the presence of dental caries then their finger were recorded. The children with whorl pattern have more prevalence of dental caries when compared to those children with loop pattern and it has found to statistically significant (P<0.05) [9].

Kaur et al in the year 2018 had discussed about the pattern of dermatoglyphics among 100 children with dental caries of aged 6-12 years in India and were divided into study and control group. The children with DMFT score> 4 were selected as study group and those children with no dental caries were choosen as control group then their salivary pH and finger prints were recorded for analysing the correlation of dermatoglyphic pattern and dental caries and concluded. The children with loop patterns was found to be more in the control group than the study group and it was found to be statistically significant (p<0.001) [15].

Bazmi et al in the year 2013 had discussed about the association of dermatoglyphics and dental caries among 300 children of aged 4-14 years in India and concluded that there was a strong association was found between dental caries and dermatoglyphics pattern. The children with whorl pattern had more dental caries when compared to children with loop pattern and it was found to be statistically significant (p<0.001) [4].

The study conducted study conducted by Deepti et al in the year 2016 had discussed about the association of dermatoglyphics between dental caries and malocclusion among 300 school children of aged 6-12 years in India and concluded that the children with increased dental caries had a greater frequency of loop pattern when compared to other pattern (p<0.03) [10].

Reddy et al in the year 2018 had discussed about the association of dermatoglyphic pattern and dental caries among 300 special children of aged 6-16 years in India and concluded that the children with dental caries had more frequency of whorl pattern whereas the children without dental caries had more frequency of loop pattern and it was found to be statistically significant (p=0.002) [16].

Saxena et al in the year 2016 had discussed about the correlation of finger prints and dental caries among 276 school children of aged 12-15 years from randomly selected schools in Kanpur city, India and they were divided into three groups based on the DMFT scores. The study concluded that the whorl pattern was most common among caries active group whereas the loop pattern was common among caries free children and it was found to be statistically significant (p<0.05) [11].

Srilatha et al in the year 2018 had discussed about the dermatoglyphic pattern and their correlation with dental caries by evaluating the streptococcus mutans level among 100 children of aged 3-6 year old children in India and concluded that the level of streptococcus mutans was found to be highest among children with whorl pattern. There was a statistically significant relation was found be whorl pattern and streptococcus mutans level (p<0.05) [17].

Agravat et al in the year 2014 had discussed about the efficiency of the dermatoglyphic pattern in the prediction of dental caries. The study was conducted among 200 children of aged 5-12 years from various schools in Ahmedabad, India and concluded that there was a statistically significant relationship was found between finger prints of whorl pattern and dental caries (p<0.05) whereas the children with loop patterns are caries free [7].

Vijender et al in the year 2014 had discussed about the effectiveness of the dermatoglyphics in determining the presence of dental caries among 100 government school children of aged 5 and years in Patiala, India and concluded that the dermatoglyphic pattern was very effective in predicting dental caries and there was a strong positive correlation was children with whorl pattern and dental caries (p<0.05) [8].

Elkwatehy et al in the year 2016 had discussed about the efficiency of the pattern of the dermatoglyphics in detecting the early childhood caries among 200 children of 3-6 years in Egypt and they were divided into two groups based on the presence or absence of dental caries. The study concluded that the dermatoglyphic pattern was very effective in predicting early childhood caries and it was found to be statistically significant (p=0.00),
The children with dental caries had highest frequency of dental caries whereas the loop pattern was found to more in caries free children\[14\].

The study conducted by Chand et al in the year 2018 had discussed about the cost effectiveness of dermatoglyphics in predicting dental caries among 100 school children of aged 4-14 years in Gujarat, India and are divided into two groups based on the presence or absence of dental caries. The study concluded that the dermatoglyphic pattern was very effective in predicting dental caries and it was found to be statistically significant (p<0.05)\[18\].

Maroli et al in the year 2016 had discussed about the dermatoglyphic pattern and its effectiveness in predicting dental caries among 100 school children of aged 5-12 years in India. There was a strong correlation was found between dermatoglythic pattern and dental caries\[13\].

Kochhar et al in the year 2014 had discussed about the pattern of dermatoglyphics and its association with dental caries and Periodontitis among 90 children of aged 12- 14 years in North India and are divided into groups caries assessment group and periodontal assessment group. The study concluded that the children with whorl pattern has a significant increase of dental caries (p<0.005) whereas the children with loop pattern had less dental caries and there was no significant relationship was found between dermatoglyphic pattern and periodontal diseases\[6\].

Matar et al in the year 2018 had discussed about the association of dermatoglyphics and early childhood caries among 60 children of aged 3-6 years in Egypt and are divided into two groups equally children with dental caries and children without dental caries. The study concluded that there was a statistically significant relation was found between the two groups (p<0.001). The children with whorl pattern are more common in children with dental caries and the loop pattern was common in caries free children\[19\].

Singh et al in the year 2016 had discussed about the correlation of dermatoglyphic pattern and dental caries among 512 preschool children of aged 2-6 years in India and concluded the children with whorl pattern had more dental caries when compared to other patterns and are found to b e statistically significant (p<0.05). Another study conducted by Thakkar et al in the year 2014 had discussed about the relationship between dental caries and dermatoglyphics among 183 school children of aged 12 years in Mangalore, India by obtaining their finger prints and the dental caries status and concluded that there was a statistically significant relationship was found between children with whorl pattern and dental caries (p<0.05)\[12,5\].

Overall analysis of the study shows that the dermatoglyphics is a best cost effective tool in predicting dental caries. This will be most helpful to both the health care professionals and the public in general for easy and early identification of the dental caries especially among mentally disabled children. Moreover it is very cost effective when compared to other diagnostic instruments and was very useful to identify and prevent the dental caries.

**Limitations:**

Only cross sectionals have taken into an account. Many studies which outfits the criteria have been excluded. Other databases should also be considered. Many studies have conducted only in India further studies should be carried out in other countries to get more relevant outcome.

**Conclusion**

Dermatoglyphic pattern was very effective in predicting the dental caries and helps the people to detect and prevent the dental caries at an initial stage. The finger prints with whorl pattern are more prone to dental caries whereas the finger prints with loop pattern are less susceptible to dental caries.

Abstract

Background: In Ayurveda Shwasa is a disease of Pranvha srotasa which is explained by all the Acharya in detail. The disease, Tamaka Shwasa in the contemporary system of medicine resembles the clinical features of Bronchial Asthma such as dyspnea, cough and chest discomfort. The etiological factors like exposure to smoke, dust, seasonal variation and exposure to cold are also similar in both the condition. A rough estimation in India shows 10-15% of Bronchial Asthma in the age group of 5-11 year old children.

Aim: present study is entitled to study the effect of Abhaya Sunthi Churna and Snehana, Swedana in management of Tamaka Shwasa. Material & Methods: The present study was designed as the comparative parallel group, interventional study, in which minimum of 30 patients were enrolled. The selected participants were assigned to the two observational groups. Each interventional group participants were administered with Abhaya sunthi churna for 14 days in both the groups A and B. Also in Group A there were additional Snehana and Swedana procedures for 7 days and in Group B consist of Churna with Conventional therapy.

Results: In comparison significant results were seen only in Kasa in group A whereas other parameters showed insignificant difference between the groups. The parameters such as Peenasa, Ghurghurkatwa, Kaphanishtivana, Astitvastha, Asinolabhesa, and Shwasakrichrrata showed reduction individually. The comparative result of both the groups on Adventitious Sound, Significant result was noted on the 14th day in group A who received Abhaya Shunthi Churna with Snehana Swedana after treatment in comparison with group B. Conclusion: we can conclude that the Symptoms of Tamaka Shwasa were reduced in both the groups (A and B) but the effect of the Abhaya sunthi churna with Snehana, Swedana i.e Group A was more significant than Group B.

Keywords- Tamaka Shwasa, Bronchial Asthma, Abhaya Sunthi Churna, Shwasa roga

Introduction

In Ayurveda Shwasa is a disease of Pranvha srotasa which is explained by all the Acharya in detail. As explained in Ayurveda with all the details of etiopathology, this disease entity stands as a very grave one as neglecting it would even cause serious complications and even death. As vital in adults it has also been specified with the same importance in children too as evident from the details of Shwasa roga given in Kashyapa Samhita, the compendium of Kaumarabhritiya. In this, Shwasa in children has been mentioned with the premonitory features in the view of early diagnosis in young children [1].

Tamaka Shwasa is one among the five types of Shwasa roga explained in all the classical textbooks of Bruhatrayee (Ayurveda)²,³. It is a disease which is said to be Yapya (manageable) and if it is of recent onset then it is Sadhya (Curable) [4].
The disease, Tamaka Shwasa in the contemporary system of medicine resembles the clinical features of Bronchial Asthma such as dyspnea, cough and chest discomfort. The etiological factors like exposure to smoke, dust, seasonal variation and exposure to cold are also similar in both the condition. Bronchial Asthma is defined as a chronic inflammatory disorder of airways which is associated with airway hyper-responsiveness. It leads to recurrent episodes of wheezing, breathlessness, chest tightness and coughing, particularly at night or early morning[5].

It is said that this disease also causes burden on the number of lost school days and interferes with academic achievement and social interaction. A rough estimation in India shows 10-15% of Bronchial Asthma in the age group of 5-11 year old children. It also increases the number of preventable hospital emergency visits and admissions[6]. The chronic disease affects an estimated 4.8 million children[7]. According to WHO by the year 2020 Asthma along with chronic obstructive pulmonary disease will become the third leading cause of death[8]. According to Indian Survey, Prevalence regarding from heavy traffic region area in school going children showed prevalence 19.34%, but children of low socio-economic population is 31.14%,While the ratio of the children from low traffic area had 11.15% respectively and lastly in the rural area also showed 5.7% aged 6-15 years[9].

Ayurveda has various treatment modalities for Tamaka Shwasa which includes both internal and external therapies. Two types of therapies are advised which are Shamana (Pacification) and Shodhana (Purification). The churna of Abhaya (Terminalia Chebula) and Sunthi (Zingiber officinalis) is explained in treatment of Shwasa roga as a Shamana (Pacification) therapy[10]. Abhaya or Haritaki acts as anulomana (facilitating downward movement of Vata) and Sunthi acts as Pachana (Digestive), Kapha-Vataharana[11]. Other therapy is Shodhana (Purification) which have Snehana (Oilation) and Swedana (Sudation) over chest region have been explained for Tamaka Shwasa by Acharya Charaka[12] and Swedana has also been explained as one of the beneficiary procedure in Tamaka Shwasa[13].

Only a few research studies have been carried out on Tamaka Shwasa in children. Thus the present study is entitled to study the effect of Abhaya Sunthi Churna and Snehana, Swedana in management of Tamaka Shwasa.

Objectives of the Study

To study the effect of Abhaya Sunthi Churna on the clinical features of Tamaka Shwasa

To study the effect of Abhaya Sunthi Churna along with local Snehana Swedana on the clinical features of Tamaka Shwasa

Material and methods

Selection of material: The Raw drugs i.e Haritaki and Sunthi were procured from a local shop and authenticated by the Department of Dravyaguna, M.G.A.C.H. and R.C. Salod (H) Wardha.

Source the drug: The trial drug Abhaya sunthi churrna was prepared at Rasashastra Department in the college as per the classical method of Churna preparation.

Preparation of material: Ingredients were cleaned properly and taken in equal quantity and dried under sunlight. Each ingredient was pounded to fine powder by Pulverizer (Mesh no.80) & sieved, Each ingredient was weighed separately, Mixed together and finally the drug was prepared and made ready by packing in the air tight container in which for age criteria 3-9 years 100 grams of Churna was packed and for 10-15 years 200 grams of Churna was packed in the air tight container.

Methods

After receiving approval for research from Institutional Ethical Committee Ref no DMIMS(DU)/IEC/2017-18/7247 the comparative parallel group, interventional study was conducted. Total 30 Children aged 3 – 15 years with clinical symptoms and auscultations of Tamaka Shwasa were enrolled from OPD & IPD, Department of Kaumarbhritya of M.G.A.C.H. and R.C. Wardha.

The selected participants were assigned to the two observational groups. Each interventional group participants were administered with Abhaya sunthi churna for 14 days in both the groups A and B which was decided following textual reference. Also in Group A there were additional Snehana and Swedana procedures.
for 7 days and in Group B consist of Churna with Conventional therapy if the participant is on any kind of conventional therapy. Detailed history of the participant was taken from the informant and the participant too with thorough general and systemic examination as per the parameters mentioned in the case Proforma which was prepared for the clinical trial of the study. From the 1st day itself the observations and laboratory sampling were recorded before and after the treatment. Hence the observational results were analyzed by statistical tests and post treatment follow up was done on 28th day.

**Administration of the trial drug:** The trial drug, Abhaya sunthi churna was administered in the following dosage for a period of 14 days.

**Table no.-1: Dosage of drug as per age**

<table>

</tr>
</tbody>
</table>

**Inclusion Criteria:**

- Diagnosed participants of TamakaShwasa between the age group from 3 to 15 years of age irrespective of caste, religion, sex, habits, occupation and socio-economic status

**Exclusion Criteria:**

- Severe persistent Asthma which needs usage of nebulization and inhalation of nasal spray (puffs).
- Diagnosed cases of Severe COPD, Respiratory Distress Syndrome (RDS), Pneumonia, Pulmonary Kochs and AIDS, Status Asthmaticus
- Any other systemic disorders which may interfere with the trial.

**Diagnostic criteria-**

A). Subjective criteria:

- The assessment was done on the basis of Classical signs and symptoms of tamaka shwasa
  - Peenasa (Coryza)
  - Ghurghuratwa (Wheezing)
  - Kasa (Cough)
  - Kapha Nisthivana (Expectoration)

- Asino Labhate Saukhyam (Relieving while sitting position)
- Shwaskrichhrata (Difficulty in Breathing) related to climate
- Nidra (Sleep)

B) Objective criteria:

- Adventitious Sound
- CBC (Complete blood count)
- A.E.C (Absolute Eosinophil Count)

**Result and Observations**

As per the demographic data maximum numbers of participants were from age group 8-13 years. Age is often considered as a risk factor for Bronchial Asthma because it is unclear if malnutrition status leads to Bronchial Asthma or if the age reflects the sum of cumulative response throughout the life. Ageing of the airway and parenchyma may lead to structural changes associated with Childhood Asthma. Out of 30 participants, males were 12 in Group A and 7 in Group B whereas females were 3 in Group A and 8 in Group B. The ratio of males is seen more which was just serendipity (coincidence) rather than any logic behind this observation.
Distribution according to area of residence revealed 53.3% of participants were from rural area in both the Group A and group B, followed by 46.7% from urban in both the Group A and B. In the past most studies have reported that prevalence and mortality rate Bronchial Asthma are greater in urban area rather than rural area because of the reflecting change and patterns of the environment and climate in developing and developed countries. All this is worsening due to one major causes i.e. pollution in urban areas which is affecting a big threat of global warming. In the present study, the site was a rural area and the population was also from the same area. The prevalence of Bronchial Asthma even in rural areas suggests that environmental pollution might have started influencing even the rural areas. Even the nearby industries might be contributing to the disease in children. Burning wood, cow dung, crop residues and coal in open fire is typically found in the location of the study which might have also contributed to this observation.

On the basis of religion, nothing specific can be predicted from the observation in the present study, as the demographic area might have played the major role in it. With respect to the status of education, all the participants were school going children and there is no such fact which relates prevalence of Bronchial Asthma in school going children.

Disturbances in sleep are an essential feature quoted in the lakshana of Shwasa in Charaka Samhita. In the present study, sound sleep was found in 53.3% of participants in Group A and 73.3% of participants in Group B which is suggestive that the sleep disturbances may not be an essential feature of Tamaka Shwasa in children as in adults. Disturbed pattern of sleep in Group A was 7 (46.7%) participants and only 4 participants in Group B. This might be because in children, sleep pattern is not considered as the major problem.

Around 10 (33.33%) participants were found to be having a familial history of similar condition and hence this observation also did not show any obvious relation. Noticeably Nidana explained for Tamaka Shwasa in Ayurveda do not include hereditary factors involved in the pathology. But as per modern medicine, significant risk has been observed in participants who frequently suffer from uncontrolled asthma symptoms, Severe Exacerbations in previous year, Exposure to potential allergens/triggering agents and Poor adherence to past treatment.

15 participants in each group were having a vegetarian and mixed diet. Majority of the participants were having the habit of consuming Ruksha Aahara like chips, packet food and fried items. As these food items are meant to cause Vata prakopa and are among the causative factors of Shwasa roga, it can be said that there is a direct relation between the type of food consumed and the disease manifestation.

Subjective Parameters

In comparison significant results were seen only in Kasa in group A whereas other parameters showed insignificant difference between the groups. The parameters such as Peenasa, Ghurghurkatwa, Kaphanishtivana, Asinolabhatesaukhya and Shwasakrichrrata showed reduction individually.

Objective Parameters:

In the comparative result of both the groups on Adventitious Sound Significant result was noted on the 14th day in group A, who received Abhaya Shunthi Churna with Snehan Swedana after treatment in comparison with group B.

Result on Hematological parameters as shown below:

In comparison the result of both the groups in Objective parameters insignificant results in the values of White blood cells at the end of the trial was seen between Group A and B with a p value of 0.547.

In the values of Monocytes, the comparative result was insignificant statistically. But in the values of Granulocytes, Lymphocytes and Basophils significant results were seen on comparison between Group A and B with a p value of 0.001, 0.001 and 0.003 respectively. In the values of Eosinophils and Absolute Eosinophil Count there were no significant results seen on comparison between the groups.

Overall assessment of the result:

Overall maximum improvement was noted on Subjective Parameters of Tamaka Shwasa in Group A
with 77.98% and Moderate improvement in Group B with 62.85%.

**Discussion**

In the present era, children are commonly seen suffering from Childhood Asthma. Although both the conditions cannot be completely looked at as the same due to differences in etio-pathological factors explained in Ayurveda, clinical correlation was the purpose in doing so. In the study Abhaya Sunthi Churna was selected as it was one among the formulations indicated in Tamaka Shwasa which contained easily available drugs. Availability of genuine herbs is becoming a grave issue day by day due to excess production of herbal products and scarcity of good quality herbs. So it was the need of the hour to have a simple but efficacious formulation in a condition like Tamaka Shwasa. Snehana Swedana being the Purvakarma are very widely practiced in many clinical conditions and are also indicated in Tamaka Shwasa during the vegavastha\(^\text{[14]}\)

In the present study, significant difference between the groups was found in only Kasa whereas other parameters showed insignificant results on comparison. All the participants in Group A had no cough on 14th day whereas 5 had occasional cough in group B. This significant effect in group A is suggestive of the enhanced action of Abhaya Shunthi Churna when administered with Snehan Swedan. The insignificant effect on comparison over Peenasa, Gherghuratwa, Kapha Nishtivana, Asinolabhate saukhyam and Shwasakrichhrata shows that both the groups were equally effective in the management of Tamaka Shwasa. When analyzing the individual percentage of relief, it is evident that the number of participants who got relieved of the symptoms were more in Group A than B. The insignificant difference between the groups may also be due to the less sample size in the present study.

In comparison with group B, group A who received Abhaya Shunthi Churna with Snehan Swedan showed significant results after the treatment i.e. on the 14th day on the objective parameter of Adventitious sounds. 14 participants out of 15 had no adventitious sounds on auscultation in group A which shows better efficacy of the treatment modality. The pathology of Shwasa does not involve only systemic changes but localization of Kapha Dosha in ura pradesha. Kapha vilayan with internal medicine always gets enhanced by the local effect of Snehan Swedana because of which these procedures have been mentioned specifically in the management of Tamaka Shwasa. The same efficacy was seen in the present study which indicates the necessity of local procedures in early relief from the symptoms.

On the basis of mean of before and after treatment significant effect was seen in the values of Granulocytes the value of which was 42.93 on day 1 but was 60.27% on day 14 in Group A. As the level of increase was within the normal limits no specific effect of the drug can be ascertained from the values. Larger sample studies might earn better conclusions. Although there was a significant difference between the effect of both the groups, the changes in the values of Lymphocytes was within the normal limits. The same was seen in the values of Basophilhs also. Although there was reduction in the values of Eosinophils and Absolute Eosinophil Count in both the groups, the difference was not significant in the study. Larger sample evaluation might give precise results. No Adverse Drug Reaction (ADR) reported during the follow up period reveals that the drugs did not cause any untoward effect in the participants.

**Probable mode of action**

In the literature of Ayurveda, the main causes of Tamaka Shwasa are the vitiation of Vata and Kaphadosha including the formation of Ama in which the drugs having the properties of Deepana, Pachana, Vata Anulomana, Shwasahara, Kasahara and tridoshahara can break the Samprapti of Tamaka Shwasa.

Tamaka Shwasa has the pathological state of Vata and Kapha Dosha in dominance. Pediatric age group has been explained in Ayurved classics as a period where there is physiological dominance of Kapha Dosha. The churna of Abhaya (Terminalia Chebula) and Sunthi (Zingiber officinalis) is explained in Shwasa chikitsa of Bhaisajya Ratnavali\(^\text{[15]}\). Abhaya or Haritaki acts as anulomana (facilitating downward movement of Vata) and Sunthi acts as Pachana (Digestive) and Kapha-Vata hara\(^\text{[11]}\). Haritaki is having immunomodulatory activity which directly has its effect on Pranavaha Srotas\(^\text{[16]}\) Sunthi acts as Antitussive in the management of Tamaka Shwasa\(^\text{[17]}\).
In this study, two modalities of interventions which are indicated in the management of Tamaka Shwasa have been compared in the same set of participants. One group was administered with only internal medication as in the routine management protocol whereas the other group was given Snehana and Swedana therapies which are a very unique contribution of Ayurveda in the management of Shwasa roga. Snehana was performed with Tila Taila (Sesame oil) which is said to be having the properties of Ushna virya, Vata shamaka and not increasing Kapha Dosha\(^{[18]}\) By virtue of its effect, Snehana might have helped in the normal movement of Vata which was extended by the added effect of Swedana. Kapha vilayana might be the specific effect of Swedana by virtue of its Ushna guna. This formulation also facilitated the normal downward movement of Vata with respect to respiration which reduced the gravity of dyspnea and difficulty in sleep. The reduction of excess quantity of sputum brought about by the drugs used helped in listening to the adventitious sound on auscultation of chest.

**Conclusion**

In the present study Tamaka Shwasa was correlated with the Childhood Asthma or Bronchial Asthma. In children Consumption of Ruksha Aahara, packet foods and Agnimandya were the major etiological factors. During the study the Abhaya sunthi churna was well tolerated by all the participants without any obvious Adverse Drug Reaction (ADR).

The results of the study revealed that the Symptoms of Tamaka Shwasa were reduced in both the groups (A and B) but the effect of the Abhaya sunthi churna with Snehana Swedana i.e Group A was more significant than Group B.

Hence it can be concluded that Abhaya sunthi churna with external Snehana and Swedana can be effectively used in children suffering from Tamaka Shwasa as compared to only oral administration of Abhaya sunthi churna for a period of 14 days.

**Ethical Clearance** is taken from Institutional Ethical Committee Ref no DMIMS(DU)/IEC/2017-18/7247.

A Study Protocol for Checking Efficacy of Leap Motion Device on Gross Hand Dexterity in Sub-Acute Stroke Patients

Vaidehi kannao1, Waqar Naqvi1
1Student, Vice Principle and Professor, Ravi Nair Physiotherapy College, Datta Meghe Institute of Medical Sciences, Wardha, Maharashtra, India

Abstract

Introduction: Stroke survivors have limited everyday living tasks, often because of dexterous issues. Videogame-based training (VBT) with the appearance of virtual reality helps to improve the role of the upper limbs. The leap Motion controller can track both hands and fingers’ fine movements. The studies thus demonstrate the efficacy of the leap motion system on gross hand dexterity in patients with sub-acute stroke.

Method: The research has been designed as an experimental study. The total of 40 participants will be taken from AVBRH, sawangi Meghe for study as per inclusion and exclusion criteria. With intervention the span of the study will be 6 months. Leap Motion-based, augmented reality training will be provided to patients for half hour, every single day, Five days of the week a month. Pre and post, box and block test and System usability scale will be taken. Those two will be the patient’s major outcome.

Discussion: This study protocol aims to assess the efficacy of the leap motion controller on the rehabilitation of gross hand dexterity in patients with stroke. The study’s expected outcome will concentrate on the evaluation of the usability of VBT using the Leap Motion Controller (LMC) to train gross hand dexterity in stroke patients’ early recovery process.

Keywords: stroke, upper limb, dexterity, virtual reality, videogame-based training (VBT), leap Motion controller (LMC), box and block test, system usability scale.

Introduction

1The World Health Organization (WHO) estimates that stroke is the second-largest cause of death in the world.2Up to 85 percent of patients who survive stroke hemiparesis due to reduced arm and hand function.3The upper limb is an important part of the human body, which is very mobile and plays a role in grasping, carrying, moving and touching different objects.4Loss of upper limb independence contributes significantly to physical disability, impacting quality of life and independence in the ‘basic’ and ‘instrumental’ everyday activities.5To further boost the outcome of the upper limbs, work is continuing to explore new approaches. Videogame-based training (VBT) together with virtual reality (VR) is an emerging therapeutic process. Recent meta-analysis suggests there is strong evidence that VR programming can be helpful for upper limb recovery following stroke.

Virtual reality training is becoming a promising technology which can facilitate motor rehabilitation by providing high-intensity, repetitive and task-oriented training with computer programs that simulate three-dimensional scenarios in which patients play by moving their body parts.6Virtual Reality (VR) may provide patients with a supportive immersive experience, with the goal of maintaining high quality and intensive
Within the literature, the following benefits of using VR within rehabilitation have been identified in improving performance, improving the affected limb and cognitive functions, encouraging neuroplasticity and greater flexibility in everyday life activities, as well as increasing patient engagement and cooperation during rehabilitation programmes. Indeed, some authors have found evidence that using virtual reality and immersive video games can be helpful in improving upper limb function and function of ADL (Daily Living Activities) when used as an alternative to regular therapy (to maximize total therapy time) or when compared to the same typical therapy dose. This makes VR a valuable resource in therapy’s future, not only because it has been shown to be effective for ill and healthy subjects, but also because it has had very little side effect and was much safer than other aggressive or violent therapies.

Leap Motion’s leap motion controller (https://www.leapmotion.com) provides a means to capture and track delicate hand and finger movements, while manipulating a virtual environment that involves hand-arm coordination as part of virtual tasks. The Leap Motion Controller (LMC) is a modern optoelectronic device designed to capture both hands’ movement and manipulate a virtual environment. Unlike previous devices, it optoelectronically monitors fine finger movements, using neither glows nor markers. This system is specifically designed for hand gesture recognition and explicitly measures the location of the fingertips and the orientation of the hand. This is made with 2 cameras and 3 LEDs in infrared. Across three-dimensional space it senses hands, wrist and elbow positions and gestures. LEAP motion setup is quick, since it only requires downloading the SDK from the official LEAP motion website.

Aims and Objective

This research aims to assess the efficacy of the leap motion controller on the rehabilitation of gross hand dexterity in patients with stroke.

Objectives

1. To demonstrate the effect of Virtual Reality based serious gaming using leap motion the dexterity of hand in patients with strokes.

2. To check the usability of VBT to train gross motor function in the upper limb hand function using Leap Motion Controller (LMC).

Methodology

This study will be conducted in the Department of Community Health Physiotherapy at Ravi Nair Physiotherapy College, Sawangi (Meghe), Wardha, India, with the approval of Datta Meghe Institute of Medical Sciences, Institutional Ethics Committee, Deemed to be University.

Study Setting: - Ravi Nair Physiotherapy College

Study Type:- Experimental study

Study DuratioN:- 6 months

Sample Size:- 40

Inclusion Criteria:-

1. Patient willingness to participate
2. Age 30-70 years old
3. Those who rated stage 4 or above in the stages of arm and hand recovery in the Brunnstrom motor.
4. Those who mastered the doctor’s guidance in Mini-Mental State Evaluation, with or above 24 marks.
5. About 4–24 weeks had passed since the onset of the stroke.
6. Capable of raising the affected arm and wrist independently of their residual voluntary movement or at least capable of carrying out an ante-flexion of their upper arm and length of one or more fingers against gravity

Exclusion Criteria:-

The exclusion criteria are as follows:

1. Non-willing to participate
2. Recent fractures
3. Visual, hearing deficits
4. On Brunnstrom grading patient score 1.5 or
5. The background of the ischemic transient
attack (TIA);

6. Vital body parts including brain, lung, liver and kidney failure;

7. Past neurosurgery or epilepsy experiences inside the brain;

8. Significant cognitive disability or aphasia (incapable of following the directions of the therapists);

9. Not appropriate for MRI scanning (including but not limited to: metal pieces in the eyes or face; insertion of any electronic devices such as (but not limited to) cardiac pacemakers, cardiac defibrillators, cochlear implants or nerve stimulators; operation on brain blood vessels or heart valves; or defects in the brain or skull);

10. participation in another clinical trial concerning the treatment of physical or investigational medicines.

OUTCOME MEASURES:-

1. The dexterity will be measured using the box and block test.

2. 5-point Likert scale for System Usability Scale.

PROCEDURE:-

The game is played with both hands beginning with non-affected first hand. Participants should sit on a chair with a rectangular pillow on their lap (if not in a wheelchair), so that the elbows can rest on the pillow. The LMC is positioned on a table in front of the person, between the body and the LED screen. During each session, the principal investigator will sit beside the participants, providing online feedback (if necessary) through verbal, visual and/or physical guidance. The LMC is comprised of three infrared emitters and two charged device cameras to monitor all movement of hands, wrists, and forearms. The infrared emitter light reflects back from the hands' surfaces so no markers are required.

Petal-picking-game:- Designed by picking lotus petals in a simulated environment to develop the finger pinching motor skills. This also strengthened digital dexterity and coordination.

Experimental procedure:- Leap Motion-based, augmented reality training will be provided to patients for half hour, Every single day, Five days of the week a month.

Material Required

- Printed copy of brunnstrom scale, mini mental scale, system usability scale
- Pillow
- Chair with arm rest
- Table
- Stopwatch.
- Wooden box dimensioned in 53.7 cm x 25.4 cm x 8.5 cm.
- 150 wooden cubes (2.5 cm in size)

INSTRUMENTATION:-

Leap motion controller
LED screen

Data Analysis

Analysis of data will be carried out using concise and inferensive statistics using unpaired t test students in chesquare. The software used in the study will be the SPSS 24.0 version, the paradox prism 7.0 version and the degree of significance < 0.005 (p>0.005 m) is considered.

Ethics And Dissemination

The approval of the Committee on Institutional Ethics must be obtained prior to the start of the study. Patients must be treated with respect first. Upon meeting the requirements of inclusion and exclusion criteria, the patients are taken for review.

Observation And Expected Results:-

The study’s expected outcome will concentrate on evaluation of VBT usability using the Leap Motion Controller (LMC) to develop gross hand dexterity in stroke patients’ early recovery process.

Discussion

This study protocol aims to assess the efficacy of
the leap motion controller on the rehabilitation of gross hand dexterity in patients with stroke. The purpose of this study will help to explain the process of creation of a series of VR mini-games designed to improve the encouragement of patients with stroke when performing repetitive upper limb movements. The study's expected outcome will concentrate on the evaluation of the usability of VBT using the Leap Motion Controller (LMC) to train gross hand dexterity in stroke patients’ early recovery process.

**Source of Funding:** There will be no direct support for this research from public and private organization. The department of physiotherapy, at Datta Meghe institute of Medical Science, Deemed to be university will provide material needed for research.

**Conflict of Interest:** Nil

A Novel Research Protocol to Evaluate Psychological Perception Using Brain Gym Exercises in Physiotherapy Students

Vaishnavi K. Siroya¹, Angela Kapoor²

¹Final year Student, ²Assistant Professor, Department of Cardio-respiratory Physiotherapy, Ravi Nair Physiotherapy College, Datta Meghe Institute of Medical Sciences (DU), Wardha, Maharashtra, India

Abstract

Brain Gym is an academic kinesiological program that is promoted and applied with a consistent learning purpose that aims at enhancing performance such as memory, psychological perception and cognitive skills. The technique requires the participant to communicate with a series of activities that help the body to understand the primary behaviour and learn how to coordinate the brain and entire body. Brain Gym activities includes of 26 basic motions, which are believed to improve perception and stimulates brain hemisphere by neural re-modelling to facilitate whole brain learning. By ways of balancing both the side of brain, behavioral difficulties, social and intellectual burdens are expected to be reduced.

Aims and Objective: This study aims to evaluate the psychological perception and decrease depression in the undergraduate physiotherapy students.

Method: Here’s a idea we suggest to check the psychological perception with brain gym intervention and the duration for practices comprises of three days a week session, duration of 25 minutes, which is completed in one hour. The depression anxiety stress scale (DASS 21) is used to evaluate disorder which is a valid and reliable tool. This study will be conducted in Ravi Nair Physiotherapy college, Sawangi, Meghe, Wardha. The duration of the study will be six months. The study design is of before after-type with simple randomized sampling.

Result: The data will be analysed using Student paired t test.

Conclusion: The expected outcome includes the detection of stress, depression and anxiety levels which will be evaluated by using DASS-21. Data analysis will be done using students paired t test and conclusion of the study will be published after the results are analysed.

Keywords: Psychological perception, Depression, Stress, Anxiety, DASS-21, Brain gym

Background

It is an interventional type with before-after study design which focuses on the evaluation of the psychological perception after intervention of brain gym exercise. Brain Gym was developed in 1970 as an educational and psychological training system developed and enforced with a specific learning intent. Brain Gym activities includes of 26 basic motions, which are believed to improve perception and stimulates brain hemisphere by neural re-modelling to facilitate whole brain learning. The neural mechanism and white matter connectivity of the brain is influence by the intervention of the exercises.

Brain Gym is a instructional curriculum intended to improve social, mental, emotional and physical efficiency and use 26 moves. According to Brain Gym literature, the abstract framework on which brain activity is conceptualised is generally simplified and defined along dimensions: laterality, attention and centring. Laterality, the synchronization between the
brain’s right and left hemispheres, which is considered important for reading, writing, hearing, communicating and being able to walk and think. Focusing, the ability to process information in the brain, which is connected to perception and lack in attention / hyperactivity. The final section, centring, the top and bottom brain parts organized as necessary to combine rational thought with emotion (5). Brain gym intervention aims at the optimization of activity, social participation, and quality of life, as well as the health condition of people with acute and chronic disabilities. The most beneficial way to stimulate the brain is by incorporating kinesthetic and tactile learning, techniques and audio and visual activities to combine the high- and low-brain functions. Brain exercise contributes to sensory integrity, motor learning and a link between brain and body. Recently, brain-inspired methods have gained more popularity in overcoming command and decision-making challenges (6). A motion in the mental workout has been shown to have increased blood circulation and stability, good oxygen levels and healthy metabolism (7).

As per the founders, the daily practice of brain gymnastics leads to activation and development of various sections of the brain, particularly the cortex which allows for smoother and more organized communication between the two sides of the brain for high-level thinking (8). The brain is a complex organ which focuses on motion and according to Hannaford, “activity is necessary for learning” (9). Brain stimulation is very important in neuro-rehabilitation, reducing atrophy, lessen the risk of brain structure lesions and increasing cognitive performance. It is important therapy for elderly patients with depression, as its neuronal advantages have increased for age-related atrophy exacerbated by neuropathology (10). Neuroimaging research has indicated motor development, improve perception and integral approach involve stimulation of domains of auditory perception and more operation of cerebral cortex. The study describes the importance of brain gym exercise in physiotherapy. Exercise can stimulate the brain in such a way that neurons are often in a condition to handle the different data from outside and are capable of responding to a “corporate member” of their duty in compliance with parts of brain activity using the principle of “brain-body link”. Brain Gym is a great source of personal development, enabling individuals to obtain rapid transformations and also improve the quality of life in a different age group.

Many recent experiments have been carried out to determine the efforts required to enhance and stimulate the psychological perception of brain (11). Perception is defined as a essentially relational process in which visual stimuli is translated progressively into projections which serve as the basis for action (12). If a person is nervous or distressed then automatically the energy is pumped into the brain and the brain loses control, thus caused the primed, unexpectedly impaired reaction. Brain gym training can minimize mental stress and encourage brain concentration and perception (13). Students nowadays are under stress from waking up to not having proper sleep in addition to all the pressure of appraisals and examinations (14). This undoubtedly influences the attitude of the student towards leaning and academic success (4).

Dr. Chaitanya Kulkarni, Dr. Sanjivani Ramesh Khandale have done a project to detect the effects of brain gym exercise on the attention span of the young students and concluded that the mechanism of reading, recoding and comprehension has been improved. Also, the effect of these exercises demonstrated an improvement in eye power and hand control, as well as helping to focus on the same focal point while reading and writing concurrently. E Effendy, N Prasant Conducted a analysis demonstrating the effect of brain gymnastics on the population of Nursing Home Care Medan ‘s and found that brain gymnastics increased PSQI and HARS score levels in the intervention category and reduce stress and depression, in year 2019 (15) here they have found a significant change in life style and improved quality of life in the elderly patient. Keith J. Hyatt in year 2007, conducted a study on school students and finished with a segment explaining Brain Gym exercises to encourage literacy ability, oral reading comprehension, communication skills, pronunciation and learning, self-esteem, memory, analytical thought, imaginative thinking. Brain exercise has seen to be effective in attention improvement, in research and more on it is shown to be very helpful in enhancing concentration, attention, vision and memory as well as helping to relieve stress.

This research explores the impact on the psychometric characteristics of undergraduate students.
in the exercise program called as brain gym\textsuperscript{(16)}. Specially because it seems to be a accurate and easy-to-administer scale, the Depression Scale, Anxiety, and Stress-21 are chosen. The DASS-21 consist of three self-report measures used to assess depression, anxiety, and emotional tension\textsuperscript{(17)}. Depression spectrum tests dysphoria. Anxiety assessment tests autonomic activation, psychological anxiety\textsuperscript{(18)}. Stress is the very common condition faced by students nowadays and causes disturbance in their daily lives.

Thanh Duc Tran, Jane Fisher performed a study on the Efficacy of DASS-21 in a cohort of Northern Vietnamese people in rural communities as a screening tool and the study concluded that it can useful in clinical practice and the components such as depression, and stress levels are determined by summing the ratings for the elements in question\textsuperscript{(18)}.

The research aims to calculate the impact of brain gym exercise on stress, anxiety and depression in the student of undergraduate physiotherapy using the scale of DASS-21 as an evaluation method. The brain gym exercise intervention will be performed in all the subjects and then evaluation of the psychological perception will be conducted.

**Methodology**

The study will be conducted in Ravi Nair Physiotherapy College, after the approval the Institutional Ethics Committee (IEC) of Datta Meghe Institute of Medical Sciences, Deemed to be University, Sawangi (Meghe). The study design is of before after-type with purposive sampling.

**Study design**: Interventional study

**Sample Size**: 220

**Duration of study**: 6 months

**Inclusion Criteria**:  
- Age group - 18 to 23 years  
- Physiotherapy undergraduate students

**Exclusion Criteria**:  
- Not-willing to participate  
- Student with migraine headache  
- Diagnosed with psychological condition  
- History of neurosurgery or cognitive damage

**OUTCOME MEASURE**:  
- Depression, anxiety and stress scale (DASS-21)

- The DASS-21 is a valid and reliable instrument for determining the mental status, with reliability for depression = 0.81, anxiety = 0.89, stress = 0.78 respectively.

- The DASS-21 has sensitivity = 89% and specificity = 76%.

**NEED OF STUDY**:  
1. To calculate the psychological perception among undergraduate students in physiotherapy.  
2. To reduces depression, anxiety and emotional stress in undergraduate students.  
3. To assess the effects on psychometric properties in undergraduate students.

**PROCEDURE**:  

The Institutional Ethics Committee (IEC) Clearance will be obtained priorly. Students will be selected as per the inclusion criteria that has been mentioned. The participants will be informed the aim of the research and will get informed consent. They will be given pre and post interventional assessment using DASS-21 scale, reading will be recorded and the exercise intervention will be given for a month. After the results have been obtained, data collection will be done and statistical analysis will be obtained and the conclusion will be given and a research paper will be created according to the study and published.
**Brain Gym Exercises Treatment Protocol:**

The **Marching** exercise is performed at the beginning as warm-up, in which subjects stand straight and lift both the legs continuously slight above the hips for a time duration of 1 minute. A **Cross Crawl** exercise is performed to enhance the coordination between both the sides of the brain; it is done for a time duration of 2 minutes (5 sets of 8 repetitions). Subject is instructed to stand straight and lift up the leg up to the chest and touch the knee with the opposite elbow.

**Positive Points** helps to improve memory and reduce stress levels. The subject is instructed to breathe deeply and gently press the eyeballs with eyes closed for a time duration of 1 minute (10 repetitions). It helps to stimulate the lateral and side to side coordination.

A **Step Touch** exercise is done and is performed in the standing position and the subject is instructed to simultaneously move right legs toward left and left towards right, should be done for a duration of 5 minutes (30 repetitions).

A **Neck Circles** exercise helps to reduce stress on the neck muscle, head movement coordination and move the neck in circular motion for a time frame of 2 minutes (3 sets of 8 repetitions). A **Cook’s Hook-Up** helps it stimulates the neurons and enhances the balance between hand and brain. The subject is instructed to extend and cross both the hands and fix the fingers together and internally rotate the hands for a time duration: 5 minutes (repetition).
A Brain Button - This exercise is performed and helps to improve the flow of electromagnetic energy and, helps in relaxation. The subject is instructed to palpate belly button with one hand and other hand over the collarbone and perform circular motion with finger for a time duration of 2 minutes (10 repetition) (17). The Thinking Cap helps to enhance learning speed and mood, increase attention span, and improve memory. The subject is instructed to press the top of ear and the bottom continuously (3) duration: 1 minute (15 repetition) (24).

A Lazy Eight helps in boosting eye muscle control, balance, and concentration. The subject is instructed to extend the hand and make the figure of Eight horizontally in front (3) Duration: 1 minute (5 repetition). A Trace X helps to increase attention span and improve focus (25), where the subject to close eyes and imagine a figure of “X” and do eyeball movement the duration is 2 minutes (10 repetition).

Expected Result

Once the study is completed statistical analysis will be done using Student paired t test and presented in the form of research paper.

Discussion

The study protocol aims to evaluate the psychological perception in an undergraduate student by using the DASS-21 scale. We hypothesis that there will be improved ability to concentrate and improved focus. The research will help to prevaricate the effectiveness of brain gym exercise on stressed student and help with strategies involved to decrease stress and anxiety.

The DASS-21 is chosen as the aspects addresses the challenges faced by the current generation i.e. stress, anxiety and depression and it entirely evaluate the mental status of a person. The Adaptive practices for students include everyday life activities, effective speech, cognitive skills, adaptability, and learning skills that are observable and based on national norms.

Conclusion

The expected outcome includes the detection of depression and anxiety levels in Undergraduate physiotherapy students which will be done by using DASS-21. Brain gym exercises as an intervention will be taught to the participants to evaluate the psychological perception and solve their intellectual and behavioural challenge.

Ethical Clearance: Institutional Ethics Committee (IEC) of Datta Meghe Institute of Medical Sciences, Deemed to be University, Sawangi (Meghe).

Socio-demographic Profile of Deaths due to Poisoning at a Tertiary Care Hospital in Bangalore

Vidusha Vijay¹, Pradeep Kumar M.P²
¹Senior Resident, ²Assistant Professor, Department of Forensic Medicine and Toxicology, Bangalore Medical College and Research Institute, Fort, Krishna Rajendra Rd, Bengaluru, Karnataka

Abstract

Background: Deaths due to poisons form inexorable part of all unnatural deaths in the current era of social, cultural and personal dilemma existing among mankind. Stress, poverty, financial insecurities, personal conflicts, unemployment, ill health, psychological disturbances, difficulties in psycho-social adaptability and loneliness contribute significantly to the ever-increasing mortality in poison deaths.

Methods and results: A 20-month prospective descriptive study was conducted at the Department of Forensic Medicine and Toxicology, Victoria Hospital, Bangalore Medical College and Research Institute on cases of death due to poisoning. Out of 110 cases, maximum number of cases were male (63.63%), in the age group of 21-30 years (33.63%). 92.72% belonged to Hindu religion and 55.45% belonged to the upper lower class. 54.54% belonged to urban areas and 60% were married victims. Maximum numbers of cases (38.18%) were recorded in winter, commonly between 5pm – 10pm (39.09%) and 84.54% occurred at the place of residence. 84.54% of cases were suicidal in nature with psychological causes being the most common motive (30.90%). 81.81% of cases received treatment and 34.53% succumbed to death within 1-7 days of consumption of poison. Organophosphorus group of insecticide (50%) was the most common poison encountered, followed by Phoshide ions (30%).

Conclusion: Poisoning is a major epidemic of non-communicable disease in the present century. Suicidal and accidental poisoning are significant contributors to morbidity and mortality throughout the world.

Keywords: Demographic profile, Phoshide, Poisoning, Organophosphorus

Introduction

According to the World Health Organization, a poison is a substance (solid, liquid or gaseous), which if introduced to the living body or brought into contact with any part thereof, will produce ill health or death, by its constitutional or local effect or both. As per WHO, about 3 million cases of poisoning with 2,20,000 death occur annually worldwide, of which 90% of the cases occur in developing countries particularly among agricultural workers. According to NCRB (National crime records bureau) statistics of 2015, 37232 persons committed suicide by poisoning in India, of which 23930 persons committed suicide by consuming insecticides and 13302 persons consumed other poisons. 39.1% of deaths (26173) were attributed to accidental poisoning. Poisoning suggests an acute event demanding immediate care and attention.

History indicates that the use of poisons has been known since time immemorial. In the antiquity, the main way to poison an enemy was by adding plant or animal toxins into food and drinks. In the Middle Ages, the progress within this area moved forward. Inorganic toxic compounds prevailed. Moreover, such substances were applied more sophisticatedly, i.e., by poisoning of...
the gloves, page corners, wigs, etc. Additionally, there was one more intermingling feature—usage of poisons for unfair purposes had not been usually proven. Thus, criminals had a big chance to escape the punishment. In the Middle Ages, poisons were freely sold in pharmacies. The first attempt to stop free trade with poisons was made in Italy. In modern day India, there are a number of legislatures in place, such as Drugs and Cosmetics Act of 1940, Narcotics Drugs and Psychotropic Substances Act of 1985 and its 2014 amendment that prevent the illegal manufacture, possession and distribution of poisons and other toxic substances.

Poisoning is a major epidemic of non-communicable disease in the present century. Among the unnatural deaths, deaths due to poisoning come next only to road traffic accident deaths. The choice of poisoning agents depends on availability, cost, harmful effects of poison and regional consideration. Pesticides which were invented to protect crops from rodents, insects and humans from starvation have themselves become an important contributor to unnatural deaths. This study was conducted to know the various influencing factors associated with death due to poisoning like age, sex, marital status, occupation, availability of poison and socio-economic status. Knowledge regarding the type of poison chosen might help in imposing restrictions on the sale of those poisons and hence help in preventing deaths due to poisoning.

**Material and Methods**

All cases of deaths due to poisoning brought to Department of Forensic Medicine and Toxicology, Victoria Hospital, Bangalore Medical College and Research Institute for autopsies between October 2016 to May 2018 were selected on a purposive sampling basis.

Following inclusion criteria were taken into consideration:

1. Autopsy on all cases of deaths due to poisoning conducted at Department of Forensic Medicine and Toxicology, Bangalore Medical College and Research Institute during the study period.

2. Cases confirmed as poisoning by chemical analysis report from Forensic Science Laboratory and based on the hospital case sheet records.

Following exclusion criteria were taken into consideration:

1. Autopsy on unidentified bodies.
2. Autopsy on decomposed bodies.
3. Cases of poisoning where the Forensic Science Laboratory report and/or hospital case sheet records are unavailable.

The details of family history, previous medical history and any treatment records, when available, were obtained from concerned police. Autopsy was performed using the Letulle’s evisceration technique, examining all organs. Viscera and blood were sent for chemical analysis to Forensic Science Laboratory. The data obtained from this study was then analysed statistically using Statistical Package for the Social Sciences (SPSS 20) and the data was presented in the form of appropriate tables, computing descriptive statistics such as percentages.

**Results and Discussion**

During the study period, a total of 110 cases of poisoning were studied and the corresponding chemical analysis reports from Forensic Science were obtained. In this study, the maximum number of cases i.e. 70 were male (63.63%) and the rest i.e. 40 were female (36.36%). This can be attributed to the fact that males form the majority of the population and being the sole breadwinner in most families, have to shoulder many responsibilities making them more vulnerable. Whereas, women who are commonly subjected to post-marital problems such as cruelty by husband/in-laws tend to fall prey to suicides by poisoning. Similar findings were observed in the study conducted by Kanchan T, Menezes RG. In this study, the maximum number of cases i.e. 37 were in the age group of 21-30 years (33.63%), followed by 19 cases in the age group of 31-40 years (17.27%). The least number of cases were observed in the 71-80 years (0.90%) and 81-90 years (0.90%) age group (Table 1). Ambition, adventurous mind, aggressive personality, opportunity hunting, academic pressure and challenges,
allure of opposite sex affect the younger age group. Study conducted by Singh B, Unnikrishnan B noted similar findings, whereas contrasting findings were noted in the study conducted by Lee WJ, Cha ES, Park ES et. Al.

In this study, maximum number of cases i.e. 102 belonged to Hindu religion (92.72%), followed by Muslims (5.45%) and Christians (1.81%). This can be explained by the fact that Hindus form the majority of the Indian population. This is supported by the study conducted by Patel NS, Srivastava AK, Amit Kumar et.al., and the study conducted by Gupta BD, Vaghela PC.

According to modified Kuppuswamy socioeconomic status classification, in this study, it was found the maximum number victims belonged to the upper lower class (55.45%) and the least number of victims (1.81%) in the upper class (Table 2). Lack of education, inability to achieve desired educational qualification, financial inadequacy to pursue education, work pressure, job dissatisfaction, failure to achieve targets, strain in employer-employee relationship, excessive debt, low income, over expenditure are the common issues encountered among the lower strata of the society. Patel DJ, Tekade PR have observed similar findings in their respective studies. Whereas, opposing findings were noted in the study by Bharath K Guntheti, Uday Pal Singh.

The distribution of domicile pattern of the victims showed that 60 were from urban areas (54.54%) and 50 were from rural areas (45.45%). This can be attributed to the fact that this study was conducted in the metropolitan city of Bengaluru. Problems of urbanization include over population, intense competition, adaptability issues, unemployment, stress, high cost of living, financial mishaps, desire to make a quick buck and living beyond one’s means. Contrasting findings were observed in the study by Gargi J, Tejpal H R, Ashok Chanana et. al., and the study conducted by Sharma BR, Nidhi Relhan, Neha Gupta et. Al.

It was noted that the maximum number of cases were seen among married victims i.e. 66 cases amounting to 60%, followed by unmarried victims i.e. 44 cases amounting to 40%. Early marriage, lack of compatibility, high expectations from the spouse, adjustment problems with in-laws and the new environment especially among women, lack of parental support - more so in love marriages, dowry demand, infidelity, domestic violence, cross-cultural clashes are the common issues that plague the institution of marriage. Similar findings were noted in the study by Dipayan Deb Barman, Vijaya Kumar Nair, Karnaboopathy GR. Opposing findings were noted in the study by Patel NS, Srivastava AK, Amit Kumar et.al.

Maximum numbers of cases i.e. 42 were recorded in winter (38.18%), followed by 26 victims each in summer (23.63%) and monsoon (23.63%). Even though it is very difficult to establish a genuine correlation for this, factors such gloomy weather, predisposition to respiratory illnesses, lack of job opportunities could play a significant role. In the study by Tüfekçi I B, Curgunlu A, Sirin F, same observations were made. This finding is deviant from the observations in the study conducted by Kar SM, Sidartha Timsinha, Prashant Agrawal.

It was observed that the most common time of incident was between 5pm – 10 pm (43 cases – 39.09%), followed by 10am – 5pm (35 cases - 31.81%). The least number of cases were observed between 6am – 10am (13.63%). It is not possible to arrive at a precise conclusion for increased number of deaths for the above said duration. However, leisure time after work hours resulting in family interaction and conflicts, recapping of distressing events, alcohol consumption etc. can lead to the fatal event. Similar finding in males was noted in the study by Kanchan T, Menezes RG. Contrasting findings were noted in the study by Bharath K Guntheti, Uday Pal Singh.

The place of residence was the most common place of occurrence of incident as seen in 93 cases i.e. 84.54%. Two cases of accidental cyanide poisoning in children were noted at their father’s workplace which was a goldsmith’s shop (Table 3). Privacy of one’s own home, closed doors and an unsuspicious environment made the victim’s residence the place of choice for such an extreme step. Dipayan Deb Barman, Vijaya Kumar Nair, Karnaboopathy GR noted similar findings in their respective studies.

The present study shows that 84.54% of cases i.e. 93 were suicidal in nature. Accidental poisoning constituted 12.72% of cases and 2.72% of cases were homicidal in nature. Poisoning is one of easiest methods...
of committing suicide. Easy availability, vast spectrum of poisons, cost-effectiveness and surety of death make poisoning an appealing means of committing suicide. In their study, Lee WJ, Cha ES, Park ES et. Al\(^9\) have noted similar findings. The observations in the study by Lan Zhou, Liang Liu, Lin Chang et. al.\(^{18}\) was deviant from these findings.

The most common motive for death was found to be psychological reasons in 34 victims i.e. 30.90% of cases, followed by domestic reasons in 29 victims i.e. 26.36% of cases (Table 4). In the current scenario of rapid and irrational urbanization where ever-changing pattern of life is affecting the individual at all levels – personal, educational, occupational, marital, social, cultural and financial; conflict within oneself and with one’s environment is inevitable. The burden of imbalance of one or more of these factors is borne by the psyche of the victim, leading to the ultimate decision of suicide. Depression, psychosis, bipolar disorder, schizophrenia, drug and alcohol dependence are some of the psychiatric disorders affecting such victims. Domestic reasons include premarital factors such as romantic misendeavours, loss of dear ones, coercion/blackmailing by a trusted partner, conflict with parents and partner rejection; and post-marital factors include lack of compatibility, infidelity, adjustment problems with in-laws, dowry demand, domestic violence etc. Such findings were also observed by Patel NS, Srivastava AK, Amit Kumar et.al.\(^{10}\), in their study.

It was observed that maximum number of cases i.e. 99 were booked under Section 174 CrPC (90%) This can be explained by the fact that majority of the medicolegal autopsies fall under Section 174 CrPC which deals with unnatural deaths. Two cases (1.81%) were registered under Section 174 ‘C’ CrPC which deals with suspicious deaths. Three cases (2.72%) were booked under Section 176 CrPC which deals with Magistrate inquest, conducted when death occurs in police custody. Three cases (2.72%) were booked under Section 306 IPC which deals with abetment of suicide. These were cases of married women where their husband / in-laws were held responsible for the abetment of the victim’s suicide. Two cases (1.81%) were booked under Section 498(A) IPC which deals with husband or relatives of husband subjecting a woman to cruelty. One case (0.90%) was registered under Section 304(B) IPC which refers to dowry death. There were two cases (1.81%) booked under Section 302 IPC which is the punishment for murder. The circumstance of this case was that the mother, who was a victim of domestic abuse, decided to end the lives of her children in a bid to free them from the abuse.

Out of the total 110 cases that were studied, 90 victims were admitted in a hospital and received treatment (81.81%). The rest did not receive any treatment. This study was conducted at Victoria Hospital which is a tertiary care hospital catering to a significant local population and also to the surrounding towns, cities and states; a large majority of patients seek treatment here resulting in good numbers of treated patients. Timely action by the relatives, speedy transport and swift intervention by the doctors also contributed towards majority of victims being treated. High dose of consumption, rapid action of poison and act of poisoning going unnoticed by the relatives could be factors which resulted in non-treatment.

The most common poison encountered in this study was Organophosphorus group of insecticide (55 cases - 50%), followed by Phosphide ions in 33 cases - 30% (Tables 5 and 6). The findings are in accordance with the findings observed in the study by Shetty AK, Jirli PS, Bastia BK\(^{19}\). Opposing findings were noted in the study by Shadnia S, Esmaily H, Sasanian G et.al\(^{20}\), where the most common agent was drugs. In the study by Lan Zhou, Liang Liu, Lin Chang et. al.\(^{18}\), the most common poison was the rodenticide tetramine and in the study by Sharma BR, Nidhi Relhan, Neha Gupta et.al.\(^{15}\), the most common poison was aluminium phosphide. Easy availability over the counter as well as an accessible poison in the form of insecticides especially in the house of farmers, cost effectiveness, fatal nature of the compound, awareness about toxicity of compound among general population make organophosphorus compound the most common poison encountered. Its effectiveness as a rodenticide, regular use in grain storage, unsafe storage practices and easy accessibility as a household poison especially among women, makes Phosphide compounds second in popularity.
It was observed that maximum number of victims (34.53%) succumbed to death within 1-7 days of consumption of poison, followed by 17 cases (15.45%) were brought dead. Only 6.36% of cases survived for less than 1 hour. This is in contrast to the findings noted in the study by Shetty AK, Jirli PS, Bastia BK.

The intermediate clinical manifestations observed in Organophosphorus compound consumption could be responsible for the delayed deaths. In addition, the effective therapeutic measures would have prolonged the toxic sequelae of Organophosphorus compounds resulting in death at a later date. Majority of the time, the victims ingest formulated Organophosphorus compounds instead of pure active ingredients. Different compounds such as xylene or cyclohexanone maybe be used as solvents. The clinical manifestations of poisoning with these solvents are often poorly studied and uncertain. Other individual-specific factors like general condition of the patient, tolerance, delayed gastric emptying time, response to treatment could have also contributed to the delayed deaths. In our study, it was observed that 10 cases of Phosphide poisoning succumbed to death in 1-7 days. Even though phosphides cause immediate deaths due to rapid toxicity, the delayed deaths in our study may be due to low dosage, reduction in potency due to interference with atmospheric moisture and effective management of dysrhythmias which may otherwise lead to immediate death.

**Conclusion**

Public education programs about suicide are an important component of pesticide-suicide prevention programs. They suggest that public education should focus on convincing the public that suicide is an important public health problem that can be prevented. Educational activities should aim at changing the prevailing attitudes. Significant number of deaths can be prevented by providing local first-aid kits, better training of physicians, faster transportation to hospitals, and ensuring that adequate supplies of antidotes and essential hospital equipment are readily available. Poison information centres are uniquely centralized repositories of data about human exposures to chemicals, including information about the agents involved, the circumstances giving rise to exposure, and the health effects of exposure. Establishment of such centres help reduce the incidence of poisoning by identifying emerging toxicological hazards, stimulating preventive measures by manufacturers and regulators; and assessing the efficacy of such measures.

**Ethical Clearance:** A prior approval was obtained from the Institutional Ethics Committee, BMCRI.

Abstract

Background: As the incidence of medical emergencies is rising, the demand of the knowledgeable and skilled personnel is also needed. It is important for every person to be competent enough to tackle all the emergency situations anywhere. First aid training helps to make a person able to give actual immediate care and safety awareness. The objective of the study is to assess the effectiveness of first aid training program in term of knowledge and skill among school teachers.

Methodology: A Quasi-Experimental study following one pre-test post-test design was used. Participant’s data was collected from 105 school teachers from 12 schools (9 govt. and 3 private) using Total enumerative sampling and the schools were conveniently selected. Knowledge and skills were assessed by using structured knowledge questionnaire and observational checklist respectively.

Conclusion: Data was analyzed using SPSS 16. The t test analysis showed a significant difference before and after the administration of first aid training program in term of knowledge(t=37.05 and p= 0.001) and skills (t=84.485 and p=0.000) at 0.05 level of significance. There was significant association of pre-test knowledge scores with educational status of school teachers.

Key words: effectiveness, First Aid Training Program, knowledge, skills, school teachers.

Introduction

First aid is a valuable key for all beings. It helps individual to become efficient in providing immediate care to the on spot victim, also it helps him to assist persons who are willing to help other injured ones. The knowledge and practice of First Aid is important in limiting the pain and complications brought out by negligence and it can improve the condition at hand only, more the comprehensive knowledge and efficient skills, less will be the risk of mortality.1

The First Aider should always be prepared in order to save life.2 The common types of school accidents are fainting, epistaxis, shortness of breathing, fractures, joint dislocation, bruises, burns, choking, seizures, insect bites and poisoning.3
According to the study by Henry et al at America found that 30% of children younger than 5 years and 56% of children, aged 6 to 10 years had at least one episode of nosebleed. According to the report by Heart institute at Cincinnati’s children’s pediatric heart program, around 20% of young children’s parents reported their children underwent fainting.

According to Indian guidelines and protocols it has been mentioned that honey bee sting and insect sting accounts for 1% incidence in children and 3% incidence in adults. A bee sting is always potentially dangerous as 30-50 stings from a bee have been proved fatal.

Teachers are the main caregivers and the first line of protection for school students. Their role complements that of parents. They are the first respondent in cases of disasters or emergencies. Therefore, they must be able to deal appropriately with medical emergencies, for all healthy students and those students with special health care needs. This role can be achieved if teachers are equipped with the required skills to provide effective First Aid services that promote recovery and prevent future serious health consequences.

Material and Method

The study was conducted during the period from March 2018 to June 2019 in the state of Haryana, India as a Quasi-Experimental research design “one group pre-test post-test design”. The ethical clearance was obtained from university research ethics committee (MMU/IEC/1305) and the study was carried out in accordance with the guidelines laid by Indian Council of Medical Research ICMR (2006). The written consent from school teachers was collected prior to the study. A sample of 105 school teachers from 12 schools (09 from Government and 03 from private school) participated in this study with the prior permission from the principals of selected schools and board of education Mullana. The sample was selected through Total Enumeration Sampling Technique. The sample size for the study was estimated using Cochran’s sample size formula. First aid training program was given with Lecture cum discussion and demonstration method with the help of power-point presentation, videos and demonstration in simulated setting using case scenarios regarding First Aid Management of selected conditions including wound care, fracture, epistaxis, choking, fainting and honey bee sting.

DESCRIPTION OF TOOL

Section I: description of sample characteristics

It consisted of nine items related to selected sample characteristics of school teachers i.e age, Gender, education status, job experience, marital status, no of children, previous Knowledge of First Aid, if yes then source of information, previous handling of First Aid, if yes, then specify condition, previously had taken any First Aid Training.

Section II: Structured knowledge questionnaire

A preliminary list of 30 items on knowledge was prepared. All the 30 items were multiple choice type questions. Each item had a single correct answer. Every correct answer was accorded a score of one mark and every wrong answer assigned zero mark. Thus the maximum score was 30 and the minimum score was zero. The level of knowledge was categorized as very good, good, average and below average.

Section III: An observational checklist

For skill assessment of school teachers on selected condition of First Aid. Paper pencil technique was used for description of selected sample characteristics and structured knowledge questionnaire. Observation technique was used to assess the skills of school teachers.

A preliminary list of 64 items on observational check list was prepared on management of wound care, fracture, epistaxis, choking, fainting and honey bee sting. Each item was marked as yes if followed or no if not followed. Total score ranges from 0-64 and the maximum possible score was 64 and minimum possible score was zero. The level of skills was categorized as very good, good, average and below average.

The reliability coefficient for structured knowledge questionnaire was calculated by using Kuder-Richardson- 20 (KR20) formula and it was found to be 0.8.

Data Analysis

KS (Kolomogorov- Smirnov) test was applied to check the normality of the data. Data was normally
distributed hence parametric tests were applied. The entire hypothesis was tested at 0.05 level of significance.

**Descriptive statistics**

- Frequency and Percentage Distribution to describe sample characteristics.

- Frequency and percentage distribution, Range of score, Mean, Median and Standard Deviation

**Inferential statistics**

- Karl pearson correlation was used to find relationship between knowledge and skills

- ANOVA and t-test was used for association of selected sample characteristics with knowledge and skill among school teachers.

**Result**

Data was entered in Microsoft excel and analysis was done with SPSS version 16. Result of the study shows that first aid training program is effective in improving the knowledge and skills among schoolteachers.

1. **Findings related to selected sample characteristics:**

In the present study, Less than half of the subjects (32.2%) were above 40 years. Almost all (98.09%) of them were female, more than (54.28%) of them were post graduate and less than half (34%) of the school teachers had 6-10 years of experience. Majority (92.28%) of them were married, for less than half (39.47%) of them source was friend and relatives and More than half of teachers did not 53 (50.47%) performed first aid previously.

2. **Findings related to the effectiveness of First Aid Training program in terms of knowledge among school teachers**

In pretest of knowledge, majority of the school teachers (85.71%) had below average and only few (14.28%) had average knowledge whereas in post test more than majority of the teachers (80%) had good level of knowledge , few (10.47%) had very good level of knowledge and less than few (9.52%) had average level of knowledge.

“t”(104) = 1.660 at 0.05 level of significance

**Table 1 shows** that the level of knowledge among school teachers after administration of first aid training program. The t test was applied and the mean difference was found to be statistically significant (“t”=37.054, p=0.001) at 0.05 level of significance. Hence, it can be inferred that the First Aid Training Program was effective in increasing the knowledge of school teachers on First Aid Management.

3. **Findings related to the effectiveness of First Aid Training program in terms of skills among school teachers**

In pre-test of skills through observational checklist all (100%) of the school teachers were having below average skills. Whereas in the post-test most of the school teachers (73.33%) were having good skills, 24.76% were having very good skills, 0.009 were having average skills and 0.009 below average skill.

“t” (104)= 1.660 at 0.05 level of significance
**highly significant p<=0.001

Table 2 depicts that the level of skills among school teachers after administration of first aid training program. The t test was applied and the mean difference was found to be statistically significant (“t”= 84.485, p=0.000) at 0.05 level of significance. Hence, it can be inferred that the First Aid Training Program was effective in increasing the skills of school teachers on First Aid Management.

4. Findings related to the relationship between knowledge and skills among school teachers on selected conditions of First Aid

TABLE 3: Correlation between Knowledge and Skills Scores

<table>
<thead>
<tr>
<th>Knowledge</th>

<td>-0.04(0.6)</td>
</tr>
</tbody>
</table>

df(104 ),r(105)= 0.194 significant(p<=0.05)

Table 3 depicts the relationship between knowledge and skills of school teachers regarding First Aid Management of selected conditions. During Pre-test no significant relationship was observed between knowledge and skills(r=-0.06,p=0.95). During Post-test also, no significant relationship was observed between knowledge and skills(r=-0.04,p=0.6). The calculated r-value in pretest and post-test shows that there was no significant relationship between Knowledge and skills. This indicates that there is no significant relationship between knowledge and skills score of school teachers on First Aid Management of selected conditions.

5(A) Findings regarding association of knowledge scores of school teachers regarding First Aid with their selected sample characteristics using t-test and ANOVA

The ANOVA/’t’ value of age (0.729), gender (1.326), job experience (1.64), marital status (0.54), no of children (1.090), Previous knowledge regarding First Aid management (0.48), Source of information (3.230), Have you performed first aid previously (0.41) were found to be statistically non-significant except educational status (8.442), hence post hoc test was applied. It infers that knowledge was independent of selected sample characteristics except educational status (Post Graduates had higher knowledge than J.BTs).
Table 4: Post hoc Test Showing Mean Difference for Association of Pre Knowledge Scores with Selected Sample Characteristics

</table>

Table 4 shows significant mean difference for association of knowledge with educational status. It depicts that school teacher who has the education status as Post Graduation had better knowledge than the teachers with education status as JBT (Junior Basic Training) as mean difference was significant at 0.05 level of significance.

5(B) Findings regarding association of skills scores of school teachers regarding First Aid with their selected sample characteristics using t-test and ANOVA

The ANOVA/‘t’ value of age (0.869), gender(0.461), educational status(2.648), job experience (1.683), marital status(0.72),no of children(1.037), Previous knowledge regarding First Aid management (0.326), Source of information(0.455), Have you performed first aid previously (0.185) were found to be statistically non-significant. It denotes no association with knowledge.

Discussion

The main aim of the study was to evaluate the effectiveness of First Aid Training Program in terms of Knowledge and skills of school teachers related to First Aid of selected conditions.

Effectiveness of First Aid Training Program in terms of Knowledge among school teachers related to First aid of selected conditions.

In the present study the mean post-test knowledge score of school teachers (23.911+1.923) was higher than the mean pretest knowledge score(11.15+ 2.5378). The computed “t” value (37.054) was found to be significant at 0.05 level of significance. Hence, the null hypothesis ($H_0$) was rejected and research hypothesis ($H_1$) was accepted. This indicates improvement in knowledge after the administration of First Aid Training Program on first aid management of common conditions. These findings were consistent with a study conducted by Sumithram 2017 where mean post-test knowledge score of school teachers (25.3+3.15) was higher than the mean pretest knowledge score(18.9+ 2.99).

Effectiveness of First Aid Training Program in terms of Skills among school teachers related to First aid management of selected conditions.

In the present study, there was a significant difference in the mean skill score. The post-test skill score (49.59+4.632) was higher than the mean pre-test skill score (4.21+2.191). The computed “t” value (84.48) was found to be statistically significant at 0.05
level of significance. Hence, the null hypothesis ($H_{02}$) was rejected and research hypothesis ($H_2$) was accepted. Thus, it can be inferred that the First Aid Training Program was effective in improving the skills of school teachers related to First Aid of selected conditions. These findings were consistent with a study conducted by Shobha Masih2017 where there was a significant difference in the mean post-test skills score (18.52±2.63) was higher than the mean pre-test skill score (14.52±2.39).

**Conclusion**

The first aid training program was effective in enhancing knowledge (pretest score=11.15±2.5378 and post test score=23.911±1.923) and skills (pre-test 4.21±2.191 and post-test 49.59±4.632) of school teachers on common conditions of first aid. There was no relationship between knowledge and skill scores of schoolteachers on common conditions of first aid. There was no significant association of First Aid Training Program with pre-test knowledge and Skills scores.

**Conflict of Interest:** NIL

**Funding Sources:** NIL

**Ethical approval:** The ethical clearance was obtained from university research ethics committee of Maharishi Markandeshwar (Deemed to be University), Mullana, Ambala (MMU/IEC/1305) and the study was carried out in accordance with the guidelines laid by Indian Council of Medical Research ICMR. The permission was taken to conduct the study from the principals of the selected institutes. The written consent from the students was collected prior to the study. The purpose for carrying out research project was explained and assurance of confidentiality was given to the participants.

Oral Hygiene as a Risk Factor in Periodontitis

Abdul Majeed Wadi

Professor, B.D.S M.Sc. Periodontology / AL Rasheed Collage - Dentistry Department - Iraq - Baghdad

Abstract

Dental plaque is the etiological factor for initiation of periodontal disease due to secretion of toxins and proteolytic enzymes by the microbial accumulation in the cervical region of teeth & sub gingival area.

Gingival inflammation will progress into the continuing destruction of supporting tissues like resorption of alveolar bone Joss of attachment increase pocket depth if we don’t remove the microbial dental plaque, by daily oral hygiene practice through mechanical tooth brushing of the person himself & periodic clinical examination to remove the plaque, calculus & other retentive factors to maintain the oral hygiene in a good manner.

The oral hygiene is considered as a risk factor in the prevention or progression of periodontal disease depending on daily removing of dental plaque by the person & professional recalling system clinically.

Key Words: Gingival inflammation, Dental plaque, patient, Iraq

Introduction

The aim of personal oral hygiene combined with professional cleaning by clinical parameters is to remove the dental microbial plaque. (1,2) The oral hygiene done by the subject include the mechanical tooth brushing, dental flossing, Interdental brushing & chlorhexidine mouth wash 0.2% combined with deep scaling, subgingival duration of bacterial groups, including the roots of infected teeth & polishing which done by the dentist clinically through periodic table once in month of at least. (3,4,5,6)

By these previous two steps we can maintain the oral hygiene in a good manner & prevention of the disease with treatment of periodontal lesion which include treatment of gingivitis, new attachment Level gain, decrease pocket depth, decease tooth mobility & formation of new bone support of teeth. (8,9,10)

Even the periodontitis done by surgical interference, there should be a post-surgical maintain of oral hygiene by the patient combine with clinical recalling system by the operator to maintain The oral hygiene by motivation & give instruction to the patient about the oral hygiene by himself & periodic visit to the clinic scaling in order to remove the accumulation of dental plaque continuously. (11)

This issue bears some limitations. In addition, previous studies have reported inconsistent findings in this regard. With this background in mind, the present study aimed to compare infertility-related stress among the infertile couples and its relationship with infertility factors.

Materials and Methods

1- Selection of 20 patients complaining from periodontitis.

2- Divided in 2 groups: test group & control group.

3- on base line. we record the following clinical parameters of the 2 groups.

a- Collection of dental plaque sample sub gingivally to identify the presence of microorganisms by an immunological assay method which as follow:

This method uses for detection of sub-gingival pathogens (antigen) using antibodies specific to that bacterial antigens. collection of plaque samples of sterile paper points (diluted) fixed to slide
(stained by incubation with antibodies)

this technique demonstrated that the presence of specific pathogens corresponded with increasing pocket depth.

this test is passed on antigen-antibody binding in the subgingival dental plaque.

(b) At base line: -

1- Report the personal and hygiene practice.

2- Measurement of clinical periodontal examination by periodontal probe for each subject that include: plaque index, probing pocket depth, attachment level.

(c) data collection is obtained for each subject clinically for the presence of microorganism subgingivally & the oral hygiene practice (at baseline) & then compare it with the results at the end of this study in the healing of periodontitis after following of good oral hygiene measurement of self-perform plaque control practice & by clinical recall system including the (control group) only.

But the (test group) which are not include this system of oral hygiene (personal & clinical) but they follow only the person method of hygiene without clinical follow up system and compare them with a control group.

Results

All subjects at baseline are subjected to plaque index (40%), measurement pocket depth (5mm), and the attachment level (1.34mm)

In test group: -

1- Plaque index: after 6 months was 35% Plaque index; after (1) year of the trial was 30%.

2- Pocket depth: at the beginning of the trial was 5mm Pocket depth at the end of the trial was 3.6mm.

3- The attachment level at first was 1.34mm

The attachment level at the end of trial was 1.12mm

In control group: -1-plaque index:
1st month 40%
2nd month 30%
3rd month 22%
4th month 18%

Continue to reduce the percentage until it reaches 5% at
the end of the trail

2- pocket depth: -
1st month 4.8 mm
2nd month 4.2 mm
3rd month 3.6 mm
4th month 3.1 mm

Continue to reduce the depth of the pocket until it
reaches 2 mm at the end of the study.

3-the attachment level lose: -
1st month: 1.34 mm
2nd month: 1.26 mm
3rd month: 1.12 mm

It continues to reduce the level of losing the attachment
until it reaches 0.8 mm at the end of the study.

Discussion

Despite that, there is a putative pathogen in the
area of shallow subgingival pocket, but the recalling
regular personal clinical oral hygiene status has a value
in reducing the problem of progression of periodontitis.
(12,14) This is a duo to continue removing the bacterial
level of pocket depth. plaque index, attachment level
at baseline & at the end of this study. (13) The risk of
oral hygiene will be reduced by following the periodic
program of removing the accumulation of dental plaque
& examine the self-perform oral hygiene & clinical
checking of the plaque remnants. (15,16)

Conclusion

Regular personal self-perform & clinical
professional dental care are of essential factors to
reduce the problem of periodontitis. This is done
by the regular periodic program for continuing to
remove of bacterial accumulation of dental plaque in
the shallow subgingival pocket depth by healing the
attachment level & reducing the plaque index with the
healing of periodontal problems.

Incidence of Hydatidosis in Slaughtered Animals and their Relation to Public Health at Baghdad Province

Abdulkareem Thamer Mohammed
Research Scholar, Dijlah University Collag

Abstract

Hydatid cysts disease is an important public health problem and economic losses especially at developing countries such, Iraq. A study of incidence of hydatidosis in sheep and cattle, which are slaughtered food animals, was carried out at different areas of Baghdad province outside the government abattoirs, during a period of 18 months from November 2016 to May 2018. Both slaughtered livestock animals (sheep and cattle) which are local breed of both sexes, they are of difference areas in boundary at Baghdad city, and with ages having non descriptive features. Hand palpation and visual inspection were followed in this study. A total, 2594 carcasses were examined comprising 1632 sheep and 962 cattle, from these 33, 11 (sheep and cattle) respectively were found to harbour the cysts, recording percentages of (2.0%, 1.1%) respectively. The predominant location cysts at the liver (48.4%, 45.4%) in sheep and cattle respectively, next by the lungs, in sheep and cattle (39.3%, 36.3%) respectively. Next to the mixed organs (liver + lung), the incidence was (18.1%) in cattle and (9.0%) in sheep. The percentage of cysts in heart of sheep was (3.0%) but in cattle it was (0%) Zero. The results revealed that fertile cysts only, were present in sheep with (87.8%) fertility. Cysts in the organs ranged(1-13,2-7) in sheep and cattle respectively. It can be observed that, sheep play a major role for distributions the disease. Suggestive control measures and public health hazard were mentioned.

Keywords: Hydatidosis; Incidence; Cyst; Abattiors; Fertility; Carcasses

Introduction

Hydatid cysts disease or Hydatidosis is one of the silent helminthic zoonotic infection. The larval stage of cestode belonging to the genus *Echinococcus* (family teaniidae) was the main reason of the disease, which considers major public health problem (1).

Cystic hydatidiosis is of worldwide distribution in the Mediterranean region, including countries of the Middle East (2). The infected stage (Hydatid cyst) is the larval stage of the canine tapeworm found in the internal organs of infected herbivores (3,4). Adult worms produce eggs which is passed with the dogs fecaes (7,8). If eaten by herbivores or humans, the eggs hatch releasing larvae (oncosphere) that invade through, the intestinal wall and evolve to hydatid cysts (9,10).

The four types of medical *E*. and public health importance are; *E. granulosus* (which causes cystic echinococcosis), *E. multilocularis* (which, causes, alveolar echinococcosis), *E. vogeli* and *E. oligarthrus* (cause polycystic echinococcosis) (11,12).

Parasite is common in countries where dogs are close contact with humans, and where favourable conditions of life cycle of the parasite are available, as presence of wide variety of hosts, the lack of proper slaughter facilities (13). The disease infects the livestock food animals, that causes, reducing of their production and high economic losses (14). In Iraq Jarjes and Al-Bakri (15). Said that the infestation rates of food animals species range between zero and 40% as a results of previous studies of local workers in Iraq. The present study was desigen to investigate the prevalence of hydatid cysts disease among slaughtered food animals (sheep and cattle) to provide some necessary required data of public health to prevent or at least to minimize the possible hazards of disease.

Materials And Methods

In this work a survey was carried out to determine the prevalence of hydatid cysts at different areas of Baghdad province where livestock food animals were slaughtered outside the government abattoirs during a period of (18 months) from November 2016 to May 2018. Regular visits were performed weekly to the places of animals slaughtering in which butchers men selling of meat. Most the animals slaughtered come from surrounding areas of rural region. A total of 2594 carcasses, comprising 1632 sheep and 962 cattle were examined during post-mortem inspection to identify hydatid cysts using perfect examination and search of cysts were done by visual inspection, hand palpation and incition of the organs which are; liver, lung, mixed organs (liver and lung) and heart. The hydatid cysts fluid was collected from individual cyst, washed by phosphate buffer saline and checked for the presence of protoscoleces, by sending the samples to the laboratory by suitable box and do centrifugation for the cysts fluid contents at 3000 RPM for 5 minutes, then microscopically examined for the detection of protoscoleces (Latif, et al (16). The cysts were recorded according to animal species, total number of examined animals, the number of animals harbouring hydatid cysts and the cyst location in the organs.

Results

The infection rates of cysts for both species that were slaughtered in different areas of Baghdad province was shown in table (1).

A total of 2594 carcasses of slaughtered food animals were examined, comprising (1632) sheep and (962) cattle, of these numbers (33) sheep and (11) cattle were found to have the cysts, recording percentages (2%,1.1%) respectively. Table.(2) Showed the distribution of hydatid cysts in different organs; which revealed that, in sheep and cattle, liver was more commonly infected with hydatid cysts than the lungs and other organs, recording incidence of (48.4%, 45.4% respectively). In case of lung, in sheep and cattle the incidence (39.3%, 36.3%) respectively.However in mixed organs (liver and lung) the higher incidence was (18.1%) in cattle and lower in sheep (9.0%). The heart was only affected in sheep (3.0%) but in cattle it was none (0%).

The current study revealed that only sheep has fertile cysts (87.8%), while cattle, has sterile cysts these sterile cysts had calcified or caseated appearances. Table. (3) showed that the intensity of cysts was relatively high in sheep (1-13) cyst and less in cattle (2-7).And also the number and fertility percentage of cysts present in sheep and cattle.

Discussion

Hydatidosis is more important and wide spread infection in the world. livestock species are more susceptible to infection by contamination through the viable eggs of Echinococcus granulosus (18). Human risk for the cysts is by ingestion food or water contaminated with fecal material containing E.granulosus eggs passed from infected dogs (19,20). In most studies dealing with the incidence of hydatidiosis in livestock, the main source of data is obtained from abattoirs (21). In this study the data was obtained from different areas at Baghdad city or province where slaughtering animals carried out at the places outside the abattoirs, with absent of the veterinarians supervision. Cystic hydatidiosis was recorded early in Iraq by Babero et al (22).

Adult worm i.e E. granulosus was reported earlier in the 1940 in the intestine of stray dogs (23). As regards to the infection rate of hydatid cysts, the current study revealed that, the lower rates of infection in an examined slaughtered animals were relatively similar to the results of study conducted by Iraqi researchers (15) in Mosul city, (24) in Kirkuk.

The lower incidence in sheep was attributed to the nature of grazing that may be done Torgerson and Buke (25) but the lower incidence of infestation in cattle, is due to breed difference, no contact with source of infection (26). Results of infection rates of this study were lower than those studies by a number of researchers in Iraq (27-32).

And also studies that were reported in some Arabian and neighbouring countries i.e Egypt (13), Jordan (33), Kuwait (34), Yemen (35), Iran (14) and Turkey (36). The main feature of the present work, is the small sample of animals slaughtered compared with previous local studies (27-32). The variation of infection rates could be related to differences among strains of E. granulosus (21).

Regarding to infection rates of organs involvement, the commonest sites of infection are, the liver and lung Markell et al (37). Liver in sheep and cattle is the predominant location of the cysts followed by lung, mixed organs (liver+lung) and heart later. These results are relatively similar to that findings by Jarjes and AL-Bakri (15). Muqbil et al (35), in Aden, Yemen and Elmajdoub and Rahman (21), in Libya. The present study showed that, only sheep were found to harbour fertile cysts, while in cattle all the cysts were sterile.

All local studies mentioned above confirm that, fertility rate of cysts in sheep is higher than other livestock animals, so it is in agreement to the results of this study.

Variation in fertility rate among different intermediate hosts was, due to the difference in E. granulosns strains (39). Sterile cysts of cattle in current study were similer to those studies by Al-Abassy et al (28) . In Iraq , Elmajdoub and Rahman (21), in Libya. The life cycle for parasite, disseminating the disease due to high infection rates and fertility. The recommended measures which are suggested to prevent or at least to minimize hydatidosis disease are. Rehabilitation and improve Baghdad abattoirs and abattoirs of the all provinces in Iraq, prevent slaughtering livestock animals outside the government abattoirs, make control programs for Standard meat inspection under supervision of veterinarians, control of dogs by killing stray dogs, vaccination against hydatid cyst disease in
sheep is advisable.

Lip prints and bloodstains may be left behind in many crime scenes and may reveal the identity of the victim and the suspected person. This study was aimed to investigate the inheritance pattern of lip prints and blood groups among parents and their offspring in the Javanese population. 105 subjects from 25 Javanese family frames participated in this study. Lips print pattern was recorded and analyzed according to Suzuki and Tsuchihashi classification. A blood group test was also performed for each subject. The statistical analysis carried out using IBM® SPSS® Statistics version 23.0 (IBM, Armonk, New York, USA). The results of this study revealed that type II was the predominant pattern of lip prints among the Javanese population (34.3%). Blood group A was the predominant type in subjects with lip prints type II (15%). The result also shows that the lip prints pattern in girls tends to be inherited from the mother. However, the inheritance of lip prints pattern in boys couldn’t be determined precisely. The heritability of lip prints pattern was observed between parents and their offspring. Also, there was a tendency of blood groups to have a certain pattern of lip prints.

Keywords: blood group, forensic odontology, heritability, lip prints, personal identification

Introduction

Establishing the individual identity is a primary importance at the beginning of the criminal cases investigation. According to Interpol DVI Guide, 2018, teeth, DNA, and fingerprints are the primary and the most reliable means in human identification. Besides, several biological evidence such as lip prints, bloodstains, and saliva may support the process of human identification.

Many studies have been developed to explore the usefulness of lip prints pattern in personal identification based on its uniqueness and permanence. Amongst the established methods, the classification by Suzuki and Tsuchihashi is the most commonly used and simple method for lip prints analysis. Suzuki-Tsuchihashi classified the lip prints pattern as: complete straight grooves (type I), half-straight grooves (type I'), branched grooves (type II), intersected grooves (type III), reticulated grooves (type IV), and undifferentiated grooves (type V).

A study by Patel et al, 2010, in Malaysia, involved 20 sampling frames (10 families with siblings and 10 families with twins) reveals that the lip prints pattern was inherited from parents to their offspring in 2 out of 5 families with twins' children. It was also found that most subjects with type II of lip prints tend to have the blood group type A.

In the actual cases, correlating lip prints with blood groups may help the forensic team to establish the human identity accurately. The objective of this study was to investigate the inheritance pattern of lip prints and blood groups among parents and their offspring in the Javanese
The Javanese population is the largest ethnic group in Indonesia who predominantly located in the central and eastern parts of Java Island, Indonesia.

Methods

Data acquisition

This study was conducted under the approval from the Ethical Committee of Faculty of Dental Medicine Universitas Airlangga, Surabaya (number: 302/HRECC. FODM/V/2019). 105 subjects from 2 generations (parents and children) in 25 family frames who met the inclusion criteria participated in this study. The inclusion criteria of this study are:

- Javanese family consisting of father, mother, and one or more biological children.
- Without cross-marriage history in the family.
- Agreed to participate in this study

The exclusion criteria of this study are:

- Subjects with a history of aesthetic surgery on the lips.
- Subjects with hypersensitivity to lipstick.
- Subjects with congenital abnormalities appear on the lips.

All subjects were asked to complete the informed consent after a brief explanation of their participation in this study. All of the individual lip prints and blood group were analyzed.

The subject was asked to set up straight with relaxed position of their lips. The research personnel cleaned up the lip’s surfaces using a wet cotton swab and gently applied one layer of lipstick (Purbasari No. 83, PT Gloria Origita Cosmetica, Indonesia). After 2 minutes, a scotch tape (5 x 12 cm) was gently stacked on the lips surfaces and removed smoothly with a single motion from left to right (Fig. 1). The imprinted lip prints were then pasted on a white paper (Fig. 2) and analyzed using Suzuki and Tsuchihashi classification (Fig. 3). The blood groups (ABO) test was performed for each subject using antigen serum (Glory Widal Serology Test Kit, PT. Medika Farma Alkesindo, Indonesia).

![Figure 1](image.png)

Figure 1 A scotch tape (5 x 12 cm) was gently stacked on the lips surfaces and removed smoothly with a single motion from left to right.
Figure 2 Recorded lip prints pattern obtained from one family frame.

Figure 3 Lip prints classification according to Suzuki and Tsuchihashi, 1971.
Statistical analysis

The classification of lip prints pattern and the blood type were tabulated and analyzed using Spearman and Pearson test to investigate the correlation of its inheritance pattern from parents to their offspring. The Fisher Exact test was used to observe the significance of the tendency of lip print patterns towards the blood type. The statistical analysis of this study was carried out using IBM® SPSS® Statistics version 23.0 (IBM, Armonk, New York, USA).

Results

Table 1 shows the overall appearance of lip prints pattern in all subjects of this study. These results indicate that type II is the most dominant lip prints pattern among the Javanese population, with 36 appearances out of a total 105 subjects (34.3%), while type V was not visible in all subjects.

Table 2 shows that the lip prints pattern in boys’ subjects, 16.7% were inherited from their father, 38.9% from mother, and 44.4% of the inheritance pattern couldn’t be determined precisely. The Spearman correlation test showed that there was no significant correlation of the lip prints pattern between boys and their parents, \( p > 0.05 \). On the other hand, the inheritance pattern of lip prints was observed in girls’ subjects, with 38.5% were inherited from their father, 46.2% from mother, and 15.4% tends to have a different type from their parents. The Spearman correlation test shows a significant correlation of lip prints pattern between girls and their parents, \( p < 0.05 \).

Discussion

Individual identification is an essential proceeding to assist the process of recognizing the victim and the suspected person’s identity in criminal cases. Many studies have shown that lip prints are unique and remain unchanged during a lifetime. In some cases, such as sexual abuse, the lipstick and bloodstains are often found in a crime scene and become a piece of evidence that correlated with the victim or the suspected person. Untraced lipstick stain on any objects may be easily lifted by aluminum and magnetic powder [11–18].

In the present study, type II was found to be the most predominant lip prints pattern in males and females, and type V has not appeared in all subjects. The result also indicates that the lip print patterns were inherited from parents to the offspring in the Javanese population. The lip prints pattern of girls tends to be inherited from their mother; however, these inheritance patterns couldn’t be determined precisely in boys’ subjects. These results are in agreement with the previous study conducted by George et al in 31 families of the Malaysian population [18,19]. Another study by Arisetiawan (2014) showed that the lip prints pattern of girls tends to be inherited from their father, and boys from their mother [20].

The statistical analysis shows that there was no significant correlation between the lip prints pattern and
blood group type. These results correspond with the previous studies in India with the Ancestral North Indian population sample by Karim and Gupta (2013), which stated that there was no significant correlation between lip print patterns and blood type ⁴.

Many aspects, such as the duplication technique and observer subjectivity, were considered as the influence factor in the study of lip prints pattern. There are several techniques of making a lips impression, such as conventional technique and photographic assistance ²¹. This study used a simple conventional technique which has some limitation related to the problem during the lipstick application, hand pressure, and the variety of lipstick products.

**Conclusion**

There is a resemblance of the lip print patterns between parents and their offspring. The lip prints pattern of girl subjects tends to be inherited from the mother, while for boys, the inheritance pattern couldn’t be determined precisely. There is no significant correlation between the lip prints pattern and blood group type. Further studies with larger samples number are suggested to obtain more accurate results.

Abstract

Background: Age estimation are often calculated using bone and teeth samples, but are limited to human skeleton findings. The aim of this research is to estimate human age through DNA methylation method from bite mark samples. Result: There were 40 bite mark samples obtained from healthy volunteers. DNA samples were isolated using DNAzol reagent and converted using DNA methylation kit. The isolated DNA were amplified and electrophoresis was conducted using agarose gel. Electrophoresis result was used as length reference for the sequenced band and analyzed for methylation percentage and correlation with age estimation. Statistical test showed that there was a significant correlation between DNA methylation percentage with age estimation both in men (r Pearson 0.767) and women (r Pearson 0.878). Conclusion: CpGplot emboss analysis for DNA methylation mean percentage in men tend to increase in accordance to age categories, whereas for women, the mean DNA methylation percentage in age categories was stable or constant.

Keywords: Age estimation, DNA methylation, Bite mark

Background

Forensic identification helps investigators determining a person’s identity. Personal identification is often a challenge in both criminal and civil cases. Determining personal identity appropriately is very important in investigations because errors might bring fatal consequences in judicial process.1

Corresponding author:
Assoc. Prof. Dr. Ahmad Yudianto, dr., Sp.F(K)., M. Kes., SH Department of Forensic and Medicolegal, Faculty of Medicine, Airlangga University, Surabaya - Indonesia . Jalan Prof. Dr. Moestopo No. 47, Surabaya 60132, Indonesia.

Forensic medicine plays a crucial role in identification, especially for unidentified corpses, damaged corpses, decomposed corpses, burnt corpses and corpses that were involved in mass accidents, natural disasters, riots that resulted in many deaths, as identification for pieces of human corpses or skeletons or others. Forensic identification also plays a role in various other cases such as kidnapping of children, swapped babies, or babies with questionable parents. A person identity can be confirmed if at least two methods give positive results (no doubt).2

In certain cases, for example sexual assault, bite marks are often found. The presence of physical evidence such as bite marks in rape, murder and violence cases is crucial. Bite marks are the most common evidence in rape cases. This evidence also plays a role to determine the physical violence type and the offender’s age.3,4
Suspect identification process using bite marks as evidence is generally carried out by comparing photo interpretation with teeth model of the suspected offender, including analysis and measurement of size, shape and position of each tooth. However, this technique does not always bring accurate results, therefore another way to identify bite marks is conducted through irrigation technique on bite marks to conduct DNA identification. DNA samples from bite marks could be taken from saliva, attached stains, mucosal epithelial remains in saliva, and others.

Age estimation using biomolecular approach can be carried out based on analysis of cell, mitochondrial DNA (mtDNA) sequences’ changes and epigenetic changes, which do not affect DNA. Oral cavity as well as teeth tissues have various cells that could be used as genetic material source. Several methods that might be used to determine chronological age from teeth samples include aspartic acid racemization (AAR), mitochondrial DNA mutations, telomere shortening, advanced glycation end-products (AGEs), and DNA methylation. DNA methylation is a modification process of 5 ’carbon atoms in cytosine residue followed by guanine residue, therefore it is called as CpG(s)/CpGsites dinucleotides. Replication process in DNA methylation is only found at 5 pyrimidine rings position from cytosine in CpG dinucleotide sequence. DNA methylation is the best epigenetic modification method for estimating age from human biological samples. The purpose of this study was to determine age estimation through DNA methylation analysis from bite mark samples.

**Methods**

**Methods and samples**

This study was an analytic cross-sectional design observational study. The samples in this study were bite marks on glasses used by 40 volunteers who have assigned their informed consent, consisting 20 men and 20 women ranging ages from 5 to 65 years. This study has received ethical eligibility from Faculty of Dentistry which number: 350 / HRECC.FODM / VII / 2020.

**Sample preparation**

A total of 30 bite mark samples were stored in conical tubes/dinking glasses (figure.1) and were labeled with 1-40 (sample number’s order)-XY/XX (sex)-category (according to WHO). Human age categories according to WHO (Depker RI, 2009) is divided into four groups: children (5 - 11 years), adolescents (12-25 years), adults (26-45 years) and elderly (46-65 years).

</table>
Isolation / extraction was carried out using DNAzol reagent. Samples in pellet form inside conical tubes were added 1 ml of DNAzol reagent, both were mixed by vortex, then incubated for 5 minutes at room temperature. Afterwards, 10,000 rpm centrifuge was carried out for 10 minutes at 40°C, the viscous supernatant was taken and transferred into a new tube. The new tube is added 0.5 ml of 100% ethanol (absolute), mixed, and incubated at room temperature for 1-3 minutes, and then centrifuged at 4000 rpm speed for 1-2 minutes at 4°C. Supernatant was removed carefully to prevent accidental removal of DNA (pellets). The pellets were washed with 0.8-1 ml of 75% ethanol 2 times and each time the tube was washed back and forth for 3-6 times. The tube was placed in an upright position for 0.5 - 1 minute, then 75% ethanol was removed by pipetting or decanting. The pellets were dried by leaving the tube open for 5–15 seconds. The pellets containing DNA were dissolved with 25-30 ul of distilled water, and then were vortexed adequately, and then stored at -20°C. Furthermore, DNA level and purity measurement were carried out using a UV Spectrophotometer, the results were mean DNA level and purity, as in table 1 and figure 2.

**Bisulfite conversion (MethylEdge™ Bisulfite)**

Fifty microliter of DNA samples in eppendorf tube were added with 130 µl of CT Conversion Reagent. This mixture was then centrifuged at 5000xg speed for 1 minute. PCR tube was placed in PCR machine with the following setting: 980°C for 8 minutes, 640°C for 3.5 hours, and kept in a storage at 40°C for up to 20 hours. Furthermore, 600 µl of M-Binding Buffer was poured into Spin IC column with samples from PCR results. The column was closed and stirred by turning the column several times. Afterwards, it was centrifuged at 10000xg speed for 30 seconds, then the supernatant was removed. The resulting pellets were washed with 100µl M of wash buffer into the column, and then centrifuged at 10,000xg speed for 30 seconds. The supernatant was removed, and the pellets were added with 200µl M of Desulphonation Buffer, and then incubated at 200°C for 20 minutes. Centrifuged was carried out again at 10,000xg speed for 30 seconds. Pellets were then washed twice with 200µl M of Wash Buffer and then centrifuged at 10000xg speed for 30 seconds. Finally, 10µl M of Elution Buffer was added and centrifuge was carried out at 10000xg speed for 30 seconds.

**PCR amplification**

PCR amplification was carried out using T7 promoter tag primer and 10 mer tags and HotStarTag Plus Master mix kit. The setting was as followed: temperature of 950°C for 5 minutes in 30 cycles (denaturation: temperature of 940°C for 1 minute, annealing: temperature of 650 C for 1 minute, extension: temperature of 720C for 1 minute), temperature of 720C for 10 minutes. PCR result using 1% agarose gel electrophoresis showed bands between 150pb-300pb (figure.3).

The sequencing process required 30 µl of PCR sample to identify CpG sites as methylation age marker. The primer used was T7 with 5-CAGTAATACGACTCACTATAGGGAGAAGGCT-3’ order. The results of sequencing with Applied Biosystems 3130 XL Genetic Analyzers were read with bioedit®. In FASTA form, CpG sites percentage was calculated using an online application, Emboss Cpgplot (http://www.ebi.ac.uk/Tools/seqstats/emboss_cpgplot/) (Table.2)(figure.4).

Table 2. Percentage of DNA methylation in bite marks samples at a length of 300 bp
Results

Figure 2. Graph of average DNA concentration in bite marks sample

Figure 2 above shows that average DNA concentration sample from bite marks was 55.78 ng/µl, while DNA purity ranged from 1.02 to 1.65. Electrophoretic DNA visualization with 1% agarose gel revealed DNA bands ranging from 150bp to 300bp.

Figure 3. PCR visualization of bisulfite converted DNA bite marks samples

Figure 3 above shows the results of agarose gel electrophoresis from bite marks samples through DNAzol isolation. Afterwards, isolated DNA were conducted bisulfite conversion using DNA methylation kit from MethyIEdge TM Bisulfite promega. Isolated DNA samples were then analyzed in PCR machine using reagents from HotStarTaq Plus Master Mix with T7 promoter tag primers and 10 mer tags. All samples have bands / bands in 300bp core sequence.

All visualized samples were in 300bp core sequence, therefore sequencing was carried out in 300bp core sequence using Applied Biosystems 3130 XL.
Genetic Analyzers that was read with bioedit® and analyzed on CpG sites using Emboss Cpgplot application. DNA methylation percentage from bite marks samples are presented in table below.

**Figure 4. Graph of average percentage of DNA methylation based on age criteria**

Figure 4 shows average DNA methylation percentage in men tends to increase in accordance to age categories, whereas for women the DNA methylation percentage is stable or constant. This is most likely to be influenced by lifestyle, environmental, and previous disease factors.

**Discussion**

In genome, methylation occurs in a CpG-rich region named CpG island. Protein and methyl-CpG bonding domains will bind specifically to CpG island, inducing repression and transcriptional activation.

As humans get older, DNA methylation pattern gradually shows DNA hypomethylation and hypermethylation on a specific CpG island-associated promoter. Correlation between DNA methylation and aging can be described in two parts, which are epigenetic drift and epigenetic clock. Epigenetic drift shows a variety of changes in individuals that are associated with age due to environmental factors, on the other hand, epigenetic clock is only markedly related to age, therefore it might be used to predict an individual chronological age.

Between male and female, CpG site has different DNA methylation rates. CpG site is located at X chromosome, therefore differences in sex-specific methylation at X chromosome tend to be more unstable. Women susceptibility to stress and certain diseases also greatly influences DNA methylation rate, thereby factors that influence DNA methylation are widely variable between individuals. Degenerative diseases and metabolic syndrome of each individual also greatly affect DNA methylation percentage. The course of degenerative disease targets cellular epigenetic machine elements, altering epigenetic machines expression and activity therefore inducing epigenetic changes in each individual.

DNA methylation process might turn into a dynamic process, where individual hormonal state greatly affects cytosine hydroxymethylation role. The use of certain oxidative and antioxidant drugs will also affect histone modification rate. This might occur, for example, via cytosine mutations in case of methylation on normal cells. Methylated cytosine absence might lead to permissive histone modification and allow genes to be expressed. Unlike genetic mutations, epimutation does not alter DNA basic sequence and is potentially reversible. Certain diseases such as neoplastic, degenerative, metabolic, and inflammatory might cause oxidative stress that affects gene activation, such as...
epigenetic-DNA methylation.15

**Conclusion**

Mean DNA level from bite marks was 55.78ng/µL. There was a significant correlation between DNA methylation percentage (CpG sites) from bite mark samples with human age estimation both in men and women.

Abstract

This study aim to evaluate and compare the deflection of premolar teeth cusps that filled incrementally with conventional composite (Universal Ceram X One Sphere TEC TM) and various types of bulk fill composite materials (Kerr SonicFill™3 , 3M Filtek™ Bulk Fill and Shofu Beautifil Bulk Fill). In this study 40 human, healthy maxillary first premolars were collected and large MOD cavity were prepared in them. According to restorative materials, the teeth were haphazardly categorized in 4 groups (n=10 per group). Group I : The teeth were filled with SonicFill™3 Kerr composite, Group II : The teeth were filled with Filtek Bulk Fill, Group III : The teeth filled with Shofu Beautifil Bulk Fill composite, and Group IV : The Teeth were filled with Dentsply Ceram X One Sphere TEC TM. By the aid of digital microscope intercuspal distance on the tips of the cusps between two index reference points was measured pre preparation of the cavity post preparation, after 15 minutes of completion of fillings. The cuspal deflection was calculated by determination of the changes in measurements. Inward cuspal deflection was occurred in all teeth after filling, minimal cuspal deflection reported in all study groups that filled with bulk fill filling in comparison with group IV that filled in layering technique with conventional composite. Greater cuspal deflection produced by Beautifil Bulk Fill restorative in comparison with other groups. As a conclusion of this study that using of new bulk filling restorative materials could dramatically minimize cuspal deflection.

Keywords: Deflection in the cusp, Ceram X One Sphere TEC ™, SonicFill™3

Introduction

The demands for tooth color restore are increased nowadays so Commonly composite filling materials is used for direct restoration for posterior teeth (1). However, the polymerization shrinkage when using direct composite resins is considered a major drawback which is prompted by curing of the composite resin matrix (1).

Two clinical problems (cuspal deflection and microleakage) are associated with the polymerization shrinkage stress. Bonding strength results from the polymerization shrinkage stress is higher than the bonding strength of the adhesive material, which may lead to marginal Gap creation and failure of the composite-tooth interface. Thus Can lead to sensitivity after restoration and development of secondary caries, while when adhesion bonding strength is sufficient to withstand the stress of polymerization; cuspal deflection occurs and can cause tooth fracture, cracks in the enamel, this described by the patient clinically as pain and sensitivity postoperatively (2).

Two major biomechanical factors are influencing the type and the amount of deflection of the cusp, the previous geometrical factors (involve cavity wall thickness post preparation and dimension of the cavity) and the properties of the material (polymerization shrinkage, elastic modulus, the flow of the material...
and hygroscopic expansion), this representing the first factors group; whereas the second factors group is clinical one; including the techniques of restoration placement, indirect or direct technique of restoration, low modulus of elasticity liners as layers to absorb stress, and the system of light curing and the protocol of usage (3,4).

In large cavities, the golden standard technique for resin composite placement is Incremental layering technique since it is capable of minimizing the effects of stress related to shrinkage and enable an acceptable conversion level (5).

The introduction of new kinds of restoration materials (Bulk fill composites restoration) which minimize the needed Placement time. The layer thickness could be 4-5mm of these materials with adequate polymerization and low polymerization shrinkage stress (6). Indeed, the data which is available about these restoration materials influence of on cuspal deflection is little. The aim of this study was to evaluate the deflection of the cusp by restoration of maxillary first premolars with advanced new kinds of bulk fill restoration materials and make a comparison between their results with incremental layering technique by using conventional composite material.

Materials and Methods

In this study forty non carious, healthy human max. first premolar teeth were gathered. The aim of teeth extraction was for orthodontic cause, they stored instantly in special container with distilled water. Any calculus deposits were carefully removed from the teeth with air sonic scaler, washed and polished by using pumice. Cracks examination was done for all selected teeth through visual examination with the aid of magnifying lens and using transillumination from light cure unit. The roots of each tooth have been mounted by the use of dental surveyor vertically into custom made silicon mold. 3M single bond universal used to bond two heads of pins as a reference points into indentation prepared by small round bur on the Buccal and palatal cusps tips of each tooth. After that high speed hand piece with water coolant used to prepare each tooth to large MOD cavity by the use of flat ended fissure bur. To confirm standardization of cavity a modified dental surveyor was used to control the motion of hand piece in all preparation, to ensure high quality of cutting burs were discarded every five preparations. The preparation of each cavity was 3 mm depth and 3 mm width at gingival seats of the boxes and at the pulpal floor. The cavo surface cavity margins were created at 90° with cavity rounded internal line angle.

Three M universal single bond was used in etch and rinse technique in each prepared tooth. Next, according to kind of restoration, the teeth divided into 4 groups; Group I: The teeth were filled with Kerr SonicFill™ composite. Group II: The teeth were filled with 3M Filtek Bulk Fill composite in the same manner of Group I. Group III: Teeth were filled with Beautifil Bulk Fill in one bulk increment same to Groups I and II. Group IV: the teeth were filled in multiple increments of with Universal Ceram X One Sphere TEC™ in 2 mm of each layer thickness. Following the manufacturing instructions, The curing time of each increment was twenty seconds. The measurement the intercuspal distance of each sample was done with the aid of Dino lite digital microscope.

Intercuspal distance was calculated at three different times: for intact tooth, after finishing the preparation of each tooth, and the last record was done in 15 minutes after tooth restoration. Cuspal deflection after the preparation of cavities (CD1) was determined by intercuspal distance subtraction after the cavity preparation from the intercuspal distance for unchanged teeth. Initial distance was recorded from the intercuspal distance post preparation, whereas the final distance was recorded from inter cuspal distance after 15 minutes (7). After that, subtraction of final distance from initial distance was done to measure the cuspal deflection that happened as a consequence of polymerization shrinkage stress (CD2).

Results

Inward cuspal deflection (CD1) and (CD2) measured in (mm) micrometer units (descriptive statistics) are shown in the table no. 1.
Table 1. Inward cuspal deflection (CD1) and (CD2) measured in mm (descriptive statistics)

All groups post cavity preparation showed no significant differences in CD1 using one way ANOVA with P value > 0.01). Although, after 15 minutes of complete the filling, Significant difference was reported among all study groups (P = 0.000).

**Discussion**

The common problem of composite restoration is cuspal deflection due to the resin-based composite stress on the surface of the tooth, which could serve as a preload encouraging tensile fractions of the tooth and could be the key cause of failure during the curing of the composite (8,9).

The deflection of the cusp was assessed by using of extracted teeth since the problem of supporting structures and the testing system compliance have been eliminated (10). In this study, Maxillary first premolar teeth were used because they are evenly sized and shaped (11).

Then, large MOD cavity was prepared to get high C factor ,the remaining tooth structure weaken, and cause 63% of the cusp strength loss ; As a result, possibility of the deflection of cusp is increased (12,13) . When comparing MO or DO against MOD fillings ,the shrinkage strength of the composite polymerization can cause lower negative deflection in cusps because minimum amounts of restorative material are required (14–17).

The cuspal deflection was estimated after 15 minutes of finishing restoration by measuring the distance between both reference points which was longer and slower than other composites in the polymerization shrinkage, through this time the largest degree of inward displacement was happened as reported by many previous studies (18–20).

This is due to the remaining free radicals. There have continued to react double bonds in composite restoration. Therefore, after complete polymerization, For several minutes the deformation continued (21,22).

These finding was consistent with other studies that conclude that after polymerization, an inner cuspal deflection occurred because of polymerization shrinking stress development (7,23–26).

The results of this study is defection in the cusps deflection when compared with conventional type (6,25–30). The addition of stress relievers to the bulk fill composite alter the dynamics of shrinking, decreasing resin matrix with Increased loading of the filler, and thus minimize polymerization shrinkage stress and decrease in cuspal deflection (26,28,30).

On the other hand, this disagree with other studies, which has shown that there is no difference between bulk resin composites and conventional composites in shrinkage stress composites and cuspal deflection (31).

After restoration, minimal mean value of cuspal deflection had been reported in teeth filled with Filtek™ Bulk Fill (group II), removal of TEGDMA monomer from its resin compartment might be the cause for that.
In this study, there is no statistical significant difference between teeth filled with SonicFill™3 (group I) and teeth filled with Filtek™ Bulk Fill (group II). Filtek™ Bulk Fill and SonicFill™3 composites in order to minimize shrinkage stress because their manufacturers have revolutionized their manufacturing mechanism and their monomers composition respectively. In this study, greater cuspal deflection reported in teeth filled by Beautifil Bulk Fill (group III) than other groups of bulk fill kinds used, because of the presence of high molecular weight polymerization modulators which minimize polymerization shrinkage in the remaining groups of bulk fill composite material that had been used in this study.

Conclusion

Bulk fill resins-based material resulted in lesser cuspal deflection in comparison with conventional incremental composite. In Bulk fill composite material the cuspal deflection magnitude is related and affected by the kind of composite restoration materials.

Abstract

The study was conducted as a quasi-experimental design in Khartoum North teaching hospital to assess the role of health education in the promotion of health care waste management. A sample size of (103) targeted workers (cleaners) were used in the investigation. Data collected was analyzed using the T-test and chi-square test by computer using SPSS. The results revealed remarkable improvement in the knowledge of the respondents, as regards the hazards of the health care waste (53%-100%) before the intervention, after the intervention, it increased to 100% showing highly significant change. The opinion of the respondents to use the protective clothes ranging from (45% - 100%) before the intervention, rose after the intervention to (70.5% – 100%) showing significant change. The practice of workers about touching contaminated cotton and linen with patient body fluids was 16.7% before the intervention, after the intervention only 7.4% touch the waste showing significant change.

Keywords—Health Education, Health Care Waste Management, Health workers, Health Promotion.

Introduction

Health care waste includes all the waste generated by health care facilities, research facilities and laboratories. It includes the waste originating from minor or scattered sources such as that produced in the course of health care under taken in the home (dialysis, insulin injection etc.) (¹). Hazardous health care waste is classified to: Sharps, non-sharps blood, body parts, chemicals, pharmaceuticals, medicals, devices and radioactive materials (²). WHO stated that, between 75% to 90% of health care waste produced by health-care providers is non-risk or “general” health-care waste, it is comparable for domestic wastes. The remaining 10-25% of health care waste is regarded as hazardous, may be infectious, toxic, or radioactive (³). Health care waste is a reservoir of potential harmful major organisms which can infect hospital patients, visitors, health-care workers and the general public particularly the rage pickers (⁴).

Integrated waste management systems for health care waste are not introduced in most developing countries resulting in mixing of hazardous and nonhazardous waste (¹). Poor management of health care waste causes serious diseases in health care personnel, waste workers, patients and the general public. The main sources of illness from infectious waste is probably due to needle stick injuries, which can cause hepatitis B and C and an estimated 250000 cases of HIV. There are, however numerous other diseases that could be transmitted by contact with infectious health care waste (⁵). WHO stated that the main reasons for failure of waste management are absence of effective waste management, lack of awareness about the health hazards, insufficient financial and human resources, poor control of waste disposal, and many countries do not have appropriate regulation or do
not enforce them (4). These are to some extent the same reasons for the failure of health care waste management in Sudan which it is still treated as municipal waste concerning collection, storage, transportation, treatment and disposal (6).

In many health facilities the health care waste is handled in the same manner as domestic refuse and collected in black bags and this is unsafe and mishandling, collection, storage movement transportation and disposal practices e.g. the waste collected in open container and full until the waste scattered in the ground. Central Storage areas in many health care facilities may provide breeding sites for vectors for many diseases and provision of the food for cats (7). Comprehensive risk assessment of all activities involved in health care waste management carried out aiming to promote health care waste management, will allow the identification of necessary protection measures, these measures should be designed to prevent exposure within safe limit. Once the assessment is completed health staff should receive suitable training and increasing the awareness is indispensable in this program which could be achieved via information dissemination thus health promotion expected to play leading role in the protection of health staff.

The preset study aimed that to raise the awareness of workers to words health care waste management and potential risks associated with health care waste. To assess the knowledge, attitude and practice of the cleaners about health care waste management. To encourage the usage of protective measures to protect the workers from the hazards of health care waste.

Materials and Methods

Study Area: Khartoum North Teaching hospital was founded 1965 in area of 65000 (Km)^2, and consists of 15 department.

Study design: Quos experimental [interventional. hospital based study

Study population: Cleaners (325) in Khartoum North Teaching Hospital

Sample size: The sample size was determined from Khartoum north teaching hospital cleaners by the formula: N= z^2 p q d^2 / d^2 Sample size = (103 worker)

Sample selection: The individual of the study population in the hospital were selected using the systematic random sample from the total.

Phases of the stud:

Phase One: (Data collection)

Preliminary survey was conducted in order to assess the knowledge, attitude and practice of the cleaners using these methods.

Questionnaire: The questionnaire contains the following variables wastes segregation, packaging, safe handling, storage, color coding and collection of the medical waste. A questionnaire was prepared to assess the knowledge, attitudes and practice of the cleaners towards the health care waste. needle stick –injury, hepatitis infection, immunization, protective cloth, regular examination and the knowledge of the hazards of health care waste.
