6 were reported that cupping play an important role in excretion of old RBCs and replaced by new red blood cells when red blood cells increases, also decrease in hematocrit and blood viscosity makes the blood less thicker, and increase flow of the blood. 16 showed WBCs count decline less than this decrease statistically highly significant. In addition, there was an increase in WBCs count after 2 weeks. Lipid profile values were detected in blood samples from volunteers before and after one week and two weeks of hijima which include total cholesterol ,LDL-ch,HDL-ch ,Triglyceride and VLDL-ch. 10 showed reduction of LDL and cholesterol beside increase HDL and no change of triglyceride in all of subjects were treated with cupping in one time. 12 were reported that the Patients with hyperlipidemic who subjected to cupping showed a significant decrease in total cholesterol, LDL cholesterol, triglyceride and LDL/ HDL ratio in weeks 1 and 2 respectively by comparison before cupping. While there were significant changes and increase in serum HDL cholesterol in weeks 1 and 2 after Cupping. These results agreed with 6 for the biochemical parameters, significantly lower ALP levels in the cupping blood when compared to the venous blood,.where ALP has an important role in the metabolism by permitting the cells to uptake the inorganic form of phosphate . 20 were reported that serum ALP levels significantly decreased after the cupping therapy in humans. AST and ALT levels were observed to be non- significantly increased after 3 days after cupping, this increase was followed by decrease in its levels after 2, 4, and 8 weeks of cupping. However, AST can normally be detected in many different tissues such as the muscles, liver, kidney, brain, and heart, and its levels are increased if any damage occurs to one of these tissues; therefore, it is not considered as a specific indicator for mammalian liver profiles . 18 found a significant decrease in serum creatinine and potassium level after hijama and significant improvement in chloride concentration towards normal, hence all these changes indicates that there have been improvement in renal function in patients after making Al-hijama. Random blood glucose was decreased significantly, which might be one of the reasons for decrease in fatigue and increase metabolism and improvement in appetite 17. The cupping therapy can increase the sensitivity of insulin which decreases its levels in the blood of diabetic patients; however, the adverse effects can be attributed to the health status of the animals and some species variations (17,19). Blood samples that obtained after hijama showed significant rise in serum Calcium ions (Ca+2) after one and two weeks of making Al-hijama as compared to the serum calcium level before making of Al-hijama.

**Conclusion**

Repeated cupping (hijima) therapy was useful in improve complete blood picture (CBC), improved serum lipid such as the total cholesterol, LDL and Triglyceride levels,also improve HDL-ch which observed significant increase after two weeks of hijima. Al-hijima observed significant effect on some biochemical parameters, improvement in levels of total proteins and increase activity of liver function enzymes (AST and ALT) and significant rise in serum Ca+2 with decline in Na+2 , Cl- and K+ after one and two weeks of Al-hijama, for this results that observed in this study the cupping may be consider safe technique, might be associated with decreased risk of cardiovascular disease, obesity and enhanced and improved kidney function test . So we recommend to ministry of health to encourage the practice of prophetic medicine including (Alhijama) in hospitals officially in a pure medical atmosphere to close the way in face of unqualified mal practitioners.

Knowledge and Attitudes of Women Toward Breast Self-Examination in Hilla City: Application Health Belief Model

Rehab. F. H1, Salma. K J2
1Msc. Student, in maternal and child Health Nursing/ College of Nursing, Babylon University, Babylon Province- Iraq, 2prof, Community Nursing/ College of Nursing, Babylon University, Babylon Province- Iraq

Abstract

Background: Breast cancer in all parts of the world begins to be seen at about 20 years of age. Afterward, age specific incidence steadily rises until the menopause when geographic differences begin to be seen. In the developing world, a flattening and then a decline occur about 10–15 years after the menopause. In developed countries, the age specific incidence accelerates after the menopause, and at age 70 and above doubles that seen at 45–49 years old.

Methodology: A descriptive design study was accomplished at teaching hospitals in Babylon province. The study aimed to assess the knowledge and attitudes of the women toward the breast self- examination by the application health belief model from 25th November/ 2018 to 13th June/ 2019. A non-probability “convenient sample” of (250) women were selected from outpatients of the main teaching hospitals of the hilla city. The researcher selected 10% from the number of visitors prior to the month of data collection from each of the three hospitals.

Results: The results of the present study show that the demonstrates the distribution of women according to their knowledge about breast self-examination items. With regard to their knowledge reported (Do not know) that puberty as the age of initiation of BSE, it should be done monthly and it should be done five days after menses (59.1%), (61.6%), (70.8%) respectively. Item (1) only reported fair assessment.

Conclusions: Study focuses on clarifying the knowledge and attitudes of women regarding breast self-examination according to health belief model in hilla city hospitals.

Keywords: attitudes of women, breast self-examination

Introduction

Breast cancer is the most frequent malignancy of women worldwide. It is the leading cause of female cancer related disability and mortality. Globally, breast cancer is the most frequent cancer among women comprising about 23 % of all female cancers 1 .

The life style changes contributing to increase post-menopausal. Breast cancer are largely pre-menopausal and includes obesity, low rates of childbirth, infrequent or no lactation, early menarche, and late menopause. These factors, that are common in high-risk countries, promote a state of relative hyperestrogenism and the development of estrogen responsive tumors. The life-style factors are becoming more common in countries considered low-risk particularly in their growing urbanized communities 3 .

Breast cancer represents 10% of all cancers diagnosed worldwide annually and constituted 22% of all new cancers in women in 2000, making it by far the most common cancer in women. The incidence of breast cancer in women in high-income countries in 2000 was at least twice that of any other cancer, similar to the incidence of cancer of the cervix in low-income countries. The risk of breast cancer is low in the low-income regions of sub-Saharan Africa and in Asia, including Japan where the probability of developing...
breast cancer by the age of 75 is one third that of other high-income countries. The crude incidence of all cancers was 61.69 per 100,000 (53.31 in men and 70.59 in women). During that year, 4,115 cases of breast cancer were reported, accounting for 19.5% of all newly diagnosed malignancies and 34% of the registered female cancers, with an incidence approximating 22 per 100,000 female population. The highest frequency was observed in middle-aged women (45-49 years old), whereas the peak age-specific incidence was reported in women 50-54 years old. It has been documented that there is a tendency for the disease to be diagnosed at advanced stages, with a likely prevalence of poorly differentiated tumor forms illustrated in significantly high rates of nuclear aneuoploidy, thus yielding a mortality incidence of approximately 60%.

Breast cancer is the most common type of malignancy among the Iraqi population in general; responsible for about one third of the registered female cancers and almost one quarter of female deaths from the disease. Within the last two decades, there has been an obvious increase in the incidence rates of breast cancer, which became one of the major threats to Iraqi female health. It has a tendency to affect middle aged women in whom it is often diagnosed in advanced stages with a likely prevalence of aggressive behavior yielding high mortality incidence ratio. Breast cancer is becoming an epidemic for women in Kurdistan due to women’s lack of health awareness and breast cancer is becoming more aggressive and affects women at young ages while in other countries it is affecting women after year 50. Several risk factors for breast cancer have been identified; a family history breast cancer is one of the strongest risk factors. Breast cancer risk increases with increasing age. Breast self-exam (BSE) is considered an important public health procedure; primary prevention should be given the highest priority in the fight against cancer. The breast self-exam (BSE) in women is a topic fairly addressed by the professions of nursing and medicine, prioritizing breast cancer prevention by assuming that this illness has an increasing tendency on these days, and it is also the second pathology in the world.

Methodology

The study aimed to assess the knowledge and attitudes of the women toward the breast self-examination by the application health belief model.

Design of the Study: The study was a cross sectional descriptive through the period (from 25th November/2018 to 13th June/2019).

Sample of the Study: Sample of (250) women were included in this study was the women above age 20 years who attended and visited to the outpatients department of the main teaching hospitals of the hilla city.

Study Instrument: Throughout an extensive review of relevant review, the instrument of the study was developed and reconstructed by the researcher for achieving the study objectives. The instrument comprise of three parts

Part I: Demographical characteristics of the sample includes: age, Age of first menarche, level of education, occupation, marital status, economics status, Menstrual history, Family history of breast cancer

Part II: Knowledge of the women regarding breast self-examination.

Part III: Women’s responses to the different attitudes items according health belief model

Data Analysis: Descriptive and inferential statistical study tests used through the use of the (SPSS ver-24).

In respect to the knowledge of breast cancer (BC) Table (3) shows that majority of women (72.4 %) answered that BC is curable in its early stages, and (66.8%) considered it as fatal if not treated, (57.2%) of them agreed that the disease is painless in early stages. (43.6%, 44.0%, 48.4%) do not know that the breast cancer more common in women over 50, occur in one breast only and this disease is more common in obese women respectively.

**Discussion**

Breast cancer (BC) in women is the a major health burden worldwide. It is the most common cause of cancer among women in both high and low income countries. According to world health organization (WHO) breast cancer has become one of the most important health problem for the women in Arab countries. Socio-demographic characteristics and other personal data have an essential effect on individuals health and beliefs about health, because those variables related to deal with the disease and has important role in prevention and coping with treatment. There are differences between age groups of the young women to old, educated – uneducated, working or not …etc. The study findings indicate that more than forty-three percent from 250 participants aged within the twenties, the usual age of women for marriage and reproduction. Women who attend the hospital are mostly within this age group. At the same time many studies mentioned that this is illegible period for most of them. One of the studies that came along with the present study done by Abed
El-Azim et al., (2016) who found that (73.9%) from the sample aged between (20-25) years. And a study carried out by (asghari;2016) among Iranian university students found that the average age of the sample was 21.76±2.6 . The current study shows that more than fifty of sample their age of menarche within twelve years with mean= 12.57, this finding is agreed with Sideeq et al., (2017) who found that among the sample underwent the study the mean age at menarche was 12.56±1.17 years. Another study result found by (Shakweer et al; 2016) stated that majority of their participants represented (84%) started menstruation (Menarche) at age range from 12-14 years.

Conclusions

Clarifying the knowledge and attitudes of women regarding breast self-examination according to health belief model in hilla city hospitals. Age of the sample distributed between (20-33) years old with mean age =33.3 and standard deviation= 1.159

Knowledge of Parents toward Children with Attention Deficit Hyperactivity Disorder in Baghdad City

Iman H. Alwan

Lecturer, Department of Psych. Nursing, College of Nursing, University of Baghdad, Baghdad City, Iraq

Abstract

Attention deficit/hyperactivity disorder (ADHD) is one of the most common psychiatric disorders in child and teenage psychiatry. ADHD children are at risk for a school organization constrains a multimodal treatment database. This study surveys parent’s knowledge and attitudes towards attention deficit hyperactivity disorder. The study aimed to assess the level of the knowledge and perspective for Parents who have children with Attention Deficit Hyperactive Disorder. A non-probability, purposive sample of 75 child and 75 parents (40 mothers and 35 fathers), who had children with ADHD between the ages of (4 and 12) were selected. A descriptive study was conducted at the Child Psychiatric Unit at Ibn Rushed Psychiatric Teaching Hospital and Central Child Hospital Teaching in Baghdad City, from September 8th to October 30th, 2017. A questionnaire format used for data collection and constructed by the researcher to achieve the objectives of the study. Reliability of questionnaires was estimated through a pilot study which was carried out for the period from December 10th 2017 to December 30th 2017. Data were analyzed through the application of descriptive statistical analysis and the application of inferential statistic. The results of the study indicate that the ADHD parents are no significant association between father knowledge and socio-demographic except income, child age, gender and received medication which was correlated significantly at p-value 0.01 respectively. The researcher recommended that future researches should be directed toward teaching parents and teacher to increase their knowledge about the ADHD and provide many strategies to help them to reduce parents burden and coping.

Key words: knowledge, Attention deficit hyperactivity disorder, Parents

Introduction

Attention-deficit/hyperactivity disorder (ADHD) is a commonly diagnosed behavioral disorder of childhood that is characterized by symptoms of inattention, hyperactivity and impulsivity. There has been a dramatic increase in diagnoses of ADHD in recent years. The primary features of the disorder are inattention, hyperactivity, and impulsivity, which combine in various ways to create three different subtypes of ADHD. Predominately Inattentive, Predominantly Hyperactive-Impulsive, and a Combined type. Prevalence rates for ADHD for example in New Zealand are around 5% of school-aged children with rates for boys 3 times higher than those for girls. Similar prevalence rates are found in the U.S. and internationally. A prevalence of 3–5% in the general population is the name of a group of attention-related symptoms that are often found together, especially in children and young adults. Prevalence rates among school-age children in the United States range from roughly 4% to 12 more, the percentage of children treated for ADHD in the United States increased dramatically from the 1980s to the 1990s. Attention Deficit Hyperactivity Disorder (ADHD) is one of the most common reasons behind children referral to mental health clinics with estimated prevalence rates of 5% of school aged children. As noted ADHD is a chronic condition characterized by impairments in impulse control, sustained attention, and the regulation of behavior in response to situational demands. Educational programs which increase parents and community awareness toward ADHD should be encouraged through the media. Establishing special school or institute for ADHD children to provide special services to decrease parents’ psychological distress. Constructing a special program for children performing...
at home and in the school in cooperation with the parents. This will depend on positive reinforcement for satisfactory behavior management. Monitoring ADHD children by their teacher using special questionnaires and standards of their behavior, to measure the type and degree of the child’s behavior al distress. Establishing supportive groups allow for a personal touch where parents with similar problems and stressors might be more willing to share one to one.

**Methodology**

A descriptive-analytic study was carried out at the Child Psychiatric Units at Ibn Rushed psychiatric Teaching Hospital and Central Child Teaching Hospital in Baghdad. A purposive sample (75 children) was selected for the present study (The total number of children who had diagnosis with ADHD is 338). Seventy five parents of children with a primary diagnosis of pure ADHD were selected. The subject pool for this phase included 40 mothers and 35 fathers between the ages of 30 and 55 who had children between the ages of 4 and 12 years. Questionnaire is constructed for the purpose of the study through a review of relevant literature and consultation from a panel of experts. The questionnaire includes three parts which are distributed as follows: Part I is a covering letter to obtain the agreement of patients and their family members to participate in the present study. Part II Parents demographic characteristic that included age, level of education, level of family income and marital status. Part 3 Attention-Deficit/Hyperactivity Disorder Knowledge Survey (AKOS-R). Onto their next visit to the clinic, participants were randomly assigned to parents after receiving an educational lecture about ADHD. All participants again completed and the AKOS-R.

The validity of questionnaire was determined by exposing it to (10) expert of different fields. Reliability was determined through a pilot study that was carried out on (15) parents who had ADHD child and were visiting in the Child Psychiatric Units. The internal consistency of the instrument was determined through the computation of Spelt-half. The results of the reliability were r=0.88.

**Result and Discussion**

Table (1) show that the mother age range group were fallen within the age 30-39 years old (48%). However the majority of percentage of father’s age group were not fallen only within the age of 30-39 years (37.3%) but also within the range of 40-50 years old and shows that the most mothers were secondary school and university graduated (42.7%), (41.3%), respectively that the majority of parent’s educational score were fallen among fathers group 3 (37.3%) and group four (42.7% ) whose score levels were within higher educational groups (secondary and Colleges). Table shows that the majority of Children with ADHD (58.7%) were receiving medication up to three years, the majority of ADHD Children were among urban regions (71%) while only 9.3% of children with ADHD were from rural area. that the majority of children with ADHD were male (81.3%), this table shows that the majority of Children with ADHD (58.7%) were receiving medication up to three years. Knowledge about ADHD was comparatively low, 86% of parents agreed that children with ADHD are usually brighter than those without AHD. 58% of the parents considered the most effective treatment of school-aged children are stimulant medication, behavior modification, or a combination of the two. The attitude score towards ADHD children was also low. 76% agree that medication often reduces child’s tendency to be aggressive with others at school. 72% believe that almost all children with ADHD meet national and state standards for learning disabilities. 69.3% of parents believes that children who are hyperactivity at the age of 3 almost always become identified as having ADHD by the age of 7. 74.7% of parents unsure that in most cases, medication will help a child achieve better grades in school, also about 64% of them considered most children with ADHD, psychology treatment are not as effective as medication in improving attention and reducing disruptive behavior.

Histopathological Changes in Liver Induced by Piroxicam Administration in Adult Male Albino Mice *Mus musculus*

Intidhar Mohammed Mnati¹, Baydaa Hussain Mutlak¹

¹ Lecturer, Department of biology / College of Education for Pure Science (Ibn Al- Haitham) / Baghdad University, Iraq

**Abstract**

**Background:** Piroxicam is one of non-steroidal anti-inflammatory drugs which is widely used in treating rheumatic disorder. **Aim of the study:** Studying the effects of piroxicam pertaining on the liver tissue to the chronic administration in male albino mice *Mus musculus* histologically and histochemically changes.

**Material and methods:** A total number of (30) adult male albino mice were utilized in this study, they were randomly distributed into three groups, the first and second groups were orally treated with concentrations (75, 150) mg/kg of piroxicam respectively for one and two months, the third group considered as control group were orally treated with distilled water, liver samples were collected every one and two months for the histological and histochemically study. **Results:** This study recorded the presence of histopathological changes in liver tissue of the treated mice with concentration 75 mg/kg represented by degeneration of hepatocyte, sinusoidal dilation, inflammatory cellular infiltration, vascular congestion in the portal vein and beginning of calcium casts formation, while the group treated with 150 mg/kg of the drug showed portal vein congestion and dilation, blood sinusoidal were highly obliterated, proliferation of bile duct and nuclei appeared pyknotic, in addition there were a remarkable decrease in the glycogen controls of cells. **Conclusion:** It could be concluded that piroxicam drugs has drastic effects on liver tissue as represented by the observed histopathological changes.

**Key words:** Piroxicam, Histopathological changes, Liver, Albino mice.

**Introduction**

Non steroidal anti-inflammatory drugs(NSAIDs) are some of the most commonly prescribed and utilized medication. These agents have proven particularly effective in the treatment of a variety of inflammatory disease. Some disease like osteoarthritis required their use for long periods of time ¹. All NSAIDs are well absorbed when given orally. They are eliminated from the body by the liver and kidney ². Piroxicam is one of the most popular (NSAIDs) belong to the oxicam group and used for the treatment of inflammatory conditions and rheumatic disorders, it is useful in the management of ankylosing spondylitis, acute musculo_skeletal disorders and dysmenorrhea, they exert their therapeutric effect by reducing prostaglandin biosynthesis through inhibition of cyclooxygenase(cox) enzymes ³.

The studies showed that piroxicam has many side effects on digestive system, represented by ulcers, gastritis ⁴, furthermore there were side effects of piroxicam on the testes of male mice ⁵, ⁶ also suggested that injecting piroxicam caused a remarkable histopathological symptoms in kidney of male albino. On the other hand, several NSAIDs drugs have been associated with liver damage ⁷. Many NSAIDs have been withdrawn from the market because of adverse hepatic drug reaction. Some cases of liver disease have been reported in patients taking piroxicam ⁸. Therefore, the present study was designed to investigated the histological effects of piroxicam on the liver of adult laboratory mice treated with the drug piroxicam.

**Material and Method**

-**Experimental animals**

A total number of (30) healthy adult albino mice *Mus musculus* and age approximately (8-10) weeks old ranging in weight from (25-30)gm, purchased from Iraqi
national center for drug control and research, Baghdad, Iraq. They were randomly distributed into three main groups of ten mice for each group, they were housed in cages and were kept in the laboratory under constant conditions for at least one week before use, they were fed a standard commercial diet.

**-Experimental design**

The drug used in this study was piroxicam in capsule form of (20)mg, concentrations (75,150)mg/kg were prepared daily and they were given orally using stomach cannula for the periods one and two months, two of the three groups were orally treated with concentrations (75,150)mg/kg respectively, the third group considered as control group were treated with 0.1ml of distilled water for two months.

**-Histological and histochemical preparations**

Animals from control and treated groups were scarified, dissected and small pieces of liver were quickly removed, then fixed in 10% formalin and bouin’s fixatives for (20-22)hours followed by changing the fixative with 70% alcohol after washing the specimens for many times, following the washing specimens were dehydrated, embedded and then sectioned to 6 µ thickness, for the histological examination, sections were stained with haematoxylin and eosin then examined under light microscope (Olympus), photographs were taken by digital camera.

In the histochemical study, sections were stained with periodic acid Schiff’s method (PAS) to demonstrate carbohydrates.

**Results**

**Histological examination in liver tissue**

**- Control group**

Section of this group appeared with normal histological structure the liver covered with thin capsule composed of loose connective tissue called Glisson’s capsule. The liver of this group are normal in shape and size (Fig.1).

Histological examination of mice livers of this group showed normal liver histology with hepatic cords or plates are arranged around central vein (Fig.2).

These hepatic cords separated from each other by blood sinusoids, the blood sinusoidal are lined with two types of cells, first type of cells represented by endothelial cell that appears flattened cell and second type of cells represented by kupffer cell that appear as a big cell with circular nuclei (Fig.1).

The portal area of liver composed of branch of portal vein, hepatic artery, bile ducts and lymphatic vessel (Fig.3).

**-Groups treated with (75)mg/kg of piroxicam**

The examination of liver sections of treated mice with(75)mg/kg of piroxicam for two periods revealed many pathological changes compared with control group. The changes are represented by degeneration of hepatocyte, hepatic sinusoidal dilation, also inflammatory cellular infiltration, few vacuoles in the cytoplasm of hepatocyte and congestion of central vein after one month of administration (Fig.4,5), while after two months of administration the cytoplasm appeared to be highly vacuolated and the nuclei of most of the hepatocytes appeared pyknotic and some nuclei appeared disappeared (Fig.6), as well as the beginning of calcium casts formation, vascular congestion in the portal vein, cellular infiltration was more intense around the portal area than the previous treatment and dilation of portal vein in the portal area (Fig.7,8,9).

**-Groups treated with (150)mg/kg of piroxicam**

The results of microscopic examination showed severe changes that represented by cellular infiltration and portal vein dilation in the periportal area, the blood sinusoidal were highly obliterated than the previous group. In addition, the nuclei of most of the hepatocytes appeared with dense clumps of chromatin and some nuclei appeared Pyknotic after one month of administration (Fig.10,11), whereas after two month of administration the changes were proliferation of bile duct, congestion of portal vein, the cellular infiltration was more intense than the previous group, detachment of basement membrane of hepatocytes and hepatocytes were swollen (hypertrophy). In addition, the cytoplasmic vacuoles were less in number. (Fig. 12,13,14).

**Histochemical changes in the liver**

Control liver sections stained with PAS method
showed a positive reaction to the stain as an indication for the existence of carbohydrates in the basement membrane of hepatocyte glycogen appeared around the cell membrane (Fig.15). Liver tissue of treated mice with (75,150) mg/kg of piroxicam after two months of administration showed decreased of glycogen content. The reaction increase with the increase of concentration and administration period (Fig.16,17)

Figure (17): Cross section of liver (treated group with 150mg/kg) for two months showing severe decrease in carbohydrate deposition (CD) (PAS 40X)

Discussion

In this study, we tried to identify the effect of piroxicam depended in the liver of adult male albino mice. It was clear that its effect was time depended, there were increased effects with prolonged time of dose administration this result is in agreement with 10.

In general, NSAIDs are well known to induce hepatic injury (7,11). Also the pathological changes may lead to impaired liver function which interferes with the secretion of plasma proteins 8. This lead to decreased blood osmotic pressure with subsequent decreased drainage of tissue fluids, which explains the congestion observed in the different tissue.

The histological examination revealed that there were histopathological changes in the liver of treated groups with the concentration (75 and 150)mg/kg, the histopathological changes treated with 75 mg/kg showed vascular congestion and beginning of calcium casts formation, these findings in agreement with foundation of 12.

There was also a remarkable histopathological changes in this groups treated with piroxicam that represented by vascular congestion that may be related to the use of drug that cause an acute inflammation this lead to change the blood flow inside blood vessels, which may cause a relaxation and an extension in these blood vessels, thus the blood will accumulate into the vessels (12,13).

Result showed formation of calcium casts, this may attributed to the elevation of hydrogen peroxidase \( \text{H}_2\text{O}_2 \) that cause the nephrotoxicity which is responsible for changing the permeability of mitochondrial cellular membrane, hence the amount of calcium taken by the mitochondria will increase and with the existence of oxygen, the mitochondria will break down and the calcium will be released in the liver tissue 13.

Result also showed a remarkable cellular infiltration in the hepatic tissue. This supported 14, whose studies suggested that abundance of leucocyte, and lymphocytes, in particular, are a prominent response of body tissue facing any injurious impacts. Leukocyte elevations and adherence to the vascular endothelium have been suggested by 15 to play an important role in the pathologenesis of NSAIDs associated injury.

In this study, the vacuolation of the cytoplasm of the liver cells appeared at first in the hepatocytes of the peripheral zone of the hepatic lobules, extending gradually toward the center. This may be due to the direction of the lobular blood supply. Vacuolation and damage of liver cells were noted by other investigators following treatment with different agents 16, 17.
The present study also showed the presence of histopathological symptoms in the group treated with (150)mg/kg of piroxicam that represented by blood sinusoidal dilation, detachment of basement membrane and hypertrophy of hepatocyte, these findings in agreement with(12, 18).

Also results showed degeneration of hepatocyte and damage of hepatic cells 19 suggested that the high exposure of drug and chemicals results in cell death or apoptosis. These two factors(drug and chemical) may show either functional or structural side effects as well as the loosing of the liver capacity to stress, but when reaching the threshold, the liver cell will reach the final irreversible stage which was death.

Also results showed hypertrophy which is characterized by enlargement of cells in comparison with control group. This enlargement of cell may be due to the enlargement of the component of these cells and this swelling may mostly due to accumulation of water inside the cell 20.

Regarding the histochemical changes observed in this study under piroxicam administration, results showed a reduction in the polysaccharide in the liver tissue, the decrease in carbohydrate content was attributed by some investigators to be due to increased stress on organ, which lead to high energy consumption(10, 21), or may be due to the depletion of mucopolysaccharide in tissue which is attributed to the turbulence of Golgi apparatus 22.

It is clear form this study that piroxicum has toxic effects on the liver tissue as represented by the observed histopathological damages.

Prevalence of Negative Exploratory Laparotomy in Some the Hospitals of Al-Russafa Side of Baghdad City

Israa Dawood Salim¹, Mohammed Abdulridha Alzamili ², Sameeha Naser Abed³

¹Assist. Lecturer, Department of Health Administration, AL-Mansoor Technical Medical Institute, AL-westa Technical University, Baghdad, Iraq, ²FIBMS, Al-sader general hospital, Baghdad health AL-Rusafa directorate, ³Lecturer, Department of community health, Kut Technical Institute, AL-westa Technical University, Baghdad, Iraq

Abstract

Not all abdominal trauma need laparotomy thus this study has been conducted to evaluate the prevalence of negative laparotomy in some of the hospitals of Al-Russafa side of Baghdad city. A retrospective cross-section study was be conducted in four hospital (Baghdad Teach hospital, Al-kindy, Al-sadder, Al-emam Ali hospital) in Baghdad city. The period for data collection are (8) months from February to September 2014. Data was analyzed using the SPSS.

This study revealed that the distribution of –ve labratomy are ( 6) for AL-Sadder hospital and (4) for other hospitals in sample with (12%) for Al-sadder hospital ,(11.76 %) for Al-emam Ali and Baghdad hospitals, and (8) for Al –kindy hospital,The results of this study indicated that one ten of all expletory lapratomy was negative lapratomy. The prevalence distribution of expletory lapratomy are difference between hospitals of Al-russafa and also there is difference in the prevalence of –ve expletory lapratomy among these hospitals.

Based on this study Reliance on algorithm for patients with abdominal trauma should be to identify injuries requiring surgical repair, and to avoid unnecessary laparotomy. In addition provide imaging modalities and other investigative techniques in all hospitals and training of medical staff working in hospitals on focal assessment sonography for trauma program(FAST).

Key words: exploratory laparotomy, negative lapratomy, prevalence.

Introduction

“Exploratory laparotomy defined as a laparotomy process that purpose for obtaining information that is not available by clinical diagnostic tools. It is usually performed in patients with acute, or unexplained abdominal pain, in patients who complained persistant abdominal trauma, and in patients with a malignancy” ¹² Exploratory laparotomy indications included acute-onset abdominal pain and clinical results of intra-abdominal pathology necessitating emergency surgery, and abdominal trauma associated with shock, Peritoneal irritation and Hemodynamically unstable trauma patients ¹³ Availability of good imaging instruments and facilities (C.T.U.S) have restricted or reduced the use of exploratory laparotomy in these cases ⁴⁵⁶ “The essential contraindication for exploratory laparotomy is unsuitable for general anesthesia. Peritonitis with severe sepsis, advanced malignancy, and other conditions may maker patient’s unfit for general anesthesia ¹. “Non therapeutic exploratory laparotomy is associated with significant long-term morbidity, including adhesive intestinal obstruction and incisional hernia,For most cases the non-therapeutic laparotomy rate will be unacceptably high. With the incidence of consequent with a negative laparotomy of 12% - 41%, with remain

in the hospital of 4-8 days, this lead to health risk to the patient and economic burden to hospitals" (7, 8, 9). Trauma is one of the common reasons of death because of the increase of violence in our society, and is a major economic and health problem. The abdomen is the third most common injured region, Abdominal trauma is classified as either blunt or penetrating , and not all abdominal trauma need laparotomy” (10, 11,12).

In the past two decades from exploration, the trend has moved in to selective approach “(13,14,15), laparotomy for penetrating abdominal stab wounds leads to unnecessary operations in 38–40% of patients “(16, 17).” The goal of any algorithm for patients with abdominal trauma should be to identify injuries requiring surgical repair, and avoid inappropriate laparotomy with its linked morbidity” (18-19). This study aimed to provide data on prevalence of expletory laparatomy among patient with abdominal trauma in random sample of some of AL-russafa side of Baghdad city hospitals, and the –ve expletory laparatomy among those patients.

Method

Setting of the study: This study was be conducted in four hospital in some of ALrusafa side of Bghdad (Baghdad Teach hospital, Al-kindy, Al-sadder, Al-emam Ali hospital) in Baghdad city.

Design of the study: A retrospective cross- section study.

Duration of the study: The period for data collection are (8) months from February to September 2014.

Study sample: The data were collected retrospectively from case sheet for (168) patients with abdominal trauma and exploratory laparotomy were done for them. Data collection were carried out from four main general hospitals that selected randomly from eight main general hospitals in Alrusafa side of Baghdad.

Inclusion criteria:- All patients with abdominal trauma and exploratory laparotomy were done for them.

Exclusion criteria:- Patients were done exploratory laparotomy and without abdominal trauma.

Data analysis: Data was put in computer file for storage and statistical tables were used to represent the frequency and percentage of the results. Statistical data obtained were analyzed using Statistical package for the social sciences (SPSS version 16).

Findings

Figure (1) displays the percent of exploratory laparotomy. Among the 168 cases, 18(11%) of -ve laparotomy and 150 (89%) of +ve laparotomy, the study found The study found the prevalence of –ve expletory laparotomy (10.7%) 18 cases and +ve expletory laparotomy are (89.3%) 150 cases from total number of the sample. High prevalence of –ve expletory laparotomy lead to economic burden to health institutions in addition to the burden on the patients (7,8,9). Navasaria and colleagues at south africa, they assessed 86 patients with abdominal stabs where expletory laparotomy done for them, there were 7 negative laparotomies (8.1%) 20. Other study at Al-Zahra hospital in Isfahan show the penetrated anterior abdominal fascia without visceral evisceration and in the absence of signs of peritoneal irritation, rate of negative laparatomy was 82 percent 3. Other study done at the Los Angeles County, University of Southern California Medical Center,over the six year study period a total of 1871 laparotomies were performed, of which 73 (3.9%) were negative” 21. High percent of unnecessary laparatomy in our study may due to lack of imaging and other investigative techniques and depend on physical examination for case evaluation in our hospitals.
Figure (1) Distribution of the patients according to type of exploratory laparotomy

The total of exploratory laparotomy was (168) in four main general hospitals in Alresafa side of Baghdad during the period of the study.

Table (1) show that Al-kindy and Al-sadder hospitals have (50) exploratory laparotomy, these number is large compared with other Al-russafa side of Baghdad city hospitals. This may because it cover a large population density, the high violence and explosions in the coverage area for these hospitals. And Al-emam Ali and Baghdad hospitals have (34) exploratory laparotomy. The cases that done laparotomy in AL-emam Ali hospital are lower than Al-sadder hospital(50laprotomies) inspite of the both hospitals located in the same geographical area and provided medical health services to the same population.

this difference may be due to restoration done in Al-emam Ali hospital and limitation of surgical bed number. Number of laprotomies in Bagdad hospital 34 laprotomies, this low number in spite of this hospital is center teaching hospital in Baghdad with large bed number and good resources, this low number of laprotomies may because of the distance from the area where the explosions abound and away from large population density.

Table (1): Distribution the patient according to hospitals that exploratory laparotomy done.

**Conclusion**

The present study was concluded that one ten of of all exploratory laparotomy was negative laparotomy.

The prevalence distribution of exploratory laparotomy are difference between hospitals of Al-russafa and also there is difference in the prevalence of –ve exploratory laparotomy among these hospitals.

**Recommendations:-**

1. Reliance on algorithm for patients with abdominal trauma, should be to identify injuries requiring surgical repair, and to avoid unnecessary laparotomy.

2. Provide imaging tools and other diagnostic techniques (C.T,U.S,M.R.I) in all hospitals

3. Training of medical and health staff working in hospitals on focal assessment sonography for trauma program (FAST).

**Ethical Clearance:** At the beginning of the study we obtained an official approval ethical to conduct study from the Ministry of Health (MOH) and Directory of Health / Baghdad Al-Rusafa.

**Conflict of Interest:** Nil

**Source of Funding:** Nil

Cloning, Sequencing and Expression of the *Brucella Melitensis* Novel Lomr Protein

Othman Jamal Nassrullah¹, Mohammed Omer Mohammad², Shwan Kamal Rachid³

¹Assist. Prof., Infectious Diseases, Clinic and Medicine Department, College of Veterinary Medicine, Sulaimani University, ²FICMS-FRCP of medicine. College of medicine Sulaimani University, ³Prof., Molecular, Pharmaceutical and Biotechnology. Charmo University

Abstract

**Aim:** Brucellosis is a zoonotic infection transmitted from animal to human directly by the animal or indirectly from their products. It is worldwide distribution especially in the middle east including Iraq and Kurdistan Region. **Materials and methods:** The gene coding for the outer membrane protein assembly factor LomR of 18kDa, now designated of *Brucella melitensis* 16M was cloned and sequenced. Cloning of insert DNA from bacteria into pET-28, allowed the selection of a plasmid bearing a 5.5-kb NcoI fragment that seemed to contain the entire omp gene under control of its own promoter. **Results:** LomR was localized within a region between the NcoI and XhoI insert of approximately 396 bp. The reliability of the constructed plasmid was established by restriction enzyme mapping and sequencing. LomR was expressed after induction with IPTG in Escherichia coli BL21. Recombinant LomR was purified by chromatography through Ni-agarose. Sequencing of this region revealed an open reading frame of 390 bp encoding a protein of 132 amino acids and a predicted molecular mass of 20 KDa. **Conclusion:** The availability of recombinant LomR and the identification of the antigenic determinant recognized will allow the evaluation of their potential protective activity and their potential for the development of subunit vaccine against brucellosis.

**Keywords:** (PCR, cloning, LomR, DNA, Gene, Protein, expression, Brucella melitensis)

Introduction

Brucella types are facultative intracellular gram-negative bacterial pathogens that infect both phagocytic and nonphagocytic cells. *Brucella abortus* causes abortion and economic losses in dairy cattle and furthermore different zoonotic diseases in human. *Brucella melitensis* is the most pathogenic species for people and may cause premature births in sheep, goats, and cows. Immunization of sheep and goats against *B. melitensis* with live attenuated smooth *B. melitensis* Rev. 1, the strain most generally use for disease control, this bacterium needs to oppose oxygen consumption. Without treatment, brucellosis may get continuous, bringing about restricted disease of liver, spleen or brain.

*Brucella melitensis* Rev.1 vaccine induces abortions when applied during pregnancy, is virulent for humans, and elicits antibodies to smooth lipopolysaccharide (LPS) of Brucella interfering in serodiagnosis. Moreover, Rev.1 is resistant to streptomycin, an antibiotic used to treat the disease. Effective brucellosis vaccines not interfering in the diagnosis of infected animals would represent a major breakthrough.

The sickness remains a general medical issue and results in serious monetary misfortunes regarding loss of fetus and loss of animals.

There is significant financial weight of brucellosis reflecting, either the expenses of accomplishing and keeping up illness free status, or the expense of infection regarding loss of profitability and control costs. Over numerous years Brucella taxonomists
built up a characterization framework that perceived six established species dependent on unpretentious phenotypic and antigenic contrasts and differential host specificity. Accordingly generally *B. abortus* (cow), *B. melitensis* (caprine and ovine), *B. ovis* (ovine), *B. canis* (canine), *B. suis* (porcine, rangiferine, leporine) and *B. neotomae* (rat) are perceived. 4.

The live attenuated strain *B. melitensis* Rev.1 is viewed as the best immunization accessible for the prophylaxis of brucellosis in sheep 5.

During the last two decades, a number of *Brucella* antigens have been identified, such as Omp16, Omp19, Omp25, Omp31, SurA, Dnak, trigger factor (TF), ribosomal protein L7L12, bacterioferritin (BFR) P39, and lumazine synthase BLS 9. These antigens were selected based on empirical screening approaches that are typically laborious and expensive and require strict safety precautions and particular lab facilities, as the relevant species of *Brucella* are classified as biosafety level 3 microorganisms. This insufficiency of the empirical methods represents a great need for a rational and comprehensive approach to discover potential antigen candidates that can be used to develop a safe and effective anti *Brucella* vaccine. In any case, its utilization is known to invigorate counter acting agent reactions in sheep serum by the current ordinary serological tests from those saw in *B. melitensis*-infected sheep. These tests, of which the most ordinarily utilized are the Rose Bengal test, the seroagglutination test, and the complement fixation test, chiefly measure antibodies against the immunodominant smooth lipopolysaccharide (S-LPS) 7.

Hence, a noteworthy objective in immunological investigations of brucellosis has been the ID of protein antigens valuable for analysis and conceivably helpful for recognizing the immunological reactions of infected animals from those of animal inoculated with live attenuated strains. The aim of this work was to discover antigen candidates conserved among the three pathogenic species. In the present study we purified a protein that is a part of the *Brucella melitensis* membrane to try using it later as antigen for diagnosis and control concepts.

**Materials and Method**

**Ethical statement:** This study was performed in strict accordance to the ethical committee condition of the university of Sulaimani, college of veterinary medicine.

**Bacterial strains**

Bacterial strains E. Coli XI blue and BL21 (DE3) a gift from (Genetic department, Tehran University of Medical Sciences) were used for expression of LomR recombinant protein. Bacterial strains were routinely grown at 37°C in LB broth or agar.

**Cloning and DNA sequencing LomR gene:**

Bacterial DNA from cultures of *B. melitensis* 16M full-grown all night was isolate using a Qiagen DNA taking out kit. The DNA was checked using agarose gel electrophoresis, and the purity and quantity were calculated using a spectrophotometer. The section encoding the LomR gene, consisting of 554 bp, was amplified and legated into pET-28a.DNA of recombinant phages pET-28a expressing was recovered following the protocol of Maniatis *et al.* for the rapid, small-scale isolation of DNA. Plasmid DNA was then incise with NcoI and XhoI restriction fragments were ligated into pET-28a (Promega) cut with NcoI. Competent *E. coli* DH5α cells (Promega) were transformed with recombinant plasmid DNA as described by Maniatis *et al*. Then spread on LB-kanamycin (50 mg ml) plate’s one positive colony was further selected for restriction analysis of the insert containing the gene coding for LomR. Restriction analysis was done with the following enzymes of the multiple cloning site sequence of pET-28a NcoI, XhoI.

**Expression and Purification of recombinant LomR protein.**

The ligated product was then used to change the expression host *E. coli* BL21. The exponential-phase culture of the established LomR clone was induced with different IPTG concentrations of 0.5, 1.0, 1.5 and 2.0 mM, and checked for expression at hourly intervals up to 5 h. Induced cells, as well as uninduced cells exposed to the identical conditions, were lysed in 1× lysis buffer (PBS) and analysed by 10% PAGE, as described by Laemmli (1970). In order to find out the location of the expressed recombinant protein, the bacterial cell suspension was sonicated for 10 min with a pulse interval of 8 s. The
sonicated extract was centrifuged at 14000 rpm for 30 min at 4 °C. The supernatant and cell pellet, with suitable controls and molecular mass markers, were analyzed by 12% SDS-PAGE. After verification of the solubility, the protein was purified by His-tag binding affinity to Ni-NTA agarose. Purification of the cell lysate was carried out using a ROTH (Germany) Ni-NTA spin column with a native purification protocol as specified by the maker, and mass purification was approved by gel filtration affinity column chromatography using Ni-NTA Super flow (ROTH). The purified protein was checked by SDS-PAGE followed by coomassie blue staining, and protein concentration was expected by the Bradford method using BSA as a standard.

Results:

Cloning and sequencing of DNA coding for rLomR protein

Genome DNA ready from B. melitensis was use as guide in the PCR by using Prime DNA polymerase. Outcome show that single band through accurate molecular weight has been augmented for LomR gene. Fig 1

![Fig 1](image1.png)

Fig. 1. Confirmation of cloning, expression and purification of LomR. Lane 1: pET-28a+ LomR, Lane2: pET-LomR digested with XhoI and MluI, Lane 3: molecular marker. Digestion Conditions Digestion in water-bath, 37°C for 40 minutes about 300ng plasmid digested 1% Agarose gel.

Cloning of the B. melitensis LomR gene

Viewing of the recombinant pET-28a plasmids were passed with restriction digestion and sequenced (Fig. 1). Insertions were excised from recombinant pET-28a with positive results and sub cloned into pET28a (+). Cloned plasmids were examined with restriction digestion XhoI and NcoI restriction enzyme and plasmid sequencing.

Expression of rLomR in E. coli

Expression of induced cells was checked, at hourly intervals up to 4 hours after induction with 1mM IPTG (Fig 2).

**Discussion**

Brucellosis is an extensive zoonotic disease that can communicate a disease to variety of farm animals and wildlife. This disease is widespread in many countries and it leads to cost-effective losses. Rev1 and S19 are Brucella typical vaccines which used generally. They are live attenuated bacteria strains. These vaccines have some harm, such as weak inducible for immune system and have potential of human infection. Based on this data, the detection of immunogenic bacterial constituent is vital component of subunit vaccine and diagnostic development process. Surface proteins of the bacteria have been reported to take part in significant role through Brucella infection and inducing immune response. Commonly, successful vaccines against their bacteria mainly induce antibodies against surface composition. These surface proteins of the bacteria have been thought of as helpful antigens for progress of both diagnostic reagent and vaccine candidates. Antigen based diagnosis of brucellosis has not been basically used and so antibody based diagnosis is only efficient substitute that can be used in laboratories. The antibodies against different Brucella antigens can be detected in sera from little days of infection and up to 3 months.

Selection and production of new vaccine candidates are the primary practical steps toward introducing new vaccines. During the last two decades, a number of *Brucella* antigens have been identified, such as Omp16, Omp19, Omp25, Omp31, SurA, Dnak, trigger factor (TF), ribosomal protein L7L12, bacterioferritin (BFR) P39, and lumazine synthase BLS.

The OMPs of Brucella spp. have been broadly characterized as immunogenic and protective Ags. Yet studies have been focused on the major OMPs. Immunization with purified recombinant LOmp16 or L-Omp19 protein plus IFA induced protection against B. abortus infection prompted us to study in further detail different aspects that we consider important at the moment of choosing an Ag for further commercial use as a vaccine. In this regard, the capacity to manufacture an Ag that is molecularly defined and pure is highly beneficial in terms of safety, effectiveness, and large-scale production.

At present, native antigens like, complete cell extract and lipopolysaccharides have been used in serological assays. RBPT which is based on the stained complete cell heat killed acidified bacteria is used for early screening. Although RBPT has high sensitivity but low specificity because these antigens show cross reactivity with other bacteria like E. coli O: 159, Y. enterocolitica O: 9, Vibrio cholera, and Salmonella spp.

The gene of LomR was PCR synthesized and cloned into the pET28a (+) expression system. The system provides assistance for best expression of Brucella melitensis 16M outer membrane proteins.

**Conclusion**

The outer membrane resembling protein LomR protein is a novel protein that expressed. These expressed recombinant proteins have been intended to be fused with 6-His tags at their N terminal. In this study, all expressed proteins were confirmed by SDS-PAGE. Purified recombinant proteins with Ni-NTA agarose resins arranged like truth folding proteins. Purified 21 KDa proteins candidate for diagnostic purpose. This recombinant protein will be examd later in vivo model to test their immune stimulation.

Attitudes of Secondary School Students toward Health Promotion Behaviors in Al- Hilla City

Hasaan Abd Ali¹, Salma K . Jihad²

¹Master Student, ²Prof. Dr., Community Health Nursing, Faculty of Nursing, University of Babylon

Abstract

Objectives To identify the school students sociodemographic characteristics . To assess the attitude of participants toward health promotion .

Methodology: A cross-sectional descriptive study consisting of (177) students, to Attitudes of Secondary School Students toward Health Promotion Behaviors of secondary school student in Al- Hilla City

Result: Analysis of data reveals that there is a (67.8%) of adolescent have a normal body mass index, and (15.8) have underweight, (12.4%) overweight, while(4%) only have obesity.

Conclusion: Most of the students maintained normal weight status according to their BMI. Most of students aged at middle adolescence period, males more than females, majority of students were un married, at fourth grade, most of them were urban residence and ordered as 2nd member in the family, majority of them were not smoking and live with their parents.

Keywords: Attitudes of Secondary School Students toward Health Promotion.

Introduction

A huge proportion of the world’s population more than 1.75 billion young, aged between 10 and 24 years. Adolescents (aged 10 to 19 years) have specific health and development needs, and many face challenges that hinder their wellbeing, including poverty, a lack of access to health information and services, and unsafe environments. Interventions that address their needs can save lives and foster a new generation of productive adults who can help their communities progress. Many boys and girls in developing countries enter adolescence undernourished, making them more vulnerable to disease and early death. Adolescents are neither children nor adults; their needs can be easily overlooked in policies. Health interventions for adolescents cannot be effectively implemented without the appropriate policy and legal environment and its effective application.

Often defined by its age range (which is thought to extend from age nine or ten through the early twenties), adolescence represents a sensitive developmental period for learning about and adopting a wide range of health behaviors.

A good health-promoting behavior depends on the living habits adopted during early years. Adolescents are at a dynamic transition period bridging childhood to adulthood, characterized by rapid, interrelated changes in body, mind and social relationships. Most discussions concerning adolescents health promotion include the topic of improved bio-psychosocial wellbeing for example enhancing regular exercise, nutrition, stress management, spiritual life and interpersonal relationship behaviors. People tend to change their attitudes and lifestyle due to the physical, mental, and social problems as well as the mechanical life, one example of this sport as a social factor in controlling and curing a lot of social difficulties and injuries. According to scientists healthy and routine physical activities not only prevent and cure diseases, they are cheap and useful instruments in controlling stress, depression and...
aggression of present life 17

Methodology

Study Design: A cross-sectional descriptive study

Attitudes of Secondary School Students toward Health Promotion Behaviors in Al-Hilla City. Randomly sample of (177) students from secondary schools were selected. All of these adolescent measured by their weight, height, body mass index. The content credibility of the instrument was estimated through a panel of (14) experts, the stability of the items was based on the internal consistency of the questionnaire was evaluated by calculating Alpha Cronbach’ which as= 0.79. Data analysis: Through the used descriptive statistical (SPSS) version 24 analysis approach that includes, frequencies, percentages, mean of scores, standard deviation.

This table describe the weight status according the body mass index categories. (67.8%) of adolescents have normal weight status, (15.8) of them have underweight, (12.4%) of them have overweight and only (4%) of them were obese. The adolescents have a positive attitude when response to the items of the nutritional domains and the total mean was (2.34) at positive attitude of assessment. According to the social support domain, they have a positive attitude and the total mean was (2.37). According to the health responsibility domain, they have a positive attitude and the total mean was (2.36). According to the Life appreciation domain, they have a positive attitude and the total mean was (2.68). According to the exercise domain, they have a neutral attitude and the total mean was (2.22). According to the Stress management domain, they have a positive attitude and the total mean was (2.44). Finally the grand mean of all the domains was (2.4) and that indicate the adolescents had a positive attitude toward health promotion behaviors according to the level of assessment.

Discussion of the Study Results

Distribution of the Students by their Body Mass Index

In respect to the Body Mass Index results indicated that mostly participants have normal weight status, and only few of them reported as obese. The body built and weight abnormalities either low or high is considered nowadays the subject of concern because of its seriousness and this documented by so many agencies especially when it affect this age group due to the future effects and outcomes. This result disagreed with the findings of 1 they found that the prevalence of obesity was 21.3% and 22.3% respectively among adolescents’ students.

Part-3-Adolescent’s Attitudes toward Health Promotion Behaviors: Concerning the nutritional behaviors of the students, a positive nutritional attitudes were found. Most of students agree about eating three meals daily and snacks, choosing foods without too much oil, include dietary fiber (e.g. Fruits or vegetables), Drink at least 1500 cc of water daily (or 6-8 cups), Each meal includes five food groups (bread, meat, milk, fruit and vegetable) and eat breakfast daily. Kollatage et al., (2011) supported our findings, they found 83.2% of the respondents eating regular breakfast, and 62.6% have regular light lunch.

In regard to the social support behavior domain of the students, they believe in the social support behavior positively according to the mean (2.37). Most of students agree about speaking up and sharing feelings with others, caring about other people, talking about concerns with others, make an effort to smile or laugh every day, enjoy keeping in touch with relatives, make an effort to have good friendships and disagree with talking about troubles to others. 3 clarified that students reported a high scores when response to social support scale.

According to the present study, the health responsibility behavior of the students, and according to their answers shows positive healthy responsibility behavior at the mean (2.36). Most of students agree
about read food labels when shopping, watching weight, discuss health concerns with a doctor or nurse, observe body at least monthly, brushing teeth and using dental floss after meals, wash hands before meals, read health information and make an effort to choose foods without preservatives. Those vital results are supported by 4 who identified that high percentage of students gained high scores at healthy responsibility behaviors.

The same table demonstrated the attitude regarding the life appreciation behavior of the students, results show a positive attitude mean (2.68). Most of students agree about make an effort to like myself, make an effort to feel happy and content, usually think positively, make an effort to understand strengths weaknesses and accept them, make an attempt to correct the defects, make an effort to know what’s important for the human, make an effort to feel interesting and challenged every day and make an effort to believe that life has purpose. The present results supported by 6 when they revealed that students had high total scores when response to life appreciation scale. Concerning the exercise behavior of the students, they have neutral attitude toward exercise behavior. Most of students partially agree about perform stretching exercise daily, also they are agree about exercising rigorously 30 minutes at least 3 times per week, participating in physical fitness class at school weekly, warm up before rigorous exercise and make an effort to stand or sit up straight. Keskin et al., (2017) supported the findings of the present study, they found that a large number of the students (63.9%) had a habit of doing sports regularly and the number of students who practice sports in a sports club is considerably high (43.8%).

The stress management behavior of the students is another crucial domain, the present study findings revealed that mean of scores of attitudes show positive result. This may be due to social and cultural relationships, students agree about most of the items. Such as make an effort to spend time daily for relaxation, make an effort to determine the source of stress, make an effort to watch mood changes, sleep for 6–8 hours each night, make schedules and set priorities and try not to lose control when things happen that are unfair. The results came along with 4 who agreed that students had good stress management behavior.

**Conclusion**

1. Most of students aged at middle adolescence period, males more than females, majority of students were un married, at fourth grade, most of them were urban residence and ordered as 2nd member in the family, majority of them were not smoking and live with their parents.

2. Mostly their family’s income was insufficient, high percentage of student’s fathers education was bachelor degree and mothers had secondary school graduated, most of fathers were employer occupation and mothers were housewives.

3. Most of the students maintained normal weight status according to their BMI.

4. The students scored positive and neutral attitudes in most of the domains and sub-domains of the health promotion scale.

**Financial Disclosure:** There is no financial disclosure.

Investigation of \textit{mec} A and (\textit{tst-1}) Genes Among \textit{Staphylococcus aureus} Isolated from Skin Infection in Al-Diwaniyah Iraq

Rasool kadam-alheyawey\textsuperscript{1}, Ibtisam Habeeb Al-Azawi\textsuperscript{2}

\textsuperscript{1}M.Sc. Student, \textsuperscript{2}Assit. Prof. Dr., Department of Microbiology, College of Medicine University of Al-Qadisiyah, in Al-Diwaniyah Iraq

Abstract

In this study one handered and five samples were collected from skin infection in hospital Diwaniyah Dermatology Consultancy in Al-Diwaniyah governorate. from December 2018 to April 2019. All samples were cultured and Identified by using phenotyping tests. The results revealed that 41 isolates were \textit{Staph. spp.} and 30 Isolates out of them Diagnosed \textit{Staphylococcus aureus} by using (API staph). Virulence factors were explicated by using polymerase chain reaction (PCR) methicillin-resistant \textit{staphylococcus aureus} (MRSA), were identified by detecting (\textit{mec}A gene), which revealed that all skin infections were MRSA (100%). Also, toxic shock syndrome toxin (TSST) were identified by using PCR to detect (tst-1 gene 326 bp.), which revealed that 23 isolate were positive out of 30 isolate (76.33%).

Keywords: Investigation, \textit{mec} A and (\textit{tst-1}) Genes, \textit{Staphylococcus aureus}

Introduction

Many patients who are hospital reviewers suffer from Skin lesions and considered an important health problem \textsuperscript{1}. \textit{S.aureus} is one of the most important pathogens found in most places and also found naturally on human skin and is associated with a wide range of skin diseases The threat of this \textit{S. aureus} is its morbidity, which is the factor of virulence produced \textsuperscript{2}. The skin invasion of \textit{S.aureus} either an essential internal source or external source \textsuperscript{3}. The emergence of strains of \textit{S.aureus} resistant to antibiotics such as MRSA is a global problem in clinical medicine \textsuperscript{4}. Staphylococcal resistance to penicillin is mediated by producing penicillinase. Staphylococcal cassates chromosome mec (SCCmec) is a family of mobile genetic elements of \textit{S. aureus} \textsuperscript{5}. Resistance is given by the \textit{mec}A gene by a protein associated with penicillin (PBP2a or PBP2), which has less affinity for act with $\beta$-lactams; allowing resistance to all $\beta$-lactam antibiotics, this mobile gene component has been acquired by different strains in separate gene transfer events, indicating that there is no common ancestor for the different MRSA strains. \textsuperscript{6} Toxic shock syndrome is a condition caused by this bacterial toxins, the primary mechanism involves the production of high-contrast antigens during topical Staphylococcal infection. The progression of the disease arises from superantigen toxin that activating multicellular T cells \textsuperscript{7}.

Material and Method

The study was conducted on patients with skin lesion caused by \textit{Staphylococcus aureus} in Al-Diwaniyah city / Iraq / 2019 and collected 105 samples included male and female. Patients (children, young and adults) range in age from 1 to 60 years in AL-Diwaniyah Teaching Hospital.

Isolation and Identification:

One handered and five samples were collected through a questionnaire (name, sex, age,) from skin lesion by transport media swab, then cultured on conventional media (blood agar, mannitol salt agar). This dishes were incubated at 37 °C for 18-24 and 48 h respectively, and diagnosed by biochemical testing. The diagnosis were isolates basis on phenotypic, catalase, oxidase, and coagulase. These isolates were recognized based on common biochemical tests. (API Staph), that differentiate between species belonging to staphylococcal \textsuperscript{8}.

Discussion

The most commonly utilized antimicrobial substances in present clinical treatment procedures are β-lactams with intervention that includes inhibition of the last phase of the synthesis of bacterial cell-wall. These medicines have a smooth bactericidal with time-relied activities. They usually have excellent via-blood dissemination and little toxicity. Changes in the initial molecule resulted to the introduction of new substances with a wider antimicrobial action profile; however, in certain clinical environments, the use and effectiveness of beta-lactams are restricted because of increased bacterial resistance against those drugs 10.

Resistance to β-lactams can be induced by various genes; however, the most well-known worldwide distributed gene is mecA. The staphylococcal cassette chromosome has a gene called mecA which codes for PBP that is responsible of resistance against β-lactam antibiotics 11.

The action of the PBPs is manifested by their enzymatic activities due to inhibition-binding to β-lactams which results in destruction in the β-lactam chemical action properties. The PBP binding to β-lactams is occurred via the similarity present between the chemical structure of β-lactams and the chemical structure of the backbone of the sugar-amino acid that is an important part of the peptidoglycan 12.

Resistance via the presence of mecA can be induced due to random use of antibiotics in various clinical conditions; however, resistance to certain antibiotics due to this gene were found to occur even with no previously exposure to those antibiotics 13 suggesting different means by which bacterial species can acquire such genetic resistance. One of the most important tools that bacteria employ to receive resistance is horizontal genetic transferr (HGT). Bitrus et al., 14 have recognized that mecA gene can be transmitted from methicillin resistant S. aureus to susceptible strains via HGT, and this confirms that resistance can be present even with no previous history use of certain antibiotics. S. aureus can generate pathogenicity by employing various bacterial techniques; however, it can enhance potential damages to human body via harboring important genes such as toxic shock syndrome toxin (tst-1) gene. The work of this gene is recognized by its coding for an extracellular toxin that induce toxic shock syndrome. The health condition is characterized by the presence of severe symptoms such as fever, hypotension, rash, and malfunctioning of some body organs. In infants, TSS can generate Kawasaki syndrome, TSS-like exanthematos disease, and sudden infant death syndrome. The nowadays-reports refer to increasing the worldwide distribution of the tst-1 gene to even higher levels than the already known elevated spreading 15. It has been found that this gene has genetic variations which might suggest different virulence levels 16.

Medical Physiology, 2MBChB,FIBMS- Neurosurgeon/ Hilla Teaching Hospital Neurosurgical department, 3Prof. Dr., Medical physics /Medical College /University of Babylon, 4MBChB,FIBMS Assistant Prof. In Neurology Medical College/University of Babylon, 5MBChB,MSc.PhD, Prof. Neurophysiology. Head of Physiology and Medical Physics Department at Medical College /University of Babylon and Director of Neurophysiological center in Merjan Teaching Hospital/Iraq

Abstract

This study was a case/control study in which a total of (450) subjects, into (150) with primary headache ( male and female) and this was included in this study, 128 with migraine headache, 22 with non-migraine headache and 300 were normal, as control group. The electrophysiological tests were done at the neurophysiology unit of Mirjan Teaching hospital in Babylon City, during the period from 28 / October/ 2014 until 22 / May/2015. This study reveals that involvement of the migraine are more than that of the non-migraine in headache patients when compared with control group and when compared between the migraine and non-migraine headache patients. The most common EEG changes in headaches patients were diffuse slowing and spike wave of back ground activity, in such a way that 54 (42.2%) migraine patients had abnormal EEG changes, in comparison to 4 (18.2%) of non-migraine patients. Visual evoked potential (VEP) was dependable marker for central nervous system affection in primary headache (migraine and non-migraine ) and the most common abnormalities were prolonged latency and amplitude is stay in normal ranged (5-10) µ.volt.

Keywords: EEG, VEP, migraine headache, non-migraine headache.

Introduction

Headache is defined as a pain arising from the head or upper neck of the body. The pain originates from the tissues and structures that surround the brain because the brain itself has no nerves that give rise to the sensation of pain (pain fibers) 1 . Headaches can radiate across the head from a central point or have a pincering vise-like quality. They can be sharp, throbbing or dull, appear gradually or suddenly and last for multiple days or less than an hour 2.

All headaches are considered primary headaches or secondary headaches. Primary headaches are not associated with other diseases. Examples of primary headaches are migraine headaches Typically the headache affects one half of the head, is pulsating in nature, and lasts from 2 to 72 hours. Associated symptoms may include nausea, vomiting, and sensitivity to light, sound, or smell. The pain is generally made worse by physical activity 3.

Migraines are believed to be due to a mixture of environmental and genetic factors. About two-thirds of cases run in families. Changing hormone levels may also play a role, as migraines affect slightly more boys than girls before puberty, but about two to three times more women than men (4,5). The risk of migraines usually decreases during pregnancy.

Subjects And Methods:

This study was carried out through the period from October 2014 to May 2015, In the brain alone planning and optic nerve, as well as in consultation nervous in Mirjan Hospital in the city of Babylon. By using the history, as a cross section observational study, we select (150) patients with primary headache, in addition to (300) healthy control subjects, underwent EEG and VEP study with age and sex matched healthy control group
should be selected for this study. All of them met the criteria of episodic headache (migraine with, without aura & non migraine) according to the international classification of headache disorder.

Subjects:

Two groups of subjects were studied:

The control group:

This group comprised thirty hundred healthy volunteers, (135 males and 165 females) ranging in age from (9 to 67) years, with a mean age of (30.40±7.38) years.

The patients group:

One hundred and fifty headache patients were selected all types of primary headache in Mirjan Teaching Hospital, they were (43 males and 107 females) ranging in age from (7 to 69) years with a mean age of (31.23±12.38) year.

Methods:

All the subjects were approved for:

- Electrophysiological tests:
  - Visual evoked potential (VEP).
  - Electroencephalography (EEG).

Visual Evoked Potentials (VEPs) Study:

Visual Evoked Potential test was carried out in a dark, quite room, with the subjects sitting comfortably on a chair and advised not to move or blink continuously during the test in order to decrease muscle contraction artifacts from eyes and skeletal muscles which blur the evoked potential waves, thus it is of paramount importance to avoid such artifact.

Instrumentation:

Using in this study Evoked Potential machine, serial no.GH 17 H9NW315431B, model 171S, (Italy) was used for electrophysiological analysis of the VEP using the VEP program. The VEP system include four channel preamplifiers which are connected to plasma screen as a photo-stimulator source.

Procedure:

Recording Visual Evoked Potentials:

The subject is call him to sit on the chair while made recording and told him to see in same level of the red point sited in the center of the screen, and the space between his state and the screen is fixed at rate equal to 100 cm.

The patient should asked him to cleaning and lesser his hair then asked him to sleep on the bed then begin applying gel on the surface of electrodes (to made skin impedance slighter) on the subsequent positions: on the right side from the beside of the head and about five centimeters from frontal side placed the three electrodes (F7,T3,T5), in the anther side(left side) placed the three other electrodes (F8,T4,T6), and then placed the five electrodes from the right side also, in frontal side (Fp1,F3,C3,P3,O1), and then placed the five electrodes from left frontal side (Fp2,F4,C4,P4,O2). At the end all of these electrodes were connected to the referential inputs by electrode cables.

Stimulation:

The full-field checkerboard pattern reversal (black and white checkerboard pattern), displaying at a rate of 3.5 reversals/second (Hz). Mean luminance of the screen was fixed at 60-cd/m and contrast level of 100%. With visual angle of 16 (degrees) subtended by the stimulus field. The checkerboard size was selected according to the visual acuity of the subject between 60-90 (minutes). Each eye was stimulated separately by covering the other eye with a gauze patch (Monocular testing). VEP tests were filtered and amplified by the VEP computer program, and averaged of 200 runs according to response clearance. The amplifier bandwidth was 0.1 – 100 Hz, with amplifier sensitivity of 2 µV and sweep speed of 500 msec/Div. Two series of examination of each eye were done to ensure reproducibility of the traces and results of VEP. During the test, the fixation point of the eye was kept on a target on the center of the screen (red dot), the subjects eye lids were fully opened to allow maximum amount of face and neck muscles, avoiding swallowing, moving tongue, speaking and frequent blinking, in order to minimize the artifacts during the
recording procedure.

**Electroencephalography (EEG) study:**

Electroneurodiagnostics is the study and recording of electrical activity in the brain and nervous system. Tests are performed by technologists who record information on paper or computer, and the results are then interpreted by a specially trained physician.

Brain cells continually send messages to each other that can be picked up as small electrical impulses on the scalp. The process of picking up and recording the impulses is known as an EEG.

The billions of nerve cells in your brain produce very small electrical signals that form patterns called brain waves. During an EEG, small electrodes and wires are attached to your head. The electrodes detect your brain waves and the EEG machine amplifies the signals and records them in a wave pattern on graph paper or a computer screen. A normal EEG means that you have a normal pattern of brain D wave activity. An abnormal reading means that abnormal patterns of brain activity are being produced and picked up.

**EEG Procedure:**

Electrical impulses in the brain are evaluated using an EEG. The test measures this electrical activity through several electrodes placed on your scalp. An electrode is a conductor through which an electric current can pass safely. The electrodes transfer information from your brain through wires to an amplifier and a machine that measures and records the data. The test is administered at a hospital, at your healthcare provider’s office, or at a laboratory by a specialized technician. The test usually involves the following steps:

You will be asked to lie down on your back in a reclining chair or on a bed. The technician will measure your head and use a pencil to mark where electrodes will be attached to your scalp. These spots are then scrubbed with a special cream that helps the electrodes get a high-quality reading.

**Results**

In this study, the overall mean age of patients with headache and control was (31.23±12.38) and (30.40±7.38) years old, respectively, the distribution of patients and control by sex, (28.7%) and (47.3%) of patients and control were males, as shown in the Figure 4.

In this study, the differences between patients with headache and control by EEG changes were significant differences between patients and control by EEG. Patients with headache were 30 times more likely to have an abnormal EEG, as shown in Table 1.

In this study, the differences of patients with headache types and control during hyperventilation and photic stimulation of EEG. 24%, 14.66%, 1%, 1%, as shown in Figure 5.

Table 2 shows the Mean Differences of VEP amplitude parameter by Patients with Headache and Control Groups. There were significant mean differences of VEP Amplitude RT and LT by study groups. Table 3 shows the Differences of Patients with Headache and Control Groups by VEP latency and waves morphology. There were significant differences of Patients with Headache and Control Groups by RT Latency Positive1, RT Latency Negative1, LT Latency Positive1, LT Latency Negative1, RT Latency Positive2, and wave morphology. Case group were 6, 2, 19, 3, 13 and 24 times to have abnormal right latency 1 positive and negative and left latency 1 positive and negative, right latency 2 positive and abnormal wave morphology, respectively.

In this study, the distribution of patients by types of headache (71.30%), (13.3%), (10.0%), (2.7%), (2.0%) and (0.7%) of the patients had migraine without aura, migraine with aura, tension headache, cluster headache, chronic headache and TAC headache, respectively, as shown in Figure 1.

In this study, the distribution of different EEG abnormalities in different types of migraine. Spike 25.96%, poly spike 12.96%, sharp 12.96%, slow 48.14%, as shown in Figure 2. In this study, we show the distribution of different EEG abnormalities in different types of Non-migraine. Spike 0.0%, poly spike 0.0%, sharp 4.54%, slow 13.63%, as shown in Figure 3.

Fig. 1: Distribution of Patients by types of Headache.

Fig. 2: The distribution of different EEG abnormalities in different types of migraine.

Fig. 3: The distribution of different EEG abnormalities in different types of non-migraine.
Discussion

Concerning the gender distribution, we have found that migraine is more common in females than males in different age groups at ratio of about 2.3:1. We found in figure (4) that female (47.30%) was susceptible to infected headache more than male (28.70%) in compared to control group. These findings are agreed with 20 who found females 2:1 for headache, as well as with other studies of 21 and also agreed with 22 who found that female to male ratio is about 3:1, but 23 found female to male ratio 3:2 , so that there is a significant preponderance in females over males, this may be attributed to hormonal changes that occur in females mainly estrogen 24. we found higher incidence of migraine without aura, then followed by migraine with aura, tension headache, cluster headache, chronic daily headache, trigeminal autonomic cephalgia (TAC). (66.0%), (13.3%), (10.0%), (2.7%), (2.0%) and (0.7%). This agreement with (Stephen L. Hauser, MD, 2006) who found Migraine without aura is more common than migraine with aura in our study group with ratio of 2:1.

Conclusion

This study stated that EEG, the significant abnormal findings in patients with migraine headaches are more than patients with non-migraine headaches. The abnormal EEG findings in migraine patients were found mainly during hyperventilation and photic stimulation. Epileptic discharge were found in about of the whole migraine patients represented by spike and wave, polyspike and sharp waves respectively, 25.69%, 12.69%, 12.69%. In VEP, regarding the latency of P75, N100 and P 145 there were significantly higher in patients with headache in compared to the control group, while there were significant changes related to the amplitude, but stay in normal range.

Abstract

Objectives: The study objectives to detect the effect of angioplasty upon lung functions among patients with ischemic heart disease and to find out the relationship between the patients lung functions and their demographic and clinical characteristics.

Methodology: A descriptive (correlation) design was conducted on the Al-Najaf center for cardiac surgery and catheterization. Starting from 1st April 2019 to 1st October 2019. In order to detect the effect of angioplasty on lung functions among patients with ischemic heart disease. A non-probability (purposive) sample of (52) patients, those who admitted to angioplasty unit and coronary care unit without any respiratory diseases. Patients were ischemic heart disease. The patients’ demographic and clinical data collected through the utilization the semi-structured questionnaire and by means of interview technique with the subject, while the pulmonary functions test collected by using spirometer instrument. Data was analyzed by using descriptive statistic (percentage and Frequencies) and inferential (person’s correlation coefficient, independent sample t-test, and paired t-test).

Results: The results shows that there is a high significant relationship between the pulmonary functions pre and post cardiac catheterization, and most the patients with low PFTs post angioplasty.

Conclusions: The present study recommended the nurses whose work at the open Heart Center should teach the patient undergoing cardiac catheterization breathing exercises to increase the lung capacity as particular and the respiratory system as general and the patient should be given oxygen for at least 60 minutes before and after cardiac catheterization to ensure an increase in the oxygen level and perfusion in the body tissues.

Keywords: Percutaneous Coronary Intervention, Patients, Ischemic Heart Disease.

Introduction

Ischemic heart disease it is the most common cause of death in most western countries. Ischemia means a “reduced blood supply”. The coronary arteries supply blood to the heart muscle and no alternative blood supply exists, so a blockage in the coronary arteries reduces the supply of blood to heart muscle. The vascular narrowing or closure is predominantly caused by the covering of atheromatous plaques within the wall of the artery rupturing, in turn leading to a heart attack (Heart attacks caused by just artery narrowing are rare). A heart attack causes damage to heart muscle by cutting off its blood supply. Most ischemic heart disease is caused...
functions. Analgesics and sedatives in combination may impair the patient also leads to major changes in pulmonary changes in rib cage and hemodynamics. The posture of sedation agent impairs pulmonary functions by the capacity and by changes in lung mechanics. Induction alveoli. This is maintained by utilizing ventilatory reserve bypass grafting. The primary task of the lungs is to maintain oxygenation of the blood and eliminate carbon dioxide through the network of capillaries alongside alveoli. This is maintained by utilizing ventilatory reserve capacity and by changes in lung mechanics. Induction of sedation agent impairs pulmonary functions by the impaired level of consciousness, depression of reflexes, changes in rib cage and hemodynamics. The posture of the patient also leads to major changes in pulmonary functions. Analgesics and sedatives in combination may exacerbate the effects. Many studies have shown the associations of reduced lung function with future risk of mortality, respiratory outcome, and cardiovascular outcomes. In current practice, forced expiratory volume in 1 s (FEV₁) is considered to be abnormal when it is lower than –2 standard deviations from the population mean for age, height, and sex. However, there is little data on whether mild abnormalities in lung function, within clinically normal range, are associated with similar increases in poor health outcomes. Furthermore, it was found that pulmonary impairment is more frequent after cardiac surgery and major cardiac procedures. Deterioration in pulmonary function is a common complication following CABG surgery and there is still speculation to the precise causative factors thereof.

**Methodology**

A descriptive correlation design was conducted at Al-Najaf center for cardiac surgery and catheterization. Starting from 1st April 2019 to 1 October 2019. In order to detect the effect of Percutaneous Coronary Intervention (PCI) on lung function among of patient with ischemic heart disease and find out the relationship between the patient lung function and their demographic and clinical characteristics. An official permission is approval is issued from the Ministry of Health/AL-Najaf Health Directorate \ Al-Najaf center for cardiac surgery and catheterization. The study is conducted at Al-Najaf center for cardiac surgery and catheterization. A non-probability (purposive) sample of (52) patients, those who admitted to angioplasty unit and coronary care unit without any respiratory diseases. Patients were ischemic heart disease. The pulmonary functions measures for each patients’ sample pre-angioplasty and post-angioplasty. Questionnaire form was developed by the researcher to obtain appropriate answers which including Part I: demographical data include: (age, gender, smoke, occupation, residency, weight, height, body mass index), Part II: clinical data include : (diagnosis, duration, and chronic disease), and Part III: include items about pulmonary function as following: forced vital capacity (The volume of air that can be maximally forcefully exhaled), forced expiration volume (volume that has been exhaled at the end of the first second of forced expiration), peak expiration flow rate (It is the peak flow rate during expiration) and this measures by spirometer is an apparatus for measuring the volume of air inspired and expired by the lungs. It measures ventilation, the movement of air into and out of the lungs. Spirometer is the mainly piece of equipment used for basic pulmonary function tests, measuring lung function, specifically the amount and speed of air that can be inhaled and exhaled. Spirometer with flow
volume loops assesses the mechanical properties of the respiratory system by measuring the expiratory volumes and flow rates. This test requires the patient to make a maximal inspiratory & expiratory effort. The patient in a sitting position breathes into a mouth piece and nose clips are placed to prevent air leak. It is essential that the patient gives full effort during testing. In this study the pulmonary function test was made to each patient before entering the operating room and after leaving the operating room to comparison between two results depending on the forced vital capacity, forced expiratory volume, and peak expiratory flow. At each assessment time, spirometer was performed at least three times to be able to meet the criteria of the European Respiratory Society (ERS). The validity of an instrument concerns its ability to gather the data that it is intended to gather. Content validity for the early developed instrument is determined through the use of panel of experts (who have more than 5 years of experience at their jobs field). A preliminary copy of the questionnaire was designed and presented to (6) experts. The data were interred into Spss (version 22) in order to describe the statistical results as follow (Frequency distribution, Bar chart, and independent t-test).

*PEF= peak expiratory flow (PEF), FVC= Forced expiratory volume, FEV= Forced expiratory volume, St. dev.= standard deviation, df= degree of freedom, p-value= probability value, HS= highly significant, NS= non-significant.

This table indicates that there is high significant difference for the pulmonary functions pre and post cardiac catheterization at p value (0.05).

![Figure (4) mean difference of patients’ lungs capacities pre and post procedure](image)

**Discussion**

The primary function of the lungs is to provide an adequate gas exchange for maintaining normal oxygen content in blood and eliminate carbon dioxide. This is achieved by optimizing lung volumes to meet higher metabolic demand during the peri-operative period. The factors affecting pulmonary function include loss of consciousness, mode of ventilation (spontaneous or mechanical), posture of patient, actions of anesthetic agents and drugs, used during anesthesia on respiratory smooth muscles and secretions. This study was made to describe the PFTs complications as result cardiac disease and cardiac surgery and procedures and to detect...
the underlying causative factors. Spirometer test had been used as it is an objective, valid and reliable method to measure the PFTs. In addition, it is a non-invasive method that can be handled without any inconvenience to the patient especially after surgery Handojo et al. (2006) agreed with that with present study. In the table (1) and (2); the most of patient are within the age interval 50 and more years old (71%), (80.8%) were male, and the majority group of the study sample within the hypertension (61.5%). The study done by Nozari and Khazaeipour, (2012); their study results showed that the Mean age of men was 58±8.37 (35-75) years, and (48.69%) with history of hypertension. Asimakopoulos et al, (2005) reported that the range of age for patients underwent CABG procedure was between 55 to 75 years old. While other study has reported the mean of age was 57.6 years old (Reents, 2014). Marshal et Al., (2019) mentioned that the mean of age of all participants was 57.6 ± 4.6 years old. In this study, men were noted in 22 patients (62.9%) compared to 13 (37.1%) women. Majority of patients underwent CABG is men with comparison of 80% to 20% between men and women. Furthermore; table 3 & table 4 distinguished that there is high significant difference for the pulmonary functions pre and post coronary angioplasty. Which nearly similar to the results of the study done by Arabaci et al., (2003) found that after PCI the PFTs values decreased significantly in smokers and non-smokers patients but the deterioration in the smoker group was highly significant. In their study, patients in both groups developed a severe restrictive pulmonary defect after coronary artery catheterization (P< 0.0001 for both), but this restriction was also statistically significant in the smoking group compared to non-smokers after surgery. They applied comparison t-test between the smokers and non-smokers but did not correlate the factor of smoking habit with the pulmonary function as had been done in the current study. Önemlidir, (2018) claimed that the respiratory functions affecting morbidity and mortality in open heart surgery are the most important preoperative risk factors. After cardiopulmonary bypass, pulmonary function tests, especially in FEV1 and FVC, are reduced by 60-70 %. Impaired respiratory functions return to normal after 3-4 months. In addition to the poor pulmonary gas exchange it produces after cardiac catheterization. Chandra et al. (2006) found a significant deterioration in the pre discharge Spiro-metric values of FVC, FEV1, peak expiratory flow rate, flow rate at 25–75% of expired vital capacity.

**Conclusion**

The researchers are concluded that PCI and IHD result in low PFTs values of restrictive pattern. This study is documented that the patients post coronary angioplasty had lower PFTs values than pre coronary angioplasty. No definite causative factor appeared to be responsible for those results although mechanical deficiency. More comprehensive investigation is required to resolve the case.

The Role of Fractional CO₂ Laser in Treatment of Keloid and Hypertrophic Scar used Alone and in Combination with Intralesional Steroids

Nadia H. Sahib¹, Mohammed K. Al-hattab², Fatin Ahmed Fakhry³, Ihsan Jara Atiyah⁴

¹ Lecturer, ² Prof. Dr., ³ Bachelor of Medicine, University of Babylon – Hammurabi Medical College, ⁴ Iraqi Board for Medical Specializations, Imam Al-Sadiq Teaching Hospital

Abstract

Background: The hypertrophic and keloid scars are thick, raised, disfiguring areas of skin with abnormal prolonged inflammatory response of wound healing process and overproduction of collagen. Carbon dioxide (CO₂) laser has been used in the treatment of hypertrophic scar and keloids for more than 20 years.

Aim of Study: To evaluate the effect of (CO₂) laser in treatment of keloid and hypertrophic scar with use of intralesional triamcinolone acetonide (kenacort) 40 mg/ml as adjuvant therapy.

Methodology: The study was done on 22 patients in Imam al-Sadiq teaching hospital in Hilla city with dividing the patients randomly into two groups, one group treated with four sessions of intralesional corticosteroids and the second group treated with four sessions of intralesional corticosteroids with carbon dioxide laser.

Keywords: Hypertrophic scar, Keloid scar, CO₂ laser, Corticosteroid.

Introduction

The scar is an area of fibrous tissue that replace the normal skin tissue after an injury. Deregulation of the process of wound healing that is complex, regulated response to the injury leads to development of scar. Despite both hypertrophic and keloid scar are common but the keloid scar is more challenging to treatment and may have significant physical and psychological impacts on patients life. The scar biology is less well understood till now and search for the ideal treatment still continues and despite the different types of treatments including radiation, pressure therapy, cryotherapy, intralesional steroid or interferone, topical silicon and many other lines of treatment, no one is 100% curative as the first line treatment. Parameters that used to assess the scar clinically involve scar colour, blood flow, erythema, itching, skin hardness, extension beyond the wound margin and healing spontaneously. Hypertrophic scar is more common than keloid. Its erythematous, itchy, elevated lesion and less nodular than keloid scar and it is not extend beyond the wound margin and may heal alone and its size depends on the size and depth of the original wound. The origin of word keloid from the Greek word Chele which means pincers of crab, the suffix oid means like, so it called keloid because it grows in pincers of crab like lesion. Keloid scars are erythematous, nodular lesions extend beyond the margin of the injured site and not regress spontaneously. The pathogenesis of keloids involve hyperproliferative state due to abnormal molecular and cellular driving with four folds decrease in cell apoptosis and increase in survival marker AKT. Keloid scar may develop due to trauma, burn, injury or spontaneously as reported in patients with bethlem myopathy due to mutation in collagen type four. Hypertrophic scar results from injury, burn, surgery and unlike keloid scar, it is more linear in nature and within the wound margins. Keloid is a dermal lesion with excessive collagen and glycosaminoglycan around the wound with increase tissue growth factor B1 and the studies show increase in the incidence of keloid in patients who receive tissue growth factor B1 treatment and decrease incidence in those who receive anti tissue growth factor B1. Keloid is common in young
black female as polypoidal, glistening hairless nodule with different size and by histology it composed of irregularly arranged thick, large collagen fibers, increase elastic tissue in dermis, no involvement of epidermis or papillary dermis and normal number of fibroblast cells while in hypertrophic scar there is fine collagen fibers parallel to epidermis, absent elastic tissue in dermis and flat epidermis.  

Carbon dioxide laser to be developed and is still one of the useful types that used in resurfacing of skin, it exerts its effect by production of mid-infrared energy at primary band of (10,600 nm). It consist of mixture of carbon dioxide, nitrogen and helium. The rule of nitrogen is to increase efficiency by exciting the CO₂, causing more light emission while the helium allows the returning of CO₂ to the ground state and fostering heat transfer. The target of carbon dioxide laser involves the water content of the cell resulting in vaporization of intracellular water and ablation of cell, also it causes denaturation of collagen protein and collagen contraction and decrease to one third of its original length. The biochemical changes seen after laser resurfacing include increase in procollagen (1 and 3), increase in several cytokines like interleukin 1 beta, tumor necrosis factor alpha, transforming factor beta. Low complication rate had been seen with use of fractional CO₂ laser even after repeating it after (1-6) minutes but the complication rate increase with 3 concurrent treatments of multiple body locations. Laser safety must be taken seriously because of the combination of high output power and an invisible beam with high voltage supplies cause real risk of heart damage from the direct or reflected beam more to anterior structure of eye including cornea, lens, vitrous body but unlikely to reach to retina.

Clinical features hypertrophic and keloid scars regarding colour, site and size were shown in table (1) and figure (1).

### Table (1): Features of scar.

The goal of study to measure the results of use fractional CO₂ laser followed by intralesional triamcinolone acetonide (kenacort), 40 mg/ml in one group of hypertrophic scar patients and to compare it with another group of patients used intralesional steroid injection alone. The duration of treatment was every month sessions with a total course of 4 months. Each patient subjected to topical anaesthetic gel by topical lidocaine 8% for (0.5-1) hour before starting laser and intralesional steroid injection. Fractional CO₂ laser parameters used for patients in the study regarding wavelength, power and pulse duration.

The energy used by CO₂ laser depending on the site of hypertrophic scar, and depth of ablation (µm) was shown in table (2). Regarding the combination treatment group, five minutes after the completion of CO₂ laser session, intralesional steroid was injected until blanching of scar was happened.

### Table (2): Energy used for different sites.

After the sessions of laser, ice packs were put on the lesions for (5-10) minutes, patients also instructed to use moisturising cream (Arden healing and soothing cream) twice/day to prevent development of erythema and swelling following laser therapy.

Three blinded observers evaluated photographs taken both at baseline and at 4 months following the final session. Photographs were obtained using (I phone high resolution camera). The observers determined which photograph was before and after. They evaluated the improvement in the appearance and degree of hypertrophy.

![Figure (1): Number of patients according to cause of scar.](image1)

![Figure (2): Site of scar and laser energy used for each site.](image2)

The degree of improvement was utilised according to the following 4-point scale:

- Improvement for < 25% was 0
- Improvement for 25-50% was 1
- Improvement for 50-75% was 2
- Improvement for > 75% was 3

In our study, mild response to treatment considered if degree of improvement < 25 % , moderate response to treatment if degree of improvement for 25-75% and a good response if degree of improvement > 75% .

**Results**

A total 22 patients with hypertrophic scars and keloids were exposed to treatment by fractional CO₂ laser therapy in combination with intralesional steroid and with intralesional steroid alone. There was 13 males and 9 females , their age ranged from (14 – 37) years , the duration of the scar ranged from 6 months – 20 years .The patient were divided into two equal groups. The first group (11 patients; seven males and four females ) received combination therapy with CO₂ laser and intralesional steroid, the second group (11 patients, six males and five females) received intralesional steroid alone. Every patient in each group subjected to four
sessions every month.

The overall average improvement score including hypertrophy, texture and colour improvement for both treatment groups was seen in figure (3). Three blinded investigators were determined at four months post treatment.

![Figure (3): Average general improvement score as determined by investigators.](image)

Average general score assessed by the 4 blinded observes for first group was 2.8 corresponding to (2- 3) scale. The highest average improvement score was 3 which seen in 7 of 11 patients figure (4).

![Figure (4): The score of improvement as resolved by three investigators at four months post treatment.](image)

The overall average improvement score for the second group (intralesional steroid alone).

The highest average overall improve score was 2.5 which was seen in 2 of 11 patients.

Treatment was tolerable by patients and no adverse effects were reported except mild pain and transient erythema in some patients immediately after treatment.

**Discussion**

Keloid and hypertrophic scar are improper body responses to trauma resulting in itchy, painful nodular lesion that may cause serious functional and cosmetic disability. Different lines of treatments have been used for both keloid and hypertrophic scars, among them are: surgical excision with or without grafting, pressure therapy, interferon, topical and local corticosteroid, local injection of bleomycin, laser therapy, silicone gel sheeting, onion extract gel and other therapies directed at collagen synthesis. Corticosteroid was used for the treatment of pathological scars since the mid-1960s, still have major rule in the regression of hypertrophic scars and keloids. Although there are multiple lines of
treatment of scar but still some of patient not response well to any one of these lines completely and no one of them was 100% curative, make the search for new treatment continue 23.

Steroid injections have been shown to cause regression in scar by its anti-inflammatory effect, increase tissue hypoxia and decrease fibroblast this lead to decrease synthesis of collagen and glycosaminoglycan 24. The most common steroid that used in treatment of scar is triamcinolone acetonide (10-40 mg /ml) alone or with lidocaine to decrease pain, once or twice monthly sessions are required for treatment 25.

Despite the few randomized, prospective studies, the intrallesional steroid represent the first line therapy for keloid scar and second line therapy for hypertrophic with response rate 50-100% and recurrence rate 9-50% 26.

Manuskuatti and Fitzpatrick showed that the use of intrallesional steroid with contratubex together are more effective than steroid alone in treating hypertrophic and keloid scar with lower side effects 27.

Recent advance in laser application provide another option in treating scar with fractional ablative laser that produce zone of ablation with different depth followed by wound healing process leading to collagen remodelling also remove the fibrotic tissue. This application also used postoperative to enhance delivery of the drug and other substance.

The result of our study indicated that the combination same - session treatment with both fractional carbon dioxide laser and intrallesional steroid in treatment of hypertrophic and keloid scar was more effective and efficient than intrallesional steroid alone. Various aspects of scar parameters like texture and hypertrophy were improved with this treatment.

**Conclusion**

The combination of same-session treatment with fractional carbon dioxide laser and intrallesional steroid produce an efficient and more effective therapy in treatment of hypertrophic and keloid scars.

Isolation, Amplification Approaches of Human Pokemon gene (ZBTB7) and Incorporation into Yeast Vector

Nawal Kadem Mohammed

Assist. Lecturer, Ministry of Education, Directorate of Education, Iraq

Abstract

The transcription repressor protein ZBTB7 (FB11, BTB-ZF protein LRF) known as a Pokemon is critical factor in oncogenesis which is encoded by ZBTB7 gene. ZBTB7 processes by controlling the pathways that are required to transform normal cell to cancerous one. It produces its effects by repressing the function of other proteins including a tumor suppressor protein ARF leading to lymphomas and other oncogenic effects and present in very high level in certain type of B cell. So the structural study of the translation product of this gene is an important task to know about the carcinoferous effect of ZBTB7 along with their interactive pattern with co-repressor which prone transcription repression by stopping the activity of transcription factors. In the present project DNA binding domain of ZBTB7 gene’s cDNA is developed and cloned into suitable yeast vector.

Keywords: Isolation, amplification, Pokemon gene (ZBTB7), yeast vector

Introduction

Many cells normally undergo a programmed form of death (apoptosis). Activated oncogenes can cause those cells to survive and proliferate instead. Most oncogenes require an additional step, such as mutations in another gene, or environmental factors, such as viral infection, to cause cancer 1. The first oncogene was discovered in 1970 and was termed src (pronounced sarc as in sarcoma) 2. Src was in fact first discovered as an oncogene in a chicken retrovirus. Experiments performed by Dr G. Steve Martin of the University of California, Berkeley demonstrated that the SRC was indeed the oncogene of the virus. 3 In 1976 Drs. J. Michael Bishop and Harold E. Varmus of the University of California, San Francisco demonstrated that oncogenes were defective proto-oncogenes, found in many organisms including humans. For this discovery Bishop and Varmus were awarded the Nobel Prize in 1989. Since the 1970s, dozens of oncogenes have been identified in human cancer. Many cancer drugs target those DNA sequences and their products 4. Most, if not all, cancer cells contain genetic damage that appears to be the responsible event leading to tumorigenesis. The genetic damage present in a parental tumorigenic cell is maintained (i.e. not correctable) such that it is a heritable trait of all cells of subsequent generations. Genetic damage found in cancer cells is of two types:

1. Dominant and the genes have been termed proto-oncogenes. The distinction between the terms proto-oncogene and oncogene relates to the activity of the protein product of the gene. A proto-oncogene is a gene whose protein product has the capacity to induce cellular transformation given it sustains some genetic insult. An oncogene is a gene that has sustained some genetic damage and, therefore, produces a protein capable that were originally identified as resident in transforming retroviruses were initially designated as c–indicative of the cellular origin as opposed to of cellular transformation.

The process of activation of proto-oncogenes to oncogenes can include retroviral transduction or retroviral integration (see below), point mutations, insertion mutations, gene amplification, chromosomal translocation and/or protein-protein interactions.

Proto-oncogenes can be classified into many different groups based upon their normal function within cells or based upon sequence homology to other known proteins. As predicted, proto-oncogenes have been identified at all levels of the various signal transduction
cascades that control cell growth, proliferation and differentiation. The list of proto-oncogenes identified to date is too lengthy to include here, therefore, only those genes that have been highly characterized are described. Proto-oncogenes \( v \)- to signify original identification in retroviruses.

2. **Recessive** and the genes variously termed tumor suppressors, growth suppressors, recessive oncogenes or anti-oncogenes.

Given the complexity of inducing and regulating cellular growth, proliferation and differentiation, it was suspected for many years that genetic damage to genes encoding growth factors, growth factor receptors and/or the proteins of the various signal transduction cascades would lead to cellular transformation \(^5\). This suspicion has proven true with the identification of numerous genes, whose products function in cellular signaling, that are involved in some way in the genesis of the tumorigenic state. The majority of these proto-oncogenes were identified by either of two means: as the transforming genes (oncogenes) of transforming retroviruses or through transfection of DNA from tumor cell lines into non-transformed cell lines and screening for resultant tumorigenesis.

**Pokemon Linked to Aggressive Tumors**

The investigators have confirmed Pokémon’s cancer-causing role by inserting the oncogene into mice. Pokemon does its damage by repressing the function of other proteins, including a tumor suppressor called “ARF.”

The mice used developed aggressive, fatal forms of lymphoma. In further work, using a technique called “tissue micro arrays” to study tumor samples from people with many types of cancer, the researchers have confirmed that Pokemon is present in very high levels in certain types of B-cell and T-cell lymphomas. They also found that tumors with high levels of Pokemon protein were much more likely to be aggressive. \(^6\)

“Pokemon is a member of a family of proteins that are known to be transcription factors and are mutated in human cancer,” according Takahiro Maeda, MD, PhD, a postdoctoral research fellow in Dr. Pandolfi’s laboratory who was the paper’s first author. “It is likely that the protein plays a role in solid tumors as well, and we now have means to specifically interfere with the activity of these transcription factors.”

**Gene Amplification**

An example of gene amplification, which usually occurs during tumor progression, is the amplification of the dihydrofolate reductase gene (\( DHFR \)) in methotrexate-resistant acute lymphoblastic leukemia. Amplification of \( DHFR \) is accompanied by cytogenetic alterations that mirror amplification of oncogenes. The amplified DNA segment usually involves several hundred kilobases and can contain many genes. Members of four different oncogene families are often amplified: MYC, cyclin D1 (or CCND1), EGFR, and RAS \(^7\). \( MYC \) is amplified in small-cell lung cancer, breast cancer, esophageal cancer, cervical cancer, ovarian cancer, and head and neck cancer, whereas amplification of \( NMYC \) correlates with an advanced tumor stage. The \( t(11;14) \) translocation juxtaposes \( CCND1 \) and immunoglobulin enhancer elements and is characteristic of mantle-cell lymphoma. \( CCND1 \) amplification also occurs in breast, esophageal, hepatocellular, and head and neck cancer. \( EGFR \) (\( ERBB1 \)) is amplified in glioblastoma and head and neck cancer. Amplification of \( ERBB2 \) (also called \( HER2/neu \)) in breast cancer correlates with a poor prognosis.\(^5\) A monoclonal antibody against the product of this oncogene (trastuzumab) is effective in breast cancers that overexpress \( HER2/neu \).

**Chromosomal Rearrangements**

Recurring chromosomal rearrangements are often detected in hematologic malignancies as well as in some solid tumors. These rearrangements consist mainly of chromosomal translocations and, less frequently, chromosomal inversions. Chromosomal rearrangements can lead to hematologic malignancy via two different mechanisms:

1. the transcriptional activation of protooncogenes or
2. the creation of fusion genes.

**Gene Activation**

The \( t(8;14)(q24;q32) \) translocation, found in about 85% of cases of
Burkitt lymphoma, is a well-characterized example of the transcriptional activation of a protooncogene. This chromosomal rearrangement places the \textit{c-myc} gene, located at chromosome band 8q24, under control of regulatory elements from the immunoglobulin heavy chain locus located at 14q32.98 The resulting transcriptional activation of \textit{c-myc}, which encodes a nuclear protein involved in the regulation of cell proliferation, plays a critical role in the development of Burkitt lymphoma. The \textit{c-myc} gene is also activated in some cases of Burkitt lymphoma by translocations involving immunoglobulin light-chain genes. These are t(2;8)(p12;q24), involving the \kappa locus located at 2p12, and t(8;22)(q24;q11), involving the \kappa locus at 22q11.

Although the position of the chromosomal breakpoints relative to the \textit{c-myc} gene may vary considerably in individual cases of Burkitt lymphoma,

**Gene Fusion**

The first example of gene fusion was discovered through the cloning of the breakpoint of the Philadelphia chromosome in chronic myelogenous leukemia (CML). The t(9;22)(q34;q11) translocation in CML fuses the \textit{c-abl} gene, normally located at 9q34, with the \textit{bcr} gene at 22q11 (Figure 6-7). The \textit{bcr/abl} fusion, created on the der(22) chromosome, encodes a chimeric protein of 210 kDa, with increased tyrosine kinase activity and abnormal cellular localization. The precise mechanism by which the \textit{bcr/abl} fusion protein contributes to the expansion of the neoplastic myeloid clone is not yet known. The t(9;22) translocation is also found in up to 20% of cases of acute lymphoblastic leukemia (ALL). In these cases, the breakpoint in the \textit{bcr} gene differs somewhat from that found in CML, resulting in a 185 kDa \textit{bcr/abl} fusion protein.

It is unclear at this time why the slightly smaller \textit{bcr/abl} fusion protein leads to such a large difference in neoplastic phenotype. In addition to \textit{c-abl}, two other genes encoding tyrosine kinases are involved in distinct gene fusion events in hematologic malignancy. The various partners in \textit{ALL1} fusions encode a diverse group of proteins, some of which appear to be nuclear proteins with DNA-binding motifs. The \textit{ALL1} fusion protein consists of the aminoterminus of one of a variety of fusion partners. It appears that the critical feature in all \textit{ALL1} fusions, including self-fusion, is the uncoupling of the \textit{ALL1} amino-terminal domains from the remainder of the \textit{ALL1} protein. Solid tumors, especially sarcomas, sometimes have consistent chromosomal translocations that correlate with specific histologic types of tumors. In general, translocations in solid tumors result in gene fusions that encode chimeric oncoproteins. Studies thus far indicate that in sarcomas, the majority of genes fused by translocations encode transcription factors. In myxoid liposarcomas, the t(12;16)(q13;p11) fuses the \textit{FUS} (\textit{TLS}) gene at 16p11 with the \textit{CHOP} gene at 12q13. The \textit{FUS} protein contains a transactivation domain that is contributed to the \textit{FUS/CHOP} fusion protein. The \textit{CHOP} protein, which is a dominant inhibitor of transcription, contributes a protein-binding domain and a presumptive DNA-binding domain to the fusion. Despite knowledge of these structural features, the mechanism of action of the \textit{FUS/CHOP} oncoproteins is not yet known.

**Oncogenes in Cancer Initiation and Progression**

When chronic myelogenous leukemia converts to acute leukemia, the malignant clone acquires an additional t(9;22) translocation, an isochromosome, or trisomy of chromosome 8. When follicular lymphoma becomes aggressive, the lymphoma cells often bear a t(8;14) translocation in addition to the original t(14;18) translocation. These findings support the hypothesis that most hematopoietic tumors and soft-tissue sarcomas are initiated by the activation of an oncogene, followed by alterations in tumor-suppressor genes and other oncogenes. In contrast, most carcinomas are initiated by the loss of function of a tumor-suppressor gene, followed by alterations in oncogenes and additional tumor-suppressor genes. This multistep process in human cancer has also been found in mouse models carrying activated oncogenes or inactivated tumor-suppressor genes, in which the duration and aggressiveness of the disease can be changed by introducing into the mouse genome the same sequential genetic alterations observed in human tumors. Methylation of \textit{CpG} islands located in the promoter regions of a number of tumor-suppressor genes has also been considered an important epigenetic step in the process of carcinogenesis. This topic will be covered later in this series.
Oncogenes as Therapeutic Targets

Oncogenic proteins in cancer cells can be targeted by small molecules and, when the oncogenic protein is expressed on the cell surface, by monoclonal antibodies. Table 1 contains a summary of the targets and drugs (small molecules and monoclonal antibodies) being used in the treatment of a variety of human cancers.

* EGFR denotes epidermal growth factor receptor, FLT3 FMS-like tyrosine kinase 3, PDGFR platelet-derived growth factor receptor, and VEGF vascular endothelial growth factor.

Imatinib targets the initial step of the multistep process in chronic myelogenous leukemia. The same drug can affect the KIT and PDGFR receptor kinases. Of particular interest are inhibitors of the BCL2 family, which can induce the apoptotic death of cancer cells. In acute promyelocytic leukemia, which is initiated by a t(15;17) chromosome translocation that fuses the PML gene to RARα (a nuclear receptor for retinoic acids; see Table 2 in the Supplementary Appendix), retinoic acid can induce terminal differentiation and death of APL cells. This modality is called differentiation therapy.

Materials and Method

DNA Preparation from Frozen Tissue

**Reagents**

- Chloroform
- EDTA, 0.5 M
- Ethanol, absolute
- Propanol
- Phosphate Buffered Saline (PBS), 1X
- Sodium dodecyl sulfate (SDS) solution, 10%
- DNA buffer (Tris-EDTA)
- 1 M Tris pH 8.0 20 ml
- 0.5 M EDTA 20 ml
- Sterile water 100 ml

**Procedure**

1. Put 5 mg of tissue in a petri dish with buffer and divide the tissue into pieces.
2. Take them in centrifuge tubes and keep it in 4°C
for 5 mins

3. Centrifuge for 2 min at 1500 rpm.

4. Remove the supernatant, and wash twice with 1 ml 1X PBS

5. (It is possible to store the pellet at -80°C; in that case, add 1 ml 1X PBS and resuspend the pellet)

6. Remove supernatant and resuspend the pellet in 2.06 ml DNA-buffer.

7. 25 μl 10% SDS, shake gently, and incubate overnight at 35°C temperature

8. If there are still some tissue pieces visible, add 20 μl of 10% SDS and incubate for another 5 hr at 45°C.

9. Add 2.4 ml of Propanol, shake by hand for 5-10 min, and centrifuge at 3000 rpm for 5 min.

10. Pipette the supernatant into a new tube, add 1.2 ml Propanol, and 1.2 ml chloroform shake by hand for 5-10 min, and centrifuge at 3000 rpm for 5 min.

11. Pipette the supernatant into a new tube, add 2.4 ml chloroform shake by hand for 5-10 min, and centrifuge at 3000 rpm for 5 min.

12. Pipette the supernatant into a new tube, add 25 μl 3 M sodium acetate (pH 5.2) and 5 ml ethanol, shake gently centrifuge it for DNA precipitates.

13. Wash the DNA in 70% ethanol and dry it.

14. Dissolve the DNA in 0.5-1 ml sterile water overnight at 4°C.

RESTRICTION DIGESTION OF YEAST VECTOR

- To the restriction enzyme containing vial, 25 μl of yeast plasmid is added.

- To the above tube, 25 μl of 2% assay buffer is added.

- The contents are mixed by tapping the vial for few seconds or briefly spinning at low speed in a micro-centrifuge.

- The vial was incubated in a 37°C water bath for 1 hour. After 1 hour the vial is removed from water bath and 10 μl of gel loading dye is added into the vial and kept on ice.

- 10 μl of λDNA from the vial containing only λDNA substrate is transferred into a fresh 1.5 ml appendorff tube.

- Now the sample in all the appendorff tubes is loaded in different wells of 1% agarose gel. When sample loading is over start the electrophoresis set up.

DNA ELECTROPHORESIS

- Measure 1 g Agarose powder and take it in a 500 ml flask.

- Add 100 ml TAE Buffer to the flask.

- Melt the agarose in a microwave or hot water bath until the solution becomes clear. (if using a microwave, heat the solution for several short intervals - only until the solution starts to boil).

- Let the solution cool to about 50-55°C, swirling the flask occasionally so it cools evenly.

- Place the combs in the gel casting tray.

- Pour the melted agarose solution into the casting tray and let cool until it is solid (it should appear milky white).

- Carefully pull out the combs.

- Place the gel in the electrophoresis chamber.

- Add enough TAE Buffer so that there is about 2-3 mm of buffer over the gel.

Loading the gel

- Add 10 μl of each sample to 2 μl of 6X Sample Loading Buffer (make sure the order in which each sample is loaded be recorded).

- Carefully pipette the mixture into separate wells in the gel.

- Pipette 5 μl of the DNA ladder standard into another well of the gel.

Running the gel

- Place the lid on the gel box, connecting the
· Connect the electrode wires to the power supply, making sure the positive (red) and negative (black) are correctly connected.

· Turn on the power supply and maintain around 100 volts.

· Check to make sure the current is running through the buffer by looking for bubble formation on each electrode.

· Check to make sure that the current is running in the correct direction by observing the movement of the blue loading dye – this will take a couple of minutes (it will run in the same direction as the DNA).

· Let the power run until the blue dye approaches the end of the gel.

· Turn off the power.

· Disconnect the wires from the power supply.

· Remove the lid of the electrophoresis chamber.

· Carefully remove the gel.

Abstract

Recurrent aphthous ulceration (RAU) is the most common oral mucosal disease which characterized by recurrent episodes of multiple or solitary painful ulcerations without association with systemic diseases. The objectives of our study were to investigate the relation of RAU to demographical, education level and smoking habit. The study was conducted on 120 patients, personal data (age, sex), site, level of education and smoking habit were taken. The results showed that females were affected more than males, the buccal mucosa and tongue (58 %, 24%) respectively were the most common site of occurrence. There was higher prevalence rate of RAU among patients with higher educational level (60%) and in non-smokers (93.3%).

Keywords: Risk factors, recurrent aphthous ulceration, patients

Introduction

Ulceration is one of the most common complaints of patients who attend seeking medical advice with an oral problem and the differential diagnosis is extensive. Ulcers of different causes may have very similar clinical appearance and a few important key questions in the history provide useful diagnostic clues ¹. A mouth ulcer, also termed an oral ulcer, or a mucosal ulcer, is an ulcer that occurs on the mucous membrane of the oral cavity. Mouth ulcers are very common, occurring in association with many diseases and by many different mechanisms, but usually there is no serious underlying cause ². The two most common causes of oral ulceration are local trauma (e.g. rubbing from a sharp edge on a filling) and aphthous stomatitis (“canker sores”), a condition characterized by recurrent formation of oral ulcers for largely unknown reasons ³. Mouth ulcers often cause pain and discomfort, and may alter the person’s choice of food while healing occurs (e.g. avoiding acidic or spicy foods and beverages). They may occur singly or multiple ulcers may occur at the same time (a “crop” of ulcers). Once formed, the ulcer may be maintained by inflammation and/or secondary infection. Rarely, a mouth ulcer that does not heal for many weeks may be a sign of oral cancer ⁴. Oral ulcerations prevalence is estimated 25% of the global population and thought to be affected by aphthous ulcers which is one of the most common causes of oral ulceration. In the UK, 20% of the population and 4% in USA. are believed to be affected by recurrent aphthous ulceration. Aphthous ulceration is more common in women those under the age of 40 and in non-smokers patients ⁵.

Aims of Study

The study has been done to investigate the most common risk factors of recurrent oral ulcers in relation to demographical data (Gender, age group), site, education level and smoking habit.

Patients & Method

The source of data is from out patients attending the private clinics and including patients referred from other specialties the study was conducted through the period 2018-2019. The number of cases were 120 of oral ulcers included in the study. The patients data are collected by taking history, detailed clinical examination and relevant investigations. Clinical diagnosis is confirmed by blood tests and biopsy for histopathological examination. The
patients aged between 10-70 years of both the sexes were included. All individuals underwent an interview in which they had to answer specific questions include personal data (age, sex), site of occurrence, smoking habit and family history and level of education [(level 0 (illiterate), level 1 (primary school), level 2 (secondary school), level 3 (university and postgraduate),

Statistical analysis was performed using SPSS program version 20. Associations between categorical variables were tested using chi-square test; Statistical significance was set at P < 0.05.

**Results**

The total number of patients were 120. The study conducted through the period 2018-2019. The age range of the patients was between 10-79 years, with mean age of (34.27). 56 (46.7%) of participants were males and 64 (53.3%) were females, with male/female ratios of 0.8:1. Patients were divided in to 7 age groups (10 years for each interval). Accordingly, more than half of patients 64 (53.3%) were in the 2nd and 3rd age group.

Approximately 60% of patients have positive family history of RAU.

Lips and buccal mucosae were the commonest sites of ulcerations (58.3%), followed by tongue (24%), floor of mouth (10.8%), gingiva and palate (5%).

Prevalence of RAU was increased as the level of education is increased (level 0=5.8%, level 1= 17.5%, level 2=21.6, level 3=55%).

In relation to smoking habit, the incidence of RAU was higher in non-smokers than in smokers. It was (93.3%) in non-smokers while (6.7%) in smokers.

**Discussion**

Epidemiological studies shown considerable variation in the prevalence of RAU among different regions throughout the world. The prevalence range among different populations has been documented as 5-66%.\(^6\) It was reported (25.2%) in Iran\(^{11}\), (25.5%) in Turkey\(^{12}\) and 17.7% in Sweden\(^7\) but lower than the prevalence reported in Jordan (5%)\(^8\). These variations could be explained due to the fact that different methodologies used (whether it is registered when the lesion is present, or it’s done through the clinical history\(^9\) socioeconomic level\(^{10}\), genetic predisposition, lifestyle of patients and stress\(^8\). In present study RAU was more common among females than males (p<0.004). Several other studies showed higher prevalence of RAU among females\(^8\). In relation to the female predisposition to RAU, some authors have suggested that this association is related to hormonal rates\(^{11}\). As a minority of women with RAU have cyclical oral ulceration related to the luteal phase of the menstrual cycle\(^{12}\) and also a decrease in its incidence during pregnancy, thus relating the episodes of RAU to progesterone levels\(^{13}\). On the contrary, Rivera-Hidalgo et al.\(^8\) found a higher prevalence of RAU among males, although without statistical significance. There is some evidence that the disease has a higher prevalence in younger adults, decreasing in both incidence and severity with age\(^{14}\). In this study, the most commonly affected age group was 20-29 years, the prevalence is decreasing as the age is increasing. This result is in accordance with the finding of Davatchi et al.\(^{15}\) in Iran.

Regarding family history of RAU, a genetic predisposition for the development of aphthous ulcer is strongly suggested, as in one study about 40% of patients have a family history and these individuals develop ulcers earlier and are of more severe nature\(^{16}\). Various associations with HLA antigens and RAU have been reported. These associations vary with specific racial and ethnic origins\(^{17}\). A number of several other studies have shown a familiar trend in the development of RAU\(^{18}\) and the correlation is also greater in identical twins\(^{19}\), demonstrating the existence of a genetic influence in the episodes. Similarly, in this study, 60% of patients reported that other family member suffered previously from RAU.

This study demarcates that lips and buccal mucosa were the commonest sites of RAU which are in accordance with the finding of Safadi\(^{20}\) in Jordan. This may probably because these 2 sites are thin delicate mucosa and more prone to trauma.

Educational level had great impact on the prevalence of RAU; prevalence of RAU is increasing as the level of education is increasing and the highest prevalence rate was among students. This finding supports the role of

**Table (2). Relation of RAU to family history, site of occurrence, Level of education and smoking**
stress and anxiety in occurrence of RAU among educated patients, especially during school exam.

An inverse relationship between tobacco use and the appearance of RAU has been observed in the literature. Some researchers thought that smoking has protective effect and this protective effect is related to the increased keratinization of the oral mucosa in smokers and that this keratin layer acts as a mechanical and chemical barrier against trauma or microbes. Few investigators suggested that smokers may be less psychologically stressed than nonsmokers and that some psychological trigger might affect RAU development. The association found in this study between heavy cigarette smoking and less prevalence of RAU suggests that smoking may play a role in preventing the occurrence of RAU. Although such lower prevalence of RAU in the heavy smokers shouldn’t encourage smokers who suffer from RAU to increase their consumption.

Macular Thickness and Its relation with Age and Gender in Healthy Eyes Using Cirrus-HD Optical Coherence Tomography

Qasim Kadhum Farhood1, Ahmed Ali Ibrahim2

1 M.B.Ch.B., F.I.C.M.S (ophth.), Department of Ophthalmology, College of Medicine, Babylon University, Iraq, 2 M.B.Ch.B, Department of Ophthalmology, Al-Sadder Teaching Hospital, Babylon University, Iraq

Abstract

Purpose of the Study: To provide a normative data for macular thickness in healthy Iraqi eyes using Zeiss cirrus HD-OCT and to determine the effects of age and gender on their measurements.

Materials and Methods: Two hundred healthy adult volunteers (≥20 years), four hundred eyes underwent macular cube scanning using Zeiss cirrus-HD OCT. Macular thickness from all 9 regions of the Early Treatment Diabetic Retinopathy Study map was documented for each subject. Variations in macular thickness by age and gender were determined.

Results: The mean age of volunteers was 37±10.4 (range 21-67) years. The mean of central foveal thickness was 254.6±17.3 Mm, the mean macular thickness was 279.0 ± 10.7 Mm, and the macular volume was 10.0 ± 0.4 mm3. Females were found to have a significantly thinner macula (P< 0.001) than males in all 9 ETDRS regions except outer inferior quadrant. Central foveal thickness was found to have very weak correlation with age which was not statistically significant. All other macular regions, mean macular thickness and volume showed statistically significant nonlinear reduction with age (p value<0.001).

Keywords: Macular Thickness, Healthy Eyes, OCT

Introduction

Macular edema is a common cause of impaired vision, and the degree of deterioration in visual acuity is significantly correlated with the degree of increment in macular thickness. This increase in retinal thickness due to fluid accumulation is happened in many ocular diseases or interventions like diabetic retinopathy, age-related macular degeneration, post intraocular surgery, central serous chorio-retinopathy (CSCR), retinal vein occlusion and intraocular inflammatory conditions. Traditional investigations that used for evaluating macular thickening or oedema, such as slit lamp biomicroscopy, fundus photography and fluorescein angiography (FA), can provide only qualitative information, which is relatively insensitive to subtle changes in macular thickness. Many studies showed significant differences in macular thickness amongst subjects of different race, gender and age.

Macular changes with increasing age involve alterations in its function, structure and blood supply. Many genetic and environmental factors may enhance the aging process or induce an irreversible and progressive loss of central vision. Some of these factors seem to be affected by sex hormones. Gender related differences exist in both healthy and diseased eyes. It has been suggested that the macula is thinner in females than males.

Background on OCT: Optical coherence tomography (OCT) has revolutionized ophthalmic clinical practice. OCT uses low coherence interferometry of light to examine the retina in vivo (10). With progression of this technology, a true, non-contact, non-invasive “optical biopsy” of the posterior segment of the eye is achievable.

Macular map on OCT: According to early treatment diabetic retinopathy study map(11), macula is divided into 9 regions with 3 concentric rings measuring...
1 mm (innermost ring), 3 mm (inner ring) and 6 mm in diameter (outer ring) centered on the fovea. The innermost 1 mm ring is the fovea while the inner 3 mm inner ring and outermost 6 mm ring are further divided into four equal regions.

Figure 1. Example of macular thickness measurements obtained with Cirrus HD OCT system.(12)

Subjects and Methods

Subjects: In this cross sectional study, four-hundred eyes of two-hundred healthy Iraqi volunteers, underwent macular thickness measurements by OCT at Ibn-Alhaithem Teaching Eye Hospital between April 2017 and February 2018 and the measures were matched for age and gender. Each volunteer was informed of the purpose of the study, and a verbal informed consent was obtained from all participants before examination. Each one underwent a complete medical history, ophthalmic history and examination, including (best corrected visual acuity by Snellen’s chart, applanation tonometry by Goldman tonometer, slit lamp biomicroscopic examination, dilated fundus examination by non-contact 90 D slit lamp indirect lens) then referred to be examined by OCT.

Inclusion Criteria:

1. Age range between 20 and 70 years.
2. Best corrected visual acuity (BCVA) ≥6/6 using snellen’s chart.
3. Refractive error between -1 and +1 diopter.
4. Intra ocular pressure less than 21 mmHg.

Exclusion Criteria:

1. Age less than 20 and more than 70.
2. Best corrected visual acuity (BCVA) worse than 6/6 using snellen’s chart.
3. Intraocular pressure more than 21 mmHg or any
evidence of glaucoma.

4- Eyes with a media opacity that obscures OCT view or signal of OCT less than 6.

5- Eyes with retinopathy due to any diseases like hypertension, diabetes or neuro-ophthalmological disorders or previous uveitic attacks.

6- Patients with history of interventional ocular surgeries or laser.

Optical coherence tomography scanning: All the volunteers were examined by the same OCT device (cirrus HD OCT Carl Zeiss Meditec, Dublin, CA, model 5000 and software version 7.0). this OCT has a Speed of 27,000 A-scans/second, axial resolution of 5 Mm, single compact unit and contour maps of ILM-RPE. Pupillary dilatation was done by using topical tropicamide 1% eye drops, imaging was performed 2 times for each subject, on the same day, by same experienced operator trained in using the Cirrus HD OCT system.

Macular thickness measurements: The macular thickness map protocol was used for macular thickness measurements. It consists of a series of 6 to 24 equally spaced line scans covering an area of 6×6 mm in the macular region displayed with numeric averages of thickness measurements for each of the 9 map regions within a 6×6 mm area centered on the fovea, as defined by the ETDRS(11).

Statistical analysis: Data were analyzed using the statistical package for social sciences (SPSS) version 24. Descriptive statistics presented as simple frequencies, percentages, mean and standard deviation. Independent sample or student’s t test for two groups was used to compare means between males and females while ANOVA test (analysis of variance) was used to compare the means across the age groups. The mean difference was calculated to assess the variation in the values in both gender and across the age groups. The predicted relationship between age and retinal thickness, in fovea, pericentral and peripheral ring of macula assessed using fractional polynomial multiple linear regression. Level of significance of ≤ 0.05 considered significant difference or correlation.

Results

Age and gender distribution of the study: Two hundred participants were enrolled in this study with a mean age of 37.9 ± 10.4 (range: 21 – 67) years. Males represented 64% of the studied group, (Table 3.1.). A total of 400 eyes were examined.

Comparison of macular thickness on basis of gender: The comparison of retinal thickness in both genders revealed significant difference in all measurements that males are likely to have thicker macular measurements than females (p value <0.001) in all parameters (mean macular thickness, central foveal thickness and macular volume). Also males have thicker measurements in other eight quadrants than females (p value <0.001) except Outer inferior quadrant at which males had relatively higher thickness but the difference did not reach the statistical significance, (P>0.05), (Table 3).

Comparison of macular thickness on basis of age: Further assessment of the retinal thickness across different age groups which categorized in decades, revealed a significant correlation between retinal thickness and age; in all quadrants, retinal thickness was thicker in younger age groups of 40 years and younger, and became thinner with advancing age above 40 years of life, (P<0.001), in all comparisons across the age groups and the 8 quadrants. The central foveal was insignificantly different across the age, (P>0.05). (Table 4).

Discussion

Normal Macular Tomography: In present study, the central foveal thickness was 254.6 ± 17.3 μm, mean macular thickness was 279.0 ± 10.7 μm and macular volume was 10.0 ± 0.4 mm³. The fovea (innermost 1 mm ring) was the thinnest area of macula. The inner macula (inner 3 mm ring) was thicker in all four quadrants i.e. superior, inferior nasal and temporal compared to outer macula (outermost 6 mm ring), thus the retina thinned towards the periphery. The nasal macula (inner and outer) was found to be significantly thicker than the temporal macula (table 2). The nasal quadrant (325 ± 15.2 μm) was the thickest in the inner region of the macula, followed by the superior (323.9 ± 15.1 μm), inferior (321.2 ± 14.9 μm) and temporal (310.5 ± 14.5 μm) quadrants. In the outer region, the nasal quadrant (295.7 ± 15.3 μm) also was the thickest, followed by the superior (277.6 ± 14.8 μm), inferior (269.1 ± 14.2 μm) and temporal (261.7 ± 13.4 μm) quadrants. These patterns were consistently present in both genders and across all age groups; this attributed to the presence of papillomacular bundle in the nasal macula, so it has the thickest nerve fiber layer than other quadrants, then it comes the superior and inferior arcuate bundling of the nerve fibers and lastly the temporal macula, our results in agreement with other studies (13,14).

Comparison of Macular Thickness on basis of age: In our study, the central foveal thickness did not correlate significantly with age (p value 0.11) as in (table 4). Regarding mean macular thickness and macular volume measurements were significantly thicker in age groups 40 years and less and became thinner in age groups more than 40 years (p value <0.001) as in (table 4). Regarding macular thickness in other eight quadrants of macula (inner and outer rings) was also thicker in age groups 40 years and less and became thinner in age groups 40 years and more (decreased with age) with p value <0.05 as in (table 4). These results suggest that inner and outer macular regions are thick in young adults, whereas macular thickness tends to have less variable in older adults with a smaller magnitude in thickness changes from the foveola toward the central macula and inner and outer macular regions.

Comparison of macular thickness on basis of gender: Our study showed that central foveal thickness, mean macular thickness and macular volume were greater in males as compared to females (P<0.05) than males in all 9 ETDRS regions except outer inferior quadrant which was not statistically significant (p value 0.125). The central foveal thickness was found to be 262.1 ±18.4 μm vs 241.4 ±20.7 μm for males vs females, the average macular thickness was found to be 281.5±11.2μm vs 274.5±8.1 μm for males vs females and the macular volume was found to be 10.1±0.4 mm³ vs 9.9±0.3mm³ for males versus females. Tewari et al. (19) and Grover et al. (20) showed no significant difference was seen in the foveal thickness, mean macular thickness and macular volume in men and women which may be due to differences in ethnicity of study subjects or differences in study design. However, other similar studies (18,14) found males to have significantly higher mean macular thickness, foveal thickness and macular volume as compared to females which were in partial agreement with our study as outer inferior quadrant was not statistically significantly.

Conclusion

The macular thickness was determined in 9 ETDRS regions. The fovea was the thinnest area. Using the criteria of mean ± 2 SDs, which includes 95% of the population, we suggest that 237.7 μm to 272 μm be taken as the normal range for central foveal thickness in the Iraqi population for Zeiss cirrus HD OCT. Females were found to have a significantly thinner macula (P<0.001) than males in all 9 ETDRS regions except outer inferior quadrant. Central foveal thickness was found to have very weak correlation with age which was not statistically significant.

Effectiveness of an Education Program on Knowledge of Primary School Teachers toward Mumps Disease

Haqi I. Mansoor¹, Kahtan H. Hussein²

¹Assistant Lecturer, College of Nursing/University of Kerbala, Iraq, ²Prof. Dr., College of Nursing/University of Babylon, Iraq

Abstract

This study aims to determine the effectiveness of an education program on primary school teachers’ knowledge toward mumps disease and to identify the relationship between the primary school teachers’ knowledge and some demographic variables. Quantitative research a quasi-experimental design (pre-post tests) has been used in the present study for the period of January 2018 to the end of June 2019. A nonprobability (purposive sample) sample of 60 teachers has been selected from 30 primary schools in Holy Kerbala City. The sample of the study was divided into two groups: (30) teachers for the study group, who have been exposed to the education program, and (30) teachers for the control group, who not exposed to the education program. The groups are almost matched relative to their characteristics. The questionnaire was submitted to the teachers for the pre-test before the implementation of the program. Post-test I was conducted immediately after that. Post-test II was conducted two months later. The findings of the data analysis indicate that the teachers’ knowledge among the study group improves as a result of the implementation of the education program. Among the control group, there is no significant difference in the level of teachers’ knowledge. The study recommends the cooperation between the Ministry of Education with the Ministry of Health to develop a national plan regarding mumps and other communicable diseases to raise the awareness of the school community (students, teaching, and non-teaching staff, and parents) regarding this diseases.

Keywords: Effectiveness, Primary School Teachers, Knowledge, Mumps

Introduction

Mumps is an acute disease of children and young adults, caused by a paramyxovirus of which there is only a single serotype. Mumps virus infection produces no symptoms in about one-third of infected persons¹. The hallmark of infection is swelling of the parotid gland. Aseptic meningitis and encephalitis are common complications of mumps together with orchitis and oophoritis, which can arise in adult men and women, respectively; other complications include deafness and pancreatitis. Clinical diagnosis can be based on the classic parotid swelling; however, this feature is not present in all cases of mumps and can also occur in various other disorders².

The points of arguments related to this research topic that mumps virus is a highly infectious pathological agent, despite the use of vaccination, outbreaks continue to occur worldwide and affect all age groups. There is no specific treatment for mumps. Someone may ask what is the need for this research and what is important for the community? This contagious disease is widely distributed in low- and medium-income countries like Iraq, mumps is an insignificant and neglected public health problem because of poor documentation of clinical cases and lack of published epidemiologic studies. By the end of 2015 around 12957 mumps cases were reported in Iraq, the numbers of incident cases increased dramatically in the year 2016 (73919 case) this was unexpectedly very high as compared with numbers in neighboring countries in the same period as documented by WHO update report; Saudi Arabia 14, Syrian Arab Republic 84, Jordan 168, Kuwait 318, and 344 in Turkey³.

Methodology

Quantitative research a quasi-experimental design (pre-post tests) has been used in the present study for the period of January 2018 to the end of June 2019. A nonprobability (purposive sample) sample of 60 teachers has been selected from 30 primary schools in
Holy Kerbala City. The sample of the study was divided into two groups: (30) teachers for the study group, who have been exposed to the education program, and (30) teachers for the control group, who not exposed to the education program. The groups are almost matched relative to their characteristics. The education program for teachers has been constructed according to the results of the assessment of the teacher’s needs to knowledge about mumps and from review the related literature. The questionnaire involved two parts: the first, demographic data of teachers such as age, gender, and specialization, level of education, years of employment, participation in training course or workshop toward communicable diseases and second part, concerning teachers’ knowledge about mumps in primary schools were comprised of (36) items divided to (6) items related to knowledge about anatomy and physiological of salivary glands, general knowledge about mumps (5) items, knowledge about signs and symptoms of mumps disease (7) items, knowledge about diagnosis and complications of mumps disease (6) items, knowledge about mode of transmission for mumps infection (6) items, knowledge about prevention and treatment of mumps disease. The content validity has been determined through the panel of 17 experts their specialties fields are nursing and medicine. The reliability of the questionnaire is determined through the use of pre-posttest technique and computing of correlation coefficients ($r=0.93$). The questionnaire was submitted to the teachers for the pretest before the implementation of the program. Post-test I was conducted immediately after that. Post-test II was conducted two months late. the data of the study were analyzed through the use of Statistical Package for Social Science Program (IBM SPSS) version 24 24 through a statistical approach that includes (frequency, percentage, Mean of score (M.S.) and standard deviation (SD) and an Inferential statistical approach that includes (ANOVA and t-test). Results were determined as significant at (P<0.05).

**Results and Discussion**

**The demographic characteristics of sample:**

The majority of teachers among study group are with age (28-43) years old 50% in study group while 40 % in control group from same age groups. This result is consistent with Ahmed and Hameed, (2013) who revealed that the majority of the studied teachers at age 25-44 years old. The findings reveal that more of teachers are females among the study and control group with a percentage of (73.3%) this result agrees with Ganpatrao’s study in 2014 that indicate about (73%) of teachers were females in the sample of the study. Regarding the variable of specialty, more of teachers are specialized with sciences among the study group (70%) and control group (73.3%). This result coincides with the findings of Faraj and Khalifa (2014) who has been selected the same specialty (teachers of sciences) for study. The level of education refers to diploma among teachers of both groups; the study group (70%) and control group (73.3%) while (30% and 26.3 %) of them in sequentially for the study and control groups with bachelor’s degree. These findings getting close to Hussein (2018) when study academic achievement showed that (60%) of teachers in the study group were graduates of teachers’ preparation institute while more than half of them in the control group were graduates of colleges (56.7%)². Regarding years of employment, the highest percentage among the study group reveal (11-18) years (33.3%), while the same percentage among control group that reveals (27-34) years. This result agrees with Ail, 2018 in the study group but disagrees in control group, (50%) of teachers in the study group have work experience of (11-13) years and (26.8%) of teachers in control group who have (4-6) years of employment. When calculating the total number of for training courses from 60 teachers the results indicate (28.3 %) from them were participated in training courses related to communicable diseases (only 8.3% among the study group and 20 % among the control group).This result agrees with Khalifa and Faraj (2010) about (28) of the sample have participated in training courses.

**The effectiveness of an education program about teacher’s knowledge concerning mumps diseases:**

Determination the effectiveness of the education program has been employed through the comparison between the levels of teachers’ knowledge before and after their participation in the education program by the findings of pre-test and post-test 1 and through the comparison between the levels of teachers’ knowledge after period of time from post-test1 by the findings of post-test 1 and post-test 2. The findings of the data analysis indicate that the teachers’ knowledge among the study group improves as a result of the implementation of the education program. Among the control group, there is no significant difference in the level of teachers’ knowledge.
This result agrees with the study of Hussein in 2018 has been showed that the effectiveness of educational program on teachers’ knowledge about early detection of communicable diseases; the program is highly effective as shown by high significant differences among teachers’ knowledge in post-test 1 and post-test 2 in the study group whereas no significant differences have been seen among periods of control group which means that the program is effective on teachers’ knowledge. Which supported through Al- Jourani ‘s (2014) study indicates the successful implementation of an educational program to improve teacher’s knowledge concerning communicable diseases. He said that “There were significant statistical differences in teacher knowledge, practices, and attitudes after implementation of the communicable diseases control educational program compared with their knowledge, practices, and attitudes in the period before the implementation of the program.”

The relationship between teachers’ knowledge and their demographic variables: The demographic variables are attributes of subjects that are collected to describe the sample, in this study some demographic variables regarded teachers at primary schools are selected included age, gender, specialty, level of education, years of employment, participation in the training course, and course’s duration. During the following paragraphs will discuss the relationship between these demographic variables with the items of study which included anatomy and physiology of the salivary glands, general knowledge about mumps, signs and symptoms of mumps, diagnosis and complication of mumps, mode of mumps transmission, prevention and treatment of mumps and overall knowledge. Concerning the relationship between teachers’ knowledge about mumps disease and their demographic variables, the study in table (2) confirms that no significant association between teachers’ knowledge improvement effect result after application of the program, while there was a significant association between the prevention and treatment of mumps with their level of education, also between the symptoms, signs, diagnosis, and complication of mumps with their participation in training courses and duration of training courses, %: Percentage

Conclusion

Generally, the pre-test evaluation of teachers’ knowledge relating to mumps disease at the primary schools, indicates a poor level of overall knowledge but there are significant improvements in teachers’ knowledge about mumps disease after the implementation of the education program. The study recommends the cooperation between the Ministry of Education with the Ministry of Health to develop a national plan regarding mumps and other communicable diseases to raise the awareness of the school community (students, teaching, and non-teaching staff, and parents) regarding this disease.

Effects of Cement Dust on Electrolytes and Osmolality in Serum and Urine of Kufa Cement Factory workers

Noor Amer Hakim AL-Mamoori1, Nada Saad Naji AL-Taee2

1M.Sc. Student, 2Assist. Prof., Department of Environmental pollution /College of Environmental Sciences/ University of AL-Qasim Green/Iraq

Abstract

Cement industry is considered one of the serious pollutants in the environment inducing different kinds of health problems among workers. However, there have been few studies examining the adverse effects of cement dust on the levels of electrolytes and osmolality among workers. In the current study, we investigated the potential impacts of the cement dust on the levels of electrolytes and osmolality in both serum and urine among workers of Kufa Cement Factory. The workers were grouped into three groups according to their departments. The workers, who were aged between 38-48 years, were grouped into oven workers (N=20), mills workers (N=16) and control workers (N=22). While workers who were aged between 49-59 years, were also grouped into oven workers (N=14), mills workers (N=13) and control workers (N=9). Serum and urine samples were collected from all studied subjects. Regardless of age groups, the results showed that the levels of serum sodium and potassium were significantly increased among workers at the oven and mills departments compared to control. While the levels of blood serum calcium and osmolality were significantly reduced among workers at the oven and mills departments compared to control group. In the urine samples, the levels of sodium were significantly higher among oven workers compared to the findings in both mills and control. While the levels of calcium and osmolality were significantly higher in both oven and mills workers compared to the control.

Keywords: Cement dust, electrolyte, osmolality, blood serum, urine

Introduction

The demand for cement are increasing with the increasing population; resultant in a rapid growth of cement industry. Like all other industrial processes cement manufacturing involves the generation of waste materials that are of concern from both health point and environmental of view1. Based on the massive amount of gases being used and emitted; cement industry can be measured as one of the serious pollutants in the environment2. It has been suggested that the effects of cement dust and its gasses on the subject’s health can be varied according to different factors3. Duration time of the exposure which is shown to be positively correlated with the negative effects4,5. Work place of the subjects as workers at the oven or packing departments are more influenced than others3,6,7. In addition , residency of the people as people that live near the cement factory are more targeted than others8,1. The cement dust and its gasses can invade human’s body through different routes such as inhalation, ingestion, and absorption through the skin9. There are considerable evidences showing the adverse effects of the cement dust and its gasses on the human health. Previous research indicated that cement dust had induced several bad impacts on the different internal organs such as liver , lung and kidney among workers at the cement factory. To date, there have been few studies performed investigating the potential effects of cement dusts and its gasses on the levels of electrolytes and osmolality in both serum and urine among workers in different work places at the Cement Factory3,6,7. Therefore, in the current study we
investigated the potential effects of cement dust on the levels on several electrolytes (sodium, potassium and calcium) and the osmolality in both serum and urine among workers at the different sections of Kufa cement factory.

**Material and Method**

**Criteria of participants**

A sample of 325 workers aged between 38 and 59 years was selected among workers of Kufa cement factory. About 120 of blood serum sample aged between 38-48 years were divided to:

- A1: worker in ovens department N=(20),
- A2: worker in mills department N=(16),
- A3: control department N=22,

while the rest sample of blood serum aged between 49-59 years were divided to:

- B1: worker in ovens department N=(14),
- B2: worker in mills department N=(13),
- B3: control department N=9.

In addition to workers aged between 49 and 59 years was selected among workers of Kufa cement factory. About 120 of urine sample aged between 38-48 years were divided to:

- C1: worker in ovens department=20,
- C2: worker in mills department=16,
- C3: control department=22,

aged between 49-59 years were divided to:

- D1: worker in ovens department=14,
- D2: worker in mills department=13,
- D3: control department=9.

**Collection of Data**

The data were collected using a self-administered questionnaire and it is built on several axes: (name - age - work section - height and weight - duration of exposure - smoking case - the family history and diabetes). The Criteria for selecting workers were that no one should suffer any medical complication such as heart disease, stroke or any other disorder. Blood samples were collected from all studied workers by venipuncture approach. Five milliliters were drawn of each worker and collected in a gel tube. The collected bloods were then centrifuged at 3000/rpm for 15 minutes, then serum was kept at -20 for later analysis of serum electrolytes and osmolality. Urine samples were also collected from every worker at 10 a.m. The collected urine was split into two tubes. The first tube was directly used for the electrolytes measurements, while the other one was centrifuge at 3000 /rpm for 15 minutes. The supernatant was then for osmolality measurement.

**Methods of measuring electrolytes and osmolality**

Serum micro-minerals (mg/L) were determined from all samples in serum and urine. Sodium was measurement by ELZA. While measurement potassium and calcium was measured by test kits and spectrophotometer device. Randox and spectrum laboratories. Osmolality (mosm/Kg) was determined by using standardized procedures of single-sample Micro- Osmometer device.

**Statistical Analysis**

All data were checked for normality using Shapiro-Wilk test. One way ANOVA was used for normal distributed data, while Kruskal-Wallis test was performed for not-normal distributed data. In these models, the group was fitted as a fixed factor, while the dependent variables like the values of electrolytes and osmolality were included as a response. The statistical outcomes were expressed as a Mean ± Standard deviation. A post hoc test was also used for detecting the significant differences among groups, P<0.05 was considered as statistically significant. Minitab version 18 (USA) was used to analyze the data in the current study.

**Results and Discussion**

**Electrolytes and osmolality in serum:**

In the current study, we examined the potential effects of cement dust on the health of workers by measuring their electrolytes in both serum and urine. The results indicated that the levels of serum sodium among workers with age group 1 in both oven and mills department were significantly higher (p<0.05) compared to the values observed in the control group (table 1). While in the age group 2, the significant difference was disappeared between workers in mills department and control group (table 2). These results are consistent with previous studies. High levels of serum sodium observed among workers in both oven and mills departments may indicate that the cement dust could cause this elevation. It has been suggested that the concentration of serum sodium that exceeds 145 mg/dL can be physiologically considered higher. The results of the current study indicated the effects of cement dust were almost the same in both age groups. However, The picture was an opposite direction in terms of the levels of serum calcium and osmolality. The workers in both oven and mills department had significantly
(p<0.05) decreased the serum calcium and osmolality compared to the values found in the control group (see table 1,2). Although the exact reason for the lowering serum osmolality is unknown, reduction of other factors (not measured in our study) that may drive the serum osmolality could explain why the serum osmolality was significantly decreased among workers. It has been suggested that the serum osmolality is influenced by several factors\textsuperscript{11,12}. Another possible explanation for such reduction observed in serum osmolality could be indirect effect of cement dust on the lung function especially forced expiratory volume and then this effect could be behind the reduction of serum osmolality\textsuperscript{13}. The changes in serum osmolality have been observed among workers exposed to different kinds of pollutants. Levels of serum potassium was significantly increased (p<0.05) among workers with age group 1 in oven department compared to what have been seen among workers in both mills and control departments (table1). However, levels of serum potassium was only significantly different (p<0.05) to that observed among workers in control group with age group 2 (table 2).

**Electrolytes and osmolality in urine:**
The results indicated that the levels of urine sodium among workers with age group 1 in the oven department were significantly higher (p<0.05) compared to the values observed in both mills and control departments (table 3). The changes observed in the findings measured with age group 2 were also followed the same path. Levels of urine sodium among workers in the oven department were significantly higher (p<0.05) compared to the values observed in both mills and control departments (table 4). This elevation was in the same direction to what we have seen in the levels of sodium measured in the serum of the same subjects, suggesting that the pollutants derived from the cement dust could cause this elevation in both serum and urine. To our knowledge, this is the first study examining the potential effects of cement dust on the levels of electrolytes in the urine. Our results also indicated the subjects with high levels of sodium in their serum had increased the levels of osmolality measured in their urine. One possible explanation for such link is that the hypernatremia found in the serum of the workers in both oven and mills department could induce the body to secret more sodium and other electrolytes like calcium in the urine and hence increase the ratio of these solutes in the secreted urine which ultimately leading to increase the osmolality. Levels of urine potassium was significantly different (p<0.05) among the two groups within both age groups in which the lowest levels were observed in the control, while the highest levels were found among workers in the mills department (table 3, 4). Levels of urine calcium among workers with in both age groups in the oven and mills department were significantly higher (p<0.001) compared to the values observed in the control group (table 3, 4). This picture was also correct for the findings of urine osmolality. The levels of urine osmolality within both age groups were significantly (p<0.001) lower in both oven and mills workers compared to the findings in the control group (table 3, 4). The current study had highlighted the role of cement dusts on the levels of the electrolytes and osmolality among workers at the cement factory. This study also expanded our awareness towards the serious effects of the pollutants a rounded us.

Conclusions

Levels of the electrolytes and osmolality measured in both serum and urine were significantly influenced by cement dust among workers came from different departments. These results should encourage the workers to protect themselves by following the safety instructions which ultimately constrain the possible adverse effects caused by cement dust. In addition, workers at cement factories should be a ware of using some of antioxidant supplementations which could mitigate the potential oxidative damage by cement derived molecules.

Assessment of Risk Factor for Developing Acute Kidney Injury in the Setting of Acute ST Elevation Myocardial Infarction

Shawqi Watheq Mohammed Ali¹, Fareed Murad Kareem², Yihia Mousa Al-Sunbly³

¹Resident, CABM (neph), FICMS (neph), FICMS (med); Al-hakeem General Hospital, Najaf, Iraq, ²Resident, FICMS (med); Alnassiriyah Hospital Thi Qar, Iraq, ³Resident, MD; Al-Hakeem General Hospital, Najaf, Iraq

Abstract

Background: An acute kidney injury (AKI) is a recognized complication in patients with ST elevation myocardial infarction (STEMI) by several mechanisms and it adversely affects morbidity and mortality on long-term bases (¹, ², and ³). Few studies have investigated which patients with STEMI are at risk of developing AKI (⁶), and this study is aiming to do this assessment.

Patients and Methods: We enrolled patients with STEMI who were admitted to the CCU. KDIGO definitions was utilized to search for development of AKI in these patients throughout their stay in the CCU (their baseline serum creatinine was measured and traced daily thereafter; and their urine output was monitored). Common epidemiological and some relevant medical parameters were recorded for all patients.

Results and conclusion: low baseline systolic blood pressure, ejection fraction % and estimated glomerular filtration rate (eGFR); in addition to use of diuretics; are the major risk factors for the development of AKI in the setting of STEMI.

Keywords: acute kidney injury, ST elevation myocardial infarction

Introduction

Deterioration in renal function is well recognized in patients struck by STEMI; and it is important to know what parameters or risk factors would make patients more vulnerable to such complication. These are investigated by some researchers who found that severity and hemodynamic impairment due to STEMI is the most important predictor (¹). Acute kidney injury- previously called “acute renal failure “– affects many patients with acute myocardial infarction (AMI) especially with cardiogenic shock and is associated with high morbidity and mortality (²,³). AKI that complicate AMI is supposed to be mediated by hemodynamic changes that activate renin-angiotensin-aldosterone system, sympathetic nervous system and anti-diuretic hormone release (²). So, patients taking ACE inhibitors/ARBs are most susceptible to hemodynamically mediated AKI as blocking angiotensin action with ACE inhibitors or ARBs decreases efferent arteriolar tone and decreases glomerular capillary perfusion pressure specially when blood volume is reduced for any reason as in case of intravascular volume depletion caused by diuretics use which may result in prerenal azotemia. Prolonged renal hypoperfusion may lead to acute tubular necrosis (ATN) (⁵). Use of contrast media and other nephrotoxic agents play a role in development of AKI (⁵). It was difficult to study the outcomes of these conditions because the diagnosis of acute kidney injury has not been standardized. Rodrigues et al reported finding more than 30 definitions of “acute renal failure” in the medical literature; this variety causes confusion and made it difficult to compare the results of multiple literatures that were published by different authors (⁷-¹¹). New definitions have been set to standardize the diagnosis of acute renal failure. These established the concept of acute kidney injury by emphasizing the subtle but important differences between the terms “acute kidney injury” and “acute renal failure” One important distinction between these is that injury precedes failure.

Several studies have shown that small increases in serum creatinine levels during hospitalization are associated with a worse prognosis for the patients. In 2012, the Kidney Disease Improving Global Outcomes (KDIGO) Clinical Practice Guidelines for AKI were designed to compile information systematically on this topic by experts in the field. In short, AKI is defined as increase in serum creatinine by ≥0.3 mg/dl within 48 hours OR increase in serum creatinine to ≥1.5-fold the baseline, which is known or presumed to have occurred within the prior 7 days OR Urine volume <0.5 ml/kg/h for 6 hours (12-17). Few studies have investigated the risk factors for developing AKI in early periods after AMI; and these revealed that AKI development (as evidenced by increase in serum creatinine) is associated with high morbidity and mortality (18-20). The effect of pre-existing impaired estimated glomerular filtration on occurrence of AKI and mortality with AMI in such patients remains controversial (21, 22).

**Myocardial infarction:** In industrialized countries; acute myocardial infarction (AMI) is one of the most common diagnoses in hospitalized patients. AMI related deaths occur before reaching the hospital exceeds 50% but in-hospital mortality has declined from 10% to about 6% over the past decade with 15% 1-year mortality specially in elderly group (23). ST-segment elevation myocardial infarction (STEMI) is a clinical syndrome defined by characteristic symptoms of myocardial ischemia in association with persistent electrocardiographic (ECG) ST elevation and subsequent release of biomarkers of myocardial necrosis (24).

**Cardiorenal Syndrome (CRS):** Although many definitions has been proposed ; the term (cardiorenal syndrome) can simply be thought to reflect the interplay between abnormalities of heart and kidney function, with deteriorating function of one organ while therapy is administered to preserve the other; so this term is being recognized increasingly as a complication of acute decompensation of heart failure (ADHF). About 30% of patients hospitalized with ADHF have abnormal baseline renal function, with associated increase in morbidity and mortality (28-30).

**Patients & Methods**

This is a cross sectional study, done at al-Sadr teaching hospital between April 1, 2015 and December 31, 2015.

**Inclusion criteria:** Patients enrolled in the study were those who were admitted to the coronary care unit with the diagnosis of acute ST elevation myocardial infarction, with no exclusion criteria.

**Exclusion criteria:**

1. Patients who were referred to the cardiac center for doing primary percutaneous intervention (PCI).
2. Presence of obstructive uropathy (depending on baseline clinical presentation and investigations).
3. Patients on maintenance dialysis.
4. Patients who died on arrival before doing the required management.

**Data collection:** Acute STEMI was diagnosed according to the Third universal definition of myocardial infarction 2012 depending on symptoms, ECG abnormalities and cardiac enzymes. (38).

The following data were collected for each patient:

1. Age ,sex, history of H.T ,history of D.M, history of coronary artery disease, history of dyslipideamia, smoking and drug history.

2. Serum creatinine level was measured for every patient on admission and daily thereafter during the stay period in the coronary care unit, with continuous monitoring of urine output. Estimated GFR (eGFR) was calculated using the CKD-EPI CREATININE 2009 EQUATION.

3. Systolic and diastolic blood pressures monitored using mercurial sphygmomanometer.

4. Troponin I was assessed by rapid test cassette (Halogen Company).

5. Ejection fraction (EF) was calculated by 2D echocardiography.

6. Abdominal ultrasound was done to assess renal status and to exclude urinary tract obstruction.

AKI was defined according to KDIGO – AKI Work Group guidelines (39).
Statistical analysis: Statistical package for the social sciences version 21.0 was used for analysis of data (SPSS inc.2013). All variables were examined for normally distribution and descriptive statistics presented as frequency and proportion for categorical variables and as mean ± standard deviation for continuous variables. A student’s t-test and analysis of variances tests were used to compare means. Chi square test was used to compare frequencies and proportions. Level of significant (P. value (was set at ≤ 0.05 to be considered as significant difference or correlation.

Results

A total of 55 patients were included and forty of them were males (72.7%) as illustrated in Table-1 which also revealed prevalence of important comorbidities in the study group and different therapeutic interventions used. In addition to baseline serum creatinine (and hence eGFR); some other parameters were also recorded initially on admission, and outlined in Table-2. The patients enrolled were monitored for development of acute kidney injury; where only seven out of fifty five had developed AKI. Table-3 reveals the correlation between the site of AMI and the development of AKI; and there were no significant relation. Table-4 reveals association between AKI occurrence and all variables recorded for the study group, where patients who developed AKI were more likely to have lower mean systolic blood pressure, ejection fraction and eGFR. Moreover; diuretic use revealed the same significant association.

Discussion: Most of the study group lies between the age of 51-70 yrs. and the majority were males which is well expected as male are known risk group for coronary artery disease. The main prevalent risk factors in the history of the studied group (in order of frequency) are hypertension, diabetes mellitus, dyslipidemias and smoking (Table-1). All patients in the study were prescribed Aspirin, clopidogrel and an anticoagulant; while 40 of them were candidate to undergo thrombolysis according to guidelines which reflect good access to the facility in the recommended time limit for use of thrombolytics. Because of its favorable role in improving outcome of patients with STEMI; ACEi were prescribed for the majority (72.5%) of studied group, while less than 20% were in need for adding diuretics, which possibly reflects good outcome due to successful reperfusion achieved by thrombolytics in about 80% of patients. Although about 70% of patients had history of hypertension before the heart attack; we noticed that mean blood pressure was only 130.7 mmHg (+/- 23.7) which may be related to myocardial depression secondary to acute MI as evidenced by reduced mean ejection fraction of 48.5%. All patients were well above eGFR of 60 ml/min/1.73m² and hence accepted renal function and will provide good media for searching for future development of acute kidney injury. We found that patients with inferior MI comprise the largest portion when compared to other sites of MI, followed by those with anterior MI (19 patients). During their in-hospital stay we monitored the patients for development of acute kidney injury; and found that seven patients developed features of acute kidney injury. All of those patients were treated conservatively except one who required dialysis. Similarly, Ying Liao et al, had found that incidence of AKI in AMI patients were 12.1 %\(^{(15)}\).

Conclusions

1. Low baseline systolic blood pressure, ejection fraction % and eGFR are the major risk factors for the development of acute kidney injury in the setting of ST elevation myocardial infarction.

2. Use of diuretics in the setting of ST elevation myocardial infarction is associated with high risk of development of acute kidney injury.

Psychological Factors Associated with Relapse in Psychotic Patients attending Teaching Hospitals in AL_Furat Al-Awsat Governorates

Ali A. ALHatab¹, Saja H. Mohammed²
¹Ph.D., ²Prof. Department of Psychiatry and Mental Health Nursing, College of Nursing, University of Babylon, Hillah City, Iraq

Abstract

Background: Relapse demonstrates a large problem in general health; the relapse effects on the family and the client together social contact with other people and financially.

Objectives: To find out the relationship between the Psychological factors of relapse and sociodemographic data of psychotic patients attending teaching hospitals in AL_Furat Al-Awsat Governorates.

Methodology: The design was (Descriptive-Correlational) used to describe the variables and the relationships that occur among them in this study. The sample was (a non-probability) purposive of (181) relapsed psychotic patients were selected from our patients centers from teaching hospitals in AL_Furat Al-Awsat Governorates, during the period from 9th May 2019 to 20th August 2019. The instrument included two parts: sociodemographic variables and the psychological factors associated with relapse. The researcher used descriptive statistics tools such as frequency, percentage, mean of score and used in inferential statistics such as Chi-Square.

Results: The findings of the study indicate that (45.86%) of the sample their diagnosis was schizophrenia, (25.97%) were schizoaffective and (11.60%) were major depressive disorder with psychotic features. Also, the findings of the study indicate that (39.2%) of the study samples they have poor psychological factors, (34.8%) they have moderate psychological factors and (26%) they have good psychological factors.

Conclusion: There is a high significant relationship between the most sociodemographic data and psychological factor (that included high express emotion and stigma factors).

Keywords: Psychological Factors, Relapse, Psychotic patients.

Introduction

Mental illness indicates a wide range of mental health situations that influence behavior, mood, and thinking. Mental disorders lead to a negative perspective in daily life events like; work, relationships, and school, mental illnesses responsible for suffering in society (1). Psychotic disorders were a set of mental diseases described through hallucinations, delusions, emotion and other problems of thought (2). Relapse: it is a returning to a previously diagnosed state of mental illness and regains the symptoms appeared, (it is a recurrence of symptoms of a disease after a period of improvement) (3). Relapse can occur at any time during treatment and recovery, and relapse can be expected in 70% of patients after the first episode (4). Relapse demonstrates a large problem in general health; the relapse effects on the family and the client together social contact with other people and financially. The relapse in mental disorders is extremely painful and costly for the patient and his family as well as for the community. These frequent readmissions are strain on the health institutions and on the Ministry of Health Budget (5). The risk of relapse can lead to a victim of violence and crime, (especially when responding to command hallucinations), substance abuse, poverty, homelessness and poor quality of life for such individuals (6). Frequent relapse of psychosis is
a main cause of significantly increased hospitalization costs compared to other costly outpatient services and drug expensive (7).

**Objectives**

1. To assess the type of diagnosis with most relapse rate.
2. To identify the psychological factors that contribute with most relapse clients.
3. To find out the relationship between the psychological factors of relapse and sociodemographic data of psychotic patients.

**I. Methodology:**

✓ **Design of the study:** A descriptive-correlational was used to describe the variables and the relationships that occur among them in this study. This design was carried out to accomplish the aims of this study using assessment method on psychotic patients attending the out patients clinic of teaching hospitals in AL_Furat Al-Awsat Governorates, during the period from 9th May 2019 to 20th August 2019.

✓ **Sample of the study:** The sample was (a non-probability) purposive of (181) relapsed psychotic patients were selected from teaching hospital out patients center in AL_Furat Al-Awsat Governorates.

✓ **Study instrument:** A questionnaire was created by the researcher to reach the study objectives. A large body of relevant literature were extensively reviewed to find the appropriate tool for the current study.

- All the instrument domains are measured and rated on three levels rating as a 3-point Likert scale from 1 to 3 respectively; 1 indicates never, 2 indicates sometimes, and 3 indicates always.

- The psychological factors associated with relapse of patients with psychotic illnesses are determined based on the mean of items scores. Effect levels of these domains were measured as follow:
  - Low effect = 1-1.66 (Low effect = 1-1.66 (1 - 2.34-3)).
  - Moderate effect = 1.67-2.33 (Moderate effect = 1.67-2.33 (2.34-3)).

✓ The instrument included two parts: sociodemographic variables and the psychological factors associated with relapse.

**Part1: The Socio-demographic information:**

This part includes: (gender, age, age at diagnosis, duration of disease, level of education, social status, occupation, monthly income, type of living, residence, family type, who give care to the patients, number of relapses, admitted to the hospital, type of diagnosis).

**Part 2: Psychological Factors associated with relapse:**

Includes the association psychological factors with psychotic patients relapse:

- **Psychological factors:** consists of (13) items, divided to (2) domains:
  - High express emotion (8 items).
  - Stigma subdomain (5 items).

✓ **Data Analysis:** The results of the study were analyzed and assessed using the Statistical Package for Social Sciences program (SPSS, Version 26). The researcher used descriptive statistics tools such as frequency, percentage, mean of score and used in inferential statistics such as Chi-Square.

Table 2: Psychological Factors associated with relapse of psychotic patients.

This table show (39.2%) they have poor psychological factors, (34.8%) they have moderate psychological factors and (26%) they have good psychological factors.

This table shows that there is a highly significant relation in (gender, age, social status, occupation, residence, who give care to the patients, number of relapses and admitted to the hospital) with (psychological factors) at $p \leq 0.05$. Also, this table shows that there is a significant relation in (age at diagnosis, duration of disease, level of education) with (psychological factors) at $p \leq 0.05$. While this table shows that there is non-significant relation in (monthly income, type of living and family type) with (psychological factors) at $p > 0.05$.

Discussion

The results shows that (45.9%) of the study samples have schizophrenia, (26%) have schizoaffective and (11.6%) have major depressive disorder with psychotic features. (Table 1). This result comes with (Fikreyesus, et al., 2016) they found that (72.5%) have schizophrenia, (14.2%) have brief psychotic and (13.3%) have schizophreniform and schizoaffective. Also, this result was agree with (Hui C, et al, 2013) they found that nearly one-fourth ($n = 70$) of respondents with diagnosis of schizophrenia had relapse. This is due to the fact that first episode psychosis showed that the diagnosis of schizophrenia was associated with high risk of relapse and elevated severity level, also the nature of the disease according to previous studies, is more severe and less responsive to treatment and suffer many relapses.

The psychological factors included (high express emotion and stigma factors). (Table 2). The result of our study shows that (39.2%) of the study samples they have poor level of psychological factors, (34.8%) they have moderate level of psychological factors and (26%) they have good level of psychological factors. This result was supported by (Linszen, et al, 1991) who found that high express emotion is the major risk factor for psychotic relapse in patients with a first-psychotic episode. This is due to the fact that the nature of psychotic patients and discrimination against them could cause interpersonal relationships to deteriorate and reduced social contacts and they haven’t any close friends, so many may have no one to turn to for help. When the stigma was severed may be affects the patients seeking to treatment which leading poor adherence to treatment which subsequently results in frequent relapse.

The result shows that there is a high significant relationship in psychological factors with gender at $p$ value (.000). This result was agree with (Sachit & Al-juboori, 2013) they found a significant relationship between high express emotion level and age. While this result was disagree with (Samuel, A. 2017) he found non-significant relationship in internalized stigma with age at $p$ value (.000). This result may be because our community thought about stigma especially with female patients which lead them to keep them in the home instead of sending them to the hospital.

The result shows that there is a high significant relationship in psychological factors with age at $p$ value (.000). This result was agree with (Sachit & Al-juboori, 2013) they found a significant relationship in internalized stigma with age at $p$ value (.000). This is because most of the samples in the study were between the ages of 38-47 years who were significantly affected by psychological factors.

The result shows that there is a significant relationship in psychological factors with level of education at $p$ value (.010). This result was agree with (Sachit & Al-juboori, 2013) they found a significant relationship in psychological factors.
relationship between high express emotion level and level of education (11). Also, this result was agree with (Brohan E, et., al 2010) they found a higher level of education may improve self-esteem and thus limit the impact of illness on internalized stigma (14). This result may be due to frequency of psychotic episodes in a patient result in decrease in level of education due to conflict of school attending resulting from recurrent relapse and deterioration in cognitive functions.

The result shows that there is a high significant relationship in psychological factors with social status at p value (.000). This result was agree with (Sachit & Al-juboori, 2013) who found a significant relationship between high express emotion level and social status (11). While this result was disagree with (Samuel, A. 2017) he found non-significant relationship in internalized stigma with marital status at p value (.000) (10). This result may be due to the fact that most families deal with their patients in a manner that exposes them to strong express emotions, who are more likely to experience relapse more than patients with less express emotions. Examples that include high express emotions are hostility and intense criticism by parents for not benefiting from their patients and unable to rely on themselves. Incapability to regularly function and the extreme assistance and tolerance that must be received from the husband, family and brother, all these reasons may lead to a relapse of the patient.

The result shows that there is a high significant relationship in psychological factors with occupation at p value (.000). This result was agree with (Sachit & Al-juboori, 2013) who found a significant relationship between high express emotion level and employment (11). This result may be due to the fact was that stigmatized people have a low level of self-esteem, and therefore tend to consider themselves inefficient, reducing their chances of finding work and were likely to be unemployed. For workers, they face hostility and reduced responsibilities and may lose their jobs due to inefficiency (12).

The result shows that there is non-significant relationship in psychological factors with monthly income at p value (.653). This result was disagree with (Sachit & Al-juboori, 2013) they found a significant relationship between high express emotion level and income (11). Also, this result was disagree with (Samuel, A. 2017) he study income a high significantly related to internalized stigma (10).

The result shows that there is non-significant relationship in psychological factors with type of living at p value (.891). This is due to the fact that most of the study sample live with their families like parents or brothers and most of them have housing so there is no relationship with the high rate of relapses.

The result shows that there is a high significant relationship in psychological factors with occupation at p value (.000). This result was supported by (Chaurotia, et al, 2016) they found that long distance is a significant relationship to the patient’s failure with compliance to treatment, especially for those living away from the hospital such as rural areas. This is due to the fact that most of the study samples were taken from the city center (13).

The result shows that there is non-significant relationship in psychological factors with family type at p value (.147). This result was agree with (Samuel, A. 2017) he found non-significant relationship in internalized stigma with living situation at p value (.000) (10). While this result was disagree with Sachit (2013) they study found a high significant relationship between high express emotion level and family size (11).

The result shows that there is a high significant relationship in psychological factors with who give care to the patients at p value (.000). This result was agree with (Sachit & Al-juboori, 2013) they found a significant relationship between high express emotion level and caring responsibility (11). This result may be due to the fact that all the previous studies support that the psychiatric patient, especially in psychosis, needs to be followed up by the family, but most of the samples in this study were followed by their brothers, so they were may be the reason of relapse due to neglect, poor follow-up and not to give them treatment and the adoption of incorrect methods and far from treatment, such as witches and charlatans.

The result shows that there is a high significant relationship in psychological factors with admitted to the hospital at p value (.008). This result may be due to the fact that psychotic patients who weren’t compliant
to treatment do have increased risk for violence. This is due to the result of most of the patients in the study who violently violated them before admitting to the hospital and receiving treatment for the first time and very affecting their social relationships, especially if the target of the violence is the employer or a family member, friend or teacher and husband. Therefore, most families are forced to bring the patient for not tolerating the harm of the patient to others. Family use in this manner increases the severity and relapse of the illness.

Conclusions

The majority of samples were diagnosed with schizophrenia. All psychotic patients have non-significant relationship between type of living of sociodemographic data with psychological factors. There is a high significant relationship between the most sociodemographic data and psychological factor (that included high express emotion and stigma factors).

Recommendations:

1. Providing psychological units in educational hospitals in AL_Furat Al-Awsat region to enter the patients who need hospital admission to provide care for them and be equipped with doctors, nurses, medication and all the necessary supplies.

2. Providing qualified nurses in the field of psychiatric nursing to follow up patients who need hospitalization.

3. Educational program for families of psychiatric patients about the importance of caring for the mentally ill patient and not feeling stigmatized, because mental illness is like any other diseases and needs treatment to Reducing or eliminating symptoms that cause family embarrassment.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved and all experiments were carried out in accordance with approved guidelines.

Unmet Supportive Care Needs of General Cancer in Kurdistan Region- Iraq

Ezaddin Kamal Mahmod 1, Saadia Ahmed Khuder2

1 Assist. Lecturer, 2 Prof. Dr., College of Nursing and Midwifery, Hawler Medical University, Erbil, Kurdistan Region- Iraq

Abstract

Background: Cancer is a class of diseases or disorders characterized by uncontrolled division of cells.

Objective: The study aims to determine the SCNs of cancer patients in Iraq.

Methodology: The present cross-sectional study and data was conducted in Rezgary teaching and Nankaly Oncology Hospital in the Kurdistan Federal Region of Iraq. A total of 300 eligible cancer patients were invited to participate in the study from February to August, 2018. Eligibility criteria included: 18 years or above; having a definite diagnosis of any type of cancer; physically or mentally able to participate in the study; and being aware of exact diagnosis for at least three months.

Results: In 15 items of the SCNs, more than 60% of the participants reported that their needs were unmet. Most frequently, unmet needs were related to health system and information, physical and daily living, psychological, and patient care and support domains, and most met needs were related to physical and daily activity domains.

Conclusions: Kurdish cancer patients had many unmet needs and there is a need for establishing additional supportive care services and educational programs to increase quality of life in Kurdistan Region- Iraq.

Key words: Cancer patient, Supportive Care Needs, Kurdistan region.

Introduction

Cancer is the second leading cause of death worldwide, with an estimated global health burden of 193.6 million disability-adjusted life years. 1 As a result, the diagnosis of cancer may be experienced as a stressful event that negatively impacts many aspects of patients’ lives.2 Rapid changes occurred in the lifestyles of Kurdish people that affected patterns and rates of cancer trends in Kurdistan. Additionally the populations suffer from the cumulative impacts of three vicious wars in Iraq, including targeted genocide against the Kurds and the use of chemical weapons, creating long-term environmental pollution and increasing cancer incidence aside from their immediate casualties with especially high rates of hematological malignancies. Tentative published data evidences the increasing cancer Prevalence in Kurdistan 3, 4-6 Aside from their oncology condition, cancer patients often experience many ancillary problems, including negative physical symptoms, social isolation, spiritual suffering, and often psychological distress. 7, 8 This underpins the need for a wide range of robust supportive care services. 2, 9 Supportive care services can be defined as services designed to help patients, their families, and caregivers with their experiences during the diagnosis, treatment, follow-up, and palliative stages of the cancer journey. 6 Nowadays, providing supportive care is considered to be of equal significance to diagnosis and treatment of cancer, and it involves more holistic healthcare provision compared to the biomedical approach that dominates...
mainstream oncology treatment.\textsuperscript{11} The first step in planning any supportive care services for cancer patients is identifying their supportive care needs (SCNs).\textsuperscript{10,12}

SCNs are a culture-dependent concept. Therefore, in order to develop an effective supportive care program, cultural issues must be considered.\textsuperscript{19} In an extensive review of the literature, we identified no previous studies that have investigated the SCNs of cancer patients in Iraq or any other Middle Eastern countries. Therefore, this study aims to determine the SCNs of cancer patients in Iraq.

**Materials and Method**

This study was conducted in Rezgary teaching and Nankaly Oncology Hospital in the Kurdistan Federal Region of Iraq. Both hospitals are educational centers affiliated to Hawler Medical University, a referral center for sub-special cancer treatment.

A total of 300 eligible cancer patients were invited to participate in the study from February to August, 2018. Eligibility criteria included: 18 years or above; having a definite diagnosis of any type of cancer; physically or mentally able to participate in the study; and being aware of exact diagnosis for at least three months.

Participants completed an instrument consisting of two parts. The first part assessed basic demographic and disease-related characteristics of participants. Information on medical treatments was obtained from the patients’ health records. The second part consisted of a SCNs Survey (SCNS). The long form of SCNS was used to investigate the SCNs of cancer patients; it is diverted from previous studies.\textsuperscript{20} This scale contains 48 items addressing five domains of needs: psychological (11 items), health system and information (15 items), physical and daily living (7 items), patient care and support (8 items), sexuality (3 items), and no specific items (4 items). Patients reported their SCNs in each item based on a five point Likert scale (1 = not applicable or no need, 2 = satisfied, 3 = low need, 4 = moderate need, 5 = high need). To determine the SCNs, the five point Likert scale was dichotomized to unmet need (if the response was moderate need or high need) or no need (if the response was not applicable, satisfied, or low need). This scoring system has been widely used in previous research.\textsuperscript{19}

Two independent English-Kurdish translators translated the English version of the SCN SF48 into Kurdish. The questionnaire was reviewed by eight academic staff at Hawler Medical University/College of Nursing for face and content validity, and minor revisions were made based on their comments. The internal reliability coefficients (Cronbach’s alpha values) of the translated questionnaire were substantial, greater than 0.90) when piloted with 25 cancer patients.

Data analysis was performed using SPSS version 22 (SPSS Inc, Chicago, Illinois). Descriptive statistics including frequency, percentage, mean, and standard deviation were used to analyze the demographic characteristics, cancer-related information, and unmet and met SCNs of participants.

**Results**

**Table 1. Top 15 unmet SCNs of cancer patients**

Discussion

To our knowledge, this is the first study that has investigated the SCNs of cancer patients in the Kurdistan Federal Region, and indeed Iraq in general. The results demonstrate that Kurdish cancer patients have many unmet SCNs, especially in the domains of health system, information, physical and daily living. Most of the participants reported unmet SCNs in 13 items of SCNs.

In an extensive review of the literature, it was found that some studies reported that cancer patients have low needs; 10, 16 but most studies highlight that cancer patients in both non-Western 15-18 and Western countries 9, 17, 14 have many SCNs. None of the analyzed studies reported such high levels of needs as reported by the participants of our study.

The results of our study demonstrate that 6 out of 15 most frequently unmet SCNs of cancer patients are related to the health system and information domain. This finding is to some degree different with previous studies conducted in the Western countries that reported health system and information domain as the second or third domain in which cancer patients’ needs are not met. 5, 9, and 13 In contrast, the results of some studies in Southwest Asia showed that the needs from health care and information domain are between the most frequent unmet SCNs of cancer patients. 15, 17, and 18 Similarly, the results of a comparative study showed that Hong Kong breast cancer patients rated health system and information needs as the most frequent unmet SCNs, while German women consider needs from physical and daily living and psychological needs to be the most frequent unmet supportive care they experienced. 16 Therefore, this finding supports that the SCNs are a culture-dependent issue.

The results of our study also indicated that psychological needs are the second category of unmet SCNs of Kurdish cancer patients, after needs from health system and information. This finding is consistent with the results of other studies in non-Western countries. 15, 18 It should be noted that Kurdish cancer patients are often unaware of the prognosis of their diseases, and consider cancer to be a conventional curable disease. Consequently, it can be inferred that the nondisclosure of cancer prognosis for most Kurdish cancer patients may explain the unusually low level of psychological SCNs found among Kurdish cancer patients.

There are limitations to our study. This study was conducted in two oncology centers in the Kurdistan Region of Iraq; even though the setting comprises the main referral center for a large province in northern of Iraq, it does not include all areas of Iraq. The findings related to no specific SCNs ought to be interpreted with caution, considering the taboo associated with sexual issues in Iraq and Kurdish culture. Further studies are necessary that investigate the SCNs of different cultures in the Middle East; using other data collection methods, including private interviews, which may increase the validity of results in the sexual domain of SCNs.

Conclusion

This study highlights that Kurdish cancer patients have many unmet needs in all domains of SCNs. These findings indicate that programs and services to address the SCNs are urgently needed. Future research in Iraq should shed light on the particular SCNs of patients in cultural contexts, to help tailor more comprehensive and holistic care, particularly for cancer patients, in order to improve the quality of healthcare services provided.

Studying The Effect of *Mentha Longifolia* Plant Extract In Inhibition Growth of Some Bacteria and Inhibiting the Emergence Fourth Stage Larvae of Mosquitoes Aedes Aegypti

Alaa Adnan Al-janabi¹, Atyaf Ali Sahib¹, Farah Jabbar Ali¹

¹AlSafwa University College, Iraq

Abstract

This study make as research about activity of secondary compounds in *Mentha longifolia* plant extracts as crude, the effect of crude extract of *Mentha longifolia* leaves make as inhibitory growth factor for two types of bacteria Staphylococcus aureus and Escherichia coli, and inhibit emerge four stage larvae of mosquitoes. Watery and alcohol plant extracts of *Mentha longifolia* leaves were prepared, were appear variation effect in bacteria, the water plant extract show simple effect in Staph. aureus, while alcohol extract show clear effect in E. coli. In state of emerge four stage larva of mosquitoes, there are clear effect for alcohol extract in larvae comparing with water extract.

*Keywords:* *Mentha longifolia, plant extract, inhibition growth, bacteria.*

Introduction

Plant extracts of various types are an important and effective tool for the development and progress of studies and scientific research at present. The studies took the plant extracts of today a great place and space. The man turned to seek a way to get rid of the pain and disease with compounds with a few side effects and began to treat some herbs and plants that are believed to be connected to healing. One of the important tests in which plant extracts and their inhibitory effects are used are bacteria, which are small organisms and very important to humans because of their damage and benefits in many aspects. *Staphylococci* are Gram-positive bacteria, with diameters of 0.5 – 1.5 μm and characterised by individual cocci, which divide in more than one plane to form grape-like clusters. To date, there are 32 species and eight sub-species in the genus *Staphylococcus*, many of which preferentially colonise the human body.

The staphylococci are non-motile, non-spore forming facultative anaerobes that grow by aerobic respiration or by fermentation. Most species have a relative complex nutritional requirement, however, in general they require an organic source of nitrogen, supplied by 5 to 12 essential amino acids, e.g. arginine, valine, and B vitamins, including thiamine and nicotinamide.

Staph. aureus is an opportunistic pathogen and a hospital pathogen. It is often acute and fatal. If untreated, the infection may spread to the surrounding tissue or through bacteremia and blood clots to other sites to include other organs. The other intestinal bacteria that cause diarrhea is *E. coli*, a Gram negative bacilli, non-sporing, motile, some of which have the ability to form capsules and are a member of the intestinal family enterobacteriaceae. Their colonies appear to be small, slightly convex, that kill at 55 °C for an hour, but some of them can resist the temperature of pasteurization (2-8) m for 30 minutes. Although the therapeutic effects of many herbs have not been proven in practice, research is continuing to learn more about how these plants work and to identify the effective ingredients given by the therapeutic properties. Scientists hope that these research will reveal new, effective plant ingredients that can someday form the basis of cancer-fighting drugs and AIDS. The treatment of medicinal plants in today’s place and place in the great science of medicine preferred herbs and medicinal plants and no pharmacy in the world devoid of herbal medicines, so we find in Europe pharmacies especially to describe medicinal herbs, knowing that more medicines and chemical drugs are of plant origin, For patients who use herbs and
medicinal plants to treat their diseases, thus avoiding the side effects caused by the chemical drugs, as well as that the active substances in plants reduced and easy and the objects can interact with them gently in its natural form. As a result of the ongoing increase in scientific research on the importance of the plant kingdom as the inexhaustible source of organic compounds of medicinal importance against microorganisms, many studies have been conducted in the use of plants as anti-bacterial agents that cause wounds and assist in the healing and healing of wounds. In many tropical and subtropical countries diseases transmitted by arthropods are among the major causes of illness and deaths (WHO, 1992). Mosquitoes serve as vector for various tropical and subtropical diseases which cause destructive effects to human health (WHO, 1998). The most common disease associated with mosquitoes are Japanese encephalitis, chikungunya, filariasis, malaria, dengue and yellow fever. Chemical pesticides are still one of the most important means in the control of insect pests. However, the intensive use of different pesticides in plant protection programs has led to environmental malfunction and the emergence of pests and resistant strains and their high toxicity and toxicity in the environment and its harmful effects on humans and animals. Not to distinguish between harmful insects and beneficial, resulting in an imbalance in the ecosystem and the cumulative nature of chemical pesticides in the food chain and the high economic costs in the manufacture and its effects on the genetic side of the plant cell and contamination of surface water to river and sea and air pollution.

Therefore, specialists are trying to find alternative methods such as the use of biological control methods, genetic control and the use of pesticides of plant origin.

Plant extracts are natural plant compounds that affect several methods, either as direct substances, toxic or infertile, or organized for the growth of the insect or modified their behavior and found many chemical groups have an anti-feeding effect or to lay eggs in many insects.

**Material & Methods**

**Preparation of raw extracts of mentha longifolia leaves**

Preparation of hot water extract for Mentha longifolia leaves for the purpose of obtaining the hot water extract of the leaves of the Mentha longifolia plant, a method of was followed with some modifications and as follows:

- Place 50 gm. of the Mentha longifolia leaves in a volumetric flask of 1 liter
- Add 500 ml containers of distilled water and close the hole by the cellophane.
- Place the beaker in the vibrator and let it blend well, at room temperature, and quickly (60 cycles, min).
- After 24 hours, the solution was filtered using medical gauze first and then with filter paper Wattman No. 1.
- Distribute the leachate in the centrifugal discharge tubes at a speed of 3000 cycles/minute for 10 minutes.
- Ignore the precipitate and take the leak to the rotary evaporator device for the purpose of concentration and then the weight of the extracted raw extract.

**Preparation of the crude extract of ethanol for the leaves of the Mentha longifolia**

Follow the steps of preparing the raw water extract to obtain a dry plant extract. Ethyl alcohol was used with 80% distillation of distilled water. (Anessiny and Perez, 1993) except for the difference in time period where the solution was placed in the vibrator for 72 hours rather than 24 hours.

**Preparation of a medium to activate the bacteria**

Dissolve 0.13 g of nutrient broth in 10 ml of distilled water in a vial of volume. The mixture should be placed in the autoclave after closing the bottle with medical cotton for the purpose of sterilization and then left to cool a sample of Staph. aureus is activated by a needle isolated to the center and placed in the bottle after closing tightly to the incubator where incubated 37 °C for 24 hours and the same method was followed to prepare the activation medium E. coli bacteria and applied this paragraph in the room sterile hood.
Preparation of concentrations of extracts

* Concentration of 200 mg / ml

2 g of the extract and add to 10 ml of distilled water in the baker where the mixture is then blended after being placed in a bottle of volume and using the method of dilution obtained the following concentrations:

100 mg / ml , 50 mg / ml and 25 mg / ml

Preparation of the agricultural medium used for the growth of bacteria

Mueller-Hinton agar was found to dissolve 12.16 g of sugar in 320 distilled water in a conical flask and sealed the flask with cotton and sterilized with a sterilizer.

Left for 10 minutes to cool down. The medium was then poured into the Petri dishes near the flame to ensure that the germs did not enter and contaminate the dishes and left until the medium solidified. The diffusion method was followed by well diffusion in the medium of mm6 by means of the thorny fellini, the dishes were fertilize by a swab immersed in a bacterial suspension with a mass equivalent to the standard McFarland tube in tightly sealed tubes that passed on the surface of the center homogeneously except for the inside and sides of the well.

Effect of extracts used to inhibit the onset of mosquitoes

A concentration of 1% of concentrations used in the treatment of bacteria was prepared.

Treatment of fourth stage larvae

The fourth phase larvae were treated after isolating them from the sample by ten larvae per replicate (and repeaters for each concentration) in 100 mL plastic dishes. After the desired concentrations were prepared in other dishes, they were transferred using a boring cloth and the dishes were monitored for one week to calculate the percentage of inhibition that could result effect of extracts.

Result and Discussion

The inhibitory effect of the types of Mentha longifolia extracts

The effect of plant extracts used in this study showed at the two types of gram positive bacteria Staph. aureus and the negative E. coli by using the diffusion method of drilling has different effect on the two types of bacteria.

Effect of plant extracts on bacteria Staphylococcus aureus:

The results in Table (1) show that there is a slight inhibitory effect of the hot water and alcohol extracts of Mentha longifolia leaves in bacteria. We note that treatment with concentration (25-50-100-200 mg / ml) of two types of extracts have no effect in inhibiting the growth of bacteria, compared with 18.2 + 0.5 when using Gentamicin.

Table (1): shows the effect of hot water and alcohol extracts of Mentha longifolia leaves in bacteria Staph. aureus:

</tbody>
</table>

The reason for the low and ineffective inhibition of the studied plant extracts may be due to plant extracts may contain compounds that inhibit the growth of some microorganisms, but some may lose its ability.

In addition to the reduction of this activity originally in some plant extracts or during certain reactions. The method of preparation and concentration of plant extracts is an important and influential factor in the inhibitory action of each extract.

The study were agreed with Majid & Al- Shatti (2002), who found that there was no effect of water extract in Staph. aureus bacteria at a concentration of 10%.
Effect of plant extracts in bacteria Escherichia coli:

The hot water extract of the Mentha longifolia leaves has no effect in bacteria. With the alcohol extract, the rate of inhibition increased with increasing concentration. Inhibition with 25 mg/ml concentration was 3.95 and increased with 50 mg/ml concentration to 4.75, 6.45 and 6.35 with concentrations of 100 and 200 mg/ml, respectively. This was not consistent with Akroum et al. (2009) and there was no effect of alcoholic extract in the inhibition of bacterial growth. Gentamycin 10 mg/ml, which reached 17.3.

Table (2): Shows the effect of alcohol extract on bacteria E. coli:

The high effect of the ethanol extract may be due to the high content of flavonoids, which are known to have a strong effect against bacteria (Cushnie et al., 2003; Martini et al., 2004).

The results obtained have confirmed the benefits offered by medicinal plants. In fact, some of the flavonoids found in them have shown a significant antibacterial activity and the effect of acute toxicity is very low.

Ethanol extract has a significantly greater effect than the water extract the degree of polarity of the solvents used as the coefficient of extinction. For water 9 and ethanol 5.2 polarity index.

The polarity of the solvent by choosing another solvent may increase its effectiveness in dissolving active compounds.

Effect of the extracts on inhibiting the emergence of fourth stage larvae of mosquito Aedes aegypti:

The first three concentrations of the alcohol extract were 100% inhibition, while the concentration of 25 was 81.6.

When using the water extract, when the concentrations were used 25 mg/ml, the percentage of inhibition was 13.6% and increased with concentration increased to 57.1% when using concentration 200 mg/ml. As shown in table (3), we will notice a positive relationship between the concentrations used for two types of extracts.

Table (3): Shows the effect of treatment of fourth stage larvae of mosquitoes with Mentha longifolia extracts in percentage of inhibition of onset:

Accidental loss can be attributed to the fact that active compounds can be concentrated in the channel. These substances may interfere with the functioning of the endocrine system, leading to malfunction. The process of growth and increase in insect loss.

Conclusions

1. The hot water extract of the leaves of the Mentha longifolia crushed has a inhibitory effect on the positive bacteria of the gram stain.

2. Alcoholic extract showed a disincentive effect on the bacteria.

3. The alcohol extract has a clear effect in inhibiting the larvae of the fourth phase mosquitoes compared to the water extract.
Financial Disclosure: There is no financial disclosure.

Relationship between H. Pylori Patients and Autoimmune Thyroid Disease

Marwah Ali Oudah
Department of Community Health Technologies, Aldewanya Technical Institute, Alfurat Alawsat Technical University, Iraq

Abstract
Autoimmune Thyroid Disease (AITD) Autoimmune Thyroid Disease is one of the diseases, more common in women than men, caused by a combination of reasons discussed later. In this study, we have tried to understand how Autoimmune Thyroid Disease is related to H. pylori or Helicobacter Pylori. We have discussed the pathology and the manner in which AITD is developed.

This report depicts the relationship between Helicobacter pylori (H. pylori) and Autoimmune Thyroid Disease or Autoimmune Thyroiditis. However, some other reports concerning the relationship between H. pylori infection and Autoimmune Thyroiditis are conflicting. We’ve discussed how AITD is developed, along with the causes and effects of the disease. In this study, we’ve also aimed at determining the presence of H. pylori bacteria in AITD patients, particularly in Hashimoto’s Thyroiditis and Grave’s disease two of the commonly occurring thyroid diseases. The manner in which AITD develops is multi-factorial and H. pylori infection is reported more in AITD patients (adults). H. pylori is said to be involved usually in non-gastrointestinal conditions.

Keywords: Helicobacter pylori infection, H. pylori, Autoimmune Thyroid Disease, Cag-A, Grave’s Disease, Hashimoto’s Thyroiditis

Introduction
Thyroid is a tiny gland located in the front portion of the neck that produces organ-controlling hormones. These can be any organs in the body. When there’s deficiency of these hormones in the body, the functioning of the body is affected, which in turn affects your energy level and mood, along with gain in weight. If the thyroid is inflamed, the condition is known as Thyroiditis. In some cases, the antibodies produced in by the body attacks the thyroid accidentally. This condition is known as autoimmune thyroiditis. It is also known as chronic lymphocytic thyroiditis.

The commonly occurring Autoimmune Thyroid Disease (AITD) or Autoimmune Thyroiditis are:

- Grave’s Disease (GD)
- Hashimoto’s Thyroiditis (HT)
- Atrophic Thyroiditis (AT)
- Painless Thyroiditis (PT) or Silent Thyroiditis (ST)
- Subacute Lymphocytic Thyroiditis (SLT) or Postpartum Thyroiditis (PPT)

The presence of autoantibodies against Thyroglobulin (TgAbs), TPO-Ab, and Thyrotropin Receptor (TRAbs) was a typical marker of GD and HT. The pathogenesis of Grave’s Disease (GD) and Hashimoto’s Thyroiditis (HT) is nearly same, in which the autoantibodies act against Thyroglobulin (TgAbs), Thyroperoxidase (TPO-Ab) and Thyrotropin Receptor (TRAbs).
Figure 1. Pathogenesis for Grave’s Disease is described in the above diagram. The role of H. pylori is showed for the commencement of Grave’s Disease.

**Causes of Autoimmune Thyroiditis**

The Autoimmune Thyroid Disease is said to be caused by both genetic and environmental factors. The H. pylori bacteria mirror the antigen present in the thyroid cells and play a major role on the onset of AITDs. According to the data captured, the H. pylori bacteria have predominantly affected people in the third world countries. Its presence seemed to be profound in older people. It proliferates with age in some people. Apart from being the causative factor for the commencement of AITDs, these motile bacteria also cause diseases related to abdomen, such as ulcer (gastroduodenal ulcer), gastritis, and carcinoma. An individual has the tendency to get autoimmune thyroiditis for a combination of reasons given below 3:

- If you are a woman
- You are middle-aged
- If you are suffering from any of the other autoimmune disorders such as:
  - Lupus
  - Type 1 diabetes
  - Rheumatoid arthritis
- If a person having autoimmune thyroiditis is related to you
- If you are affected by environmental radiation

**Helicobacter pylori (H. pylori or Hp)**

Helicobacter pylori is a gram-negative gastric pathogen that causes disorders such as gastritis, gastric & duodenal ulcers, gastric mucosa-related lymphoid tissue lymphoma, and gastric cancer. Moreover, it has been proved that H. pylori infection can bring about autoimmune processes against mucosa, with resulting autoimmune gastritis. Also, H. pylori is believed to be involved in the pathogenesis of non-gastrointestinal condition, including rosacea, ischemic heart disease, and Type 1 diabetes. Finally, H. pylori infection is seen in most of the adult AITD patients 4.

**H. pylori-specific Antibody Determination**

Antibodies to H. pylori was identified during the first diagnosis in patients affected by Autoimmune Thyroid Disease. In patients having Turner Syndrome, serology for H. pylori was assessed in cases without thyroid autoimmunity and well before the emergence of autoantibodies.
Gastric mucosa that contains glands and gastric pits is the primary target of Helicobacter pylori that groups and destroys surface epithelium and brings about a chronic inflammatory reaction in lamina propria, a thin layer of loose connective tissue that lies beneath the epithelium. Lamina propria and epithelium collectively constitute mucosa. Gland atrophy and intestinal metaplasia are two of the long-term consequences of this process. The H. pylori prompts antibodies that are cross-reacting with epithelial components of gastric mucosa, periglandular T cells, and elevated glandular cell apoptosis that might bring about diffuse, restricted corpus fundus, and atrophic gastritis of autoimmune type. Some of the clinical consequences of H. pylori include Achlorhydria with secondary hypergastrinemia, with or without pernicious anemia, and elevated risk for gastric enterochromaffin.

This examination suggested that thyroid gland might be another target for H. pylori-invoked immune-inflammatory response and Autoimmune Thyroid Disease might be its consequence. Significantly increased existence of H. pylori was identified in patients having Autoimmune Thyroid Disease, with or without Turner Syndrome.

### Material & Methods

The current study was carried out on 100 subjects in the age group of 30 to 70 years. The serum levels of Thyroxine (T4), Thyroid Stimulating Hormone (TSH), Thyroid Peroxidase Antibody (TPO-Ab), and H. pylori Immunoglobin G (IgG) antibody were also tested. All the subjects that had a history/family history related to thyroid disease were not considered for the study.

### Laboratory test

The thyroid test was carried out in the lab that included T4 test, TSH test, and TPO-Ab test. The concentration of serum TPO-Ab was fixed using BRAHMS anti-TPO on Radioimmunoassay, maintaining the sensitivity of the solution at about 30 U/mL. As a conclusion, the TPO-Ab of over 60 U/mL was calculated as positive.

In the laboratory, the H. pylori bacteria were considered, in order to measure the presence of anti-H. pylori IgG. This complete test included solid phase, 2-step, and chemiluminescent enzyme immunoassay.

A careful examination is necessary to detect H. pylori as it helps in the diagnosis of H. pylori bacteria infection. An invasive procedure was carried out since it helps better diagnose a disease. Because H. pylori has a role to play in gastroduodenal ulcer, an invasive procedure was carried out in some cases, especially in people whose age ranges from 32 to 45. The invasive procedure comprised of historical test, culture test, and rapid urease test.

### Findings

The thyroid autoimmunity was considered positive regardless of whether there is thyroid dysfunction or not. The presence of IgG antibodies and Helicobacter pylori was considered:

- Conclusive for 1.6 U/mL or more
- Ambiguous for 0.8 U/mL to 1.6 U/mL
- Negative for 0.8 U/mL or less
The H. pylori and IgG were ignored for ambiguous cases.

**Examination of H. pylori Present in Stool Samples**

All the samples were tested in the lab and the diagnosis of the subjects were perplexing. The samples were proved with the help of the same kind of amplified enzyme immunoassay in order to determine the H. pylori antigens. The test value >0.155 was considered positive for H. pylori.

**Exposure of Cag-A Antibodies**

Cag-A (Cytotoxin-associated gene A) is a H. pylori virulence factor. All the raw samples were taken for ELISA (enzyme-linked immunosorbent assay). Because the value for anti-Cag-A immunoglobulin-G for those samples was over 15 U/mL Cag-A was considered positive.

**Results**

The H. pylori bacteria were present in the stool samples of the one hundred patients who were diagnosed with Autoimmunity Thyroid Disease. Out of these 100 patients, 89% had Grave’s Disease and 74% of them had Hashimoto’s Thyroiditis and about 54% of them had a p value of < 0.0001.

When immunoassay test was carried out, the results were positive for patients who had H. pylori bacteria infection in gastric mucosa in the past than for cases that didn’t have H. pylori bacteria infection. Also, there was no correlation between smoking and presence of H. pylori bacteria infection.

83% of H. pylori-positive patients who had Grave’s Disease and 89.5% of H. pylori-positive patients who had Hashimoto’s Thyroiditis were positive for Cag-A antigens. The result showed significant difference when compared for the presence of Cag-A H. pylori-positive patients.

The H. pylori bacteria are present globally, affecting close to 50% of the population, in the developed nation. Cag-A has found to be the most fatal antigen. According to a recent study, a significant correlation was seen for Cag-A carrier for H. pylori strains and for Grave’s Disease. The results were not dependent on the hormone levels of the patients who were examined.

On the other side, many studies have demonstrated the association between microorganisms and Hashimoto’s Thyroiditis (HT), where there were conflicting results and a few other studies have shown a significant correlation. So, to avoid any discrepancy and correctly analyze the infection caused by the H. pylori bacteria, a number of techniques we’re used. With the serological test for H. pylori, distinguishing between the past and present condition was not possible whereas the 13-C urea breath test or immunoassay test, done with fresh stool samples, helped determine the present condition of the H. pylori bacteria infection. These procedures come under the non-invasive method of examination. Apart from this, if the analogous antigenic sites were present for Cag-A and TPO, the obtained results were false positive.
Apart from this, other thyroid tests were performed in patients with Hashimoto’s Thyroiditis, such as Frank Hypothyroidism test. However, this test wasn’t found to be a reliable one. On doing the stool antigen test, we were able conclude that there was some Correlation between patients with H. pylori and hyperthyroid GD patients. However, such a correlation was not seen been patients with H. pylori (HT) and hyperthyroid patients.

In the result, it was noticed that the presence of Cag-A was proportionately present in both the groups – GD and HD. These results were in agreement with the previous observation for TH patients. Other factors such as subclinical or Frank Hypothyroidism may mislead the conclusion of the study. The stool antigen test clearly showed the correlation between, pylori and hyperthyroid GD patients.

**Discussion**

According to recent studies, we learned that there was a significant correlation between Cag-A carrier, H. pylori strains, and Grave’s Disease and the results did not depend on the hormonal status of the cases considered for study. There may be other studies that show a positive relationship between H. pylori and Hashimoto’s Thyroiditis. According to some observations, gastroduodenal tract need not necessarily be the only cause of attracting H. pylori infection. A number of studies gave a convincing explanation about the correlation between H. pylori infection and Autoimmune Thyroid Disease. One such study declares that people having a history of Atrophic Thyroiditis are at the risk of attracting H. pylori infection. In our current study, we looked into the presence of Cag-A antibodies, monoclonal antibodies for Cag-A, having H. pylori strains had Thyroid glandular cells, which in turn contain an endogenous peroxidase.

Further, when the infected bacteria were cultured, it was observed that it became more susceptible to thyroid disease. It was observed that patients who possessed thyroid disease had the tendency to have autoantibodies against thyroid cells, such as thyroglobulin and mitochondrial peroxidase.

According to a recent study by Tom et. Al, H. pylori can encode genes for an endogenous peroxidase and facilitates the immune system of an individual by promoting the bacterial enzyme activity, which in turn reacts with the receptors on human tissues. Subsequently, the serum autoantibody titer for peroxidase and thyroglobulin was tested and Thyroid Stimulating Hormone (TSH) receptors were monitored. In the process, the receptors kept decreasing after H. pylori bacteria were reacted. In one case, the titer reduced sixteen-fold after H. pylori.

A few microorganisms give rise to complicate carbohydrates, which resemble the constituents of Glycoconjugate that can be seen on the superficial surface of human blood cells and CD4 on the cells of other organs.

According to Hein HO et.al, genes have the specificity for H. pylori infection as well as duodental ulcer development. Ultimately, we can conclude that the inflammation brought about by the bacteria H. pylori has induces a few pathological changes like increased TLC, neutrophils, and basophilis. The association of H. pylori infection, particularly by strains that articulate Cag-A with autoimmune thyroid diseases is not coincidental and further study is necessary.

**Conclusion**

According to a study, the thyroid gland might be a target for H. pylori-invoked immune-inflammatory response and Autoimmune Thyroid Disease might be its consequence. An increased existence of H. pylori bacteria was identified in Autoimmune Thyroid Disease. The H. pylori bacteria were present in the stool samples of the one hundred patients who were diagnosed with Autoimmune Thyroid Disease. Out of 100 patients, 89% had Grave’s Disease and 74% of them had Hashimoto’s Thyroiditis. It was also concluded that there was a correlation between H. pylori and Grave Disease and HT. By eliminating H. pylori infection, we can reduce thyroid autoantibodies. The existence of TPO-Ab (Thyroid Peroxidase Antibody) was more frequent in cases having H. pylori infection.

Female Adolescents Knowledge Regarding Reproductive Health

Ibtisam Sahib Asal 1, May Sallal Sahib 2, Manal Saheb Hamza3, R.N. Kadhim Hussein Jassim4

Abstract

Background: Adolescence as the period of human growth and development that occurs after childhood from 10 to 19 years of age. The physical and psychological wellbeing is vital for knowledge of this group considering their health.

Method: The study was conducted among girls aged 16–20 years in female secondary school in AL-Hilla city. Collected about 141 samples so we collected these samples to educate and increase of awareness of reproductive health. We use a developed and well-constructed questionnaire, the data collected by the methods of self-administered technique. We used accurate details to know the percentage of adolescent girls on the concept of reproductive health and discuss the concept of puberty with their parents, teachers, sisters or brothers as well as knowledge of diseases related to the reproductive system.

Result: Sixty-eight percent have low knowledge about the concept of reproductive health. This means that they are risky factors to have reproductive diseases such as UTI or STD for the lack of awareness of how to take care and maintain of themselves and all of that because their lack of education and knowledge about the reproductive health and this constitutes a negative impact on the concept of reproductive health.

Keyword: Knowledge, Reproductive health, adolescent, Female

Introduction

Adolescence is a period of life during which individuals reach sexual maturity. It is the period of transition from childhood to adulthood and it is often characterized by biological and psychosocial changes as well as sexual experimentation 1. Globally, adolescents constitute about one billion of the world’s population, with 75% living in developing nations. 4 With the rapid expansion of mobile phone ownership in low- and middle-income countries (LMICs) over the past decade, the field of mobile health (mHealth) has emerged as a novel and potentially cost-effective way to increase access to health information and improve health knowledge as well as health outcomes 5. According to national data, receipt of contraceptive, sexually transmitted disease and/or gynecological services from a provider differs by age, gender, insurance coverage, sexual experience, and number of partners. It is imperative to begin identifying the social, psychological and logistical barriers that prevent diseases. 6 In Kenya, the site of this study, the 2008 census reported that about 33% of the population lived in urban areas and about 72% of the Kenya urban population lived in slum areas with poor access to clean water and sanitation. The period of transition from childhood to adulthood is called adolescent and it is often characterized by physical and psychosocial changes as well as sexual experimentation. About a billion of world’s population of adolescent age grouped constitutes this group. The physical and psychological wellbeing is vital for knowledge of this group considering their health. An earlier study shows the lack of knowledge Leeds to negative results considering pregnancies, abortion and its complication and sexually transmitted infection. The concept of reproductive health gained currency in the 1980s as a symbol of a fresh perspective on women’s rights and family planning. The premise of this perspective is the principle that every woman has
a right to reproductive health, that is, to regulate her fertility safety and effectively to understand of disease, disability, or death associated with her sexuality and reproduction and to bear and rear healthy children.

Adolescent must a knowledge certain facts regarding their health such as the concept of contraception, safe sexual practices, healthy pregnancy and postpartum behaviors and preventive care is important to keep women healthy and leading productive lives. Adolescents have to keep in mind certain facts considering the use of condom, use of contraception, decision to keep a pregnancy, use of safe abortions. Services are some of choices and reproductive health decisions adolescent make. Ignorance of health literacy has been increasingly recognized as an important area of focus for women’s reproductive health. Knowing about reproductive health services is essential to enable them make informed choices. The type of choices made by these young adults could either impact positively or negatively on their lives, their families and the society at large. According to the 2014 Chana demographic and health survey (GDHS) about 14% of the female aged 15:19 years had begun child bearing. Of these 14% about 11% have had a life births and 3% were pregnant at the time of survey (8).In sub-Saharan Africa, where a fourth of all adolescent are reported to have sexual experience, education of sexual and reproductive health are generally reported to be low. This study aims to assess the female Adolescents’s knowledge regarding productive health

Methods

Design of the study: Descriptive design survey study was conducted through September 2019 to the end of Jan 2019.

Study setting: Female Secondary School in Al- Hilla City

Samples of the Study: Female Secondary School in Al- Hilla City, total student were (200 students) for all stages, researchers sent to (300 students) the accepted papers were (141) participants which estimated about (30% from total students)

Instrument of the Study: Data were collected through using construction questionnaire after did some adjustment on questionnaire like reducing the scale from five to three scale, and delete some points from demographical data (“Increasing the number of scale categories did not necessarily improve performance”. The questionnaire divided into two sections, first one: demographical data (gender, age, educational qualification, monthly income). The second one consists from items. all these had Cronbach’s alpha coefficients (CCα) 0.73

Data Collection: With using a developed and well-constructed questionnaire, the data collected by the method of self-administered technique. In addition, the researchers met all the principals to clarify the points which were not clear.

The Statistical Analysis: The questions all that used in collecting data were checked out for any mistake or error and scrutinized, then it transferred and computerized and coded by their numbers in Microsoft excel 2016. Data of the 250 participant’s were entered and analyzed by means of the statistical package for social sciences (SPSS), 24.0, 2016.

Ethical Consideration: All participants were informed fully about current study and its aims and then a voluntary verbal consent was obtained from the participants in order to participate in the study. Besides, it has been taken into account the confidentiality of information obtained from students,

The study was approved by the ethical consideration committee in Babylon health department. Participants voluntarily accepted and were warned in detail of the nature of the paper,

Results

(65.7%) of the female students age group was Early Adolescent aged, (43.6%) were 4th class, and (95.0%) were mother alive and (88.6%) were father alive
Table (1) shows the total score of nursing student’s knowledge regarding Islamic eating guidelines.

Discussions

This study aims to assess the female adolescents’ knowledge regarding productive health; according to the results of the study most responses had low level of student’s knowledge.

Adolescents in study conducted by Joseph Maaminu Kyilleh (2018) said generally engaged in risky reproductive health choices that can negatively affect their reproductive health. Adolescents in this part of Ghana have challenges utilizing available reproductive health services because of socio-cultural and health system barriers, that agree with this results of Iraqi female sources of knowledge.

Adolescents’ knowledge and access to reproductive health services is important for their physical and psychosocial wellbeing. It has been found in an earlier study that the lack of knowledge about the consequences of unprotected premarital sex among adolescent females predisposed them to unwanted pregnancies, unsafe abortion and its complications, and sexually transmitted infections.

Knowledge on reproductive health services is essential to enable them make informed choices. The type of choices made by these young adults could either impact positively or negatively on their lives, their families and the society at large. Adolescent girls face substantial sexual and reproductive health risks, including unintended pregnancy, unsafe abortion, and HIV infection.

The Shujaaz comic book that was familiar to about a third of the young people surveyed was a targeted media approach that seemed to be attractive to urban youth. The comic covered themes that were relevant to young people while at the same time it used slang and language
that young people are comfortable with. Prior research suggests that targeted print media is more effective than more generalized print media where the messages are not specific to a health behavior or to a target population.

**Conclusion**

Study concludes that most female adolescents had low knowledge regarding productive health, which correlated for student’s age, sources of knowledge as weak correlation.

**Recommendations:**

Take care of the parents and especially the earliest of them to the class under consideration taking into account the need to explain and communicate the idea of physiological changes in the immersion of the late childhood and adolescent like giving the girls in the first menstrual cycle some recommendation and instructions. On the other hand, we would like to draw the role of the teaching staff, especially the role of guidance in following these aspects, taking into consideration in the terms of educating this group with such changes.

**Financial Disclosure:** There is no financial disclosure.

**Conflict of Interest:** None to declare.

**Ethical Clearance:** All experimental protocols were approved under the Babylon Health directorate and all experiments were carried out in accordance with approved guidelines.

Estimation of Phenylalanine Hydroxylase Activity in Patients with Chronic Renal Failure

Najlaa Jawad Hasani
Assist. Lecturer Al-Furat Al-Awast Technical University/ Babylon Technical Insitute; Iraq

Abstract

Renal failure is a serious disease that affects the kidney and leads to different chemical changes and most cases lead to death. The aim of the study is to measure the activity of phenylalanine hydroxyls (PAH), and biochemical variables (urea, creatinine, and albumin) in the blood and urine of healthy and chronic renal failure (CRF) individuals. The study included 80 patients aged between 78 and 20 years and 80 healthy subjects between the ages of 23-65 years. The results showed significant differences in the activity of PAH at P ≤ 0.0001 in sera and urine chronic renal failure patients compared to healthy, as the activity significantly decreased in sera of patients with CRF and increased in urine. The mean activity of PAH was 54.67 ± 6.03 (IU / ml) in sera for CRF patients, whereas in healthy individuals it was 120.83 ± 23.21 (IU / ml), and the average activity of enzyme was 61.34 ± 7.12 in urine of patients with CRF compared with 33.87 ± 3.08 ( IU / ml) in healthy individuals. The activity of PAH enzyme was compared according to age groups, showing a decrease in the age group more than 45 years more than those in the age group less than 45 years with significant differences. In conclusion, the current study demonstrated that CRF is associated with loss of secretory function, and metabolism Endocrine actions in the kidneys, seems likely to lose renal activity phenylalanine hydroxylase.

Keyword: Chronic renal failure, phenylalanine, phenylalanine hydroxylase, renal function tests.

Introduction

It develops chronic kidney disease (CKD) is usually over many years, with a long latent period when the disease is clinically silent, and is characterized by the gradual substitution of the structure of the natural kidney fibrous tissue. When these structural changes become apparent, it leads to a decline in the ability of the kidneys to process wastes in the blood and perform other functions. We knew the results of Kidney Disease Outcomes Quality Initiative (KDOQI) of the National Foundation for the kidneys (NKF) on chronic kidney disease (CKD) as damage to the kidney (structural or functional) or low filtration glomerular rate of less than 60 ml / min / 1.73 m2 for 3 months or more. KDOQI company also established a classification system of five stages for CRF, which primarily depends on the glomerular filtration rate. During the early stages patients may show a normal or slight decrease in the rate of glomerular filtration (GFR) and albuminuria; later it progresses, leading to end-stage kidney disease (ESRD) or renal failure. Diagnosis, evaluation and treatment mainly on the vital indicators that assess kidney function depends. Glomerular filtration rate (GFR) is still the ideal brand for kidney function. Measuring GFR may take a long time, and therefore GFR is usually estimated from equations that take into account internal filtration markers such as serum creatinine and cystatin C. Other biomarkers such as albuminuria may precede decreased kidney function and have shown strong associations with disease progression. The results showed that new biomarkers appeared with a promise to detect kidney damage before the signs currently used.

An important enzymes that revealed modern clinical studies reported in patients with infections, inflammation and general immune activity is phenylalanine hydroxylase. The involvement of this data down regulating the activity of phenylalanine hydroxylase by oxidative stress in immune activation in vivo.
The activity of this enzyme was found in the liver, kidney(6,7), and pancreas cells of mice, in a previous study, laboratory enzyme activity was measured in mouse tissues, was the majority for the effectiveness of phenylalanine hydroxylase in the liver. Both kidneys combined, 10% of total body enzyme activity, and pancreatic activity of phenylalanine hydroxylase formed a low fraction of total phenylalanine hydroxylase activity in the body 7.

Mammalian PheH is active as a homotetramer 8, each consists of three polypeptide monomer zones are the regulatory domain of the terminal N, and the domain’s central catalyst, and the terminal tetramerization of the C domain containing the α-helix is used to tangle monomers 9. The structures of the regulatory domains of PAH have an ACT domain 8. While the dimeric shape structure of the rat PAH contains both catalytic and regulatory domains but lacks the C-terminal remnants 24 needed to form a tetramer. Phenylalanine PAH activation involves a consensual change in which the remnants of the N-terminal move away from the active site 9.

Phenylalanine hydroxylase (PAH) is a key enzyme in the catabolism and disposal of phenylalanine, therefore is responsible for serum Phe levels 10. PAH stimulates the hydroxylation of L-phenylalanine (L-Phe) to L-tyrosine (L-Tyr), It is a mixed-function oxidase depends on the iron, used cofactor tetrahydrobiopterin (BH4) as a reducing agent to provide the two electrons needed for the reaction (11,12), by molecular division of O2, add one atom to the phenylalanine ring and convert the other into water 13. This interaction in humans is vital to prevent the accumulation of neurotoxicity amounts of L-Phe (14,15).

Materials and Method

1- Subjects: Between October 1st 2018 and April 31, 2019,160 subjects were recruited in this study, and 80 consecutive patients(37female & 43 male) diagnosed by expert physicians to be CRF from Murjan Medical City, plus 80 without kidney failure( 46 female & 34 male) as a control group.

2- Sample collection:

Serum Preparation

Five ml of blood was obtained from each subject by puncturing the vein in a sitting or lying position, then slowly pushed into disposable tubes containing a separating gel. Blood in the gel containing tubes was allowed to coagulate at room temperature and then centrifuge at 1000 x g for approximately 15 min and then the supernatant was obtained and stored at -20 °C until analysis 8.

Urine Preparation

I attended a sample urine obtained in plastic packaging after being deposition of salts and impurities other by using the centrifuged at1000 cycles / minute (10 minutes) and directly measure to the activity of the enzyme.

Methods Used

The activity of PAH enzyme was measured based on Bublitze (1969) (154) method, which includes the addition of enzyme DMBH4 and the phenylalanine based on tyrosine in the presence of PAH enzyme. Orange Absorption measured at 450 nm wavelength. This absorption is directly proportional to the enzyme activity.

Solutions of the Materials Used: The phenylbenzene base substance (Phe) dissolved in the Tris HCl regulating solution to adjust pH = 7.2, Catalase enzyme solution (CAT), DL- Dithiotheritol Solution (DTT), DMPH4 solution (6,7-dimethyl-5,6,7,8-tetrahydropterine), Trichloroacetic acid (TCA), HNO3 20%, Reagent 1-Nitroso-2-naphtol (NNS) 0.1%, Standard tyrosine solution.

The concentration of urea was determined by the use of the diagnostic tool provided by CAM TECH MEDICAL and spectral method, Creatinine concentration is determined by Jaffe reaction by the use of Biolabo- Franc Diagnostic Kit and Serum albumin is administered by the use of a diagnostic kit equipped by the French company Biolabo.

The Lowry method 16 was used to measure protein concentration in urine and using Bovin serum albumin (BSA) as standard protein.

Statistical Analysis

The data is calculated and analyzed using the Statistical Package for Social Sciences (SPSS) version
Results

The study included (80) cases suffering from chronic renal failure by taking a blood and urine samples from patients, also included (80) samples of healthy persons as a comparison group. The overall mean age of patients with CRF and control were (60.16±13.20) and (57.12±12.71) years old, respectively. Table (1) shows the differences between patients with chronic renal failure and control by social and demographic characteristics.

The activity of phenylalanine hydroxylase in the blood and urine of CRF patients and with healthy people was measured and compared using the Bublitze method (1969) \(^{17}\). When compared statistically, there were statistically significant differences between the activity of the enzyme in patients compared to the health level of probability \( p \leq 0.001 \) in the blood and urine, where the enzyme is less effective in patients with CRF in the blood while increasing the effectiveness of the enzyme in the urine as shown in Table (3).

The activity of PAH enzyme in blood and urine in males and females according to different age groups has been studied. Tables (4) shows the mean and standard deviation of the effect of age and sex and their interaction on enzyme activity, the results showed that there were significant differences between patients and healthy individuals, as well as significant differences between the age groups of patients. When comparing healthy and chronic kidney failure patients by age group, the enzyme activity in the blood was decreased for both age groups (age <45 yr.) And (age> 45 yr.), and over 45 years of age were more than people in the age group less than 45 years, as Increased enzyme efficiency in diuresis has been shown for both groups, the rise of the enzyme PAH for those over 45 years older than the age group under 45 years.
Figure 1: Activity of PAH enzyme in blood for CRF patients and control by age group

Figure 2: Activity of PAH enzyme in urine for CRF patients and control by age group

Figure (3): Activity of PAH enzyme in the blood of patients with CRF compared to control group by sex
Discussion

The number of people with CRF in the city was higher in rural areas. This is due to several factors including environmental pollution\textsuperscript{(18,19)} unhealthy eating habits, urban adoption of fast food \textsuperscript{(20,21)}, and canned foods \textsuperscript{22}. In addition to psychological and economic factors, all these factors affect the occurrence of many diseases, including kidney failure\textsuperscript{(23,24)}. This is consistent with the studies that have pointed to the high activity of the enzyme PAH in healthy blood and decline in urine and vice versa in patients with renal failure, as in the Diem K and his group (1970) \textsuperscript{26} and Daphnis E and his group (2001) \textsuperscript{27} in both males and females, as well as Pregnant women as in Lindheimer MD and his group (2001) \textsuperscript{28}. The presence of significant differences between the age groups of patients corresponds to studies that showed that the most vulnerable to kidney failure are those aged between 50-67 years and men are more likely to develop kidney failure compared to women \textsuperscript{29}, unlike some studies that proved that women are more vulnerable The renal failure of men and the nature of the effectiveness of the kidney on glomerular filtration is less than men \textsuperscript{30,31}. Unlike some studies that have shown that women are more likely to have kidney failure in men and the nature of kidney effectiveness on glomerular filtration is lower than men \textsuperscript{30}

Conclusion

Our study provides data that patients with CRF impaired renal function may also alter PAH enzyme activity. However, results need to be confirmed by further investigation.

Hand Hygiene Practices and Infection Control Measures among Emergency Units Health Care Providers

Anees Flayyih Abdulhassan¹, Sahar Adham Ali²

¹M.Sc. Adult Nursing Department- College of Nursing|University of Babylon, ²PhD. Assist. Professor Adult Nursing Department- College of Nursing|University of Babylon

Abstract

Background: Emergency units is a main part for hospital admission. It is the front line of the healthcare systems in the response to emergencies and public disasters, so the infection preventive measures practices can be easily overlooked or neglected by immediate and life threatening issues.

Objectives: To assess the practices of health care providers regarding hand hygiene.

Methodology: A descriptive cross-sectional study design carried out from the period between (Sep. 2018 to Aug. 2019). The study has been conducted in the emergency units at Al-Hilla teaching hospitals. Non probability (purposive) sample of (125) health care providers who work in the emergency unit were selected, (110) nurses, (15) physicians were selected related to special criteria. Special checklist prepared, inter-observer reliability calculated the statistical results recorded (r: 0.90), which is statistically accepted.

Results: The results shows that the higher percentage of the study sample 104 (83.2%) were between (20-30) years age group, 73 (58.4%) were male, while most of the study sample 67 (53.6%) were Bachelor or postgraduate degree holder, related to the study sample marital status, the higher percentage 64 (51.2%) were married. Overall hand washing practices which consider as the most important measures to control of infection were poor (1.61 0.748).

Conclusion: Regarding to the healthcare providers practices in hand washing with respect to the infection control measures during their daily caring in the emergency units the statistical results show low level of practices.

Recommendation: Effective educational program should take place for all healthcare providers by task based strategies to utilize the practices include bedside procedures.

Keyword: Infection control, measures, practices, emergency unit.

Introduction

Hand hygiene strategy is a cornerstone in the infection control protocols, the hands of healthcare providers are essential vehicle to transmit the infection to the patient. Hand hygiene recognize as treating interventional strategy to reduce the transmission of the pathogens in the healthcare climate. Hand hygiene practices decrease the incidence of the respiratory tract, gastrointestinal and skin infections. Recently alcohol-based practices included with hand hygiene strategy¹. Semmelweis and Holmes pointed that infectious diseases were transmitted by contaminated hands of healthcare providers, he suggested hand scrubbing should be performed with chlorinated solution prior to any direct handling with the patient particularly after leaving the autopsy laboratory, after this procedure the mortality rate decreased to (13%). Semmelweis, intervention consider as a model of epidemiological directed strategies to prevent infection².

In America recommended that even antimicrobial soap or any antiseptic agent which may use for hands cleaning when leaving the patients units with multi
drug resistant bacteria. Recently their guidelines which published in 2002, focused on the issue of alcohol – based hand rubbing where accessible standard directed to hand washing practices for the healthcare setting.

Geneva’s university hospital study many basics strategies focusing on alcohol hand rub, the applied study shows significant improvement of healthcare providers compliance related to hand hygiene which reduce the hospital associated infections.

One of the factors which effecting hand hygiene non-compliance is dermatitis, skin irritation and pain, which may produce by abrasive cleansers when used for several times during shift time prevent healthcare providers from washing their hands before, during, after providing care for their patients.

Objectives: To assess the practices of health care providers regarding hand hygiene.

Methodology: A descriptive (observational) cross-sectional study design is selected to study the phenomena of interest related to assessing the infection control measures practices for emergency unit healthcare providers.

Setting: The study has been conducted in the emergency units in the following teaching hospitals in four teaching hospitals at Al-Hilla city.

Sample: Non probability (purposive) sample of (125) health care providers who work in the emergency unit were selected, (110) nurses, (15) physicians related to special criteria.

Checklist: Special checklist prepared after comprehensive reviewing of related literature. Standard infection control measures practices adopted after modification to make it suitable for emergency unit healthcare providers, divided to three parts:

Part I: Consist of the demographical characteristics of the study sample includes: (6) Items: (Gender, age, educational level, marital status, residency, specialty).

Part II: Includes general informations related to (Years of experience, years of experience in emergency unit, training courses related to Infection Control).

Part III: Consists of (8) items related to hand hygiene.

Validity: Content validity obtained for the checklist by (9) expert panel to determine the relevancy, and clarity of the checklist to study the phenomena of interest.

Pilot study: A pilot study carried out to define the reliability of the checklist , (10) healthcare providers who work in the emergency unit included in this study, after obtaining their consent to participate in the study, each participant expose to three observation from three observer at the same time. Those (10) healthcare providers were excluded from the study sample.

Reliability of the checklist: Inter-rater or inter-observer reliability applied to obtain the stability of the checklist content/ when many observers award consistent estimation for the same phenomenon, it is a score of how much homogeneity or consensus exists in the ratings given by various judges. The researcher and two colleagues who graduate from nursing college to perform this step, each participant in the pilot study exposed to observed from three observers at the same time for each practice, the statistical results recorded (r: 0.90), which is statistically accepted.

Ethical consideration: Ethical consideration in quantitative research is one of the most important elements, this type of researches commonly use of human subjects. The consent may be given in written or oral form depending on the nature of the research. Ethical standards also protect the confidentiality and anonymity of the subjects. The formal agreement obtained from the study sample related to special agreement form.

Data collection: Self-report method adopted as a method to complete the first and second parts of the prepared checklist, which takes about (5 to 10) minutes. While the third parts needs one to seven days to complete three observation for each participant. The data collection extended about (56) days, it started from (18 of May and ended in 5 July. 2019).

MS (Poor Practice =1-1.6, Fair Practice = 1.7-2.3, Good Practice = 2.4-3)

Table (3) Shows that most of the study sample recorded poor level of practice related to hand antisepsis (1.00 0.00).

Discussion

The majority of sample were male, while most of the study sample in Kilic, 2016, were female, the disagree in this point is regarding the cultural status of our country and the stressful of emergency unit that needs so much effort that is difficult to a female to manage it. Regarding the educational level most of the sample (53.6%) were with high educational level (bachelor and post graduate), which agree with a study carried out by , in Jordan related to healthcare providers in emergency department that shows the majority of sample (59.5%) were hold a Bachelor degree. The results shows that most of the sample (51.2%) were single, while regarding to Kilic, 2016, the majority (53.2%) were married, the reason behind this disagreement is because the healthcare providers that included in this study were young and newly graduated. Table (1) Shows that the majority (41.6%) were Nurses who work in emergency unit, this findings
agree with Kilic, 2016, that presents (68.5%) were nurses working at emergency unit. 

Regarding to the years of experience the results show that (89.6%) have (1 to 10) years of experience which almost all of them spent (5 or less) years in the emergency unit, Al Bashtawy, 2016, in his study mention that the majority (43.2%) have about (5) years of experience in emergency unit. 

Table (2) Represent that most of the sample shows poor practice regarding hand washing that considered as key element of infection control, a longitudinal quantitative study in Brazil carried out by Zottele, 2017, about the healthcare professional compliance related to hand hygiene in an emergency room, shows that hand hygiene compliance was low, he suggested multidisciplinary approach is necessary to develop learning and compliance related to hand hygiene 

Table (3) This table shows that majority of the healthcare providers who participate in the study related to hand anti sepsis for not visible soiled hands in the emergency units were poor (100%), these findings seems to be similar with a study carried out in Boston which carried out by Venkatesh, 2011, this study, concluded that adequate supply of hand rub solutions, and training program does not ensure adequate performance of hand antisepsis still this issue needs focus program to improve adherence. 

Infection control measures and its compliance issue, commonly needs special knowledge and training for the move, its compliance requires change in the personal behavior to obtain this results the healthcare personnel needs educational and training programs and proper environmental and facilities to practice properly, while continuous monitoring and evaluation needed to maintain correct practices in order to improve quality of care and patients safety.

### Conclusion

Regarding to the healthcare providers practices with respect to the infection control measures during their daily caring in the emergency units the statistical results show low level of practices related to hand hygiene.

Abstract

Chitosan/polyvinyl alcohol cross-linked with genipin at different concentrations were utilized to synthesize films by solvent casting for bone tissue engineering applications. Fourier transform infrared spectroscopy (FTIR), swelling degree, degradation rate, contact angle, tensile strength was investigated. The results revealed a decrease in swelling degree, degradation rate, contact angle with an increased genipin concentration, while tensile strength increased. It can be indicated that cross-linked CS/ PVA with genipin could be applied in application for tissue engineering.

Keyword: chitosan, degradability, lysozyme enzyme.

Introduction

Regenerative medicine is a specialized field for restoring, safeguard and improvement body functions 1. Scaffold materials are a significant component for regenerative medicine because it can mimic with cells of tissue that contribute to the construction of new tissues 2,3. Chitosan, a polysaccharide biomaterial which amalgamates adorable group physiochemical and biological properties that authorize to utilized for variety applications 4. Chitosan can be used in body of human due to biocompatible, biodegradable, and biomedical 5. Chemical modification of chitosan is required to enhance properties to concur with application 6. Polyvinylalcohol is hydrophilic material utilized in vitro and vivo medical application due to biocompatibility 7. PVA blended with many natural polymers such as chitosan, gelatin due to its ability to form film 8. Genipin is naturally cross linker have been used for biomedical applications due to its susceptibility and biocompatibility to form crosslinked products stable and biocompatible 9. Physical and mechanical properties for chitosan biomaterials can be improvement by crosslinking remediation because of amino and hydroxyl groups for chitosan have capability to construct amide, ester linkages 10. Bones have capability to renew but existence of obstacles such loss of bone due to injury or disease may hinder this ability so bone tissue engineering can solve this problem 11. The purpose of the present research is improvement the blend of chitosan/poly (vinyl alcohol) films properties crosslinked with different concentrations of genipin. Dimida s. et.al, studied the effect of natural crosslinking genipin with different concentration for chitosan scaffold in (PBS) phosphate buffer saline solution that containing lysozyme enzyme. Rate of degradation of scaffolds was degreased with genipin concentrations 12. Kadhm A. et.al, studied enzymatic degradation of chitosan blend. The weight loss of chitosan blend increased through four weeks. Degradation rate of chitosan improvement by addition of genipin 13. Bi L.et.al, prepared the scaffolds of chitosan and collagen with various concentration of genipin to investigate the degradation rate of scaffolds from 7 to 21 day. Results shown that, degradation behavior of the scaffolds was decreased when the concentration of genipin increased 14.

Experimental:

Materials

Chitosan (CS) powder with deacetylation degree(75%), molecular weight (161) g/mol importation
from Xianm Shaanxi (China), Acetic acid 99% importation from Chem-lab NV (Belgium), Ethanol (EtOH, 99.9 %) from Schkarau (Spain), polyvinyl alcohol molecular weight (1300-2300) from CDH (India), Genipin importation from (CN Lab Nutrition), Asian Group (China), (PBS) pH7.2 from HIMEDIA (India). lysozyme enzyme was (LZ, ≥ 90 % proteins, activity ≥ 40 000 U/mg ) from CDH (India).

**Prepare of blended Films:**

Chitosan (CS) powder was dissolved in acetic acid aqueous solution (2%) via magnetic stirred at 1400 rpm, 50°C for 1hr. polyvinyl alcohol powder was dissolved in distilled water via magnetic stirred at 1400 rpm, 120°C. The blend films was prepared by mixing two polymers at ratio (80:20). Genipin added at concentration (0.2%, 0.4%, 0.6% wt.) to the polymer blend. Table 1 indicated the composition of the polymer blend. The polymer blend solution was casted in petri dish and after 3day the films dried at room temperature.

**Fourier transform infrared spectroscopy:**

The FTIR spectra was carried out on FTIR microscopy (Bruker, Germany) to determine the vibration of function groups of blended films.

**Degree of Swelling:**

Swelling degree was utilized to assay the swelling degree of blended films according to ASTM D4546-08. The blended films inundation in solution of (PBS) pH 7.2 for 24h at room temperature. Swollen blended films were taken away, then removing the surplus solution by a filter paper. The swelling degree was determined by using the Eq (1).

\[
\text{Degree of swelling (\%)} = \times 100 \quad (1)
\]

Where, \( w_1 \), \( w_2 \) were weights of dried, swollen samples, respectively.

**Degradation rate:**

To study the enzymatic degradation behavior, blended films were submerged in (PBS) solution that containing lysozyme enzyme 0.0001 g/L according to ASTM F1635-04a. And incubated at 37°C for 6 weeks. The solution was revived every three days. Blended films removed from solution after each week, then washed by phosphate buffer saline solution (PBS), dried and then weight. Degradation rate was determined by the Eq. (2).

\[
\text{Weight loss (\%)} = \times 100 \quad (2)
\]

Where \( w_0 \) dry weight of film before degradation rate and \( w_f \) the dry weight of film after degradation rate.

**contact angle test:**

Knowledge the extreme time of blended films to become more hydrophilic was very significant so as to boost the cell attachment with the blended films. The method consist of measuring contact angle of the water droplet on surface blended films (Young-Laplace fitting method) according to ASTM standard D5946-04.

**Tensile test:**

According ASTM Standard Method D 882-0 the tensile test was determined. According to this standard, the samples have length 80 mm, the width of the sample 10mm, the thickness (0.25-0.3 mm) and the crosshead speed was fixed at 1 mm/min.

**Results**

**FTIR:**

Figure 1 illustrated the FTIR of films blended. Peaks at 3388 and 2924 cm\(^{-1}\) was linked to C-H and N-H stretching band, respectively. The peak noticed at 1631 cm\(^{-1}\) was correlated to N-H stretching in amide II. chitosan blended with PVA, peak at 1743 cm\(^{-1}\) was noticed illustrated the reaction between O-H to PVA and N-H to chitosan, see figure 1. CS: PVA crosslinked with genipin peaks at 1253 cm\(^{-1}\), 1405 cm\(^{-1}\), and 1629 cm\(^{-1}\) related to C-O, CH3, and C=C bonds, respectively. This indicate the reaction between carboxymethel group of genipine with amine group of chitosan.
Swelling Degree:

Figure 2 shows swelling degree of blended films submerged in phosphate buffer saline solution. The assay indicated the cells can fasten with the blended films. Incorporation of two polymer CS: PVA forming flexible network which give swelling to the blended films. With an increased genipin concentration, swelling degree decreased due to increase bonding forces between the blended polymers resulting from increase cross-link density. This manner may be demonstrate by reaction between the crossliker genipin and –NH$_2$ that reduces of amino groups concentrations, resulting reduction of reaction with water.
Degradation Rate:

Biodegradability is a significant property for films in biomedical applications. Enzymatic degradation rate of CS: PVA blended films and CS: PVA cross-linked with natural crosslinker genipin were investigated. Figure 3 shows weight loss for CS: PVA blended films and CS: PVA cross-linked blended films. The results show that the degradation rate of CS: PVA blended films was completely degraded after 3 weeks while CS: PVA cross-linked films was decreased through 6 weeks due to limited breakthrough of lysozyme through the films resulting in the increase cross-like density. However, significant change was indicated between the films with and without cross-linker additions 12.

Contact Angle:

The wettability of the films was investigated via contact angle analysis. Water contact angle of films are shown in Table 2. The average contact angle of CS: PVA films reveals the hydrophilic nature of chitosan. Decrease of average contact angle has been attributed to increase cross linker concentration make it more hydrophilic. It is obvious that genipin addition affected the hydrophilicity of the blended films because its addition decreased contact angle value. This is may be due to the high cognition between molecules of genipin and water considering that both of them are polar. Amendment in hydrophilicity of the films lead to good cells attachment 12.

Tensile Test:

The tensile strength and elongation (%) of CS: PVA blended films and CS: PVA cross-linked were indicated in Figures 4 and 5. The results investigated that the tensile strength of CS: PVA blended films increased as crosslinker concentration increased while elongation (%) varied thus due to formation intermolecular hydrogen bonds between carboxymethyl group of genipin and amine group of chitosan that form secondary amid 22.
Conclusion

Chitosan/Polyvinyl alcohol has been invented with Genipin as natural crossliker. Crosslinked chitosan/polyvinyl alcohol films by using different concentrations of Genipin enhanced mechanical and physical properties appropriate for application tissue engineering. The investigation has discovered that combination of genipin to chitosan/polyvinyl alcohol enhanced the swelling degree, degradation rate, contact angle and tensile strength. This study allowed use chitosan/polyvinyl alcohol crosslinked with genipin for bone tissue engineering.

Assessment of Primary Dysmenorrhea and Its Effect on the Quality of Life among Female Students at University of Babylon

Zainab Abdulameer Abdulrasol¹, Salma K.J.Al.Ibrahimi²

¹ Student, Maternal and Newborn Health Nursing, College of Nursing, University of Babylon, ² Prof., Community Health Nursing, College of Nursing, University of Babylon

Abstract

Objectives: The objectives of this study were to assess primary dysmenorrhea condition among participants. In addition to, find out the correlation between primary dysmenorrhea and quality of life of among female students at Babylon of University.

Methodology: A cross sectional study design used in this applied quantitative research through the period of 4 August 2019 to 22 October 2019. The study conducted in Babylon province, Iraq at University of Babylon. Four faculties has been selected randomly as setting of current study. The total participants were (N=145) females students, selected as 20% from each faculty, by using purposive non-probability sampling approach. The data collected by using an adapted questionnaire and analyzed electronically by using SPSS program.

Result: The findings of the present study revealed that (89%) of participants were unmarried. Almost the entire of sample had family history of primary dysmenorrhea. According to NPRS scale for assessing pain intensity (62.1%) with severe primary dysmenorrhea. The study’s finding found out a negative significant correlation between primary dysmenorrhea intensity and overall quality of life scale at P≤0.05 (r= - 0.642, P=0.000).

Conclusion: Primary dysmenorrhea is a very common problem among female students at university of Babylon; it affects their quality of life. QoL decreases with the increase in the severity of primary dysmenorrhea.

Keywords: primary dysmenorrhea, quality of life.

Introduction

The transformation of females from childhood to sexual maturity and become capable of production termed as puberty. Throughout this transitional phase several alterations will take place which include hormonal, psychological, cognitive and physical changes besides to the evolution and sexual developments, these changes occur synchronously. The prime physiological change in girl life is the onset of menarche which is special event of females’ life due to the first occurrence of menstruation. Menstrual cycle is natural phenomenon, it is a significant signal of females’ health, and it’s an important indicator of endocrine function. There are several structures of women’s body that will cooperate with each other in order to initiate the menstrual blood flow, these structures are: hypothalamus, pituitary gland, ovaries, and uterus. One of most common menstrual disorders is dysmenorrhea; is episode of uterine cramp in the lower abdominal segment, immediately before or during cycle, dysmenorrhea variance among women. There is lack in the understanding of menstrual cycle disorders especially dysmenorrhea. Furthermore, lack of knowledge related to this condition among young girl

Corresponding author:

E-mail: SARAAAMEER44@gmail.com
because they received scarce education on dysmenorrhea. Dysmenorrhea either primary which mean it’s not related to pathological reasons or secondary related to pathological reasons. Primary dysmenorrhea (PD) occurs because of excessive amount of prostaglandin which produced during the disintegration of pre-menstrual uterine endometrium. While, the pain caused by a disorder in the women’s reproductive organs, such as endometriosis, adenomyosis, uterine fibroid, or infections, called secondary dysmenorrhea. Pain severity may be measured by using scaled as “no pain, mild pain, moderate pain, severe pain and worst possible pain”. Yet, data on experience of menstrual cycle and its influence on the health conditions, quality of life (QoL) and social integration among females in developing countries are still insufficient.

Objectives of the Study

1. Assessment primary dysmenorrhea among female students.
2. Find out the correlation between primary dysmenorrhea and quality of life of among female students at Babylon of University.

Methodology

A cross sectional study design used to apply quantitative research through the period of of 4 August 2019 to 22 October 2019. The study conducted in Babylon province, at university of Babylon. 4 faculties selected randomly. The total participants were (N=145) female students their age between (18-25) years old female students selected as 20% from each faculty, by using purposive non-probability sampling approach. The questionnaire was constructed and developed as a tool for data collection, and it includes three parts; the first part was sociodemographic data of female students. Second part was Numeric pain rating scale to assess the intensity of primary dysmenorrhea. The third was SF-36 Health Survey of quality of life scale consists of 36 items divided into seven sub-scales (General health domain, Limitation of activities domain, Physical health problem domain, Emotional health problems domain, Social activities domain, Pain domain, and Energy and emotion domain). These domains are rated on (3 level type Likert scale) included (always, sometimes, and never) and scored as (1, 2, 3) respectively. Positive items in the QoL scale reversed for the statistical purposes. The items of SF-36 rated based on a 3-level Likert scale, which was determined according to the mean of items’ scores to poor quality of life (1 - 1.66), fair quality of life (1.67 - 2.33) and good quality of life (2.34 - 3).

Mean of scores calculated as follow:

\[ M.S = \frac{\sum S f}{N} \]

where M.S = mean of scores, f = frequencies, S = scores, N = numbers of samples.

Range of Score = 0.66

Methods of Data Analysis

The data of the present study analyzed electronically via the Statistical program (SPSS) version 25. The method that used in this program aimed to find out the descriptive and inferential statistic such as frequencies, percentage, correlation coefficient, and chi-square and Pearson correlation of entering data in order to achieve the objectives of the study.

Result

f= frequency, %= percentage, SD= standard deviation

Table (1) reveals that a (61.1%) of the sample were within the age group (18-21) years old, the highest percentage represented (42.1%) of the female students are in second grade. According to the occupational status majority of participants (92.4%) were not working. The largest proportion of them sample were unmarried represented (89%). The table shows that (57.2%) were satisfied with their socio-economic condition; with respect to the sample address it has been found that (84.8%) of them live in the urban. Majority of them (95.9%) living with their families. Finally, (64.1%) of study sample were recorded a BMI (18.5< BMI< 25).

</table>

f = frequency, %= percentage

The table shows that highest percentage represented (61%) of the sample their age of menarche were between (13-15) years old; (52%) their duration of menstrual cycle between (3-5) days. Moreover, a (62.1%) of sample were with regular interval of menstrual cycle.

**Discussion**

Many studies and literatures emphasize that the sociodemographic characteristics are relate to most of the nursing subjects because nursing as a science deals with human being, people life, and health issues in different age groups and situations, the present study deals with the primary dysmenorrhea and its effect on QoL of female students; result show in Table (1), that high percent of sample undergone the study with (61.4%) which consider the largest proportion are within age group (18-21) and, their mean (21.01) (SD ± 1.557) this may due to criteria of selection of the current study’s sample, and the lawful age of students in colleges and universities; this result consistent with A cross-sectional study on (240 ) undergraduate female students at the University of Hong Kong by Chia et al. (2013) who studied the primary dysmenorrhea among university’s students; their findings show that mean and SD of age is (20.1 ± 1.4).

In regard to the place of residency it has been found about (84.8%) of female students were living in urban as display in Table (1) and that finding is matches with a cross-sectional study by Tawfeek (2008), who select (322) females students from different colleges , her result show that (273) of them from urban and the rest were from rural areas; while, findings of a cross-sectional study by Aziem et al. (2011) , on (900) girls from (8) schools; show that (469) were of rural residence while (431) were urban ones. The current study results revealed that (89%) of the sample were un married , and (11%) are married that congruent with a descriptive study at University of Jos by Emmanuel et al. ( 2013), their findings were (228 of 245) un married females students. The findings of the present study showed that more than fifty percent were satisfied with their socio-economic condition, which form the highest value, on the other hand, Assefa et al. (2016) a cross-sectional study in Ethiopia ; on (440) participants, it exhibited that (50.1%) stated as satisfied to some extent; this variance may belong to the contentment that widely spreading in Iraqi community and that not indicated in necessary that they are with good socio-economic status but it give them sense of satisfying of what they have. In the light of this study and regarding the BMI a high percentage of respondents were showed normal weight, this finding in line with Shaik et al. (2015)which contributes, to a number of diseases affecting women’s future health. The objective of this study is to assess the mean age at menarche in girls of ages 9-16 and observe its relationship with their body mass index and other covariates in Riyadh, Saudi Arabia.
304 female students of both private and governmental schools in Riyadh, Saudi Arabia, during March –May 2013. Data on demographics, socioeconomic status, physical activity, diet, and age at menarche were collected from students and their mothers, using self-administered questionnaires. Physical examinations were conducted to collect the anthropometric measurements. Results: Out of 304 students with a mean age (SD their study about the cross-sectional study was conducted among (304) female students of both private and governmental schools; it confirmed that the majority (79.9%) had BMI within the standard range, while only (4.9%) of students were under-weight and the prevalence of obesity & overweight (4.9%) & (10.2%), respectively.

Table (2) demonstrated the result of Numeric Pain Rating Scale for assessing pain severity; which shows the highest proportion reported sever pain as (62.1%) then followed by moderate as (25.5%), and finally mild as (12.4%) with mean (6.88) and SD (2.21). It’s well known that even with mild level of pain the quality of life of girls may be affected. The study’s finding is not consistent to Kazama et al. (2015) who found that only (17.7%) of their participants experience severe primary dysmenorrhea during their period, in their cross-sectional study that targeting female junior high school students in different cities in Japan, a total of (2,819) female students attended the (28) schools. This result seem to be close to findings of the study conducted by Faramarzi & Salmalian (2014) in Iran on (360) medical science female students, they verified that their outcomes show that the number of students who drank tea was (72 %). The onset of menstruation is a part of maturation process, after retrieved articles documenting the menstrual history related to primary dysmenorrhea, studies revealed that the history of first period vary according to the country and the climate as well as the geographical area. It has been appeared from the current study that Mean and SD of menarche’s age for females was (13 ± 1), usual menstrual duration (per days) was (5±1) and more than half of the respondents were with regular menstrual period as illustrate in Table (5); a study conducted in Johannesburg, South Africa by Iacovides (2013) on (20) females showed that Mean and SD of the age of menarche was (13 ± 2) and Mean & SD for menstrual period duration was (5 ± 1) these finding similar to current study’s findings. In addition to a correlative study in Mansoura city, Egypt by Mohamed & Mansour (2013)

Vitamin D Level Status and Hypertension among Old Adult Iraqi People in Al Hillah City

Ismael Hasan Jawad, Hasan Alwan Baiee

1 Ph.D. Student, Nursing Student, University of Babylon College of Nursing,
2 Prof. Dr. University of Babylon College of Nursing

Abstract

Background: Vitamin D has different biological actions in the body. Vitamin D has the pleiotropic effects in multiple organ systems, and vitamin D deficiency was suggested to be associated with high blood pressure according to previous reports. Several interventional studies have examined the effect of vitamin D supplementation on high blood pressure patients.

Objective: to identify Vitamin D level and its correlate with hypertension among old adults.

Methodology: This was across sectional descriptive observational study included convenient sample of elderly people in Hilla City, Babylon province, the period of the study started from the first of January through August 2019, a pretested semi structured questionnaire was used to interview the participants who attended primary health centers after obtaining their verbal consents, the sample included (300) old adult of both gender, serum level of Vitamin D was assessed by chemo immunoassay method, the blood pressure was measured single handy by the researcher using mercury sphygmomanometer to diagnose hypertension.

Results: The study included 300 participants 83.0% of the study sample had either insufficiency or deficiency of Vitamin D level. Hypertensive people had significant Vitamin D Deficiency (both deficiency and insufficiency of vitamin D, 81% and 70% respectively as compared to normotensive participants, this difference was statistically significant p<0.05.

Conclusion: there was a significant inverse relationship between vitamin D level and blood pressure.

Keywords: Vitamin D levels, Hypertension, Old adults, Iraq

Introduction

There is a remarkable increase in incidence of cardiovascular diseases in both lower- and middle-income countries including Iraq, hypertension is also increasing. Arterial hypertension is an important and serious public health problem which is responsible for 6% of deaths globally every year and can result in devastating complications such as peripheral vascular disease, heart failure, stroke, and renal failure. Vitamin D deficiency has been blamed to be a risk factor of arterial hypertension for both systolic and diastolic blood pressure.

Since elderly population have low intake of vitamin D, limited exposure to sunlight, and insufficient capacity in their skin to produce vitamin D, they are at high risk of deficiency and related complications including hypertension. There is a growing body of evidence from animal and clinical studies that vitamin D-mediated reduction of hypertension involves increased activation of the renin–angiotensin–aldosterone system other studies reported that vitamin D can be taken as a drug for hypertensive patients mainly by the elderly people, the gold standard of epidemiological studies of vitamin D blood levels and hypertension have been null.

This study was conducted to identify the prevalence of Vitamin D Deficiency (VDD) among hypertensive patients and non-hypertensive to estimate the association between these variables.

**Methodology**

This was a cross-sectional descriptive observational study included a non-probability (convenient sample) of elders (>65 years both women and men) in Hilla City, Babylon province, Iraq. The period of the study started from the first of January through August 2019, the sample size was calculated according to the sample size calculation equation with 95% confidence level, 300 elderly people participated voluntarily in this study, all of them agreed to participate after explaining the objective of the study by the researcher (response rate 100%). This study was approved by the Ethics Committee of College of nursing - University of Babylon, a pretested questionnaire was used to interview the participants after obtaining their verbal consents, the sample included old adults, apparently health & not receiving vitamin D supplement, serum level of Vitamin D that made by chemo immunoassay method (maglumi instrument). Data about demographic characteristics, drug uses, number of chronic diseases, as well as measurement of mean systolic and diastolic blood pressure of each participant were done single handy by the researcher himself. Blood pressure was measured in the sitting position. Patients were kept seated quietly for at least 5 min in a chair. Blood pressure was measured using a sphygmomanometer with an appropriate cuff the cutoff values, blood pressure more than 140/90 considered hypertension in this study or those who diagnosed previously as hypertensive and taking antihypertensive drugs. Vitamin D levels are divided into three categories: deficient < 20 ng/ml, insufficient between 23-29 ng/ml and normal level 30-100 ng/ml. Data were analyzed by using the (spss) package version 23. The chi-square test was used to test the associations between variables. The association considered statistically significant when the P-value is less than 0.05.

**Results**

The study included 300 participants, 83.0% of the study sample had either insufficiency or deficiency of Vitamin D level. The proportion of adults with hypertension were more common among participants with deficient and insufficient vitamin D, 81% and 70% respectively, the difference was significant p<0.05.

This table (4) shows the prevalence of VDD among old adult women (79%), a highly statistically significant association between low Vitamin D level (less than 30 ng/ml) and Hypertension among elderly females, chi square value=59.1, df=2, p<0.001.
Discussion

This study examined vitamin D serum levels in apparently healthy old adults both males and females in Hilla city – Babylon province, Iraq, in order to determine the prevalence of vitamin D deficiency and its association with blood pressure. In this study, the vitamin D level status among Iraqi Patients in Al Hillah City and the relation of these dependent and independent variable were assessed in 300 patents the most of sample are females 67%. The low mean of serum vitamin D deficiency in this study is higher in women than in men. Overall, we found that vitamin D deficiency was very common the study group, the prevalence of Vitamin D Deficiency (VDD) in the current study is about one fifth, this high prevalence health problem is similar to that reported by a study conducted by Kara A and Datta S in India who found that Vitamin D deficiency is significantly prevalent in otherwise healthy old aged population.

The Korea National Health and Nutrition Examination Survey reported prevalence of vitamin D deficiency (≤20 ng/mL) of 47.3% in males and 64.5% in females, but in a nationwide population-based study conducted in Thailand, only 5.7% of the population had a 25(OH)-D level <20 ng/mL. The prevalence of VDD in our study is higher than that found in local Iraqi study conducted in Baghdad on 20 Parkinsonism Iraqi patients with mean age 59 years (62.5%) the same study reported that the proportion of VDD was much lower in the control group (27.5%) 21. Studies found that there is an increasing prevalence of vitamin D deficiency with age. In general, elder people are more liable to VDD due to many reasons, not only due to decrease skin production of Vitamin D but also due to decreased sunlight exposure, decreased dietary intake, impaired intestinal absorption, and diminished hydroxylation in the liver and kidney. Our study depicts a strong association between low serum consecration of vitamin D and increasing both systolic and diastolic blood pressure, this finding goes in line with the findings of other studies that evaluated the association between the level of vitamin D and the blood pressure, the risk of hypertension diminished following elevation of plasma concentrations of 25(OH)D. Another study found an inverse association between 25(OH)D and cardiovascular disease (including arterial hypertension) mortality in old adults with serum 25(OH)D levels of ≤21 ng/mL. Other studies have reported contradictory results regarding the association between vitamin D level and hypertension in elderly men and women, there is evidence that VDD causes multiple diseases including hypertension and complications. Various mechanisms supposed to play role in the effect of vitamin D on blood pressure, one of which is the renin-angiotensin system which the important contributor to systolic blood pressure. Studies in animals have shown that 1,25-dihydroxyvitamin D reduces renin gene expression by a mechanism that is bound to the vitamin D receptor and thus reduces blood pressure. Vitamin D can also exert antihypertensive effects through different molecular mechanisms. A recent study recommends that Vitamin D can be used as an adjuvant drug to control the blood pressure on hypertension patients with vitamin D deficiency.

Conclusion

The results of the current study show a widespread, severe Vitamin D deficiency among participants of both gender in Iraqi elderly people there is a strong association between VDD in elder men and women and hypertension, we suggest starting public educational campaigns to raise public awareness about the relationship between low level of vitamin D and high blood pressure. We recommend further large scale studies are needed to confirm our findings. The health care providers (physicians and nurses) should keep a check on the Vitamin D levels of elderly people in order to curb the ever-increasing incidence of hypertension.

Attitudes of Secondary School Students toward Health Promotion Behaviors in Al- Hila City

Hasaan Abd Ali¹, Salma K . Jihad²
¹Master Student, ²Prof. Dr., Community Health Nursing, Faculty of Nursing, University of Babylon

Abstract

Objectives To identify the school students sociodemographic characteristics . To assess the attitude of participants toward health promotion .

Methodology: A cross-sectional descriptive study consisting of (177) students , to Attitudes of Secondary School Students toward Health Promotion Behaviors of secondary school student in Al- Hilla City

Result: Analysis of data reveals that there is a (67.8%) of adolescent have a normal body mass index, and (15.8) have underweight, (12.4%) overweight, while (4%) only have obesity.

Conclusion: Most of the students maintained normal weight status according to their BMI. Most of students aged at middle adolescence period, males more than females, majority of students were un married, at fourth grade, most of them were urban residence and ordered as 2nd member in the family, majority of them were not smoking and live with their parents.

Keywords: Attitudes of Secondary School Students toward Health Promotion.

Introduction

A huge proportion of the world’s population more than 1.75 billion young, aged between 10 and 24 years. Adolescents (aged 10 to 19 years) have specific health and development needs, and many face challenges that hinder their wellbeing, including poverty, a lack of access to health information and services, and unsafe environments. Interventions that address their needs can save lives and foster a new generation of productive adults who can help their communities’ progress. Many boys and girls in developing countries enter adolescence undernourished, making them more vulnerable to disease and early death. Adolescents are neither children nor adults; their needs can be easily overlooked in policies. Health interventions for adolescents cannot be effectively implemented without the appropriate policy and legal environment and its effective application.

According to scientists healthy and routine physical activities not only prevent and cure diseases, they are cheap and useful instruments in controlling stress, depression and...
aggression of present life

Methodology

Study Design: A cross-sectional descriptive study of Attitudes of Secondary School Students toward Health Promotion Behaviors in Al-Hilla City. Randomly sample of (177) students from secondary schools were selected. All of these adolescent measured by their weight, height, body mass index. The content credibility of the instrument was estimated through a panel of (14) experts, the stability of the items was based on the internal consistency of the questionnaire was evaluated by calculating Alpha Cronbach’ which $\alpha = 0.79$. Data analysis: Through the used descriptive statistical (SPSS) version 24 analysis approach that includes, frequencies, percentages, mean of scores, standard deviation.

Result of the Study

This table describe the weight status according the body mass index categories. (67.8%) of adolescents have normal weight status, (15.8) of them have underweight, (12.4%) of them have overweight and only (4%) of them were obese. The adolescents have a positive attitude when response to the items of the nutritional domains and the total mean was (2.34) at positive attitude of assessment. According to the social support domain, they have a positive attitude and the total mean was (2.37). According to the health responsibility domain, they have a positive attitude and the total mean was (2.36). According to the Life appreciation domain, they have a positive attitude and the total mean was (2.68). According to the exercise domain, they have a neutral attitude and the total mean was (2.22). According to the Stress management domain, they have a positive attitude and the total mean was (2.44). Finally the grand mean of all the domains was (2.4) and that indicate the adolescents had a positive attitude toward health promotion behaviors according to the level of assessment.

Discussion of the Study Results

Distribution of the Students by their Body Mass Index

In respect to the Body Mass Index results indicated that mostly participants have normal weight status, and only few of them reported as obese. The body built and weight abnormalities either low or high is considered nowadays the subject of concern because of its seriousness and this documented by so many agencies especially when it affect this age group due to the future effects and outcomes. This result disagreed with the findings of $^1$ they found that the prevalence of obesity was 21.3% and 22.3% respectively among adolescents’ students.

Part-3-Adolescent’s Attitudes toward Health Promotion Behaviors: Concerning the nutritional behaviors of the students, a positive nutritional attitudes were found. Most of students agree about eating three meals daily and snacks, choosing foods without too much oil, include dietary fiber (e.g. Fruits or vegetables), Drink at least 1500 cc of water daily (or 6-8 cups), Each meal includes five food groups (bread, meat, milk, fruit and vegetable) and eat breakfast daily. Kollatage et al., (2011) supported our findings, they found 83.2% of the respondents eating regular breakfast, and 62.6% have regular light lunch.

In regard to the social support behavior domain of the students, they believe in the social support behavior positively according to the mean (2.37). Most of students agree about speaking up and sharing feelings with others, caring about other people, talking about concerns with others, make an effort to smile or laugh every day, enjoy keeping in touch with relatives, make an effort to have good friendships and disagree with talking about troubles to others. $^3$ clarified that students reported a high scores when response to social support scale.

According to the present study, the health responsibility behavior of the students, and according to their answers shows positive healthy responsibility behavior at the mean (2.36). Most of students agree
about read food labels when shopping, watching weight, discuss health concerns with a doctor or nurse, observe body at least monthly, brushing teeth and using dental floss after meals, wash hands before meals, read health information and make an effort to choose foods without preservatives. Those vital results are supported by 4 who identified that high percentage of students gained high scores at healthy responsibility behaviors. 

The same table demonstrated the attitude regarding the life appreciation behavior of the students, results show a positive attitude mean (2.68). Most of students agree about make an effort to like myself, make an effort to feel happy and content, usually think positively, make an effort to understand strengths weaknesses and accept them, make an attempt to correct the defects, make an effort to know what’s important for the human, make an effort to feel interesting and challenged every day and make an effort to believe that life has purpose. The present results supported by 6 when they revealed that students had high total scores when response to life appreciation scale. Concerning the exercise behavior of the students, they have neutral attitude toward exercise behavior. Most of students partially agree about perform stretching exercise daily, also they are agree about exercising rigorously 30 minutes at least 3 times per week, participating in physical fitness class at school weekly, warm up before rigorous exercise and make an effort to stand or sit up straight. Keskin et al., (2017) supported the findings of the present study, they found that a large number of the students (63.9%) had a habit of doing sports regularly and the number of students who practice sports in a sports club is considerably high (43.8%). 

The stress management behavior of the students is another crucial domain, the present study findings revealed that mean of scores of attitudes show positive result. This may be due to social and cultural relationships, students agree about most of the items. Such as make an effort to spend time daily for relaxation, make an effort to determine the source of stress, make an effort to watch mood changes, sleep for 6–8 hours each night, make schedules and set priorities and try not to lose control when things happen that are unfair. The results came along with 4 who agreed that students had good stress management behavior.

**Conclusion**

1. Most of students aged at middle adolescence period, males more than females, majority of students were un married, at fourth grade, most of them were urban residence and ordered as 2nd member in the family, majority of them were not smoking and live with their parents.

2. Mostly their family’s income was insufficient, high percentage of student’s fathers education was bachelor degree and mothers had secondary school graduated, most of fathers were employer occupation and mothers were housewives.

3. Most of the students maintained normal weight status according to their BMI.

4. The students scored positive and neutral attitudes in most of the domains and sub-domains of the health promotion scale.

Investigation of mec A and (tst-1) Genes Among Staphylococcus aureus Isolated from Skin Infection in Al-Diwaniyah Iraq

Rasool kadam-alheyawey, Ibtisam Habeeb Al-Azawi

1 M.Sc. Student, 2 Assit. Prof. Dr., Department of Microbiology, College of Medicine University of Al-Qadisiyah, in Al-Diwaniyah Iraq

Abstract

In this study one handed and five samples were collected from skin infection in hospital Diwaniyah Dermatology Consultancy in Al-Diwaniyah governorate from December 2018 to April 2019. All samples were cultured and identified by using phenotyping tests. The results revealed that 41 isolates were Staph. spp. and 30 isolates out of them diagnosed Staphylococcus aureus by using (API staph). Virulence factors were explicated by using polymerase chain reaction (PCR) methicillin-resistant Staphylococcus aureus (MRSA), were identified by detecting (mec A gene), which revealed that all skin infections were MRSA (100%). Also, toxic shock syndrome toxin (TSST) were identified by using PCR to detect (tst-1 gene 326 bp.), which revealed that 23 isolate were positive out of 30 isolate (76.33%).

Keywords: Investigation, mec A and (tst-1) Genes, Staphylococcus aureus

Introduction

Many patients who are hospital reviewers suffer from skin lesions and considered an important health problem. S. aureus is one of the most important pathogens found in most places and also found naturally on human skin and is associated with a wide range of skin diseases. The threat of this S. aureus is its morbidity, which is the factor of virulence produced. The skin invasion of S. aureus either an essential internal source or external source. The emergence of strains of S. aureus resistant to antibiotics such as MRSA is a global problem in clinical medicine. Staphylococcal resistance to penicillin is mediated by producing penicillinase. Staphylococcal cassetes chromosome mec (SCCmec) is a family of mobile genetic elements of S. aureus. Resistance is given by the mecA gene by a protein associated with penicillin (PB2a or PB2), which has less affinity for act with β-lactams; allowing resistance to all β-lactam antibiotics, this mobile gene component has been acquired by different strains in separate gene transfer events, indicating that there is no common ancestor for the different MRSA strains. Toxic shock syndrome is a condition caused by this bacterial toxins, the primary mechanism involves the production of high-contrast antigens during topical Staphylococcal infection. The progression of the disease arises from superantigen toxin that activating multicellular T cells.

Material and Method

The study was conducted on patients with skin lesion caused by Staphylococcus aureus in Al-Diwaniyah city / Iraq / 2019 and collected 105 samples included male and female. Patients (children, young and adults) range in age from 1 to 60 years in AL-Diwaniyah Teaching Hospital.

Isolation and Identification:

One handed and five samples were collected through a questionnaire (name, sex, age) from skin lesion by transport media swab, then cultured on conventional media (blood agar, mannitol salt agar). This dishes were incubated at 37°C for 18-24 and 48 h respectively, and diagnosed by biochemical testing. The diagnosis were isolates basis on phenotypic, catalase, oxidase, and coagulase. These isolates were recognized based on common biochemical tests. (API Staph) that differentiate between species belonging to staphylococcal.
antimicrobial susceptibility:

To perform the antimicrobial susceptibility testing, the agar discs diffusion method as that described by 9.

Bacterial DNA Extraction:

The extraction DNA has been done according to the manufacturer instructions.

To determine the presence of the desirable amplicon, electrophoresis that in 1.5% gel agarose stained with adding ethidium bromide, and the products that visualized using a UV transil-luminator.

**Statistical analyses:** the used, Chi square, were performed. A p-value less than 0.05 was considered statistically significant.

**Results:** In this study 30 isolates of *S. aureus* out of 105 isolates, were isolated from skin lesion such as abscesses, boils, pimples and folliculitis at Al-Diwaniyah Teaching Hospital, which was determined by phenotypic characteristics and via biochemical testing then confirmed. Ten different antibacterial were used against *S. aureus*. Resistance showed against some antibiotic, (30 isolates 100%) resistant to each Ampicillin, pencillin, cefoxatin, azithromycin, and trimethoprim, resistance was moderate to levofloxacin, chloramphenicol (12 isolates 40%), clindamycin (15 isolates 50%) While lowest resistance to Amikcin (2 isolates 6.66). But they are wholly active vancomycin (30 isolates 100%). Polymerase chain reaction (PCR) used for amplification of *mecA* and *tst-1* genes. All the isolates from *Staphylococcus aureus* appeared to be carriers of *mecA* gene, which were 100% by using specific primer 855 bp as figure (1). While were results *tst* that shown 23 (76.66%) samples from the out of 30 isolates was positive by using specific primer 326 bp as figure (2).

**Figure (1)** Ethidium bromide Gel electrophoresis (1.5%) of PCR of *MecA* amplicon product. (1-30) all positive for this *mecA* gene with amplicon size (855bp) in skin lesion isolates of *Staphylococcus aureus* for 1 hr. at 80 volts.

**Figure (2)** Ethidium bromide Gel electrophoresis (1.5%) of PCR of *tst-1* amplicon product (1,2,3,5,6,7,13,14,15,16,17,18,19,20,21,22,23,25,26,27,28,29,30) were positive for this gene, (4,8,9,10,11,12,24) were negative for *tst-1* gene with amplicon size (326bp) in skin lesion isolates of *Staphylococcus aureus* for 1 hr. at 80 volts.
Discussion

The most commonly utilized antimicrobial substances in present clinical treatment procedures are β-lactams with intervention that includes inhibition of the last phase of the synthesis of bacterial cell-wall. These medicines have a smooth bactericidal with time-relied activities. They usually have excellent via-blood dissemination and little toxicity. Changes in the initial molecule resulted to the introduction of new substances with a wider antimicrobial action profile; however, in certain clinical environments, the use and effectiveness of beta-lactams are restricted because of increased bacterial resistance against those drugs.

Resistance to β-lactams can be induced by various genes; however, the most well-known worldwide distributed gene is mecA. The staphylococcal cassette chromosome has a gene called mecA which codes for PBP that is responsible of resistance against β-lactam antibiotics.

The action of the PBPs is manifested by their enzymatic activities due to inhibition-binding to β-lactams which results in destruction in the β-lactam chemical action properties. The PBP binding to β-lactams is occurred via the similarity present between the chemical structure of β-lactams and the chemical structure of the backbone of the sugar-amino acid that is an important part of the peptidoglycan.

Resistance via the presence of mecA can be induced due to random use of antibiotics in various clinical conditions; however, resistance to certain antibiotics due to this gene were found to occur even with no previously exposure to those antibiotics suggesting different means by which bacterial species can acquire such genetic resistance. One of the most important tools that bacteria employ to receive resistance is horizontal genetic transm (HGT). Bitrus et al., have recognized that mecA gene can be transmitted from methicillin resistant S. aureus to susceptible strains via HGT, and this confirms that resistance can be present even with no previous history use of certain antibiotics. S. aureus can generate pathogenicity by employing various bacterial techniques; however, it can enhance potential damages to human body via harboring important genes such as toxic shock syndrome toxin (tst-1) gene. The work of this gene is recognized by its coding for an extracellular toxin that induce toxic shock syndrome. The health condition is characterized by the presence of severe symptoms such as fever, hypotension, rash, and malfunctioning of some body organs. In infants, TSS can generate Kawasaki syndrome, TSS-like exanthematous disease, and sudden infant death syndrome. The nowadays-reports refer to increasing the worldwide distribution of the tst-1 gene to even higher levels than the already known elevated spreading. It has been found that this gene has genetic variations which might suggest different virulence levels.

Electroencephalogram and Visual Evoked Potential Changes in Patients with Primary Headaches

Nidaa S. Mohammed1, Mohammed Jaber Al-Mamoori 2, AbdAlK. Albermani3, Wahab. R. AbudAlameer4, Farah N. Abbas5

1M.Sc. Medical Physiology, 2 MBChB,FIBMS- Neurosurgeon/ Hilla Teaching Hospital Neurosurgical department, 3 Prof. Dr., Medical physics /Medical College /University of Babylon, 4 MBChB,FIBMS Assistant Prof. In Neurology Medical College/University of Babylon, 5 MBChB.MSc.PhD, Prof. Neuropsychology: Head of Physiology and Medical Physics Department at Medical College /University of Babylon and Director of Neurophysiological center in Merjan Teaching Hospital/Iraq

Abstract

This study was a case/control study in which a total of (450) subjects, into (150) with primary headache ( male and female) and this was included in this study, 128 with migraine headache, 22 with non-migraine headache and 300 were normal, as control group. The electrophysiological tests were done at the neurophysiology unit of Mirjan Teaching hospital in Babylon City, during the period from 28 / October/ 2014 until 22 / May/2015. This study reveals that involvement of the migraine are more than that of the non-migraine in headache patients when compared with control group and when compared between the migraine and non-migraine headache patients. The most common EEG changes in headaches patients were diffuse slowing and spike wave of back ground activity, in such a way that 54 (42.2%) migraine patients had abnormal EEG changes, in comparison to 4 (18.2%) of non-migraine patients. Visual evoked potential (VEP) was dependable marker for central nervous system affection in primary headache (migraine and non-migraine ) and the most common abnormalities were prolonged latency and amplitude is stay in normal ranged (5-10) µ.volt.

Keywords: EEG, VEP, migraine headache, non-migraine headache.

Introduction

Headache is defined as a pain arising from the head or upper neck of the body. The pain originates from the tissues and structures that surround the brain because the brain itself has no nerves that give rise to the sensation of pain (pain fibers) 1. Headaches can radiate across the head from a central point or have a pincering vise-like quality. They can be sharp, throbbing or dull, appear gradually or suddenly and last for multiple days or less than an hour 2.

All headaches are considered primary headaches or secondary headaches. Primary headaches are not associated with other diseases. Examples of primary headaches are migraine headaches Typically the headache affects one half of the head, is pulsating in nature, and lasts from 2 to 72 hours. Associated symptoms may include nausea, vomiting, and sensitivity to light, sound, or smell. The pain is generally made worse by physical activity 3.

Migraines are believed to be due to a mixture of environmental and genetic factors. About two-thirds of cases run in families. Changing hormone levels may also play a role, as migraines affect slightly more boys than girls before puberty, but about two to three times more women than men 4,5. The risk of migraines usually decreases during pregnancy.

Subjects and Method

This study was carried out through the period from October 2014 to May 2015, In the brain alone planning and optic nerve, as well as in consultation nervous in Mirjan Hospital in the city of Babylon. By using the history, as a cross section observational study, we select (150) patients with primary headache, in addition to (300) healthy control subjects, underwent EEG and VEP...
study with age and sex matched healthy control group should be selected for this study. All of them met the criteria of episodic headache (migraine with, without aura & non migraine) according to the international classification of headache disorder.

Subjects:

Two groups of subjects were studied:

The control group:

This group comprised thirty hundred healthy volunteers, (135 males and 165 females) ranging in age from (9 to 67) years, with a mean age of (30.40±7.38) years.

The patients group:

One hundred and fifty headache patients were selected all types of primary headache in Mirjan Teaching Hospital, they were (43 males and 107 females) ranging in age from (7 to 69) years with a mean age of (31.23±12.38) year.

Methods:

All the subjects were approved for:

- Electrophysiological tests:

- Visual evoked potential (VEP).

- Electroencephalography (EEG).

Visual Evoked Potentials (VEPs) Study:

Visual Evoked Potential test was carried out in a dark, quite room, with the subjects sitting comfortably on a chair and advised not to move or blink continuously during the test in order to decrease muscle contraction artifacts from eyes and skeletal muscles which blur the evoked potential waves, thus it is of paramount importance to avoid such artifact.

Instrumentation:

Using in this study Evoked Potential machine, serial no.GH 17 H9NW315431B, model 171S, (Italy) was used for electrophysiological analysis of the VEP using the VEP program. The VEP system include four channel preamplifiers which are connected to plasma screen as a photo-stimulator source.

Procedure:

Recording Visual Evoked Potentials:

The subject is call him to sit on the chair while made recording and told him to see in same level of the red point sited in the center of the screen, and the space between his state and the screen is fixed at rate equal to 100 cm.

The patient should asked him to cleaning and lesser his hair then asked him to sleep on the bed then begin applying gel on the surface of electrodes (to make skin impedance slighter) on the subsequent positions: on the right side from the beside of the head and about five centimeters from frontal side placed the three electrodes (F7,T3,T5), in the anther side (left side) placed the three other electrodes (F8,T4,T6), and then placed the five electrodes from the right side also, in frontal side (Fp1,F3,C3,P3,O1), and then placed the five electrodes from left frontal side (Fp2,F4,C4,P4,O2). At the end all of these electrodes were connected to the referential inputs by electrode cables.

Stimulation:

The full-field checkerboard pattern reversal (black and white checkerboard pattern), displaying at a rate of 3.5 reversals/ second (Hz). Mean luminance of the screen was fixed at 60-cd/m and contrast level of 100%. With visual angle of 16 (degrees) subtended by the stimulus field. The checkerboard size was selected according to the visual acuity of the subject between 60-90 (minutes). Each eye was stimulated separately by covering the other eye with a gauze patch (Monocular testing). VEP tests were filtered and amplified by the VEP computer program, and averaged of 200 runs according to response clearance. The amplifier band width was 0.1 – 100 Hz, with amplifier sensitivity of 2 µV and sweep speed of 500 msec/Div. Two series of examination of each eye were done to ensure reproducibility of the traces and results of VEP. During the test, the fixation point of the eye was kept on a target on the center of the screen (red dot), the subjects eye lids were fully opened to allow maximum amount of face and neck muscles, avoiding swallowing, moving tongue, speaking and frequent blinking, in order to minimize the artifacts during the recording procedure.
**Electroencephalography (EEG) study:**

Electroneurodiagnostics is the study and recording of electrical activity in the brain and nervous system. Tests are performed by technologists who record information on paper or computer, and the results are then interpreted by a specially trained physician.

Brain cells continually send messages to each other that can be picked up as small electrical impulses on the scalp. The process of picking up and recording the impulses is known as an EEG.

The billions of nerve cells in your brain produce very small electrical signals that form patterns called brain waves. During an EEG, small electrodes and wires are attached to your head. The electrodes detect your brain waves and the EEG machine amplifies the signals and records them in a wave pattern on graph paper or a computer screen. A normal EEG means that you have a normal pattern of brain wave activity. An abnormal reading means that abnormal patterns of brain activity are being produced and picked up.

**EEG Procedure:**

Electrical impulses in the brain are evaluated using an EEG. The test measures this electrical activity through several electrodes placed on your scalp. An electrode is a conductor through which an electric current can pass safely. The electrodes transfer information from your brain through wires to an amplifier and a machine that measures and records the data. The test is administered at a hospital, at your healthcare provider’s office, or at a laboratory by a specialized technician. The test usually involves the following steps:

You will be asked to lie down on your back in a reclining chair or on a bed. The technician will measure your head and use a pencil to mark where electrodes will be attached to your scalp. These spots are then scrubbed with a special cream that helps the electrodes get a high-quality reading.

**Results**

In this study is show the overall mean age of patients with headache and control were (31.23±12.38) and (30.40±7.38) years old, respectively, the distribution of patients and control by sex, (28.7%) and (47.3%) of patients and control were males, as show in the Figure (4).

In this study is show the differences between patients with headache and control by EEG Changes there was significant difference between patients and control by EEG, Patients with headache were 30 times more likely to have abnormal EEG, in the (Table 1).

In this study is shows the differences of patients with headache types and control during hyperventilation and photic stimulation of EEG. 24%, 14.66%, 1%, 1%, as show in the figure 5).

Table (2) shows the Mean Differences of VEP amplitude Parameter by Patients with Headache and Control Groups. There were significant mean differences of VEP Amplitude RT and LT by study groups. Table (3) shows the Differences of Patients with Headache and Control Groups by VEP latency and waves morphology. There were significant differences of Patients with Headache and Control Groups by RT Latency Positive1, RT Latency Negative1, LT Latency Positive1, LT Latency Negative1, RT Latency Positive2, and wave Morphology. Case group were 6, 2, 19, 3, 13 and 24 times to have abnormal right latency 1 positive and negative and left latency 1 positive and negative, right latency 2 positive and abnormal wave morphology, respectively.

In this study is shows distribution of patients by types of headache. (71.30%), (13.3%), (10.0%), (2.7%), (2.0%) and (0.7%) of the patients had migraine without aura, migraine with aura, tension headache, cluster headache, chronic headache and TAC headache, respectively, as show in the figure (1).

In this study is shows The distribution of different EEG abnormalities in different types of migraine. Spike 25.96%, poly spike 12.96%, sharp 12.96%, slow 48.14%, as show in the figure (2). In this study show the distribution of different EEG abnormalities in different types of Non-migraine. Spike 0.0%, poly spike 0.0%, sharp 4.54%, slow 13.63%, as show in the figure (3).

Discussion

Concerning the gender distribution, we have found that migraine is more common in females than males in different age groups at ratio of about 2.3:1. We found in figure (4) that female (47.30%) was susceptible to infected headache more than male (28.70%) in compared to control group. These findings are agreed with 20 who found females 2:1 for headache, as well as with other studies of 21 and also agreed with 22 who found that female to male ratio is about 3:1, but 23 found female to male ratio 3:2, so that there is a significant preponderance in females over males, this may be attributed to hormonal changes that occur in females mainly estrogen 24. We found higher incidence of migraine without aura, then followed by migraine with aura, tension headache, cluster headache, chronic daily headache, trigeminal autonomic cephalgia (TAC), (66.0%), (13.3%), (10.0%), (2.7%), (2.0%) and (0.7%). This agreement with (Stephen L. Hauser, MD, 2006) who found Migraine without aura is more common than migraine with aura in our study group with ratio of 2:1.
Conclusion

This study stated that EEG, the significant abnormal findings in patients with migraine headaches are more than patients with non-migraine headaches. The abnormal EEG findings in migraine patients were found mainly during hyperventilation and photic stimulation. Epileptic discharge were found in about of the whole migraine patients represented by spike and wave, polyspike and sharp waves respectively, 25.69%, 12.69%, 12.69%. In VEP, regarding the latency of P75, N100 and P 145 there were significantly higher in patients with headache in compared to the control group, while there were significant changes related to the amplitude, but stay in normal range.

Pulmonary Thromboembolism in Organophosphorus Poisoning – A Rare Complication

Haneil Larson Dsouza1, Anita S 2, Pavanchand Shetty1, Ranjit Immanuel James3

Abstract
Organophosphate based insecticides constitute the cause of a large number of mortality and morbidity cases in the developing world. The reasons include easy availability, being inexpensive, and lack of regulations regarding their sale and storage. Another factor that has made organophosphate insecticides a major source of suicidal ingestion is the perceived fatality associated with them. Though the muscarinic, nicotinic and central nervous system complications of organophosphate poisoning are well known, the organophosphate toxidrome can sometimes present with unusual presentations and unexpected complications. In the scenario that exists wherein there are substantial number of cases, there arises the possibility that these presentations and complications will only increase in number. In this context it becomes important to know the possible mechanisms that cause unusual presentations and take adequate safeguards. In the case examined herein, a geriatric patient consumed organophosphorus insecticide. Treatment included an initial stomach wash, standard atropine therapy and supportive management. The patient experienced multiple diverse presentations related to the poisoning before eventually succumbing after 1 month. On autopsy the immediate cause of death was found to be pulmonary thromboembolism. The increased susceptibility of thromboembolism could have multiple reasons such as increased immobilization, myopathy resulting in inefficient venous return and deep vein thrombosis, or vessel damage due to inflammatory mediators. This case illustrates the need to consider pulmonary thromboembolism as a potential lethal complication of organophosphorus poisoning.

Keywords: Organophosphorus poisoning, Pulmonary thromboembolism, heparin prophylaxis, inflammatory response

Introduction
Among the group of chemicals used as insecticides in agriculture, organophosphates (Ops) are among the most widely used. Easy availability, being inexpensive, and lack of regulations regarding their sale and storage are some of the reasons due to which OPs are regularly used as suicidal poisons in additions to accidental, occupational and bystander exposures. The most common routes of poisoning are ingestion, absorption through the skin or by inhalation. Organophosphate poisoning mostly affects the nervous system. (1) Organophosphates bind irreversibly as well as covalently at the activity region of acetylcholinesterase (AChE).(1) Hence clinical presentation of acute organophosphorus poisoning includes symptoms of the nicotinic, muscarinic and central nervous systems. To counteract these symptoms, the treatment protocol consists of atropine, oximes (AChE reactivators) and diazepam. It has been stated that prior studies on the poisonous effects of organophosphates in non-target tissues have been limited. (2) The studies that were conducted however, indicate that organophosphate poisoning may induce
Oxidative stress, increase lipid peroxidation and reduce glutathione levels. Due to this high oxidative stress, tissues may show a persistent inflammatory response and sustain damage leading to cellular necrosis. This chronic inflammatory response due to OP poisoning can lead to endothelial injury or dysfunction which in turn can cause coagulation abnormalities and an increased risk of pulmonary thromboembolism and deep vein thrombosis. This paper presents a case of pulmonary thrombosis (PT) in a patient of suicidal OP ingestion, and will list out various possible mechanisms for the same.

Case Description

A sixty-two-year-old male geriatric patient had consumed approximately two hundred millilitres of an organophosphate insecticide compound. He was taken to a primary care centre where initial first aid and stomach wash was performed. He was then transferred to a tertiary care centre where atropine infusion was started immediately. The patient then developed breathlessness, muscle weakness and hypotension. He also had an episode of a cardiac arrest but was brought back to sinus rhythm. In addition, the patient started having myoclonic movements and was treated for the same. At this juncture a diagnosis of intermediate syndrome was made as a result of organophosphorus poisoning. The patient initially succumbed one month later. Due to unremittent breathlessness and respiratory failure, the patient had to undergo a tracheostomy procedure. At the time of death, the patient was also diagnosed to have sepsis with septic shock along with broncho-pneumonia as a complication of organophosphorus poisoning. The autopsy showed atypical findings of basal ganglia haemorrhage in the brain. On histopathological examination, both lungs showed findings of pulmonary thromboembolism with the lobar pneumonia. There were however no thromboemboli present in the heart or the veins of the lower limbs. The stomach wash that was collected at the time of primary treatment tested positive for organophosphate insecticide compound whereas the other viscera and blood sent from the autopsy tested negative. The final cause of death was opined as due to pulmonary thromboembolism as a complication of organophosphorus poisoning.

Discussion

To our knowledge, this is the first documented case of pulmonary thromboembolism in a case of organophosphorus poisoning with no associated deep vein thrombosis or heart involvement. The clinical presentations of OP poisoning are classically shown as one of the following three stages: (i) Initial acute cholinergic crisis due to accumulation of acetylcholine at nicotinic and muscarinic sites and accumulation within the central nervous system resulting in altered sensorium and seizures, which present within 24-72 hours; (ii) intermediate syndrome, wherein weakness of ocular, neck, respiratory muscles and proximal limbs is seen after 24-96 hours; and (iii) delayed peripheral neuropathy that is often permanent. As per Virchow’s triad, the three major risk factors that primarily contribute to thrombosis are (i) hypercoagulability; (ii) turbulence or stasis (haemodynamic instability); and (iii) dysfunction of the endothelium or its injury. In general, organophosphate poisoning may not be a risk factor for pulmonary thromboembolism or deep vein thrombosis per se, but chronic inflammatory conditions are associated with coagulation abnormalities and increased risk of deep vein thrombi, and pulmonary thromboembolism. A recent study however showed that lipid peroxidation and increased reactive oxygen species (ROS) may be associated with OP poisoning. One of the outcomes of thus high oxidative stress is an intense inflammatory response. This inflammatory response may cause thrombotic tendencies leading to microvascular thrombosis as a result of inhibiting natural anticoagulant pathways and increasing procoagulant factors. The properties of the endothelium may also become affected leading to loss of anticoagulant, vasodilatory and anti-aggregation properties. These mechanisms may explain the causation of pulmonary thromboembolism in our patient. In addition, prolonged immobility due to hospitalization which lasted almost a month may have been an additional factor. However, lack of deep vein thrombosis points to additional factors and mechanisms. We would also like to hypothesise that muscle weakness and myopathy as a result of OP poisoning are additional risk factors for the formation of deep vein thrombi and pulmonary thromboembolism.
A Taiwanese study, which was a population-based longitudinal cohort study done nationwide on the danger of development of deep vein thrombi and pulmonary thromboembolism on patients with organophosphate poisoning, found that these patients had a 1.55-fold increased risk of deep vein thrombi when equated with the general population. A recent report has also been published of pulmonary thrombosis in acute organophosphate poisoning.\(^{(11)}\) Another case of OP poisoning presenting with clinical features of coronary thrombosis and pulmonary thromboembolism has been reported that occurred during the delayed phase.\(^{(12)}\) A rare case of upper extremity deep vein thrombosis in OP poisoning has also been published.\(^{(13)}\)

**Conclusion and Implications for Clinical Practice**

With more studies now showing a clearer association between a chronic inflammatory state and organophosphorus poisoning, deep vein thrombosis and pulmonary thromboembolism must be considered significant complications that may arise. This is especially true in those cases that require prolonged hospitalization. In view of this, we recommend prophylactic heparin therapy for those patients that progress to the delayed phase of organophosphorus poisoning. We also suggest that in cases of OP poisoning with a presentation or development of breathless and hypoxaemia, pulmonary thromboembolism as a complication of organophosphate poisoning should be considered a differential diagnosis.

An Analysis of Autopsied Maternal Deaths in Dakshina Karnataka District Over A 10-Year Period

Nimisha Ratra 1, Haneil Larson Dsouza2, Pavanchand Shetty2, B Suresh Kumar Shetty 3, Jagadish Rao Padubidri2

1Undergraduate, 2Associate Professor, 3Professor, Department of Forensic Medicine and Toxicology, Kasturba Medical College, Mangalore, Manipal Academy of Higher Education (MAHE), Karnataka

Abstract

Introduction: Though all deaths are accompanied by profound sorrow and anguish, maternal deaths are perhaps more so. Unfortunately, when these deaths are reported as medico-legal cases, the agony is then prolonged. Anguish from the family members is understandable, but opportunities to conduct autopsies on these deaths present an opportunity to examine in detail the pathophysiology of these deaths. This study is an attempt to find the cause of death in autopsied maternal death cases that have been filed as medico-legal cases and to compare the trends of autopsied maternal deaths with other regions.

Objectives: To find the cause of death in autopsied maternal death cases that have been filed as medico-legal cases and to compare the trends of autopsied maternal deaths with other regions.

Methods: A record-based study was conducted consisting of maternal deaths in the past 10 years based on the medico-legal autopsied reports from Government Wenlock Hospital mortuary.

Results: Among the causes of death attributed, the most common cause of death was embolism related with 4 deaths. This included deaths due to amniotic fluid embolism, trophoblast embolism and their complications such as DIC. Haemorrhage was the cause of death in 2 cases. In 2 cases, the cause of death was acute liver failure. However, one of these cases also had features of gestational acute respiratory distress syndrome. In one case, the cause of death was attributed to coronary artery disease complicated by pregnancy. One case was of ruptured ectopic pregnancy. In another case, the cause of death was a surgical complication of a dilatation and curettage procedure. In the remaining 3 cases, the cause of death could not be ascertained even after histopathological examination, chemical analysis, and a complete autopsy.

Key words: Autopsied maternal deaths, embolism, haemorrhage, maternal mortality

Introduction and Background

Three hundred thousand women die every year because of the various complications and obstacles of giving birth (1). Unfortunately, even as recently as 2008, more than fifty percent of all recorded pregnancy-related deaths were in 6 countries namely India, Afghanistan Ethiopia, Pakistan, Nigeria, and the Democratic Republic of Congo (2). Valid and reliable epidemiological data can lead to more effective and efficient health and social policies that will improve overall maternal health (3). It is said that the difficulties in reporting maternal deaths arise because of “the lack of information about deaths among women in the reproductive age group, their pregnancy status at or near the time of death and the medically certified cause of death. These components can be difficult to measure accurately, especially in regions where deaths are not comprehensively or accurately reported” (4). In addition, in developing countries, data

Associate Professor, Department of Forensic Medicine and toxicology, Kasturba Medical College, Mangalore, Manipal Academy of higher education (MAHE), Karnataka
on the cause of pregnancy-related deaths are still mainly from verbal analyses and clinical histories which do not give the complete picture.

The reasons causing women to die in pregnancy and childbirth are multi-layered. The major complications that are said to account for nearly seventy-five percent of all pregnancy-related deaths are said to be “haemorrhage, infection-related, blood pressure disorders of pregnancy, complications related to delivery, and unsafe abortion”. However, many maternal deaths are still not identified due to various reasons (5).

Our study is an attempt at finding the cause of death in autopsied pregnancy-related deaths that have been filed as medico-legal cases and to compare the trends of autopsied maternal deaths with other regions.

Aim and Objectives

The study aimed to find out the causes of deaths of autopsied maternal deaths. We also hoped to analyse the trends in numbers of medico-legal autopsied maternal deaths as an indirect indicator of maternal health services and provide information that could lead to the better delivery of health services.

Materials and Methods

This was an organized longitudinal retrospective record-based study of 14 maternal autopsies performed at a government tertiary care mortuary (Government District Wenlock hospital) by the Forensic medicine and toxicology department of the attached medical college (Kasturba Medical College Mangalore). This hospital serves the health requirements of the population of Dakshina Kannada and neighbouring districts.

Inclusion criteria: All cases of maternal deaths classified as medico-legal cases which had been brought to District Government Wenlock hospital mortuary and cases that had been filed as closed by the police.

Exclusion criteria: Non-medico-legal cases of maternal deaths; sub-judice cases of maternal deaths.

This study protocol was presented for approval from the Institutional Ethics Committee (IEC) of Kasturba Medical College, Mangalore. After the authorization was obtained from the ethics committee, authorization was then obtained from the Head of the institution, after which permission was taken from the respective medical officer for analysis of their post-mortem reports. In total, 14 pregnancy-related deaths were autopsied during the 10-year period from 1st January 2009 to December 31st, 2018. The autopsy was done as the maternal deaths were registered as medico-legal cases either on behest of the treating doctor to find out the exact cause of death; when requested by the relatives of the deceased; or where the cause of death was uncertain. Clinical details, where ever available, were reviewed, either prior to or after conducting the autopsy. Complete autopsies were conducted in each case, with tissue specimens preserved in 10% formalin for further histopathological examination. Blood and viscera were also preserved, sealed, packed, and sent for toxicological analysis to the Forensic Science Laboratory located at Mangalore. The cause of death was opined based on perusal of hospital records (where available), chemical analysis report, histopathological examination report and the autopsy report.

Results

There were 8465 autopsies conducted at the Government Wenlock district hospital mortuary by the Forensic Medicine and Toxicology department, Kasturba Medical College Mangalore, during the study period. Of these 14 autopsies were related to maternal deaths, i.e. 0.16%. Among the autopsied maternal deaths, the minimum age of the deceased was 21 years and maximum age was 38. Table No.1 shows the frequency of deaths on a year-wise basis. There were no autopsied maternal deaths in three years, i.e. 2009, 2010 and 2016. The highest number of cases were in 2015 and 2014 with 3 deaths each. Deaths in the other years ranged from 1 to 2.

Among the causes of death attributed (Table No.2), the most frequent cause of death was embolism related with 4 deaths. This included deaths due to amniotic fluid embolism, trophoblast embolism and their complications such as DIC. Haemorrhage was the reason of death in two cases. In 2 cases, the reason of death was acute liver failure. However, one of these cases also had characteristics of gestational acute respiratory distress syndrome. In one case, the reason for death was assigned to coronary artery disease complicated by pregnancy. One case was of ruptured ectopic pregnancy. In another
case, the cause of death was a surgical complication of a dilatation and curettage procedure. In the remaining 3 cases, the underlying triggering reason for death could not be determined even after histopathological examination, chemical analysis, and a complete autopsy.

**Discussion**

The process of first obtaining the record of deaths and then designating a cause is not a simple one, and this, in itself, makes demonstrating trends – an increase or decrease – difficult (6). “Up to two-thirds of the world’s population reside where regular registration of deaths is missing, and for the other third, misclassification or wrong classification of causes or circumstances may lead to false trends and conclusions about progress” (7). Without an appropriate analysis of the causes of pregnancy-related mortality, there will not be present a proportional allocation of resources to reduce its incidence. “In many developing countries only deaths occurring in a health facility are assigned a medical cause of death, as certification of deaths at home is rare and relatives’ version of signs and symptoms might not be adequately accurate or dependable to draw conclusions. Also, for deaths at home, verbal autopsy techniques are often
used to determine the likely cause of death” (8). Thus, the leading source of data on pregnancy-related deaths can be said to be clinical records and verbal autopsies in developing countries. Both of these sources have considerable constraints as a result of inconsistencies between the clinically assumed and the definite cause of death (9). It has also been noted that verbal autopsies have little validity in attributing maternal deaths to a single specific medical cause and that there are intrinsic limitations in obtaining medical event records from non-medical informants who may not be literate and lack a medical background (10). Another finding seen is that “Misclassification of medical cause of death is common for many categories of death, including in developed countries with sophisticated statistical systems (11) as well as in developing countries”. (12)

It has been made repeatedly apparent that “Evidence provided by medical autopsies has played an important role in improving the accuracy of cause-of-death reports and improving clinical practice in the developed world” (9,13). A trustworthy ascertainment of the causes of pregnancy-related mortality thus requires an autopsy (14). The value of an autopsy in establishing the cause of death was revealed in the study of Sonderegger-Iseli et al. (9) with clinical differences in up to thirty percent of cases. Evidence from autopsies has been shown to invaluable for obtaining information that will prevent maternal deaths (15,16). It is also apparent that “In the absence of a routine autopsy, many deaths in developing countries remain recorded as ‘unknown’.”

Time of death around pregnancy: Studies have “shown that maternal deaths cluster around labour, delivery and the twenty-four hours immediately postpartum” (17). This is similar to the findings in our study which showed that the majority of deaths were in the third trimester and within 24 hours post-partum.

Cause of death: The major causes of maternal mortality in India have been identified as “anaemia (64.4%), pre-eclamptic toxaemia (PET) & eclampsia (25.5%), sepsis (20.6%) and haemorrhage (19.8%)” (18). This contrasts with our study wherein the majority of deaths were related to embolism and its complications. Haemorrhage only accounted for two deaths in our study and showed an equal incidence to acute liver disease of pregnancy. The reasons for the cause of death being unascertained in three cases can be attributed to incomplete medical information furnished, a lack of hospital records, or natural causes of death that are difficult to diagnose at autopsy. Our study also shows different findings when compared to the study done by Bardale et al., where “haemorrhage was the leading cause of death (38.09%) followed by indirect causes (23.80%), undetermined (19.04%), sepsis (9.52%) and postpartum pre-eclamptic shock (9.52%)” (19).

**Conclusion**

Maternal mortality autopsies have perhaps more importance than autopsies of other deaths because these reports are then used to make suggestions for improving clinical obstetric practice and defining the cause of death (20). In conclusion, maternal autopsy investigation offers an exact cause of death in most cases and is still an important tool for identifying the cause of maternal mortality (20). The information gathered from maternal autopsies deliver feedback to clinicians which will help to improve clinical practice (15).

Morphometric Measurements of Cervical Spine using Computed Tomography

Husseina Hassanali 1, Prateeksha S1, Fayas P1, Saikiran Pendem2, Priya P S3

1BSc. 2Assistant Professor, PhD in Medical Imaging Technology, Department of Medical Imaging Technology, Manipal College of Health Professions, Manipal Academy of Higher Education, Manipal, Karnataka, India, 3Assistant Professor, Department of Radiodiagnosis and Imaging, Kasturba Medical College and Hospital, Manipal, Karnataka, India

Abstract

The cervical spine anatomy exhibits wide variations. For cervical spine pathologies which require surgical treatment, the prior knowledge of these anatomic variations would reduce the surgical complications. The aim of the study is to perform CT based measurements of cervical transverse foramen and spinal canal in Indian population which would be useful in providing road map and guidance for surgical interventions of cervical spine. This is a retrospective study. A total of 73 patients (49 males, 24 females, age range: 18-75 years) indicated for CT cervical spine from June 2018 to June 2019 were included. The sagittal spinal canal Diameter (dSSC), sagittal (TFs) and transverse diameters (TFt) of transverse foramen, distance between transverse foramen and spinal canal (dTF-SC) were measured at C1-C7 levels. We found that significant difference in sagittal spinal canal diameters at all the levels of cervical spine (C1-C7) between males and females (p<0.01). Our study also found significant difference in sagittal (TFs) and transverse (TFt) diameters of transverse foramen at all cervical levels in males and females between right and left side (p<0.01). Significant difference were noted for distance between transverse foramen and spinal canal (dTF-SC) at all the levels of cervical spine in males and females between right and left side (p<0.01). From our study we conclude that a thorough comprehension of cervical anatomy with CT-based measurements help in preoperative planning and reduce the complications in surgical interventions. Our study noticed significant reduction in distance between transverse foramen and spinal canal (dTF-SC) in both males and females on left side. Hence, care must be taken while performing surgical procedures of cervical spine on the left side in males and females at all cervical levels.

Keywords: Cervical Spondylosis, Spinal canal, transverse foramen, cervical myelopathy

Introduction

The cervical vertebral structure is complex and has wide variations in anatomy. Cervical spondylosis is age related chronic degenerative disease of the spine with a prevalence of 13.76% 1. Spinal canal stenosis is commonest factor leading to Cervical myelopathy and cord injury2-5. Cervical spine instrumentation procedures such as posterior and anterior stabilization for spondylosis and fractures requires prior knowledge of variations for reducing the surgical complications. Due to presence of vertebral artery the precise placement of screws is major requirement in most of the cervical spine interventions 6-9. The literature also suggest wide variation in pedicle and lamina measurements, hence prior knowledge is required for selection of screws for fixation10-12. CT plays important role in diagnosis of pathologies of cervical spine. In addition, it also provides accurate information regarding the measurements such as spinal canal diameter and vertebral body measurements13-14. There are many cadveric studies described cervical

The literature also reported ethnic differences in cervical spinal canal, vertebral measurements\(^{15-19}\). There are only few studies done on CT cervical spine measurements which are relevant for surgical procedures\(^{20-21}\). Hence, the purpose of the study is to perform CT based measurements of cervical transverse foramen and spinal canal in Indian population which would be useful in providing road map and guidance for surgical interventions of cervical spine.

**Materials and Method**

The approval for study was obtained from Institutional Research Committee, School of Allied Health Sciences and Institutional Ethics Committee, Kasturba Hospital, Manipal. This is a retrospective study which included 73 patients indicated for CT cervical spine. Out of 73 patients, 49 were males and 24 were females. The age range of the study was 18-75 years (mean age 33.5±5.3 years) The CT cervical scans with fracture, neoplasm, infection, congenital anomalies were excluded.

The CT cervical spine imaging was performed using 128 slice CT scanner (Philips Incisive 128 slice CT, Netherlands). Axial sections were obtained with 1 mm slice thickness.

**CT Measurements**

Figure 1: Mid-Sagittal image of CT Cervical spine showing Sagittal Spinal Canal Diameter (dSSC)

Spinal canal diameter (dSSC) was measured on mid sagittal section as antero posterior diameter from the back of each vertebral body to the nearest spinolaminar line (Figure 1).

Figure 2: Axial image of CT Cervical spine showing Sagittal diameter of Transverse foramen (TFs), transverse diameter of Transverse foramen (TFT) and Distance between transverse foramen and spinal canal (dTF-SC)

Sagittal (TFs) and transversr diameters of transverse foramen (TFT) were measured on axial section as antero posterior and cranio caudal diameters of transverse foramen respectively. Distance between transverse foramen and spinal canal (dTF-SC) was measured on axial image as antero posterior distance between them (Figure 2).

All the measurements were done using measuring tools in DICOM Imaging software of Mediff technology and were noted in millimeter (mm). The data were measured by two readers A and B to check for variability.

**Statistical Analysis**

The data analysis was done using statistical package for social sciences (SPSS) version 20.0. The Students paired t-test was performed for the three measurements to find significant difference between right and left side.

**Findings**

Seventy-three patients (49 were males and 24 were females) 511 vertebrae from C1-C7 were evaluated in this study. The measurements were done on right and left sides of vertebrae.

**Sagittal Spinal Canal Diameter (dSSC)**

The Canal diameter was noted wider at C1 level for both males and females. The CDs measured were narrower at C6 level in the males and at the level C4 in females. Significant differences in canal diameters were noted at all the levels of cervical spine (C1-C7) between
males and females (Table 1).

Discussion

The literature states wide variations in anatomy of cervical vertebrae\textsuperscript{10-12}. There also ethnic differences in spinal canal and vertebral measurements \textsuperscript{20-21}. Due to necessity of surgery in cervical spine pathologies such as trauma, degenerative and inflammatory conditions, the prior preoperative knowledge of anatomical variations is utmost important for the surgeon. The diameter of the cervical spinal canal is vital and any reduction in the measurement might lead to myelomalacia secondary to spondylosis\textsuperscript{2-5}. There are limited studies performed using CT, which is gold standard and provide road map for preoperative planning\textsuperscript{15-19}.

In our study, the spinal canal diameter (dSSC) was noted wider at C1 level for both males and females. The spinal canal diameter declined gradually from C1-C6 and increased at C7 level. The findings of our study are partially contrary to the studies conducted by Binit Sureka et al., Evangelopoulos et al.\textsuperscript{25-26}. Study done by Ambuj Kumar et al\textsuperscript{27} have also observed decline in cervical spinal canal diameter from C1-C4, inaddition our study has shown decline in dSSC till C6 Level and increased at C7 level.

The literature suggests that the diameters of the vertebral arteries are of unequal size and the left side vertebral artery is often larger compared with right sided vertebral artery\textsuperscript{28}. Significant differences were noted for sagittal diameter of transverse foramen (TFs) at all cervical levels in males and females between right and left side (p<0.01). Significant differences were noted for transverse diameter of transverse foramen (TFt) at all cervical levels in males between right and left side (p<0.01). Significant difference were noted for (TFs) at C3 level in females between right and left side (p<0.01). We also significantly noticed the diameters of transverse foramen larger on left side in males and females which supports the literature that left sided vertebral is larger than right. These measurements would provide the surgeon to choose appropriate side for placement of screws and also the knowledge about the various screw sizes to be used for fixation procedures. The findings of our study are slightly different to the results of recent studies done by Binit Sureka et al., Evangelopoulos et al.\textsuperscript{25-26}. They have stated increase in diameter of transverse foramen on left side only in females compared to males. However, our study noticed increased diameter of transverse foramen in both males and females on left side.

In our study, significant differences were noted for distance between transverse foramen and spinal canal (dTF-SC) at all the levels of cervical spine in males and females between right and left side (p<0.01). The findings of our study are slightly different to the results of studies done by Binit Sureka et al., Evangelopoulos et al.\textsuperscript{25-26}. They have stated decrease in distance between transverse foramen and spinal canal (dTF-SC) on left side only in females compared to males. However, our study noticed decreased distance between transverse foramen and spinal canal in both males and females on left side.

Our study would add new contribution to the literature that the diameter of transverse foramen is larger on left side in both males and females at all the cervical levels. Hence care must be taken will doing fixation of screws in males and females especially in left side.

There are few pitfalls in our study. Firstly the sample size opted for the study is substantial. Secondly, we have not included the pediatric age group who are more prone for anatomical variations. Thirdly, we did not compare the transverse foramen and distance between the foramen and spinal canal between the genders.

Conclusion

Multidetector CT examination would provide precise measurements of anatomical structure of cervical spine and helps in identifying the variations. The CT preoperative measurements would be helpful in providing road map and mitigate the possible damage to vertebral artery and neural structures while performing surgery. The measurements from our study recommends adequate care to be given while performing surgeries on left side of cervical vertebrae for males and females.

Determination Reference of Concentration (RfC) Xylen Exposure Based on Xylen NOAEL in White Rats and Workers’ Body Weight and Height in Surabaya Car Painting Area, Indonesia

Abdul Rohim Tualeka¹, Juliana Jalaludin², Prihartini Widiyanti³, Syamsier S Russeng⁴, Pudji Rahmawati⁵, Ahsan Ahsan⁶, Indri H Susilowati⁷

Abstract

This study aims to calculate the value of RfC from xylen exposure around the car painting area of Surabaya, Indonesia. This is an observational cross-sectional study with quantitative data analysis methods conducted manually. The population in this study was groups of car painting workers and groups of car repairer on Jalan Pengenal Kota Surabaya. The sampling technique was proportionate stratified random sampling to take 51 people. The measurement of xylen concentration around the car painting area was 635.98 mg/m³ (146.47 ppm). This value is above the threshold value according to Minister of Manpower and Transmigration Regulation Number 13 of 2011 and Minister of Manpower Regulation Number. 5 of 2018 is 434 mg/m³ (100 ppm). RfC of car painting workers with NOAEL 50 mg/kg was 7.76 mg/kg.

Keywords: Xylen, RfC, car painting worker

Introduction

Xylen is an aromatic hydrocarbon which is often used as a solvent namely cleaning agents, diluents for paints, and varnishes. Xylene is colorless, flammable, and volatile. It is often used in the printing, rubber and leather industries. The chemical industry produces xylene from petroleum (ATSDR, 2007)¹.

In the process of painting the car by spraying, workers are constantly exposed to xylen when the paint is sprayed. Workers are exposed not only to the vapor, but also from a collection of fine particles (mist). This form is easily absorbed by workers or into the skin, especially if workers do not wear proper personal protective equipment (WWAC, 2009)². The main exposure pathway occurs through inhalation, yet dermal exposure (through skin contact) and oral can also occur (IPCS, 2004)³. Individuals who routinely work on conditions that are periodically exposed to high levels of solvent vapors can be acutely affected such as intoxication, fatigue, poor endurance, headache, nausea, tremor, balance complaints to mild depression (Spurgeon et al., 1994)⁴.

E-mail: abdul-r-t@fkm.unair.ac.id
Kurnianto (2016) stated that the results of measuring xylene concentrations in the car painting area of Surabaya at 5 painting locations showed an average yield of 146.47 ppm which was above the threshold according to Minister of Manpower and Transmigration Regulation No. 13 of 20116 and Minister of Manpower Regulation Number. 5 of 20187. The set threshold value is not much different, namely 434 mg/m$^3$ (100 ppm). While it does not cause a carcinogenic effect, it has an impact on health if one is continuously exposed.

Research conducted by Ilhan in 2004 on workers in Turkey showed that as many as 131 workers exposed to organic solvents with a noise of 85 dB in the workplace experienced increased hearing damage in the paint-making industry and painting workers with higher xylene organic solvents than workers who were only exposed to noise with the same level (Ilhan et al., 2014)$^8$. Exposure to 10,000 ppm xylene inhaled shows complaints of kidney function characterized by increased levels of β-glucoronidase and albumin and the excretion of red blood cells and white blood cells in the urine (Malathi, 2014)$^9$.

Based on the previous research, calculations of xylene Reference of Concentration (RfC) on workers around the car painting area of Surabaya by using anthropometric data of Indonesian people has not been made. RfC as a safe concentration of xylene which is recommended for car painting workers in Indonesia still uses research references from America and Europe so that it is not accurately used as a reference in determining risk for Indonesian people. The xylene response dose was obtained from IRIS (2003) in US EPA10 which stated an inhalation reference dose (RfC) for non-xylene carcinogen exposure in the air by 0.1 mg/m$^3$. The RfC number is multiplied by the default value of the adult inhalation rate by 20 m$^3$/day (Kolluru, 1996) 11 and divided by the default value of adult body weight 70 kg (EPA, 1991) 12 resulting in 0.03 mg/kg.

In this study, the calculation of RfC was derived from experimental doses of NOAEL (No Observed Adverse Effect Level) using the characteristics of the experimental animals of white rats (Rattus norvegicus) from Indonesia and anthropometric factors (Wb, tE, fE, and Dt) car painting workers. The value of NOAEL xylene average body weight, the average height of Indonesian people is then obtained. The purpose of this article is to determine the xylene RfC for workers around the car painting area of Surabaya, Indonesia so that the results can be used as a reference to estimate the amount of exposure each day that workers can receive without causing harmful effects during their lifetime.

**Material and Method**

This is an analytic observational study conducted in a cross sectional manner. The study population consisted of 2 strata of groups of workers namely car painting workers on Jalan Pengenal Kota Surabaya and group of car wreckers. The sampling technique was proportionate stratified random sampling which produced 51 samples consisting of 36 painters and 15 repairer.

The research design starts from secondary data collection related to the general description of the location, number of workers, and work schedule obtained from the chairman of the Welding and Painting Employers Association (PPLDC) Surabaya. Literature studies are carried out by studying scientific books, research reports, research journals related to xylene toxicology. Furthermore, primary data collection related to xylene content in the air was carried out by collaborating with the Prodia laboratory and UPT K3 East Java Province.

The research variables were xylene concentration, body weight, height, respiratory rate, exposure time in a day, body surface area of workers, weight of white rats, body surface of white rats, highest dose of toxin without effect on experimental animals (NOAEL), Km factor in animals (Animal Km), factor Km in society (Human Km), RfC. Data analysis in this study was carried out by using quantitative data analysis manually to determine the xylene RfC.

**Findings**

A. Characteristics and Body Surface Area of Experimental Animal

The experimental animals used in this study were white rats (Rattus norvegicus). The properties of white rats are perfectly known, easy to maintain, and are relatively healthy and suitable for various studies. In general, human response to toxicity is qualitatively similar to that of animals. This fact is the basis of extrapolation of animal data to humans.

Based on data from Table 1, body surface area of white rats is calculated using the following formula.

\[
BSA = 0.09 W^{0.67} H^{0.67}
\]

Where

- \( BSA \): Body Surface Area (m²)
- \( W \): Weight (kg)

B. Characteristics, Worker’s Body Surface Area and Worker’s Respiratory Rate

The characteristics of workers in this study included weight and exposure time of 51 respondents who settled around the fertilizer industry. The average body weight is 62.14 kg and the average exposure time is 6.67 hours. Community height uses the average value of Indonesian adult height of 159 cm.

Based on data on body weight and height, people’s body surface area and respiratory rate were calculated using the following formula.

Worker’s body Surface Area

\[
BSA = \sqrt{W \cdot h^{3600}/W \cdot h^{3600}}
\]

WHERE

- \( BSA \): Body Surface Area (m²)
- \( W \): Weight (kg)

Based on the calculation results of the average body surface area of the worker is 1.65 m² and the average respiratory rate is 0.62 m³/hour.
B. Xylene Concentration

The results of xylene concentration measurements in the car painting area showed different results at 5 workshop locations. The workshops at this location consist of open and semi-closed workshops.

<p>| Table 3. Distribution of Xylene Concentrations around Surabaya Car Painting Area |</p>

Based on the results of measurements, the xylene concentration around the car painting area was 635.98 mg/m³ (146.47 ppm) with the highest concentration of 1480.59 mg/m³ (341 ppm) and the lowest concentration of 137.64 mg/m³ (31.7 ppm).

C. Animal Km and Human Km

Determination of safe dosage of toxin for the community begins with the calculation of Animal Km and Human Km.

1. Animal Km

\[
Animal\ Km = \frac{W_{\text{animal}}}{BSA_{\text{animal}}}
\]

Where:

Animal Km : Km factor on human
W : Wight of Experimental Animal (white rats)
BSA : Body Surface Area of Experimental Animal (white rats)

The results of the Animal Km calculation are shown in table 4 with an average Animal Km in experimental white rats of 5.81.

2. Human Km

\[
Human\ Km = \frac{W_{human}}{BSA_{human}}
\]

Where:

Human Km : Km factor on human
W : Workers’ weight
BSA : Workers’ Body Surface Area

The results of the Human Km calculation are shown in table 5 with Human Km average for workers of 37.41.

**D. No Observed Adverse Effect Level (NOAEL)**

One of the objectives of research activities in the field of toxicology is to evaluate the safety of a substance. The safe limit of the concentration of a chemical begins with the toxicity test for determining the highest dose without causing effects on experimental animals or No Observed Adverse Effect Level (NOAEL). Korsak et al. (1994) in U.S. The 2003 Environmental Protection Agency10 stated that NOAEL xylene is 50 ppm (mg / kg: ppm is 1: 1).

**E. Reference of Concentration (RfC)**

\[
RfC = \frac{\text{NOAEL}}{\frac{\text{Animal Km}}{\text{Human Km}}} 
\]

where:

- \( RfC \): Reference of Concentration
- Animal Km: Km factor on animal
- Human Km: Km faktor on human

Results of Calculation of Reference of Concentration (RfC) obtained from NOAEL, Animal Km averages, and Human Km averages are as follows.

\[
RfC = \frac{50 \times \frac{5.81}{5.81}}{37,4137,4135.96} = 7.76 \text{ mg/kg}
\]

Based on the results of calculations, the inhalation Reference Concentration (Rfc) for workers around car painting area of Surabaya is 7.76 mg/kg.

**Discussion**

Based on the measurement results, the average xylene concentration around the car painting area of Surabaya was 635.98 mg / m\(^3\) (146.47 ppm) with the highest concentration of 1480.59 mg/m\(^3\) (341 ppm) and the lowest concentration of 137.64 mg/ m\(^3\) (31.7 ppm). The value of xylene concentration is higher than the results of a study conducted by Irawati (2010)\(^{17}\) on shoe shop workers in the small industrial area of Jakarta with an average value of 0.05 mg / m\(^3\) with the highest concentration in the section 0.18 mg/m\(^3\). This is in line with the research conducted by Cahyana et al (2015)\(^{18}\) in informal car painting workers in Bandung with xylene values between 0.042 and 4.447 ppm. The significant difference in concentration between this study and other studies was caused by differences in sources of xylene exposure. For research conducted in the car painting area in Bandung, there are 3 types of workshops of open, semi-open, and closed that the results are smaller. In this study there were only 2 types of open and semi-closed workshops.

RfC in the present study is 7.76 mg/kg. Calculation of RfC xylene in this study is greater than that of RfC according to IRIS (2003) in US EPA 1991 of 0.03 mg/ kg. There were significant differences in RfC results because the calculations were carried out using relatively...
different data on Indonesian body weight and height. In addition, the concentration of xylene in the air of the car painting area of Surabaya, Indonesia is also high. The greater the RfC, the greater the safe concentration so that it becomes less stringent and less safe for workers. Thus, control measures are still needed to reduce xylen exposure.

Control measures that can be taken are the provision of air vents (local exhaust) especially for semi-closed workshops, the use of paint containing safer organic solvents, the use of appropriate personal protective equipment in the form of half mask respirators with organic vapor cartridges to minimize xylen vapor exposure (ATSDR, 2007)\(^1\).

**Conclusion**

The average xylen concentration around the car painting area of Surabaya, Indonesia is 635.98 mg/m\(^3\) (146.47 ppm). This level of concentration is above the threshold value according to Minister of Manpower and Transmigration Regulation Number 13 of 2011 and Minister of Manpower Regulation Number. 5 of 2018 is 434 mg/m\(^3\) (100 ppm). The average body weight is 62.14 kg and the average exposure time is 6.67 hours. For community height data, the researchers used the average value of Indonesian adult height of 159 cm.

The results of RfC car painting workers with NOAEL 50 mg/kg is 7.76 mg/kg.

Therapeutic Health Benefits of Religion Among Elderly—A Population based Representative Survey from Iran

Adeleh Sadeghloo 1, Somayyeh Meshkani 2 Hamid Hojjati 3, Devender Bhalla 4
1Research Scholar, Young Researchers and Elite Club, Aliabad Katoul Branch, Islamic Azad University, Aliabad Katoul, Iran, 2Research Scholar, Department of Midwifery And Nursing, Gorgan, Golestan university of Medical Sciences, Gorgan, Iran, 3Associate Professor, Young Researchers and Elite Club, Aliabad Katoul Branch, Islamic Azad University, Aliabad Katoul, Iran, 4Associate Professor, Tropical Unit, Nepal Interest Group of Epilepsy and Neurology, Kathmandu, Nepal

Abstract

Background: We determined whether practice of religious beliefs influence health-related lifestyle among general elderly population.

Methods: We recruited elderly (60+years) subjects from among the general population who were invited to answer practice of religious belief and healthy lifestyle in Iranian elderly questionnaires.

Results: A total of 218 elderly subjects participated (51.3% males, mean age: 68.3 years, SD 9.2, range 60-92). The mean religious belief was 73.0 (SD 11.5) without male-to-female difference (p=0.9). The mean lifestyle was 100.9 (SD 14.7, range 61-138) with a 9.3% male-to-female difference, p=0.0001. The odds of better lifestyle with religion was 5.5 (p=0.001, effect-size=0.18, variance=29.5%). The most benefit was in prevention (effect-size 0.18), nutrition (effect-size 0.15), and social relationship (effect-size 0.12).

Conclusions: Based on a representative un-selected validated sample, and by using a systematic questionnaire, and after controlling for various possible confounders, and within current evaluation limits, we may conclude that religion may mitigate health-related lifestyle.

Keywords: Epidemiology, religion, mental health, transcultural, social, health,

Introduction

Since the beginning of human history, religion has always had a strong association with the practice of medicine and healthcare in general [1, 2]. For instance, early community health and medical facilities up to French revolution had mostly been initiated by the religious institutions and clergies-cum-physicians [1, 3].

Thus, religion has not had a strong association with the early practice of medicine but still has a valid clinical context[4]; for instance 1/4th of all mental illness cases can be explained through religion [5].

Despite considerable public and clinical significance, the research on this topic is often avoided [1] [6], and religious aspects are never or rarely enquired about in a day-to-day clinical practice[4]. Thus, by avoiding such topics, we may unintentionally devoid others, especially elders, of possible benefits from practicing religion. This is because elders have a different frequency of practicing religion [7], they have different spiritual [8] and health [1, 5] needs, and they are far more inclined to seek health and welfare benefits from religion [9]. The prevalence of aging is increasing [10]. Thus, continuing with our vision of establishing a reliable mental health (and neurological) profile and an international positive participation of scientifically-silent countries, and with an objective to examine an association between practice of religion and health-related lifestyle among general

E-mail: hojjati_hamid2019@yahoo.com
elderly population, we performed this work in Ali Abad Katool (Iran).

Methods

Iran is one of the most prominent countries of the MENA region, and a country of our major interest. For many reasons, our choice of Iran was appropriate, figure 1. For instance, in principal, Iran is religiously unitary which is not the case in many countries. For instance, in UK, there are likely to be about 170 distinct religions [11]. Another reason was that, although other religions are allowed, Iran principally follows Islam, which was again advantageous in this context. For instance, in Hinduism, there are said to be 33 million god-bodies. In Christianity, although there is no exact number, but the sects and denominations are likely to be in 1000s. Thus, belief system is likely to change with each sect or denomination. The choice was further appropriate since Islam is already dose-defined (including the time, nature, and quantity) which is not likely to be in other religions. For instance, in Christianity, The Bible says “to pray without ceasing” (Romans New Testament 12:12).

Besides, all this, today, Islam is the fastest growing religion in the world and may sooner or later become the most prevalent. For instance, Islam grew 15.0% in the last five years in Australia; the Christians are reduced to 70.0% in Sweden; in 2008, 61.0% of those who annually migrated to France belonged to Meghreb [12]; by 2040 the Islam would become the 2nd largest religion in USA; in UK about 100,000 convert to Islam every year which showed a 12.0% growth in the last three years. It is also important to note that for MENA countries, like Algeria and Tunisia, having the nationality of their colonial country (i.e. France) is almost a right (Personal data, D Bhalla). Thus, a greater understanding through Islam populations is not a privilege anymore but a full necessity.

The project was conducted in Ali Abad Katool (Iran). Ali Abad Katool is a mountaneous area covered with Alborz mountains with a general population of about 46000. A participation was invited from among the residents through three population-based sources (i.e. elder leisure center, main mosque, main park). The participants were required to meet our inclusion criteria as below. Those who didn’t meet these criteria were not invited. The inclusion criteria were:

- Muslim, age 60 years and above, any gender,
- Ability and interest to participate,
- Being cognitively intact, as defined through primary assessment and interview,
- No substance abuse or other conditions that may preclude participation

To determine practice of religion and health-related lifestyle, we used 25-item practice of religious belief (PRBQ) and 46-item healthy lifestyle among Iranian elderly (HLEQ) questionnaires. Both have earlier been demonstrated to be valid in our cultural context, and have a cronbach alpha of 0.91 [13] and 0.76 [14], respectively. For this work, PRBQ scores were categorized as <50, 51-74, and >74, while HLEQ scores were categorized as undesirable lifestyle (upto 98), medium desirable lifestyle (99-155), and fully desirable lifestyle (>155).

The required sample size was estimating by using a simple formulae after assuming a type1 error as 0.05, type2 error as 0.2 and correlation factor of 0.2 [15]. This required a sample of 194 subjects however we aimed to recruit additional 10.0% to this. All data was entered into MS-Excel. The statistical approach was according to the type of variable and purpose. The data was described in number, range, frequency, standard deviation (SD), mean, median, 95% confidence interval (CI). The statistical significance testing of a group proportion (eg. gender) and means was done for parameters we deemed suitable. By using an ordinal regression, religion was regressed with lifestyle to determine respective odd ratios (OR) and respective statistical significance. A Tukey’s posthoc test was thereafter performed to determine value of contrast and significance between different religion score categories. Similarly, five lifestyle domains (prevention, physical activity, nutrition, social relationship, stress management) were regressed with religion to identify which domains are likely to be affected by religion. By using an independent t-test, the means of both religion practice and health-related lifestyle were seperately examined for all possible sociodemographic indicators (including number of children (categorised as <5 children or >5 children), literacy (illiterate or literate), marital status (married or unmarried), employment (employed or unemployed), age (<75 years or >75 years)). Those factors which were found to be statistically significant above were later controlled-for in the regression while determining relationship between religion and lifestyle. The proportion of variance ($r^2$) in the dependent variable
that can be explained by our independent variable was also determined. The effect size (ES) was also calculated by using means, SD, 95% CI, and population size. The ES is more intuitive since it is independent of the sample size. Lastly, we had taken informed consent prior to allowing participation along with an ethic permission from the institutional review board of the Islamic Azad University. The funding agency had no undesirable role during this project.

**Results**

Overall, a total of 218 elderly subjects participated, and they had an overall mean age of 68.3 years (SD 9.2, range 60-92, 95% CI 63.8-66.2). Of them, 112 (51.3%) were males. A comparison of two proportions (male-female) was not statistically significant, \( p=0.9 \). The remaining details are provided in Table 1 below.

The mean religious score among overall population was 73.0 (SD 11.5, range 35-95, 95% CI 71.5-74.5). Among males and females, the religious score was 73.0 (SD 11.5, range 43-95) and 72.9 (SD 11.5, range 35-92), \( p=0.9 \), respectively. Similarly, the mean lifestyle score among overall population was 100.9 (SD 14.7, range 61-138). Among males and females, this score was 110.9 (SD 14.7, range 61-138) and 101.0 (SD 14.7, range 61-129), \( p=0.0001 \), respectively. To simplify, both religious and lifestyle scores were medium, and, religious score was nearly identical for males and females (\( p=0.9 \)), while, lifestyle score was significantly better among males than females by about 9.3% (\( p=0.0001 \)).

**Lifestyle domains:**

The mean lifestyle score across individual domains was: prevention (39.2, SD 6.1, range 24-53), nutrition (25.6, SD 4.9, range 15-39), physical activity (10.5, SD 2.6, range 6-19), stress management (8.8, SD 3.0, range 4-18) and social relationships (16.5, SD 3.7, range 7-26). By gender, only social relationship domain (17.0±3.4 vs 16.0±4.0, \( p=0.04 \), ES= 0.01, respectively) was statistically different between males and females.

Associators and predictors (sociodemographic factors) of lifestyle and religious belief:

By using an independent t-test, the mean religious score was both numerically and statistically higher among those with <5 children (75.1, 95% CI 72.7-77.4 vs. 71.2, 95% CI 69.3-73.2, \( p=0.007 \), and the literate ones (76.7, 95% CI 74.4-79.0 vs. 70.2, 95% CI 68.2-72.1, \( p=0.0001 \). By using an independent
t-test, the mean lifestyle score was higher for those with <5 children (103.0, 95% CI 100.5-105.4 vs. 98.5, 95% CI 95.3-101.6, \( p=0.01 \), ES=0.02), and the unmarried ones (108.2, 95% CI 105.1-111.3 vs. 99.2, 95% CI 96.9-101.4, \( p=0.0002 \), ES=0.10).

Interaction between religious beliefs and lifestyle, and role of moderators:

Based on an ordinal regression, for a one unit increase in religion category, the odds of having a high lifestyle was estimated to be 5.5 (95% CI 3.1-9.7, \( p=0.001 \), ES=0.18, \( r^2=29.5\% \)), given that all of the other variables in the model are held constant. Based on a Tukey post-hoc test, all three religion categories were statistically different as follows: between <50 and >75 (contrast 24.4, 95% CI 12.8-35.9, \( p=0.001 \)), between <50 and 51-74 (contrast 12.8, 95% CI 1.4-24.3, \( p=0.02 \), and between 51-74 and >75 (contrast 11.5, 95% CI 7.1-15.8, \( p=0.001 \)). After controlling for above three moderator factors (marital status, number of children, and employment), for a one unit increase in religion category, the odd of having a high lifestyle was estimated to be 5.8 (95% CI 3.1-10.5, \( p=0.001 \), ES=0.19).

According to five lifestyle domains, by using an ordinal regression, the religion practice successfully predicted the domains of prevention (OR=0.18, 95% CI 0.11-0.28, \( p=0.001 \), ES=0.18), nutrition (OR=0.21, 95% CI 0.13-0.34, \( p=0.001 \), ES=0.15), social relationship (OR=0.25, 95% CI 0.16-0.40, \( p=0.001 \), ES=0.12). The other two domains did not have any significant prediction.

**Discussion**

Aging is a period of life in which the elderly may face many psychological problems[18].

We performed an important work to determine any health-related association with regards to the practice of religion. For this, we used structured detailed questionnaires. Moreover, our sample was from various population-based sources and no particular gender was overly-present in our sample (\( p=0.9 \)).

Our work provides new knowledge and dissipate myths as well. For instance, hyper-religiosity is popularly perceived for Iran, Muslims, and the MENA region[16]. However, our religion score was fairly moderate, both for males and females, without any gender-based difference (\( p=0.9 \)). Despite popular beliefs, this should not be unexpected because Islam is a dose-defined religion
(including the time, nature, and quantity of prayers one has to do), for both males and females, which is visibly not in other religions. For instance, in Christianity, The Bible says “to pray without ceasing” (Romans New Testament 12:12). Moreover, based on a United Nations survey, the most violent region in the world is Latin America, followed by Africa, and not the MENA region [17], as popular perceptions might indicate.

Conclusions

Based on a representative un-selected validated sample, and by using a systematic questionnaire, and after controlling for various possible confounders, and within current evaluation limits, we may conclude that religion may mitigate health-related lifestyle.

Acknowledgment: We acknowledge all, named or unnamed, that might be. Funding was procured from the Islamic Azad University, Iran. The funding agency had no undesirable role during either planning or the implementation of this survey.

Conflict of Interests: There is no conflicting interest.

Abstract
This was an analytical study with cross sectional design. Collection of blood specimens was carried out by consecutive sampling during March-June 2019. Blood specimens in this study were healthy adults aged ≥21 years who underwent general medical check-up or blood donors who met the inclusion criteria and signed informed consent. A total of 71 samples were stored at room temperature and temperature 4-8 °C, then PT (prothrombin time) and aPTT (activated partial thromboplastin time) checks were carried out at 0, 4, 12, and 24 hours. Data were analyzed by using Kolmogorov-Smirnov Test, paired t test and Wilcoxon Signed Rank Test. There were differences in the results of PT in the room temperature specimens and 4-8 °C at 4 hours, 12 hours, and 24 hours with p value <0.001. This was also found in the aPTT parameter, but for specimens at 4-8 °C at the 24th hour examination the results of changes in aPTT were not statistically significant with p values 0.062. Different PT and aPTT tests at the two storage areas and at different examination times obtained different and statistically significant results with p value <0.001. Examination of hemostasis physiology requires special attention, where pre-analytic plays an important role which can influence the overall test results. The aspects of time and storage on the stability of PT and aPTT specimens are illustrated in this study where significant differences were obtained with p values <0.001. Examination and storage of coagulation study specimens in accordance with CLSI recommendations will provide accurate results and accurately describe the state of the specimen according to the patient’s clinical condition.

Keywords: activated partial thromboplastin time, examination time, preanalytic coagulation study, prothrombin time, hematology

Introduction
Coagulation is a physiological routine test requested at a clinical laboratory to identify the occurrence of coagulation disorders and monitor anticoagulant therapy. In the last few decades, various ways have been developed to improve the quality of preanalytic, analytic and standardized coagulation tests. However, poor control and standardization of the preanalytic phase still needs to be improved as it disrupts the reliability of the results. Therefore, continuous efforts to identify and prevent preanalytic errors are needed[1,2].

Although the integrity of specimens is important for each laboratory test, coagulation testing that requires plasma specimens seems to be very sensitive to even small deviations from standard practice regarding anticoagulant concentrations, container materials, collection techniques, centrifugation, examination time and blood specimen storage. Coagulation physiological testing is a routine test carried out in laboratories in general, and in Dr. Soetomo Hospital, Surabaya, Indonesia[1,2].

Similar to reagents, specimens also decline over time, which leads to a number of false test result points.
In most cases, laboratories can safely use manufacturer’s or published study information to determine the stability of the specimen, but in some conditions the stability of the specimen is not available yet\(^\text{[3,4,5,6]}\). Because of this reason, research related to recommendations of storage and examination time on the stability of PPT and aPTT blood specimens in the testing of coagulation physiology in Dr. Soetomo Hospital laboratory is very important, considering that the results of an accurate, fast, and precise testing is closely related to the financing and quality of blood testing services at Dr. Soetomo Hospital, Surabaya, Indonesia.

### Materials and Method

The study used analytical study with cross sectional design. Blood specimens in this study were obtained from healthy adults aged \(\geq 21\) years old who underwent general medical check-up or blood donor that met the inclusion criteria and was willing to take part in the study. The collection of blood specimens was carried out by consecutive sampling during March-June 2019.

Blood specimens were calculated using equation:

\[
\alpha = 0.05, 1-\beta = 0.90, \sigma = 5.8, \sigma_0^2 = 33.64, \mu_0 = 28.3, \mu_a = 30.7 \\
n = \frac{\sigma^2(Z_{1-\beta/2} + Z_{1-\alpha})^2}{(\mu_0 - \mu_a)^2}
\]

So that the value of blood specimen is 62. Blood specimen value was calculated using the hypothesis tests for a population mean (two-sided test). Patients were excluded from the analysis if they did not meet the inclusion criteria and did not sign informed consent.

Statistical tests were done using SPSS version 17.0. A total of 71 specimens were collected, then divided and stored at room temperature and 4 - 8 ° C. Afterwards, PT and aPTT at 0 hours, 4 hours, 12 hours, and 24 hours were assessed. Prior to the statistical test, normality test was performed using the Kolmogorov-Smirnov test. Normally distributed data was analyzed using paired t test while not normally distributed data was analyzed using the Wilcoxon Signed Rank test. Data was displayed as mean±standard deviation with \(p <0.05\) significantly.

### Results

A total of 71 specimens that met the inclusion criteria and signed the informed consent were obtained for this study.

Discussion

Preanalytic conditions that can potentially cause errors in hemostasis testing include improper sampling or improper handling of specimens. In these circumstances, the test results do not accurately reflect the state of the specimen according to the clinical condition of the patient[7]. In this study, as many as 71 specimens that met the inclusion criteria were collected, then PT and aPTT examinations were carried out at two different storage locations, namely at room temperature and at 4-8 °C, each at 0 hours, 4 hours, 12 hours and 24 hours. Clinical and Laboratory Standards Institute (CLSI) recommends storing specimens for the testing of physiological hemostasis at room temperature or non-refrigerated temperature and examined in the shortest time possible, preferably 1 (one) hour after collection[8]. At the Clinical Pathology Laboratory of Dr. Soetomo Hospital, Surabaya, the testing of physiological hemostasis is a routine test. Several conditions that occur in the field after the collection of specimens, either from the inpatient room or from the outpatient specimen collection room, may cause a variety of time delays between the collection and examination of the specimen. This can certainly affect the results of the examination and it is feared that results cannot describe the condition of the specimen according to the clinical condition of the patient accurately. Therefore, the time between specimen collection and specimen examination needs to be considered.

Prior to the testing of physiological hemostasis, the specimen must be stored at room temperature to prevent deterioration of unstable clotting factors such as factor V and factor VIII, and specimens do not need to be delivered in refrigeration, but at temperature of 15-22 °C. Extreme temperatures must be avoided and delays in transportation can affect unstable factors (factor V, factor VIII), which may cause prolongation of freezing time due to loss of activity of these factors[9,10]. In accordance with CLSI guidelines, specimens must be assessed as soon as possible (ideally within 1 hour after collection) to maintain specimen integrity.

According to the 71 specimens in this study, it can be generally said that there was a difference in the results of PT and aPTT on specimens examined at room temperature and at 4-8 °C. The mean±standard deviation of PT obtained at room temperature showed values of (10.05±0.361) seconds at 0 hours, (9.85±0.445) seconds at 4 hours, (9.95±0.351) seconds at 12 hours and (10.22±0.588) seconds at 24 hours. The data obtained
revealed information on the tendency of prolonged PT from the examination of 4 hours until the examination of 24 hours. However, the median variation did not show great differences with PT minimum value (9.0 seconds) and maximum value (12.5 seconds), where numbers were still in the range of PT reference values, namely (9-12) seconds.

The mean±standard deviation of PT at temperature of 4-8 °C revealed results of (10.10 ± 0.364) seconds at 4 hours, (10.13 ± 0.457) seconds at 12 hours and (10.41 ± 0.900) seconds at 24 hours. According to this data, there was a tendency of prolonged PT from the time of specimen collection to the 24-hour examination. It is important to pay attention to the storage of specimens at 4-8 °C, where examination at 24 hours showed a wide range of minimum - maximum values of PT parameter, namely (7.9-15.8) seconds. This shows that the storage of specimens at temperature of 4-8 °C can affect factor VII, thus prolong PT value beyond the reference value.

Difference test results of aPTT parameter on the room temperature specimen group at 4 hours, 12 hours and 24 hours showed p value of p <0.05. It can be concluded that there were statistically significant differences between specimens assessed at 0 hours with specimens assessed at 4 hours, 12 hours and 24 hours. The mean±standard deviation obtained at room temperature showed values of (29.01±2.160) seconds at 0 hours, (28.26±2.568) seconds at 4 hours, (30.60±2.120) seconds at 12 hours and (31.48±2.417) seconds at 24 hours. According to the data it can be informed that there was a prolonging of results, however the median of aPTT was in a range that was not much different (28.4-31.3) seconds. In this study, difference test was done on the results of specimens that were immediately assessed (0 hours), with the results of specimens assessed at 4 hours, 12 hours and 24 hours. Mean±standard deviation was obtained with variations that were still in the range of the standard reference value or slightly prolonged. So, although results are statistically reported to be significantly different with p value of p <0.001, results need to be further clinically studied to know the patient’s clinical condition and disease history.

Difference test results of aPTT at temperatures of 4-8 °C showed p value of p <0.001 at 4 and 12 hours, while at 24 hours, results showed p value of p = 0.0062. It can be concluded that statistically there was no significant difference in the results of aPTT at 24 hours. An interesting finding in the examination of aPTT at 4-8 °C and at 24 hours is that results showed very small differences, which were 0.23 seconds and 0.07 seconds, thus it can be concluded that there was no significant difference. This study is in accordance with the study conducted by Magnette et al. who concluded that physiological coagulation specimens are recommended to be stored at room temperature (15-25 °C) and the examination of specimens should be carried out <4 hours for whole blood specimens that are not centrifuged and <1 hour for centrifuged samples. Further research with a wide variety of storage time and larger quantity of specimens may provide data or results with higher accuracy in the form of cut off time and optimum storage temperature for PT and aPTT examination[5].

**Conclusion**

Is sum, the examination of hemostasis physiology requires special attention, where pre-analytic processes play an important role and can influence the overall test results. The aspects of time and storage on the stability of PT and aPTT specimens are illustrated in this study where a significant difference with p value of p <0.001 was obtained. Testing and storage of physiologic hemostasis specimens in accordance with CLSI recommendations will provide accurate results and accurately describe the state of the specimen according to the clinical condition of the patient.

Correlation of Urine Leukocytes and Urine Bacteria Using Current Sitometry Using Urine in Patients of Children Channel Infection

Adriyani Amin1, IGAA Putri Sri Rejeki1, Ninik Soemyarso Asmaningsih1

1Department of Clinical Pathology, Faculty of Medicine, Universitas Airlangga, Dr.Soetomo General Hospital, Surabaya. 60285 Indonesia

Abstract

Background: Urinary tract infection (UTI) in children is a common illness. The gold standard for UTI diagnosis is urine culture, but it takes a long time and often gives negative results. Currently developed a method of flow cytometry for checking urine sediments. This tool is able to detect leukocytes urine and urine bacteria in quick time. The purpose of this study is to analyze the relationship of urine leukocyte count and the number of urine bacteria using flow cytometry with urine culture in patients with UTI.

Method: Eighty-four patients were enrolled in this study that consisting of 43 patients with suspected UTI and 43 patients with non-ISK treated at Inpatient Installation, Emergency Installation Department of Health Sciences at Dr.Soetomo General Hospital, Surabaya for 4 months. The examination of urine leukocytes and urine bacteria was using current cytometry method (UF-500i, Sysmex, Japan). While, examination of urine culture using blood agar plate and Mac. Conkey.

Results: There was a significant relationship between the number of leukocytes and the number of colonies. The relationship between leukocytes and the number of colonies was weak, this was indicated by Spearman correlation coefficient (rho) value of 0.376. There was a significant relationship between bacteria and the number of colonies. p <0.05. The relationship between the number of urine bacteria and the number of colonies was quite strong indicated by rho = 0.729.

Conclusion: There was a relationship between urine leukocyte count and the number of urine bacteria using flow cytometry with a urine culture.

Keywords: Urine leukocytes, Urine bacteria, Urine culture, Urinary tract infections.

Introduction

Urinary tract infection (UTI) in children is a common illness that found in addition to upper respiratory tract infections and diarrhea and the second most common cause of fever after upper respiratory tract infection 1. Urine culture examination takes a long time and can give false negative results. It may delay the diagnosis of UTI, which in the end the management of UTI is also delayed, which may lead to poor UTI prognosis. The incidence of UTI in children at Indonesia ranges from 0.1% to 1.9% of all cases that children treated within 5 years (1984-1989) 2.

The high incidence of UTI causes many requests for urine culture examination3,4. Positive urine culture when bacterial growth of more than 100.000 colony forming units (CFU)/mL from one pathogen5. 60 - 80% urine culture examination did not contain any infectious bacteria or just contaminants that can be solved by filter test 4,6,7. Examination of bacteria with Gram staining (sensitivity 96%, specificity 93%), examination using 10 cell/μL hemositometer (83% sensitivity and specificity) 8. Microscopic examination can give results faster than culture, more simple and inexpensive. But
the results of the examination require skilled, trained, and interpretation among interrogators can be different. In addition to microscopically, examination of urine and urine leukocyte bacteria can use the method of flow cytometry. Current cytometry methods can distinguish particles in urine and quantitatively calculate them, including leukocytes, erythrocytes, epithelium, bacteria, fungi, cylinders, and crystals. Sysmex UF-500i is one example of urine sediment examination tool using current cytometry method. This tool is able to check large quantities of samples with fast time.

The sensitivity and specificity of the examination using flow cytometry to confirm the diagnosis of UTI is non-existent. Previous studies have suggested that the 65-bit bacteria/mL and 100 leukocyte/mL cutoff points gave 98% sensitivity, specificity 62.1%, negative predictive value 98.7%, positive predictive value 53.7%. Other studies also stated that at the point of cutting of 230 bacteria/μL, urine culture <105 CFU/mL obtained 95% sensitivity and 80% specificity and able to reduce the number of urine culture examination by 52%. Research using flow cytometry in Indonesia is still rare. In this research will be examined using flow cytometry to assess the relationship of urine and urine leukocytes with urine culture results.

Method

This research was an observational analytic research with the cross-sectional design. The research started from the literature search, research proposal preparation, sample collection and workmanship, data management, and research report preparation conducted from March until June 2013. The research was conducted at Inpatient Installation, Outpatient Installation and Emergency Installation of Department Child Health Science Dr.Soetomo General Hospital/Faculty of Medicine Universitas Airlangga Surabaya, as the place of sampling. Sample examination was performed at the Clinical Pathology Installation of Dr.Soetomo/Faculty of Medicine Universitas Airlangga, Surabaya. The sample of the study was the pediatric patient and divided into two groups: groups of patients with UTI and Non-UTI that meet the inclusion criteria.

The inclusion criteria for samples meeting the criteria in this study included patients with suspected UTI aged 2 to 18 years, patients receiving antibiotics, doing urinalysis examination and obtaining positive esterase leukocyte, positive nitrite, uric microstatic leukocyte>5/Lpb or found urine bacteria microscopic, and willing to sign informed consent. Urinalysis results obtained negative nitrite, leukocyte esterase negative, leukocyte urine microscopic <5Lpb or not found microscopic urine bacteria.

This study was started by selecting the sample according to the inclusion criteria, then the urine sampling was performed by catheterization in children less than 6 years old and the way of urine transmit clean in children more than 6 years old. After the urine sample is directly sent to the Installation of Clinical Pathology Dr.Soetomo General Hospital for urine examination using flow cytometry (UF 500i) (Sysmex Corporation, Japan) and urine culture was done within ≤ 1 hour.

All collected data collected in the data collection sheet was presented in tabular form, the diagram was processed statistically in the form of descriptive analysis. To calculate sensitivity, specificity, positive predictive value, negative and ROC curve, and to know the relation of urine leukocyte count and urine bacteria, statistic analysis test using Pearson correlation test if the data was normally distributed if the data not normally distributed using Spearman correlation test.

The results of the examination of the number of urine bacteria obtained the lowest value of 0.0/µL and the highest 58017.8/µL. Median examination results of urinary bacterial counts in the UTI group of 671.85/µL with a range of 19.4/µL to 58017.8/µL. Median examination results of urinary bacterial counts in the non-UTI group were 7.2/µL with a range of 0.0/µL to 832/µL. There was a significant difference in the number of urine bacteria between group UTI groups rather than UTI, p <0.05 (Figure.4B). Current cytometric examination can also display a scattergram image that can be viewed on scattergram B1 (Figure.3BA). Urine bacteria is represented by a purple (purple) color. There are two typical features of the slope of the bacterial scattergram namely the inclination 1 (Figure.3BB) and the slope 2 (Figure.3BC). 26 samples were tested to match the results of identification of urine cultures with current isometric illustrations. There were 18 samples that can be tested suitability and 18 samples cannot be analyzed because it does not give a typical picture. The 18 samples had bacterial counts <105 CFU/mL. The slope of 1 was 66.7% according to the culture of urine, whereas on the slope 2 there was 93.3% according to the culture of the urine (Table 1). The results of the examination of leukocyte counts with 40/µL cutoff points were 28 (32.56%) of the samples, and 58 (67.44%) of
the samples were not-UTI (Table 2). The sensitivity of leukocyte examination with cutting point 40/μL to the culture of urine was 65.4%, with specificity 81.7%. The positive predictive value and negative predictive value was 60.7% and 84.5% respectively. The diagnostic value of urine leukocyte examination using flow cytometry (Table 3).

The ROC curve formed for examination of urine leukocyte counts using flow cytometry at the cutting point ≥40/μL against urine culture results ≥ 5x10^4 CFU/mL (Figure.5A). The under the curve (AUC) area was 0.793 (medium). p <0.05. (95% CI 0.69 - 0.89). When using the cutoff point 30/μL then obtained the sensitivity of 69.2% and specificity 71.7%. The results of the examination of the number of bacteria with 125/μL intake point were 21 samples (24.4%) and 65 samples (75.6%) samples instead of UTI (Table 2). The sensitivity of examination of urine bacteria with the 125/μL cutting point for urine culture was 69.2%, with specificity 95.0%. Positive predictive values and negative predictive values were 85.7% and 87.7% (Table.3) respectively. The ROC curve formed for examination of the number of urine bacteria using flow cytometry at the point of ≥ 125/μL against the urine culture result ≥ 5x10^4 CFU/mL (Figure.5B). The under the curve (AUC) area was 0.946 (very good). p <0.05. (95% CI 0.902-0.989). AUC obtained on bacterial examination is wider than in urine leukocyte examination.

Discussion

Based on the results obtained, there was the growth of 3 kinds of colonies of germs or more without dominant species that considered as contaminants. If there were 3 or more different organisms in urine culture then a strong allegation of shelter errors and handling of urine samples. But it can also be found in patients who use permanent urinary catheters 12.

There is a growth of fungi in urine culture results, these results were consistent with earlier studies, in which UTI may also be caused by pathogens (fungi, parasites, and viruses) colonizing the urinary tract. Mushroom (Candida spp) is one of the causes of UTI 13-15. The presence of fungi in urine culture is an indicator of pyelonephritis that derived from hematogenous spread (descending path). Haematogenous spread is usually as a result of bacteremia or in patients with immune system disorders 6.

The result of urine culture obtained significant growth. These results were different from previous studies, the difference may be due to the screening of patients suspected of strict UTI. When more rigorous screening was performed then the possibility of a positive urine culture percentage will be even more. However, it is also known that the main problem of urine culture examination lies in the collection of samples, the length of urine in the bladder, the density of the urine, if the low urine weight may be due to increased urinary frequency, the number of colonies obtained is also low. Sampling and transportation of samples, culture techniques and interpretation of results also greatly influence urine culture test results 12.

The incidence of UTI depends on age and sex 2,5. In this study, girls with UTI were more likely to be in the age group 0-1 years and over 5 years, while the 1-5-year-olds were more likely to suffer from boys. Girls are more at risk of developing UTI by the first year of life than boys because of different anatomical features. Moisture of the periurethral and vaginal areas stimulates the growth of uropathogenic. A shorter urethral size increases the chances of ascending infection to the urinary tract. Besides, women are more likely to receive UTI because the uropathogenic, which is part of the normal flora of the stool, can colonize in the perianal which can then rise to the vaginal introitus. The spread of uropathogenic into the periurethral, urethra and bladder can be inhibited by the normal vaginal flora (Lactobacillus sp) causing the acidic vaginal pH. If the vaginal flora is also impaired it can cause uropathogenic to stick to the urinary tract and multiply and the incidence rate of UTI will increase in estrogen deficiency 6,15.

The most common pathogenic bacteria causing UTI were Escherichia coli (E. coli). E. coli was associated with childhood UTI in developing countries. Bacteria can survive and replicate because they have virulence factors such as expression of fimbriae, synthesis of aerobactin and enterobactin (iron-binding protein), which is very high affinity to iron, useful for bacterial replication, producing hemolysin, glycolalylx-mediated adherence, somatic Ag expression, producing urease, may move and be resistant to serum bactericidal activity 15. There was a significant number of urine bacteria between group UTIs rather than UTIs. p <0.05, so the number of bacteria with current cytometric examination can be used for screening examination of suspected UTI patients, thus reducing the number of urine culture requests. However, it is known that direct bacterial
examination cannot distinguish between uropathogenic or contaminants 15

There were two images of the slope of the scattergram bacteria (scattergram B1), which a slope of 1 that formed from densely dispersed points and extends along a diagonal line. This describes was suspected of the bacteria in the form of coccus. Tilt 2 was the slope formed from the points collected/concentrated in the narrow zone. This picture of the possibility of urine bacteria in the form of stems 16. The compatibility between the slope 2 and the shape of the stem bacteria was 93.3%, while for slope 1 only 66.7%. The same result was obtained in the previous research which got 2 slope suitability of 100% while the slope of 1% was 75% from 47 samples under study 16. The formation of a typical slope image is caused by the working principle of bacterial examination using a red (semiconductor) laser that concerns the bacterial distribution of B_FSC (describes particle size) and B_FLM (describes the intensity of the nucleic acid color of the particles) 14

The result of the analysis shows that there was a significant correlation between urinary leukocyte count and the number of colonies, but the relationship was weak, it indicated by the correlation coefficient (Spearman) only 0.376. The flow of urine can usually clear the urinary tract of pathogens. Urine itself also has specific antimicrobial properties, including low urine pH, high urea content, high organic acid content, polymorphonuclear cells, and Tamm-Horsfall glycoprotein, which can inhibit bacterial adherence in the bladder mucosal wall 6,15. The relationship between urine bacteria and the number of colonies was quite strong, this indicated by the value of the correlation coefficient (Spearman) that quite large by 0.729. Urine bacteria found in current cytometric examination was associated with positive urine culture results but direct bacterial examination cannot distinguish between uropathogenic or contaminants 15.

**Conclusion**

Based on the results of research and discussion can be concluded that there was a weak relationship between urine leukocytes and the number of bacterial colonies, but a strong relationship between urine bacteria with the number of bacterial colonies.

Ecological Analysis of Stunted Toddler in Indonesia

Agung Dwi Laksono¹, Ina Kusrini²

¹Senior Researcher, Center of Research and Development of Humanities and Health Management, Indonesia Ministry of Health, Jakarta, Indonesia, ²Researcher, Unit of Health Research and Development Magelang, Indonesia Ministry of Health, Central Java, Indonesia

Abstract

The results of the Indonesia Basic Health Survey (Riskesdas) in 2007, 2013 and 2018 showed the stunted rate for toddlers was still above 30%. While proven poverty often comes with stunted on toddlers. The study aimed to answer whether poverty factors and the availability of health services are related to the prevalence of stunted toddlers in provinces in Indonesia. This study was a secondary data analysis “Data and Information: Indonesian Health Profile in 2017”. The results showed that the high percentage of the poor population (>14.43%) was dominated by the high prevalence of stunted toddlers (22.51%-30.0%). In the category of health center ratio per 100 thousand high population (≥4) seen dominated by the prevalence of stunted toddlers in the high category (22.51%-0.0%). In the category of nutritionist ratio per 100 thousand high population (>12), it appears to be dominated by the prevalence of stunted toddler in the high category (22.51%-30.0%). In the category of midwife ratio per 100 thousand high population (>97) was dominated by the prevalence of stunted toddler (22.51%-30.0%). It was concluded that the percentage of the poor population was positively related to the prevalence of stunted toddler. While health service input factors (health center, nutritionists, and midwives) were not related to the prevalence of stunted toddlers.

Keywords: ecological analysis, stunted toddlers, health profile, poverty.

Background

The quality of growth in the first 1000 days of life is one of the focuses in health development. The importance of meeting nutritional needs at this time will also determine the quality of growth and development be optimal. Because this period is called a critical period because the failure of growth that occurs in this period will affect the quality of health in the future¹, including the quality of education².

One indicator of non-optimal growth quality is the high prevalence of stunted toddler. Stunted is a condition of malnutrition which is marked by the z score of height according to age under -2 elementary school. The high prevalence of stunting in toddlers shows the disruption of the quality of growth in the golden period. The 1000 day life period starts from the baby in the womb until the first two years of life³,⁴.

According to the results of the Riskesdas in 2007, 2013 and 2018, in Indonesia still showed stunted rates in toddlers above 30%. This means that there are 3 stunted toddlers out of 10 toddlers born in Indonesia⁵. The high prevalence of stunted certainly requires serious treatment. The serious impact will threaten the quality of human resources in the continuous life chain. Stunted toddlers will grow into a stunted adult with various impacts that will be caused⁶,⁷. Besides giving birth to babies with the same nutritional problems, for example, the birth of stunting babies or babies with low birth weight, growth failure is also closely related to the long-term impact of increasing the prevalence of non-communicable diseases in the future⁷.

Adequate nutrition during pregnancy and supervision of the health of pregnant women through antenatal care services is one of the sensitive efforts in stunted...
Poverty is proven to often occur together with the occurrence of stunted in toddlers. Poverty is not only present and contributing individually to one family, but macro poverty in an area is also allegedly closely related to the high prevalence of stunting in a colony or community group. Poverty is closely related to the availability of food to the family\textsuperscript{10,11}.

The study aimed to answer whether poverty factors and the availability of health services are related to the prevalence of stunting under five in provinces in Indonesia. This research is important to do because existing studies always focus on toddlers individually. No studies have been found that ecologically analyze aggregate data at the provincial level. The results of this study are important for health policymakers at the provincial and national levels for efforts to improve the nutritional status of children under five, especially the category of height indicators per age.

**Materials and Method**

This research was an ecological analysis using secondary data. Secondary data sourced from “Data and Information: Indonesian Health Profile in 2017” issued by the Indonesian Ministry of Health\textsuperscript{12}. Data were available at the link www.pusdatin.kemkes.go.id. The unit of analysis in this study was the provinces of Indonesia. In total (total sampling) 34 provinces were analyzed in this study.

The main variable to be predicted was “Prevalence of stunted toddlers”, ie the percentage of children aged 0-59 months with indicators of height per age included in the very short and short categories. Predictor variables consisted of the percentage of poor population, the ratio of health center per 30 thousand population, ratio of nutritionist per 100,000 population, and the ratio of midwives per 100,000 population. The variable prevalence of stunted toddlers was categorized into 4 strata based on WHO criteria that the prevalence of 30\% and above was a serious public health problem\textsuperscript{5}. While other variables will be categorized into 4 strata with statistically the same cut of points. Data were analyzed descriptively by cross-tabulation. Because the data processed was a total sample of the entire province, it was not necessary to see the level of significance.

**FINDINGS**

Figure 1 showed the distribution of stunted toddler prevalence per province in Indonesia. Only 1 province (Central Kalimantan) has a prevalence rate of stunted toddlers more than 30\%. Based on WHO criteria, the prevalence of stunted toddlers in Central Kalimantan falls into the category of serious public health problems\textsuperscript{5}.

Table 1 is a statistically descriptive of the 5 variables analyzed in this study. There is a very high gap in all variables. The lowest prevalence of stunted toddlers is Bali Province (13.60%), and the highest is in Central Kalimantan Province at 30.40%. The variation in the percentage of the poor population is also quite high. The lowest of 4.00% is Jakarta Province, and the highest proportion of the poor is Papua Province at 28%. While the health service input variable also shows a high gap.

Percentage of Poor Population and Prevalence of Stunted Toddlers

Table 2 is a crosstabulation between the prevalence of stunted toddlers and the percentage of the poor population. In the low percentage of the poor population category (<6.36%), it is seen that it is dominated by the prevalence of toddlers with moderately stunted toddlers (15.00%-22.5%). While in the category of the high percentage of the poor population (>14.43%) it appears to be dominated by a high prevalence of stunted toddlers (22.51%-30.0%). This means that the higher the percentage of the poor population in a province, the prevalence of stunted toddlers is also higher.
The ratio of Health Center and Prevalence of Stunted Toddler

Table 3 is a crosstabulation between the prevalence of stunted toddlers and the Health Centers ratio per 100,000 population. In the category of low health center per population ratio (1), it appears to be dominated by the prevalence of stunted toddlers in the medium category (15.00%-22.5%). While the Health Centers ratio per 100 thousand high population (≥4) was seen to be dominated by the prevalence of stunted toddlers in the high category (22.51%-30.0%). This means that the ratio of Health Centers in a province has no effect on the prevalence of stunted toddlers.

The ratio of Nutritionists and Prevalence of Stunted Toddler

Table 4 is a crosstabulation between the prevalence of stunted toddlers and the ratio of nutritionists per 100,000 population. In the category of nutritionists ratio per 100 thousand low population (<4) seen dominated by the prevalence of stunted toddlers in the moderate category (15.00%-22.5%). While the ratio of nutritionists per 100,000 population is high (>12) it seems to be dominated by the prevalence of stunted toddlers in the high category (22.51%-30.0%). This means that the ratio of nutritionists in a province has no effect on the prevalence of stunted toddlers.

The ratio of Midwives and Prevalence of Stunted Toddler

Table 5 is a crosstabulation between the prevalence of stunted toddlers and the ratio of midwives per 100,000 population. In the category of midwives ratio per 100 thousand low population (<53) seen dominated by the prevalence of stunted toddlers in the moderate category (15.00%-22.5%). While in the category of midwives ratio per 100 thousand high population (>97) it appears to be dominated by the prevalence of stunted toddlers in the high category (22.51%-30.0%). This means that the ratio of midwives in a province has no effect on the prevalence of stunted toddlers.

</table>

The results of this study indicate that poverty is a factor that has a major contribution to the high prevalence of stunted toddlers in Indonesia. This is in line with the basic concept of growth and development which states that socio-economic factors are variables that have an influence on the quality of growth and development\textsuperscript{13,14}. The poverty factor is considered to be closely related to family characteristics such as education level, purchasing power so that it will affect family access in the search for health services, providing quality food and also providing a clean and healthy environment\textsuperscript{15,16}.

This study is in line with the results of an analysis of the causes of stunted between other low and high socioeconomic factors. A Guatemalan study in 2010 found a high prevalence of stunting in families with low socioeconomic status\textsuperscript{17}. In another study, it was also mentioned that large disparities between groups with low and high socioeconomic factors were associated with meeting nutritional needs during pregnancy and alcohol use\textsuperscript{18}.

The results of studies in four states in India multivariate found that food security, toilet use, and low body mass index status of mothers were the main predictors of stunted and underweight in children. While acute respiratory infections are a major predictor of weight loss and diarrhea is a major predictor of stunted\textsuperscript{19}. All predictors show the inherent poverty characteristics of a family.

A case study in Mexico distinguishes rural and urban factors in identifying the cause of stunted toddlers. In urban areas, stunted is mostly found in toddlers with the type of work parents are farmers and with a low level of attendance to child health services. While in rural areas, parents do not work as a contributing factor to stunted, although it is also related to other factors,
namely duration of breastfeeding and attendance in child health services. A multilevel analysis of factors causing stunted in Indonesia states that the variance of stunted at the provincial level by 51.9% can be reduced to 44.1% if the provincial economic level is improved.

The results of this study are considered limited in terms of useful macro policy because the data processed is aggregate data at the provincial level. Further research is needed at the individual level as a basis for more detailed policy decisions at the micro-level, with more involvement in target families.

Conclusions

Based on the results of the study it could be concluded that the percentage of the poor population was positively related to the prevalence of stunted toddlers. Or the less the percentage of the poor population, the less the prevalence of stunted toddlers. While health service input factors (health centers, nutritionists, and midwives) were not related to the prevalence of stunted toddlers.

The Use of Touch DNA Analysis in Forensic Identification
Focusing on STR CODIS LOCI THO1, CSF1PO and TPOX

Ahmad Yudianto1, Simon Martin Manyanza Nzilibili2, Pudji Harjanto2, Fery Setiawan2

Airlangga University, Surabaya

Abstract

Introduction: Identification through DNA analysis is an accurate diagnostic tool. DNA analysis is via Variable Number of Tandem Repeat (VNTR) and Restriction Fragment Length Polymorphisms (RFLP). Up to date, blood spots/blood, sperm spots, vaginal swabs, buccal swabs and bones are specimens that are widely used in the field of forensics for DNA analysis. At the crime scene, the perpetrator’s skin may accidentally be in contact with surrounding objects thereby transferring trace evidence to the objects.

Method and Materials: Laboratory observation to demonstrate identification through DNA isolation from the objects that are touched (touch DNA), using the STR CODIS locus, with a momentary research design. DNA was isolated from buccal swabs and swab properties (watches and mobile phones) from volunteers who have signed the consent form. A total of ten samples were used in this study.

Results and Discussion: Mean levels of DNA [UV-Visible Spectrophotometer] buccal swab: 167.89 ± 85.71 µg / ml, watch swab: 59.19 ± 5.58 µg / ml, mobile swab: 38.09 ± 2.12 µg / ml and the purity of the buccal swab DNA: 1.79 ± 0.71, the watch swab: 1.69 ± 0.76, the mobile swab:1.53 ± 0.56. Visualization of PCR products on Polyacrylamide Agarose Composite Gel Electrophoresis [PAGE] stained with Silver and amplified using the standard primers THO1, TPOX and CSF1PO for STR CODIS showed a 100% detection of amplicons. Allele profiles on all samples of STR CODIS were a match or identical to the positive control K562.

Conclusion: Property (handphone and watch) swabs can be used as alternative materials in forensic identification using Touch DNA analysis. It was able to be isolated and amplified by using Polymerase Chain Reaction on the STR CODIS loci THO1, CSF1PO and TPOX

Keywords: Touch DNA, STR CODIS, Identification

Introduction

Identification is a way of identifying individuals with characteristics and features to distinguish them from others. Currently the identification method has evolved towards molecular forensic DNA (Deoxyribonucleic acid). DNA is the smallest unit and is present in all living things from microorganisms to higher organisms such as humans, animals and plants.

Identification through DNA analysis is an accurate diagnostic tool. DNA analysis includes analysis of Variable Number of Tandem Repeat (VNTR) and Restriction Fragment Length Polymorphisms (RFLP). DNA analysis through VNTR is a DNA examination method that is based on certain repeated base sequences (core sequences). DNA repeated sequence areas with base size less than 1 kb (kilo base pair), are known as ‘microsatellite’ or Short Tandem Repeat (STR).1
The Federal Bureau of Investigation [FBI] designed 13 STR locus as a synergistic forensic identification system with the Combined DNA Index System (CODIS) database. The STR locus used by FBI includes TH01, TP0X, CSF1PO, vWA, FGA, D3S1358, D5S818, D7S820, D13S317, D16S539, D8S1179, D18S51, and D21S11, plus amelogenin markers used to determine the sex of the victim.2,3

At the crime scene the perpetrator’s skin surface or part of his body is often accidentally exposed to the surrounding objects, resulting in the transfer of trace evidence to the objects. In this case one of the technologies namely touch DNA / contact trace DNA can be used, through DNA that is transferred through skin cells when objects are held or touched. Up to date, personal identification through touch DNA testing is not widely known.4

**Materials and Methods**

The type of research was experimental laboratory. Research sample: the watch and handphone used by the respondent and the buccal swab. All respondents used in this study signed the consent form after they freely agreed to participate as subjects of the research. The sample size used was 12.

Research Materials: DNAzol Reagent, 100% & 70 % ethanol solution. PCR Mix [ATP,CTP,TTP GTP, MgCl2,TaqPolymerase], Nuclease Free water, STR CODIS primers of locus:

- TH01: CTGGGCACGTGAGGGCAGCGTCT/-TGCCGGAAGTCCATCCTCACAGTC
- TP0X: ACTGGCACAGAACAGGCTAGG-/- GAGGAAGTGGGAACCACACAGGT
- CSF1PO: AACCTGAGTCTGCCAAGGACTAGC/- TCCACACACCACCTGGCCATCTTC

PCR products were visualised using Polyacrylamide Agarose Composite Gel Electrophoresis [PAGE] and the gel was stained with silver. To amplify the STR CODIS locus, the standard primers [THO1, TP0X and CSF1PO] were used and all buccal swab and property [watch and handphone] swab samples showed positive results signifying a 100% detection. Allele profiles in all samples were a match with the positive control, K562, as shown in both Figure 1 and their purity profiles were also shown on table 1.

![Figure 1. Visualization of STR CODIS PCR product using at locus TH01 [156 – 195 bp]](image-url)
The figure 2 below shows the visualization of PCR products with PAGE stained with Silver. The samples were amplified using the primer CSF1PO [amplicon product 321–357 bp] and all the results were positive as shown by the matching bands with the positive control [K562]: 9 : 10.

**Figure 2. Visualization of STR CODIS PCR product using at locus CSF1PO [321 – 357 bp]**

**Discussion**

The results were obtained by measuring the average amount of DNA using a UV-Visible Spectrophotometer. The average DNA level of all samples was at a minimum amount of 0.25 ng with a purity of 1.8-2.3

The above Figure shows the visualization of PCR products on Polyacrylamide Agarose Composite Gel Electrophoresis [PAGE] stained with silver. Repeat - Combined DNA Index System [STR- CODIS] locus THO1 [amplicon product 156 – 195 bp] showing that all samples were detected as compared to the positive control [K562]: 9,3;9,3.5,6

**Figure 3. Visualization of STR CODIS PCR product using at locus TPOX [262 – 290 bp]**

Figure 3 above, shows the visualization of PCR products with PAGE stained with silver and the amplicons were amplified using the CODIS STR TPOX locus [amplicon product 262 - 290 bp] and all samples were detected as positive [detection +] when compared with the positive control [K562]: 9: 10. For adequate visualization of the results, sufficient levels and purity of the DNA is needed in order for the DNA to be used
as an examination material, including in this case of identification and paternity test.\(^7\)

Failed PCR amplification is characterized by the absence of bands on agarose gel. Incomplete PCR cycles were minimized by PCR optimization for all the respective primers used.\(^8\)

In this study, 3 STR CODIS loci were used, showing that all the samples for buccal swab and property swab (watch and handphone) were detected positive, as well as the allele profile of each locus in each sample showing matched results. Matched results have the understanding that the allele profile on the buccal swab is identical to the allele profile on the swab property. Only one sample showed a different allele, the sample is A\(^2\) (handphone) [ allele 8 : 9,3]. This could be due to contamination during DNA analysis checking process, starting from the process of sample collection.\(^9\)

As a positive control, that is K562 which is a positive control in the examination of DNA analysis with STR CODIS and 100 bp ladder markers. DNA analysis tests have a 100% accurate value, when done correctly. This DNA analysis test gave a results probability of 100%.\(^9\)

The following is a profile table of STR CODIS allele detection results [THO1, CSF1PO, TPOX] on DNA samples [watch swabs, handphone swabs and buccal swabs].\(^10\)

Research on STR CODIS as a whole has not yet been reported, only a few primers. Some studies have been conducted from several STR CODIS focus areas. The accuracy of research at the loci THO1, TPOX, CSF1PO, and has been reported in several studies including: chromosome populations and allele sequences at the THO1 locus, population in Thailand with 8 STR loci included THO1, TPOX, CSF1PO and vWA. Research on Chinese population in Taiwan with STR research on genetic variation in Caucasia revealed that genetic variation in the population of Filipinos and Thais living in Taiwan using 9 STR loci. Whereas in Indonesia, a research on the THO1 allele pattern in the Batak population in Surabaya and locus D1S80 and D17S5 populations in Surabaya. STR loci typing method especially the THO1 locus is a reasonable, strong and efficient method making it a useful method in forensic cases. 5 to 6 STR loci has a ratio of 1: 100 billion so that in principle regarding the number of loci examined, the more loci used the better the accuracy value.\(^11\)

**Conclusion**

Property (handphone and watch) swabs can be used as alternative materials in forensic identification using Touch DNA analysis with an average DNA yield of: 59.19 ± 5.58 mg/ml and: 38.09 ± 2.12 mg/ml for watch and handphone swabs respectively. Both the buccal swab, watch swab and handphone swabs had trace amount of DNA that was able to be isolated and amplified by using Polymerase Chain Reaction on the Short Tandem Repeat locus - Combined DNA Index System [STR-CODIS] loci THO1, CSF1PO and TPOX.

Abstract

The manipulation of digital images has become easy due to powerful computers, advanced photo-editing software packages and high-resolution image-capturing devices. The identification of image authenticity has received much attention because of the increasing power of image editing methods. Object removal is an image forgery technique, which is usually achieved by the Exemplar-Based Inpainting (EBI) method without any noticeable traces. Some legal issues may arise when a tampered image cannot be distinguished from a real one by visual examination. Therefore the manipulation of digital images has become a huge challenge to passive image forensics. There are a lot of forgery techniques that use to detect on these images after removing the object, but these techniques have limitations when used some post-processing operations such as super-resolution processing, noise addition, blurring and compression processes. To address this issue, this paper proposes a novel forgery detection technique to recognize tampered inpainting images, using topological data analysis (TDA) approach. TDA is a mathematical approach concern studying shapes or objects to gain information about connectivity and closeness property of those objects. This proposed technique is applied for a large number of natural images with getting a good results.

Keywords: Image forgery. Image inpainting. Topological Data Analysis. Local Binary patterns. kNN classifier.

Introduction

In recent years, the field of digital image forgery detection has remained active and has received significant interest from the scientific community. A wide-ranging study about image forgery detection have been introduced in (1).

A copy-move and object removal are a famous forgeries processes at this time. There are a lot of techniques for detecting the copy-move regions in images in the literature, also there are a lot of techniques for detecting the forgery regions in images. However, we will focus on techniques for the detection of object removals in an image, which is usually completed by EBI method in an unnoticeable way. Up to now, there are few works which report about the blind detection of image inpainting (2), (3), (4), (5), (6).

As the first attempt, the authors in (2) introduced a forgery detection method for EBI based on zero-connectivity features, and fuzzy membership is proposed to detect specific image doctoring to yield the degree of matching of blocks in suspicious regions and identified forged regions by the fuzzy membership. However, this method failed to detect the forged regions in the compressed and JPEG images.

Later, the authors in (3) presented an automatic forgery detection method for EBI process. The proposed method contains two major processes: suspicious region detection and forged region identification. The proposed method performs well with regard to both accuracy and speed while detecting forged regions. However, this method still incapable to locate the forged regions of small sizes.

Therefore, Bacchuwar et al. in (4) proposed a novel method to detect inpainting forgery and copy-move regions using a jump patch-block matching, which makes this method robust and faster than the already existing methods. This method reduces computational costs.

Corresponding author:
Ahmed K. Al-Jaberi .

In recent work, the authors in (5) presented an efficient forgery detection technique for object removal by EBI method. This proposed technique combines central pixel mapping, greatest zero-connectivity component labelling and fragment splicing detection. The proposed technique has succeeded in detecting the tampered regions in images and reduction of computational complexity; but this method fail to when those inpainted images are further subjected to some post-processing operations such as super-resolution process, noise addition, blurring, and compression.

Therefore, the authors in (6) proposed a hybrid forensic technique to detect object removal in the images. First, the technique in (5) is used to detect whether the image is forged or not. Second, the DCT is computed for the undetectable images, then the joint probability density matrix is computed for each difference array to model the correlations among adjacent DCT coefficients. This technique has succeeded in detecting the object removal either with or without post-processing but this work still has some limitations, because it is only working if a candidate image is forged. So to detect the forged image either with or without post-processing, we propose a new technique based on the TDA approach.

The rest of the paper organized as follows. The topological data (image) analysis is clarified. After that Local binary patterns are introduced as an image texture descriptor to build Rips complexes. Then TDA approach is proposed to detect which of these images has had an object removed from it. Next the experimental results of the proposed technique are illustrated. Finally, conclusion and future work will be presented.

**Topological Data/Image Analysis**

The topology has used to study the shapes of data (objects) (7), (8), (9). Once the shape of the data (e.g. images) constructed, then topology has rich tools to study the connectivity and closeness properties of that shape/object, using a finite combinatorial process known as Simplicial Complex (SC). Roughly speaking simplicial complexes are made up of zero-dimensional simplices (i.e. vertices), then building one-dimensional simplices (i.e. edges between the vertices) from them, then 2nd dimensional simplices (i.e. triangles) from zero and one-dimensional simplices and then higher dimensional simplices are constructed similarly. Finally, one gets a SC by gluing these simplices ‘nicely’ together along their edges and faces. There are many types of SCs, but here we are using what is known Vietoris-Rips (Rips) SCs as it is easy to construct and compute in comparison with other types of SCs. Traditional construction of Rips SCs are based on selecting a single distance threshold and calculating corresponding topological invariants such as betti numbers ($\beta_n$ for $n = 0,1,2$), Euler characteristics, cliques and other topological invariants.

The popular mathematical theory used to characterise topological features is known as homology theory. More precisely, the rank of the $n$-th homology group equals to what is known as betti numbers $\beta_n$, where $\beta_0$ is equal to the number of connected components (CCs), $\beta_1$ is the number of holes and $\beta_2$ is the number of cavities in the constructed Rips SC. Instead of computing aforementioned topological invariants at a single distance threshold, TDA depends on calculating the persistency of these invariants across an increasing series of distance thresholds using what is known as persistent homology (9), (10).

The first step in building a SC is to consider landmark points (i.e. zero-dimensional simplices) in order to be able to build on them higher dimensional simplices such as edges, triangles and tetrahedrons. For this task, the approach suggested in (11) is followed which is the use of uniform Local Binary Patterns as a tool to systematically choose landmark points from images of interest to build topological objects.

**Local Binary Patterns (LBP)**

Ojala et al. in (12) first introduced LBP as an image texture descriptor. In this paper, the original idea proposed in (12) is followed. Given any image, LBP replaces each pixel of the image with an 8-bit binary code, which encapsulates texture and local structure, determined by its 8 neighbouring pixels in a $3 \times 3$ window surrounding it in clockwise order, see Figure 1. The process works as follow: starting from the top-left corner of the window; subtract central pixel from its 8 neighbouring pixels, assign 0 if the result is negative, and 1 otherwise. Mathematically this process can be written as follow:
Uniform LBP (ULBP) refers to 8-bit circular bytes that have no more than 2 circular transitions. For the sake of clarity, examples of ULBPs are 11110000 (2 transitions), 11111111 (0-transitions) and examples of non-uniform LBP are 10101010 (8-transitions), 11001110 (4 transitions). This means that ULBP of any monochrome image consists of 58 unique uniform geometries, see Figure 2. It has been shown that ULBP codes constitute 90% of LBP codes in natural images \(^{(13)}\). There are seven groups (of 8 binary codes) of ULBP according to the number of 0’s and 1’s in their binary codes, excluding the cases 00000000 and 11111111. Each of these groups is related to certain types of image textures. The ULBP codes have \(t\) consecutive 1’s as geometry-\(t\). Our experimental investigation contains the set of pixels in all geometries as potential landmark candidates to build SC.

Regarding uniform LBP patterns classifications based on the number of ones included in the pattern in the natural images database which described in \(^{(14)}\); the patterns in G0, G8, (G2 and G4), (G3 and G5), and G6 describe the flat area, spot area, edges, corners, and line ends in the image, respectively.

**Construction of Rips Simplicial Complexes**

For each class of geometry-\(t\) in ULBP, its corresponding positions are extracted in the forged and original images of the given data. As a result, we end up with a set of image pixel positions of the 8 sets of \(t\)-ones ULBP codes. First, the known Euclidean distance is calculated between all pairs of points in the set, and then an increasing 8 sequence of \(T\)-dependent Rips complexes is constructed, one for each rotation of the geometry-\(t\) codes. For \(T = 0\), only 0-dimensional complexes are constructed.
simplices are obtained, i.e, the points. Then $T$ is gradually increased and computed $\beta_0$ at each $T$.

Robert Ghrist in (10) illustrated that there is no optimal method to select the best threshold that best captures the topology of data sets. A fixed number of distance thresholds are used, as follows:

$$T_1 = 0, T_2 = 3, T_3 = 5, T_4 = 7, T_5 = 10, T_6 = 12, T_7 = 15, T_8 = 17, T_9 = 20.$$ .

This approach is motivated by the work of A. Asaad and S. Jassim in (11), as they used the TDA approach to assess the quality of degraded images. In particular, they focused on discriminating face images degraded by shadows and blurring. The topological invariant which is used across this paper is the zero homology groups, which correspond to the number of CCs, as shown in Figure 3.

More specifically, the Rips complex graph for forged images and the original image are identical, except the forged region which we highlighted by red box in Figure 3. The TDA approach is used to detect forged images by counting the number of CCs in the images, where the CCs is computed in 8 rotations in each one of these 7 geometries at different thresholdings.

Forgery detection-based TDA approach

A new forensic technique is proposed to detect the forged images using the TDA approach. The steps of the proposed technique are as follows:

1) Image pre-processing: Before the features extraction process, converting these RGB images into a grayscale images, then transforming them into the LBP domain.

2) Feature extraction: Applying the TDA approach to the LBP image domain, the number of CCs will be counted in each geometry (i.e. G1, G2,..., G7) at different thresholds (i.e. T=0, T=3, T=5, T=7, ...) until the number of the CCs be 1 in each rotation.

3) Classification: The purpose of a classifier is to discriminate the given images and classify them into two
categories which are original and forged images based on the number of CCs in each geometry at different thresholds. The kNN classifier method is used to classify the images into two groups which are original and forged groups (i.e. decision stage)\(^\text{(15), (16)}\).

**Testing Experiments**

The forgery proposed method is applied to detect forged images from the yokoya natural database in\(^\text{(17)}\), which consists of 100 original and 100 forged (inpainted) images of size 200x200, as see in Figure 4.

![Figure 4: Example of six out of 100 training natural images.](image_url)

To detect the inpainted images, the TDA approach is used by selecting landmarks from the whole image to build SCs and then computed their corresponding homological features (i.e. the number of CCs). The number of CCs is computed from different increasing distance thresholds and the pattern of change in the components while we increase the threshold is stored. We stop when the number of CCs becomes one for both classes (original and inpainted images). Finally, we train kNN classifier when \(k=1\) (i.e. Nearest Neighbour) on those 200 images with 3 different classification protocol as follow:

- Protocol One: 30% of the data used for Training
- Protocol Two: 50% of the data used for Training
- Protocol Three: 70% of the data used for training.

Each protocol is repeated 100 times, across seven ULBP groups and 10 different increasing distance thresholds. Experimental results showed the number of CC is sensitive to the degradation present in the inpainted images. Furthermore, among the 7 geometries we used as landmarks to build the topology G1, G5 and G7 geometries more sensitively detect the changes in the edges and corners in the inpainted images\(^\text{(18)}\), as see in the Tables 1.

![Table 1: kNN classifier on CCs features from natural images.](table_url)

Examining the whole distribution of accuracies from \(T=0\) to \(T=20\), the accuracy is starting in a low rate around 52% then gradually increasing until reach the peak at \(T=10\) and then gradually decreasing. The highest obtained accuracy is 90% for detecting the inpainted images at \(T=10\). Also, the number of images in the training does not affect the accuracy of the image classification, that means the classification features are strong.
The values of accuracy for classifying the natural images into original and inpainted images are not absolutely correct. There are two kinds of error which are False Positive (FP) and False Negative (FN). The FP represents the original images that classify as forged images, while FN represents the forged images that classify as original images (19). Tables 2 show the average of FP and FN values for each geometry at different thresholds in above three protocols, respectively.

Table 2: False Positive and False Negative values from natural images.

Tables 2 showed the average values of FP and FN in G1, G5, and G7 at threshold $T=10$ are less than in other geometries and in other thresholds. This clearly shows that TDA can be used as an effective technique for inpainting detection.

Summary and Conclusion

A novel forgery detection technique has been proposed to recognise tampered inpainting images (i.e. by the EBI method). TDA has been used to detect the forged images (i.e. to detect which of these images has had an object removed from it). The number of CCs has been used as a component in the feature vector in the classifier methods. The kNN classifier has been used to classify the images into original and forged images. The proposed method has been applied to natural database images. The experimental results showed that the proposed method performs well in detecting inpainted images with promising results. Also, the FP and FN error are calculated for all geometries at different thresholds for natural database images. In the future, we will extend our investigation to detect the suspicious regions in the forged image by applying TDA approach.

Moringa Leaf (*Moringa oleifera* Lam) Nanoparticle Supplementation on Zygote Cleavage in Goat Embryo Culture In Vitro

Alfina Aisatus Saadah¹, Widjiati², Hendy Hendarto³

¹Master of Reproductive Health Science, Faculty of Medicine, ²Embryology Department, Faculty of Veterinary Medicine, ³Obstetrics and Gynecology Department, Faculty of Medicine, Airlangga University, Surabaya, Indonesia

Abstract

One of the causes of failure of zygote development is oxidative stress in the culture medium. Where oxidative stress can damage the structure and function of zygotes due to free radicals Reactive Oxygen Species (ROS). *Moringa oleifera* Lam contains antioxidant polyphenol compounds, flavonoid flavonols namely quercetin which is the most antioxidant content in *Moringa* leaves which is expected to fight excess ROS. The purpose of this study was to prove that the supplementation of *Moringa oleifera* Lam leaf nanoparticles to increase zygote cleavage in goat embryo culture in vitro. The research subjects used goat oocytes which were divided into 4 groups consisting of 1 control group and 3 treatment groups. Each group consisted of 31 samples. Control group K1 without Moringa leaf nanoparticle supplementation, treatment group I P1 Moringa leaf nanoparticle supplementation with a dose of 0.5 µM, treatment group II P2 supplementation of Moringa leaf nanoparticles with a dose of 1.0 µM, Treatment group III P3 supplementation with Moringa leaf nanoparticles with a dose of 2.0 µM. Embryo culture was carried out in a 5% CO₂ incubator, temperature 38.5°C for 48 hours, then observed under an inverted microscope. The results show that there are significant differences with the value of p = 0.041 which means p <0.05. Supplementation of moringa leaf nanoparticles (*Moringa oleifera* Lam) can significantly increase zygote cleavage at embryo culture stage in vitro.

**Key Words:** *Moringa oleifera* Lam, Reactive Oxygen Species (ROS), Zygote Cleavage

Introduction

Infertility has an impact on population decline leading to zero population growth (without changes in mortality and migration)¹. An estimated 4-6 million couples need infertility treatment to get offspring such as hormonal treatment, In vitro Fertilization (FIV)². The success of In Vitro Fertilization (FIV) is not only influenced by oocytes, but also by spermatozoa which are used to fertilize and physiological conditions of the culture medium used³.

The success of In Vitro Fertilization in couples of childbearing ages is 32.2% (Ramalingam et al., 2016). Based on the ability of zygotes to overcome cell block (developmental barriers) in the development of zygotes into phase two cells in the M16 medium at 85.09% and on the HTF medium at 83.36%. The zygote obtained from FIV in the culture medium can develop into a two-cell stage, but there are also zygotes that cannot develop and the cells undergo apoptosis, picnosis, and fragmentation³.

One of the causes of zygote failure to overcome cell block is due to oxidative stress in the culture medium due to free radicals Reactive Oxygen Species (ROS). Endogenous antioxidant defenses in zygotes are not enough to fight the oxidative stress encountered during in vitro culture so that it can cause membrane lipid peroxidation, DNA, and protein in zygotes⁴.

Modifying the condition of in vitro culture medium is one technique to increase the number of fertilization and viability of zygotes to blastocysts⁵. Modifying the condition of the culture medium by the addition of exogenous antioxidants has been carried out by Gaviria et al.⁶ about the addition of the antioxidant resveratrol which is present in many plant foods, especially red wine...
in in vitro culture media in enhancing the development of bovine embryos from the stages of cleavage, morula and blastocyst. In addition to red wine, there are also exogenous antioxidants from plants, namely Moringa oleifera Lam leaves made in the form of nanoparticles to overcome oxidative stress\(^7\).

Moringa oleifera Lam contains antioxidant polyphenol compounds, flavonoid flavanols namely quercetin which is the most antioxidant content in Moringa leaves. Quercetin will bind free radical species in the presence of hydroxyl groups (OH-) at C to 3, 5, 7, 3’, and 4’ and catechol ring β\(^8\). With the presence of natural antioxidants from moringa leaves, it is expected to reduce oxidative stress in the culture medium thereby increasing zygote cleavage in stage 2 cells\(^7\).

**Material and Method**

The process of making Moringa leaf nanoparticles is carried out in Nanobox Jl. Raya Serpong KM.2 Setu, Tangerang. All protocols were approved by the Animal Care and Use Committee (ACUC), Faculty of Veterinary Medicine, Airlangga University No. 2.KE.136.07.2019.

**Experimental design and sampling**

This study uses a research design that is a pure experiment using a completely randomized design (CRD) with the Randomize Posttest-only Control Group Design approach carried out 5 times. The study was conducted in the in vitro laboratory of the Faculty of Veterinary Medicine of Airlangga University in July - October 2019. The research subjects used goat oocytes which were divided into 4 groups consisting of 1 control group and 3 treatment groups. Each group consisted of 31 samples. All data are first tested for normality using the Shapiro-Wilk test and Homogeneity test using the Levene test. Then proceed with the Kruskal Wallis test, obtained significantly different results (p <0.05) then proceed with the Mann Whitney test between 2 treatments each.

**Findings**

**Zygote Cleavage**

</table>

Based on the table above, the most different groups are in the P\(_3\) group against K\(_1\), P\(_1\), and P\(_2\), namely .050, .014, .014. These results indicate that the supplementation of Moringa oleifera Lam Moringa leaf nanoparticles at a dose of 2.0 µM can significantly increase zygote cleavage.

Figure 1: Mean graph of zygote cleavage at embryo culture
In Figure 1, the results of the study showed that the highest zygote clavage (16.66) was found in group P3 (Treatment III Nano dose 2.0 μM).

**Figure 2: Results of the cleavage of zygote 2-cell using an inverted microscope**

**Figure 3: The results of the cleavage of zygote 4 cells and 8 cells using an inverted microscope**

**Discussion**

At the time of embryo culture in vitro can trigger the occurrence of Reactive Oxygen Species (ROS) due to external conditions or in vitro culture medium. ROS can come directly from gametes and embryos, or from their environment. Although ROS can regulate cell function and activate key signaling pathways, increased ROS can cause the formation of highly radial hydroxyl which can increase lipid peroxidation, increase DNA oxidation and damage DNA nuclei, increase protein oxidation.

In the female reproductive system such as the ovary there are endogenous antioxidants which naturally protect the embryo from oxidative damage, but in the production of embryos in vitro, the embryo lacks endogenous antioxidants because it continues to be exposed to stressors that are too high. To determine the ability of the zygote through the observation of developmental barriers (cell block), which is based on the ability of the developing embryo to reach the stage of two cells. In addition, ROS levels exceed basal levels, nuclear factor-kappa B subunit 1 (NFkB) is induced. NFkB is activated by ROS during embryo development, so that it can result in cell death in the embryo.

Moringa oleifera Lam leaves contain a source of vitamin A, C, B calcium, protein, and potassium. In addition, it contains special plant pigments with strong antioxidants. The most antioxidant in moringa leaves is quercetin, where the system works by binding to free radical species in the presence of hydroxyl groups (OH-) at C to 3, 5, 7, 3’, and 4’ and catechol ring. Quercetin is a powerful antioxidant whose strength is 4-5 times higher compared to vitamin C and vitamin E which are known as potential vitamins. Quercetin as an antioxidant can prevent oxidation through hydrogenation and complex formation and prevent auto-oxidation.

This is consistent with Uswatun’s research that Antioxidants are needed to fight excess ROS in zygote cells so as to prevent zygote cell death and can develop to the next stage. The right concentration of antioxidants can contribute to the generation of high-quality embryos.

In this research, Moringa oleifera Lam
containing exogenous antioxidants is made in the form of nanoparticles to more quickly penetrate the space between the intended cells and to specific cells\textsuperscript{18}. Exogenous antioxidants can be added to a culture medium to protect the embryo from oxidative stress (OS) during in vitro culture (IVC) via the lipophilic cation conjugation pathway by penetrating the zygote cell membrane lipid bilayer\textsuperscript{19}.

There is research conducted by Barakat et al.\textsuperscript{14} about Moringa oleifera found that with a dose of Moringa oleifera extract 100 µg/ml effectively increases the level of maturation of sheep oocytes and can act as a promoter to induce mRNA gene expression (Cyclin B and CDK2 for cell cleavage control), and synthesis of essential proteins, eg. MPF (Maturation Promoting Factor). MPF is a complex protein consisting of two subunits including a catalytic subunit (P34 CDK2 kinase) and a regulator subunit (Cyclin B). While MAPK (Mitogen Activated Protein Kinase) activates cyclin (cell cycle protein). The abundance of specific transcripts in mRNA pools is important for the first embryonic cell cleavage\textsuperscript{14}.

Where MAPK (Mitogen Activated Protein Kinase) namely Cyclin B (cell cycle protein) is activated by serine protein and MPF (Maturation Promoting Factor) namely CDK2 is activated by threonine protein. The binding between Cyclin and CDK triggers mitosis by activating cyclin binding CDK to Cyclin CDK Complex so that it triggers cells to pass the G2 check point to the M phase (Mitosis) in the cell cycle\textsuperscript{20}.

Determination of the 0.5 µM and 1.0 µM doses of the researchers refers to the study of Gaviria et al.\textsuperscript{6} Supplementation of medium culture with low levels of resveratrol improves embryo quality\textsuperscript{21}. Low doses cause a significant decrease in cleavage age and blastocyst rate, which does not produce a fast-developing blastocyst percentage.

In pharmacodynamic tests, it is only fitting that the greater the dose used, the greater the effect will be on the dose-response effect. The therapeutic effect is a function of dose and time, such charts illustrate the dose-response relationship that is not time-dependent. In this situation the maximum effect intensity (ceiling effect) can be caused\textsuperscript{22}. In this condition, it can also be concluded that the dose of moringa leaf nanoparticles which can cause an effect that is an increase in zygote cleavage is at a dose of> 2.0 µM while the doses of 0.5 µM and 1.0 µM do not have pharmacological effects in this case do not support embryonic cell cleavage.

Osman et al (2015) reported that the dose of Moringa leaves was given incorrectly and could cause toxicity to the cells themselves\textsuperscript{23}. These effects can be mutually supportive but can also be contradictory. The variety of active chemicals found in plants will work in synergy to produce the expected therapeutic effects and these effects can be lost or can cause adverse effects when the chemicals are not in accordance with the target cell needs\textsuperscript{24}.

The form of the reproductive system of living things for each species is different so that the ability to reproduce is also different. The lust cycle will affect the time for holding in vitro fertilization and affect the success of fertilization. The process of fertilization in goats is around 20-24 hours while in cattle it is 36 hours. So that the positive effect of antioxidants on embryonic development in vitro is shown in cows on embryonic development to blastocysts because cow embryos can tolerate low antioxidant concentrations in order to produce beneficial effects\textsuperscript{23}. In addition, goat spermatozoa have phospholipase A2 in plasma causing early acrosome reactions and result in spermatozoa cells being damaged more quickly than cattle spermatozoa. As a result, the failure of in vitro embryo production among goats is higher than cattle\textsuperscript{25}.

So, resveratol with a dose of 0.5 µM and 1.0 µM has been able to increase the development of cow embryos due to the adequacy of energy and antioxidants while a dose of 0.5 µM and 1.0 µM in moringa oleifera produces energy and antioxidants needed are still lacking so that it can trigger embryonic cell damage.

Antioxidants can cause prooxidant activity under certain conditions, such as at high doses or when there are metal ions. Prooxidant activity is highly dependent on its concentration at high doses (> 50 µM) can potentiate superoxide radicals (O2-) in isolated mitochondria and cells that are cultured, reduce cell survival and cause damage to DNA, proteins, lipids while too low doses can induce cytotoxicity, DNA strand breaks and apoptosis\textsuperscript{26}.

\textbf{Conclusion}

In the number of doses between Moringa leaf extract and nanoparticles is not much different in increasing zygote cleavage in vitro because there has been no research on organic nanoparticles against zygote cleavage in vitro so in this study the amount of Moringa
leaf nanoparticles dose is based on previous research journals on natural antioxidant extracts in plant.

Study of Tuberculosis Related Topics in Baghdad, Iraq 2012-2016 Tuberculosis Related Topics

Ali Kareem Durib¹, Ekterina Valerievna Blinova²

¹Lecturer, Medical Institute Baghdad, Middle Technical University, Baghdad, Iraq, ²Faculty Surgery Department, National Research Ogarev Mordovia State University, 68 Bolshevistskaya, Saransk, Russia

Abstract

Objective(s): The present study designed to explore topics related to Tuberculosis, such as new smear positive cases, causes, treatment and new pulmonary positive cases in Baghdad City, Iraq for 2012-2016.

Methods: A descriptive “retrospective” design was performed throughout the present study from the period of November 12th 2017 to February 13th 2018. All registered tuberculosis patients in Baghdad, Iraq for the period of 2012-2016. An instrument was constructed for the purpose of the study. Data were collected from the health records at the National Tuberculosis Center, State TB center, and district TB center for the period of 2012 to 2016 with the use of the study instrument. Data were analyzed through the application of descriptive statistical data analysis approach of frequency, percent, incidence rate and ratio.

Results: The study findings depicted that most of the new smear positive cases are accounted for the age group of (15-24) year old during the years of 2012-2016. Causes of Tuberculosis in the rural area were accounted for poverty (39.95%), smoking (22.39%), untreated cases (12.4%), alcoholism (11.32%), malnutrition (10.30%) and overcrowded (3.57%) respectively, and accounted for alcoholism (27.77%), overcrowded (27.16%), malnutrition (24.69%), smoking (11.93%), poverty (7.62%) and untreated cases of Tuberculosis (0.80%) respectively in the urban area.

Conclusion: The study concluded that Most of the new smear positive cases are accounted for the age group of (15-24) year old during the years of 2012-2016. Patients, in 2014, had benefited out of the Tuberculosis Program more than others based on the success rate.

Key Word: Study, Topics, Tuberculosis, Baghdad City, Iraq

Introduction

Roughly one-third of the world’s population has been infected with M. tuberculosis, and new infections occur at a rate of one per second (¹). However, not all infections with M. tuberculosis cause tuberculosis disease and many infections are asymptomatic (²). In 2007 there were an estimated 13.7 million chronic active cases, and in 2010 there were 8.8 million new cases, and 1.45 million deaths, mostly in developing countries (³,⁴). 0.35 million of these deaths occur in those co-infected with HIV. In 2015, across the world 1.8 million out of 10.4 million people affected by the disease died (⁵,⁶).

Any person who coughs and who was in contact with smear positive index case (smear positive pulmonary TB patient) should have three sputum examinations. Children aged less than 5 years: any contact aged less than 5 years who has a positive tuberculin that not previously vaccinated with BCG with signs or symptoms of TB should be treated as suffering from active TB. Those without signs or symptoms of disease should be given preventive chemotherapy (INH for 6 months). Children under one year of age with mothers who are
being treated for smear positive pulmonary TB should be given Isoniazid if the tuberculin test is negative at the end of three months, INH may be stopped and BCG may be given \(^{(7,8,9)}\).

Drug Resistance Tuberculosis is a man-made disease (due to non-compliance, improper drug regimen, etc.). Primary resistance is prevented by giving the patient combination of drugs. Secondary (acquired) TB resistance is expected to be developed \(^{(10-12)}\).

1. A large bacillary population such as patient with cavitations.

2. Inadequate drug regimens (inappropriate drugs, insufficient dosage), drug side effects and complications.

3. Treatment of DR TB should be done by or in close consultation with an expert in the management of these cases and on hospitalization bases.

4. A single new drug should never be added to a failing regimen.

5. Treatment duration for DR TB patient may last 18-24 months by using 4-6 drugs (capreomycin, cyclocerin, ethionamide, levofloxacine, and PAS).

6. Second line regimens often represent the patient’s last hope for being cured inappropriate management can thus have life threatening sequences.

Based on the early stated facts, the present study ought to carry out a retrospective study to investigate related issues to detected cases of tuberculosis in Baghdad, Iraq for 2012-2016.

**Method**

A descriptive “retrospective” design was employed throughout the present study from the period of November 12th 2017 to February 13th 2018 in order to investigate related topics to Tuberculosis, such as new smear positive cases, causes, treatment and new pulmonary positive cases in Baghdad City, Iraq for 2012-2016. A convenient sample of (11680) registered patients with tuberculosis in Baghdad, Iraq for the period of 2012-2016. These patients were males and females and they were one year to over than 65 year of age.

An instrument was constructed for the purpose of the study. It was comprised of items that focused on patients’ characteristics of age, gender and type of Tuberculosis. A pilot study was conducted for the determination of the study instrument’s content validity, internal consistency reliability and adequacy. The study was carried out for the period of December 10th -20th 2017. Content validity of the instrument was determined through panel of (15) experts. These experts were (5) faculty members at the College of Nursing University of Baghdad, (5) Faculty members at the College of Medicine University of Baghdad and (5) epidemiologists at the Ministry of Health and Environment. They were presented with copy of the study instrument and asked to review it and provide comments for its modification to be more appropriate measure of the study. They had reviewed the instrument and presented their comments with an agreement that the instrument is content valid. Internal consistency reliability was determined for the study instrument through the use of split-half technique and measurement of Cronbach alpha correlation coefficient. The results indicated that Cronbach alpha correlation coefficient was \(r=0.85\) which adequately reliable measure for the problem underlying the present study.

Data were collected from the health records at the National Tuberculosis Center, State TB center, and district TB center for the period of 2012 to 2016 with the use of the study instrument. Data were analyzed through the application of descriptive statistical data analysis approach of frequency, percent, incidence rate and ratio.

**Results**

Results out of table (1) indicate that most of the new smear positive cases are accounted for the age group of (15-24) year old during the years of 2012-2016.

Table (2) depicts that causes of Tuberculosis in the rural area are accounted for poverty (39.95%), smoking (22.39%), untreated cases (12.4%), alcoholism (11.32%), malnutrition (10.30%) and overcrowded (3.57%) respectively, and accounted for alcoholism (27.77%), overcrowded (27.16%), malnutrition (24.69%), smoking (11.93%), poverty (7.62%) and untreated cases of Tuberculosis (0.80%) respectively in the urban area. So, poverty and smoking are considered the most effective causes for patients in the rural area. In contrast, alcoholism, overcrowded and malnutrition are considered as the most effective causes for patients in the urban area.
Results of treatment out of table (3) reveal that success rate are (69%) in 2014, (61%) in 2013 and (51%) in 2012 respectively. Such rate can present evidence that patients in 2014 have benefited out of the program more than others.

Table (4) shows that age specific incidence numbers, percentage and incidence rate by gender. The percentage and the numbers in age group 15-24 years old was the highest and declined thereafter while age was increasing for both male and female. But the incidence cases in age group 0-14 in both male and female were almost the same.

Though the incidence rate of both male and female cases the same in the age group 0-14 years old and difference was much higher as age groups increased from 15-24, 25-34, 35-44, and the highest was found among the age group 55-64 years old while the rapid decreasing was found in the age group 65 + years old.

Conclusion

The study concluded that Most of the new smear positive cases are accounted for the age group of (15-24) year old during the years of 2012-2016. The urban zone’s incidence rate was greater than that of the rural zone. Poverty and smoking were considered the most effective causes for patients in the rural area. In contrast, alcoholism, overcrowded and malnutrition were considered as the most effective causes for patients in the urban area. Patients in 2014 had benefited out of the Tuberculosis Program more than others based on the success rate. The incidence rate of both male and female cases the same in the age group of (0-14) years old and difference was much higher as age groups increased from (15-24), (25-34), (35-44), and the highest was found among the age group (55-64) years old while the rapid decreasing was found in the age group 65 + years old.
**Recommendations:**

Based on the early stated conclusion, the present study recommended that:

1. An educational program can be designed, constructed and implemented public-wide to increase individuals and patients’ awareness toward tuberculosis as public health problem and the benefits of its treatment.

2. The Ministry of Health and Environment in Iraq can present appropriate and effective attention to people who were at risk of Tuberculosis.

3. Further research with a large sample size and wide range of variables can be conducted.

Analysis of Factors Related to Pesticide Poisoning in Rice Farmers in Teweh Selatan Subdistrict, Barito Utara District

Ali Sodikin1, Ruslan Muhyi2, Eko Suhartono3, Husaini3, Lenie Marlinae4

1Barito Utara District Health Office, 2Faculty of Medicine, Lambung Mangkurat University, Indonesia, 3Biochemistry Department, Faculty of Medicine, Lambung Mangkurat University, Indonesia, 4 Master of Public Health Science Study Program, Faculty of Medicine, Lambung Mangkurat University, Indonesia, 5 Public Health Study Program, Faculty of Medicine, Lambung Mangkurat University, Indonesia

Abstract

The results of monitoring and examination of farmers in Barito Utara District by examining the cholinesterase enzyme by the Regional Health Laboratory and the District Health Office of Barito Utara in the blood of farmers found 71.19% experienced organopathic pesticide poisoning. This study aims to analyze the risk factors associated with the level of pesticide poisoning in rice farmers in Teweh Selatan Subdistrict, Barito Utara District, namely mixing dosage, spraying time, spraying frequency, spraying duration, working period, wind direction, and use of personal protective equipment. The research design used was observational with cross sectional approach. The number of samples is 55 people taken by simple random sampling. Rice farmers who experienced pesticide poisoning by 56.4%. Chi-Square Test showed four variables had a significant relationship with the incidence of pesticide poisoning and were a risk factor for the occurrence of pesticide poisoning namely mixing dose (p=0.003 OR=6.909; 95% CI=2.020-23.627), frequency of spraying (p=0.004; OR=6.300; 95% CI=1.913-20.749), working period (p=0.020; OR=4.416; 95% CI=1.402-13.906) and wind direction (p=0.007; OR=5.714; 95% CI=1.756-18.591). Multiple logistic regression test showed that the most dominant factor related to the incidence of pesticide poisoning was the frequency of spraying. Risk factors associated with the incidence of pesticide poisoning are mixing dosage, frequency of spraying, working period and wind direction.

Keywords: farmer, mixing dose, frequency of spraying, working period, wind direction, poisoning, pesticides

Introduction

An increase in farmer groups that cause a lot of use of pesticides which can ultimately increase the risk of poisoning due to pesticides in Central Kalimantan. The cases of pesticide poisoning in Central Kalimantan in 2016 amounted to 48 cases, while in 2017 there were 56 cases. An increase in poisoning cases due to pesticides is in line with the increase in farmer groups in Central Kalimantan.1

Factors that can influence the occurrence of pesticide poisoning on farmers are the characteristics of farmers, namely age, sex, nutritional status, level of education, length of work, behavior of farmers in using pesticides, among others, the number of pesticides used, mixing pesticide doses, frequency of spraying, duration spraying, the use of personal protective equipment (PPE).2 Farmers can be contaminated with pesticides when storing and moving pesticides, preparing pesticide solutions, applying pesticides and washing application tools. Applying pesticides when spraying often results in pesticide contamination.3

There was a significant relationship between variable spraying frequency (p=0.001) and spraying time (p=0.000) with pesticide poisoning in Jati Village, Sawangan Subdistrict, Magelang District.4 There is a significant relationship between the frequency of spraying (p=0.020), duration of spraying (p=0.002), wind direction (p=0.020) and the use of personal protective equipment (p=0.002) with cholinesterae activity blood in farmers in Naman Teran Subdistrict Karo District, as

Corresponding Author:

Yetro Sinseng

Indonesia, sodikinali78586@gmail.com
well as according to Suparti S, et al. (2016) which states that there is a significant relationship between frequency of spraying ($p=0.002$), pesticide dose ($p=0.001$), duration of spraying ($p=0.001$), spraying time ($p=0.016$) and wind direction ($p=0.039$) with pesticide poisoning to farmers.5

Based on data from the Barito Utara District Health Laboratory it is known that in 2018 from the results of the examination of 21 farmers, 76.19% of farmers experienced pesticide poisoning. The recapitulation of the District Health Office of Bairto Utara states that the average age of farmers is 54 years with an average working period of 23 years, 57.1% of farmers mixing pesticide doses do not match the label stated, 52.4% of farmers used to spray pesticides during the day days and with a frequency of spraying more than twice a week as much as 47.6%. 28.6% of farmers sprayed for more than 3 hours in one spraying and 33.3% of farmers in the technique of spraying downwind, and the average farmer did not use a complete PPE of 61.9%.6 Thus, farmers are a group that is vulnerable to exposure to pesticides that have an impact on pesticide poisoning. However, not many studies have revealed the factors that cause pesticide poisoning, especially in lowland rice farmers in Teweh Selatan Subdistrict, Barito Utara District.

**Materials and Method**

The research design used was a cross sectional approach. The study was conducted in Teweh Selatan Subdistrict, Barito Utara District, considering that the rice rice farmers group in Teweh Selatan Subdistrict was the farmer group that used the most pesticides assisted by the Agriculture Office Program of Barito Utara District and had never done any research on the factors related to pesticide poisoning in rice farmers. The study was conducted in March - June 2019. The population in this study were all rice farmers who sprayed with pesticides in Teweh Selatan District as many as 240 people. The number of samples was 55 respondents. The dependent variable in this study was pesticide poisoning of rice farmers (measured by the cholinesterase enzyme level <75%).

The Relationship between Mixing Doses and Pesticide Poisoning on Rice Farmers

The results of the analysis stated that there was a relationship between mixing dose with pesticide poisoning on rice farmers in Teweh Selatan Subdistrict, Barito Utara District with p-value 0.003 <α (0.05). The OR score of 6.909 means that farmers who mix the dosage incorrectly on the label are 6.9 times at risk of experiencing pesticide poisoning compared to rice farmers who mix pesticides according to the dosage on the label.

The rice farmers mix the dosage with pesticide insecticides mixed with three different brands of pesticides namely Winder, Selden and Spontan. The pesticide when it enters the body of rice farmers can inhibit and reduce the production of the enzyme kholineterase in the body. This situation will cause nervous system disorders in the form of cholinergic activity continuously due to achethilcholine (AchE) not hydrolyzed. This disorder is known as signs or symptoms of poisoning such as dizziness, headaches, and nausea.7

The Relationship between Spraying Time and Pesticide Poisoning on Rice Farmers

Based on the results of the analysis showed that there was no significant relationship between the time of spraying with pesticide poisoning on rice farmers in Teweh Selatan Subdistrict, Barito Utara District with p-value (0.708)> α(0.05). The rice farmers spend more time during the day and poisoning ie at 11:00 to 13:00 at 31.82%. As for farmers who work at noon. 11.00-15.00 pm but the blood cholineterase level is classified as normal at 46.67%. Normal levels of cholineterase in the blood due to the spraying time range between 2:00 pm to 3:00 pm there is a decrease in air temperature so that the rate of expansion is also reduced. In addition, it is supported by an infrequent spraying frequency of ≤ 2 times a week by 80%.

The Relationship between Frequency of Spraying and Pesticide Poisoning on Rice Farmers

The results showed that the frequency of spraying carried out by rice farmers was >2 times a week and experienced pesticide poisoning by 77.8%. The average frequency of farmers spraying pesticides 3 times a week is 100%. The more often farmers spray using pesticides, the greater the possibility of poisoning. Exposure to pesticides with frequent frequency and with short time intervals causes pesticide residues in the human body to be higher.

Statistical analysis showed that there was a significant relationship between the frequency of spraying with pesticide poisoning on rice farmers in Teweh Selatan Subdistrict, Barito Utara District with a p-value (0.004) <α (0.05). OR results of 6.300, meaning that farmers who do frequent spraying frequency >2 times a week have a risk of 6.3 times experiencing pesticide poisoning compared to farmers who spray pesticides as much as ≤ 2 times a week.

The Relationship between Spraying Duration and Pesticide Poisoning on Rice Farmers

Chi-square test results with a 95% confidence level to see the relationship between spraying duration and the incidence of pesticide poisoning in rice farmers obtained p-value 0.696 (p> 0.05) which states that there is no relationship between spraying duration and the incidence of pesticide poisoning. In lowland rice farmers in Teweh Subdistrict.

The results of the analysis showed that the rice farmers who did the spraying duration >3 hours but the normal blood cholineterase level was 20%. Spraying duration depends on wide area of land worked by farmers. The area of rice fields that farmers have influenced the incidence of pesticide poisoning. The longer time the spraying is, the more pesticides are exposed. This can affect the body’s exposure or entry...
of pesticides so that it can cause poisoning. However, the normal level of cholinesterase in the blood occurs because the farmer mixes the dosage according to the label and the working period of the new rice farmers is ≤ 5 years as much as 63.6%.\(^9\)

**The Relationship between Working Period and Pesticide Poisoning on Rice Farmers**

Based on the results of the analysis showed that farmers who worked more than 5 years more experienced pesticide poisoning which was 74.1% compared to respondents who worked ≤ 5 years ie 39.2%. In addition, the age of rice farmers who have worked for more than 5 years is classified as at risk by 92.6%. Naturally, human endurance will decrease with age, while the emergence of pesticide poisoning is strongly influenced by human endurance factors. There is a tendency for older farmers to have lower blood cholinesterase activity.\(^10\)

The number of farmers who have a long working period allows farmers to experience longer exposure to pesticides so that the levels of pesticides in their blood are higher and bioaccumulation will occur in the body. This has the potential to cause chronic poisoning to pesticide spraying farmers. If the longer the farmer works and spraying, the longer the contact with pesticides so the risk of exposure to pesticides is higher.\(^11\)

**The Relationship between Wind Direction and Pesticide Poisoning on Rice Farmers**

Based on the results of the analysis states there is a relationship between the direction of the wind with pesticide poisoning on rice farmers in Teweh Selatan Subdistrict, Barito Utara District with p-value (0.007) <\(\alpha\) (0.05). The OR results of 5.714 means that farmers who spray not in the direction of the wind are 5.7 times at risk of experiencing pesticide poisoning compared to rice farmers who spray in the direction of the wind.

Rice rice farmers who did the spraying technique were not unidirectional and experienced 72.7% poisoning. The observations showed that farmers sprayed without regard to the wind direction, but with alternating directions according to the rows of plants. Actually farmers know that a good spraying direction is in accordance with the direction of the wind but they consider spraying with attention to the direction of the wind more troublesome and time-consuming. Farmers who do not follow the direction of the wind will risk being exposed to pesticides such as being splashed or exposed directly to body parts and clothing due to gusts of wind that turn towards the body of the sprayer. More risky if pesticides are sprayed directly on the eye that is not protected with protective glasses.

**The Relationship between The Use of PPE and Pesticide Poisoning on Rice Farmers**

Based on the results of statistical analysis, there was no significant relationship between the use of PPE and pesticide poisoning on rice farmers in Teweh Selatan Subdistrict, Barito Utara District with a p-value of 0.978 (> 0.05). The results of the analysis stated that the majority of rice farmers did not use PPE as much as 72.7% greater than those using PPE that met the requirements. Only 27.3% of rice farmers who use PPE are eligible. This causes the use of PPE that there is no meaningful relationship. There is no relationship between the completeness of personal protective equipment (PPE) with the pesticide poisoning in farmers with p-value = 0.355.12

PPE is used to protect farmers from exposure to pesticides ranging from headgear/hats, masks, long sleeve clothes, gloves, glasses and shoes. Based on field research, it was found that the type of PPE that farmers usually use when spraying is 45.5%, boots 49.1%, long sleeves 29.1% and gloves 27.3%. The interview results showed that the awareness of farmers to wear a head cover in the form of a hat by 70% on the grounds not because of the dangers of pesticides but farmers to protect their heads from the sun’s heat.

<td>0.053</td>
<td>4,195</td>
<td>0.985</td>
</tr>
</tbody>
</table>
Based on the results of multiple logistic regression analysis of four independent variables that are significantly related to pesticide poisoning on rice farmers there are two variables that are most related to pesticide poisoning, namely the frequency of spraying and mixing dose. Based on p-value <0.05 in the second stage of multiple logistic regression analysis, from the two variables it was concluded that the most dominant variable was related to pesticide poisoning on rice farmers, namely the frequency of spraying because it had the highest OR (OR = 11.081) and a p-value of 0.007 states that there is a significant relationship on rice farmers who spray more than 2 times a week having a risk of 11.08 times experiencing pesticide poisoning compared with paddy farmers who spray ≤2 times a week.

The frequency of spraying more than 2 times a week can increase the risk of poisoning because it allows an increased risk of exposure to insecticides and the risk of poisoning. The more often farmers spray, the higher the risk of poisoning. Spraying should be done in accordance with the provisions. The time needed to be in contact with pesticides is a maximum of 5 hours per day.13

The exposure to pesticides on the human body with frequent frequency and with short time intervals causes pesticide residues in the human body to be higher, indirectly the activities of farmers who reduce the frequency of spraying can reduce the exposure of these farmers by pesticides.7

**Conclusion**

Risk factors associated with the incidence of pesticide poisoning are mixing the dose, frequency of spraying, working period and wind direction. The dominant factor associated with the incidence of pesticide poisoning in lowland rice farmers is the frequency of spraying.

Abstract

Objectives:

• Prevalence of zinc deficiency among preschool children in the study.
• Impact of zinc supplementation on cognitive function and the nutritional status among preschool children.
• Health education for healthy food and their requirement from the food regard the age and sex.

Study design:

This is a pre-post intervention study included 50 preschool child.

Method: The children randomly assigned to receive zinc supplementation daily for 6 months according to the level of plasma zinc. They were A self- administered questionnaire was used included (socio-demographic data, food frequency questionnaire and 24 hr. recall), anthropometric and cognition were assessed at the beginning and the end of the supplementation period. In addition to health education about healthy food throughout the follow up 6 months.

Results:-The study included males (46%) and females (54%);

-There was a significant difference in weight for age and height for age between the group before and after zinc supplementation.

- A significant difference in cognitive function, which the full-scale IQ, verbal IQ and nonverbal IQ between the group before and after zinc supplementation

- The health education effect positively on increasing the consumption of healthy food as protein, CHO, fruits, and vegetables to the normal proportions also effect on decrease consumption of unhealthy food as manufactured potatoes, fizzy drinks, and sweats.

Conclusions: zinc supplementation has an effect on cognitive and nutrition status on preschool age.-

Health education about healthy food have good feedback on the study.

Keywords: Prevalence, Zinc, Cognitive, Nutrition, IQ
Introduction

Zinc is an important vital micronutrient for humans, and zinc deficiency among children is deleterious to growth and development, and cognitive function.1

The main sources of zinc are beef, pork, poultry, fish and shellfish. Vegetables represent a good plant source of zinc.2

Adequate nutrition is a cornerstone of health and essential in early childhood to ensure healthy growth, proper organ formation and function, a strong immune system, and neurological and cognitive development.3

Method

Study design and settings:

This is a pre-post intervention study carried out on pre-school age children attending the Family Medicine center clinic of Nikla village at Giza.

Inclusion criteria:

Apparent healthy children randomly chosen aged 2-5 years who came to the clinic starting from January 2018.

Exclusion criteria:

Any child had a chronic disease, any child with congenital anomalies, any child with chronic diarrhea and IQ test below 80

Sample size & sampling

A total sample size of (45). Based on the previous data, the expected difference in IQ results over time is 6.4±13.4 Using power 85% and 5% significance level. 39 children needed to be studied to be able to reject the null hypothesis that this response difference is zero. This number increased to 60 children to compensate for possible losses during follow up. The sample size was calculated by the PS program.

Data collection by different tools:

1) A structured interviewing questionnaire:

- Socio-demographic Characteristics adopted from Gelani questionnaire.

- Food frequency questionnaire and 24-hour recall for full dietary assessment. The FFQ was derived from a validated FFQ and was adjusted specifically for the National Institute of Nutrition in Egypt (NIN).

2) General examination:

Anthropometric assessments done to every child while wearing light clothing and barefoot. The anthropometric measures recorded according to the WHO Child Growth Standards charts for boys and girls (from birth to 5 years / Z-scores).

3) Laboratory investigation: to assess the level of zinc in plasma.

5) Written models of healthy food, the amount of food calculated for each child regard to child sex, age, and writing models for unhealthy food to avoid.

Zinc dose supplementation plan:

According to zinc level, in normal children, they supplied according to RDA of zinc for age 2-5 years (3-5 mg zinc sulfate oral / day), but deficient children received therapeutic dose (0.5-1 mg zinc sulfate oral / kg/day) divided 2 times/day in the form of zinc sulfate. Then calculated the dose of zinc to each child in the form of syrup.

Study time

The study carried out from 1st January 2017 to the end of March 2019.

Statistical Design:

The collected data were computerized and statistically analyzed using the Statistical Package for Social Science (SPSS) program version 17. Using descriptive and analytical statistics

Results

- Table (1) the study group included 50 children distributed 54% females and 46% male also shows that zinc deficiency in females and males represented (24% and 22%) respectively so prevalence of zinc deficiency 46% of the studied group.

- Noticed that increase in weight, height, and serum zinc measure and showing highly significant differences before and after zinc supplementation in table (2).
- As regards the anthropometric measures improved after intervention regarding growth curves in table (3).

- This table illustrated improving of all factors of IQ scores and their subtypes according to age by months and shows statistical significant differences intervention with p-value (0.000) in all illustrated in table (4).

- The table (5) shows high significant differences in mean values of total energy for all food components after health educations for 6 months.

- Notice in table (6) that enhancement increase of daily food-frequency of egg, milk products, potatoes, fruits and vegetables and also weekly food-frequency of, milk, rice, and pasta but decrease consumption of junk food.

Discussion

The prevalence of zinc deficiency in the current study represent 46%. Male to female represent (22%, 24%) respectively. Regarding World Bank Nutrition-Related Activities in Egypt, Vitamin and Mineral Deficiencies Cause Hidden Hunger although they may not be visible to the naked eye and 9% of the population at risk for insufficient zinc intake. But Rabeh 2010 showed that the prevalence of zinc deficiency in their study about 70%, male to female represent (38%, 32%) respectively. This variation finding due to the variation of community and habits.

Concerning the mean weight and height of this study group before and after zinc supplementation showed a highly significant difference as the mean of weight before and after represented (15 ± 2 and 17 ± 2 kg) respectively and the mean of height represented (98 ± 6 and 103 ± 6 cm) respectively. While Garremo in NOPLAS project in United Arab Emirates (UAE) founded the mean of weight and height in children 2-3 years (13.9 ± 2 kg and 92.6 ± 4.8 cm) and the children more than 3 years (15.5 ± 2 kg and 99.7 ± 6 cm). Although our observations show that zinc supplementation stimulated growth, the mechanisms for this effect are unknown. The effect of zinc may result from increased appetite and improved ingestion of protein.

Results of the current work illustrated that weight gain and linear growth improved more after zinc supplementation, as before zinc supplementation the underweight and wasting represented (2%) and the stunting represented (24%), whereas after zinc supplementations only (6%) represented the stunting. This agrees with Islam et al., done in India, El-Farghali et al., done in Ain shams university and Bhutta and Das, who prove that preventive zinc supplementation in populations at risk of zinc deficiency increases linear growth and weight gain among infants and young children. In contrast, a meta-analysis by Ramakrishnan, based on 43 studies found no significant effect of zinc supplementation on linear growth in
children < 5 years of age.\textsuperscript{11} this is against another meta-analysis done by Liu et al., based on 78 trials included 54 in infancy/childhood (target age of our study) which found improved specific growth outcomes including height, weight, and WAZ. They also identified evidence for potentially stronger effects on height and HAZ by child age, with greater effects when supplements were given to children aged ≥2 years, rather than infants.\textsuperscript{12}

We found that zinc supplementation significantly increased FSIQ, NVIQ, VIQ, and also subtypes which indicated that preschool children increased their abilities in reasoning, solving problems, and adapting to the cognitive demands of the environment. more recently studied as de Moura et al., which founded that children supplemented with zinc alone presented better particularly in reasoning, orientation– engagement and hand and eye coordination.\textsuperscript{5}

The results of the present study showed highly significant differences after health education regarding the contribution of approximately total energy and energy intake from dietary carbohydrate, protein, and fat in daily diets. This study agreement with the recommended RDA of total energy and macronutrients by FAO\textsuperscript{13,14}.

The current results approximately illustrating improve in the frequency of food rich in protein (meat, liver, poultry, egg, fish, bean, legumes, milk and milk products), vegetables, fruits, CHO (rice, pasta, and potatoes) and fat among studied group by FFQ and showed highest significant difference between before and after 6 months follow up to nearly meeting their needs recommended by FAO and WHO and UNICEF.\textsuperscript{13,14} This improvement is due to teaching the mother about the balanced diet to meet the needs of children should be distributed, regarding energy/caloric intake, according to the rules of healthy nutrition, i.e. the diet should be varied and include foods which provide the necessary nutrients in terms of proportion and quantity.

**Ethical Clearance:** The study protocol was discussed by selected staff members of the Family Medicine Department, Faculty of Medicine, Cairo University, and was approved by its council held in Juan 2017. and taken from center direct for Research and Health Development from Ministry Of Health and Population (Com.No/Dec. No:1-2018/7). An informed consent was obtained from every child-parent before filling the questionnaires.

Abstract

During the period from June of 2018 to February 2019 (150) isolates of *Streptococcus pneumoniae* were isolated from 600 patients with clinical symptoms of Lower respiratory tract infections (LRTI) (pneumonia), otitis media and meningitis obtained from Baqubah Hospitals. The results showed that not only *S. pneumoniae* causes pneumonia and it can causes diseases other than pneumonia such as otitis media and meningitis but with less frequency. *S. pneumoniae* showed different susceptibilities towards antibiotics used in this study. The total susceptibility was (65.8%) and the total resistance was (34.2%). The highest pneumococcal susceptibility was showed to the cell wall inhibitors (44.4%) followed by protein synthesis inhibitors (28%) and quinolones (17.3%), and the lowest susceptibility was to folate antagonists with 0%. The highest rates of susceptibility was to penicillin (100%), chloramphenicol (86%), vancomycin (80%) and moderate rates of susceptibility to levofloxacin (90) 60%, linezolid (42.7) %, cefotaxime (40%), ofloxacin (40%) whereas there was a relatively lower susceptibility rate towards other antibiotics such as ampicillin, imipenem, amoxicillin, trimethoprim/sulfamethoxazole. Therefore, it should be avoided in the treatment in addition to tazobactam, amikacin, gentamicin, which had lowest rates susceptibility against *S. pneumoniae*. As a result, it required more research to identify new antibiotic or vaccine to reduce the risk of pneumococcal infection.

Keywords: *Streptococcus pneumoniae*, pneumonia, otitis media, antibiotic sensitivity.

Introduction

*Streptococcus pneumoniae* is an important respiratory pathogen responsible for high rate of morbidity and mortality around the world. This bacterium causes many infections, which lead to die especially in children according to the World Health Organization (1). The pneumococcus causes many different types of infections such as otitis media, sinusitis and conjunctivitis, and pneumonia. *S. pneumoniae* can invade the bloodstream to cause sepsis or septicemia and spread to other human sites to cause meningitis, collectively called invasive pneumococcal disease (IPD) (2), which most infect children less than 2 years old, adults over 65 years old and immunocompromised individuals (3). The human nasopharynx is the only reservoir of pneumococci which spread by droplet between individuals (3). This bacterium produces different virulence factors that assist its spread from the nasopharynx to other human sites such as the lungs, blood and brain (4). Antibiotics are the drug of choice for pneumococcal infection. In the last twenty years, the antibiotic resistance among pneumococci has become a big problem and is affected by the types of antibiotic use and population density (3). However, vaccination can give protection against most of pneumococcal serotypes. On the other hand, there are different problems with current vaccination strategies, and horizontal gene transfer, which can reduce the efficacy of vaccines and antibiotics (5).

Antibiotics are one class of antimicrobials, which produced through chemically derived substances from different organisms, such as bacteria and fungi (6). The antibiotic treatment relays on the infection human site and the age of patient (7). Effectiveness and allergic of potential antibiotic will detect a sole or combined administration of such prophylactic drug agents. However, pneumococcal diseases still connected with significant morbidity and mortality around the world. A growing proportion of *S. pneumoniae* in the aetiology of
morbidity and mortality is highly correlated with a high incidence of individual (especially to penicillin) and multiple antibiotic resistance. Antimicrobial resistance of *S. pneumoniae* is not only local but also a global problem. Resistance of pneumococci leads to changes in the clinical presentation of diseases which in turn leads to more difficult diagnosis and treatment. The resistance may result from several different mechanisms, such as the inactivation of the antibiotic by bacterial enzymes, low permeability to antibiotics bacteria, changes in the target protein, leading to reduced binding of the antibiotic, or overproduction of the target protein structure and by passing the metabolic pathways of the target (8). Therefore, the aim of this study was to detect the prevalence of sensitivity and resistance of *S. pneumoniae* to antibiotics that act on the cell wall synthesis, protein synthesis, folate antagonists and quinolones, in order to achieve proper treatment of pneumococcal disease and reduce morbidity and mortality.

### Materials and Method

#### Study design

This study is of prospective-retrospective and analytical nature was conducted in the Bacteriology Unit of Baqubah teaching hospital. Invasive and non-invasive *pneumococcal* samples were collected from adult patient (>16 years) suspected to have pneumonia and otitis media and meningitis, a total of 600 of samples were collected between June of 2018 to February 2019 From the hospital, non-invasive isolates such as sputum and ear swab.

#### Bacterial Strains and Growth Conditions

All the infectious samples were cultured on blood agar base (BAB) (Oxoid, UK) supplemented with 5% (v/v) defibrinated horse blood, Chocolate agar, and MacConkey agar (Oxoid, UK) and incubated at 37°C for 24 hr. Blood agar plates and Chocolate agar Plates were incubated in the presence of 5-10% CO2 at 37°C for 34 hr. Sputum samples were homogenized and mixed with an equal volume of normal saline by a vortex. Then, it was take 0.1 ml of homogenized sputum samples and cultured on the plates. The cultures were made for all the infectious samples (9).

### Identification of Bacteria

The diagnosis of *S. pneumoniae* was done according to colony morphology, sensitivity to optochin test and biochemical reactions as described in (10). A blood agar plate was cultured with a pure isolate colony of the bacteria that need to be tested. Then, optochin disc was placed in the center of the plate and incubated at 37°C with CO2 for 24 hr. The showing of a zone of inhibition growth around the disc more than 14 mm was considered the bacteria as sensitive (11).

### Antibiotic Susceptibility Testing

Disk diffusion method was used according to the instructions of the Clinical Laboratory Standards Institute (12). A pure isolated colonies of identified bacteria was used for culture on 5 ml of tryptic soy broth and then incubated for 2 hr to produce a turbidity that was the same with the turbidity of 0.5 McFarland standard tube. Inoculum from the standardized bacterial suspension was cultured by a sterile swab on a Muller–Hinton agar plate supplemented with 5% horse blood. The antibiotic discs were put on the surface of this plate and incubated at 37°C for 24 hrs. The inhibition zones around the antibiotic discs were measured and compared with standard zones to detect the sensitivity of the bacteria to each antibiotic (12).

### Statistical analysis

Graphpad Prism software (Graphpad, California, USA) was used for statistical analysis. The results were expressed as means ± standard error of the mean (SEM), significance was defined as (* p<0.05, ** p<0.01, *** p<0.001 and **** p<0.0001).

### Results

The samples for pneumococcal isolated were obtained from sputum (300) and (100) from ear swab, and the remaining was from CSF (100) and blood (100). As can be seen in Figure 1, most of *S. pneumoniae* was found in sputum (100) and ear swab (50) while a limited number of the microorganism isolated from CSF and blood (<25).
In Figure 1 shows that of 300 sputum samples, 100 samples of sputum culture appeared \textit{S. pneumoniae} and 150 of them produced no growth, the remaining results of sputum culture was another microorganisms such as \textit{K. pneumonia}, \textit{P. aerugenosa}, and \textit{Acinetobacter}.

In Figure 2 shows that of 300 sputum samples, 100 samples of sputum culture appeared \textit{S. pneumoniae} and 150 of them produced no growth, the remaining results of sputum culture was another microorganisms such as \textit{K. pneumonia}, \textit{P. aerugenosa}, and \textit{Acinetobacter}.

In 65.8\% of \textit{Streptococcus pneumoniae} that isolated appeared sensitivity against antibiotics, while they were shown resistance in 34.2\%.

The representation of the susceptibility of cell wall inhibitors as penicillin 14.7\%, vancomycin 11.8\%, cefotaxime 5.9\%, meropenem 4\%, piperacillin 3\%, amoxi-clav 2\%, amoxicillin 1.4\%, cefepime 1.5\%, ceftriaxone 1.2\%, ampicillin 0.5\%, imipenem 0.2\%, tazobactam 0.2\%. While susceptibility of protein synthesis inhibitors as chloramphenicol 12.8\%, linezolid 6.4\%, tetracycline 3\%, erythromycin 2\%, azithromycin 1.6\%, doxycycline 1.5\%, amikacin 0.8\%, gentamycin 0.6. Susceptibility of quinolones as levofloxacin 8.9\%, ofloxacin 5.9\%, ciprofloxacin 1.6\%, gatifloxacin 0.8\%, trimethoprim/sulfamethoxazole 0.2\%.

The results of this study showed the susceptibility of each group antibiotics according to the number of susceptible \textit{S. pneumoniae} (150). We will find that the susceptibility of cell wall inhibitors: penicillin (150) 100\%, vancomycin (120) 80\%, cefotaxime (60) 40\%, meropenem (42) 28\%, piperacillin (26) 17.3\%, amoxi-clav (20) 13.3\%, cefepime (14) 9.3\%, ceftriaxone (12) 8\%, amoxicillin (10) 6.7\%, ampicillin (4) 2.7\%, imipenem (2) 1.3\%, tazobactam (2) 1.3\% Figure 3.
Protein synthesis inhibitors were shown sensitivity as chloramphenicol (130) 86%, tetracycline (30) 20%, erythromycin (20) 13.3%, azithromycin (16) 10.7%, doxycycline (14) 9.3%, amikacin (8) 5.3%, gentamycin (6) 4%, nitrofurantoin 1.3% Figure 3. Quinolones were appeared sensitivity as levofloxacin (90) 60%, ofloxacin (60) 40%, ciprofloxacin (16) 10.7%, gatifloxacin (8) 5.3%, trimethoprim/sulfamethoxazole (2) 1.3% Figure 4. However, folate antagonists were shown full resistance against pneumococcus and the sensitivity was 0% Figure 3.

**Discussion**  
Annually, invasive pneumococcal diseases (IPD)
cause an estimated 1.6 million deaths, including 1 million children less than 5 years old (3). The available population-based surveillance shows significant differences in the incidence and mortality rates of IPD worldwide between industrialized and developing countries. Pneumonia cause death more in children under five years of old than other infection around the world. It was reported that the estimated 9 million child deaths were through pneumonia. The results of this study shows that most of S. pneumoniae infection presented as pneumonia and otitis media less commonly with meningitis (Figure 1). In addition, it can be seen that not only S. pneumoniae causes pneumonia, it can caused by other microorganisms such as K. pneumoniae, S. aerugenosa, and Acinetobacter (Figure 2). Not very low representation of resistance (34.2%) that was observed in this study may be due to inadequate prescription and consumption of medicines, predisposed specific serotypes of S. pneumoniae in the development of resistance to antibiotics and their different geographical distribution.

For many years penicillin has been the mainstay of therapy for pneumococcal diseases. Clinical resistance to penicillin was first reported in 1960’s. Since this early reported, penicillin resistance has been encountered with increasing frequency in strains of Streptococcus pneumoniae from around the world. Our results showed that penicillin sensitivity is 100%, comparing our results in which 86% of chloramphenicol and very low sensitivity of erythromycin 13.3% (15). The new fluoroquinolones are widely performed to treat respiratory tract infections. It was showed that a high rate 96.5% of ciprofloxacin susceptibility in S. pneumoniae, it was higher than rates found in a recent study. The high consumption of quinolones could explain the lower susceptibility rate (16).

The differences showed in the rates of sensitivity to ciprofloxacin and levofloxacin are within 16 samples with first-step mutations in the quinolone resistance-determining regions. These isolates (ciprofloxacin susceptible and levofloxacin resistant) may become highly resistant under selective fluoroquinolone pressure and are associated with treatment failure when quinolones are used (17).

The emergence of high-level resistance to antimicrobials is an increasing threat to global health (18), and even a small increase in antibiotic-refractory bacterial subpopulations or MIC could herald the emergence of higher-level resistance (19). Therefore, any factor leads to rise the antibiotic resistance is essential.

The most important result of this study is the sensitivity level of Ceftriaxone (from 32.4 % to 8%), Meropenem (from 83.8% to 28%), Imipenem ( from 100% to 1.3%), cefepime (from 86.9% to 9.3%),While there is an increase in the results of erythromycin from 0% to 13.3% and chloramphenicol from 32.4% to 86% and penicillin from 18.9% to 100%. Therefore, this study showed that these antibiotics are the most common used in the Iraqi hospitals, and this is still a good antibiotic choice for the treatment of pneumococcal pneumonia, otitis media, and meningitis.

**Conclusion**

The lowest frequency in isolated pneumococci is recorded with imipenem 1.3%, trimethoprim/sulfamethoxazole 1.3% and gentamicin 4%, while the higher incidence of isolated sensitive pneumococci is recorded at penicillin 100%, chloramphenicol 86% and vancomycin 80%. Defining representation of antibiotics groups in the overall susceptibility make it easy to suspect their representation in the total resistance which show therapeutic adequacy of the same. This point was of great importance, because it approximately can serve as a guide in the selection of a therapeutic agent in the case of impossibility of making susceptibility testing or therapeutic coverage waiting period. For example,
quinolones and folate antagonists have significantly lower representation in the overall susceptibility make them to have the greater representation in the overall resistance and are therapeutically inadequate. It is evident that the presence of inhibitors of the cell wall in the overall susceptibility is very high, but that also has a much significant share in the overall resistance.

The results obtained in this study indicate the existence of a great need for rational use of antibiotics and establishing adequate monitoring patterns of pneumococcal resistance. We should determine the serotypes and the spread of resistant strains. Physicians should keep local and regional patterns of resistance at the consideration during the selection of empirical therapy for diseases caused by this agent. For further control of the resistance development necessary is a multidisciplinary approach that includes the clinicians, epidemiologists, microbiologists and pharmacists.

**Ethical Clearance:** The project of this study was taken from the ethical committee of College of Medicine/University of Diyala.

**Source of Funding:** The research was funded by ourselves, and there is no other funding cover this study or manuscript preparation and publication.

Abstract

Background: Trauma is a serious health problem especially when an individual is poor. They cannot reach hospital timeously, and also could not afford to get a quality of care in hospital. Transkei is the poorest region in South Africa with poor infrastructure like transport and health care.

Objective: To study the incidence of blunt force trauma deaths in the Transkei sub-region of South Africa.

Results: There were 26 855 autopsies were conducted over the period of 23 years. Of this, 2960 (11 %) deaths are related with blunt force trauma. Majority were males 2477 (9.2%). The male to female ratio is 6:1. About one-fourth 720 (30.21%) are between 21 and 30 years of age group. The average blunt force trauma fatalities is 20.2 per 100 000 per year. The highest rate of deaths, 25 per 100 000 has recorded in the year 1993.

Conclusion: There has been an increasing trend of deaths as a result of blunt force trauma in the Transkei sub-region of South Africa. Poverty is probably a major underlying factor in these deaths.

Keywords: blunt, trauma, assault, unnatural, death

Introduction

Blunt force trauma is one of the most common injuries encountered by forensic pathologists in different scenarios such as motor vehicle accident, jumping of falling from heights, blast injuries and struck by firm objects. Injuries result in 5.8 million deaths per year and the projections for year 2020 show that 8.4 million deaths per year are expected in the world. As a consequence of this, injury in particular blunt force injury will be the second most common cause of disability adjusted years of life lost within the next 13 years (second to HIV/AIDS). More than 90% global deaths from injuries occur in low-and middle-income countries. Males in Africa and the low-and middle-income countries of Europe, and females in Africa and India, have the highest injury-related mortality rates worldwide.

South Africa, a country not at war, faces an unprecedented burden of morbidity and mortality arising from violence and injury. South Africa had 59935 deaths due to injury in 2000, which is an overall death rate of 157.8 per 100 000 population. The rate is higher than the African continental average of 139.5 per 100 000, and is nearly twice the global average of 86.9 per 100 000 population. The blunt –force trauma to the body noted in most cases in a study carried out by Herbst et al in 2015 at Cape Town mortuary. The sticks, metal bars and sjamboks are the common objects, used for causing death by blunt force trauma. These objects were ordinary items that were incidentally found at the scene and easily accessible to the perpetrators of the presumably spontaneous assaults. A mortuary based audit conducted at provincial capital in Kwa-Zulu Natal has shown that trauma trends do seem to be changing. Blunt trauma contributed to 55.7% of all deaths. This is in contrast of 90% of trauma mortality being secondary to penetrating trauma in Durban in the 1990. Males account for 82% of all homicide victims, and the highest
among them between 15 and 29 years of age group, followed by aged 30-44 years. Blunt force trauma contributed 27% of all homicide deaths in South Africa. Nearly half of the violent and/or traumatic deaths occurred in the 21-to 40-year age groups according to this study.

A detailed analysis of the relation between socioeconomic inequalities and violence, based on survey data from 63 countries, shows that income inequality, low economic development, and high gender inequality are strong positive predictors of rates of violence. The health and social cost of alcohol misuse are estimated to be R9 billion per year, which is roughly twice the amount received in excise duties in alcohol in South Africa. The purpose of this study is to highlight the problem of blunt force trauma related deaths in the Transkei sub-region of South Africa.

Patients and Method

This is a retrospective descriptive study from the autopsy register of Mthatha Forensic Pathology Laboratory. The Mthatha Forensic Pathology Laboratory is the only laboratory in this region catering for more than half a million of the population in the region of Mthatha. A total number of 27036 autopsies were conducted between 1993 and 2015 (Photograph 1). It is difficult to determine the cause of death in cases of advanced putrefied human remains, and therefore also excluded from study. The terms ‘blunt trauma’ and ‘assault’ are used interchangeably and mean the same. All the cases of assault (blunt force trauma) are recoded in the post mortem register year wise. Data were collected on a sheet of paper designed to record the post-mortem number, year, gender and cause of death. These data were transferred to the Excel computer program and analysed by using the SPSS computer program.

Results

There were 26 855 medico-legal autopsies performed between 1993 and 2015 on the victims of unnatural deaths (Table 1). Of this, 2960 (11%) were died as a result of traumatic violent deaths by a blunt objects (Table 1). The average annual rate of blunt force trauma deaths was 20.2 per 100 000 (Table 2). It was the highest (25/100 000 population) in the year 1993, and lowest (16/100 000) in the year 2002 (Table 2 and Figure 1). Among males the average deaths rate as a result of blunt force trauma was 16.2 per 100 000, and among females, it is 3.4/100 000 (Table 2 and Figure 1). It was highest 21.5/100 000 in the year 1993 among males, and 5.6/100 000 in 2003 in females (Table 2 and Figure 1). Males’ subjects were outnumbered than females with ratio of 6:1 (Table 1, 2 and Figure 1).

The highest (30.21%) victims were between the age group of 21 and 30 years of age, followed by 23.66% between 11 and 20 years of age in this study (Table 3 and Figure 2). Surprisingly, there are victims of deaths from blunt force trauma 2.72% under the age of 10 years, and 1.29% above the age 80 years in this study (Table 3 and Figure 2). Blunt force trauma deaths were taking over to the gunshot injury deaths in the Transkei sub-region of South Africa (Figure 3).

Discussion

Seventy-three percent of the rural people in the Eastern Cape were living on less than R300 per month in 2005/2006., and more than half of them on less than R220 per month. There were 26 855 non-natural deaths recorded in the post mortem register over a period of 23 years (1993-2015) in the Transkei sub-region of South Africa. Out of this, 2960 (11%) deaths as a result of blunt force trauma, which ranks 3rd in homicide, and 4th in traumatic deaths in this sub-region (Table 1). Assault also ranked the 4th cause of death among males, and 5th among females (Table 1). The average annual rate of blunt force trauma deaths was 20.2 per 100 000 population in this study (Table 2 and Figure 1), which is little less than an earlier study (1993-1999) carried out by the author (24/100 000) in the same region. There was one third fall (33%) in rate of murder by blunt objects between 1993 and 2002. i.e. from 25/100 000(1993) to 16/100 000 (2002) in this region (Table 2 and Figure 1). This fall could not sustained any more, and it started climbing up from the 2003, and reached almost at the same level in year 2015 i.e. 24.7/100 000 (Table 2 and Figure 1). This dipping in murder rate by blunt objects is an interesting finding in this study (Table 2 and Figure 1). It is difficult to understand the pattern of fall and rise of murder rate by blunt force trauma (Table 2 and Figure 1). The benefit of ‘gun control act of 2002’ was nullified by the excessive use of blunt object in committing deaths (Figure 3) Deaths as a result of gunshot has almost come down to more than half over a period of 23 years (1993-2015), but the deaths due to blunt force trauma has reached the same high level, as it was in 1993 (Table 2 and Figure 3). The trauma burden consisted predominantly of
blunt trauma (69.6%) followed by penetrating trauma (30.4%). This is not the case in Transkei sub-region. The average murder rate as a result of penetrating injuries were increased to three times (62 per 100 000) than that of blunt force trauma (20.2/100 000) (Table 2 and Figure 1). Of the 615 deaths related to blunt trauma, 153 (24.87%) were secondary to assault. There is 9580 case of blunt trauma deaths were admitted in mortuary between 1993 and 2015 (Table 1). Of this, 2960 (30.89%) were related with assault (Table 1). It indicated that the total number of deaths as a result of assault were more common in this region than Pietermaritzburg area.9 This difference is because of the level of poverty, which is more profound in Transkei region than Pietermaritzburg area.15

It is a well-known fact that South Africa is unique country in the world with a high number of traumatic deaths, and it is also true that Transkei region is unique in South Africa with excessive number of deaths.16 An Average (16.8/100 000) blunt force trauma related deaths were recorded among males (Table 2 and Figure 1). It is complimentary and congruent to total number of murders by blunt force trauma (Figure 1). Xhosa women are more resilient and have more survival skills than their male counterpart. An average deaths were accounted in this study is only 4 deaths /100 000 population, which one sixth of male’s deaths (Table 2 and Figure 1).

The victims of blunt force traumatic deaths were young adult (41%) males between the age of 21 and 40 years (Table 3 and Figure 2). This is the age where they takes maximum risk to the life and also consume a lot of alcohol. South Africa is a hard drinking country. It is reckoned that we consume in excess of 5 billion litres of alcohol annually.17 A study carried out by the author has shown that about half (49.5%) of traumatic deaths were related with alcohol in Transkei region.18 More than one-fifth (22.11%) victims were teenager and young- young adults,’ school boys between the age of 11 and 20 years in this study (Table 3 and Figure 2). A study carried out in schools of six African countries showed that risky drinking and illicit drug use were common in the school children.19 It is surprising that 2.72% children of the age of ten, and under ten were also get murdered by blunt objects (Table 3 and Figure 2). Of this, it is difficult to understand that male’s child is almost 3 times (2.01/100 000) more vulnerable to death by blunt object than a female child (0.71/100 000) in this study (Table 3 and Figure 2). Traditional custom of lobola, also known as “bride-price” or “bride-worth”, may sometimes be misunderstood by western eyes but in African culture, it is a ritual that helps to bring two families closer together.20 Dowry system was the root cause of female foeticide in India, thus it should be treated first.21 A victim of blunt force trauma has fair chances of survival than the victim of penetrating injury, provided one will get an early emergency care. A study carried out by the author in the Transkei region showed that about 12% pre-hospital deaths are preventable.22

Both trauma and HIV are competing and complimenting each other, and have cause and effect relationship. The 2013 Mortality and Causes of Death release shows that HIV disease has moved from being ranked sixth in 2012 to being ranked third in 2013.23 Traumatic deaths (homicide) are also ranked high in the Transkei sub-region (Figure 2). A published study by Chiumia et al in 2014, showed that a third of South African suffering from mental health disorder. More than 17-million people in South Africa are dealing with depression, substance abuse, anxiety, bipolar disorder and schizophrenia.24 During his first address to Parliament in 1994, former President Mandela specifically singled out alcohol abuse as a major cause of crime, poverty, reduced productivity, unemployment, dysfunctional family life, political instability, the escalation of chronic diseases such as AIDS and TB, injury and premature death.25

Limitations

The annual growth in population is accepted as 3%, which may not be strictly accurate in view of the lack of precise death and birth ratios. However, the author has tried to estimate as accurately as possible.

Conclusion

There is an increasing trend of blunt force traumatic deaths in the Transkei sub-region of South Africa over a 23 years study period (1993-2015). Murder as a result of blunt force trauma is neutralising the beneficial effect of Gun Control Act of 2002. It is a frightening finding in this study, as a little less than a quarter (23.66%) of school age children (11 and 20) were murdered by blunt objects. Female child were having some protective effect than males. Poverty alleviation is an important steps to curb these premature deaths in this region along with improvement in pre-hospital and hospital care to avoid these preventable deaths. Community education, and deterrent law enforcement could be helpful in reduction of crime.

Abstract

Background: Health condition of workers affects their productivity. The relationship between general health and safety attitudes is not quite clear.

Objective: The present paper is an attempt to examine the relationship of general health condition with safety attitude and demographical specifications of workers at car after-sale services workshops in Ardabil-Iran.

Materials and Method: The study was carried out as a descriptive-analytical cross-sectional study. The sample group consisted of 650 workers in small car after-sale services workshops located in Ardabil City. Three questionnaires including a demographical form, the General Health questionnaire (GHQ-28), and the safety attitude inventory were used for data gathering. The collected data was analyzed in SPSS19.

Results: The mean score of safety attitude was 71.05±2.3 and the mean score of general health was 24.96±3.35. The score of general health had a significant relationship with age group, work experience, marital status, education level, and history of work incident. The mean scores of safety attitude was significantly different depending on age group, work experience, workshop ownership status, marital status, education level, income, and history of work accident.

Conclusion: The subjects had a low safety attitudes score and high probability of general health disorders. General health condition was directly related to safety attitude of the participants. Therefore, providing applied educations based on the workers’ needs to increase awareness and improve safety attitudes of workers can lead to a decrease in the rate of work accidents and a higher general health in the workers.

Keywords: General Health, Safety Attitude, worker, Small Workshops

Introduction

Attitudes is a preset collection of answers that people develop throughout experiencing similar situations. In addition, attitude can be defined as one’s tendency to a specific behavior in specific situation and positive (accepting) or negative (rejecting) response...
to others, things, and situations (1). Observing safety
codes has to do with the attitudes that affect safety
behaviors and might decrease the risk of accidents (2-
3). Studies have shown that work environments with
workers who have a positive attitude to safety have a
lower rate of job accidents and that there is a significant
relationship between safety attitudes and the risk of
accidents and injuries at work. An increase in safety
attitude at work leads to a decrease in work accidents
(4). Some safety experts even believe that all accidents
are rooted in negative attitudes to safety in workers (5).
Some studies have shown that demographical variations
are effective in the safety attitudes in workers so that
it grows with age and work experience (6). Normally,
small workshops (less than 10 workers) fail to provide
adequate and quality safety and health services and jobs
are done in poor work conditions. In contrast however,
small workshops play the key role in the development
of national economy, creating job, and self-employment
(7). Small workshops are one of the pillars of economy
in all countries (8). The work force at small industries
constitute 40% and 60% of total workforce in the
industrial and developing countries respectively (9).
As the statistics by the Ministry of Health, Treatment,
and Medical Education in Iran show, small workshops
constitute 98% of workshops and more than 80% of job
opportunities in the country. Depending on the economy
and the level of development, different definitions are
available for small workshops. According to instruction
by the Ministry of Industries in Iran, workshops with
10 or fewer workers are considered as small workshops
(10). These workshops are a growing source of creating
job opportunities and supported by economic and
development policies of the county; still, safety and
health in them are at an undesirable level (11). Several
studies have been conducted on the general health of
workers and among many a study on general health and
the factors in a power board factory is notable (12).
In (13), the effect of job stress on general health and performance
of flight safety personnel was examined. Lack of safety
control and safety knowledge in workers have increased
the rate of debilitating accidents and diseases at
workshops (14-15). Workers’ attitude about safety is affect
by several variables; although, the relationship between
these variables and safety attitude are not quite clear.
Therefore, examining safety attitudes and the factors
and actual role of each factor in the attitude, mainly in
small workshops that host the majority of workforce in
Iran, can be a large step towards attenuating the risk of
damages caused by accidents and diseases (16). While
there have been several studies about safety attitudes in
large industries, there is a paucity of studies on safety
attitude in small industries. Given the importance of
general health and safety attitudes in workers, the
present study is an attempt to survey the relationship of
general health with safety attitudes and demographical
specifications of workers in small car after-sale services
workshops in Iran (2019).

Material and Method

Participants

A descriptive-analytical cross-sectional study was
carried out in 2019. Study population was comprised
of the workers in 550 small workshops (less than
10 employees) of car after-sale services in Ardabil.
Inclusion criteria were desire to participate and working
in a small workshop of car services (engine, paint, body
repair, services, and electrician technicians) in Ardabil.
Exclusion criterion was reluctance to participate.

The data was collected using a demographic form,
the General Health Questionnaire (GHQ-28), and the
safety attitude inventory. The participants were selected
from 550 small workshops in Ardabil in June 2019.
The questionnaires were distributed among the workers
by two researchers (n=1134) and collected after three
weeks by revisiting the workshops. Totally, 650 workers
took part in the study.

The demographics form included age, work record,
workshop ownership status, marital status, education,
income, history of accident at work, and severity of
accidents.

To determine safety attitudes, a standard safety
attitude questionnaire was used. With 25 questions, the
questionnaire measures safety attitudes in the workers.
The questions are designed based on Likert’s five-
point scale . Total score range is 25-125 so that scores
≥75 indicate a positive safety attitude and scores<75
represent a negative safety attitude. The higher the score
the more positive the safety attitudes (17).

To measure general health of the participants
GHQ-28 was used, which is a questionnaire with 28 items
designed by Goldberg and Hiller (1979). Validity
and reliability of the Farsi version were supported by
Noorhala et al. (26). The questions are designed based
on Likert’s four-point score. Total score ranges from 0
to 84 and scores ≥23 indicate probable health disorders
and scores <23 indicate an acceptable general health condition (18).

Data analyses were done in SPSS19 so that the mean score of quantitative variables were compared using independent-sample T-test and one-way ANOVA. To examine the relationship between quantitative variables, Pearson’s correlation was used and the relationship among qualitative variables were examined using chi-square (p=0.05).

Results

The mean age of the participants was 36.48±10.3 and the youngest and oldest workers were 15 and 75 years old respectively. The mean work experience was 15.3±9.6 and the shortest and longest work experiences were 1 and 53 years respectively. The mean score of general health was 24.96±3.35 -i.e. probable general health problems. The mean scores of general health were significantly different in terms of age, work experience, marital status, education level, and history of work accident. Workers older than 50 years old and those with more than 20 years of work experience had the highest score of GHQ-28. In addition, the unmarried, and those with low education level also had high GHQ-28 scores. High GHQ-28 score indicates the high probability of general health problems. There was a significant difference in safety attitude scores in terms of age group, work experience, ownership status of the workshop, education level, income, and a history of work accident. The workers younger than 30 years old and those with a work experience of less than 10 years had the lowest score of safety attitudes. The illiterate workers and those with low income levels had a lower safety attitude. Those who had rented the workplace and married individuals had a lower safety attitudes. The workers who had experienced a work accident had a lower safety attitude.

The correlation test showed that there was a significant relationship among general health, safety attitudes, age, and work experience. The general health score had an inverse and significant relationship with safety attitudes and since the lower general health score means a better health condition, the higher the safety attitude the better the general health condition. Workers with strong safety attitudes had a better general health condition (Table 1). Moreover, there was a direct relationship between general health condition and safety attitudes.

Discussion

Workers who had experienced a work accident had a higher general health score and for this the experience of accident must be taken into account. Gholami et al. (2014) studied general health condition and the factors in workers of a power board manufacturer in Kerman. They showed that factors like education level can be effective in general health condition of the workers, which is consistent with our results. It is possible to improve general health condition by studying and focusing on the controls of accidents and education (12). Demographical variables like age and work experience had an inverse relationship with general health so that an increase in age and work experience decreased general health condition. The reason form this can be the aging phenomenon that increases health problems including general health problems. Sanaie Nasab et al. (2016) examined the effect of stress at work on general health and productivity in personnel of flight control services. They argued that stress had a negative effect on productivity and that general health was a mediatory variable between work stress and productivity of flight control personnel (19). The safety attitudes score was significantly different in terms of the severity of work accident. Loosemore et al. (2019) conducted a study titled “safety education and creating positive safety attitude in Australian
manufacturing industry” and found that age, gender, and education were potential mediators in the process of development of positive safety attitudes. Studies have recommended paying more attention to using new technologies in developing safety education programs (21). A study by Sanaie Nasab et al. showed that the mean score of awareness was significantly related to education level (19). Yin et al., on the other hand, showed that there was no relationship between education level and safety attitude (22). Williamson et al. maintained that a mere reliance on engineering approaches without improving safety attitudes of the workers or creating an effective safety system surely fails. Their results highlighted the importance of improving safety attitudes (16).

**Conclusions**

The results showed that the safety attitudes were negative and the general health condition of workers was low. The effective variables in safety attitudes were age, education level, and experience of accident. An improvement of safety attitudes can lead to a better general health condition. Therefore, holding face-to-face and virtual education workshops designed based on the workers’ needs by the state supervising bodies are recommended to improve awareness and attitudes of workers. Such measures, hopefully, lead to a lower rate of accidents and a better general health in the workers.

15. Pouya AB, Jame RN, Abedi P, Azimi Z. Identification and Assessment of Occupational
Personal Hygiene and its Effect on the Treatment of After Cesarean Section Debridement in NTB General Hospital

Chairun Nasirin¹, Sri Wahyuningsih¹
¹Lecturer at College of Health Science (STIKES) Mataram, Indonesia

Abstract

Personal hygiene is important for after cesarean patients because personal hygiene will affect one’s health and psychological well-being. Patients with after cesarean wounds should be given immediate wound care by cleaning to prevent infection during the wound care. This will affect the wound healing process in cesarean surgery patients. This study aims to determine the relationship between personal hygiene and healing of after cesarean wounds in the NTB General Hospital. An accidental sampling technique of 52 patients with after cesarean section who experienced personal hygiene during wound care in the NTB General Hospital was used in this study using a prospective cohort study design. By using data analysis based on the chi-square test, the results showed that personal hygiene in after cesarean patients was mostly good category of 40 respondents (76.9%), cesarean section wound healing in after cesarean patients most of the categories were cured as much as 46 respondents (88.5%) and obtained a p-value of 0.002 <0.05. The results of the study confirmed the relationship between personal hygiene and healing of after cesarean wounds in the NTB General Hospital. This study recommends that nurses and other health teams develop theories and guidelines for the implementation of personal hygiene that are more effective and efficient in order to reduce infection after cesarean section.

Keywords: personal hygiene, debridement, cesarean section, chi-square, cohort.

Introduction

Personal hygiene is important for patients after cesarean section.¹ Personal hygiene will affect one’s health and psychological well-being. The purpose of personal hygiene is to provide comfort, relaxation and prevent infection. Personal hygiene also affects the wound healing process because germs can enter through the wound at any time.² In the treatment of wounds caused by surgery on the abdominal wall and uterus, the physiological process of wound healing goes through four stages: the stage of acute inflammatory response to injury, the destructive stage, the proliferative stage, and the stage of maturation.³ Patients with after cesarean wounds should immediately be given debridement treatment by cleaning to prevent infection during treatment of the wound. This will affect the wound healing process in cesarean surgery patients. Cesarean section is surgery on the wall in the abdomen and uterus because surgery is easier and can be done faster.⁴ Based on data from the NTB General Hospital received 320 patients in 2014 after cesarean section (Table 1).

Table 1 shows that the number of patients undergoing cesarean delivery is still quite high and the highest data occurred in February 2014. This is due to the lack of
knowledge of patients about the risk of cesarean delivery. The large number of patients delivering by cesarean section is a challenge for nurses as professionals who have more time compared to other health care workers in the order of service required to improve quality nursing care. Meanwhile, in cesarean section patients, personal hygiene occurs due to an abdominal surgery. This will affect the wound healing process because germs can enter through the wound at any time if personal hygiene is lacking. This study examines the effect of personal hygiene on after cesarean wound healing, and the relationship of after cesarean wound healing related to personal hygiene

Method

Research methodology is a scientific way to obtain data with specific objectives and meanings based on rational, empirical and systematic. This type of research is quantitative research. This study aims to look for the relationship of personal hygiene with wound healing after cesarean section. This research method will describe the research subject, population, data collection techniques, identification of variables, frameworks and data analysis.

The subjects in this study were patients with after cesarean section who experienced personal hygiene during wound care in the NTB General Hospital. In this study, the sample was determined by sample criteria, namely patients who received after cesarean wound care, patients who experienced personal hygiene after cesarean section, and patients who were willing to become respondents. The number of samples in this study were 52 people.

This study was designed in the form of a prospective study (cohort) ie research observing the independent variable of risk factors. The subjects were followed until a certain time to see the effect on the dependent variable.

For data collection and data processing techniques, observations were made by direct observation of research subjects to determine personal hygiene with wound healing. In addition, interviews and documentation were also conducted to analyze the relationship between personal hygiene and wound healing in the NTB General Hospital.

To determine the relationship of personal hygiene with after cesarean wound healing using the chi-square test with the SPSS program, it is said to have a relationship between personal hygiene with after cesarean wound healing indicated by p-value <0.05.

Results

This section presents the results of research and discussion on personal hygiene with after cesarean wound healing in the NTB General Hospital. The findings identified post cesarean wound healing by performing personal hygiene after being given wound care treatment and analyzed the relationship of personal hygiene with post cesarean wound healing in the NTB General Hospital. Specific data presents results that illustrate the relationship of personal hygiene with wound healing after cesarean section in the NTB General Hospital. Test results regarding the identification of patients’ personal hygiene after a cesarean section in the NTB General Hospital, showed that patients who experienced good personal hygiene were 40 (76.9%), personal hygiene was as much as 9 (17.3%), personal hygiene less as much as 3 (5.8%). This happens due to lack of knowledge about after cesarean wound care.

Furthermore, to identify wound healing in after cesarean patients in the NTB General Hospital, the results showed that 46 patients (88.5%) healed wound healing and 6 respondents who did not heal wound healing (11.5%). This happens because there are other diseases suffered by respondents such as nutritional status and consumption, personal hygiene, lack of mobilization, anemia, and DM (Diabetes Mellitus). 8,9,10,11

The results of the analysis of the relationship of personal hygiene with after cesarean wound healing, showed the relationship of personal hygiene with after cesarean wound healing based on the compilation of documentary studies, observation sheets and interviews conducted on respondents. The results showed that 40% of respondents experienced good personal hygiene (76.9%). Of the 40 respondents who experienced healing wounds healed as many as 39 (75%) patients and healing wounds not healed as many as 1 (1.9%) patients. Of the 9 respondents who experienced healing wounds healed as many as 6 (11.5%) patients, and wound healing did not heal as many as 3 (5.8%) patients. For respondents who experienced less personal hygiene, there were 3 (5.8%) patients. Of the 3 respondents who experienced healing wounds healed as many as 1 (1.9%) patients and healing wounds that did not heal as many as 2 (3.8%) patients. Statistical analysis using the chi-square test with the help of SPSS showed a significance level of 5% obtained p value 0.002 <0.05. This means that there is a relationship between personal hygiene and wound healing after a cesarean section in the NTB General Hospital. This study also suggests that to prevent the complications of childbirth by cesarean section of surgical site infections, health workers must provide health education about personal hygiene so that cesarean patients can implement this. 12 Thus, the incidence of infection in the surgical wound does not occur.

</table>

The results showed that the majority of post-operative personal hygiene in the good category were 40 respondents (76.9%), quite as many as 9 respondents (17.3%) and less as many as 3 respondents (5.8%). Before surgery, the client and the client’s family are given health education about the importance of personal hygiene as well as ways of performing personal hygiene after a cesarean section. Personal hygiene is self-care carried out to maintain health, both physically and psychologically. 13 Cleanliness can provide a sense of comfort, relaxation, and prevent infection. Personal hygiene also affects the wound healing process because germs can enter through the wound at any time.

After surgery personal hygiene cleanses the dirt contained in the wound using povidone iodine, 14 after that the wound is wrapped using gauze and bandages that aim to cover the wound so as not to be contaminated with the environment around the patient and to keep the wound from becoming infected. Every patient who will be given wound care certainly hopes that the wound heals quickly. Therefore, nurses are required to provide wound care, the main thing is also needed physical and psychological readiness. Wound healing occurs when the patients do not feel heat, pain, redness, swelling, and decreased lip function.

The results showed that the majority of after cesarean wound heal healing categories were as many as 46 respondents (88.5%), not recovering as many as 6 respondents (11.5%). Observation to assess wound healing after cesarean section was done on the fifth day
after cesarean section. Injury is the destruction of normal anatomical structures and functions due to pathological processes originating from internal or external and affecting certain organs. Injuries due to cesarean section are intentional injuries because there is a clear purpose and purpose. A good wound healing or healing category will appear dry sores and there are no signs of infection. This is supported because the majority of after cesarean patients perform personal hygiene well, while wound healing is not good because patients do lack personal hygiene.

In cesarean section, there are injuries to both the abdominal skin and abdominal muscles and the uterine wall. The existence of after cesarean wounds is one of the factors that prolong the patient’s after cesarean section care in the hospital. By doing personal hygiene, it is expected to affect the wound healing process because germs can enter through the wound at any time if personal hygiene is lacking. The opposite explanation, if the patient does not perform personal hygiene well after the cesarean section, the infection in the area of the surgical wound will hamper the process of wound healing. Poor healing of wounds or categories not healed will show symptoms of infection such as swelling around the wound, redness, pain, heat in the wound and the presence of pus or pus in the wound. Thus, the duration of treatment will increase and longer.

Conclusion

The results of the study showed that the personal hygiene of after cesarean patients was self-care carried out to maintain health, both physically and psychologically. Based on the results of the study it can be seen from the 52 patients who experienced good personal hygiene there were 40 (76.9%) patients, who experienced enough personal hygiene 9 (17.3%), and patients who experienced less personal hygiene and 3 (5.8 %). For wound healing in after cesarean patients, the results showed that after cesarean wound healing was mostly cured in the category of 46 respondents (88.5%), not recovering as many as 6 respondents (11.5%). Observation to assess wound healing after cesarean section was done on the fifth day after cesarean section.

Analysis of the relationship of personal hygiene with after cesarean wound healing showed the results of the chi-square statistical test on the relationship of personal hygiene with after cesarean wound healing in NTB General Hospital with a value of 16.18> 5.991. These results empirically prove that there is a relationship between personal hygiene and wound healing after a cesarean section in the NTB General Hospital. These results confirm that good personal hygiene can accelerate the healing process of cesarean section wounds so that complications such as infection can be prevented and shorten the length of patient care in the hospital.

Factors Affecting the Incidences of Needle Stick Injury on The Nurses Emergency Department of Hospital East Java

Adity Adha Putra1, Ni’matu Zuliana1, Zikri Fathur Rahman1, Noeroel Widajati1, Abdul Rohim Tualeka1
1Department of Occupational Health and Safety, Faculty of Public Health, Universitas Airlangga, 60115 Surabaya, Indonesia

Abstract

Hospital with all the facilities and equipment that can be a source of health and safety hazards of potential, especially for health workers if no management following the standards of safety and health procedures. Needle stick and sharp object injuries is a significant challenge for health workers, and nurses are jobs are most often associated with the incidence of needle stick injury. The purpose of this study was to determine the factors that influence the prevalence of needle stick injury to nurses in the emergency department of hospital Eas Java. This study using 64 samples from a total of as many as 76. The ER nurse that most of the variables age category ≥ 29 years, ≥ five years of working life, has never participated in occupational safety and health training, and education level diploma 3 — workers who perform unsafe actions as much as 37.5%. The Bivariable analysis showed that age, work periode, education level, and training has a significant value above 0.05 was no meaningful relationship to the needle stick injury. Unsafe action was a value of 0.026, which means significance was a substantial relationship with a needle stick injury. The multivariable nurses who perform dangerous activities are at increased risk of needle stick injury 4x compared to nurses who work safely. Prevention of occupational accidents to human factors include labor regulations taking into account the limits of the abilities and skills of workers, nullify the things that reduce the concentration of workers, enforce work discipline, avoid actions that bring accidents and eliminate their physical and mental incompatibility.

Keyword- Nurses, Needle Stick Injury, Emergency Department

Introduction

Hospital with all the facilities and equipment that can be a source of health and safety hazards of potential, especially for health personnel, if it is not done according to the standard management of occupational health and safety procedures1. As is well known, hospital activity is closely associated with the use of equipment or sharp objects as a means of support. Nurses play a full part in a 24 hours service on the side of the patient. Therefore, nurses have the highest intensity to interact with patients when compared to others2.

According to the Center for Disease Control and Prevention (CDC) estimates that each year 385,000 incidences of stab wounds as a result of syringes and sharps to health care in American hospitals. Health workers at risk of occupational exposure to blood and body fluids of infected (bloodborne pathogens) can lead to infection with HBV (hepatitis B virus), HCV (Hepatitis C Virus) and HIV (Human Immunodeficiency Virus) that one of them through a stab wound syringe known as Needlestick Injury (NSI)3. A total of 66.1% of nurses in public hospitals Sarajevo Bosnia experienced something stick injury needle4.

Needlestick and sharp object injuries are a significant challenge for health workers, and nurses are the most frequent jobs associated with the incidence of needlestick injury5. Implementation of the continuing education program showed that training could improve the awareness of nurses in Indonesia and can reduce needlestick injury6. Behavioral prevention of needle
stick injury incidence is related to age, education, employment, knowledge, and training. This training can be used as a program to reduce or prevent the occurrence of an accidental needle stick. For that reason, this study aims to determine the factors that influence the incidence of needle stick injury to nurses in the emergency department of a hospital X Tulungagung.

**Materials and Method**

This study uses observational study design, with design crossectional was an observational study design. This research was conducted in the ED Hospital “X” Tulungagung. The population in this study were all nurses in the emergency department (ED) Hospital X Tulungagung with a total of 76 nurses and a sample of 64 nurses. Data obtained from observation and interview. The variables were divided into two dependent (needle stick injury) and independent (age, years of services, Education level, training, and unsafe action). The age factor was divided into two categories: <29 years and ≥ 29 years, a working period divided <5 years and ≥ five years, training was divided already training and not exercise, education divided bachelor and diploma, unsafe action is divided yes and no hazardous. The data analysis used was descriptive, relationship analysis by chi-square test, and influence analysis by logistic regression test.

**Results**

Results obtained from interviews and observations. Interviews to collect information on age, length of employment, training, and education. The representations were made to get unsafe data action. Rate dangerous activity judged by indirect discard disposable needles into safety box, do recapping, not uses gloves, not to wash your hands before and aftercare to patients. The research results are as follows:

a. Variable(s) entered on step 1: Unsafe_Action.

Table 4 shows the multivariable analysis showed that the unsafe action influences the incidence of needle stick injury. Nurses who perform dangerous activities are at increased risk of needle stick injury 4x compared to nurses who work safely.

**Discussion And Conclusion**

The incidence of needle stick injury is one of the occupational accident’s occurrences mild but can cause a moderately severe impact. The results of this study showed as much as 31.3% of respondents had experienced these events. Needlestick injury can be prevented, among others, by administrative control. The application of this control can be made by giving some rules or policies such as the creation of SOPs, and if there have as been an exposure attempts to do is to minimize the impact.

The results of the analysis bivariable between age and incidence of needle stick injury is not a significant relationship between age and the prevalence of needle stick injury. International Labor Organization (ILO) states that the issue of age and years of service is a crucial cause of the accident problem, but it must be remembered that the high age does not necessarily have a long service life as well. The results of the analysis

bivariable between working period with the incidence of needle stick injury showed no significant correlation between working period with the frequency of needle stick injury. These results are in line with the results of studies that there is no meaningful relationship between the length of employment with stab wounds incident syringe. Work experience is not an indication that is linked to workplace accidents. This result is different from the standard AS / NZS 4360 that risk control is generically carried out with the approach one of them by providing training to workers on how to work safely, safety culture and safety procedures. Education is not a significant relationship with the incidence of needle stick injury. This result differs from the opinion stating the level of knowledge related to how quickly a person in making decisions. If a worker education levels low so often late or hesitant in making decisions that could lead to accidents.

The results showed that there were a significant relationship and the influence of variables unsafe act on the incidence of needle stick injury. The theory of the swiss cheese model describes the accident that the accident with the leading causes of accidents was caused by human error (human error). Accidents that arise within a specific time will be able to accumulate, which can then be combined into an active failure or consist of unsafe actions that ultimately lead to accidents. The principles to prevent workplace accidents are actually very simple, namely, to eliminate the causes of the so-called dangerous acts and unsafe Events.

Based on the discussion, it can be concluded that nurses who work with unsafe action can increase the
risk of needle stick injury by 4x compared to nurses who work safely\textsuperscript{15}. Prevention workplace accidents to human factors include labor regulations taking into account the limits of the abilities and skills of workers, nullify the things that reduce the concentration workers, enforce work discipline, avoid actions that bring accidents, and eliminate their physical and mental incompatibility\textsuperscript{16}.

Abstract

Post mortem organ weight is one of indicator that serves as supporting evidence in determining the cause of death, because if there is a difference between the post mortem organ weight with normal organ weight indicates the occurrence of pathological conditions that may be related to the cause of death. The objective of this study was to determine post mortem organ weight in autopsy cases at Bhayangkara Pekanbaru Polda Riau Hospital in 2017-2018. This research is a retrospective descriptive study using secondary data. Data were obtained from autopsy data in the forensic section of Bhayangkara Pekanbaru Polda Riau Hospital in 2017-2018. Data were analyzed by using univariate analysis carried out on each variable of the research results. The results of this study were obtained from twenty one autopsy cases with a mean value of organ weight: the brain (1334.29 grams), liver (1130.90 grams), right lung (370.48 grams), left lung (311.24 grams), heart (275.33 grams), left kidney (114.52 grams), right kidney (114.00 grams), and spleen (113.43 grams). Organs in men are heavier than women, except the liver. Organ weight has decreased in old age. People with short bodies tend to have lighter organ weights than people with tall bodies. The conclusion of this study is the average value of post mortem organ weight in this study is different from the weight value of organs found in forensic textbooks.

Keywords: autopsy, post mortem, organ weight

Introduction

Autopsy is one of the important parts in medical science, because in addition to establish the final diagnosis, the function of autopsy also to find the relationship between the cause of death with abnormalities in the organs that cause death, and can explain the relationship between these. An autopsy is done in suspicious death case, death due to murder, and sudden death without apparent cause.¹

Autopsy consists of 2 types examination, external and internal examination. On internal examination, one of the examinations is weighing post mortem organ weight.² It plays an important role as supporting evidence in determining the cause of death, because if there is a difference between the weight of a post mortem organ with the average weight of the post organ mortem is normal, it indicates a change in the organ caused by a pathological state in the organ that is likely related to the cause of the death.³

Standard values of post mortem organ weights are needed to determine whether a person’s organs are normal or not, such as those found in forensic books and studies that have been conducted in other countries, like South Africa, India, Korea, Thailand, Iran. Research by Vadgama et al. in 2014 in Jamnagar region, India, stated that the standard weight of organs contained in forensic books written by authors from other countries is not appropriate if used in populations in India.⁴ It shows that the standard weight of organs using samples in other countries may not necessarily be used as a reference to determine Indonesian organs are normal or not.
The value of organ weight obtained using samples in other countries may not be appropriate if it is used as a standard for assessing the weight of Indonesian, because between one country and another country has different races and ethnicities and it is known that both of these are some factors that influence weight post mortem organ. These racial and ethnic differences affect organ weight due to differences in the type of food consumed, the amount of water consumed, climatic conditions, and genetic variations in various ethnicities in various countries in the world. In addition to race and ethnicity, there are other factors that may influence weight post mortem organs, namely sex, age, body weight, body length, and body mass index.

In addition to race and ethnicity, there are other factors that may influence weight post mortem organs, namely sex, age, body weight, body length, and body mass index. Based on that problems that have been described, the author wants to know the average value of post mortem organ weight in autopsy cases that performed at Bhayangkara Pekanbaru Polda Riau Hospital, Indonesia and the average value of post mortem organ weight based on age, gender, and body length.

**Method**

This research is a retrospective descriptive study using secondary data. This research was conducted in the forensic department of the Bhayangkara Pekanbaru Polda Riau Hospital from August 2018 to May 2019.

The population in this study were all of the autopsy data in the forensic section of Bhayangkara Pekanbaru Polda Riau Hospital in 2017-2018. The sample studied in this study was taken from autopsy data in the forensic section at the Bhayangkara Pekanbaru Polda Riau Hospital in 2017-2018. The sample is part of the population that meets the inclusion and exclusion criteria.

Data was collected from the results of postmortem examinations at Bhayangkara Pekanbaru Polda Riau Hospital in 2017-2018 which were included in the inclusion and exclusion criteria. Data that has been obtained from the data collection process will be changed in the form of tables, then the data is processed using computer software.

Based on the characteristics table of the research subjects it is known that there are more men subjects than women subjects, 76.2%. The highest number of cadavers is found in the 21-28 year age group, which is 33.3%. Meanwhile, the highest number of cadavers was found in the 158-165 cm body length group, which was 38.1%.
Based on table 2, it is known that the brain is an organ that has an average value of the heaviest organ weight (1334.29 grams), while the spleen is the lightest organ (113.43 grams) compared to other organs. Comparison of weight between the same organs with different position, such as the lungs and kidneys shows different results, namely the right lung is heavier (370.48 grams) compared to the left lung (311.24 grams), while the right kidney weight (114.00 grams) lighter than the left kidney weight (114.52 grams).

</table>
In this study, it was obtained that most organs increased according to a person’s height. In the 150-157 cm body length group, brain, heart, right lung, left lung, and liver are lighter than the 158-165 cm body length group. Organs in the body length group > 173 cm are heaviest compared to organs in other body length groups.

**Discussion**

In this study, the average value of post mortem organ weight obtained from 21 autopsy cases started from the organ with the heaviest to the lightest organ weight, namely the brain (1334.2 grams), liver (1130.9 grams), right lung (370.4 grams), left lung (311.2 grams), heart (275.3 grams), left kidney (114.5 grams), right kidney (114.0 grams), and spleen (113.4 grams). Research conducted by Yosiati et al. in 2012 obtained the results of the average weight value of organs, namely the brain (1218.9 grams), heart (312.2 grams), right lung (477.4 grams), left lung (417.0 grams), liver (1252.9 grams), spleen (162.8 grams), right kidney (150.6 grams), and left kidney (151.0 grams). The average value of organ weight obtained from research conducted by Yosiati et al. is not much different from the average weight of organs obtained from this study. The results of this study are also not much different from the research conducted by Govender et al. in the Mongoloid race and the Negroid race. The weight of post mortem organs in the colored skin in Mongoloid race obtained by Govender et al., heart (353.6 grams), right lung (613.0 grams), left lung (486.9 grams), liver (1384.3 grams), spleen (120.8 grams), right kidney (125.0 grams), and left kidney (136.3 grams). Meanwhile, the weight of organs in the Negroid race are the heart (319.7 grams), right lung (613.0 grams), left lung (477.4 grams), liver (1252.9 grams), spleen (162.8 grams), right kidney (150.6 grams), and left kidney (151.0 grams). The average value of organ weight obtained from research conducted by Grandmaison et al. in 2000 which showed differences in organ weight in each race. In the study conducted by Peddle and Kirk in 2017 with Negroid race samples also obtained results that are in line with this study, namely the average value of men organs is heavier than women organs. Similarly, research conducted by Yosiati et al who obtained the result of organ weight in men is heavier than organs in women.

Govender et al. in 2017 conducted research on three different races, namely the Negroid race, the Mongoloid race (colored and Indian skin), and the Caucasoid race showed differences in organ weight in each race. In the research of Govender et al. conducted on the Caucasoid race, there is a very clear difference in the value of organ weight when compared with the value of organ weight in this study which examined the Mongoloid race. The value of organ weight in the study of Govender et al. performed on the Caucasoid race that is the heart (433.4 grams), right lung (753.4 grams), left lung (628.7 grams), liver (1843.8 grams), spleen (233.0 grams), right kidney (164.9 grams), as well as the left kidney (179.3 grams). Based on the results of research by Govender et al. carried out in this Caucasian race, it seems clear that the Caucasian race has heavier organs than the Mongoloid race. This is due to differences in the type of food consumed, the amount of water consumed, climatic conditions, and genetic variation.

The average weight of post mortem organs by sex in this study differed between men and women. In men, the average weight of post mortem organs were obtained, namely the brain (1350.0 grams), the heart (284.1 grams), the right lung (385.6 grams), the left lung (320.9 grams), the liver (1130.8 grams), spleen (120.3 grams), right kidney (116.5 grams), and left kidney (115.6 grams). Meanwhile, the average weight of post mortem organs in women are the brain (1284.0 grams), heart (247.0 grams), right lung (322.0 grams), left lung (280.2 grams), liver (1131.0 grams), spleen (91.2 grams), right kidney (105.8 grams), and left kidney (110.8 grams). Based on these results, it is known that almost all men organs have an average weight value that is more compared to women, except that the liver in men has a weight that is almost equal to the weight of the liver in women. This is in line with the research of Kim et al. which shows that the liver has almost the same weight in both men and women. Men have organs heavier than women due to the influence of physical posture, ie men tend to be taller and heavier than women. This physical posture affects the weight of the organ.

In the study conducted by Peddle and Kirk in 2017 with Negroid race samples also obtained results that are in line with this study, namely the average value of men organs is heavier than women organs. Similarly, research conducted by Yosiati et al who obtained the result of organ weight in men is heavier than organs in women.

The results of this study are in line with research conducted by Grandmaison et al. in 2000 which showed that men had heavier organs than women. The weight of men organs are heart (365 grams), right lung (663 grams), left lung (583 grams), liver (1677 grams), spleen (156 grams), right kidney (162 grams), and left kidney (160 gram), while the weight of women organs are the heart (312 grams), right lung (546 grams), left lung (467 grams), liver (1475 grams), spleen (140 grams), right kidney (135 grams), and left kidney (136 grams). Nonetheless, the average value of post mortem organ weight obtained from this study was very different from
the study conducted by Grandmaison et al., because the average value of organ weight obtained from the study of Grandmaison et al. is heavier than the average value of organ weight in this study. This is likely due to the differences in the sample races studied.

In this study, the weight of the heart organ in the 21-28 year age group was not much different from the weight value of the heart organ in the 21-30 year age group obtained by Deepika et al., but there was a considerable difference in the value of the weight of the heart organ. Deepika et al. obtained 280 grams for heart weight and 1311.03 for liver weight, while this study obtained a weight value of 214.86 for the heart and 1020.29 grams for the liver weight. Meanwhile, the value of organ weight in the age group 37-44 years and 45-52 years in this study were not much different from the weight value of organs obtained from studies conducted by Sheikhzadai et al. in India in 2009.12

In this study, it is known that the value of organ weight has increased if the weight of organs in the age group 21-28 years compared with the age group 45-52 years, then experienced a decrease in organ weight in the age group > 52 years. The results of this study are in line with organ weight values contained in Knight’s Forensic Pathology, which shows that the weight of organs in the youngest age group is heavier than the oldest age.13 This is due to the reduced amount of potassium in the aging process. Potassium is a component that plays a role in the body’s metabolic function, so it is an indirect indicator of muscle mass. Reduced muscle mass causes reduced organ mass.14,15

In addition, almost all of the organs that studied had the heaviest organ weights in the age group of 45-52 years, except for the brains that had the maximum weight in the 29-36 year of age group. The results of this study are in line with the results of research conducted by Singh et al. in 2004. Research Singh et al. states that the brain and liver have a maximum weight in their 20s and 40s compared to other ages, while the lungs and spleen have a maximum weight at 45-50 years of age.16 Research conducted by Kim et al. also in line with the results of this study, where the weight of the kidneys and liver reaches a maximum weight in their 40s.10 The heart becomes heavier with age and most organs (spleen, liver, and kidneys) are heavier in individuals in their 40s.17 After reaching maximum weight, the weight of the organs will decrease due to the aging process which can cause the size of these organs to decrease. In the heart, when middle age, blood pressure will increase, so that the heart’s work increases and causes an increase in heart mass.14 Meanwhile, brain weight tends to increase until adulthood in line with the growth of neurons and glia cells as its supporters, then after through adulthood the brain’s weight has decreased.17

In this study, it was found that almost the entire weight of the organ increased in accordance with an increase in a person’s body length, except in the body length group of 166-173 cm. In the 150-157 cm body length group, the weight of the brain, heart, right lung, left lung and liver organs is lighter than the 158-165 cm body length group. In addition, in this study it appears that all the organs studied have maximum weight in the highest body length group, which is > 173 cm. Based on the results obtained from this study it can be interpreted that people with shorter bodies tend to have lighter organ weights than people with higher bodies. This is because the growth of body organs goes hand in hand with human physical growth.18 Body proportions will determine the body’s metabolism, so the size of the organs must adjust to body proportions.8

The results of this study are in line with research conducted by Sheikhzadai et al. in 2009, which found that the weight of organs in both men and women increased with increasing body length. Organs in the body length group 176-192 cm heavier than the body length group 166-175 cm and organs in the body length group 166-175 cm heavier than weight than organs in the body length group 151-165.12

Organ weight in this study in each group of body length has a weight value that is very different from research conducted by Grandmaison et al. 2001 in the Caucasian race. In this study, the organ weight of body length groups of 166-173 cm namely heart (257.1 grams), right lung (352.8 grams), left lung (312.4 grams), liver (1041.0 grams), spleen (148.4 grams), right kidney (115.7 grams), and left kidney (120.1 grams). The weight of organs at body length intervals of 165-175 cm, including the heart (360 grams), right lung (625 grams), left lung (551 grams), liver (1637 grams), spleen (150 grams), right kidney (157 grams), and the left kidney (175 grams) had very large differences in organ weight and organ weights of 166-173 cm in the length of the body in this study. This very large difference in organ weight values is likely due to differences in race in the sample studied, ie the race studied in this study is the Mongoloid race, while the race in the study of
Grandmaison et al. is a Caucasoid race, because racial differences cause differences in genetic variation. In addition, the Caucasian race also has a longer body length interval than the Mongoloid race.\textsuperscript{11}

**Conclusion**

Based on research that has been done at Bhayangkara Pekanbaru Polda Riau Hospital, the average value of post mortem organ weight, namely the brain (1334.29 grams), liver (1130.90 grams), right lung (370.48 grams), left lung (311.24 grams), heart (275.33 grams), left kidney (114.52 grams), right kidney (114.00 grams), and spleen (113.43 grams). The organs in men are heavier than in women, except the liver. Organ weight has decreased in old age. People with shorter bodies tend to have lighter organs than taller people.

Awareness of Senior and Specialist Dental Student Toward the Importance of Cost Analysis and Business Practice Management: Cross Sectional Study from a Public University in Indonesia

Anisa Nur Halimah, Aulia Ramadhani

1Graduate Student of Dental Health Science, Department Dental Public Health, Faculty of Dental Medicine, Universitas Airlangga, 2 Staff of Dental Public Health Department, Faculty of Dental Medicine, Universitas Airlangga

Abstract

Background: Dental students not only develop practical skills but also management skills. Dental students must be able to understand how to determine cost analysis, which is a measure of the relationship between costs and output. Objective: to determine the awareness of senior dental student toward the importance of cost analysis and business practice management. Materials and Method: A cross-sectional study was conducted using a questionnaire with closed-ended questions. The study sample included 119 participants in Airlangga Dental College, Surabaya. Statistical analysis was performed by descriptive statistical analysis and chi square tests. Results: One hundred nineteen questioners were returned and analyzed. BDS 95 students while the specialist was 24 students. It was seen that there are 79% of specialist students who have a good level of confidence while in BDS students only 51% have a good level of confidence. BDS students (42%) and specialist students (33%) indicated that their knowledge was sufficient about the costs of practice management or business management. Conclusion: students have confidence in clinical skills but are not quite sure about practice management knowledge. Students are also interested in increasing the range of knowledge about business and practice management.

Keywords: Dental students, awareness, practice management, private practice, cost analysis.

Introduction

Dental students are challenged in the rapid development of knowledge in their fields, this shows the importance of graduate students not only preparing practical knowledge and skills but also practical skills and management1. Houlberg2 in the study stated that there was inadequate training in practice management and suggested for the future dentistry curriculum to discuss practice management training as an important component in the curriculum. They also should be prepared to have competency in business of practice management to improve their readiness and confidence as a dentist3.

One of the important things that needs to be understood by dental student is how to determine cost analysis. In economics, the Cost Analysis refers to the measure of the cost – output relationship4,5. In other words, the cost analysis is concerned with determining money value of inputs (labor, raw material)6, called as the overall cost of production which helps in deciding the optimum level of production7–9. In the study that conducted by Manakil et al10, graduate students feel they do not have enough knowledge in business management/practice costs, including administration; advertisement; equipment costs; dental consumables; and maintenance of infrastructure11; equipment overhead; ingredient12;
staff\textsuperscript{13}, etc. So it is important to calculate the value of the dental health treatment cost and balancing the income and outcome according to the performance of dentist and in accordance with the patient to produce an effective cost that could benefit the dentist and still affordable to patient\textsuperscript{14}.

Awareness is the ability to directly know and perceive, to feel, or to be aware of events. More broadly, it is the state of being conscious of something. Another definition describes it as a state where a subject is aware of some information when that information is directly available to bring to bear in the direction of a wide range of behavioral processes\textsuperscript{15}. The states of awareness are also associated with the states of experience so that the structure represented in awareness is mirrored in the structure of experience\textsuperscript{16}. This study is conducted to determine the awareness of senior dental student toward the importance of cost analysis and business practice management.

**Material and Method**

This survey is a modification of work\textsuperscript{3} and is designed to study fiscal status; trust; learning preferences; career path; overall knowledge; and integration or management of dental practices among dentist graduates. The questionnaire used in this descriptive cross-sectional study was a closed-ended questionnaire. The subject of this study are the senior undergraduate dental students from fourth and fifth year and specialist students at Airlangga dental college, Surabaya. The total number of sample are 119 students. The survey will be conducted distributed and confidential through a third party, to maintain anonymity.

The questionnaire was divided into four sections: the first section collected personal data such as age, gender and student income support throughout the program; the second part evaluates the confidence in the skills gained during the dental education program and the confidence to maintain a general private practice. The responses are measured on a five-point Likert scale with “1” being high confidence and “5” is low confidence. This section looks at perceived trust in operating skills, integrating into a dental practice, patient management skills, and business practice management skills.

The third part of the survey is analyzing student demographic work preferences such as private or public sector work, rural or city-based practices, the area of specialization of choice for practice, and the preference for establishing an independent practice. The fourth part is assessing student awareness in cost analysis and managing an independent practice. Studies evaluate students perception about the importance of the determining unit cost for dental treatment.

**Result**

The survey was conducted on 140 students, among a total of 140 questionnaires were distributed of which 119 were obtained back. The details of participants are according to the age, gender, qualification and years of experience as shown in (Table 1). Out of the 119 students, (72.3%) were females and (27.3%) were male. It was seen that most of the individuals were undergoing their undergraduate in dental medicine (82.6%) while the specialist was (17.4%). Most of the subjects fell under the age group of 21-23 years (64.7%).

There are 79% of specialist students who have a good level of confidence while in BDS students only 51% have a good level of confidence. Significant P value (0.036) had observed in question about Major cost in running a private practice with gender in undergraduate student. Another significant P value (0.000) was observed in question about how to determine the rates for dental treatment with age.

In BDS students 55% of respondents chose to practice together, this result is different from specialist students whose 58% of respondents choose to open private practice. Almost all respondents, both specialist students and BDS students agree that calculating costs
first before setting rates is important. And almost most of the respondents (BDS students: 78% and specialist students: 75%) from both groups also agreed that the way to set the right dental treatment rates is to calculate the cost of materials and tools needed for each treatment. In BDS students, 42% of respondents felt that the knowledge provided was insufficient. For specialist students, the biggest answer is in the ordinary choice of 42%.

For specialist students, significant P value had observed in some question. The first between level of confidence and age (0.043), then the sort of practice that student visualize once graduate with age (0.050). Next is the strongest experience with gender (0.002) and how to determine rates for dental treatment with gender (0.050). The last one is confidence on practice management and finance with years of practice (0.024).

**Discussion**

This survey questionnaire has been modified from previous studies and broader topics such as student financial support, preferential career paths after graduation, awareness of cost analysis, and business practice management. Self-perceived confidence is used to assess students’ preparedness for practice. From the results of this questionnaire, it can be seen that specialist students have a greater level of confidence when compared to undergraduate students. High self-confidence can be influenced by the length of experience in practice. The longer the practice, the more cases that will be faced, thus increase the confidence in the dental practice.

Having personal practices is often projected as a symbol of social success in dentistry field. However, after graduating, many students from BDS want to be employed or practice together. There is a significant difference between the kinds of practice that specialist student visualizes once graduate with age (0.050). It is believed that with the increasing age of someone, the practice experience will increase with the more dental cases they are facing thus making more experienced dentist inclined to open their private practice.

For BDS students, mentoring following graduation was considered very important. Preference in geography practices shows city practices as the first choice without significant differences between genders, age or years of experience in their choice. Dental graduates are not only required to be proficient in the patient care but must also be competent in business management or practice.

It was also reported from previous research that students felt their integration into general dentistry could be facilitated by more time for the clinical environment and more knowledge in practice management. Houlberg, report that there is inadequate training in practice management and suggest that for future dental curriculum it should discuss practice management training as an important component in a curriculum.

In the study mentioned that BDS students (42%) and specialist students (33%) felt they did not have enough knowledge about the costs of business management or practice, such as administration; advertisement; dental consumables; infrastructure equipment and maintenance costs; overhead costs of equipment; ingredients; staffing; etc. However, students’ assumptions about high-cost staffing and management in practice are wrong, they prefer to choose equipment and infrastructure as the biggest costs in carrying out dental practices.

**Conclusion**

This study shows that students feel confident about clinical skills that are developed but are not quite sure about management practice knowledge. Students are also interested in increasing the scope of knowledge about business and practice management. Improving students’ work skills after graduation is a challenge in the increasingly competitive and competitive job market; the curriculum must consider the integration of clinical skills and knowledge of practice management skills.

**Acknowledgment:** The authors acknowledge and thank all senior undergraduate and specialist dental students for participating in the study.

The Relationship of Self-Motivation in Diabetes Mellitus Management with Blood Sugar Levels of Diabetes Mellitus Type II Clients

Berthiana T
Lecturer on Department of Nursing, Polytechnic of Health, Ministry of Health, Palangka Raya Indonesia

Abstract

The purpose of this study was to determine the relationship of self-motivation to diabetes mellitus (DM) management with blood sugar levels of DM type ii clients in Outpatient Polyclinic Installation in Dr. Doris Sylvanus Hospital Palangka Raya. The research uses descriptive correlational with cross sectional research design. The sampling technique uses purposive sampling. The respondents of this study were 40 people. Data collection using a questionnaire and recording the value of blood sugar from the results of laboratory tests in the client report status. Statistical tests use the Chi-Square test. The results of statistical analysis revealed that self-motivation on clients was in the unfavorable category of 32 people (80%), blood sugar levels were in the high category of 26 people (65%) with a p-value of 0.001 (p <0.05). There is a significant relationship between self-motivation to DM management with blood sugar levels of DM type II clients in the Outpatient Polyclinic Installation of Dr. Doris Sylvanus Hospital Palangka Raya.

Keywords: self-motivation, blood sugar level, diabetes mellitus

Introduction

Diabetes mellitus is a group of metabolic diseases with characteristic hyperglycemia that occurs due to abnormal insulin secretion, insulin action or both. Based on a preliminary study in the medical record section of Dr. Doris Sylvanus Hospital Palangka Raya which was conducted on January 24, 2018, obtained data on the number of patients with Type II DM in 2016 the number of DM cases was 4111 cases with an average monthly of 343 cases and increased to 4942 cases in 2017 with an average monthly to 412 cases. The increase in cases of Type II DM is accompanied by an increase in the occurrence of cases of Type II DM complications, based on the medical record of complications that often occur is hyperglycemia which is the forerunner to the growth of various other diseases to the point of death. If hyperglycemia in people with Type II diabetes can be controlled properly, then all these chronic complications can be prevented, at least inhibited.

The goal of diabetes mellitus management for the short term is to eliminate complaints/symptoms and maintain a sense of comfort and health, while in the long run to prevent complications, both macroangiopathy and neuropathy with the ultimate goal of reducing diabetes morbidity and mortality.

Management of diabetes mellitus with 5 main pillars, namely first, meal planning by making dietary arrangements based on the nutritional status of diabetes. Second, physical exercise so that muscle contraction when doing physical exercise will make the membrane permeability to glucose increase. Third, pharmacological therapy. Fourth, counseling. The fifth routine and independent monitoring of blood sugar with sugar control can reduce the number of complications in patients with diabetes mellitus.

DM management problems that often occur in Dr. Doris Sylvanus Hospital Palangka Raya based on the results of a survey on January 24, 2018 in people with DM is the lack of self-motivation related to carrying out the four pillars of DM. One of the factors that influence
a person’s behavior in improving and maintaining their health is motivation, including in managing DM regularly as an effort to prevent complications in diabetes mellitus patients. One of the DM management is regular blood sugar control, which is one of the treatments for diabetes mellitus patients to support stable blood sugar and prevent complications, therefore there is a need for self-motivation in carrying out the examination and management of diabetes mellitus.

**Materials and Method**

This type of research is quantitative in the form of descriptive correlation which is research that aims to reveal the correlative relationship between the independent variables and the dependent variable, with the cross-sectional approach which is a study to study the dynamics of the correlation between factors and risks with effects by approaching, observing or collecting data at once in one when.

The population in this study is type II diabetes mellitus clients who seek treatment at the Internal Medicine Outpatient Clinic of Dr. Doris Sylvanus Hospital Palangka Raya. The sample used in this study with a sampling technique using purposive sampling with a total sampling of 40 respondents. This research was conducted on April 20-May 12, 2018. The time was used to collect data through a questionnaire that was filled in completely and returned to the researcher.

**Findings and Discussion**

</table>

Chi-square correlation test results obtained p-value of 0.001 (p <0.005). The results showed that only 8 people (20%) were good in self-motivation and had blood sugar levels in the normal range of 7 people (87.5%) while respondents in the good self-motivation category with high blood sugar levels were 1 person (12.5%). While the remaining 32 people (80%) with poor self-motivation category, where most of the blood sugar levels in the high category are as many as 25 people (78.1%) and as many as 7 respondents (21.9%) with self-motivation not good to have a value of blood sugar levels within normal limits. The results of the analysis of the motivational questionnaire items found that the highest score on statement number 6 is the statement “I am happy if my blood sugar is in the normal range” with a score of 138 with 19 answer choices answered “agree” and 21 respondents answered “strongly agree”. This means that the majority of respondents actually feel happy and want their sugar levels within the normal range. While the analysis of motivation questionnaire items with the lowest score on statement number 2 is the
statement “I am challenged to undergo treatment” with a score of 99. It shows that most respondents feel less challenged in undergoing treatment so that is one of the factors that can affect client motivation.

Odd Ratio (OR) value is 25.00, that is OR> 1, this shows that a person with DM with low self-motivation has a 25.00-fold risk of having uncontrolled blood sugar levels, the lowest has a risk of 2,617 times and the greatest risk is 238,787 times that of having an uncontrolled blood sugar level compared to someone with good self-motivation. The results of this study indicate the less motivation of clients in managing DM the more uncontrolled or high blood sugar levels. From the results of the study the researchers concluded that the self-motivation of Type II DM clients in the Outpatient Clinic of the Internal Medicine Polyclinic of Dr. Doris Sylvanus Hospital Palangka Raya is in the unfavorable category. This is influenced by several factors such as age, gender, level of education, occupation, marital status, and length of time with DM.

The results showed that the majority of respondents were early elderly, aged between 46-55 years. As a person ages, changes in function and composition in the body can affect one’s ability to carry out activities including one’s motivation. The results showed that the majority of respondents who came to control the disease in poly disease in the female sex. Gender also influences a person’s motivation and behavior. This is because women tend to be more obedient to the rules than men.

Most of the respondents studied had a high school education level. The level of education is an indicator that someone has taken formal education in certain fields. The higher the level of education a person will usually have more knowledge including about health and the presence of this knowledge will affect someone to have awareness in maintaining their health.

People who work tend to have less time to visit health facilities so that there will be less time available and opportunities for treatment. Whereas in this study the results were obtained that the majority of respondents were housewives/not working which means that respondents had plenty of time to visit health facilities including managing DM.

The marital status of most respondents is married and has a spouse. This is one of the factors that can affect a person’s motivation, including respondents in managing DM, because respondents get support from their husband or wife. The length of time with DM is also one of the factors that influence a person’s willingness to manage DM. The longer a person with DM, the better the coping and self-efficacy of a person and the more experienced in managing the disease.

This study is in accordance with previous research conducted by Yusi Ariani (2011) about the Relationship between Motivation and Self-Efficacy of Type II DM Patients in the Context of Nursing Care at H. Adam Malik Hospital Medan, stated that with the results of 45 respondents had poor motivation in conducting self-efficacy. Motivation the majority of patients lack self-care so it is advisable for nurses and physicians to increase patient motivation in the context of DM by increasing patient autonomy intrinsically.

Social environment, family, and health workers influence in increasing motivation and changes in patient behavior. Someone who has the support of the family, and surrounding and support from health workers who are not pressing, controlling tight or authoritarian will increase motivation in checking blood sugar levels.

Conclusion

There is a significant relationship between self-motivation and blood sugar levels of DM Type II clients in the Outpatient Poly clinic Installation of Dr. Doris Sylvanus Hospital Palangka Raya

Ethical Clearance: This research has gone ethical feasibility testing by the Ethical Research Commission of the Poltechnic of Health, Ministry of Health, Palangka Raya.

Morphological Changes in Ovaries in Rats with Experimental Polycystic Ovary

Chinara S. Zhylkichieva¹, Konstantin R. Nifontov²

¹Associate Professor at the Department of Pathology, International School of Medicine, 720054, 1F, Intergelpo Str., Bishkek, Kyrgyz Republic, ²Associate Professor at the Department of Internal Noncommunicable Diseases, Pharmacology and Obstetrics named after Professor G.P. Serdtsev, Yakut State Agricultural Academy, 677007, 3, Sergelyakhskoe Highway 3 km, Yakutsk, Russian Federation

Abstract

Polycystic ovary syndrome is one of the important causes of infertility, metabolic syndrome. Complications of PCOS are a serious health hazard. The relevance of the study of morphological changes in the ovaries in rats is justified by the need to improve the treatment of PCOS. The experiment consisted in the fact that rats from the experimental group received testosterone for 7 days and were in constant artificial daylight for 60 days. As a result of histological examination of the ovaries in this group, multiple cysts, foci of fibrosis were found. Vaginal smears in rats from the experimental and control groups were collected and compared. The extracted ovaries of rats of the experimental and control groups were compared, the differences in colour according to Van Gieson X 100, haematoxylin-eosin X 40, haematoxylin-eosin X 100, B-G X 100 were analysed. Studies indicated oestrous cycle disturbance, hormonal changes in rats with experimental polycystic. The work can serve as material for further studies aimed at identifying fast and easily accessible methods for the diagnosis of metabolic syndrome predictors.

Key words: morphology, endocrine infertility, experimental and control groups, fibrosis, cyst.
the syndrome has a polygenic nature.\textsuperscript{12}

Epi- and ontogenetic factors ("unwanted" genes are activated by the influence of the external environment, for example, folate deficiency), as previously mentioned, account for one fifth of all cases of the disease. Sometimes this happens even in utero (due to adverse environmental factors, micronutrient deficiency). Girls born to mothers with PCOS have more follicles (in diameter) from birth than their peers, and a detailed examination during the pre-pubertal period reveals moderate metabolic disturbances. The syndrome manifests during puberty, when the synthesis of androgens in the body increases.\textsuperscript{13}

The aim of our work was to study the morphological changes in female rats with experimental polycystic.

**Materials and Method**

For the experiment, sexually mature female Wistar rats were taken. Experimental animals were divided into the following groups: control (n = 20) – group I, experimental (n = 25) – group II with experimental polycystic. Rats from the experimental group received testosterone intramuscularly (400 mg) for 7 days and were kept for 60 days under constant artificial daylight. Vaginal swabs were taken daily for 30 days to study the oestrous cycle. Stained using Giemsa method. Rectal temperature was measured daily.

The cytological evaluation of rat vaginal smears was performed according to the classification of Geist, Salmon and 2 indices were determined: Maturation Index (MI) and the kariopycnotic index (KPI). MI is the percentage of three types of epithelial cells – basal/parabasal, intermediate and superficial. KPI is the percentage of surface cells with a pycnotic nucleus to all other cells. An increase in the number of surface cells with a pycnotic nucleus correlates with increased oestrogen stimulation. Blood was also taken at the end of the experiment (on day 60) to determine the lipid spectrum and the level of hormones.\textsuperscript{14,15} Testosterone, oestradiol, FSH and LH were determined, including the lipid spectrum (atherogenic index, low density lipoproteins, high density lipoproteins, triglycerides and total cholesterol) in the Express Plus laboratory in Bishkek.\textsuperscript{16,17}

Animals were taken out of the experiment with an overdose of diethyl ether and ovaries were extracted for further histological examination. Morphological research was conducted on the basis of Republican Anatomic-Pathological Bureau. The material was fixed in a solution of 10\% formalin, embedded in paraffin, histological sections were made and stained with haematoxylin and eosin, also according to Van Gieson. Statistical processing of the obtained data was performed using the Statist software package.

**Results and Discussion**

In the control group, the results of histological examination of the ovaries display the normal structures of the ovaries with a maturing egg, the absence of zones of haemorrhage, fibrosis and the formation of cysts (Figure 1A). In the group with experimental polycystic disease, multiple cysts and foci of fibrosis are found (Figure 1B).

![Figure 1. A – rat ovary from the control group, Van Gieson stain X 100; B – rat ovary from the experimental group, haematoxylin-eosin stain X 40](image-url)
Figure 2B and 2C display a dense protein coating, which is characteristic of PCOS when stained according to Van Gieson. This indicates the absence of ovulation and the formation of multiple cysts in both ovaries.

Table 1 reflects changes in hormone levels. In the group with experimental polycystic disease, there is an increase in the level of testosterone, oestradiol and LH (luteinizing hormone) compared with the control, a decrease in the level of FSH (follicle-stimulating hormone).

Table 1. Hormone level changes

Note: *- P<0.05 significantly with respect to the control group

There are many squamous cells in the vaginal smear of rats from the control group, which indicates the presence of ovulation and good oestrogen saturation (Figure 3A). Parabasal cells and white blood cells appear in the stage of meta-oestrus, that is, the epithelium is renewed and their maturation begins (Figure 3B). A large number of leukocytes was found in the di-oestrous phase and epithelial cells in the pro-oestrous phase increase in size, the cytoplasm becomes more transparent, and the nucleus begins to decrease under the influence of oestrogens (Figure 3C and 3D).
Figures 3A, 3B, 3C show oestrus, meta-oestrus, and di-oestrus stages in rats with experimental polycystic disease wherein a large number of leukocytes, parabasal cells and only a small number of epithelial cells were detected. Cell maturation does not occur, which indicates reduced oestrogen stimulation and anovulation. Impaired epithelial cell maturation due to excess testosterone is a major feature of polycystic ovary. In vaginal smears in rats from the experimental group, no pycnotic nuclei and squamous cells were found.

Conclusions

Despite intensive studies in the field of PCOS, the mechanisms underlying the formation of this pathology are still understudied and debatable, which indicates a multifactorial aetiology and the lack of a single opinion on this pathology, which is very difficult for diagnosis and treatment. In women with menstrual irregularities, metabolic disorders and an increase in low-density lipoproteins (LDL) are significantly more common. These lipid abnormalities, namely an increase in LDL, suggest that women with PCOS have a risk of developing cardiovascular disorders of up to 70%. Furthermore, PCOS is associated with increased sympathicotonia, which is associated with cardiovascular complications. Scientists at experimental PCOS have demonstrated that low-frequency electric acupuncture has a significant effect in rats with PCOS – it reduces heart rate and sympathetic activity.

However, according to other authors, obesity, insulin resistance, impaired glucose tolerance and dyslipidaemia are not pathognomonic signs of PCOS. Overweight is of primary importance in the formation of metabolic disorders, and against the background of endocrine changes characteristic of PCOS, disturbances in carbohydrate and lipid metabolism are aggravated. Violation of lipid and carbohydrate metabolism plays an important part in the pathogenesis of PCOS. A carbohydrate diet can activate lipogenesis in the liver and activate the enzymes involved in lipogenesis, while starvation works the opposite. Our studies indicated a violation of the oestrous cycle in animals with experimental polycystic disease, as evidenced by a change in vaginal epithelial cells.

Our studies demonstrated hormonal changes upon violation of the oestrous cycle in animals with experimental polycystosis, which is confirmed by the morphological change in the ovaries. Further studies aimed at identifying fast and readily available diagnostic methods for the predictors of metabolic syndrome underlying PCOS are necessary.

The Correlation between Myelulcepidase Levels and the Event of the Acute Coronary Syndrome

Citra Indah Setyaningrum1, Jusak Nugraha1, Muhammad Aminuddin1
1Research Scholar in Dr.Soetomo Teaching Hospital, Universitas Airlangga, Surabaya. 60285, Indonesia, 1Lecture in Department of Clinical Pathology, Faculty of Medicine, Dr.Soetomo Teaching Hospital, Universitas Airlangga, Surabaya. 60285, Indonesia

Abstract

Background: Acute coronary syndrome (ACS) is a collection of symptoms due to cardiac blood flow disorders consisting of acute myocardial infarction (AMI) with increased ST segment (STEMI), AMI without increased ST segment (NSTEMI) and unstable angina pectoris (UA). Myeloperoxidase (MPO) is an enzyme that plays a role in the destabilization and rupture of plaque that rises earlier within 2 hours after AMI attack so it can be used as an early marker of ACS without depending on evidence of myocardial necrosis. So, the purpose of this study is to determine the relationship between MPO levels and ACS events.

Methods: This study is using quantitative method. Research sample was 40 patients serum with the main complaint of chest pain that fulfilled the inclusion criteria who came to the emergency unit of Dr.Soetomo General Hospital Surabaya. The blood samples were examined for MPO with MPO kit from Quanticine (R & D system) using ELISA method. The diagnostic value obtained from the calculation with the 2x2 table.

Results: Patients with chest pain were 27 persons (67.5%), while non-ACS patients were 13 persons (32.5%). There were significant differences in MPO levels between the STA (STEMI, NSTEMI, UA) groups of 986.48 ng/ml and non-ACS 381.08 ng/ml (p = 0.002). Diagnostic sensitivity was 88.88%, diagnostic specificity 69.23%, negative predictive value 75% and positive predictive value 85.71%. The correlation coefficient between MPO and ACS content is r = 0.45 with p = 0.003.

Conclusion: There was a correlation between MPO levels and the incidence of ACS. The higher the MPO level the higher the incidence of ACS.

Keywords: sindroma coroner, infark miokard akut, unstable angina, nekrosis miokard.

Introduction

Cardiovascular disease is the first cause of death in the world and in Europe. Acute Coronary Syndrome (ACS) is one of the manifestations of coronary artery disease that is still a major health problem in the world. The American Heart Association (AHA) Statistics Data, in 2005 the number of patients undergoing medical treatment in the United States due to ACS is nearly one point five million people with one point one million people (80%) indicate instances of unstable angina (UA) or infarction myocardial infarction without ST-segment elevation (NSTEMI), whereas 20% of cases recorded suffer from myocardial infarction with increasing ST segment (STEMI)1.

The results from the Jakarta cardiovascular study in 2008 recorded a prevalence of overall myocardial infarction reaching five-point twenty-five percent. This figure is far above the prevalence of myocardial infarction in 2000, i.e., only one point two percent. This supports the Ministry of Health’s survey results showing that the prevalence of Coronary Heart Disease (CHD) in Indonesia is increasing from every year2.
The American College Cardiology (ACC) in its 2009 consensus states that the diagnosis of ACS if it meets at least two of the three characteristics is the presence of typical clinical symptoms, increased or decreased cardiac markers (Creatinine Kinase – Myocardial Band (CKMB), troponin T or I serum) and typical Electrocardiogram (ECG) patterns\(^3,4\). Acute coronary syndrome (ACS) consists of acute myocardial infarction (AMI) with increased ST-segment (STEMI), IMA without increasing ST-segment (NSTEMI) and unstable angina pectoris (UA). Clinical presentation is different but has a pathophysiological similarity. If there is NSTEMI increase in cardiac marker but without an increase in ST-segment, if there is an increase STEMI in ST-segment accompanied by elevated cardiac markers and is called UA when no increase in ST segment or elevated cardiac marker \(^5,6\).

The long-lasting troponin-inducing pattern may make troponin a good marker in detecting myocardial necrosis, but the limitation of its sensitivity makes it difficult to diagnose ACS at an early stage so that there is a need for a marker that can increase rapidly after the onset of clinical symptoms can speed up diagnosis and appropriate therapy in patients with an alleged ACS\(^7\).

Oxidative stress and inflammation play an important role in the pathogenesis of destabilization of the coronary arteries which refers to the onset of ACS. Macrophage and neutrophil infiltration play a role in the transformation of stable coronary artery plaques into unstable lesions. Recently, there is an increasing interest from researchers to MPO which is a proinflammatory enzyme that plays a role in the occurrence of plaque rupture. This MPO can be measured by using peripheral blood\(^8\).

The relationship between MPO levels and the incidence of ACS has not been widely studied, especially in Indonesia, the commercial kit of MPO is not yet widely available in the market so based on some of the above descriptions it is necessary to conduct research in RSUD dr. Soetomo Surabaya which aims to determine the relationship between MPO levels and the incidence of ACS so that handling and prevention can be done earlier to prevent fatal complications.

**Method**

This research was used observational analytic with the cross-sectional design. The study was conducted for 6 months starting from May to October 2013. The location of the research was in the emergency room of Dr. Soetomo General Hospital for the selection and sampling of blood and Department or Installation of Clinical Pathology Faculty of Medicine, Universitas Airlangga R & D section for serum separation and MPO examination.

The samples used were patients with chest pain complaints less than six hours with an alleged ACS that meets the criteria of sample acceptance. Inclusion criteria include patients with chest pain with less than 6 hours of onset suspected ACS, aged \(\geq 30\) years. Laboratory procedures in the form of inspection of MPO content of enzyme-linked immunosorbent assay (ELISA) method from Quanticine.

MPO examination sample is serum. The patient’s blood is taken and inserted into a yellow vacutainer containing serum separator without anticoagulation. The blood is then allowed to freeze for one to two hours at room temperature (18-250C). The blood is then separated from the serum to avoid hemolysis by centrifugation 3000 rpm for 15 minutes in the vacutainer tube. The obtained serum is then transferred into the aliquot tube and stored at -200C.

**Results**

All data were statistically tested using descriptive and inferential statistical analysis. Descriptive statistics for the distribution and frequency of sample characteristics is needed. Inferential statistics using Pearson correlation test to determine the relationship between MPO levels with the incidence of ACS and Kruskal Wallis test for the analysis of MPO levels between groups that all use the computer program SPSS 17.0 (SPSS, Inc. Chicago IL) Diagnostic value of MPO concentration as an ACS marker in Dr. Soetomo General Hospital Surabaya obtained from the calculation formula using 2x2 table to calculate the sensitivity, specificity, positive predictive value and negative predictive value.

Patients suspected of heart disease were 60 people, while those who meet the criteria of acceptance of the sample amounted to 40 people. The mean age of the sample was 57 years with an age range of between 36 and 79 years. Most of the subjects were male sex by 65%, where most of ACS patients had male sex 74.07% while for female patients only 25.93%.

Non-ACS patients of male and female were almost comparable, 46.15% and 53.85%. ACS patients were
on average 56 years of age with a 50-59 year age range of 52.5%, while non-ACS patients were on average 59 years old. Male subjects had an age range of 39 to 79 years, while female subjects had an age range of 47 to 78 years. There was an age difference between ACS and non-ACS patients but the difference was not significant (p = 0.333). Patients with chest pain suffering from ACS in this study were 27 people (67.5%) while for non-ACS chest pain patients only 13 people (32.5%). The highest number of ACS patients were STEMI, NSTEMI, and UA, which was 62.96%, 25.92% and 11.11%.

**Distribution of ACS Risk Factors**

The highest risk factors for ACS in this study were dyslipidemia (indicated by elevated triglyceride levels of 19 patients), hypertension in 18 patients, diabetes mellitus in 15 patients and smoking of 12 patients. Non-ACS patients with dyslipidemia were also the highest (12 patients) of all non-ACS patients followed by hypertension, diabetes mellitus, and smoking. ACS and non-ACS patients of the female sex all had HDL cholesterol levels <50 mg/dl. HDL cholesterol levels <40 mg / dl in male patients found a difference between ACS and non-ACS patients 85% and 50%. The results of statistical analysis showed that the RR value of the four risk factors for ACS was not significant.

Fat profile data in this study showed a significant difference in mean total cholesterol and HDL cholesterol levels among ACS patients with non-ACS (p = 0.019 and p = 0.001). Levels of triglycerides and LDL cholesterol were found to differ between ACS and non-ACS patients but the difference was not significant (p = 0.871 and p = 0.613) The number of leukocytes between the two groups in this study was significantly different with the error rate of 5% obtained significance value of 0.001 (p = 0.001).

**The Inspection Results Standard Content of MPO Solution**

The absorbance data of the standard solution content of MPO with dilution of hundred times obtained by ELISA method after the reading then the absorbance value obtained is plotted in the form of points and drawn a straight line so that obtained linear line forming a standard curve.

**The Results of MPO Levels**

There was a significant difference of MPO levels between groups of ACS patients (STEMI, NSTEMI, UA) and non-ACS using Kruskal Wallis test with 5% error rate obtained significance value p = 0.002 (Table 1). In contrast, there was no significant difference between patients STEMI, NSTEMI and UA with 5% error rate obtained significance value of 0.698 (p = 0.698). The mean values of MPO levels between groups were between ACS and non-ACS patients of 986.48 ng/ml and 381.08 ng/ml.

Calculation results based on table 2x2 with cut off of MPO350 ng/ml obtained the diagnostic sensitivity of 88.88%, diagnostic specificity 69.23%, negative predictive value 75% and positive predictive value 85.71%

Discussion

Based on the results of this study was in accordance with previous research which states that the highest number of ACS sufferers in male aged 37 to 66 years. The study also obtained that the age of female to suffer from ACS was nearly 10 years older than men. This was because of pre-menopausal women being protected by estrogen hormones that are thought to play a role in maintaining the integrity of vascular endothelium, increasing insulin sensitivity and contributing to maintaining an ideal fat profile through decreased LDL and increased HDL.

STEMI patients have typical clinical symptoms so that in this study the number of events was ranked highest. Researchers previously stated in STEMI there is a total thrombus clogged coronary arteries, so clinical symptoms look more striking compared with NSTEMI and UA that only clog the coronary artery in part so that the resulting clinical symptoms are also not too severe than STEMI. This was what drives patients to get to the hospital so that hospital events tend to be higher for STEMI than NSTEMI and UA.

High blood glucose levels in ACS patients are associated with high levels of free fatty acids, insulin resistance and impaired glucose use by cardiac muscle, thus increasing potential oxygen consumption in exacerbating the incidence of ischemia and cardiac infarction, leading to organ failure and death. This study shows that elevated cholesterol levels are directly proportional to an increase in the incidence of ACS. Any decrease of 4 mg% of HDL cholesterol, will increase the risk of AMI by 10%.

The results of leukocyte count analysis showed significant differences in the previous study which stated that there was a significant increase in leukocyte levels of ACS and non-ACS patients. Patients with elevated levels of leukocytes have a higher risk of death and recurrent AMI. Previous studies have suggested that ACS patients with negative troponin levels of 25% have positive MPO levels. MPO was also said to be more sensitive because of its increased levels in STEMI and NSTEMI patients with negative troponin levels in the first hour compared with UA patients. This supports the theory that MPO increases within two hours and reaches peak levels within 9-12 hours after symptoms in AMI patients.

Other researchers also stated the same thing that the MPO rises earlier between the hour of zero to the third hour in patients with chest pain compared with the new troponin increased between the fourth hour to the sixth hour after complaints of chest pain. MPO along with several other enzymes such as lipoxygenase will initiate lipid oxidation of the sub endothelial vessel wall. MPO and products of lipid oxidation are commonly found
in atherosclerotic lesions along with macrophages. Endothelial dysfunction in smokers is due to the presence of thiocyanate which is a substrate for increased MPO in smokers’ plasma, forming a carbonylated LDL that is easily captured by receptors on the surface of foam cells\textsuperscript{16}.

**Conclusion**

There was a relationship with the strength between the increase in MPO levels with the incidence of ACS. The MMO of this study had a diagnostic sensitivity score of 88.88\%, diagnostic specificity of 69.23\%, negative predictive value of 75\% and a positive predictive value of 85.71\% so that MPO could not be used as a single heart marker in diagnosing ACS and non ACS patients due to its low specificity.

Effect of Foot Strengthening Exercises in Osteoarthritis Knee

Cynthia S. Jagtap¹, Mandar Malawade²

¹Intern, Faculty of Physiotherapy, ²Asso. Professor, Department of Pediatrics, Faculty of Physiotherapy, Krishna Institute of Medical Sciences deemed to be university, Karad, Maharashtra, India.

Abstract

Background: Knee osteoarthritis is one of the leading cause of global disability. Patients with degenerative knee osteoarthritis clinically complain of pain, decreased muscle strength, joint instability, joint stiffness and proprioceptive deficits, all of which lead to a decrease in or loss of function. Foot pain is highly disabling, functional abilities and increases the risk of falls.

Method: This was an experimental study with total of 33 subjects who had knee osteoarthritis with foot disability. Subjects of both genders with age group of 40 – 65 years fulfilling the inclusion and exclusion criteria participated. The outcome measure used was womac scale, for pain Visual analogue scale (VAS).

Result: Statistical analysis of VAS, WOMAC and range of motion (ROM) were found to be extremely significant with a P value of <0.0001.

Conclusion: This study concluded that foot strengthening exercises were effective. It is proved from this study that foot strengthening exercises has significant effect on pain, range of motion and functional status of OA knee.

Keyword: Foot, strengthening exercises, knee, osteoarthritis, VAS, WOMAC and ROM.

Introduction

The human foot is a very complex structure, which allows it to serve many diverse functions. During standing, it provides our base of support. During gait, the foot must be stable at foot-strike and push-off.¹ The ankle pain was common in community-dwelling older adults, whereas moderate to severe symptomatic, radiographic ankle osteoarthritis(OA) occurred less frequently.²

Knee OA is a major public health problem that causes substantial pain, physical dysfunction and impaired quality of life.³

The effect of proprioceptive training on foot progression angle, weight bearing rational knee adduction moment(KAM) in patient with degenerative osteoarthritis of the knee.⁴ Quadriceps muscle weakness leads to a change in the biomechanics and axis of the knee joint,⁵ negatively affecting joint mobility, posture and gait.⁶ There was altered foot posture in people with OA knee. People with medial compartment OA showed more pronated foot type and lateral compartment OA showed more supinated foot type.⁷

A Pescavus or hollow foot or supinated foot is a foot posture in which the longitudinal arches are accentuated and the metatarsal heads are lower in relation to the hind foot so that there is a dropping of the forefoot on the hind foot at the transometatarsal joints.⁸ A Pesplanus or flatfoot or pronated foot is a foot posture in which the calcaneus goes in valgus position, whereas the metatarsal region is in pronation.⁹

Knee OA is a leading cause of joint pain and disability in middle and older aged individuals, and is one of the most commonly managed conditions in primary care.⁹ Knee OA is one of the leading causes of global disability.¹⁰

The previous research has shown associations between planus foot morphology (flat feet), knee pain, and cartilage damage. Further, many people with knee OA experience foot pain and dysfunction. However, as incident disease is a different phenomenon to worsening OA and risk factors may not be consistent across both, it is necessary to separately establish the association of foot/ankle symptoms with worsening OA. In individuals at risk of knee OA, the presence of contralateral foot/ankle symptoms in particular increases risk of developing both knee symptoms and symptomatic radiographic knee OA.

Change in foot posture may cause increased mechanical rotational stress on the knee joint and the higher degree of knee OA may also affect foot motion during walking which may lead to a compensatory response to allow typical function of the foot during ambulation and accelerates the degenerative changes at the knee joint. The relationship between ankle and knee biomechanics that indicate a more everted foot posture is correlated with lower KAM magnitudes.

Osteoarthritis also known as degenerative arthritis or degenerative joint disease or osteoarthrosis, is group of mechanical abnormalities involving degradation of joints, including not only articular cartilage but also the synovium, capsule, bone and ligaments leading to subchondral bone attrition and remodeling, meniscal degeneration, ligamentous laxity, fat pad extrusion, and impairments of neuromuscular control.

Materials and Method

This was an experimental study of analytical type conducted among total of 33 subjects who had knee osteoarthritis. They were selected after approval from ethical committee. This study was conducted in Krishna institute of medical sciences, Karad. The duration of study was 6 months. The materials used were paper, resistance band, towel, wobbled board, textures. 33 subjects including both males and females with osteoarthritis knee age of 40 – 65 years were included according to inclusion and exclusion criteria. The exclusion criteria consisted of subjects with patients with operative procedure, Limb length discrepancy, Diabetic foot, Congenital foot deformities, deformities of hip. Written consent was taken from the subjects those willing to participate. The subjects were selected by simple random sampling. The outcome measures used were foot prints, visual analogue scale for pain.

Procedure:

After the protocol and ethical clearance the procedure was started. Subjects were selected with age group 40 – 65 years with osteoarthritis knee population according to the inclusion and exclusion criteria. The consent was taken from the selected subjects. The individuals selected were evaluated using visual analogue scale and womac scale and were instructed with all the details about the assessment they were going to undergo. Range of motion of knee was measured in the beginning of the sessions. Foot strengthening exercises were given and ergonomic advice as per protocol. Data was collected in the data collection sheet. Pre and post interventional values were noted down. With the help of pre and post result of VAS, WOMAC and ROM of knee this study will be concluded by statistical analysis.

Statistical Analysis and Result:

Statistical analysis was done manually and by using the statistics software INSTAT so as to verify the results derived. The statistical analysis between the intra group value of VAS, WOMAC and ROM was done by Paired ‘t’ test. The study has p value <0.0001 which is extremely significant.

1. Gender Distribution

A total of 40 subjects were taken for the study. Out of 35 subjects 19 were males and 16 were females.

Table 5 – ROM of Knee

**Discussion**

Knee OA is a leading cause of joint pain and disability in middle and older aged individuals, and is one of the most commonly managed conditions in primary care. Patients with degenerative knee osteoarthritis clinically complain of pain, decreased muscle strength, joint instability, joint stiffness and proprioceptive deficits, all of which lead to a decrease in or loss of function. Foot pain is highly disabling, functional abilities and increases the risk of falls.

Change in foot posture may cause increased mechanical rotational stress on the knee joint and the higher degree of knee OA may also affect foot motion during walking which may lead to a compensatory response to allow typical function of the foot during ambulation and accelerates the degenerative changes at the knee joint.

The study was carried out and the result was drawn by using VAS, WOMAC and Joint ROM scores as the outcome measures. Study place was Krishna College of
Physiotherapy, OPD.

A pre-treatment outcome measure using VAS, WOMAC and ROM score was done. The specific treatment protocol was followed as per and the post treatment outcome using VAS, WOMAC and ROM scores were documented accordingly. An exercise program was designed and a proper ergonomic advice was given.

Comparison was analyzed statistically using paired t test for VAS, WOMAC and ROM Scores.

Foot strengthening exercises like toe curls, toe raise, toe splay, big toe stretch, sand walking, wobble board, resistance band exercises, golf ball roll, Achilles stretch was given for 4 weeks. Toe raise will help to strengthen all parts of the feet and toes. Toe splay was developed to improve control over the toe muscles. It can be done on both feet at once, or alternate feet, depending on comfort. Toe curls build up the flexor muscles of the toe and feet, improving overall strength. Rolling a golf ball under the feet can help to relieve discomfort in the arches and ease pain associated with plantar fasciitis. Achilles stretch tendon is a cord connecting the heel to the calf muscles. It can strain easily, and keeping it strong may help with foot, ankle, or leg pain.

In this study an attempt was made to analyze the effect of foot strengthening exercises in osteoarthritis knee. This study was done to investigate the reduction of symptoms after application of foot strengthening exercises in OA knee patients and its post treatment evaluation in a standardized manner using VAS, WOMAC and ROM scores. The result shows that there is significant difference in improvement of pain, functional performance, range of motion of knee.

Conclusion

Various conservative treatment methods are used in treating Osteoarthritis Knee but this study concluded that foot strengthening exercises were effective. It is proved from this study that foot strengthening exercises has significant effect on pain, range of motion and functional status of OA knee and thus Alternate Hypothesis that There is significant effect of foot strengthening exercises in osteoarthritis knee accepted.

Acknowledgement: Authors acknowledge the immense co-operation received by the subjects and the help received from the scholars whose articles are cited and included in references of this article. The authors are also grateful to authors/ editors/publishers of all those articles, journals and books from where the literature for this article has been reviewed and discussed.

Conflict of Interest: There is no conflict of interest concerning the content of the study.

Source of Funding: This study was funded by Krishna institute of medical sciences deemed to be university Karad.

Ethical Clearance: The study was approved by the institutional ethics committee of KIMSDU.

Correlation between Eruption of Permanent Teeth and Anthropometric Measurements among School Children

Daniel Rajendran T
1Department of Forensic Medicine and Toxicology, Sree Balaji Medical College and Hospital. No.7, CLC Works Road, Chromepet, Chennai, Tamil Nadu, India

Abstract

Background: The assessment of nutritional status of a child is essential in the clinical practice. Several clinical and laboratory parameters are being used for this purpose, of which height and weight play a major role. This study was carried out to correlate the eruption of permanent teeth with anthropometric measurements among school children.

Method: This cross sectional study was carried out among 983 school children between the age group of 4-14 years. The height and weight were measured using standardized scales. Eruption of permanent teeth were examined clinically. The classification of stunting and underweight was carried out based on CDC standards.

Results: Stunting was present in around 10% of each age group upto 7 years, followed by 20-30% between 7-8.9 years. From 9-11 years, stunting was present in around 40% of the participants and beyond 10 year, it was present in around 50% of the participants.

Conclusion: Although this study has not demonstrated statistical significance, it has elucidated the increased prevalence of malnutrition with advances in age with respect to both stunting and underweight, warranting adequate addressing of the nutritional needs of the school children.

Key words: Anthropometry, eruption of permanent teeth, nutritional status, stunting, underweight

Introduction

The period of childhood is essentially important in terms of growth, development and maturation. The entire growth comprising of accumulating energy reserves, building the body’s musculature, strengthening of the growing bones, take place during this period. Therefore, nutrition plays a major role in childhood, although it is important throughout a man’s life. During the neonatal period and infancy, fat and protein are significantly lower, and therefore, there is a maximum requirement for adequate nutrition. As the age advances, in addition to building energy and proteins, the need for accumulating extra reserves to combat infections is higher. Further, the period of adolescence witnesses another growth spurt, accompanied by sexual maturation characterized by puberty and development of secondary sexual characteristics. There is an increased demand for adequate nutrition during this phase, in order to combat the body’s requirements of various micronutrients and minerals.

The assessment of nutritional status of a child is essential in the clinical practice. Several clinical and laboratory parameters are being used for this purpose, of which height and weight play a major role. In addition, the other anthropometric measurements include mid arm circumference, triceps fold, and eruption of permanent teeth. According to Centre for Disease Control (CDC) standards, the nutritional status of a child is evaluated...
based on weight for height, weight for age and height for age and based on these measurements, malnutrition is classified as, wasting, underweight and stunting respectively. In addition to these measurements, eruption of teeth is significantly linked to the growth and nutritional status of a child. In most living individuals the age of eruption of permanent teeth remains fairly constant, within a narrow range. However, the teeth eruption is influenced by several factors include nutritional, hormonal, hereditary or genetic factors. Socioeconomic and nutritional factors caries conditions and the secular trend have also been found to have some effect on the eruption of permanent teeth. Hence, nutritional deficiencies can delay the process of teeth eruption. Malnutrition and poor nutrition in early childhood affects tooth eruption and results in the delayed emergence of the teeth.

Although several studies have documented the age of tooth eruption, very few studies have explored the correlation between the eruption of permanent teeth and anthropometric measurements. Establishing a scientific and statistical correlation between the two would help in incorporating dental assessment as a valid tool for assessing the nutritional status.

Objectives

This study was carried out to evaluate the correlation between eruption of permanent teeth and anthropometric measurements.

Methodology

Study setting and participants

This study was carried out as a cross sectional study among the school children of the urban field practice area of our medical college in Chennai. This study was carried out for a period of three months between July to September 2019.

Sample size and sampling technique

This study was carried out among all the children aged between four and fourteen years studying in a government school in the urban field practice area of our tertiary teaching institution. A total of 963 children participated.

Ethical approval and informed consent

Approval was obtained from the institutional ethics committee prior to the commencement of the study. Written consent was obtained from the principals of both the schools. Each participant was explained in detail about the study. Informed consent was obtained from both the parents and the participants prior to the commencement of data collection.

Data collection

A structured clinical proforma was used to obtain information regarding demographic characteristics like age, sex, etc. Clinical examination was carried out to measure the height and weight. Oral examination was carried out by the principal investigator to evaluate the dentition pattern among the study participants. The classification of stunting and underweight was carried out based on CDC standards.

Data analysis

Data was entered and analyzed using SPSS ver. 20 software. The pattern of eruption of the permanent teeth was expressed in percentages. Independent sample t test was used to evaluate the association between eruption and background characteristics. A p value <0.05 was considered statistically significant.

Results

This study was carried out among 963 school students in the field practice area of our tertiary teaching institution. Majority of the participants were aged between 4-7.5 years (41.4%) and were males (64.4%). (Table 1)

It was observed that central incisor had erupted in 31.1% of the participants followed by first molar (29.6%). Lateral incisor and second molar had erupted in 22.2% of the participants. (Figure 1)

The gender-wise comparison of the mean height of the participants is given in table 2. Overall, there was a negligible difference in the mean height between males and females in any given age group. While the mean height range of the boys began with 98-103.4 cm in the age group of 4.0-4.5 years, the height range of the girls in the same age group was 97.1-102.4cm. As the age advanced, the mean height range was higher for the males compared to the females.

On comparing the mean weight range between males and females for each age group, it was observed that the weight range of the males were greater than
females in the initial ages, and as the age advanced, the weight range were similar among both the groups, for any given age. (Table 3)

The correlation between stunting and eruption of permanent teeth for each age group was analyzed. It was observed that stunting was present in around 10% of each age group up to 7 years, followed by 20-30% between 7-8.9 years. From 9-11 years, stunting was present in around 40% of the participants and beyond 10 year, it was present in around 50% of the participants. (Table 4)

Underweight was present in around 40% of the participants up to 5.5 years. Later on, the prevalence of underweight was as low as 13.2% up to 7.9 years. There was again an increase in the prevalence of underweight to around 40% till 9.9 years of age. Beyond this age group, underweight prevalence increased to as high as 80%. (Table 5)

**Discussion**

Out of 963 subjects examined for height, 296 subjects belong to the low category, 441 belong to the middle category and 226 belong to the higher category. Similarly, for weight, 400 belong to the low, 393 belong to the middle, and 170 belong to high category. Height is a stable measurement of growth as opposed to body weight. Whereas weight reflects only the acute states of malnutrition, height indicates chronic malnutrition past also.[6] Weight and weight were considered in the study and there is no significant correlation of height and weight with socio-economic status and eruption of teeth. The comparison of nutritional status in terms of stunting and underweight in this study demonstrated that as the age advances, the prevalence of stunting and underweight significantly increased. However, this was not accompanied with delay in the eruption of the permanent teeth.

Dental age can reflect an assessment of physiological age comparable to age based on skeletal development, weight or height.[7] In addition, the crowns and roots of the teeth appear to be the tissues least affected by environmental influences at the time of formation. Dentition may be considered to be single best physiological indicator of chronological age among adolescents. Moreover, studies have proven that there would not be any deciduous teeth above 12 years.[8] The emergency of permanent teeth whether it is primarily in the mandibular or maxillary regions was not a part of this study as the emergence of teeth in any of the quadrants were taken as the corresponding age group of the individual but in the majority of the cases it was noted that the mandibular teeth erupts earlier than the maxillary teeth.

Although the present study did not document any statistical association between anthropometric measurements and eruption of permanent teeth, studies have demonstrated the linkages between obesity and non-eruption rates, measured in terms of waist hip ratio, weight for height and waist circumference. The present study has provided the need for further comparative analysis with respect to various other anthropometric parameters in order to identify the predictive role of various nutritional problems of childhood and adolescence.

**Conclusion**

Eruption of permanent teeth is an important phenomenon during childhood and is influenced by various factors, including nutritional status. Several anthropometric parameters like height for age and weight for age were used in the present study to correlate with eruption of permanent teeth. Although the present study did not demonstrate any correlation between these two variables, this study has highlighted the increasing prevalence of stunting and underweight during the early adolescence period, wherein a normal growth spurt is expected. There is a need for further comparative analysis with various other parameters including waist circumference and waist hip ratio in order to arrive at a consensus regarding this correlation.

Effect of Purple Leaf Extract (Graptophyllum Pictum (L.) Griff) on the Number of Macrophage Cells in Pulp Perforation

Devi Eka Juniarti¹, Tuty Kusumaningsih², Adioro Soetojo¹, Ninuk Hariyani³
¹Staff of Conservative Dentistry Department, ²Staff of Oral Biology Department, ³Staff Dental Public Health, Department, Faculty of Dental Medicine, Universitas Airlangga

Abstract

**Background:** Purple leaf (Graptophyllum pictum (L.) Griff) is one of Indonesia’s traditional medicinal plants, which has anti-inflammatory properties which is expected to stop the inflammation of the pulp accompanied by perforation. **Purpose:** To determine the effect of giving purple leaves (Graptophyllum pictum (L.) Griff) to the number of macrophage cells in pulp perforation. **Method:** The study used 24 Wistar rats divided into four groups, namely control (K), and 3 treatment groups P1, P2, P3. Each group consisted of 6 rats prepared, then P1 was given 10% purple leaf extract, P2 was given 15% purple leaf extract, P3 was given 20% purple leaf extract. On the 3rd day, the Wistar rat was sacrificed and continued with the preparation of HPA. Calculation of the number of macrophages was obtained from the One-way ANOVA test. **Results:** There were significant differences between the control and treatment groups (K with P1, P2, P3), on the results of the One-way ANOVA difference-result test (p <0.05) **Conclusion:** Purple leaf extract (Graptophyllum pictum (L.) Griff) affected increasing the number of macrophage cells in pulp perforation after the 3rd day of treatment.

Keywords: Purple leaf (Graptophyllum pictum (L.) Griff); macrophages; pulp perforation

Introduction

Mechanical trauma to the pulp treatment procedure cannot be avoided especially if caries expand to deep depths. The action of cavity preparation or removal of carious tissue in deep cavities can cause pulp perforation¹. Pulp perforation can be caused by the use of burs or other dental tools. In the condition of an open pulp, the direct pulp treatment can be performed²⁻⁻³. The surface of macrophage cells have receptors and are immune cells⁴⁻⁻⁵ that first recognize the host cell debris as an antigen⁶⁻⁻⁷. Various efforts continue to be made to find a drug that can cure pulp inflammation. Lately, there has been a lot of research into various types of plants that are suspected of having medicinal activities for human health purposes⁸⁻⁻⁹. One of them is the purple leaf plant (Graptophyllum pictum (L.) Griff). Purple leaf (Graptophyllum pictum (L.) Griff) is one of Indonesia’s traditional medicinal plants, which has anti-inflammatory properties so it is expected to stop inflammation of the pulp. The chemical content of purple leaves includes flavonoids, tannins, non-toxic alkaloids, steroids, saponins, and glycosides¹⁰.

The research conducted aims to determine the effect of purple leaf extract (Graptophyllum pictum (L.) Griff) on the number of macrophage cells contributing to the healing process of pulp inflammation caused by mechanical injury. This research is an experimental laboratory study and the variable analyzed is the number of macrophages on the 3rd day after the treatment of the mechanical injury.

**Materials and Method**

**Materials**

This research was an experimental laboratory study, using male Wistar strain rats, aged 2-3 months, with an
average body weight of 250-300 grams, obtained from the Experimental Animal Laboratory of the Department of Biochemistry, Faculty of Medicine, Airlangga University, Surabaya. The animal experiments were 24, had been adapted for 1 week, then divided into 4 treatment groups randomly, namely control groups (K), P1, P2, and P3 each of 6 mice.

The herbs tested were purple leaves (Graptophyllum pictum L. Griff) varieties of lurid-sanguineum Sims which were obtained at the same time through plant determination tests at the Indonesian Institute of Plant Conservation Institute, Purwodadi Botanical Gardens, through Identification Certificate No. 445 / IPIL06 / HM / IV / 2019. The preparation of purple leaf extract gel based on polyethylene glycol (PEG) (Sigma-Aldrich, 25322-68-3) with a concentration of 10%, 15%, 20%, was carried out at the Prescription Formulation Laboratory of the Faculty of Pharmacy, Airlangga University, Surabaya.

Method

Extraction

Dry Simplicia was taken as much as 300 grams. The extraction was carried out by the maceration method using ethanol 96% as much as 3000 ml. Maceration was done by soaking 300 grams of Simplicia in 75 parts of 96% ethanol (2250 mL) for 5 days by shaking it periodically. After 5 days of waiting, it was squeezed so that the filtrate was obtained. Added the remaining solvent (750 mL) through the pulp until it reached 3000 mL of filtrate, and after that, it was filtered. The filtrate obtained was concentrated using a rotary evaporator at a temperature of 70 °C with a speed of 70 rpm.11

Total Flavonoid Level Test

A total of 100 mg of sample was dissolved with 5 mL of ethanol, then diluted 10 times. The mixture was added 300 µL NaNO2, shaken for 10 seconds and left at room temperature for 10 seconds. 300 mL of AlCl3 3, 2 mL of 1 M NaOH and 1.9 mL of distilled water were added to the reaction mixture, then shaken for 10 seconds and measured at the wavelength of 415 nm. Quercetin with concentrations of 10, 20, 40, 60 and 80 ppm was used as a standard solution. Purple leaf ethanol extract sample was dissolved with p.a. ethanol (2% -5%), added 0.10 ml of 10% AlCl3, and 0.10 ml of 1M sodium acetate and 2.80 ml of distilled water. The mixture was shaken homogeneously then left for 30 minutes. Then the absorption is measured using an ultraviolet-visible (UV-vis) spectrophotometer at a maximum wavelength of 4.

The test was carried out in triplo. The levels of flavonoids can be calculated using the formula:

$$F = \frac{c \times V \times f \times 10^{-6} \times 100\%}{m}$$

Information:

- F: number of flavonoids AlCl3 method
- c: Quercetin equality (μm / ml)
- V: total extract volume
- f: dilution factor
- m: sample weight (g)

Animal Experiment Treatment

Before cavity preparation was performed, pain management was firstly performed on experimental animals in the form of intramuscular anesthesia with a combination of 0.2 ccs of ketamine (Ketalar®, PT.Pfizer, Indonesia) and 0.5 cc xylazine (Xyla®, PT.Tekad Mandiri Citra, Indonesia). The maxillary left molar was prepared on an occlusal surface using a diamond round bur low-speed ISO 008, diameter of 0.84 mm (Intensiv, Switzerland) forming a Class I Black cavity with a depth of 1.5 mm and a diameter of 0.84 mm to reach the pulp roof, marked with a reddish color on the base of the cavity, making pulp perforation using the tip of a straight sonde (Martin, Germany), the tip diameter of a 0.35 mm sonde was visually formed a bleeding point and was confirmed with a sterile paper point tip. Furthermore, the topical application procedure of purple leaf extract at the bottom of the cavity, the extract was measured using microsyringe as much as 0.5 µl, then applied to the base of the cavity using a straight sonde tip, and topped with the restoration of Glass Ionomer Cement (GIC) type II (Fuji IX, GC Corp, Tokyo, Japan).

On the 3rd day, the animal was terminated and the procedure was done to take the left maxilla. Maxillary tissue was fixed with 10% buffered formalin and decalcified using EDTA 10% pH 7.4. The making of histopathological preparations using Hematoxylin-Eosin (HE) staining was carried out at the Research Center of the Faculty of Dental Medicine, Airlangga.
University, Surabaya. The preparation was observed under a microscope with 400x magnification.

Data Analysis

Test data normality using Kolmogorov Smirnov. Then the results of the treatment group research data were carried out homogeneity tests using Levene’s test followed by the One-way ANOVA test to determine the data distribution. Data that were normally distributed continued with the Tukey HSD test to determine differences between different treated groups.

Results

The purple leaf ethanol extract used contained a total flavonoid of 1.49% (SD = 0.04) (Tabel 1). Data obtained from histopathological readings (HPA) indicated a predominance of macrophage cell numbers.

Based on Table 2, there were differences in the mean macrophage cells in the control group and the treatment group. In the treatment group with the given of purple leaves, it affected the concentration of 10%, 15%, 20%, therefore increasing the number of macrophage cells. The number of macrophage cells in each group could be seen in graph 1.

Figure (K) was the distribution of macrophage cells (arrows) in the control group treated without treatment on the 3rd day; (PGP10) was a distribution of macrophage cells in the treatment group given lesion + 10% purple leaf extract on the 3rd day; (PGP15) treatment group was given 15% purple leaf + seras + extract on the 3rd day; (PGP20) treatment group was given lesions + 20% purple leaf extract on the 3rd day.

Kolmogorov Smirnov test results on the number of macrophage cells showed a significant value between the control and treatment groups that is equal to 0.894. This value was greater than the significance level (α) = 0.05, meaning that the data on the number of macrophage cells in each treatment was normally distributed. The homogeneity test continued using Levene’s test obtained p > 0.05 referring to the homogeneous data. To see the differences between treatment groups, the One-Way ANOVA test was obtained, the value of p = 0.000 (p < 0.05) showing that there were significant differences between the concentration groups. Followed by the Tukey HSD Post-Hoc test to find out each sample group.

Discussion

Pulmonary perforation caused by mechanical trauma caused the formation of debris cells from odontoblast damage that the host responded to as Damage-Associated Molecular Patterns (DAMPs), and later to be able activating pro-inflammatory macrophages, with the “classically activated” nitrite oxide (NO) phenotype that played a role in neutrophil migration to the affected tissue. When inflammation occurred, macrophage infiltration increased especially on days 3 to 5.12

Macrophages had many roles especially in injured tissue including host defense, promotion and resolution of inflammation, apoptotic cell removal, and initiation of cell proliferation and tissue recovery after injury.13 In the inflammatory response, there were 2 types of macrophage cells, namely M1 and M2. M1 (Classically activated) was a cell producing pro-inflammatory cytokines, recognizing, and killing pathogens, and regulating the inflammatory response. M2 (Alternatively activated) was a cell producing anti-inflammatory cytokines and activating tissue repair.
The herbal plants used as a treatment for inflammation of the pulp in this study were purple leaves (Graptophyllum pictum L.Griff) varieties of lurid-sanguineum Sims, because these varieties had the potential as herbal medicines in the fields of medicine and dentistry, compared to the other two varieties that were generally used for ornamental plant needs. Purple leaves with lurid-sanguineum Sims varieties were reported to have anti-inflammatory, antioxidant and analgesic activity. The making of purple leaf extract in this study was done by the maceration method because the technique was simpler, safer and did not risk the damage of active substances because it was a cold extraction method without heating. One of the active compounds of purple leaf ethanol extract which functioned as an anti-inflammatory mediator in response to mechanical injury that caused dental pulp perforation, one of which was flavonoids. Following the previous studies, in this study a UV-visible spectrophotometer test was observed with ultraviolet light with a wavelength of 366 nm, an intensive yellow fluorescent solution appeared, indicating the presence of flavonoids. The mechanism of flavonoids as anti-inflammatory through inhibition of cyclooxygenase (COX). Cyclooxygenase (COX) functioned to trigger the formation of prostaglandins, and prostaglandins caused inflammation. If there was a decrease in the inflammatory process, the process will accelerate the initiation of the proliferation phase and the healing process and tissue repair. One of the cells that played a significant role in tissue repair was macrophages.

An important role of macrophages in the process of tissue healing was the production of growth factors needed to initiate the proliferation of fibroblast cells that play a role in the healing process and tissue repair. The presence of macrophages in the injured area reached peak concentrations around the third and fourth days and remained in the tissue until the healing process was completed.

Application of polyethylene glycol (PEG) was used as a control group because PEG gave no influence in triggering the host immune response, PEG was considered a placebo in this study. The results of the study proved that the administration of purple leaf extract affected in increasing the number of macrophage cells on the third day after treatment, which on the 3rd day was the end of the inflammatory phase leading to the initial fibroblastic phase, and this was when macrophages actively produced the growth factors.

**Conclusion**

This study concludes that the purple leaf extract significantly affects the number of macrophage cells in Wistar rats that are preceding given a mechanical perforation of the pulp, where between purple leaves extract concentrations of 15% and 20% have the same potential in increasing the number of macrophage cells.

Abstract

This study aims to determine the effect of statins and LPS antibodies administration combined with *E. coli* intraperitoneal injection toward proinflammatory mediators (TNF-α, hs-CRP, PCT, and MDA) urea, BUN, and creatinine) and liver function (SGPT, SGOT, and total bilirubin) in sepsis rats. This study used 30 male white rats (*Rattus norvegicus* strain Wistar) divided into 6 groups induced by *E. coli* bacteria combined with statins, LPS antibody (Ab-LPS), and a combination of statins+Ab-LPS. Examination of proinflammatory mediators (TNF-α, hs-CRP, PCT, and MDA) was carried out by the ELISA method through the examination of biochemical markers namely renal function (urea, BUN, and creatinine) and liver function (SGPT, SGOT, and total bilirubin) were analyzed by using the autoanalyzer. The data obtained were statistically analyzed using the T-test. The result shows that *E. coli*+statins gave significant changes on the MDA level at 0th hour administration and TNF-α and hs-CRP at 3rd hour administration. The *E. coli*+Ab-LPS treatment showed significant changes at the 0th hour administration for MDA, creatinine, and total bilirubin and at the 3rd hour administration for MDA. The *E. coli*+statins+Ab-LPS treatment showed significant changes in MDA, creatinine, and total bilirubin at 0th hour administration and on creatinine and total bilirubin at 3rd hour administration.

Keywords: antibody, LPS, *E. coli*, proinflammatory mediator, biochemistry marker, statins

Introduction

Sepsis is a clinical syndrome that causes body excessive response to infection. Sepsis is also followed by a doubling response of the host to the infection that will lead to dysregulations of the host response[1,2]. Sepsis is characterized by fever, mental disorder, hypotension, decreased urinary excretion, and thrombocytopenia. Up to now, sepsis is still the main cause of death in the intensive care unit[3].

Sepsis was caused by various microorganisms including viruses, bacteria, fungi, and protozoa. Gram-positive bacteria, such as *E. coli*, also plays a role in 30-50% of sepsis cases[5,6]. The main cause of sepsis is lipopolysaccharide (LPS) exposure. LPS is a proinflammatory endotoxin[7]. Elimination of natural killer cells (NK) and T cell activation can also be used as a sepsis therapy[4,8]. Anti-LPS antibodies were combined with statins. Statins acted as anti-inflammatory compounds to inhibit the expression of TNF-α and MCP-
induced by LPS as well as inhibit the activation of NF-kB and AP-19. Side effects of statins administration are myopathy, a higher chance of diabetes, and increased transaminases serum[10]. Statins are usually prescribed with aspirin to prevent and treat cardiovascular disease by decreasing lipid serum levels[11,12].

In this study, we created sepsis rats model by inducing of *E. coli* intraperitoneally to determine changes in proinflammatory mediators (TNF-α, hs-CRP, PCT, and MDA) and biochemical markers on the kidney (urea, BUN, and creatinine) and liver (SGPT, SGOT, and total bilirubin).

**Materials and Method**

**Ethical Clearance:** All procedures involving animal care in a laboratory were approved by the Faculty of Medicine, Universitas Brawijaya, Malang, Indonesia.

**Study Design**

The research method used was an experimental laboratory using a post-test only control group design. The experimental animals used were male white rats, 7-9 weeks old, 150-170 grams body weight, had not undergone any treatment or had not received any chemicals, and were in a healthy condition (actively moves and no fall out feather). Thirty male white rats (*Rattus novergicus* strain Wistar) were divided into 6 groups. All groups were treated with *E. coli* bacterial induction. Then statins, Ab-LPS, and statins+Ab-LPS were added at 0th hour and 3rd hour respectively and were examined after 6 hours. The tools used in this study were mouse cages, water baths, stirrers, laminar airflow, ELISA readers, spectrophotometry, test tube rack, test tubes, micropipettes, intragastric feeding tube, and analytical balance. Examination of proinflammatory mediators (TNF-α, hs-CRP, PCT, and MDA) was performed using the ELISA method. The analyzes on kidney function (urea, BUN, and creatinine) and liver function (SGPT, SGOT, and total bilirubin) were done by using the autoanalyzer.

**Data Analysis**

All data were analyzed by using a T-test. The test was performed using SPSS Statistic 18 Software (IBM Corporation, USA).

**Results**

The effect of statins, Ab-LPS, and statins+Ab-LPS combination at 0th and 3rd hour toward proinflammatory mediators and biochemical markers in sepsis rats model induced by *E. coli* is presented on Table 1.

Discussion

*E. coli* is gram-negative, rod-shaped bacterium that generally causes extraintestinal infections, such as neonatal meningitis, bacteremia, pyelonephritis, cystitis, prostatitis, and sepsis. Ironically, this microorganism is also a dominant facultative member of normal human gut microbiota. Adhesion is the first step of pathogenic bacteria to infect its host cell. Furthermore, the events include tissue colonization and, in certain cases, cellular invasion followed by intracellular multiplication or persistence. The adhesion process begins when the surface structure, known as an adhesin, binds to their specific ligands, receptor host cells or extracellular matrix proteins[13].

The results showed that at the 0th and 3rd hour of administration the proinflammatory mediator TNF-α on *E. coli*+statins group, *E. coli*+Ab-LPS group, and *E. coli*+Statins+Ab-LPS group did not differ significantly (p<0.05). Statins administration at the 3rd hour gave a significant change in TNF-α. This was due to excessive amounts of LPS so that it was able to induce a high level of proinflammatory cytokines (TNF-α, IL-6) production in blood circulation. This condition has caused acute inflammation, tissue apoptosis, lead to endotoxic organ injury[14,15,16].

The administration of statins at the 3rd hour gave a significant change in hs-CRP, while at the 0th hour there was no significant change. Hs-CRP has been used to help the diagnosis or refers to some therapies[17]. Significant changes occurred in PCT both at the 0th and 3rd hours. PCT is a group of peptides consisting of 116 amino acids and calcitonin precursors. The protein is synthesized by parafollicular cells, lung neuroendocrine cells, and few amounts were located in the small intestine[18]. In this study, statins and Ab-LPS administration gave significant changes to MDA at 0th hour and 3rd hour, whereas statins+Ab-LPS combination showed significant changes in MDA at 0th hour administration. MDA levels play a role as a marker of oxidative damage that occurs in polyunsaturated fatty acids (PUFA) due to the induction of *E. coli*. MDA is an aldehyde molecule that results from the formation of free radicals in polyunsaturated fatty acids. The measurement of MDA levels was performed to indicate oxidative damage[19,20,21].

Statins treatment did not give any significant changes in biochemical markers of the kidney (urea and BUN), in either the 0th hour or the 3rd hour administration. However, there was a significant change in creatinine in both the 0th and 3rd hour. The administration of Ab-LPS did not show significant changes in urea and BUN in both the 0th and 3rd hours. The administration of statins+Ab-LPS combination did not change the urea and BUN significantly. It was due to many factors that influence urea and BUN increase so that the levels of urea or BUN are easy to change sepsis condition or before sepsis occurs.

In this study, the administration of Ab-LPS and combination of statins+Ab-LPS showed a significant change in creatinine at the 0th hour administration. Whereas statins administration and statins+Ab-LPS combination showed significant changes in creatinine at the 3rd hour administration. Statins+Ab-LPS administration did not give significant changes on SGPT and SGOT, however, it gave significant changes on bilirubin at 0th and 3rd hour administration. In this study, there was no significant difference between SGPT and SGOT in terms of examination time (p>0.05). The increase in SGPT and SGOT enzymes occurs after hepatocyte damages due to inflammation caused by *E. coli*. The increases of SGPT and SGOT occur after more than 24 hours of *E. coli* infection[22]. Study on using statins as therapeutic agents in sepsis cases has been able to prove that statins can increase survival, ability, function, and protection of organs in sepsis rat induced by LPS or caused by CLP[23,24,25,26].

Conclusion

In sum, this study found that the administration of *E. coli*+statins at 0th hour gave significant changes to MDA levels and TNF-α and hs-CRP at 3rd hour administration. The *E. coli*+Ab-LPS treatment showed significant changes in MDA, creatinine, and total bilirubin levels at 0th hour administration and only MDA at 3rd hour administration. The *E. coli*+Statins+Ab-LPS treatment showed significant changes in MDA, creatinine, and total bilirubin levels at 0th hour administration and creatinine and total bilirubin at 3rd hour administration.

Abstract

BPA as a xenoestrogen negatively influences male reproductive functions as well as sperm quality. This study aimed at evaluating the correlation between urinary BPA concentrations and male fertility by assessing semen parameters as well as hormone profile. It included (150) males divided into two groups; infertile cases (n= 100) and fertile controls (n= 50). Results showed highly significant difference in mean urinary BPA concentrations between both groups being higher among infertile group (P-value < 0.001). Besides that, there was statistically significant correlation between the mean urinary BPA concentrations and deterioration of sperm concentration and motility among cases with P-values (< 0.001). Finally, there was statistically significant correlation between mean urinary BPA and hormone levels FSH, LH, T and E2 levels with P-values 0.002, 0.033, 0.001 and < 0.001 respectively.

Keywords: Bisphenol A (BPA); Endocrine disruptors; Male infertility; Sperm functions; Xenoestrogens

Introduction

Infertility is the inability of sexually active and non-contracepting couples to achieve spontaneous conception within one year duration with overall incidence about 10–15% of couples worldwide. Male factor infertility can be classified to pre-testicular causes (at the level of hypothalamus or pituitary gland), testicular (primary testicular failure) or post-testicular (obstructive or coital) exposure to gonadotoxins (either environmental or occupational) as; heavy metals, xenoestrogens, pesticides and organic solvents may negatively influence the Hypothalamo-Pituitary-Gonadal (HPG) axis, sperm functions and DNA integrity.

BPA is an endocrine disruptors of xenoestrogen family (diphenylmethane derivatives ) that possess a chemical structure [(CH₃)₂C(C₆H₄OH)₂] similar to estrogens, thus interacting with estrogen receptors as agonist or antagonist via specific signaling pathways. It is widely used in plastic industries to make them shiny, flexible and durable. It may enter the body via several routes as; contaminated food or drinks, environmental (from polluted air and water), domestic (household products and cosmetics), medical (from contaminated equipment and devices), and occupational sources (inhalation, dermal contact, and ingestion during manufacturing processes or industrial use).

Several studies have reported the potential risk of BPA exposure and various health hazards among animals and humans including; infertility, precocious puberty, and polycystic ovary syndrome, hormone dependent tumors (breast, ovarian and prostate cancer) and various metabolic disorders including diabetes mellitus and thyroid dysfunction.

Many mechanisms have been suggested its effect on male fertility including; disturbance in HPG axis with subsequent dysfunction of steroidogenesis.

and spermatogenesis. Additionally, BPA may affect sperm functions and integrity through increased DNA damage, epigenetic methylation, oxidative stress, lipid peroxidation and mitochondrial dysfunctions. Up till now, ongoing researches are being conducted to verify the exact effect of BPA on the male fertility potential and sperm functions.

**Material and Method**

Total of (150) participants were enrolled in this prospective study being age matched from 20 to 50 years old. All were recruited from the outpatient clinic of Andrology - Cairo University from February 2018 to August 2019. Approval of the local ethical committee was obtained after getting written informed consent from the participants about the purpose of the study conforming to Helsinki declaration. Notably, cases were assorted according to certain inclusion and exclusion criteria, which were:

**Inclusion criteria**

All cases (n=100) were males complaining of infertility (either primary or secondary) for at least one year duration with no obvious cause of female factor of infertility. On the other hand, the Control group included (50) fertile males with history of previous conceptions in the last year confirmed by normal semen parameters.

**Exclusion criteria**

All subjects with uncontrolled medical disorders, chronic heavy smoker (smoking index ≥ 400), and history of drug abuse, radiotherapy and/or chemotherapy, or abdomino-pelvic surgery were ruled out. Furthermore, any subjects with obesity (BMI ≥30), clinical varicocele, genetic infertility (e.g. Klienfelter’s syndrome and Y-chromosome microdeletions), or Leukocytozoospermia were also excluded.

Notably, all participants were assessed for urinary BPA concentration, semen analysis as well as hormone profile (FSH, LH, testosterone, E2 and PRL).

**Urinary BPA**

Urine specimens were collected from all included subjects in clean, glass containers labeled with the subject identification number, whereas turbid samples or those containing blood were excluded. Afterwards, all specimens were stored frozen below 20°C, and then analyzed for the mean BPA (i.e. the mean value was calculated using 3 different readings in different occasions) by High Performance liquid chromatograph (HPLC).

**Conventional Semen analysis**

The patients were instructed to abstain for (2-7 days), and bring the sample by masturbation using no lubricants in a sterile container. The samples were then incubated for 1 hour at 37°C for liquefaction and were examined using a light microscope [Olympus Co., BH-2 (BHTU), Japan] with an objective optical magnification (40 X). The standard criteria for evaluation were according to (WHO) criteria of normal semen parameters [Volume >1.5ml, Concentration >15x10^6 sperm/ml, Total sperm count >39x10^6/Ejaculate, Vitality >58%, Total motility >40%, Progressive motility >32%, Abnormal forms ≤ 96%, Pus cells < 1 million / ml].

**Hormone profile**

All studied subjects were subjected to withdrawal of venous blood sample between (8:00-11:00 am) for measurements of FSH, LH, testosterone (total), prolactin and Estradiol (E2) using an electro chemiluminescence immunoassay analyzer [Roche Co., Cobas e 602, Japan]. The normal reference values were as follow; FSH = 1.5 - 12.4 mIU/ml, LH= 1.2 -7.8 mIU/ml, testosterone (total) = 2.5 - 8.4 pg/ml, prolactin = 2-18 ng/ml, and E2 less than 40 pg/ml).

**Statistical methods**

By the end of the study, all collected Data were coded and entered using the statistical package for the Social Sciences (SPSS) version 25 (IBM Corp., Armonk, NY, USA). Data were summarized using mean, standard deviation, median, minimum and maximum in quantitative data and using frequency (count) and relative frequency (percentage) for categorical data. Comparisons between quantitative variables were done using the non-parametric Mann-Whitney test. For comparing categorical data, Chi square (χ²) test was performed. Exact test was used instead when the expected frequency is less than 5. Correlations between quantitative variables were done using Spearman correlation coefficient. P-values less than 0.05 were considered as statistically significant.

**Findings**

In this prospective controlled study, a total number of 100 infertile males (either primary or secondary...
infertility) were included and then compared to 50 normal fertile controls. The mean age of the infertile patients was 33.53 ± 5.98, while the mean age of fertile controls was 35.20 ± 8.17; and there was no significant difference between the studied groups regarding the age (p = 0.3). Both groups were assessed for the urinary BPA levels, semen analysis as well as hormone levels (FSH, LH, testosterone, E2 and PRL) as shown in table (1).

Concerning the mean urinary BPA levels, there was a highly statistical significant difference between both groups; whereas the mean levels among cases was 10.07 +/- 9.98 compared to controls that was 1.69 +/- 1.32 with P-value <0.001.

On the other hand, the semen analysis parameters among both groups showed a highly significant statistical difference concerning sperm concentration and sperm motility (p < 0.001), whereas mean sperm concentration and motility among cases were 27.93 +/- 25.75 and 37.01 +/- 22.04 respectively, compared to controls that were 45.34 +/- 22.90 and 61.40 +/- 13.78 respectively. However, there was no significant difference concerning abnormal forms among both groups (P= 0.315).

Furthermore, there was a highly significant statistical difference between cases and controls concerning FSH, LH, PRL and E2 levels (p < 0.001), whereas the mean levels were 8.28 +/- 5.63, 6.38 +/- 2.96, 12.26 +/- 4.09 and 33.60 +/- 11.26 respectively, compared to controls that were 4.23 +/- 1.00, 3.36 +/- 0.84, 8.99 +/- 3.45 and 27.56 +/- 8.05. On contrary, there was no significant difference between both groups as regard to testosterone level (P= 0.064).

Regarding the correlation between mean urinary BPA level with semen parameters as well as hormone profile among the infertile group as shown in table (2); our results have shown that there was a highly statistically significant negative correlation between sperm concentration and mean urinary BPA level (p <0.001). Furthermore, there was statistically significant negative correlation concerning sperm motility and the mean BPA level (p= 0.003). However, there was no significant correlation concerning abnormal form of sperm and mean BPA level (p= 0.178).

In another perspective, there was statistically significant positive correlation concerning FSH, LH level and BPA level, whereas the p-values were 0.002 and 0.003 respectively. Eventually, there was a highly significant negative correlation between testosterone and E2 levels and BPA level with p-values 0.001 and <0.001 respectively. On contrary, there was no significant correlation concerning prolactin level and BPA level (p=...

Discussion

Urinary metabolites of BPA represent exposures to chemicals from all routes of exposure including oral, dermal, inhalation and ingestion. As a non-persistent chemical with an elimination half-life of a few hours, the BPA concentrations in blood are lower than those in urine and decrease quickly after the exposure. There was substantial day-to-day variation of urinary levels of BPA with considerable variability with in the same subject. Therefore, the assessment of BPA exposure on the base of multiple urine measurement was recommended. In addition, consistent individual time activity patterns may lead to stable concentrations over long periods of time, so the assessment of BPA exposure on the base of multiple urine measurement. Also, one semen sample may be representative of semen quality over several weeks in epidemiological studies. Therefore, in our study we have obtained three urinary samples for the same subject in different occasions and we have calculated the mean urinary BPA levels.

Concerning urinary bisphenol (BPA), the mean levels was 10.07 +/- 9.98 for cases and 1.69 +/- 1.32 for controls denoting a highly significant difference between both groups (p < 0.001) and this agreed with Lassen et al., (2014) who found a clear match between individual exposure to biphenol A and male reproductive dysfunction.

Our results showed a highly statistically significant correlation between sperm concentration and mean BPA level (p < 0.001). Besides that, there was significant correlation between sperm motility and the mean BPA...
level (p= 0.003). These results agreed with Li et al., (2011) who found a significant correlation between the urinary BPA concentrations and the poor semen quality. However, there was no significant correlation between sperm abnormality and mean BPA level (p = 0.178). These results agreed with Li et al., (2011) who found a significant correlation between the urinary BPA concentrations and poor semen quality. However, Meeker et al., (2010) found significant correlation between higher urinary BPA concentrations and poor sperm morphology.

On the other hand, there was a highly significant statistical difference between cases and controls concerning FSH, LH, PRL and E2 levels (p < 0.001). However, there was no significant difference concerning testosterone level (P = 0.064). These results agreed with Liu et al., (2015) who found a significant correlation between the urinary BPA concentrations and the reproductive hormones. Additionally, there was statistically significant correlation concerning FSH, LH level and BPA level, whereas the p-values were 0.002 and 0.003 respectively. Eventually, there was a highly statistically significant correlation between testosterone and E2 levels and BPA level with p-values 0.001 and <0.001 respectively.

In correlation of BPA level and hormonal assay among cases, there was significant correlation with FSH, LH, Testosterone and E2, and this agrees with Liu et al., (2015) who had observed the same findings. On contrary, there was no significant correlation concerning prolactin and BPA among cases (p= 0.275), and this agrees with Meeker et al., (2010). However, this goes against Liu et al., (2015), who stated that increased urine BPA level was associated with increased prolactin.

Finally, there were some differences in results and this may be attributed to differences in races, age, sample size, environmental circumstances, and requirements of product labeling in different countries and also due to different combinations of the studied parameters that may affect the results. Additionally, it must be taken into consideration that these results are only presented as a preliminary study, thus increasing the sample size is recommended.

Conclusions

BPA is an endocrinal disruptor that negatively influences male fertility. The current study showed higher levels of urinary BPA among cases compared to controls. Furthermore, it demonstrated negative effects of BPA on semen parameters and hormone profile among the infertile group. Notably, those findings need to be confirmed in future large scale and multi-centric studies.

Effect of Video-Based Rehabilitation as an Adjunct to Physiotherapy in Post Stroke Patients

Dollar J Brahambhatt¹, G Varadharajulu²

¹Intern, Krishna college of Physiotherapy, KIMS “Deemed to be university” Karad, Maharashtra, India,
²Professor and Dean, Department Of Neurosciences, Krishna college of Physiotherapy, KIMS “Deemed To Be University” Karad, Maharashtra, India

Abstract

Objectives: Objective of this study was to evaluate the effects of video-based rehabilitation along with physiotherapy in improving the activities of daily living in stroke patients and evaluating its effects on spasticity.

Methodology: There were total 37 subjects, out of which 30 stroke patients were the participants of the study. This was a study to evaluate the effects of video-based rehabilitation along with physiotherapy in stroke patients. Here patients were evaluated on the basis of Modified Ashworth Scale and Modified Barthel Index before the treatment. Patients were showed videos of activities of daily living for 3 minutes every day after their physiotherapy session for 12 weeks and were assessed daily. At the end of the last session the patients were reassessed and re-evaluated on the basis of the same scales.

Result: There is a significant change in performing the activities of daily living and spasticity of the patients after 12 weeks of treatment compared to before treatment.

Conclusion: Activity of daily living can be performed better with the help of videos, and daily physiotherapy sessions, video-based rehabilitation and physiotherapy also has an impact on reducing spasticity in stroke patients.

Keywords: action observation therapy, video-based rehabilitation, physiotherapy, stroke, activities of daily living, spasticity, Modified Ashworth scale, Modified Barthel Index

Introduction

The World Health Organization definition of stroke is,” rapidly developing clinical signs of focal (or global) disturbance of cerebral function, with symptoms lasting 24 hours or longer or leading to death, with no apparent cause other than of vascular origin.”⁷

The high incidence and severity of stroke outcomes are so shocking that this disease is considered to be the third common cause of death after cancer and cardiac problems. It is the most common cause of disability in adults.⁸

Motor deficits are characterized by paralysis or weakness, typically on the side of body opposite the lesion.⁷

women have a lower age-adjusted stroke incidence than men. However, this is reversed in older age.⁷ incidence of stroke increases dramatically with age.⁷

Major risk factors of stroke are, hypertension, heart disease, disorders of heart rhythm, diabetes mellitus, cholesterol.

Tone-flaccidity is present immediately after stroke.\textsuperscript{7} Spasticity emerges in about 90% of vases and occurs on the side of the body opposite the lesion.

In stroke patients, upper extremity spasticity is frequently strong in scapular retractors, shoulder adductors, depressors, and internal rotators; elbow flexors and forearm pronators; wrist and finger flexors. In the neck and trunk, spasticity may cause increased lateral flexion to the hemiplegic side.

In lower extremity, spasticity is strong in pelvic retractors, hip adductors and internal rotators, hip and knee extensors, plantar flexors and supinator and toe flexors. Spasticity results in tight muscles that restrict movement.

It causes physical problems like hypertonicity which has an influence on patient’s functional capacity causing problems in performing activities of daily living.\textsuperscript{8} Stroke is an important cause of hemiplegia which causes severe disabilities in hand functions.\textsuperscript{1,2} It is very important to find a therapy that makes the patient functionally independent. Video based rehabilitation works on the principle of action observation therapy. Action observation is a dynamic state where the observer understands what is shown in the video by initiating the actions.\textsuperscript{3} The action observation therapy has two phases, the observation phase and the execution phase, thus allowing the patients to safely practice what is shown in the video.\textsuperscript{4} This technique promotes functional reorganization within the brain by activating mirror neurons.\textsuperscript{5} It also recovers damaged cerebral networks and rebuilds motor function when complemented to physiotherapy.\textsuperscript{6} The goal of this therapy is to promote functional reorganization within the brain of stroke patients via activation of these mirror neurons in order to promote function recovery.\textsuperscript{5} Mirror neurons are a unique set of neurons that represent an “observation-execution matching mechanism” which unites the sensing and implementation of an action.\textsuperscript{7,9}

The aim of this therapy is to make use of this mechanism for the rehabilitation of stroke patients in performing activities of daily living.

**Methodology**

An approval for the study was obtained from protocol committee and institutional ethical committee of KIMSDU. Total 37 stroke patients were approached from Krishna Hospital, Karad, Maharashtra out of which 30 stroke patients were selected for the study who fulfilled inclusion criteria. The procedure was explained and consent was taken from those willing to participate. The patients were assessed on the basis of Modified Ashworth Scale and Modified Barthel Index, after their physiotherapy treatment, they were be made to sit in a comfortable place and a video of functional activity was shown, the patient was then asked to observe the task carefully first and after the video was stopped, they were asked to perform the same activity. The task became more complex as and how an activity was achieved. After the therapy concluded, the patients will be were re-assessed. Both the results were compared and statistically analysed.

**Result**

**Table No. 1 Modified Barthel Index (Activity Of Daily Living)**

**Discussion**

Stroke is one of the major leading causes of functional impairments that affects the activities of daily living. Activities of daily living include all the minor and major activities performed in daily life, from lifting toothbrush to applying paste on it. Spasticity of the limbs secondary to stroke causes limitations in performing these activities. The patient becomes functionally dependent. The main goal of a physiotherapist is to make their patient functionally independent. One of the many approaches of rehabilitation is video-based rehabilitation. It works on the principle of Action-Observation Therapy.

This research was undertaken with the aim to study and compare the effect of video-based rehabilitation along with physiotherapy in post-stroke patients on activities of daily living and spasticity.

30 post-stroke patients (18 males, 12 females), age group 40-70 years approaching to OPD of Krishna College of Physiotherapy participated in the study. The patients were assessed on the basis of Modified Barthel Index for activities of daily living and Modified Ashworth Scale for spasticity.

After each patient’s routine physiotherapy session, they were made to sit in an isolated room where a video of a simple task was played, the patient was first asked to observe the task for 2-3 minutes and perform the task when the video was stopped. Each task was shown for 3 days. The task got more complex on every new video. The tasks included activities of daily living like lifting spoon and eating, opening water bottle, opening door, buttoning and unbuttoning shirt, combing, brushing, tying shoe laces.

Statistical analysis was done using paired ‘t’ test within group and unpaired ‘t’ test was applied to compare the results between two groups.
In the study pre-interventional Modified Barthel Index values were 13.533 ± 2.145, whereas the post-interventional values were 16.767 ± 2.029 (p<0.0001) the changes in the values showed statistically extremely significant. The post-intervention study shows 23.89% increase in score of Modified Barthel index (activities of daily living).

In the study pre-interventional Modified Ashworth Scale values were 2.467 ± 0.5074, whereas the post-interventional values were 1.7 ± 0.7022 (p<0.0001) the changes in the values showed statistically extremely significant. The post-intervention study shows 31% reduction in score of Modified Ashworth Scale (spasticity).

In the study gender-wise distribution of Modified Barthel Index, pre-interventional values of males were 13.000±2.196, whereas the post-interventional values were 16.111 (p<0.0001) the changes in the values showed extremely significant. The post-intervention study shows 23.93% increase in score of Modified Barthel index (activities of daily living).

In the study gender-wise distribution of Modified Barthel Index, pre-interventional values of females were 14.333±1.875, whereas the post-interventional values were 17.750±1.545 (p<0.0001) the changes in the values showed extremely significant. The post-intervention study shows 23.84% increase in score of Modified Barthel index (activities of daily living).

In the study gender-wise distribution of Modified Ashworth Scale, the pre-interventional values of males were 2.444±0.5113, whereas the post-interventional values were 1.778±0.7321 (p<0.0001) the changes in the values showed statistically extremely significant. The post-intervention study shows 27.25% reduction in score of Modified Ashworth Scale (spasticity).

In the study gender-wise distribution of Modified Ashworth Scale, the pre-interventional values of females were 2.500±0.5222, whereas the post-interventional values were 1.583±0.6686 (p<0.0001) the changes in the values showed statistically extremely significant. The post-intervention study shows 36.68% reduction in score of Modified Ashworth Scale (spasticity).

In above study, the treatment was divided in two phases, routine physiotherapy session followed by video-based rehabilitation session. This activated the mirror neuron cells in the brain. Physiotherapy session adjunct to video-based rehabilitation also reduced spasticity making it easier to perform the task shown in the video.

Therefore, action observation therapy along with physiotherapy benefited the stroke patients, both males and females. Statistically it was found that the results showed significant difference before and after 12 weeks of treatment.

**Conclusion**

On the basis of the results of the study, it can be concluded that, there is 23.89% increase in the overall score of modified Barthel index and 31% reduction in the overall score of Modified Ashworth Scale. Thus, concluding that, activities of daily living has improved and spasticity has decreased after treatment when compared to that of before treatment.

Knowledge & Perception of General Population on Forensic Autopsy in Ahmedabad City

Dushyantkumar Barot¹, Mohammed Musaib M. Shaikh², Jayjeet Trivedi³, R. S. Bhise⁴
¹Assistant Professor, ²Associate Professor, ³Tutor, ⁴Professor& Head, Department of Forensic Medicine, Dr. M. K Shah Medical College & Research Centre, Ahmedabad, Gujarat. India

Abstract

The Autopsy is beneficial in determining the cause of death, time since death, validity of therapeutic modalities, potential medico-legal issues surrounding death and providing data on disease & injury. This cross-sectional study was carried out on a general population of Ahmedabad City with the help of questionnaires specially prepared in vernacular language i.e. Gujarati. We observed that overall awareness is quite good regarding the aims and objectives of postmortem examination in the general population. But general populations have poor knowledge about legal procedure regarding post mortem examination. Among the respondents who rejected autopsy, most of them feared of disfigurement of the body of their near ones, followed by delays in funeral, the involvement of police/court & fear of removal of the organs. Refusal on the religious ground was the least common reason cited by the participants. People have to be made aware of the process and importance of a medico-legal autopsy by various programs & seminars so that the relatives won’t resist autopsy of their near ones.

Keywords: Knowledge; Perception; Medico-legal Autopsy; General Population

Introduction

The Autopsy is beneficial in determining, the cause of death, time since death, validity of therapeutic modalities, potential medico-legal issues surrounding death and providing data on disease & injury¹. Autopsy is still under the umbrella of misconceptions, myths and emotions by lay people as well as by the physicians². Though medico-legal autopsy is mandatory in most of the cases of unnatural death, the relatives of the deceased may have a negative attitude towards autopsy³.

In medico-legal autopsy the consent of the relatives is immaterial according to Indian law. In such a scenario, the response of relatives can vary greatly, ranging from objection to approval. The investigation into the experiences of the next of kin will help both family and forensic experts to deal with the borderline situations that are so often encountered⁵.

A recently expressed opinion of Behra C et al states that autopsy is not something that should be performed as a favor to the family, but is something to which the family has a right, of which they should be informed⁶. Researchers have shown that people have developed positive attitudes towards autopsy and even understood the technical aspects of the autopsy⁶, ⁷. Although social aspects affect the public view more than religious facts, Islam also now accepts autopsies when useful⁸.

It is important to explore the knowledge and perception of public towards medico-legal autopsy as it helps the police and doctors to understand the required fields where they have to inform the near relatives of the deceased about the legal requirements and procedure of an autopsy⁹. The present study was carried out to know perspective, attitude and knowledge on medico-legal autopsy among the general population.

Material and Method

This cross-sectional study was carried out on the general population of Ahmedabad City from January to June 2019. A total of 500 peoples participated in the study. The study was done with the help of questionnaires specially prepared in vernacular language i.e. Gujarati.
for the study. Questionnaires were given to interested participants after obtaining informed written consent &
responses were made anonymously. The questionnaires consisted of perspective and knowledge of the medico-legal
autopsy. After obtaining the response, some facts of postmortem examination regarding given questionnaires were
acquainted and tried to clear their doubt if any.

Results

Questionnaires were distributed among a small group of the general population and obtained a response. Total
of 500 respondents were successfully participated & included in the study. The data regarding socio-demographic
characteristics of respondents, response to a questionnaire about knowledge and perception particularly factors for
rejection for medico-legal autopsy obtained, was tabulated and analyzed. The data obtained are shown in Tables 1
& 2.

Discussion

We observed that almost all people (more than 90%) were agreed upon that the postmortem examination is required to find out cause of death, time & manner of death. The whole body has to be dissected during postmortem examination which is then stitched & reconstructed to make it presentable before handing over to police/relatives. Our findings are consistent with Subedi N et al9. We also observed that 50.6% population were agreed upon that, Blood samples collected during postmortem examination & 58.6% population were agreed upon that internal organ collected for further investigation during postmortem examination. Overall awareness is quite good regarding the aims and objectives of postmortem examination in the general population.

We observed that 76.2% people were agreed upon that, the family members must give consent before performing postmortem examination and 63.4% were agreed upon that postmortem examination is not needed if the nearest relatives of the deceased do not request for it. General populations have poor knowledge about legal procedure regarding post mortem examination. People think that if the relatives request the concerned authority, then only autopsy is initiated. Medico-legal autopsy is performed to determine the cause, manner and time since death for legal purposes and is initiated by the state. So, it is the responsibility of the relatives or anyone who suspects unnatural death of a person to inform the police. Then, police conduct necessary inquest and can forward the body to perform medico-legal autopsy10. It is no need to take consent from the relatives before the autopsy.

We observed that 20.6% of people agreed upon that, internal organ were stolen for selling purpose during postmortem examination. The percentage is relatively high and raised our eyebrows. There are myths present that internal organs were stolen for selling purpose for organ transplantation & some facts already published in the news that organs were stolen for the black magic procedure by postmortem workers in absence of doctors which was published in “The Times of India” on 5th July 2015 at Meeruth(UP).

Majority people (88.4%) were agreed upon that body is disfigured after postmortem examination, while 61.2% of people were agreed upon that, after postmortem examination body emits a foul smell. Most of the respondents were aware that medico-legal autopsy is indicated in unnatural deaths like accidental, suicidal,
homicidal, and sudden suspicious deaths.

When we had asked them whether they would reject the autopsy of their relatives, 52% of people responded that they would not. It is an important issue that many people now accept autopsies if indicated. Behera et al\textsuperscript{6}. But still large population have objection regarding the autopsy of their relatives.

Among the respondents who rejected autopsy, most of them feared of disfigurement of the body of their near ones. Similar findings were presented in studies of Behra et al\textsuperscript{6} and Parmar P et al\textsuperscript{11}. One of the objectives of a medico-legal autopsy is to cosmetically reconstruct the body. Not only the post mortem incisions have to be stitched properly, but also other injuries and tissue loss should be reconstructed for better appearance before presenting to the relatives of the deceased. This will help them to better tolerate autopsy of their near ones. Autopsy delays funeral (83.62%), the involvement of police/court (62.39%) and the fear of removal of the organ (44.02%) were other most common causes for autopsy refusal by family members or relatives of the deceased. Refusal on the religious ground was the least common reason cited by the participants.

**Conclusion**

The present study throws some light on today’s perception and knowledge of general population regarding forensic autopsy. Awareness is quite good regarding the aims and objectives of postmortem examination in the general population. But Knowledge about the legal procedure is poor. People have to be made aware of the process and need of a medico-legal autopsy so that the relatives won’t resist autopsy of their near ones. Autopsy surgeons should communicate with relatives before starting postmortem examination explaining the whole procedure and need of autopsy and clear their doubt if any. Feedback must be obtained after completion of autopsy and utilize them in future.

Correlation between High Sensitivity-Crp Level and Executive Function Disorders in Elderly Patients

Muhammad Hamdan¹, Joseph Ekowahono Rahardjo¹, Yudha Haryono¹, Devi Ariani Sudibyo¹, Dyah Anetta Afri Rahmi¹

¹Department of Neurology, Faculty of Medicine, Universitas Airlangga, Dr. Soetomo Teaching Hospital, Surabaya (60131), Indonesia

Abstract

Background: C-Reactive Protein is a marker of inflammation and vascular disease. The high serum of high-sensitivity C-Reactive Protein (hs-CRP) concentration was associated with interruption the integrity of the frontal-subcortical circuit.

Objective: To determine the correlation between high serum concentration of hs-CRP and executive function disorder in elderly patients.

Method: Thirty six elderly patients was examined by using a case control study. The subjects were enrolled from the out-patient at Neurology Deparment Dr. Soetomo General Hospital, Surabaya, Indonesia. The time period was 4 months (April to July 2015). Executive function was measured with the Trail Making Test B (TMT B) and divided into two groups, case and control. Complete blood count and serum hs-CRP concentration were measured from nonfasting blood samples. Chi-square test was used for data analysis.

Results: Eighteen subjects were enrolled in the case group (3 men, 15 women) and the other 18 subjects were enrolled in the control group (4 men, 14 women). Executive function disorder was found in 17 (94,4%) subjects of case group and 11 (61,1%) subjects of control group. High levels of hs-CRP was not associated with executive function, with p = 0,149 and adjusted OR 5,629 (CI 95% 0,538-58,860).

Conclusion: These data suggested that high levels of hs-CRP was not associated with executive function in elderly patients.

Keywords: High hs-CRP, Executive Function, Elderly Patient

Introduction

The inflammation plays an important role because it was involved in all stages of atherosclerosis. Atherosclerosis is a chronic inflammatory process that occurs in the arterial endothelium.¹ The CRP has been shown to be a marker and mediator of atherosclerosis. The previous laboratory testing methods were not sensitive enough to measure the CRP levels <10 mg /L. Hs-CRP, that was a quantitative methode of CRP concentration which could measure the levels up to <0.2-0.3 mg/L. It was an acute phase plasma protein, synthesized by hepatocyte cells and the most sensitive marker of systemic infection. Various studies reported that the high serum hs-CRP or CRP will lead to increasing the risk factors for vascular dementia, Alzheimer’s disease, cognitive disorder and White Matter Hyperintensities (WMH) ¹.

The high levels of CRP in microvascular cerebral might accelerate atherosclerosis. Narrowing of the vascular lumen and cerebral regulatory damage lead to cerebral microangiopathy. The process will affect the integrity of the frontal-subcortical circuitry thus providing a clinical picture of cognitive disorder ².
The results of Kirova et al.’s study using the prospective cohort method showed that the increase in serum CRP was associated with cognitive disorder in individuals with metabolic syndrome. In the elderly population, high levels of CRP and Interleukin 6 (IL-6) will cause worsening of cognitive function. Six meta analysis studies have shown that elevated CRP could be used as a predictor of cognitive and dementia disorders. However, some studies showed that there was no association between hs-CRP and cognitive disorder. Even four cohort studies in Scotland have shown no association of CRP gene variation with cognitive function in old age. Yilmaz et.,al investigated parents aged 64 to 85, and the results suggested that α1-antichymotrypsin was associated with decreased cognitive function, but not for CRP, IL-6, and albumin.

The difference results might be due to the measurement of inflammatory markers using the different types, the methods, and the sensitivities. The CRP levels were varied in each population. Then, more importantly, the selection of measuring instruments for assessment of cognitive function was on executive function. There were several studies relying solely on the examination of the Mini Mental State Examination (MMSE). The MMSE instrument was not as diagnostic but as a screening for cognitive disorder. One of the most sensitive and widely applied measures of executive function was TMT B.

Additionally, because of the different results and the minimal use of hs-CRP as the most sensitive atherosclerotic marker in the previous studies, it needed to determine the correlation between hs-CRP levels and executive function measured by using TMT-B.

**Method**

This study used a case-control design in all elderly patients who visited the Neurosurgery Outpatient Unit at Dr. Soetomo General Hospital and fulfilled the inclusion-exclusion criteria during the period April-July 2015. The inclusion criteria were elderly patients aged 45 - 65 years old who able to read and write also willing to participate the study. The case group was determined by value of TMT B >180 seconds, while for the control group has the value of TMT B ≤180 second.

The exclusion criteria were cognitive disorder with a definitive cause of structural lesions (cerebral tumor, moderate to severe brain injury, stroke, Parkinson Disease, brain infection); suffering from rheumatoid arthritis, lymphoma, Systemic Lupus Erythematosus, cancer; using corticosteroid drugs; showing a Systemic Inflammation Response Syndrome; hsCRP ≥10 mg/L; and they had has a history of alcoholism, schizophrenia, and depression. The elderly patients who fulfilled the inclusion and the exclusion criteria were given a careful physical examination and neurologic examination. Then they were examined the value of TMT B by Resident in Training of Neurology Department. After that, the subjects were performed complete blood tests and hs-CRP levels by Prodia laboratories.

The high hs-CRP levels were defined if the hs-CRP levels in plasma >1.0 mg/L. Plasma were taken from 0.5 ml of venous blood by using the immunometric assay technique method; and hs-CRP was examined by Immulite 2000 hs-CRP and expressed in mg/L units. The executive function disorder was defined if there was an extension of TMT-B time than normal value of ≤180 seconds.

Statistical analysis was performed using SPSS 22.0 program. Collected categorical data were tested by Chi Square test and Fisher test, meanwhile Unpaired T test was used for numerical data. The difference in the proportion of executive function in both groups was tested using Chi Square test, then analyzed using logistic regression.

**Result**

The total subjects of the study were 36 subjects then 18 subjects were included in the case group (3 men, 15 women) and the other 18 were included in the control group (4 men, 14 women). The basic characteristics of subjects consisted of demographic and clinical data were shown in table 1.

Table 2 showed the correlation between high hs-CRP levels and executive function in elderly patients. This difference was statistically significant with p = 0.041 and OR=10.818 (95% CI 1.165 – 100.439). Then, we obtained type II error (β error) of 1% in this study.
Logistic regression on the level of education, hypertension and high levels of hs-CRP was analyzed. The analysis obtained p value of education level was 0.029 with adjusted OR of 5.713 (95% CI 1.195 - 27.314). Hypertension obtained p = 0.053 with adjusted OR (95% CI 0.978 - 27.933). Meanwhile, high levels of hs-CRP did not have a significant correlation to the executive function with the p = 0.149 with adjusted OR 5.629 (95% CI 0.538 - 58.860).

Discussion

In our study, sex did not have a significant correlation to the executive function. The data were in accordance with the previous studies that showed no correlation between sex and TMT B. Studies conducted in 1447 healthy people aged >18 years reported that sex did not affect the results of TMT examination B.21 Other studies conducted in Korea with 997 subjects aged 60-90 years, indicating sex also had no significant correlation to TMT B.22 The sex effects on TMT examination results in the elderly population were still under debate.24 Meanwhile, another study reported the results of the Concept Shifting Test (CST) showed that women were superior. CST was a TMT modification that aimed to measure shifting and executive functions 12.

The median age of the subjects in our study showed that the age of case group was the older one. However, there was no difference in the mean age of executive function. Demographic data on other studies used a cross-sectional method with the aim of finding a relationship between hs-CRP with executive function and cerebral microstructural integrity, and obtained that the age range of subjects was 40-80 years, with average of 63.3 ± 0.4 years . Lukas et al reported that individuals aged> 50 years associated with abnormal TMT results. Previous studies have shown that increasing age was associated with duration to complete an executive function examination. The studies with similar results were also reported in the Dutch population, Korea, Americans, and Brazil 13.

Based on our research, the level of education had a significant correlation with the executive function. The subjects with primary education level and junior high school had a probability of 5.713 times more often to experience executive function disorder than those with high senior education level and college. Our results were consistent with the study by Hamdan AC et al. which reported that the subjects with an educational level of ≥9 years completed TMT B shorter than subjects with low education level (2-8 years). However, there was no significant difference between subjects with average education period of <9 years and subjects with education period of ≥9 years.28 Another study also proved that low levels of education was related to completion duration of TMT examination B 25.

In our study, there was no relationship between hypertension and executive function. In addition, variable dyslipidemia and obesity had no significant correlation with executive function. Our results did not match with the cross sectional study conducted by Collinson et al that consisted of 55 asian subjects aged >55 years were suffering from metabolic syndrome and 44 healthy people as the control. The definition of metabolic syndrome in the study used the International Diabetes Federation modification criteria of obesity (BMI >23) followed by at least 2 of hypertensive risk factors, type 2 DM, triglyceride elevation and low HDL. The results showed that subjects suffering from metabolic syndrome were associated with disorders in the memory domain and executive function rather than with the control group 5.

The characteristic of NSAID use had no significant correlation with executive function. Our results also did not match with the Baltimore Longitudinal Study on Aging, Rotterdam, the Cache County Memory Study, which indicated that the strongest dementia risk reduction occurred in people who have been using NSAIDs for more than two years. Thal et al reported that if the COX-2 inhibitor (rofecoxib 25 mg)/day was adminstered for 4 years, it could not prevent the progression of Alzheimer’s Disease in patients with MCI.

Our study showed that there was no correlation between high hs-CRP levels and executive function in
elderly patients. The results of this study were according to the Longitudinal Aging Study Amsterdam. The study used a cohort method, involving 1,284 subjects with an age range of 62-85 years. The cognitive examination of MMSE, memory (auditory verbal learning test), Intelligence (Raven’s Colored Progressive Matrices) and information processing (coding test) were performed then followed up after 3 years. The CRP levels were not associated with cognitive disorder in all examination modalities in the study (Dik et al, 2006). Another study investigated subjects included 97 women aged 60-70 years, who were examined the levels of hs-CRP and cognitive function (MMSE, word recall test, and Stroop test). Other cross-sectional study of 1331 subjects with age >65 years proved that high hs-CRP levels did not related with the domain of executive function and language interference 14.

However, several studies had shown that high levels of hs-CRP were correlated with cognitive function disorder. One of them, was a cross-sectional study by Rizzi and his colleagues on 149 CHD patients aged ≥50, then did the MMSE examination. The result showed that 34 subjects had cognitive disorder (case group) and the rest were in the control group. Subjects with high CRP levels (≥5 mg/ L) had 2.9 (95% CI 1.26 - 6.44) times more often suffering from cognitive disorder (p = 0.012) and leukoaraiosis was only 5.98% (p = 0.005). Thus high hs-CRP levels were associated with an increased risk of cognitive disorder in elderly patients. The results of other studies also showed that high levels of hs-CRP were associated with executive function disorder aged of 40-80 years old 15.

In this study, there was no correlation between the high hs-CRP levels and the executive function in elderly patients. This might be due to the significant differences in the number of subjects, racial differences from the study subjects and might also be influence of the confounding factors. It was such as the educational level that makes it difficult to ascertain whether the cause of impaired executive function was found purely because of high levels of hs-CRP alone 16. Vijay & Kumar reported that the inflammatory parameters measured from peripheral blood did not directly describe the inflammatory process in the brain.7 In addition, although CRP was a marker of vascular disease, elevated CRP levels did not directly affect vascular outcomes 17.

**Conclusion**

There was no correlation between the high hs-CRP levels and executive function disorder in elderly patients.

**Ethical Clearance:** The research process involves participants in the survey using a questionnaire that was accordant with the ethical research principle based on the regulation of research ethic committee. The present study was carried out in accordance with the research principles. This study implemented the basic principle ethics of respect, beneficence, nonmaleficence, and justice.

**Conflict of Interest:** The author reports no conflict of interest of this work.

**Source of Funding:** This study is done with individual funding.

Islamic Ethical Value of Customary Basis of Marriage Proposal Application in Indonesia

Edy Sismarwoto
Lecturer at Faculty of Law, Universitas Diponegoro, Semarang, Indonesia

Abstract
This community legal observance in the field of Islamic marriage is based on the concept of good deeds which can be said to be deontologically valid. The approach is based on deon/obligations arising from the principles of Islamic life. This research method is an empirical method that looks at social reality and is carried out with an ethical approach to understanding the meaning of deeds in the marriage process. Philosophical analysis is used to analyze values in the conduct of the marriage process of Islamic societies in Indonesia. The results showed that in Indonesian Islamic society, marriage and marriage registration had become a community culture that had a philosophical value of worship. This happens because there is enculturation in the form of symbols of Islamic teachings that make it easier for people to recognize the value of an action. Proposal and registration of marriage has become the culture of the Islamic community with the symbol of halal and worship in marriage. Thus the community’s obedience to Islamic law and state law is not coercion carried out by state power, but is the legal culture of Islamic society.

Keywords: charity, ethical approach, Islamic teachings, marriage.

Introduction
Good action theory according to Islamic teachings, has long been rooted in Indonesian society, and has an influence on the law-abiding behavior of the Indonesian people. This theory, academically can be said to enter into deontological ethics because it is based on an intention that gives rise to an obligation (deon) to act.\(^1,2\) The approach used is normative ethics which looks at moral existence in a good deed. Morals become the principles to do good that encourage good intentions, so this theory can also be called the Islamic moral obligation theory. Philosophy of moral obligations in Indonesia does not originate from Immanuel Kant’s teachings on obligation,\(^3\) but comes from the teachings of Islam that entered Indonesia around the 7th century AD. The philosophy can be categorized as deontology because the approach is from the perspective of the intention that is in the act or often referred to as an obligation.\(^1,4\) Human actions, depending on their intentions, in the sense that intention raises the obligation to obey the rules even though the morals contained in intention are different. These differences in intentions give rise to the quality of human actions so that some are seen as good deeds and some are seen as futile deeds. Good and bad actions are not seen in the outcome or form but in their intentions, because this intention has a dimension of value.

An ethical approach to deeds in Islamic teachings was taught as part of Islamic morality. The root of that teaching is hadith of “innamal’ amalu bi niyat”, that one’s actions depend on their intentions. It should be understood that in Islam the term “charity” only applies to good deeds legally not to bad deeds legally called immorality. Within the framework of fostering the good deeds of mankind that there is a hadith, so that the quality of good deeds becomes stratified, some are pious and some are in vain. For example, the act of marriage. In Islamic law marriage is included in charity or good deeds, but the quality of the deed depends on the intention. Intention is an invisible but real existence as a moral perspective that motivates actions. Formal intentions are formed in sentences which are the purpose and ethical basis of the action carried out. The purpose in the intention is built based on moral values, for example the moral value in marriage is to form a family, not just to justify sexual relations, then intentions that are not based on that value, have qualities as bad or vain actions in the dimensions of worship. The ethical basis in intention is a specific part of Islam which is the value of faith or
belief in God. This paper aims to examine the public understand the legal categories in their implementation of Islamic good deeds, and the effect of understanding on the compliance of religious and state law.

Islamic moral teaching

Islamic teachings contain 3 parts of which all three are interconnected, one giving meaning to the other, namely: First, the doctrine of faith or belief. Second, sharia teachings or law and third, moral teaching. The perspective of legal theory, looking at all the rules and norms in the Qur’an and Hadith which are the source of Islamic teachings is the *ius constitution*, which is the ideal rule, and will become the *ius constituendum* through the implementation of these teachings by each adherent. Jurisprudence, are detailed rules of Islamic teachings, which regulate the practice of actions which can be carried out directly by humans, both the order to do it and the command to leave it. Every human deed regulated in Islamic jurisprudence law has a legal category related to morals and creeds, namely the categories of *wajib*, *sunnah*, *halal*, *makruh* and *haram*. The first three categories of actions are philosophically the roots of good deeds, because these categories are taught to be moral as well as beliefs for Muslims in performing daily actions. The two other categories, namely *makruh* and *haram*, are orders to leave acts that are not legally permissible. The proposition of “*innamal a’malu bi niyat*” is that every act can be obligatory, *sunnah* and *halal* is still very dependent on its intention.

The introduction of Islamic teachings in Indonesian society through this category, so that people recognize it as a moral mindset of good deeds or charity.

An ethical approach is taken to understand that Islamic law is not just a regulation regarding normative conduct, but has religious values and moral values, both of which are precisely the source of Islamic society’s adherence to Islamic law. Community obedience to the law actually depends on the value of worship and moral values believed in the normative rules. The term Islamic is for a law whose normative rules do not deviate from Islamic creed and morals, including Indonesian national law. An assessment that a law is Islamic or not, is if the legal norm does not conflict with Islamic creed and morals, because in legal matters between members of the community, Islamic law adheres to the principle that the origin of all economic transaction (*muamala*) is lawful/ permissible, except for those which clearly have restrictions in the shari’a. Therefore, even though there is no prohibition in Islamic Sharia regarding economic transaction law rules governed by the state, it does not mean that the law is Islamic if it is contrary to Islamic creed and morals. This is the shape of the Islamic teachings between the Islamic theology, sharia and morals.

Islamic theology and moral also serve to provide a categorical imperative to the intention to carry out an act that obeys the law. Categorical imperative is a command that says what must be done from the point of view of purely reasoning; something is said to be categorical because what is ordered from the perspective of pure reason does not depend on plausible circumstances and always carries a primary value. This is in the form of faith with the Islamic creed and noble character taught by Islam. Existing beliefs in adherents of Islam encourage to act in accord with the faith and morals, in the form of a categorical imperative. This imperative ordered something not to achieve a certain goal, but because the command was good on him. In accepting this imperative, we are very much determined by ourselves, because we not only determine our actions freely, as Kant believes in humans in all the training of selected talents; we also accept a principle whose content is determined by what is very important to us as actors, namely our practical ratio. We thus follow our own laws (which are in the faith and morals) and therefore have autonomy when we accept categorical imperatives. Otherwise, we fall into heteronomy, or the acceptance of (free) principles whose contents are determined independently of the nature of our own rational existence. Categorical imperative reveals the power of supernatural freedom within us so we must regard ourselves as part of a world that can be understood, that is a power that is ultimately determined not by natural law but by the law of reason.

Marriage Proposal Application

In the field of marriage, the Islamic community is familiar with the culture of Islamic law. All marital procedures are actually Islamic law which has become the morality of the community. People recognize it from generation to generation and appreciate it as glory/dignity. Legal symbols make people understand actions very easily without having to understand the legal details, but are able to distinguish which good deeds are truly good, with deeds that are not good because of their intentions. Marriage in the Islamic community in Central Java must be morally preceded by an application or proposal, which is determined that someone who has
been applied for/proposed cannot accept someone else’s proposal. This provision has become a moral culture of Islamic society.

In the Compilation of Islamic Law there are provisions regarding application, Article 1 letter a stated that stipulation that a proposal is an activity in the direction of an arranged marriage between a man and a woman. Chapter 3, articles 11-13 stated that proposition can be directly carried out by people who want to find a mate partner, but can also be done by intermediaries who can be trusted. Candidates can be carried out on a woman who is still a virgin or on a widow who has expired iddah, and women whose husbands are retained are in the period of iddah raj’iah, haram and forbidden to be married. It is also prohibited to propose a woman who is being married to another man, as long as the man’s proposal is not broken or there is no rejection from the woman. Termination of proposals for men, due to a statement about the termination of discourse or secretly. The proposing man has shunned and left the woman he is asking for.

The proposal has not caused legal consequences and the parties are free to terminate the marriage relationship. Freedom to break the marriage relationship is done in a good manner in accordance with the guidance of local customs and customs, so that it is maintained harmony and mutual respect. The provisions have become the people’s morality for generations, becoming the beliefs and rules of the people’s habits. They implement these provisions for the common good and no single member of the community does not want to comply with these provisions, because marriage is something that is considered sacred and there must be a procedure. The role of intention that determines marital deeds starts from marriage. In theory, every good action depends on the intention, so also the value of the implementation of the proposal depends very much on the intention, even though the proposal is a good act legally. The act of marriage which is then carried out with worldly intentions is considered not a good deed because it does not intend to worship, only to justify mere sexual relations. Islamic teachings see that the intention can change depending on the consciousness of the person who is doing it, so that even at the time of marriage the intention is to be carnal but if there is then awareness of intention to worship, then the value of marriage becomes the value of worship to build a good household. The existence of this theory of good deeds is evident in Islamic societies, as evidenced in Islamic societies there are far more harmonious households than divorced households.

Registration of Marriage by the State

Marriage registration, is not an act that determines the legality of marriage, but determines the effect of the law that has been regulated by the state, both through the provisions of Islamic law and by the provisions of state law in general. In Indonesia there are general provisions regarding marriage because Indonesia is a multi-religious state, not only one religion is recognized by state law but there are some religions, namely Islam, Christianity, Catholicism, Hinduism, and Buddhism. These general provisions are contained in Law No. 1 of 1974 concerning Marriage. Therefore there are the same provisions that apply to all Indonesian citizens in marriage, namely marriage registration, which aims to provide legal protection to those who do marriages.

The results of research on the Islamic community in Central Java there are cases of marriage that are not recorded in a relatively small number compared to the Muslim population as a whole. It was caused by various factors, including lack of understanding of the function of marriage registration, social economic factors, and marriages that were conducted before the issuance of Law No. 1 of 1974. The Government has made efforts to improve the population administration system that can cause marriage registration to become sociologically mandatory for every married population, namely with a population identification system in managing all socio-economic and legal needs. Identification of the population requires proof of marriage that can only be done with a marriage certificate, so that the recording of marriage among Islamic societies gradually becomes a culture of society that has social sanctions in the form of denunciation, in addition to obtaining legal sanctions in the form of neglect concerned in social and economic traffic that requires verification marriage.

Obedience in the law of marriage registration in Islamic society, mainly based on the concept of the deeds of “innamal a’malu biniyah”. In this concept, marriage registration is seen as a variable of good deeds (or charity) and intention is seen as a determining factor of observance of marriage. The habit of the Islamic community in using the symbol of halal and haram causes the ability of the community to distinguish the value of the act of “registering marriage” into the value of social and religious necessity because registering marriage is not an act that is prohibited by Islamic teachings, even
encouraged by Islam. By viewing marriage registration as a variable determined by intention, it can be measured that people who do not register their marriages have ill intentions based on the assumption that: they understand the legal consequences of marital registration; and there are no socio-economic factors that hinder marriage registration.

The ethical perspective in this study shows that anatomically the act of recording marriage is a charity (good deeds) based on good intentions that have become a necessity/obligation from within the members of the Islamic community itself, is not a coercion from the state. To realize a society that has good faith must use a legal system that is rationally in accordance with the religious values of Islamic societies. The deed of innamal a’malu biniyah is the main basis of all observance of the Islamic community to the law, where the teaching has become public awareness that the nature of worship of an action depends on its intentions, not on the form of good deeds.

**Conclusion**

The Islamic community in Indonesia basically already has the concept of “good deeds” based on the deed of “innamal a’malu biniyah” which academically can be said to be deontology because they see deeds based on “deon” arising from the principles of Islamic religious life. Legal awareness of the Islamic community in Indonesia is broadly legal awareness for worship, is a social culture that contains religious values of Islam. Based on reality, this awareness exists because the regulation by the state does not conflict with Islamic law, but instead is based on Islamic teachings which strengthen and provide legal certainty to the community. Arrangements regarding marriage registration have existed since Indonesia’s independence, so it can be concluded that the process of legal awareness requires a relatively long time depending on the socialization and enculturation in Islamic societies. The problem faced in other socio-economic sectors such as banking, economics and others is how to build people’s behavior through an ethical approach, not from the perspective of comparison between Islamic law and state law.

Puberty Knowledge and Communication among Adolescent Sexual Offenders in Indonesia: A Qualitative Study

Emi kosvianti¹, ², Emy Susanti³, Windhu Purnomo⁴, Agung Suhadi⁵

¹Doctor Candidate, Faculty of Public Health, Universitas Airlangga, ²Faculty of Health Sciences, Muhammadiyah University of Bengkulu, ³Professor, Department of Sociology, Universitas Airlangga, Indonesia, ⁴Associate Professor, Faculty of Public Health, Universitas Airlangga, Indonesia, ⁵Lecturer in English Department, Muhammadiyah University of Bengkulu, Indonesia

Abstract

Introduction: Rape against women, as one of sexual assaults form, which has been became a serious issue throughout the world in social and public health. It is a gross violation on the women’s human rights, which is cannot be accepted from any perspectives. In the latest cases, the perpetrators of rape are conducted by adolescent or minor.

Purpose: This article presents the study how the young sexual offenders’ knowledge on puberty and their sexual communication.

Method: This research was qualitative toward 30 sexual perpetrators, all informants are being undergone sentences in Correctional Institutions of Bengkulu province, Indonesia. The informants were all child convicts, (aged less than 18 years) at four correctional institution in Bengkulu province.

Results of the study: The perpetrators of sexual assault were middle adolescents who were in-between 16 to 18 years. Based on the results of analysis were found that there were ineffective sexual communication patterns among perpetrators, both informants communication parents, friends, teachers and couples. Moreover, this study found inadequate puberty knowledge among sexual offenders.

Research limitations: This article only describes sexual communication and knowledge on puberty, while other individual factors and social aspects are not discussed at all in this article.

Originality: Based on the various results of previous studies, there are no researches have been found that specifically examines the behavior of sexual violence by minors in Bengkulu province.

Keywords: knowledge, puberty, communication, adolescent, sex offenders.

Background

Sexual health is an important element for realizing the goals of reproductive goals. WHO (2002) defines sexual health as the welfare state of physical, emotional, mental and social in relation to sexuality, it is not only the absence of disease, dysfunction or weakness. Sexual health requires a positive approach and respects for sexuality and sexual relations; the possibility of pleasant sexual experience, safety, free of coercion, discrimination and violence. Therefore, sexual health must be achieved and maintained, and all people’s sexual rights must be respected, protected, and fulfilled.

Women and men implicitly have the same rights to achieve a healthy sexual status without violating others sexual rights or outrage the law.

Some researches, the sexual harrassments such as rape against women is a serious problem that demands massive cost consequences due to depressive events, unwanted pregnancy and HIV/AIDS virus [¹]. Many of health problems are caused by the sexual violence, these are not only a concern on criminal law throughout the world, but also the field of public health [²].

The sexual aggression is rampant by perpetrators under age group 18 years as an illustration of the
low quality of sexual health understanding among young adolescent. It is because the sexual behavior plays an important role in producing mental and social health outcomes. But, now there has not been found a theoretical or conceptual model that is fully able to explain the relationship between sexual behavior and various aspects of health [3].

Method

Design and participants

This research used qualitative method toward 30 male adolescents less than 18 years who were the perpetrators of rape. All respondents are being undergone sentence at four Correctional Institutions of Bengkulu province.

Data collection

This research conducted within 6 months from 24 May to 26 October 2019, through semi-structured interview manner. This model is conducted with face to face interview, and strongly believed able to explore more profound exposure among each respondent. This manner will be a bridge for exploring various experiences and places within more specific context, thus allows informants (perpetrators) to re-construct their experience more details.

Data Analysis

Data analysis and theoretical interpretation refer to the formulation of research problem: how the forms of communication are conducted by the perpetrators and how the knowledge of informants on puberty. Analysis and interpretation of the data in this study was carried out by providing interpretation and production process of meaning of the text of the interview with the informant and comparing it with various studies and previous studies.

Ethical Clearence: The ethical clearence for this research was taken from Ethic Committee of Health Research Faculty of Nursing, Airlangga University with ethical approval numbers 1278-NREC.

Findings

Based on the semi-structured interview manner toward child sexual offenders, our analysis have narrowed down into two issues on sexual coercion by child offenders are knowledge on puberty and sexual communication. The cases above are not spontaneously, but as a combination of problems that are being experienced by perpetrators, family background and external influences as well from their peers or environment. As a prepubescent group, most of their attitudes are still unstable and fragile, as a result these trigger their sexual offending like rape or other sexual harrassment forms.

Knowledge on Puberty

Majority informants usually got the knowledge in term of puberty from schools; through biology subject and counseling program by health workers. Moreover, they also admitted due to the peers and older friends. Their knowledges were the puberty signs between men and women; they mentioned several signs of puberty in men, such as wet dream, Adam’s apple, mustache and beard. In women, it is usually marked by the arrival of menstrual period and enlarge breast size. However, they have wrong understanding on puberty signs; enlargement of breast size on women due to the factors often touched by opposite of sex. This reflects that sexual health of informants in term of puberty is still low. In addition, they do not know what have to do when at their puberty. The low understanding on puberty is due to there is no any program that more specific contains about puberty education both males and females. As a result of this, young adolescents have not ready yet to undergo pre-puberty and puberty period as well.

One of the main reasons why many of young adolescents have deviant sexual behavior, for instance rape, is due to the influence of peers, because peers can activate the ‘reward system’ in adolescents’ brain. The change of brain function creates psychological vulnerabilities, which can contribute to behaviors that endanger health and enhance emotions. At the same time, brain plasticity combined with social and cognitive change make adolescents’ thinking and false behavior which further have significant implication for future of health and welfare [4].

Meanwhile, in adolescents puberty, there is a change in the hypothalamus-pituitary-adrenal (HPA) system, which make adolescents more vulnerable to get stress [5]. It also has a profound affect on their vulnerability to get depression and serious health problems in the future [6]. Physical, emotional, and social changes in puberty can cause them to become stressed, especially when they feel misunderstood or have inadequate coping skills. Adults, within puberty period need to explain the problems of
puberty, emotional change and the importance of peers as part of puberty education, all are aimed at normalizing change, reducing stress, ensuring healthy choices. At this time, the puberty rises faster than before, for instance, the breast enlargement on females were at the age of 8 or 9 years, while the development of genetal organs on males begun at the age of 9 or 10 years.

The cases above indicate the necessity a puberty education system based on the stages of child development. At pre-puberty, teens need enough information to face several changes during puberty. While, adolescents who have experiencied on puberty, they need more information and strategies for facing these changes.

**Sexual Communication**

**Communication with parents**

The sexual communication practice is still rarely done openly within the family of informants; either parents or other family members. The pattern of communication are quite monotonous and in one-way communication toward older and younger persons. The talks model are between parents and informants were only shortly and allowed to discuss about general things, such as taking a bath order (Islamic belief), dating prohibition and having sex with a couple. Informants were only prohibited without being accompanied by discussion and explanation why this should be done or prohibited. This communication form allegedly rises the causative factor of deviant sexual practices among informants, for instance rape. Some previous researches have pointed out that open sexual communication between parents and young adolescents can be significant protective factor to reduce the risks of sexual behaviors by putting off intimate relationship and increase the frequency of contraception and condom use. This finding is reinforced by the results of a meta-analysis of 50 studies that confirm that parent-teen sexual communication is positively associated with safer sex behavior. Thus emphasizing the importance of understanding parental communication as a possible predictor that contributes to teenage sexual decision making.

Sexual communication between parents and children has an important role to realize sex education on children. Previous research has shown that adolescents relationships with their parents influence interactions with peers. This is because the quality of adolescent relationships with friends that develops in early life as the result of socializing experiences within family. Adolescents who have supportive values and warm relationship are more socially competent and report/tell more positive friendships.

This research found the reasons of sexual assault including rape, because it was influenced by friends and could not control the lust. Similarly, Reeb who explained sexual behavior generally occurs when adolescents begin to have romantic relationships. During this time, parents may be able to influence life style choices positively or negatively by discussing their behavior. Parents are expected to be able to play an important role for transmitting reproductive health information and skills on adolescents to ensure they can grow and achieve reproductive and safe sexual lifestyles.

**Sexual communication with friends.**

During the transition period, children tend to spend more time to be alone and with friends, on the other hand, time with parents will decrease significantly. This research found that sexual communication that occurs between informants and friends is more directed to the topic of sexual relations, pregnancy and pregnancy prevention. At the developmental stage as early adolescents, they are usually more open to friends than parents to discuss topics relating to sex.

The negative impact found in communication between informants and friends, there were wrong understanding among informants related to sexuality issues, related to some information obtained from friends. Some of these myths, among others: sexual intercourse will certainly cause a pregnant woman, it is not possible to only have sex once can cause the victim to become pregnant. Besides being related to the process of pregnancy also found myths of female reproductive organ development, especially the size of the breast with sexual behavior. Another myth related to pregnancy termination efforts, is by consuming foods such as pineapple or coffee mixed with soft drinks.

Friends can be an increasingly important source of information and become a critical social reference for adolescents. This condition can become a problem when friends who are partners within discussion also have an inadequate level of knowledge, so that it can provide wrong knowledge and understanding.
Sexual Communication with teachers at school.

Sexual communication was not specifically carried out but only became part of the subject matter at schools such as Biology and Islamic Religious Education. Information on sexuality was only obtained by informants when they are at the second and third grade of high school. The conditions revealed the contradictory results as mentioned by Butler ‘school-based sexuality education’ is believed to be the ideal context for teaching sexual communication skills on children and adolescents in the context of developing and practicing the use of these abilities. For example, from sexual education at schools, students can get training and instruction on how to communicate with parents regarding sexual issues [16].

This study found that informants obtained information related to sexuality, such as puberty, fertilization and infectious diseases when they were at second and third grade high school, while sexual behavior was formed earlier when they are at primary school. These conditions, it is necessary to provide sexual communication services that are tailored to the stage of child development. As stated by Crockett, et al (2019). Pre-puberty teenagers need enough information to deal with the various changes they will face when puberty comes, while in puberty teenagers, they need more in-depth information and strategies to be able to adapt to these changes (4).

Sexual Communication with Girlfriend

Sexual communication with their romantic partner are done face to face and through social media. Their conversation usually leads to the theme of sex. In some cases, sexual communication has become one of the triggers for sexual relations and rape by informants. There are three factors that influence the openness of early adolescent sexual communication with a couple namely length of relationship, relationship satisfaction and commitment [17]. Another phenomenon as seen from this research, the habit of having sexual communication with couples through social media What’s up and Facebook. This finding is similar to Jeff Temple’s idea on Sex and Chatting, which are often used by adolescents, it is well-known ‘sexting’. Sexting in adolescents is an important issue of public health because it can have negative psychological and legal consequences [18]. Such behavior is consistently related to adolescent sexual behavior [19]. Other researchers mentioned adolescents who have sexting have the possibility to have sex 7 times more when compared to those who are not abusers [20]. In addition, sexting also depicts adolescent sexual behavior in daily life [18].

Conclusions and Further Research

The communication practice in term of sexuality is still rarely done openly between parents’ informants. Communication that occurs between informants with friends, more leads to the theme of sexual relations. Communication with teachers is not done specifically but only becomes part of the material in one of the subjects at schools. While, the informant’s communication with a girlfriend is done directly or through social media. Their conversation was more about the theme of sex and in some cases became one of the triggers for rape. This research is only limited to sexual communication and knowledge on puberty. For the future studies may need to be conducted on sexual health practices, such as the use of condoms to prevent unwanted pregnancy and sexually transmitted infections.

Research Funding

This research is funded by the Domestic-Indonesian Lecturer Excellence Scholarship (BUDI-DN), which is managed under the Endowment Fund for Education (LPDP).

Conflict of Interest: There is no conflicts of interest associated to this publication, and financial support could not influenced its outcomes due to a compulsory report for those students who are under Domestic-Indonesian Lecturer Excellence Scholarship.

Abstract

*Moringa oleifera* is a plant that can be used and grown intensively in several Southeast Asian countries. This study aims to determine the effect of *Moringa oleifera* seed oil extract on the levels of the insulin and blood glucose levels of *Rattus norvegicus* induced by alloxan. This study used 30 female Wistar white rats induced by alloxan. Rats were divided into 6 groups. Groups 3 to 6 were injected 100, 200, 300, 400 mg/kg BW extract of *Moringa oleifera* seed oil, respectively. Group 1 neither had alloxan induction nor treatment while group 2 had been induced alloxan but no treatment. Data were analyzed using the Kruskal-Wallis test with a significance level of 0.05. The results showed that there was no effect of *Moringa oleifera* seed oil extract on insulin level (*p* value = 0.161). Conversely, there was an effect on blood glucose levels in alloxan-induced *Rattus norvegicus* (*p* value = 0.036).

**Keywords:** Diabetes mellitus, *Moringa oleifera*, *Rattus norvegicus*.

Introduction

Diabetes mellitus (DM) is a metabolic disorder of various etiologies characterized by chronic hyperglycemia due to absolute or relative deficiency in insulin secretion/insulin action or both. The number of DM patients was 171 million in 2000, which might increase to 360 million by 2030. As the number of people with DM has doubled worldwide, national and international health care budgets have increased[1,2].

Despite the many advances in therapy using expensive synthetic drugs, herbal medicines are growing. It is called not only effective with low side effects in clinical experience but also relatively spend the low cost. Herbal medicines or extracts are widely prescribed, even when the biologically active compounds are unknown[3,4]. Traditional medicine is generally obtained from natural ingredients[5]. One of the plants that has potential for traditional treatment is the *Moringa oleifera* plant.

*Moringa oleifera* is a plant that grows intensively in several Southeast Asian countries. This plant has been used for a long time since its compositions are good for traditional medicine. Almost all parts of the *Moringa* plant can be utilized especially the *Moringa oleifera* seeds. The use of *Moringa oleifera* seed oil extract can reduce blood glucose levels in hyperglycemic mice[6]. Szkudelski found that the main phytochemical element in *Moringa oleifera* seed extract is flavonoids. Bioflavonoids are known for their multi-directional biological activities including hypoglycemic effects[7].

Flavonoids are one of the most common groups of secondary metabolites found in plant tissues. Flavonoids act as an antioxidants by donating hydrogen atoms or chew metal in the form of glucosides which contain glucose side chains) or aglycones[1,2,3,4]. Extract of *Moringa oleifera* seed significantly can reduce alloxan-induced hyperglycemia because it contains not only elements like phytochemicals and micronutrient but also quercetin and kaemferol. Besides, kaemferol also have hypoglycemic activity[8].

Considering that *Moringa oleifera* plants are very potential but it is a lack of data showing the effect of *Moringa oleifera* seed oil can increase the blood insulin levels, this research aims to have further study. An extract of *Moringa oleifera* seed oil will be investigated at a dose of 100 mg/kg BW, 200 mg/kg BW, 300 mg/kg BW and 400 mg/kg BW to observe its effect on insulin levels in alloxan-induced diabetic rats. The effect of *Moringa oleifera* seed oil extract on the insulin and blood glucose levels of alloxan-induced *Rattus norvegicus* will be investigated.
Materials and Method

This study had a laboratory experimental research using a completely randomized design (CRD) in six treatment groups with five replications (6x5). This study used 30 female Wistar white rats with 30 treatment that consist of: Group 1 (K1): control animals that are only given food and drink without alloxan induction and treatment; Group 2 (K2): animals induced by alloxan without treatment; Group 3 (K3): alloxan-induced animals, and injected 100 mg/kg BW of *Moringa oleifera* seed oil extract orally; Group 4 (K4): alloxan-induced animals, and injected 200 mg/kg BW of *Moringa oleifera* seed oil extract orally; and Group 5 (K5): alloxan-induced animals, and injected 300 mg/kg BW of *Moringa oleifera* seed oil extract orally.

Alloxan monohydrate induction was given using intraperitoneal injection methods. Alloxan monohydrate powder was diluted using 0.95% NaCl saline water at a dose of 150 mg/Kg BW by measuring the body weight of experimental animals first. Injection was applied into the abdominal cavity through muscular tissue using a 1 mL syringe. *Moringa* seed oil injection was applied using the per oral method. The density of *Moringa* seed oil was created by having 1 ml of oil and measuring its mass through analytical balance. Injection volume is adjusted to the dose and weight of an experimental animal. Administration of seedling extracts was carried out for 14 days and then on the 15th day all the rats were euthanized, their blood was drawn for analyzing insulin levels using the ELISA method.

Results

Animal insulin levels after 14 days treatment were measured using INS ELISA Kit 96 and the wells from MyBiosource. The following table show the results:

This study revealed that the DM condition arises caused by alloxan, alloxan injection can affect pancreatic cells so that type 2 DM occurs with blood glucose levels increased. Measurement of blood glucose levels was carried out after alloxan was induced as much as 150 mg/kg BW intraperitoneally in 5 treatment groups (K2-K6). Besides, glucose levels were measured routinely until reaching hyperglycemic levels ≥126 mg/dL. On the 15th day after the treatment of *Moringa oleifera* seed oil extract, blood glucose levels were measured again with the following results:

a. Kruskal Wallis Test

b. Grouping Variable: Group
Discussion

Table 1 shows that the highest average insulin level is in group K2 or alloxan-induced animals without *Moringa oleifera* seed extract. Then, the lowest result was in the group K3 (alloxan-induced animals, and injected 100 mg/kg BW seed oil extract orally). The increase of hormone levels due to antioxidant levels in *Moringa oleifera*. *Moringa* seed oil regenerates β-pancreatic cells in pancreatic organs. Based on Chumark et al., phytochemical screening results from *Moringa oleifera* plant extracts showed the presence of secondary metabolites such as flavonoids, terpenoids, saponins, and tannins. Study has shown that terpenoids and flavonoids have hypoglycemic activity[9]. Anti-inflammatory and antioxidant effects reported from flavonoids can also play an important role in reducing insulin resistance[10,11,12,13,14].

Table 2 shows that Kolmogorov-Smirnov and Shapiro-Wilk test reveals data were not normally distributed on insulin levels (p value 0.000 < α 0.05). Then the data were statistically proceed using Kruskal-Wallis test as in Table 3. The Kruskal-Wallis test obtained a significance value of 0.161 > 0.05. Since the significance is greater than specified value then H₀ is accepted and H₁ is rejected. It means that there is no difference in blood insulin levels on alloxan-induced mice.

Hypothesis called that administration of *Moringa oleifera* seed is possible to increase blood insulin levels. Ethanol extract of *Moringa oleifera* leaves has strong anti-diabetic activity because it not only decreases the lowers blood glucose levels but also increases insulin sensitivity and functional beta cells in diabetic mice[14]. There are some possible mechanisms for hypoglycemic action such as stimulation of pancreatic insulin secretion and improving tissue insulin resistance. Further research is needed to ascertain the right mechanism for the anti-diabetes effect of plant extracts and secondary metabolites involved.

The therapeutic use of *Moringa oleifera* leaves has been evaluated in diabetes since their capacity to reduce blood glucose concentration. It contains polyphenols such as quercetin-3-glycosides, routine, kaempferol and glycosides. Blood sugar decreased due to *Moringa oleifera* therapy can be observed on fasting blood glucose, oral glucose tolerance test and post prandial glucose in diabetic rats, in an average decrease of 25% or more. The antidiabetic activity of *Moringa oleifera* seed powder has been observed.

In mice, glucose and amelioration of lipid peroxide levels decreased. It reduced IL-6 level and immunoglobulin A compared with positive control of diabetes in both insulin-resistant and insulin-deficient bioassays. Meanwhile Sandanamudi et al. showed that *Moringa oleifera* contained soluble fiber which increased amelioration of glucose levels, lymphocyte proliferation and nitric oxide induced from macrophages[15]. Another study observed *Moringa oleifera* fortification in diabetes can reduce fasting blood glucose. It not only reduces the entry of glucose into the mitochondria and but also releases reactive oxygen species. Besides, it also promotes glycation end products (AGEs) which increase cell adhesion and inflammation in diabetic patients. Treatment with *Moringa oleifera* has shown that after histological examination of the pancreas of diabetic rats, significant damage is reversed in the histoarchitecture of the islets of Langerhans[16].

Having several studies carried out, it is revealed that the administration of *Moringa oleifera* seed oil extract can increase blood insulin levels in rats through the mechanism of pancreatic insulin secretion stimulation. It also improves insulin resistance in tissues by active compounds contained therein such as flavonoids, sterols, triterpenoids, alkaloids, saponins, and phenolics. Statistically, the rise of insulin hormones in treated mice still occurred although it was not significant. The increase of hormone levels almost reaches a significant value since the levels of antioxidants in *Moringa oleifera*. *Moringa oleifera* seed oil regenerates β-pancreatic cells in pancreatic organs. These cells produce insulin which is secreted when the blood sugar levels rise. In addition, glucose change to fat requires insulin which is produced by langerhans, a group of cells in the pancreas. High glucose levels with insulin increase cholesterol levels in the blood. Vitamin D is important for secreting insulin in the pancreas. This study shows that individuals with low vitamin D levels are very bad at handling blood sugar and a higher risk of having diabetes[17].

Insulin resistance is a condition showing a low potential for endogenous and exogenous insulin. An assessment of homeostatic model (HOMA) β cell function and insulin resistance (IR) was first described in 1985[18]. This technique is a method for assessing the function of β and IR cells from basal glucose and insulin or C-peptide concentrations. This model has been widely used since it was first published. Therefore, we present
here an overview of the model and its proper use and limitations in clinical science.

Insulin resistance is a disruption of insulin in metabolic response where blood glucose levels increase. It requires more levels of insulin to make blood sugar levels back to normal (normoglycemic). Insulin resistance occurs in the target cell receptors on skeletal muscle tissue and liver cells. Damaged receptors increase insulin secretion which is called hyperinsulinemia [19]. This study reveals that the highest blood glucose levels were in the K2 group which is called having positive control of DM rats (275.40 mg/dL). Meanwhile, the lowest glucose levels in the DM rats group were given Moringa oleifera seed oil extract (Moringa oleifera) dose 400 mg/kg BW (131 mg/dL). The Kolmogorov-Smirnov and Shapiro-Wilk tests determine whether the data distribution was normal or not. The results of Kruskal-Wallis test shows significance value of 0.036 < 0.05. Since the the significance is smaller than specified then H0 is rejected and Ha is accepted. It means that there is a differences in blood glucose levels on alloxan-induced mice.

Aloxan monohydrate will reach pancreatic tissue and attack β-pancreatic cells. The mechanism of aloxan monohydrate action cause oxidative stress on pancreatic tissue. It permanently damage the β-pancreas cells. Damage to β-pancreas cells decrease insulin levels and increase blood sugar (hyperglycemia). The aloxan monohydrate is used to make animals experienced with blood sugar increased (hyperglycemia) [20]. Statistical analysis showed that there was an increase in blood sugar levels due to the addition of Moringa oleifera. Moringa oleifera seed oil. It make fluctuation in the control until the treatment on group 5 (K1-K5). The highest increase occurred in group 6 (K6). Blood sugar increased because of Moringa oleifera L. level. Moringa oleifera seed oil is no longer effective even though it contains antioxidants.

The therapeutic use of Moringa oleifera leaves has been evaluated in reducing blood glucose because they contain polyphenols such as quercetin-3-glycosides, routine, kaempferol and glycosides. The blood sugar decreased can be noticed in different tests: fasting blood glucose, oral glucose tolerance test, and postprandial glucose in diabetic rats with an average decrease of 25% or more [4,20]. The antidiabetic activity of Moringa oleifera seed powder has been observed in mouse models. It shows decreased glucose, amelioration of lipid peroxide levels, reduced levels of IL-6, and immunoglobulin which was compared between positive control of diabetes in both insulin-resistant and insulin-deficient bioassays.

Meanwhile Sandanamudi et al. showed that Moringa oleifera contained soluble fiber which increased amelioration of glucose levels, lymphocyte proliferation and nitric oxide-induced from macrophages. In another study, fortification of Moringa oleifera in diabetes can cause fasting blood glucose decrease [15]. It reduces the entry of glucose into the mitochondria, reactive oxygen relief, and advance glycated end products (AGEs) [20]. Therefore, cell adhesion and inflammation increase in diabetic patients. Treatment with Moringa oleifera has shown that the pancreas of diabetic rats which is significantly damaged is reversed in histoarchitecture of islet cells after histological examination. Based on the explanation and some previous studies, it is called that there is no effect of Moringa oleifera seed oil extract in increasing rat blood insulin levels. It all carried out through stimulation of pancreatic insulin secretion and/or improvement of insulin resistance with flavonoids, sterols, triterpenoids, alkaloids, saponins, and phenolics.

**Conclusion**

In sum, Moringa oleifera seed oil extract can reduce blood glucose levels and can be used as a potential plant recommendation for traditional treatment of DM.

Estimation of Age Using Kvaal Technique Based on Cone-beam Computed Tomography Images of Mandibular Canine Teeth in Bojnourd

Farzam Tajdini¹, Seyedeh Mahla Hemati², Farzad Tajdini³

¹DDS, Msc, Oral and Maxillofacial Radiologist, Assistant Professor, School of Dentistry, Bojnurd University of Medical Sciences, North Khorasan, Iran, ²Dentistry student, School of Dentistry, Bojnurd University of Medical Sciences, North Khorasan, Iran, ³MD, Community Medicine Specialist, Department of Health and Community Medicine, School of Medicine, Shahid Beheshti University of Medical Sciences, Tehran, Iran

Abstract

Background and Objective: Identifying age in anthropology and forensic medicine and examining the proper development of children and adolescents is important. Age estimation techniques using teeth are of particular value. This study tends to evaluate the accuracy of age estimation by Kvaal technique using CBCT images of mandibular canine teeth in a sample of Iranian population.

Materials and Methods: In this crossvalidation study, data from 140 samples of records of patients aged 15 years and older, during 2018-2019, available at a private oral and maxillofacial radiology center in Bojnourd was used. The parameters used in Kvaal technique were measured in mandibular canine teeth on CBCT images of patients.

Results: Using multiple linear regression model to correlate parameters of Kvaal technique based on CBCT images of mandibular canine teeth and age with stepwise method showed that variables pulp length/root length, pulp width/root width in the middle, length teeth/root length were significant in predicting age (p<0.05 in all 3 cases). According to the above method, age = 551/5-500 (M) was obtained which was able to estimate age in 35% of the samples. The mean age of the patients was estimated to be 7.9 years, which is acceptable.

Conclusion: Kvaal formula was significant for use in Iranian population. The regression formula obtained from the control group could also be generalized to the test group.

Keywords: Age Estimation Using Tooth, Mandibular Canine Tooth, Cone-beam Computed Tomography, Forensic Dentistry

Introduction

Teeth are used when none of identification techniques is not satisfactorily used. In most adverse conditions, such as degradation of a cadaver or floating in the water for a long time, there is the slightest change in texture of tooth compared to other parts of the body.¹² The tooth is the hardest body tissue and has the highest resistance to trauma, external factors, and other factors³ and can withstand the effects of long-term physical, chemical, mechanical damages and passage of time, and also remains intact years after death, but is at least affected by nutritional factors, environment and living conditions.⁴ Forensic dentistry is a major contributor to estimation of age of corpses, immigrants and wanted criminals.⁵ However, age estimation in adults is challenging in both anthropological and judicial settings compared to adolescents due to full maturity of individual teeth and bones and inaccuracy of techniques based on degenerative process.⁶ Age estimation is
still a major challenge in forensic medicine. Several methods have been employed for this purpose, and a range of results have been obtained. In 1995, Kvaal invented a non-destructive technique for age estimation based on measurement of dental pulp and root space in 6 radiographic types, which have been adopted by the American Academy of Forensic Sciences. This technique is completely based on measurements of radiographic images and does not depend on other factors such as root transparency and periodontal retraction and therefore no tooth extraction is required. Based on dental ratios including tooth length, pulp length, root length and root width in three regions of CEJ, middle part of the root and between these two regions, and by examining the mean of these items, a formula can be obtained which is helpful in estimating age. Therefore, problems with undesirable tooth angle as well as superimposition will be resolved. Due to inconsistent results in previous studies and lack of consensus on efficacy of Kvaal technique in a sample of Iranian population as well as the lack of implementation of this project in North Khorasan province, this study tends to evaluate effectiveness of this technique in this province.

Materials and Method

Studied Population, Sample Size and Sampling

Participants included people referred to a private oral and maxillofacial radiology center in North Khorasan Province who required CBCT imaging and were older than 15 years. Based on previous studies, assuming type I error 0.05 (α = 0.05) and type II error 0.2 (β = 0.2), i.e. 80% test power, and taking into account minimum coefficient of correlation (r = 0.25), the sample size was set at 110 and 30 patients were considered for the control phase (13). That is, CBCT images of 140 patients over 15 years were selected (to avoid possible confounding of age and to increase estimation accuracy, age range was set at over 15 years). After selecting the samples, CBCTs were randomly divided into two groups of 110 and 30 each. Samples were obtained from a privately owned oral and maxillofacial radiology center.

Data Collection and Validity and Reliability of Instruments

Images of all patients were analyzed using a CBCT device, Ray scan alpha 3D (LED medical diagnostics Inc., Atlanta, GA, manufactured in South Korea) previously made and exposure parameters 90 kvp, 10 mA and 14.3s with standard resolution were used. In this study, mandibular canine teeth were used to estimate age, because they had a larger pulp and a longer probability of remaining in the mouth. The relevant parameters were calculated by OnDemand 3D dental software by oral and maxillofacial radiologist. Finally, data was transmitted via DICOM format to DVD.

Method

Factors evaluated by Kvaal technique for estimating age include:

- T: maximum tooth length
- P: maximum pulp length
- R: root length from CEJ to apex
- A: root width at CEJ (level A)
- C: root width at middle root level (level C)
- B: root width at midpoint between CEJ and root center (level B)

By software adjustment in coronal and axial dimensions of multiple planar reconstruction (MPR) images, sagittal cut of tooth containing the entire length of the crown and root. Then, using OnDemand 3D dental software, all of the above were measured by a radiologist after reorienting and reslicing in the sagittal dimension on sample teeth. Then, by using the above 6 measurements, 6 ratios was obtained including:

- T: tooth length/root length, P: pulp length/root length, R: pulp length/tooth length, A: pulp width/root width at level A, B: pulp width/root width at level B, C: pulp width/root width at level C.

The mean of all the above was calculated and included in the study as a new variable (M). First, the regression formulas first derived by Kvaal et al for age estimation using canine tooth, as age = 158/8-255/7(M), were set as template and used for the data (M mean of all ratios defined). In order to compare the results of this study with Kvaal results, mean of 6 variables mentioned above was calculated as record for each studied unit and considered as new independent variable M. This new variable was substituted in the above regression equation. By modelling the Kvaal regression model, mean of all the ratios was used; by SPSS software (version 22), the corresponding equation was obtained by using the obtained data for the Iranian population.
2.5. Ethical Considerations

In this study, CBCT images archived in a private oral and maxillofacial radiology center were used; thus, no intervention was performed for the studied patients. All information obtained from the patient records remained confidential. There was no specific ethical prohibition in this study. The plan did not contradict international treaties on medical sciences such as Nuremberg and Helsinki. All collected checklists were confidential and the results were reported only in general terms.

Results

The general regression formula for estimating age is \( M = a + b \times (x) \), where \( x \) is the estimated age; thus, \( x \) (age) = \( a + b/M \). The regression equations were derived from the above equation (Table 1). Using Kvaal technique and modeling their regression equation for canine tooth, \( M = 0.784-0.001 \) (age) was set for current data; thus, age = 784 – 1000 (M). As mentioned before, \( M \) is the mean of all data. The above equation was more acceptable than the Kvaal equation but it was able to estimate age in only 21 samples (15%). Therefore, by examining the correlation tables between each variable with age, it was found that three variables were not correlated with age. Thus, the three variables B, A and R were excluded. Excluding the three variables mentioned and substituting them into the formula above, \( M = 1.103-0.002 \) (age), again yields a new regression formula: age = 551.5-500 (M). In the formula above, three variables T, P, C were used to obtain the new \( M \) (Table 2). The formula was effective in 50% (35%) of patients, indicating a higher accuracy than the original formula. The second formula, by excluding variables that did not correlate with age, had a correct estimation of age in 50 patients. By analyzing variable data of these 50 people, it was found that this formula could accurately estimate the age when these variables were in a specific range: \( T = 1.47-1.70, \ P = 1.22-1.41, \ C = 0.06-0.38, \) and \( M = 0.96-1.09 \). Outside these ranges, this formula is not responsive (Table 3).

**Discussion**

The results of our study showed that Kvaal method parameters used on human mandibular canine is effective for predicting age in adults in our studied Iranian population. Although there is a stronger correlation between age and three T, P and C variables of mandibular canine, other variables other than these variables should be considered in predicting age in Iranian population. The reason for using secondary dentin in this study is because it is surrounded not only by harder tissues such as enamel and cementum, but also by primary dentin. Consequently, this parameter used for internal evaluation is significant due to its potential to eliminate the effect of environmental factors on human remains. Given the phenomenon that due to anthropological differences between different ethnic populations, a formula devised for one population may
not be applicable to other populations, we conducted this study for the Iranian population. However, this phenomenon can be due to two-dimensional radiographic images that cannot provide accurate information about a 3D object. Sakhdari et al. obtained the age estimation equation by using pulp-to-surface ratio by digital panoramic radiographs from 120 patients over 12 years. They finally reported that pulp-to-surface ratio (AR) as a pure indicator cannot be used alone to determine an individual’s age, but can be used in combination with other indices to estimate age.

In the present study, measurements were made on mandibular canine alone because of advantages of the mandibular canine teeth, and we used CBCT images that were more accurate than panoramic images with no magnification problems or angular limitations. In the present study, we evaluated the secondary dentin deposition in mandibular canine teeth using Kvaal parameters. Cantekin used the Demirjian classification to estimate evolution of the third molar, which is a qualitative method based on images, while the present study is based on measurement of Kvaal parameters on teeth which is a quantitative method and the operator is less involved in than in a qualitative study; this study, as our study, was efficient in age estimation. Kanchan-Talerja et al. evaluated versatility of the Kvaal method for estimating dental age in the Indian population and observed that there was a large difference between actual age and the age predicted using this method. They thus argued that this large error in the Kvaal formula for estimating age in the Indian population could be due to secondary dentin deposition rate influenced by both genetic and environmental factors in Indians. The present study is based on CBCT images that have higher accuracy than periapical images and especially angle bisector technique. In the present study, the results of crossvalidation in the control group showed less real and predicted age difference than the above study. Hazhastar et al. (2011) investigated the estimation of human dental age by calculating a pulp/tooth volume ratio based on CBCT images obtained clinically from single rooted teeth. Finally, they found that age estimation was gender-independent, and the highest association between pulp-tooth volume ratios and age in their study was related to incisors. Kvaal suggested to obtain a specific regression formula for each population. Therefore, the regression formula obtained by Kvaal et al. for mandibular canine was not appropriate for estimating age in our studied population. However, since there was a significant relationship between age and P, C and T variables, there is a need for further investigation in Iranian population to identify other potential interfering factors and to include them in the regression formula. Kvaal used periapical radiography in the original study, and we used CBCT images in the present study to correct the errors of simple radiographic technique.

**Conclusion**

The Kvaal formula was suitable for use in the Iranian population, but it seems that other variables besides those studied here should be considered for age estimation based on application of the Kvaal formula in mandibular canine teeth.

It is recommended that this study be performed on other teeth in the future. It is also recommended to compare different imaging methods with each other and to evaluate the volume methods of pulp to tooth ratio in future studies.

Abstract

Quality of life is a global concept that emphasizes dimensions of health status including finance, housing, and work. The quality of life of post-stroke sufferers can experience disturbances or obstacles due to physical disabilities, cognition, psychological and social disorders. The purpose of this study was to determine the effect of ACT interventions on changes in the quality of life of post-stroke patients at Aloe Saboe Hospital. The method used in this research is quasi-experimental research method pre-posttest with the control group. The sampling technique used was the purposive sampling technique. The number of samples studied was 60 respondents divided into the experimental group (ACT Therapy and health education) and the control group (health education). The variables used are independent variables namely ACT therapy and the dependent variable is the quality of life of patients after stroke. Based on the results of the analysis, there is an effect of ACT intervention on improving quality of life in post-stroke patients as evidenced by the results of t count = -9.015, then the Significant value is 0.000. This shows that the value of p <0.05 then Ho is rejected, so the research hypothesis is proven that there is an effect of ACT therapy on the quality of life of post-stroke patients at Aloei Saboe Hospital, Gorontalo City.

Keywords: ACT; post-stroke; quality of life; therapy; acceptance; commitment

Introduction

Stroke is a disease in the brain in the form of impaired local or global nerve function that appears suddenly, progressive, and fast. Impaired nerve function in stroke is caused by nontraumatic brain blood circulation disorders. Symptoms that cause paralysis of the face and limbs, speech is not smooth and impaired vision. Stroke can be interpreted as any damage to the brain of the central nervous system caused by abnormalities/abnormalities of blood vessels. The term stroke is always used when the symptoms occur acutely, while the term cerebrovascular disease is used more generally and is not related to the time of brain damage. The World Health Organization (WHO) states that stroke is a functional impairment of vocal and global brain affecting the quality of life of sufferers.(¹)

The incidence of stroke in Indonesia has been declining over time but the prevalence of rates has increased. This shows that the number of old stroke cases increases each year, thus meaning more people with disabilities due to stroke so that the rehabilitation function is more important. Stroke recovery rates are still low, as many as 15-30% sufferers will experience paralysis or permanent disability, loss of voice or memory and various other consequences. About 25% of stroke patients die within the first year after a stroke and 14-15% experienced a second stroke in the same year after a first stroke.(²)

According to the 2013 Basic Health Research (Riskesdas) data, the prevalence of stroke in Indonesia is 12.1 per 1,000 population. That number is up compared to Riskesdas 2007 which amounted to 8.3 percent. Judging from its characteristics, many strokes are experienced by
the elderly, have low education, and live in cities. Based on data from Aloe Saboe Hospital, Gorontalo City, it was found that there were 1560 stroke sufferers in nerve poly consisting of 739 Hemorrhagic stroke sufferers and 821 Non-Hemorrhagic Stroke sufferers.

Acceptance and commitment therapy (ACT and Commitment Therapy / ACT), is one of the most popular therapies today and is considered more flexible and more effective in handling various cases. This therapy teaches patients to accept thoughts that are distracting and considered unpleasant by placing themselves following their values so that patients will accept existing conditions.\(^3\)

Acceptance and commitment have a huge impact on the development of patients with anxiety to be better. Commitment means an agreement (attachment) to do something. ACT is very effective in creating acceptance, attention and being more open in developing the capabilities of depression, anxiety, drug abuse, chronic pain, schizophrenia patients and is very effective as a model of self-training. Therefore ACT is expected to improve the quality of life in patients with post-stroke.

The results of Bays\(^4\) in the United States showed a decrease in the quality of life of post-stroke patients including daily activities, communication patterns, social activities, work, rest and recreation. Declining quality of life can affect the lives of sufferers and caregivers. Therefore the family also plays a role in improving the quality of life of sufferers. According to Nurrohma\(^5\), quality of life as a center for health promotion, quality of life is based on three areas of human life that are important dimensions in human experience, namely: Being, Belonging and Becoming. These three things occur due to interactions between a person and his environment.

Based on the description that has been explained, the researcher is interested in researching with the title the effect of acceptance and commitment therapy on the quality of life of patients after stroke in Aloe Saboe Hospital, Gorontalo City.

**Method**

This research was conducted at the Regional General Hospital (RSUD) Aloe Saboe Gorontalo City. This type of research is a quasi-experimental research pre-post test with a control group. This research was a type of research that tests an intervention in a group of subjects with a comparison group. The intervention that was tested was the provision of ACT, which in the implementation stage was modified by researchers using a spiritual approach. The study population was patients who visited the Aloe Saboe Hospital in Gorontalo City, amounting to 60 patients who were determined by the purposive side technique. The sample used was by the inclusion criteria set by the researchers, namely a) outpatients diagnosed after stroke; b) experiencing changes in quality of life; c) the level of consciousness of compos mentis; d) cooperative and willing to be respondents given ACT therapy. Data were collected using a demographic data questionnaire, namely the WHOQOL-BREF quality of life questionnaire, which contained aspects of quality of life that included physical dimensions, psychological dimensions, social relations dimensions, and environmental dimensions. Besides, an examination of risk factors, namely blood pressure, and cholesterol to see the effect on the quality of life. Data were analyzed by paired sample t-test to prove the research hypothesis by looking at differences in quality of life in the intervention and control groups before and after the intervention. To determine the homogeneity of variables between the intervention group and the control group, the equality test was conducted. The independent sample t-test was used to determine the differences between the two groups. A multivariate analysis process was carried out to prove the relationship between the characteristics of post-stroke patients with the quality of life.

**Findings**

The results of the study are presented in the table 1. Based on the table 1, it shows that the characteristics of respondents consisted of gender, age, last education, and last occupation.

Discussion

According to Wijaya & Putri (6), the incidence of stroke increases with age. Data reported by the American Heart Association in the Heart Disease and Stroke Statistics-2011 Update that young stroke sufferers between 20-45 years have increased dramatically in recent years. In 2009 the age range of ischemic stroke patients was between 20-60 years, with an average age of 58.8 years. Meanwhile, in 2010 the age range of ischemic stroke patients was between 24-90 years with an average age of 48 years. This shows that both in Indonesia and in the world, stroke has attacked many productive ages and even children.(7)

Based on the results of the study, the gender frequency distribution of stroke clients in this study was more dominated by men. This is in line with the theory that men are more often found to suffer a stroke than women.(8) Bowman also revealed that the incidence of stroke in men was slightly higher than in women, this difference occurred probably related to the increased incidence of hypertension and diabetes in the group. (9) The study is in line with the theory that men are more at risk of stroke than women, with a percentage of 20 percent higher in men than women. But after a woman turns 55, when estrogen levels decrease due to menopause, the risk is actually higher than men.(4)

The results of the analysis of the relationship between work and the incidence of stroke show that most respondents have jobs. Researcher’s assumption, there is a significant relationship between work and the incidence of stroke. Work is a risk factor for stroke. This might be caused by the relationship between work and one’s stress level. A large workload, the salary that is not as expected, and pressure from superiors can trigger stress and be a risk factor for stroke. Stressful conditions can produce the hormones cortisol and adrenaline which contribute to the process of atherosclerosis. This happens because the two hormones increase the platelet count and the production of cholesterol which can damage cells lining the arteries making it easier for fat tissue to be buried in the artery walls.(5)

The analysis showed that cholesterol risk factors before and after health education and ACT intervention had a significant effect on improving the quality of life of respondents. Meanwhile, the risk of hypertension after being given health education and ACT Interventions has a significant effect on improving the quality of life of respondents. Researcher’s assumption that cholesterol and hypertension are risk factors that affect the quality of life of respondents after a stroke due to increased body cholesterol can cause atherosclerosis and the formation of fat embolism so that blood flow slows into the brain, brain perfusion decreases.(6)

Based on the results of the study, it shows that before being given ACT therapy the average quality of life score in the intervention group had a mean value of 67.0 with the bad category. And after the intervention, it becomes 81.0 with a good category. The researcher’s assumption, this shows an increase in the quality of life score that shows the increased quality of life experienced by respondents. ACT therapy with a spiritual approach to quality of life can be said to be influential because it gets the result of t count = -9.015, then significant is 0.000. an important role in determining abnormalities. Neurons or nerve cells are the basic units of structure and function in the nervous system. Neurons are communicators that send information between the body and brain.(7)

Emotional problems are common, anxiety and depression reactions are left-brain damage reactions while the damage to the right brain often causes a strange feeling or different from the situation at hand. This is experienced by many stroke patients. They cannot assess precisely the damage done. As a result, depression arises as a symptom that often accompanies this disease. Thus, psychospiritual assistance is very helpful in dealing with depression in dealing with this disease.(8) In implementing ACT therapy, researchers modify the therapy given at each stage with a spiritual approach.

At the ACT therapy stage which is the stage of “practicing accepting selected events and values”, the spiritual approach taken is to understand that illness, recovery, and treatment are provisions and decrees from God. Similarly, at the ACT stage “commit and prevent recurrence”, it was conveyed that prevention and treatment efforts can be done by surrendering and getting closer to God.

Some neurologists examine the existence of a god spot (God’s point) in the human brain. This spiritual center is located between the connections of nerves in the temporal lobe of the cerebrum. Based on observations using emission topographic observations and positrons, the area reacts when the research subjects discuss topics with religion. Worship, regardless of religion, will lead us to focus attention in the mind with the aim of
contemplation. The activity, besides having a spiritual function, also has a health function. In the spiritual function, the prefrontal cortex will work actively. This area is associated with positive emotions and makes the cerebral cortex thicken, due to the growth of glial cells supporting neuron cells and neurons that show positive reactions by forming relationships between neurons or synapses. This synapse plays a role in the delivery of information to and from the brain.\(^9\)

Based on the results of the study, it shows that before being given a health education intervention, the average quality of life score in the control group had a mean value of 77.13 with a bad category. Then after the intervention, it becomes 78.80 with a good category. In this study, health education interventions on quality of life can be said to not affect because the results obtained \(t\) count = -1.520, then significant is 0.139. The researchers assume that ACT therapy with a spiritual approach is more effective in improving the quality of life of post-stroke respondents compared to health education in the control group because there is no significant difference between the quality of life scores before and after health education interventions are given. The control group only experienced an increase in the quality of life score of 1.67.

**Conclusion**

Based on the study it was concluded that the difference in the response to improving the quality of life in post-stroke patients in the intervention group with the control group, where after the intervention of respondents the ACT treatment group the average quality of life score increased to 81.0 while the improvement in the quality of life of the control group of respondents after being given health education became 78.8 this can be interpreted that the improvement in the quality of life of patients after stroke in the intervention group was higher than in the control group.

Abstract

Introduction: Aerococci has colony shape with Streptococcus viridans, so that it is usually missdiagnosed between of them. It has high difficulty on its identification, because it is rarely to be found and resistant of Antibiotic grup, called penicillin and vancomycin.

Material and Method: This research used two kinds of samples, such as: fried food sold on the road and toothbrush obtained from ten respondens. Then, it needs inducing its biofilm and measuring by Tissue Culture Plate (TCP) methode and ELISA.

Result: ANOVA one-way revealed that extract capsaicin has anti biofilm effect on 12.5% concentration with p=0,0000 (p<0,05) among each group.

Conclusion: Extract capsaicin can be used as an alternative herbal agent to treat infection caused by Aerococcus viridans because it has antibiofilm effect. As known before, biofilm causes antibiotic resistance to treat Aerococcus viridans’s infection.

Keywords: UTI; antibiotic resistance; Bioterrorism; ELISA; traditional herbal medicine.

Introduction

Aerococcus viridans is a bacteria that found in 1953, rarely described on the literature. It has some abilities to infect and cause some diseases for human being. Its infection is usually treated by antibiotic, namely: trimethoprim, sulphametoxazole, and penicillin. Aerococcus viridans is able to form biofilm, so that it triggers its resistancy, especially since it has been known that Aerococcus viridans can live on the root canal of the tooth. It needs searching an alternative therapy to treat biofilm Aerococcus viridans. One of the traditional herbas that can be used as an alternative therapy to treat Aerococcus viridans’s infection is capsaicin. Capsaicin is an alcoaloid crystal which formula is C₁₈H₂₇NO₃. Indonesian civilization commonly use capsaicin as a mixing substance on their food and medicine. Capsaicin has some effects, such as strong stimulant on blood and heart, and anti-bacteria. It is agonist of Transient Receptor Potential Vanilloid-1 (TRPV-1) which functioning as vanilloid receptor, that can be found on every sensory nerve ending and release neuropeptides, such as Substance P (SP) and Calcitonine Gene Related Protein (CGRP).

Aerococcus viridans has a strong relationship in dentistry, especially with decayed tooth and supragingival plaque. Another reason is Aerococcus viridans relates to the toothbrush, or everything that is usually used in oral cavity, antibiotic which can trigger its resistance, and hospitalized patients. As mentioned before, it is possible that using Aerococcus viridans as a bioterrorism agent which can endanger human civilization.

Material and Method

Experimental design
This was an experimental laboratory research which was done on Research Centre Laboratorium of Faculty of Dentistry Universitas Airlangga. There were two kinds of samples used in this research, such as: sample that was obtained from fried food sold on the road and sample was obtained from toothbrush’s. This research have been approved by the ethical committe of Faculty of Medicine Airlangga University 288/EC/KEPK/FKUA/2019.

**Experimental procedures**

![Figure 1. Samples that obtained from two kinds of samples, such as: toothbrush and food.](image)

This research was conducted by using two kinds of samples come from fried food sold on the road and the toothbrush’s respondents after being used for ten days as shown on Figure 1. There were some criterias of the respondents, 18-35 years old and did not eat pig as their food. Methode used in this research was an experimental laboratory, post test only group control design and its replication were counted by Federrer. Samples both from food and toothbrush were swabbed and cultured in Blood Agar Plate (BAP) media (Oxoid). BAP then incubated 1x24 hours at 37°C. The suspect isolate bacterias were sent to the Balai Besar Laboratorium Kesehatan (BBLK) to be Vitec tested.

The induction process was done by culturing *Aerococcus viridans* into BHIB inserted to anaerobic jar and incubator which was given gas kit, so that it could be in anaerobic condition, and incubated 2x24 hours. The specimen then was sentrifuged (Thermo Scientific), collected using micropipet 50-250 µL (Titertek) and cultured to the ELISA. There were two times and materials of staining, the first was Crystal Violet 0,1 % 50 µl. After being given Crystal Violet, it was washed using PBS 200µl and replied two times. The biofilm specimen wes fixated using ethanol 50 µl and transfered to the new ELISA. The capsaicin extract then was diluted from 100% until 0,78125% on the test tube.10,11

**Test of antibiofilm effect of extract capsaicin against *Aerococcus viridans*’s biofilm**

![Figure 2. The test of biofilm *Aerococcus viridans* using ELISA and extract capsaicin from the concentration 100% - 0,78125%.](image)

After the biofilm of *Aerococcus viridans* formed, it then inserted to the tube together with the capsaicin extract to be tested using TCP methode shown Figure 2. This methode was to test the Optical Density (OD).10,11,12

**Analysis data**

The data obtained was statistically analyzed using ANOVA one-way with post-hoct from SPSS (Statistical Package for the Social version 25 and EZR commander). The differences between group and pairwise comparison...
was conducted using ANOVA one-way and continued with post hoc to know the difference with significant level of
0.05.

Results

Table 1 showed about the normality check using Kolmogorrov-Smirnov test done by two kinds of statistic
program, namely: SPSS (Statistical Package for the Social Sciences, version 25) and EZR commander. The
distribution among each group was normal, so that the next step was to examine the different among each group
using ANOVA one-way which was also shown on the table 2. The p value and skewness of each group has been
shown on the table 1.
Anova-One way showed significant difference between group, p<0.05. a,b denotes significant differences between groups (post-hoc test)

Table 2 showed that there were significant differences among each group with the concentration of capsaicin extract using both ANOVA one-way from SPSS for Windows version 25 and EZR commander and the mean and standard deviation of each group. A substance that could inhibit the growth of biofilm, such as: the cut off value between 0 until 2 showed that weak biofilm, 2 until 4 showed moderate biofilm, and over the 4 showed that strong biofilm.
The minimum extract capsaicin which could inhibit the growth of *Aerococcus viridans* biofilm was 12.5% using TCP method. *Aerococcus viridans* biofilm qualification using TCP method can be seen on Figure 4. 13

**Discussion**

This study confirmed that extract capsaicin can be used as an antibiofilm traditional herbal to treat *Aerococcus viridans* infection which has two common life cycle, such as: planktonic and biofilm, which biofilm is a community of the bacteria which they are embedded in a extracellular polymeric substances. Bacteria which living on biofilm will be more resistant for any kinds of antibiotic. 14

This result has revealed that extract capsaicin has some active compounds, so that it can easily penetrate to the peptidoglycan layer of *Aerococcus viridans* layer. Observation of biofilm OD values in each study group was carried out using the TCP method which is quantitative method biofilms in vitro. The discussion in the 1st group, namely in the 100% capsaicin extract concentration group with *Aerococcus viridans* bacterial biofilms that had an OD cut value of 0.484, the 2nd group with a 50% capsaicin extract concentration that had an OD cut value of 0.891, 3rd group with 25% capsaicin extract concentration which has a cut off value of OD 1,290, 4th group with capsaicin extract concentration 12.5% which has a cut-off OD value 1,624, 5th group with capsaicin extract concentration 6.25% who have a cut-off value of OD 2.253, the 6th group with a concentration of capsaicin extract 3.125% which have a cut-off value of 2,625, the 7th group with a concentration of capsaicin extract 0.78125% which has a cut-off value of OD value 4,213. For the positive control group it has an OD cut value of 4,410 and a negative control group that has an OD cut value of 0.471. 10,11

Analysis conducted on several OD cut-off values with SD values for each group is in accordance with the TCP method theory, namely: the cut off value of biofilm OD in the concentration group of 100% to 12.5% has a range between 0 to 2 which means weak. Capsaicin extract concentration group of 6.25% to 1.5625% has a range between 2 to 4 which means moderate. The capsaicin extract concentration group of 0.78125% has an OD value of 4. It reflects the strongest biofilm strength. The difference in the OD cut-off value between each group is significantly different and supported by the ANOVA-one way test value between each group, namely: $p = 0.000$ which means that the $p$ value is below 0.05 so that there are Significant differences between each study group. 12,13

From the results of this research, capsaicin extract has an effect or inhibitory effect on Aerococcus viridans bacterial biofilms at a concentration of 12.5. This is consistent with the proven theory that capsaicin extract contains several active components, namely: carotenoids, phenols, flavonoids, alkaloids, and vitamin C. Flavonoids are chemical components explored in capsaicin, because they contain antibacterial compounds and removal of bacterial virulence. Flavonoids are also the largest and most polar phenol group, so they can easily penetrate into the peptidoglycan layer in both Aerococcus viridans and cause damage to cell walls. Peptidoglycan is an important component of gram-positive bacteria, especially Aerococcus viridans which functions as a protective barrier and material required for the attachment process of cleavage, morphogenesis, and bacterial pathogenesis. 14

Phenol is a compound for membrane damaging activity, activating enzymes, and denaturating proteins so that cause decrease in permeability to the cell membrane. Carotenoids, bind to porins which are transmembrane proteins found in the outer membrane of bacterial cell walls which resulting in damage to the porin and decreasing membrane permeability. Alkaloids inhibites the synthesis of cell membranes in bacteria and causes bacterial cells to be more permeable and its cytoplasmic contents easily leaving out. 14
Based on some of the things discussed above, it can be attributed to the bacteria Aerococcus viridans, biological bombs (bioterrorism), and the ability of capsaicin extract as an alternative ingredient in herbal medicine. Bioterrorism is the use of biological material as a weapon that threatens to health or death to the civilization. Bioterrorism has three types of categories, namely categories A, B, and C with the difference in each of these categories is for category A can cause high mortality rates, category B does not cause death but only causes high morbidity and category C consists of materials that can be designed to cause high levels of morbidity and effects on health care facilities. Based on the data presented above, the Aerococcus viridans bacteria can be a category B bioterrorism material because these bacteria can be easily obtained in nature and can cause high levels of morbidity. 15

**Conclusion**

Based on this research, the extract capsaicin can be used as an alternative herbal agent against the *Aerococcus viridans* biofilm.

The Evidence-Based Midwife Professionalism

Fitriani Nur Damayanti¹, Absori Absori², Kelik Wardiono², Sri Rejeki¹

¹Lecturer at University of Muhammadiyah Semarang, ²Lecturer at University of Muhammadiyah Surakarta

Abstract

Introduction: Midwife professionalism is the basic social contract between a midwife and society so that professionalism is considered to be very important. There are some cases related to midwife professionalism. Midwife as health practitioner should understand about midwifery practice very well. The midwife should realize that she works based on regulation and law.

Material and Method: The study was aimed to find out the professionalism in midwifery practice. Non-Doctrinal research was used as the research approach. The sample was taken with non-probability sampling, which is a snowball technique.

Findings: 93% of midwifery practices were qualified to administer code of ethics, 86% of midwifery practices were qualified to administer responsibility of midwifery practice, 93% of midwifery practices were qualified to precise collaboration and reference for midwifery practice, all the midwifery practices were qualified to administer continuing education in order to improve midwifery care, 93% of midwifery practices were qualified to competence for midwifery practice, 53% of midwifery practices were qualified to administer advocacy.

Conclusion: It can be concluded that the midwifery practice has fulfilled the professionalism indicators such as profession code of ethics, responsibility, precise collaboration and reference, continuing education, and competence. Nevertheless, there were some professionalism indicators which have not been fulfilled. It was giving advocacy. It was due to the lack of knowledge and comprehension about advocacy in midwifery practice.

Keywords: Professionalism, Midwife, Midwifery Service, Midwifery Regulation

Introduction

Midwife professionalism is the basic social contract between a midwife and society so that professionalism is considered to be very important¹. Midwifery is one of the professions in health area which based on theoretical knowledge, professional association, extensive education, competency test, institutional training, license, autonomous work, code of ethics, self-management, public service and altruism².

Midwifery regulation about midwife authority in administering the practice is regulated in Law No. 4 of 2019 about midwifery. Midwife authority is limited in term of health service administration. A midwife should only give help in physiological birth without complication when administering birth service. In addition, there are some residences which apply the policy that intranatal care should be administered at the public health clinic with the assistance of a midwife. In Semarang, there are only 7 referential public health clinics which become PONED (Basic Obstetric Neonates Essential Service). It is not equivalent compared to the neonatal rate which is 26.337. Besides, a midwife can only give family planning and immunization at the government’s health center and in order to do the governmental assignment³.

There were some midwifery cases which were related to professionalism. The cases mainly due to the lack of knowledge about midwife authority and competence in administering midwifery practice⁴. There were also a number of midwives who didn’t know about the newest regulation about midwifery. It can be said that most of them administer the practice based on their own experience only. One of the examples of a case in midwifery was when a midwife spontaneously helped
premature birth and the fetus experience severe asphyxia, but the midwife didn’t make any reference to the hospital. Instead, she gave treatment to the fetus and mother in her own midwife clinic. After an hour, the fetus was dead. From the case, it can be concluded that the midwife could not show professionalism since she did not give clear information about her patient condition, especially when the baby experienced severe asphyxia. In addition, a midwife should not have helped premature birth as the midwife did not have the authority and competence to do that. As a result, a maternal perinatal audit was done to give a detail description of the case, from the birth process until the death of the fetus.

One of the indicators used to measure the rate of public health achievement is mother and baby mortality rate. All the health practitioners including obstetrician-gynecologist, pediatrician, nurse, and midwife are responsible for it. A midwife is responsible to be a regulated health professional. Therefore, a midwife is supposed to understand the midwifery practice regulated by the system. A midwife should realize that they are responsible to work based on regulation and professionalism. Improving the understanding of the responsibility to be a midwife who works under the regulation is a part of midwife professionalism.

### Method

The approach used in this study was non-doctrinal research which includes empirical studies to find out the theories about the work and process of social law. This kind of research is also known as socio-legal research. The sample was taken using non-probability sampling, particularly the snowball technique. Snowball technique allows the data collection from one respondent to the other respondents which match the criteria through in-depth interview. The data collection stops when there is no new information, stuck interview, or there is repetition during the information delivery. The 15 samples were taken fulfilled the minimum education criteria, which was the diploma of midwifery.

### Results and Discussion

#### a. Professional Code of Ethics

<table>
<thead>
<tr>
<th>Professional Code of Ethics</th>
<th>Respondent</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>%</td>
</tr>
<tr>
<td>Qualified</td>
<td>14</td>
</tr>
<tr>
<td>Unqualified</td>
<td>1</td>
</tr>
<tr>
<td>Total</td>
<td>15</td>
</tr>
</tbody>
</table>

Source: primary data, processed in 2018

From the frequency distribution data of respondents’ answer about the professional code of ethics, it was gained that only 93% of midwifery practices were qualified to administer code of ethics. Meanwhile, the rest 7% was unqualified for code of ethics. Based on Burtch’s research about midwifery code of ethics, code of ethics can be the indicator of midwife professionalism. According to the national standard competent, a midwife is responsible to make sure that she understands and has enough knowledge about professionalism. The violation toward the code of ethics cannot be considered as professional, and which is contrary to the professional standard. A midwife should be able to work professionally to maintain public trust.

#### b. Responsibility

<table>
<thead>
<tr>
<th>Responsibility of midwifery practice</th>
<th>Respondent</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>%</td>
</tr>
<tr>
<td>Qualified</td>
<td>13</td>
</tr>
<tr>
<td>Unqualified</td>
<td>2</td>
</tr>
<tr>
<td>Total</td>
<td>15</td>
</tr>
</tbody>
</table>

Source: primary data, processed in 2018

From the frequency distribution data of respondents’ answer about responsibility of midwifery practice, it was gained that only 86% of midwifery practices were qualified to administer responsibility of midwifery practice. Meanwhile, the rest 14% was unqualified for responsibility of midwifery practice. A midwife is acknowledged as an occupation which accountable responsible as the trusted partner of women to give
support and care during pregnancy, intranatal, and postnatal period continuously and completely\textsuperscript{11}. It is in line with the research about responsibility conducted in England about the responsibility of midwife in the form of obeying the regulations about midwifery, give correct information and advice to the patient, give information to the patient with high risk pregnancy, make record and report about every given service, give midwifery service during antenatal, intranatal, and postnatal period, make reference to the healthcare facility in case of emergency, give maternal and fetal care\textsuperscript{12}.

c. Precise collaboration and reference

Table 3: Frequency distribution of respondents’ answer related to professionalism standard about precise collaboration and reference for midwifery practice

<table>
<thead>
<tr>
<th>Precise Collaboration And Reference</th>
<th>Respondent</th>
</tr>
</thead>
<tbody>
<tr>
<td>N &amp; %</td>
<td></td>
</tr>
<tr>
<td>Qualified</td>
<td>14 93</td>
</tr>
<tr>
<td>Unqualified</td>
<td>1 7</td>
</tr>
<tr>
<td>Total</td>
<td>15 100</td>
</tr>
</tbody>
</table>

Source: primary data, processed in 2018

From the frequency distribution data of respondents’ answer about precise collaboration and reference for midwifery practice, it was gained that only 93% of midwifery practices were qualified to precise collaboration and reference for midwifery practice. Meanwhile, the rest 7% was unqualified for precise collaboration and reference for midwifery practice. Interprofessional collaboration is important for patient’s safety, since the collaboration and communication failure may affect the mother and baby mortality rate\textsuperscript{13}. Collaboration is an act to share responsibility between partners or other health practitioners in performing health care for the patient. During the practice, collaboration is often needed to discuss the patient condition and cooperate in managing and performing healthcare\textsuperscript{14}. It is in line with the research conducted in Netherland about interprofessional collaboration in giving comprehensive midwifery care. Interprofessional collaboration is complex and suitable for midwifery care\textsuperscript{15}.

d. Continuing education

Table 4: Frequency distribution of respondents’ answer related to professionalism indicator about continuing education for midwifery practice

<table>
<thead>
<tr>
<th>Continuing education</th>
<th>Respondent</th>
</tr>
</thead>
<tbody>
<tr>
<td>N &amp; %</td>
<td></td>
</tr>
<tr>
<td>Qualified</td>
<td>15 100</td>
</tr>
<tr>
<td>Unqualified</td>
<td>0 0</td>
</tr>
<tr>
<td>Total</td>
<td>15 100</td>
</tr>
</tbody>
</table>

Source: primary data, processed in 2018

From the frequency distribution data of respondents’ answer about continuing education for midwifery practice, it was concluded that all the midwifery practices were qualified to administer continuing education in order to improve midwifery care. The continuing education for midwife is all of the activities which should be followed by midwives through non-formal education. It includes knowledge improvement (cognitive) as a process to comprehend particular knowledge\textsuperscript{16}. It is supported by research about continuing education for nurse and midwife which concluded that midwife competence is very important for midwifery care quality. In order to improve midwife competence, good quality continuing education is needed\textsuperscript{17}.

e. Competence

Table 5: Frequency distribution of respondents’ answer related to professionalism indicator about competence for midwifery practice

<table>
<thead>
<tr>
<th>Competence</th>
<th>Respondent</th>
</tr>
</thead>
<tbody>
<tr>
<td>N &amp; %</td>
<td></td>
</tr>
<tr>
<td>Qualified</td>
<td>14 93</td>
</tr>
<tr>
<td>Unqualified</td>
<td>1 7</td>
</tr>
<tr>
<td>Total</td>
<td>15 100</td>
</tr>
</tbody>
</table>

Source: primary data, processed in 2018

From the frequency distribution data of respondents’ answer about competence for midwifery practice, it was gained that only 93% of midwifery practices
were qualified to competence for midwifery practice. Meanwhile, the rest 7% was unqualified for competence for midwifery practice. The scope of midwifery care given in the midwife clinic includes the scope of premarital, antenatal, intranatal, postnatal, family planning program, neonates, baby, and toddler18.

A midwife is responsible for her patient to give safe and competent midwifery care. The responsibility of midwife to maintain their competence is important to improve their knowledge and ability. The competence improvement includes participation to maintain and improve knowledge, skill, and behavior based on the clinical practice, management, also education or training19.

f. Giving advocacy

Table 6: Frequency distribution of respondents’ answer related to professionalism indicator about Advocacy for midwifery practice

<table>
<thead>
<tr>
<th>Advocacy</th>
<th>Respondent</th>
<th>N</th>
<th>%</th>
</tr>
</thead>
<tbody>
<tr>
<td>Qualified</td>
<td></td>
<td>8</td>
<td>53</td>
</tr>
<tr>
<td>Unqualified</td>
<td></td>
<td>7</td>
<td>47</td>
</tr>
<tr>
<td>Total</td>
<td></td>
<td>15</td>
<td>100</td>
</tr>
</tbody>
</table>

Source: primary data, processed in 2018

From the frequency distribution data of respondents’ answer about advocacy for midwifery practice, it was gained that only 53% of midwifery practices were qualified to administer advocacy. Meanwhile, the rest 47% was unqualified for advocacy due to the lack of knowledge and comprehension about advocacy. Most of the midwives didn’t know about the form of advocacy they should give to the patient. As the administrator of health care, midwives should actively promote and protect women’s health, support women’s right to reproductive health, also respect ethnic and cultural diversity20.

Advocacy is the activities to exert all the resource to defend, improve, and even reform in order to achieve the demanded condition. Advocacy and women empowerment strategy to promote women’s right is needed to achieve optimum health condition 21.

Conclusion

From the findings, it can be concluded that the midwife practices have already applied midwifery professionalism by paying attention to the professionalism indicators which include a professional code of ethics, responsibility, precise collaboration and reference, continuing education, and competence. Meanwhile, advocacy is unqualified professionalism standard in the administration of midwifery practice. It is possible since some midwives didn’t know about the form of advocacy. The midwife should be able to perform professional midwifery care by implementing professionalism indicators.

9. Burtch B. Trials of Labour: The Re-emergence of
Analytical Study of Railway Accidental Deaths

G. Lavanya Kowsil¹, Kampa Venkat Nagaraju², Jakkam Surendar³
¹Associate Professor, ²Assistant Professor, ³Assistant Professor, Department of Forensic Medicine And Toxicology, Gandhi Medical College, Secunderbad, ³Assistant Professor, Department of Forensic Medicine And Toxicology, Kakatiya Medical College, Warangal

Abstract

Travel but on the other hand caused lot of damage to human lives in the form of accidents. The present study conducted at Guntur medical college, Guntur over the period of two years among the autopsies done in the forensic medicine department. Out of 1748 autopsies railway accidental deaths were 114 with male predominance. Most of the railway accidental deaths were seen in the middle age. More deaths were due to decapitation.

Key words- railway accidents, suicide, decapitation.

Introduction

Britishers were the pioneers in introducing Railways in India. Their intension was to move their troops faster, and transport these goods to distant places with an idea of proving their trade and to establish their empire in India.

Post independence with advent of urbanization and globalization the government made major move in improving transportation system throughout the country. The major transportation system is available in the following form.

a) Air way
b) Road transportation
c) Sea
d) Railway

In developing countries like India where majority of population reside in rural areas and are below poverty line. Hence the earliest, simplest and most importantly cheapest way of transportation would be the railways. In view of this the Indian government allotted more budget and subsequently developed the Railway transportation system. In India railway is the largest public transportation system.¹

Bernard knight classified railway accidents broadly into three main groups. Train accidents, to train and rolling on or affecting and failures of rolling stock, track and structures. Movement accidents is the accidents to people caused by the movements of railway vehicles excluding those in train accident to people. On railway premises but not connected with the railway vehicle.

Whereas movements fatalities are primarily concerned with involvement of the Train without any fault of train. Main reasons for the Railway accidents are:

1. Due to errors and failure of Railways.
   A) Mechanical problems:
      1. Failure of breaks.
      2. Track faults.
      3. Electrical short circuits.
   B) Human Errors:
      1. Not observing the signals by the engine driver.
      2. Not giving proper signals by Guard and cabin crew.
      3. Carrying explosives by passengers.
   C) Natural
      1. Foggy weather
      2. Calamities like Floods and earth quakes.
II. Due to movements of the fatalities across Railway line.

a) Unmanned level crossing
b) Foot board traveling
c) Getting into running train
d) Tress passing
e) Roof Top traveling
f) Using Railway track for attending call off nature.
g) Crossing below stable trains.
h) Passing on long bridges.
i) Standing on track.

We must not forget Railway track could be the place of disposal for those dead bodies of Homicidal Origin to cancel the crime. Hence it is not correct to say that all bodies found on railway track are deaths due to train injuries.

It is not reliable to say that the injuries sustained on the railway track are of Ante mortem in nature.

Hence it is found necessary to make detailed examination and wounds present on the dead bodies and different other factors, to know the cause and manner of deaths.

Aims and Objectives

1. By analyzing the pattern of injuries – To arrive at a conclusion as per the manner of death.

2. To know socioeconomic, Human related problems and any other factors responsible for the deaths occurring on the railway track.

Material and Method

Among the autopsies conducted by the department of Forensic Medicine, Guntur Medical College, Guntur, during the period from 01-01-2003 to 31-12-2004, the cases of death attributed to railway injuries were studied in detailed.

The preliminary data was collected from the inquest reports, the hospital case sheet records and the history revealed from relatives, friends etc., of the deceased where the identity was established a detailed history has been collected about the victim of railway injuries where ever possible to know whether he was getting into a moving train or was crossing the track or walking along the track it self etc., and also gathered information whether the deceased had any hearing or sight defect and whether he was on an alcoholic or a drug addict. His socio-economic status also has been taken into account. A detailed history has been collected regarding the time and place of fatal occurrence.

Observations

During the period between 1-1-2011 to 31-12-2012, 1748 autopsies were conducted at Government General Hospital, Guntur out of which 114 were Railway accidental deaths. out of which 56(6.48%) were in 2011 and 58 in 2012 (6.56%) showing marginal increase of 0.8%. even though total number of autopsies shows marginal increase of 20 cases which indicates increase in tendency of railway deaths in accordance with increase in Urbanization.

During the two years study the male autopsies were more than females. During the year 2011, total number of autopsies were 56 the male number were 49 and female were only 7. During the year 2012 total number of autopsies were 58 out of which 52 cases were of male and 6 were female cases. This shows that there is increase of 3 cases of males in the year 2012, but there was decrease of female cases by one.

Regarding the age, in the age group of 0-9 yrs there were no railway fatalities, with regards to the age group of 20-39 yrs. The number of railway fatalities were 58 i.e. year 2011 and 2012 which account to 50.88%. this shows that the middle age group is more susceptible for railway accidents.

The un identified bodies were 16 in the year 2011 amounting to 28.57% and 23 cases in the year 2012 accounting a 39.66% which shows an increase of 11% in the year 2012.it shows that the accidental deaths in the year 2011 were 34 out of 56 railway autopsies which amounts to 60.71% and suicidal cases were 20 which amounts to 35.71% and there was 3.58% of other cases. It is clearly evident that there is slight increase of accidental
deaths in year 2012 compared to 2011 i.e. 3.08%.

The deaths occurred in outskirts were 57 in both years which amounts to 50%. The bodies which were recovered in the city limits were 29 which amounts to 23.44%. The bodies found in the station limits were 28 amounting to 24.56%. The Bodies Found in the station limits were 28 amounting to 24.56% from the above, it is evident that the more deaths occurred due to railways on the outskirts of the city.

It is conclusive that the deaths during the night time are more i.e. 72 out of 114 cases amounting to 63.16%. The witnessed railway deaths were 67 out of 114 cases amounting to 58.77%.

Out of 114 cases 93 persons died on the spot amounting to 81.58% and 10 persons survived for 24 hours amounting to 8.77% and 11 persons could survived for more than two days amounting to 9.65%. 66 deaths were due to decapitation associated with lacerations, contusions and fractures amounting to 57.89%. the remaining 42.11% were having only contusions, fractures and lacerations.

During the months on November, December and January and February the railway deaths were 45 amounting to 40% of total cases.

**Discussion**

During the period between 1-1-2011 to 31-12-2012, 1748 autopsies were conducted at Government General Hospital, Guntur out of which 114 were Railway accidental deaths. out of which 56(6.48%) were in 2011 and 58 in 2012 (6.56%). this study results were closer to study of Basu, R., Bose, T.K. et al(2002) who found 299 (6.11%) cases of Railway fatalities among a total of 4893.2

There is increase of railway deaths in the year 2012 as compared to year 2011 by 0.08% because of increase in population and increase of passengers travelling by train and it is a cheaper mode of travel compared to other modes like Bus, Air and Water ways.

The deaths are more in males due to as most of times he is the responsible and earning person for the maintenance of the family, The age group between 20-40 yrs are more involved in railway deaths. which was similar to a study conducted by Pelletier A,3,4,5,6,7,8,9,10,11 which could be due to various reasons like

- Failure in examination
- Failure in love
- Un successful marital life which are common in India,
- Un employment
- Psychological problems

In India, the villagers will not have any kind of Identity cards unlike other countries, where each and every person will be having an Identity card. Due to this, it is difficult to find out the Identity of the individual in railway accidents as in most of the cases, the body will come in multiple pieces, which makes it even more difficult for identification.

The accidental deaths are more because:

1. People traveling the train even though there is heavy rush, by standing on foot board.
2. Traveling on top of the train.
3. Getting in and out of the running train and some people will use the track when the gate is closed in a hurry.
4. The Youngsters have fades like by watching movies they try to imitate the film Heroes by crossing the running train, running across the train which in films is just filmy.

In India we have some unmanned level crossing gates, some persons will cross the tracks without noticing on either side of the track in unmanned level crossing. There are number of incidences where the vehicles were made to stay on the railway track due to mechanical failure which subsequently resulted in the railway accidents.

The suicidal cases are due to

- Certainty and easy mode of death
- Some poor and under privileged people
like beggars, very frequently travel in train without purchasing tickets. Who have, chronic diseases will die in the railway compartments and platforms and lavatories of the train.

In India the distance from the residence is no bar for the occurrence of suicide or accidents but many of the accidents occurred on the track which were near to their residences as the residents in those locality are accustomed to the railway track and many of them use the tracks for daily passage, nature of call during which period accidents occur

People prefer the outskirts of the railway station for committing suicide

- Avoid witnessed by others
- As the train will be moving fast, the movement of people will not be there.

Because of the above said reasons the number of deaths are also more during the night times as it will not be witnessed by other because of darkness.

The survival period is very less in the railway fatalities which will cause instantaneous deaths in majority of the cases in the form of decapitations, fractures and multiple injuries.

Very few cases may survive for one to two days with same injuries.

The majority of suicidal cases in railway deaths – the person will lie down over the track to make certain that death occurs either by decapitation or traumatic amputation.

The more number of deaths occurred during the months of November, December, January and February are due to

- Winter season – In winter season there will be fog, mist and covering of the face and head by towel and clothes to avoid wind and chilliness for not noticing the train while crossing the track level.
- During the night most of the times under the influence of Alcohol – there will be visual disturbances and level of consciousness which results in railway accidents.

Due to failure of signals, dislocation of the tracks unfunctioning of the breaks, natural calamity even though the driver excepted the accident he will not be in a position to avoid it because of above said problems.

As per the Indian railway act the driver who notices the railway deaths on the track is supposed to inform the next near rail way station which is not being done in most of the cases resulting in dismembering of the body by animals which subsequently leads to difficulty in identification.

**Conclusion**

1. An autopsy study of 114 railway deaths are carried out during the period from 01-01-2011 to 31-12-2012. Railway deaths constituted 6.52% of total autopsies. The male and female ration of railway fatalities was 7.77:1% on average.

2. The maximum incidence of cases were in the second decade followed by third and forth decade

3. The railway deaths were more accidental less frequently suicidal and very rarely homicidal. I have not come across a single case of homicidal railway death in my study.

4. The accidental deaths in railway injuries are mostly while crossing the track or walking along the track.

5. The more deaths occurred on outskirts of railway station.

6. Decapitation or transaction of trunk is fatal injury in the majority of the suicidal cases.

7. Viscera commonly involved are spinal cord followed by brain, intestines, lungs, liver etc., it is also found that injuries to the upper half of the body are more common than compared to the lower half of the body.

**Suggestions:**

1. Most of the railway deaths are not properly investigate and even the identity of the victim has not been established in most of the cases. It is proper for the investigating Officer to establish the identity of the victim. Which in turn rule out the motive, to clear the doubts of the litigant public.

2. Most of the railway deaths are investigated by the lower level police officer – usually the Head Constable, who carries out the task as a routine one, with the sole idea of how to shift the body to the nearest mortuary and
how to cope with the expenditure. In most of the cases the scene panchanama is not properly made, let alone taking the photographs of the scene. Resgetau which becomes the main linking evidence in the interpretation of nature of death in the later part of the investigation. Hence, it is a advisable to entrust the investigation to a police officer not below the rank of sub inspector the police, the scene should be investigated properly and photographs particularly, colour photographs should be taken in different angles as far as possible before shifting the body for autopsy.

3. It is common to see people often crossing the railway track carelessly, just in front of the on coming running train even when level crossing gate is closed. It is also common to see the pedestrians and two wheeler drivers crossing the railway track. It is observed that most of the accidents victims are illiterate and ignorant people from low socio-economic strata. Grater public awareness and preventive measures may reduce the tremendous human and financial costs of train related accidents. The data sets and accidents at the crossings should made by studying the characteristics i.e., like warning devices, volume of vehicle traffic, volume of train traffic, visibility condition etc., preferably on models. This facilities are sufficient base from which the accident potential of any level crossing can be estimated and preventive measures can be taken like construction of over bridges.

4. At the unmanned level crossings there is not one to warn, regarding the fast approaching trains. The accidents are very common here, especially due to collision with two or four wheelers, hence even at unmanned gates steps should be taken to install warning devices like sirens, so that the public know that the train is approaching. Another draw back noticed with the Indian Railways is closure of railway gates some times 15 to 30 minutes before a train passes through that point. This results in traffic jams and unrest in the public crossing resulting in unlawful particularly in urban areas, this in turn has its role in increased accidental fatalities from railways. Hence, steps should be taken in such a way that the on coming train should pass to that through particular point within stipulated time [with in 5 or 10 minutes] after the closure of the railway gates.

5. To discourage suicidal or accidental death from railway injuries trespassing of railroad property should be declared as prohibited and unlawful. By taking steps like

1. Reducing public access to the tracks.
2. improving surveillance by railway staff.
3. facilitating emergency staff.
6. Getting in or down of a running train, travelling on roof tops and standing or leaning from the doors of the compartments, should be discouraged by educating the public if permitted penalized.
7. Ticket control, surveillance, law enforcement and safety engineering are also other methods of injury control interventions.
8. Environmental changes, like changing of Locomotive front design, lowing of catch guard is also suggested as strategy for reducing accidents and Suicides on railways.
9. To reduce personal injuries in train crashes suggestions are made to the improved maintenance of the seats and their frames and the use of safety belts.

Last but not the least suggestion to the Medical Officer who conducts autopsy of railway fatality, the Medical Officer should not think such a case merely as an intrusion in to his routine medical or medico-legal work. The autopsy should be carried out in similar lines. Like other medico-legal deaths, particularly violent deaths. Attention should be imparted to every minute detail, photographs taken where ever necessary supplemented by chemical and histopathological examinations, if necessary steps should be taken to preserve of chain of evidence. Re construction of events at the scene, study of injury pattern on the body corroborative evidence might lead to correct diagnosis regarding the cause and nature of death, if autopsy is carried out in a proper perspective.

Abstract

The role of the Arctic and Northern regions, especially the Republic of Sakha (Yakutia) in the geopolitical position of Russia in the world is increasing every day. The purpose of the study is to investigate the branches of life support in the Arctic upon synchronizing their development. The leading research method for this problem is the analysis method. The paper describes innovative ways to manage the life support sectors in the Arctic upon synchronizing their development, restructuring and reforming. The comparison of the Strategy for the development of a unified energy system of the Republic of Sakha until 2030 and the Republican target program is provided. The novelty of the study is determined by the fact that it analysed the urgent problem of the need to separate the management system by industry, by creating branch ministries corresponding to the structure of the Government of the Russian Federation. The practical significance of the study is determined by the need to expand and implement the existing program of targeted training, to ensure close communication between the enterprises of fuel and energy complex and educational institutions of the Republic.

Keywords: geopolitical position, infrastructure, energy, innovation, management system.

Introduction

The role of energy in the development of the Arctic is paramount. With fierce competition between technologies, machines and mechanisms, only one that consumes less energy and produces more products will win. Therefore, issues of efficient management and introduction of innovations in the field of management in the Arctic and remote areas come to the fore. The upcoming five-year plan for 2020-2025 will be significant for the energy system of the Republic of Sakha (Yakutia). When implementing strategic projects to develop the power system of Yakutia with the launch of a 220 kV transmission line, Sukhoi Log substation, 220 kV Peleduy substation in the West, and a 220 kV Tommot-May transmission line will be electrically connected to the Sibir Interconnected System in the west of Yakutia and to the Vostok Interconnected System in the east. The structure of the Vostok Interconnected System will include the Central Energy District; the Southern Energy District became part of the Vostok Interconnected System in 2007. At the first stage, the main transmission lines will be transferred to the Vostok Main Power Networks of the FSK PJSC. At the same time, in pursuance of the agreements reached on gasification of the regions with PJSC Gazprom, investment projects for gasification of the regions of the Russian Federation, including the Republic of Sakha (Yakutia), are being developed and implemented.
In the medium term, with the help of PJSC Gazprom investments, there is a real opportunity to switch the natural settlements of the Vilyui, central, southern and western parts of the Republic to natural gas. With that, the zone of centralized electricity supply in the future will affect the formation of heat supply systems through the gasification of settlements during the creation of a unified gas transmission system and through electric heating. This will significantly change the approaches to heat supply in the above regions of the Republic.

The problems of ensuring Eurasian security primarily concern Russia and the entire EAEU. For them, the CSTO acts as a security shield, the area of responsibility of which, according to the Collective Security Treaty Organization for the period up to 2025, is “the territories of the Organization’s member states, limited to state territories with other states that are not members of the CSTO (external borders), including inland waters, the territorial sea and the airspace above them, within which the interests of national and collective security of member states of the CSTO”. And this is 20.5 million km², i.e. 37% of the entire Eurasian space. In this regard, the aim of this paper is to investigate innovative ways to manage the life support sectors in the Arctic upon synchronizing their development, restructuring and reforming.

Analysis of the Structure of the Arctic Life Support Industries

With regard to the Russian Arctic, the main international treaty applicable to the Arctic Ocean is the 1982 UN Convention on the Law of the Sea, which is of strategic importance since it establishes a comprehensive legal regime for the world’s oceans and seas, and regulates all uses of the oceans and their resources and serves as the basis for national, regional, and international actions and cooperation in the maritime sector, including in the Arctic. As of June 2016, its participants are 168 states. Russia ratified the 1982 Convention; it follows that the CSTO area of responsibility is the Northern Sea Route.

In accordance with the Federal Law of July 28, 2012 No. 132-FZ “On Amending Certain Legislative Acts of the Russian Federation Regarding State Regulation of Merchant Shipping in the Northern Sea Route”, the Northern Sea Route is defined as a body of water adjacent to the northern coast of the Russian Federation, covering the internal sea waters, the territorial sea, the adjacent zone and the exclusive economic zone of the Russian Federation and limited from the east by the line of delimitation of sea spaces with the USA and the parallel to the Cape Dezhnev in the Bering Strait, from the west by the meridian of Cape Zhelaniya to the Novaya Zemlya archipelago, the eastern coastal line of the Novaya Zemlya archipelago and the western borders of the Matochkin Shar, Kara, Yugorski Shar straits, therefore, the relevant provisions of the 1982 Convention apply (Articles 2-33, 55-75, etc.).

If we compare the Strategy for the development of a unified energy system of the Republic of Sakha (Yakutia) until 2030 and the Republican target program “Gasification of settlements of the Republic of Sakha (Yakutia) in 2009-2011 and the main directions of gasification until 2020”, it is clearly evident that the development of gas supply systems will take place in the zone of centralized power supply i.e. in uluses with centralized power supply. Thus: a unified gas transmission and electric power system will be created in the Vilyui, central, southern, and western parts of the republic. The creation of these centralized systems will entail a reduction in the expenses of enterprises and the population of these regions on public utilities.

The historically evolving situation of the presence of two vital industries in the north of the republic, which are currently organizationally fragmented, necessitates the merger of SUE “Housing and Utilities of the Republic of Sakha (Yakutia)” and Sakhaenergo PJSC, and, at the second stage, Teploenergoservice PJSC into a single whole, which will lead to the effect of synergy and optimization in solving common problematic issues of industries and their complex solution. In addition to the foregoing, enterprises have the following prerequisites for combining into one structure: related goals and objectives; pronounced social orientation of both sectors; similarity of the problems being solved; a single vertically controlled system, the similarity of organizational and technical structures; single entry bases; a single organizational system of tariff setting; single supervising ministry.

Thus, at the first stage, the territorial and energy industry systems should be combined in an isolated zone into a single structure, i.e. the organizational and territorial division of the State Unitary Enterprise “Housing and Public Utilities of the Republic of Sakha (Yakutia)” should follow the principle of territorial separation of the electric power industry. At the second
stage, Teploenergoservice PJSC can be involved in the reform process.

For this, synchronization of the restructuring and reforming of the housing and utilities services and energy industry is necessary. The following actions are suggested:

– capitalization of state property leased by Yakutskenergo PJSC and Sakhaenergo PJSC, an increase in the state’s share in the authorized capital of Sakhaenergo PJSC;

– corporatization of newly created enterprises upon the division of the State Unitary Enterprise “Housing and Utilities of the Republic of Sakha (Yakutia)”;

– inclusion of a joint-stock company created upon division of the State Unitary Enterprise “Housing and Utilities of the Republic of Sakha (Yakutia)”.

Restructuring of enterprises should go along the path of introducing into the Sakhaenergo PJSC a newly created JSC formed upon the division of the State Unitary Enterprise “Housing and Utilities of the Republic of Sakha (Yakutia)” and operating in the coverage area of Sakhaenergo PJSC. This path is conditioned upon the following factors:

– extensive experience of Sakhaenergo PJSC and Yakutskenergo PJSC;

– State Unitary Enterprise “Housing and Utilities Services of the Republic of Sakha (Yakutia)”;

– work experience of Sakhaenergo PJSC in the organization of a joint stock company;

– the presence of professional training of the staff of Sakhaenergo PJSC and its high degree;

– the presence of a centralized and multi-level system of operational dispatch service, equipped with modern means of communication and information processing;

– well-established sales activities of Sakhaenergo PJSC.

An important factor determining the merger of the State Unitary Enterprise “Housing and Utilities of the Republic of Sakha (Yakutia)” and Sakhaenergo PJSC is the receipt of federal funding of the Housing and Utilities of the Republic of Sakha (Yakutia) for the cross-subsidization of diesel power. The newly formed enterprise will be financed from two levels of the budget: federal – energy industry, and republican – housing and utilities, which will increase the financial and economic stability of the new enterprise.

**Features of Innovative Ways of Managing the Life Support Sectors in the Arctic by the Government of the Russian Federation**

Currently, the electric power industry of the republic is under the control of the Ministry of Housing and Utilities and Energy of the Republic of Sakha (Yakutia). The Ministry of Housing and Utilities and Energy of the Republic of Sakha (Yakutia), in the form of which two directions are laid down (housing and utilities, and electric power industry), was created in the most difficult times (the consequences of the economic crisis of 1998 and the collapse of the post-Soviet space), when there was a need to combine problems and adopt consolidated decisions. This was the wisest decision of the Government of the Republic of Sakha (Yakutia) at that time, in the conditions of the far north, there was only one task – to survive.

The decision made by the Government of the Republic of Sakha (Yakutia) to sell the unfinished Vilyui HPS-3 of OAO AK Yakutskenergo to OAO ALROSA decided the fate of OAO AK Yakutskenergo (the country’s electricity industry), having stabilized the financial situation of the company, the creation of the State Unitary Enterprise “Housing and Utilities of the Republic of Sakha (Yakutia)” stabilized the work of boiler houses in settlements and streamlined the system of work of housing and utilities of local government. At present, the State Unitary Enterprise “Housing and Public Utilities of the Republic of Sakha (Yakutia)” has practically become an energy industry company, the key activity of which is the generation and transmission of thermal energy.

Currently, as a result of the work carried out, the republic has clear boundaries for the division of responsibility between industries and business. Also, the boundaries of responsibility of municipalities have been clarified, according to Federal Law No. 131-ФЗ “On General Principles of Organization of Local Self-Government in the Russian Federation” of October 6, 2003. However, under the pressure of numerous problems of a housing and utilities nature, the Ministry directed all efforts at solving issues of housing and
utilities and thermal energy, and was transformed into a department that handles mainly and on a priority basis housing and utilities issues.

At the same time, another part of the republic’s fuel and energy complex (coal and oil and gas sector) was subordinated to the Ministry of Industry of the Republic of Sakha (Yakutia), and then to the Ministry of Economic Development and Industrial Policy of the Republic of Sakha (Yakutia). Currently, it is subordinate to the newly created Ministry of Industry of the Republic of Sakha (Yakutia). As history shows, the direction of energy industry (FEC) has undergone many changes and reforms at the federal level as well. This is explained by the need for the control system to meet the requirements of the time. After the privatization phase of state enterprises was completed, the Ministry of Energy of Russia was created in 2008.\(^3\)\(^-\)\(^10\)

The Ministry of Energy of the Russian Federation develops and implements national policy in the industry and regulates the fuel and energy complex, including on electricity, oil-producing and oil-refining industry, gas, peat, coal, and shale industry, products of their processing, renewable energy sources development of hydrocarbon deposits on the basis of production sharing agreements in the petrochemical industry, including law enforcement and public services functions, state property management in the production and use of fuel and energy resources.

The Government of the Russian Federation, having considered all the problems and the causes of the problems existing in the country’s public utilities, decided to create a new Ministry of Construction and Housing and Utilities of the Russian Federation, which should manage all activities in the construction and housing and utilities of the country. The Ministry of Construction and Housing and Utilities of the Russian Federation was given the functions of developing and implementing national policy and legal regulation in the field of construction, architecture, urban planning, and housing and utilities, the provision of public services, management of state property in the field of construction, urban planning, and housing and utilities, including to coordinate the activities of the Federal Housing Development Fund, the state corporation – the Support Fund for the Reform of the Housing and Utilities Sector.

In the Republic of Sakha (Yakutia), there are the Ministry of Housing and Utilities and Energy of the Republic of Sakha (Yakutia) and the Ministry of Construction of the Republic of Sakha (Yakutia), which separately solve the problems of housing construction, operation of buildings and the provision of utilities, often duplicating or making inconsistent decisions. In Yakutia, the process of “construction and operation of housing facilities” has been broken at the level of government, which results in a low quality of housing construction in northern conditions. The situation would be significantly improved provided the state control and management of the process “Housing construction and operation” being performed by a single governing body.

**Conclusions**

Proceeding from the foregoing, it turns out that there is a necessity of separating the management system by industry, by creating sectoral ministries corresponding to the structure of the Government of the Russian Federation. We can state the pressing issue of considering the creation of the Ministry of Energy of the Republic of Sakha (Yakutia). For the creation of the Ministry, additional expenses beyond the budget considered by the Republic of Sakha (Yakutia) will not be required, since the existing departments and divisions of the two ministries will merge.

Also, with the development of the fuel and energy complex, the risk of impact on ethnic groups and the ecology of the republic will be minimal than in other non-mining industries, such as gold and diamond mining. The reason for this is the minimum number of specialists for the implementation of projects, less impact on the environment than in the extraction of gold and diamonds. For a clear interaction with the Ministry of Energy of Russia, it is necessary to unify the structure of the Ministry of Energy of the Republic of Sakha (Yakutia) with the federal structure.

Abstract

The country of Indonesia is an archipelago, which has various types of plants. One of them is a medicinal plant. This plant has ingredients that can be used as a treatment. But by seeing the high population growth of Indonesia, the medicinal plants are threatened. This makes the need for an action that can maintain the existence of these medicinal plants. Bioprospection conservation is an effort to preserve and develop medicinal plants so that their presence is not lost.

Keywords: Medicinal Plants, Bioprospection Conservation

Background

Indonesia is the country of the archipelago(1), which has a vast area; besides that, Indonesia is also a tropical region that has forests and even a considerable plantation area. One of the enormous potentials in Indonesia is the potential of traditional medicinal plants(2). The World Conservation Monitoring Center reports that Indonesia is a critical region because it is rich in medicinal plants. WHO defines medicinal plants are plants that contain ingredients that can be used as treatment and active ingredients can be used as synthetic, medicinal ingredients. For the Indonesian people, traditional medicine derived from plants has been used hundreds of years ago, the ancestors of the Indonesian people who have a life that is close to nature are very dependent on nature primarily in order to maintain health or heal their illnesses.

The growth of Indonesian society which is increasing makes a concern for the possibility of the destruction of medicinal plants that are in Indonesian nature, land changes from productive land both in forest friends and not in forest areas vulnerable to extinction, the need for housing, the need for industrialization causes loss or damage to medicinal plants in Indonesia.

Findings

Medicinal plants are each type of plant which in certain parts both roots, stems, bark, leaves,⁴ and the results of its expression are believed to be able to treat a disease or be useful in terms of health care. Medicinal plants in Indonesia are not only in the forest but also outside Forest. There are forest areas that are in the conservation forest but also in wood that is not conservation.

The World Health Organization estimates that some 80% of developing countries depend on traditional medicines and, of these, 85% use plants or their extracts as active substances (Sheldon et al., 1998). This means that nearly 3 billion people depend on medicinal plants⁵.

Medicinal plants are useful in the health sector, education sector, and bring economic contribution to the local community⁶. Medicinal plants (MP) are essential for the livelihoods of poor people throughout the world. Most medicinal plants are flowering plants. Out of 32000 species of higher plants (Prance, 2001), more than 10% is used as medicine⁷. Various ethnophytomedical-ethnobotany studies conducted by Indonesian researchers have been known, at least 78 species of medicinal plants used by 34 ethnic groups to treat malaria, 133 species of medicinal plants to treat fever by 30 ethnic groups, 110 species of medicinal plants to treat disorders digestion by 30 ethnicities and 98 species of medicinal plants are used to treat skin diseases by 27 ethnicities⁸.
them due to changes in the pattern of human life to start consuming drugs from natural ingredients and reduce the consumption of chemical medications, by the concept of returning to nature (back to view). Another cause is the high cost of modern synthetic medicines, so choices of herbal medication with natural ingredients are an option.

The government, through its policy, must carry out conservation of medicinal plants, one of which can be done is to conduct bioprospection. Bioprospecting (bioprospecting) is a systematic search, classification, and investigation for commercial purposes from sources of new chemical compounds, genes, proteins, microorganisms, and other products with actual and potential economic value, which are found in biodiversity.(8)

Bioprospection activities. (bioprospecting) the medicinal plant is a significant effort to obtain value-added benefits of the diversity of medicinal plants found in an area, both in forest areas and non-forest areas. Through bioprospecting (bioprospecting) of medicinal plants, it is expected that all components involved in these activities can feel the benefits, especially benefits that can be received by local communities and interests that can be acquired by an area where the medicinal plants are located.

**Discussion**

**Types of Traditional Medicinal Plants In Indonesia**

Indonesia, which is rich in natural resources, has many medicinal plants, and Indonesia is the second tropical country after Brazil Of a total of 40 thousand 30 thousand plants thought to be in Indonesia. Besides, in Brazil, many medicinal plants are found in India(9).

The types of medicinal plants that have been utilized by the Indonesian people include the following:

1. Turmeric
2. Ginger
3. Bangle
4. Brotowali
5. Curcuma

**The regulation of medicinal plants conservation**

The Government of the Republic of Indonesia conducts legal protection through preventive aspects by issuing various regulations. The regulations/policies in the development of bioprospecting are the Convention on
Biological Diversity (CBD) which regulates biodiversity that has been ratified by the Government of the Republic of Indonesia to in the Law of the Republic of Indonesia Number 5 of 1994 concerning Ratification of the United Nations Convention on Biological Diversity which was ratified on August 1, 1994\(^\text{(10)}\). The objectives of the issuance of the regulation are; First, the sustainable use of its components; The concept of sustainability is important in order to prepare for the children and grandchildren in the future and also the sustainability of development. Second, Share the benefits resulting from the efficient and equitable use of genetic resources, including through adequate access to genetic resources and with the appropriate transfer of technology, and by taking into account all rights to those resources and technology, as well as with adequate funding.

In addition to the aforementioned regulations, the government also ratified the Nagoya Protocol. Which is an international regulatory instrument for the implementation of the third objective of the Convention on Biological Diversity (CBD) which has also been ratified by the Government of the Republic of Indonesia into Law of the Republic of Indonesia Number 11 of 2013 concerning Ratification of Nagoya Protocol on Access to Genetic Resources and The Fair and Equitable Sharing of Benefits Arising from Their Utilization to the Convention on Biological Diversity (Nagoya Protocol on Access to Genetic Resources and Equitable and Balanced Benefit Sharing Arising from Utilization of the Convention on Biological Diversity) which was ratified on May 8, 2013.

The Nagoya Protocol is an international agreement on the environment in the framework of the Convention on Biological Diversity which regulates access to genetic resources and the fair and balanced distribution of benefits between the use and supply of genetic resources based on agreement based on initial information and collective bargaining and aims to prevent theft of diversity biological (biopiracy)\(^{11}\). The Nagoya Protocol Agreement is a significant agreement for the Indonesian State to get a fair and balanced benefit arising from its use of the Convention on Biological Diversity\(^{11}\) (RI Law No. 11 of 2013).

As for the benefits obtained by Indonesia through the ratification of the Nagoya Protocol, among others\(^{12}\) (RI Law No. 11 Tahun 2013):

1. Protect and preserve genetic resources and traditional knowledge related to genetic resources.
2. Preventing theft (biopiracy) and illegal use (illegal utilization) to biodiversity.
3. Ensure equitable and balanced distribution of benefits (financial and non-financial) on the use of genetic resources and traditional knowledge related to genetic resources to genetic resource providers based on mutually agreed terms.
4. Laying the legal basis for regulating access and equitable and equitable distribution of benefits from the utilization of genetic resources and traditional knowledge related to genetic resources based on mutual agreement.
6. Affirming State sovereignty over the regulation of access to genetic resources and traditional knowledge relating to genetic resources.
7. Providing incentives and funding support by statutory provisions.
8. Creating opportunities for technology transfer access to conservation activities and sustainable use of biodiversity\(^{13}\).

Also, the basis for other regulations/policies in the development of bioprospection of medicinal plants, especially in conservation areas, are as follows\(^{13}\):

- Law of the Republic of Indonesia Number 5 of 1990 concerning Conservation of Living Natural Resources and its Ecosystems
- Law of the Republic of Indonesia Number 12 of 1992 concerning Cultivation Systems
- Law of the Republic of Indonesia Number 16 of 1992 concerning Animal, Fish and Plant Quarantine
- Law of the Republic of Indonesia Number 41 of 1999 concerning Forestry
- Law of the Republic of Indonesia Number 24 of 2000 concerning International Treaties
- Law of the Republic of Indonesia Number 29
the Year 2000 concerning Protection of Plant Varieties

- Law of the Republic of Indonesia Number 18 of 2002 concerning the National System of Research in the Development and Application of Science and Technology

- Law of the Republic of Indonesia Number 32 of 2004 concerning Regional Government

- Law of the Republic of Indonesia Number 27 of 2007 concerning Management of Coastal Areas and Small Islands

- Law of the Republic of Indonesia Number 32 the Year 2009 concerning Environmental Protection and Management

- Law of the Republic of Indonesia Number 36 the Year 2009 regarding Health

- Republic of Indonesia Government Regulation Number 7 of 1999 concerning Preservation of Plant and Animal Species

- Republic of Indonesia Government Regulation No. 8/1999 concerning Utilization of Wild Plants and Animals

- Republic of Indonesia Government Regulation No. 6/2007 concerning Forest Management and Forest Management Planning and Forest Utilization

- Republic of Indonesia Government Regulation No. 3/2008 concerning Amendment to Government Regulation No. 6/2007 concerning Forest Management and Forest Management Planning and Forest Utilization

- Republic of Indonesia Government Regulation Number 28 of 2011 concerning Management of Nature Reserves and Nature Conservation Areas

- Republic of Indonesia’s Presidential Decree Number 100 of 1993 concerning Research Permits for Foreigners

- Regulation of the Minister of Forestry of the Republic of Indonesia Number: P.56 / Menhut-II / 2006 concerning National Park Zoning Guidelines

**Conclusion**

One of Indonesia’s abundant natural resources is medicinal plants that must be protected. The protection of medicinal plants can be done through bioprospection. This effort emphasizes the government’s efforts in conducting in-depth identification of medicinal plants in Indonesia, as well as strengthening the laws and regulations regarding medicinal plants in Indonesia.

Stature Estimation in Egyptian Primary School Children from Giza Governorate

Howaida Saeed Mohammed, Nadia Abd El Monem Koth, Usama Mohamed El Barrany, Mai Moustafa Magdi, Maha AbdeLrahman Mowafy
1Forensic Medicine and Clinical Toxicology, 2Family Medicine, Faculty of Medicine, Cairo University, Cairo, Egypt.

Abstract

Stature is one of the used parameters for identification in forensic anthropology. This study aimed to develop a formula to estimate the stature of children using anthropometric measurements. Ten anthropometric measurements were measured for 350 students randomly selected from two primary schools. The arm span exceeds height at old ages and the majority of measurements were higher in girls. A strong correlation was found for stature and majority of measurements.

Keywords: Stature, Estimation, Egyptian, Primary school, Children, Giza.

Background

Anthropometry is the scientific study of a variety of methods to estimate the measurements of the human body and skeleton. Stature is a measure of biological development and is determined by a combination of genetic and environmental factors.1

Stature expresses a lot of features of humans and is an inherent characteristic; therefore, its estimation is essential for identifying and clarifying the unknown livings and the human remains.2

Stature estimation resulted from measuring segments and bones in different parts of the human body, precisely upper and lower extremities, has a long history to be mentioned.3, using humerus length are nearly limited and the majority of these studies were undertaken on adults.4

Material & Methods

The current study was conducted on 350 Egyptian healthy children aged 6 to <13 years were recruited randomly from two primary schools in Giza governorate, then children were divided into 7 groups according to age each group was 50 children (25 boys and 25 girls). Children who were non-Egyptian, below or above the age and had fractures, deformities or previous surgical operations were excluded from the study. A written consent was taken from The Ministry of Education and head masters of the schools. Measurements were taken by the same person from the right side of the child. The birth data (day, month, and year) of students were taken from their school records.

- **Body Weight (kg)** was measured using Secca weight scale; the subjects were instructed to stand over the scale bare feeted with light clothing and weight recorded to nearest 0.01 kilogram.

- **Standing height**: Subjects were in standing barefoot position; with straight back. The head was in the Frankfurt horizontal plane and then the head vertex was contacted to firm and the number was recorded approximated to the nearest 0.1 cm.5

- **Sitting height**: was measured by using portable Holtain anthropometer. The child was sitting erect on a desk with her/his legs hanged free and knee flexed at 90° and fixed to the edge of the desk. The mean of three measurements was calculated and approximated to the nearest 0.1 cm.6

Address: Kasralainy, Faculty of Medicine, Cairo University, Cairo, Egypt.
Maximum head Length: measured using the sliding caliper from the glabella (the most prominent point above the root of the nose on the frontal bone, between the eyebrows) to the opisthocranion (the most prominent part of the occiput) and the measures approximated to the nearest 0.1 cm.7

Head Circumference: Head circumference was measured using a plastic tape, placed over the eyebrows and passed around the head, and over the very posterior protuberance of the occiput.8

Arm Span: measured from the left middle fingertip to the right middle fingertip using a calibrated steel tape. It was approximated to the nearest 0.1 cm.9

Upper arm Length: The distance between acromion end of clavicle and olecranon process by a sliding caliper.10

Forearm Length: measured in arm flex position from the tip of olecranon to the point between radius and ulnar tuberosity.11

Lower Limb Length: calculated by subtracting the sitting height from the stature.12

Leg Length: Measurement is taken from medial articulation of the knee joint to the most distal point of medial malleolus.13

The statistical package SPSS version 24 used for data coding and entering. Unpaired t test used to Compare between groups and Chi square (χ2) test was used for comparing categorical data but when the expected frequency is less than 5 the exact test was used. For Correlation between quantitative variables the Pearson correlation coefficient was performed. To detect factors affecting stature and age, linear regression was performed. There was a statistical significance when the Probability (P) values equal or less than 0.5.

Findings

The arm span length was shorter than height in both boys and girls at ages 6 – 9 years old. The mean of the majority of measurements was higher in girls at ages 6 & 9 years old, while at ages 7 & 8 years it was higher in boys (Table 1).

The arm span length was shorter than height in girls but exceeds in boys at 10 years, while exceeds the height at ages 11 & 12 years. There was increasing mean in the majority of measures in girls than boys (Table 2).

A significant correlation between stature and all measurements was found (Table 3). In addition, linear regression analysis revealed that stature can be estimated in boys and girls (Tables 4 and 5).

Discussion

In the current study, girls were taller than boys at ages 6 and 9 up to 12 years and heavier than boys at ages 6 – 8 and 11- 12 years, while at ages 9 - 10 years the boys were heavier than girls. This is agreeing with Reyes et al. & Tee et al.14, 15 This is can be illustrated by the fact that the growth at age (10 – 13 years) of puberty in girls is earlier than boys then boy’s puberty growth occur after age of 12 years old.

In this study, the mean arm span values were shorter than the height and longer in boys at younger ages, while exceeds height and longer in girls at older ages. This is may be related to the rapid growth at age of puberty and this is in agreement with Zhu et al., Zverev and Chisi.& Grimberg and Lifshitz. 18, 16, 17 However, disagree with Zverev and Chisi., who found that the mean arm span values exceeded height in all age groups of boys and in older girls.16

In this study the arm length was higher in girls at ages 6, 9 &12, while at ages 7- 8 and 10 - 11 years it was higher in boys. These results are in agreement with Zhu et al. & Karakas et al.18, 19

The mean forearm length values were higher in girls than boys in older ages and this agree with Karakas et al. & Zhu et al.19, 18

The mean lower limb length was higher in girls at ages 6, 9, 10, 11 years, while in boys it was higher at ages 7,8, 12 years. Agree with Reyes et al. and Malina et al.14, 20

The leg length was longer in girls in all ages except age 12 years. This result is in agreement with Malina et al. & Zhu et al.20, 18 However, Karakas et al. found that the leg lengths of girls were longer than boys at ages 8, 10 & 11 years.19

The head length was higher in boys in all ages except age 10 years and this agree with Hansi and Ashish with values less than our study.21 and this may be related to genetic, environmental factors like dietary habits, vitamin deficiencies and ethnic variability. In accordance Chowdavarapu et al. found in their study that the mean value of head length was higher in girls.22

The mean head circumference was greater for boys at ages 6 - >12 years. These results agree with Neyzi et al.23 However, disagree with Batterjee et al., who found that, it was higher in girls at ages 8 – 12 years old.24

These differences could be ascribed to the surrounding environmental, nutritional and genetic factors.

In the current study arm span, length of the upper arm, forearm, lower limb and leg showed a strong positive correlation for stature. These agree with Mishra et al. & Zhu et al.25, 18

Mishra et al. Conducted regression equations using arm span.25 and Smith using humerus, femur & tibia.26

Conclusion

The girls exceeded boys in the majority of measurements. Arm span exceeds height in older ages in both boys and girls, while head length and circumferences were higher in boys. The majority of these measurements are useful for estimating stature using multiple regression equations. Further studies should be conducted on large numbers and different regions.

Abstract

Background: The protein tyrosine phosphatase non-receptor type 22 (PTPN22) gen, has been involved in the immune response to tuberculosis infection by affecting the inflammatory response and subsequent antimicrobial immunity. This study aims to determine the PTPN22 expression and differences in the levels of PTPN22 in pulmonary TB patients (PTB) with household contacts and healthy control.

Methods: We analyzed PTPN22 expression and the level of plasma PTPN22 from pulmonary tuberculosis patients (PTB), household contacts and healthy control using real time PCR and ELISA method.

Results: Thirty PTB, 30 household contacts and 30 control were involved in this study. Analysis of the association of PTPN22 gene expression against TB showed that PTPN22 gene expression was 7.3 times upregulated compared to household contact and 12.1 times upregulated compared to healthy controls. Levels of plasma PTPN22 in PTB: 10.0620 ng/ml, in Household contact: 6.7923 ng/ml and in control: 4.4293 ng/ml. These values did not differ significantly between the patients, household contact and control.

Conclusion: Our study results found that PTPN22 gene expression is significantly increased in PTB than household contact and control. Levels of plasma PTPN22 in PTB patients did not differ significantly than in household contact and control.

Keywords: PTPN22, Pulmonary tuberculosis, Gene expression, Real time PCR, ELISA, Level of plasma.

Introduction

Pulmonary tuberculosis (TB), an infectious disease caused by Mycobacterium tuberculosis (Mtb). TB remains a major cause of morbidity and mortality in humans worldwide. One-third of the population worldwide is infected by Mtb. About 5-10% of them manifest clinically to be active TB1,5,10,15. World Health Organization in Global Tuberculosis Report 2019 revealed that there were an estimated 10 million new TB cases worldwide in 2018. TB is the top infectious killer in the world. There were 1.5 million people died from TB2,3,11,12,18. TB is the leading killer of people with HIV and a major cause of deaths related to antimicrobial resistance. Indonesia is one of the countries with the highest TB burden in the world. There were 845 thousands TB incidence (316 per 100 thousands population) and 98.3 thousands (37 per 100 thousands population)4,6,7,8,21.

Studies in United States revealed that 20-30% of the household contacts occured latent infection and about 10% became active TB9,10,13,14,28. A person susceptibility to TB infection and developing active TB is influenced by several factors including host genetics, host immunity, mycobacterium virulence and environment. The prevalence rate of TB was significant different among several ethnic minorities, therefore,
the differences in susceptibility to TB may be related to a genetic predisposition. Genetic predisposition as one of the host factors influencing risk factors for the development of TB\textsuperscript{15,16}.

Studies revealed the pivotal function played by cellular immunity in Mtb infection. The immune responses are implicated to control the infection through cytokine production and specific surface molecules interactions. T-cell activation is a crucial step in the immune response against Mtb. Several genes are associated with TB pathogenesis, one of them is protein tyrosine phosphatase nonreceptor type 22 (PTPN22)\textsuperscript{17,18,23}. The PTPN22 gene were involved in maintaining the T cells in the resting stage. PTPN22 were also responsible for bringing back the activated T cells to the resting phenotype in the absence and presence of antigen. Phosphotyrosine phosphatases are involved in reversion of T lymphoblastic proliferation Tyrosine phosphorylation in T cells is regulated by phosphatase activity.

Several transmembrane molecules, like PD-1 (programmed death 1) and CTLA-4 (cytotoxic T-lymphocyte antigen 4), play an important role in downregulating signalling through the T-cell receptor (TCR). The PTPN22 is a cytosolic inhibitor of TCR signalling. The PTPN22 geneis located on chromosome 1p13.3-p13.1. This gene product is the intracellular protein tyrosine phosphatase known as Lyp and expressed in cells of the immune system, including dendritic, T and B cells. Lyp is expressed in cells of haematopoietic origin and has a variety of substrates, including Lck, Zap70, Valosine containing protein (VCP), Vav and TCRzeta, all of them are important players in T-cell signalling. The dephosphorylation of these substrates by LYP negatively modulates T-cell activation. Lyp forms a protein complex with the intracellular tyrosine kinase (protein tyrosine kinase) Csk. The Csk protein tyrosine kinase is a potent suppressor of T cell activation due to its ability to phosphorylate tyrosine residue at Src family kinases, thereby antagonizing the action of CD45, that mediates dephosphorylation of the inhibitory C-terminal SH2 domain of Lck.\textsuperscript{19,1,4}

Numerous studies from several countries result, suggest that the PTPN22 gene affect susceptibility to TB. However, no research has been conducted in Indonesia about PTPN22 and TB\textsuperscript{4,7,12}. The purpose of this study was to compare gene expression and levels of plasma PTPN22 in pulmonary tuberculosis patients and their household contacts in Makassar, Indonesia. The results of this study are expected to provide a better understanding of the relationship gene expression and levels of plasma PTPN22 with susceptibility TB.

**Materials and Method**

**Research design and study subjects**

We analyzed gene expression and the levels of plasma PTPN22 from pulmonary tuberculosis patients (PTB), household contact and control samples using real time PCR and ELISA method. QuantiFERON-TB Gold Plus (IGRA) was used to screening latent TB infection among household contacts. A total of 90 samples were collected in this study, consisting 30 pulmonary tuberculosis patients, 30 household contacts and 30 control. Pulmonary TB patients who were participants in this study were recruited from the Community Center for Lung Health Makassar, Indonesia, which is one of the referral health facilities for tuberculosis.

All TB patients were diagnosed based on clinical manifestations, chest radiograph, microscopic smear which was further confirmed through TB culture with MGIT medium. Inclusion criteria for TB patients in this study included new TB cases (no history of anti-tuberculosis drugs treatment), ages 18 years and over, willing to participate in this study by giving written consent and having positive smear results. The exclusion criterion was HIV-positive (SD Bioline). The inclusion criteria for household contact are those aged 18 years and over, have no clinical symptoms of TB, have no history of TB or anti-tuberculosis drugs, and stay at home with TB patients for at least 6 months and are willing to participate by giving written consent. We collected blood and sputum samples from 30 TB patients, blood samples from only 30 household contacts that met the criteria and 30 blood samples from healthy control. Positive sputum samples were decontaminated and continued with the culture process at the Tuberculosis Unit of the HUM-RC Laboratory (Hasanuddin University Medical-Research Center), Makassar, Indonesia. Blood samples were centrifuged at 4,400 rpm for 10 minutes at 250C to separate plasma samples. Plasma samples were stored at -200C before ELISA. Specifically from the contact sample, we examined IGRA with the QuantiFERON Gold Plus TB Test (Qiagen, Germany) according to the manufacturer’s instruction manual\textsuperscript{20,21,4,7}.
Measurement levels of plasma PTPN22

Concentration PTPN22 was determined by the ELISA method using an ELISA Human PTPN22 kit (Diagnostics Biochem Canada Inc., Ontario, Canada) according to manufacturer’s instructions. Linear curves are used to determine the concentration of PTPN22 samples from a calibration curve. **Measurement gene expression of PTPN22 by real timePCR**

Amplified complementary DNA (cDNA) from RNA extracted blood sample by Reverse Transcriptase-PCR based on the method of Invitrogen. Using SuperScript First-Strand Synthesis System for RT-PCR. This cDNA strand stored in -20°C until used for real time PCR. Measurement gene expression (up regulation or down regulation) PTPN22 by SYBR Green Dye using the real time PCR (qPCR) method according to manufacturer’s instructions. Before amplified, a master mix was prepared by mixed 12.5 ml SYBR green dye, 0.5 ml cDNA and 0.5 ml forward primer (5’-ACAACCTGTGGCTGAGAAGCCA-3’), 0.5 ml reverse primer (5’-GTAGCTGGAATCCTCATCAGG-3’) (each primer 5 pmol/ml) and 11.3 ml H2O. The same procedure was carried out for the GAPDH gene as a control but using a different primer sequence. GAPDH forward primer (5’-CCTGCACCACCAACTGCCTTA-3’)

and GAPDH reverse primer (5’-GGCCATCCACAGTCTTCTGAG-3’) 3,7,9,10. The qPCR cycle with a condition of 50°C for 2 minutes, 95°C for 1 minute each cycle, denaturation 95°C for 15 seconds then followed by annulling 60°C for 30 second and extension 72°C for 30 seconds was repeated 40 times (cycles). The last cycle was the final extension at 72°C for 10 minutes 1,4,9,15,17.

Statistical Analysis

All experimental data were analyzed using SPSS software (version 21.0, Chicago, IL, USA). P values <0.05 were considered statistically significant. Data obtained from ELISA results were analyzed and assessed for differences between the three groups (pulmonary TB patients, household contacts and control). The Chi-square test is used for the comparative analysis of nominal variables. Data (parametric) will be presented as mean ± SD (median) and will use statistical analysis to distinguish values between the three groups. Data were analyzed using the One-way ANOVA test which compared levels of plasma PTPN22 in the three groups.

Results

We analyzed a total of 30 TB patients, 30 household contacts and 30 healthy control for the PTPN22 gene expression and levels of plasma.

* Chi-square test.
Table 1 shows the gender and age of study participants. There was a gender difference between groups (p=0.009). There were more male subjects (56.7%) than female (43.3%) in the TB patients group. However, more female subjects (80%) than male (20%) in household contacts group. It can be seen that there was no age difference between the three groups (p=0.475).

PTPN22 levels were measured using ELISA. The lines on the boxplot indicate the median and the points show extreme values. PTPN22 levels in TB patients group: mean 10.06 ng/ml with standard deviation 15.98 ng/ml. PTPN22 levels in household contacts group: mean 6.79 ng/ml with standard deviation 10.24 ng/ml. PTPN22 levels in control group: mean 4.43 ng/ml with standard deviation 6.68 ng/ml. Data were analyzed using the One-way ANOVA test which compared PTPN22 levels in the three groups.

The mean value PTPN22 levels in TB patients compared to household contacts and control, did not differ significantly (p = 0.175).

Gene expression of PTPN22 in TB patients group: 12.11629, household contacts group: 1.65801 and control 1.00000. Analysis of the association of PTPN22 gene expression against TB showed that PTPN22 gene expression was 7.3 times upregulated compared to household contact and 12.1 times upregulated compared to healthy controls.

**Discussion**

In this study, from 90 participants, there were more male subjects in the TB patients group. This was in accordance with the theory. We found that PTPN22 gene expression is significantly increased in PTB than household contact and control. Several studies analyzing the role of PTPN22 in TB show an association between
PTPN22 and susceptibility to active TB disease. Some of the earlier studies reported a significant association between PTPN22 and TB. These studies results suggest that PTPN22 gene may affect susceptibility to TB like in Colombian population, Moroccan population, Brazilian Amazon population and Chinese Uygur population.23,10,15

The mean of levels plasma PTPN22 gene on TB patients group was higher than mean of levels plasma PTPN22 gene on household contacts and healthy control. But these values did not differ significantly levels plasma of the PTPN22 gene between the three groups.24,10,28 Several studies results also found that PTPN22 gene is not associated with the susceptibility to TB, such as in Iranian population and Indian population.2,9,17,19

There were differences in terms of genetic predisposition and serum levels in TB and non-TB subjects. It was likely due to geographical location, genetic differences and the presence of other disease conditions. A person susceptibility to TB infection and developing active TB is influenced by several factors including host genetics, host immunity, mycobacterium virulence and environment.25,26 Several factors were increased susceptibility TB, such as malnutrition, Diabetes mellitus and age by suppressed the immune system.27,4,22

**Conclusion**

The PTPN22 gene expression is significantly increased in pulmonary TB patients than household contact and control. Patients with active TB have higher levels of plasma PTPN22, but did not differ significantly, compared to household contacts and control.

Acknowledgments: The authors would like to thank the patients, household contacts and healthy subjects who willingly participated in the study, and all the partners and staffs who help us in the process of this study.

Awareness Program of Pesticides Used among Farmers using Difficulty-Usefulness Pyramid (A Suggestion for Health Laws and Policies Regarding the Use of Pesticides)

Ilyas Ibrahim¹, I Ketut Sudiana², H. J. Mukono³, Suhartono⁴, Heru Santoso Wahito Nugroho⁵

¹Doctoral Student, Faculty of Public Health, Universitas Airlangga / Lecturer, Faculty of Health Science, Universitas Bumi Hijrah Tidore, ²Professor, Department of Pathological Anatomy, Faculty of Medicine, Universitas Airlangga ³Professor, Faculty of Public Health, Universitas Airlangga, ⁴Associate Professor, Faculty of Public Health, Universitas Diponegoro, ⁵Associate Professor, Poltekkes Kemenkes Surabaya

Abstract
Pesticides are toxic chemical substances that are used in agriculture to control plant pests. Excessive use of pesticides and uncontrolled can cause negative effects among farmers, such as vomiting, diarrhea, dyspnea, blurred vision, paresthesia, slurred speech, and chest pain. The prevention effort through health education was used to prevent the risk behavior of farmer, however, it still found obstacles. There are many elements need to be improved and it must be selected which element that significant and priority to change risk behavior among farmers. This study had selected the elements based on Difficulty-Usefulness Pyramid (DUP). The sample was 100 respondents who knew about pesticides in Indonesia. Personal protective equipment (PPE), storage of pesticides, procedure for using pesticides, use of pesticide doses, duration and frequency of spraying pesticides, cleaning the equipment, spraying pesticides based on the wind direction, time of pesticide spraying were selected elements in this study. Difficulty and usefulness were indicators to determine the priority of attributes. Attribute scale (1 to 10) was used based on the level of importance in each attribute. Google form questionnaire was used to collect the data. Each element was measured by: (1) difficulty and usefulness; (2) the mean score of difficulty and the mean score of usefulness; (3) range (from mean score of difficulty to mean score of usefulness). Then the range was sorted starting from the smallest and presented in the form of a pyramid. The pyramid showed that the priority elements were use of pesticide doses, procedures for using pesticides, personal protective equipment (PPE), cleaning the equipment, time spraying pesticides, duration and frequency of spraying pesticides, storage of pesticides, spraying pesticide based on the wind direction.

Keywords: Difficulty-Usefulness Pyramid; awareness; chemical pesticides

Introduction
Pesticides are all chemicals substances to control plant pests such as insects, rodents, nematodes, weeds, viruses, bacteria and microorganisms.¹ Pesticides can increase agricultural product, but it also harm the environment and human health. Excessive use of pesticides and uncontrolled can cause negative effect among farmers. The negative effects of pesticide exposure were vomiting, diarrhea, dyspnea, blurred vision, paresthesia, slurred speech, and chest pain.² Pesticide exposure also depends on the amount of pesticide dose, duration of exposure and exposure modification factors such as the use of personal protective equipment (PPE).³

Pesticide exposure is caused by improper management of pesticides, low levels of knowledge about the dangers of pesticides, not paying attention to safety regulation.⁴ The Thai Department of Occupational Health reports that farmers’ blood tests show an increase in pesticide exposure in the previous year (16% to 18%).
This is due to the low level of knowledge, and the risk behavior of formulating pesticides that inappropriate with the instructions.\(^5\)

Spraying pesticides is the most method to used pesticide, because 75\% of pesticides are applied by spraying.\(^1\) If the application inappropriate, it can have negative effect among users, targeted pests, as well as the environment.\(^4\)

The World Health Organization (WHO) estimates that 1-5 million cases of pesticide poisoning occur annually in agricultural workers with death toll raise until 220,000. However, the Ministry of Health and the Department of Agriculture of Indonesia has already given the information related to pesticides.\(^6\)

Farmers as chemical pesticide users often apply it without the standardized rules. Various efforts to control the use of pesticides from the ministry of agriculture to prevent negative effect of exposure and poisoning pesticide but it did not have affect on the behavior of farmers. The survey showed that farmers who use chemical pesticides did not use personal protective equipment (PPE) when spraying, the dosage used was according to their preferences, spraying was not based on wind direction, and it made high exposure to pesticides. Based on these problems, it is necessary to conduct awareness program by identifying priority elements related to risk behavior of exposure to chemical pesticides.

Considering that many pesticide control programs in Indonesia are still in the initial and development stages, so this research aimed was to identify and collect public opinion about the difficulties and usefulness of awareness programs for risk behaviors of exposure to chemical pesticides among farmers by using difficulty-usefulness (DUP) pyramid.

Nugroho, et al (2018) introduced DUP as a method for selecting priority elements. In this method, the determination of the elements is conducted through literature review, while the attributes that used as the basis for determining priorities are difficulty and usefulness. DUP gives equal weight to these two attributes, also the level of importance of difficulty and usefulness as a basis for improvement of elements is equal.\(^7\) Everyone has different views on the importance of difficulty and usefulness. Some people will assume that the difficult elements should be prioritized to be improved, but some people will assume that useful element should be prioritized to be improved. Based on the background, we proposed a method for selecting elements that will be prioritized, using DUP.

**Method**

The study was conducted in 2019. The sample was the general public who knew about the use of chemical pesticides in Indonesia. This study involved 100 respondents spread in Indonesia. This study used DUP to select elements based on priority and the difficulty and usefulness attributes. The following steps were:

1. **Determination of the elements**

   The selection of the priority elements of the awareness program on the use of chemical pesticides among farmers based on DUP creation study.\(^1\) The selected elements based on the review literature. Applications of pesticides from Djojosoemarto were: using personal protective equipment (PPE), storage of pesticides, the procedure for using, use of pesticide doses, duration and frequency of spraying pesticide, maintain cleanliness of equipment, spraying pesticides in the direction of the wind.

2. **Determination of attributes**

   According to DUP, difficulty and usefulness were used as priority attribute.\(^7,\text{8}^\) Based on DUP, difficulty was scored with a negative symbol (0 to -10), so the higher the difficulty of an element, the score was negative. Usefulness was scored with a positive symbol (0 to 10), so the higher the usefulness of an element, the score was positive.\(^7,\text{8}^\)

3. Data collection and analysis

At this stage, data collection was carried out through questionnaires (Table 1). Respondents were asked to fill in the Google form questionnaire that was sent via the Whatsapp application, one mobile number only can fill the questionnaire once. The next step was descriptive data analysis: (1) making the difficulty scores of each element with the importance of difficulty; (2) making the usefulness score of each element with the importance of usefulness; 3) calculating the mean score of difficulty and the mean score of usefulness; 4) calculating the range that starts from the mean score of difficulty to the mean score of usefulness; 5) rank according to the smallest range; 6) draw a pyramid diagram based on the sorted range; 7) determine the elements based on priority order according to the pyramid diagram.

Findings

The results of descriptive data analysis were shown in Table 2. The ranges were arranged sequentially starting from the smallest as shown in Table 3. The sorted ranges were presented in the form of a pyramid diagram. The largest range was in the lowest position, while the smallest range was in the top position (Figure 1).
Table 2. Mean score and range

Figure 2 showed the largest range (the lowest position in the pyramid) was the use of pesticide doses. Thus, to awareness of the use of chemical pesticides was priority “Use of pesticide doses, then the next priority is procedure for using pesticides, personal protective equipment (PPE), maintain cleanliness, time spraying pesticides, duration and frequency of spraying pesticides, storage of pesticides, and finally spraying pesticides based on wind direction. Further recommendation, the five elements with the largest range are prioritized for improvement (Use of pesticide dosages and links to resources, procedures for using pesticides, personal protective equipment (PPE), maintain cleanliness, time spraying pesticides, duration and frequency of spraying pesticides)

</table>
From the pyramid, it can be concluded that the range of the eight elements is almost the same, but if examined based on priorities, the four main elements that are prioritized for improvement are the use of pesticide doses, procedure for using pesticide, PPE and maintain cleanliness of equipment.

**Discussion**

This study had a new method to refinement the DUP. DUP is the initial method to develop awareness program of pesticides used among farmers. Determination of the awareness elements of the use of chemical pesticides are based on ten elements used in popular pesticide exposure prevention programs, namely use of pesticide doses, procedures for using pesticides, personal protective equipment (PPE), maintain cleanliness of equipment, time spraying pesticides, duration and frequency of spraying pesticides, storage of pesticides, and spraying pesticides based on wind direction.

The attributes for determining priorities based on DUP were difficulty and usefulness. In the process of creating DUP, the two attributes were chosen based on literature review. The awareness program of pesticides used is a prevention program to prevent exposure to chemical pesticides when applying pesticides either in the field or in storage of pesticide. The determinants were selected by using the text book of “Application of Pesticides” written by Djojosumarto. The analysis used the Difficulty-Usefulness Pyramid (DUP) theory. DUP mentioned that “difficulty” was an attribute that had to be reduced, so it had a negative score; while “usefulness” is an attribute that must be improved, so it had a positive score.

Figure 2 showed that the different ways of scoring for difficulty and usefulness, the result was the bars in the opposite direction. The left for “difficulty” and right for “usefulness”. In this case, the priority is the element with the largest range starting from the value of “difficulty” to “usefulness”. The use of pyramid diagrams is intended to analysis and understood the result quickly. From the pyramid, it can be concluded that the range of the eight elements is almost the same, but if examined based on priorities, the four main elements that are prioritized for improvement are the use of pesticide doses, procedure for using pesticide, PPE and maintain cleanliness of equipment.

Pyramid diagrams can be depicted using computers manually or using statistical software that provides facilities such as SPSS. In this study, DUP was created by using population pyramid, with several changes, namely: 1) “variable” form is filled by mean score, 2)
“show distribution over” form is filled by elements of alertness program use of pesticides, 3) “split by” form is filled by attributes.\(^\text{7,8}\)

By using DUP, drawing can be conducted easily because the results of data analysis are presented visually in the form of a pyramid. In this case, the element at the lowest position was the first priority, while the element at the top position was the last priority. Recommendations can also be conveyed more easily because they only refer to the priorities. Based on the conclusions and recommendations, managers can immediately plan for the improvement of the elements of awareness program of the pesticides used.

In this study, the DUP process was used to increase awareness of chemical pesticides used in the health and agriculture sectors, but it is also recommended to use DUP into other objects, such as hospital information systems, telemedicine, health service systems, e-Health, health e-journal and so on. In advance, elements must be selected through literature review, focused group discussion or brainstorming that involving the users of the related system.

**Conclusion**

Based on the result, it can be concluded that the four main elements that are prioritized for improvement are the use of pesticide doses, procedure for using pesticide, PPE and maintain cleanliness of equipment. This finding is expected to contribute significantly to increase awareness program of the pesticides used among farmers in agriculture, environmental toxicology and health.

Regional Disparities of Stunted Toddler in Indonesia

Ina Kusrini¹, Agung Dwi Laksono²

¹ Researcher, Unit of Health Research and Development Magelang, Indonesia Ministry of Health, Central Java, Indonesia, ² Senior Researcher, Center of Research and Development of Humanities and Health Management, Indonesia Ministry of Health, Jakarta, Indonesia

Abstract

Although there has been a decline in the prevalence of stunting in Indonesia in the past decade, the figure is still the highest among countries in Southeast Asia. The purpose of the study was to analyze the regional disparity of stunted toddlers in Indonesia. The analysis in this study uses data from the 2017 Indonesian Nutritional Status Monitoring. The sample used in this study was 149,571 toddlers aged 0-59 months. Data were analyzed using the Binary Logistic Regression test. Toddlers in the Sumatra region have the possibility of 0.921 times stunted compared to toddlers in the Papua region. The Java-Bali region was 0.805 times more likely than toddlers in the Papua region to be stunted. The Nusa Tenggara Region was 1.39 times more likely than toddlers in the Papua region to be stunted. Kalimantan Region has 1.161 times more likely than toddlers in the Papua region to be stunted. The Sulawesi region has 1.18 times the possibility of toddlers in the Papua region being stunted. Maluku region has a probability of 0.88 times that of toddlers in the Papua region to be stunted. There was a regional disparity of stunted toddler in Indonesia.

Keywords: child health, child nutrition, health survey

Background

A linear growth curve for toddlers with age is the best indicator in describing whether there is quality inequality in achieving optimal children’s health. Inadequate food in meeting nutritional needs and the emergence of infectious diseases is the direct and most frequent cause of this growth failure¹. Stunting is a form of growth failure that reflects chronic and multidimensional nutritional problems in the first 1000 days of life that have an impact on the quality of human resources². Decreased cognitive abilities, increased morbidity and the onset of metabolic syndrome in the future are the serious effects of stunting³.

Stunting is marked by the z value of height according to age below -2 standard deviations from the global growth reference. Data from the Global Health Observatory shows that globally nearly 150 million children under five in the world, or around 21.9%, are still in the stunting category. In line with the agenda of public health priorities in the world, it is expected that the prevalence of stunting will decrease by 2030 to 17.5%⁴. Indonesia is a country with a high enough stunting rate. Indonesia Basic Health Survey data for 2007, 2013 and 2018 show the prevalence of national toddler stunting in Indonesia respectively 36.8%; 37.2%; 30.8%⁵. Although there has been a decrease in the prevalence of stunting in the past decade, the figure still shows more than 30%. This figure is the highest among countries in Southeast Asia. This condition can be interpreted that one in three toddlers born in Indonesia is still stunted. This figure varies in 34 provinces and 541 regencies/cities, which is between 17.6%-42.3%⁶.

The success of stunting prevention cannot be separated from cross-sectoral and multidimensional collaboration. One index to measure the success of health development in the national context (Indonesia) is the Public Health Development Index (PHDI). Collection of public health indicators that comprehensively form 1 value that has a connection with life expectancy and is one of the efforts to see the ranking and progress of health development at the regional level⁷. The PHDI data for 2013 and 2018 illustrate the disparity in health development at the regency/city and provincial levels in Indonesia. Differences in the geographical environment, access, socioeconomics as well as human development underlie this inequality. Based on the background, this study was conducted to analyze the regional disparity of...
Materials and Method

This study analyzes the 2017 Indonesian Nutritional Status Monitoring data (PSG 2017). PSG 2017 was a national-scale survey using a multi-stage cluster random sampling method conducted by the Nutrition Directorate of the Indonesian Ministry of Health. The unit of analysis in this study was toddlers aged 0-59 months. The sample size analyzed in this paper was 149,571 toddlers.

The region was the division of territory grouped by the largest island. Divided into 7 regions, namely Sumatra, Java-Bali, Nusa Tenggara, Kalimantan, Sulawesi, Maluku, and Papua. The variable selection was done by using the Chi-Square test to test the dichotomous variable, while for the continuous variable the T-test was used. This statistical test was used to assess whether there was a statistically significant relationship between regional variables and other variables related to the nutritional status of toddlers for height per age. There were 8 variables in 3 groups of variables to be tested, namely the characteristics of children under five (nutritional status and age), the context of the region (urban-rural), and the characteristics of mothers of children under five (age, marital status, education level, work status). A binary logistic regression test was used at the final stage to determine the variables that were predictors of stunting in toddlers in Indonesia.

Findings

The results of the bivariate analysis found that on average each region is dominated by rural areas. On average, each region is dominated by toddlers with normal nutritional status. The largest prevalence of stunted children is in the Nusa Tenggara region. There is a significant difference between the nutritional status of children under five by region category in Indonesia. Table 1 shows that the average age of children under five is slightly older in the Papua region compared to mothers of children under five in other regions. While the average age of mothers of children under five is slightly older in the Nusa Tenggara region compared to mothers of children under five in other regions.

Based on marital status, toddlers in all dominant regions have married status. While based on the level of education of mothers of children under five in the region of Sumatra, Java-Bali, Sulawesi, and Maluku, they have a dominant high school education. While the regions of Nusa Tenggara, Kalimantan and Papua predominantly have a primary school and under. Based on work status, mothers of the toddler are dominated by those who do not work.

Table 1 displays the results of the binary logistic regression of the nutritional status of the toddler. Table 1 shows that in the Sumatra, Java-Bali, Nusa Tenggara, Kalimantan, Sulawesi, and Maluku regions, the stunted incidence disparity in toddlers has proven to be significant compared to the Papua region as a reference.

</table>
Table 1 informs that toddlers in the Sumatra region are 0.92 times more likely than toddlers in the Papua region to be stunted (OR 0.92; 95% CI 0.88-0.96). The Java-Bali region is 0.81 times more likely than toddlers in the Papua region to be stunted (OR 0.81; 95% CI 0.76-0.84). The Nusa Tenggara Region is 1.39 times more likely than toddlers in the Papua region to be stunted (OR 1.39; 95% CI 1.32-1.48). Kalimantan Region has 1.16 times more likely than toddlers in the Papua region to be stunted (OR 1.16; 95% CI 1.10-1.22). The Sulawesi region has 1.18 times the possibility of toddlers in the Papua region being stunted (OR 1.18; 95% CI 1.13-1.24). Maluku region has a probability of 0.88 times that of toddlers in the Papua region to be stunted (OR 0.88; 95% CI 0.82-0.95). It could be interpreted that toddler in the Sumatra, Java-Bali, and Maluku regions had a lower possibility than the Papua region to be stunted. While the Nusa Tenggara, Kalimantan, and Sulawesi regions had a greater risk than the Papua region to be stunted. These results are in line with some of the results of other studies that found that health development in the West (Sumatra, Java-Bali) has a better tendency than in Eastern Indonesia.8,9

Table 1 informs that toddlers living in urban areas are 0.81 times more likely to be stunted than toddlers living in rural areas. (OR 0.81; 95% CI 0.79-0.84). This means that toddlers living in urban areas were less likely to be stunted. Table 3 also shows that age, both in infants and mothers, proved to be a significant predictor of stunted events in infants.

The analysis shows that urban areas have a lower risk of stunted children. This result is in line with the results of research in several countries which found that people who live in urban areas tend to have better health status. The tendency for better health status in this urban area is found in South Africa and Iran.10,11

In the context of Indonesia, empirically it is known that the Western region has more urban areas than the Eastern region. The condition of urban areas that are more advanced makes those who live in the area have the opportunity and access to better health services than...
those in the Eastern region\textsuperscript{12,13}. This phenomenon is exacerbated by conditions in Eastern Indonesia which also tend to have an archipelago topographic, which makes physical access difficult\textsuperscript{14}.

Table 1 shows that the mother’s characteristics found to be predictors, besides age, are marital status, education, and work status. A toddler who has a married mother is 0.85 times stunted than a toddler who has a divorced/widowed mother (OR 0.85; 95% CI 0.77-0.94). This means toddlers who have married mothers have a lower risk of being stunted.

Table 1 shows that the lower the mother’s education level, the toddler is more likely to be stunted than a toddler who has a college graduate mother. A toddler who has a non-working mother is 1.03 times stunted than a toddler who has a working mother (OR 1.03; 95% CI 1.28-1.39). This means that toddlers who have mothers who do not work are less likely to experience stunted.

The results of the analysis found that some maternal characteristics also contributed to being stunted in infants. Toddlers who have married mothers have a lower risk of being stunted. Married mothers tend to have better mental states\textsuperscript{15} because the mother can share the burden and role with her husband. A better parental process will reduce the risk of fives being stunted\textsuperscript{16}.

The analysis shows that the lower the mother’s education level, the toddler has a greater risk of being stunted. These results are in line with the results of research in Malawi which found that maternal knowledge also became a predictor of undernutrition in infants. Better mother’s knowledge will reduce the risk of undernutrition in infants\textsuperscript{17}. In line with the results of research in Malawi, findings in India also received the same thing. Women’s education can reduce child stunting\textsuperscript{18}.

Toddlers who have mothers who do not work are less likely to experience stunted. Working mothers tend to have less time for their children. Poor parental time is also known to have a negative impact on the nutritional status of children\textsuperscript{19}.

**Conclusions**

Based on the results of the present study, it can be concluded that there was a regional disparity of stunted toddlers in Indonesia. While other variables that were found to influence the stunted toddler were rurality, age of toddler, age of mother, marital status of mother, education level of mother, and work status of mother. The results of this study are important for policymakers to determine the region target of an accelerated intervention program to reduce the prevalence of stunting in children under five appropriately in Indonesia.

Abstract

Influenza virus infections are a major public health threat. Influenza viruses are associated with high mortality and morbidity worldwide through seasonal epidemics. Vaccination programs are available, but unpredictable antigenic changes in circulating strains require annual modification of seasonal influenza vaccines. Influenza vaccines are given, one of which is a trivalent influenza vaccine (TIV) aimed at the formation of antibodies that are specific to influenza viruses by B cells. In this study TIV vaccination has an effect in the form of decreasing viral replication in ferret that have been tested with H1N1 and H3N2 viruses. The results of this study are data about viral replication obtained from hemagglutination tests (HA test) and ATP6V0C expression with SDS-Page.

Keywords: ATP6V0C expression, ferret, TIV vaccination, viral replication

Introduction

Influenza virus infections are a major public health threat. Influenza viruses are associated with high mortality and morbidity worldwide through seasonal epidemics. Recent studies estimate that 290,000–645,000 deaths occur worldwide due to seasonal influenza annually1.

Influenza is an acute respiratory infection caused by influenza viruses that circulate in all parts of the world. Viruses multiply through the process of replication. Measurement of the amount of virus in the body can be done after the incubation period, which is around days 1 to 3 after infection occurs. Viruses can be obtained from several specimens taken from the respiratory tract, which are recommended to detect the virus in patients with respiratory infections, for example from nasal swabs, swabs and nasopharyngeal aspirations, endotracheal swabs, and bronkoalveolar tissue2,3.

Infection starts when a virus enters a cell, the virus uses many cellular functions of the host cell in each stage of its life cycle, so the identification of the function and role of the host cell in virus replication is an important key to understanding the life cycle mechanism of the virus4.

The RNA replication process of influenza viruses occurs in the host cell nucleus, the ribonucleoprotein (RNP) complex of viruses released from the virus must be moved into the nucleus through the nucleus pore5. The transport process triggers the host cell to express the vATPase complex gene, one of which is the ATP6V0C gene. This complex gene is a gene that will encode the vacuolar ATPase component, a component in the vATPase complex that is needed in the process of acidification of intracellular organelles in the RNP transport process into the host cell nucleus6,7. Based on the recommendations of the WHO, the influenza vaccine is currently a trivalent inactivated vaccine (TIV)/trivalent whole virus vaccine made from a live attenuated virus, consisting of A/California/7/2009 (H1N1) pdm09-like virus, A/Switzerland/9715293/2013 (H3N2)-like virus and B/Phuket/3073/2013-like virus8.

Materials and Method

Object of research

Subjects in this study were Ferret, the gold standard laboratory animals in influenza virus infections and aerosol infections compared to other animals, the reasons include the similarity in clinical symptoms if ferrets were infected by influenza viruses with clinical symptoms that occur in humans, there is a distribution of similar receptors in the channel breathing in ferrets and humans and the ability to be infected with human isolates without the need for adaptation. This study used 25 ferrets that were divided into 5 groups, with the treatment of one shot vaccination with different doses.

Research Methods

The administration of intramuscular TIV vaccine in this study used an one shot method with dosage variation of 3.8 µg; 7.5 µg; 15µg; and 30µg. The vaccine and viruses used in this study came from PT. Biofarma. Blood samples were taken at the time of termination which is the 36th day. Whereas nasal wash and oral swab sampling was performed on days 3, 4, 5, 7, 9, and 14 after the challenge test.

Challenge tests using H1N1 and H3N2 viruses in the form of mixed infections. The presence and linkages of ATP6V0C host cell expression and post-vaccination virus replication can be taken into consideration in regard to the effectiveness of various vaccine doses and the vaccine delivery methods that have been given.

Samples used for examination of viral replication by hemagglutination test are samples from nasal wash and oral swab collection, while for the examination of ATP6V0C expression ferret blood serum is used, which is done by SDS-Page (Sodium Dodecyl Sulfate-Polyacrylamide Gel Electrophoresis). The SDS-Page results were followed by reading the expression of ATP6V0C protein using the DocTM EZ Gel (Biorad).

Result and Discussion

All groups showed positive results of viral replication with HA test since day 3 after the challenge test, indicating that the challenge test was successful so that positive HA values were obtained for all groups. This is in accordance with the standard pattern of influenza virus growth in the infected human body, virus titers will experience exponential growth within 2-3 days after the challenge test, then experience an exponential decline until undetectable on days 6 to 8 after the challenge test.

TIV vaccine is expected to be able to increase the production of antibodies, antibodies that are formed are expected to be able to recognize HA proteins from viruses, so they cannot be attached to sialic acid receptors on host cells. Viruses that cannot bind to the host cell receptor are blocked from entering the cell, so they cannot use the replication machine in the host cell to multiply themselves. This mechanism can reduce the number of virus replications detected in the HA test in this study.

One of the virus strains used in the TIV vaccine used in this study was the H1N1 A/California/7/2009 (H1N1) pdm09 virus, this strain corresponds to the
virus used in the challenge test, the A/California/7/2009 (H1N1 virus) pdm09-like virus. The degree of vaccine protection depends on the compatibility of the strain in the vaccine with the circulating virus. The H3N2 virus used in the challenge test is different from the H3N2 virus strain used in the vaccine, but this is expected to cause cross protection so that the antibodies produced are still able to provide protection.

Research conducted by Skowronski and the team in 2014, which carried out a vaccination test with a dose of 30 µg/mL, showed no significant difference in growth of viral titers between groups, and peak viral titer growth on days 1 to 2 then decreased from day to day 3rd after challenge testing. In another study using variations in vaccine dosage and type of vaccine administration through aerosols, it turned out that the results of growth of virus titers did not show significant differences between groups, on the 3rd day after the challenge test.

Normal clinical dose, which usually does not exceed 15 µg HA protein, WIV (Whole Inactivated Virus) induces adequate neutralizing antibody titers, but generally fails to induce any cellular response regardless of the route of administration. Research by Budimir shows that some high doses of WIV, are able to induce significant amounts of CTL (cytotoxic T lymphocyte) specific inactivated viruses in mice. This is in accordance with this study which also uses a vaccine with a dose twice the usual which is 30µg. It is possible that high doses of vaccine in this study could induce CTL thus providing a better protective role, but unfortunately this study did not measure the immune response of host cells. However, from the level of virus replication in the D1 group (dose 30 µg) there was indeed a significant decrease in the average viral replication from day of 3rd to 4th.

The important role of membrane fusion activity and the presence of viral ssRNA for CTL induction are established. This role is also in accordance with this study which suggests the role of ATP6V0C in endosome membrane fusion. Intramuscular administration of WIV has proven to be more effective in inducing CTL compared to intranasal. This was confirmed by Takeda who found that intranasal vaccination with WIV failed to induce T cell responses. This may cause viral replication to be detected several days after the challenge test in almost all vaccinated groups.

It is thought that the WIV inactivation method can have an effect on its immunogenicity. In addition to increasing doses, the cellular response induced by WIV can also be increased by the addition of adjuvants. Similar to studies with WIV, the addition of alum into the virus has been shown to damage cellular responses in mice, because it further increases the tendency for TH responses to TH2.

---

**Fig. 1 Results of SDS-Page serum ferret.** The blue ribbon and the pink line emphasized show protein expression in the area approaching the marker. Note: M: Marker 10-250 kDa; 1-9 serum ferret samples before treatment and after vaccination and challenge test. 1 = A1.3 pre vaccination; 2 = B1.3 pre vaccination; 3 = B1.3 post vaccination; 4 = C1.2 pre vaccination; 5 = C1.3 post vaccination; 6 = D1.2 prev. 7 = D1.2 post vaccination; 8 = E1.2 pre vaccination; 9 = E1.3 post vaccination.
The humoral immune response generated by inactivated virus vaccines currently does not provide adequate cross-protection against inactivated virus vaccines that do not match the type of infecting virus. Specific inactivated virus vaccine T cells must recognize the epitope that they are conserving and therefore must have the potential for cross-protection.\(^{21}\)

ATP6V0C is one of the factors expressed by host cells, which have a role in the process of replicating influenza virus cells. Vaccination is expected to prevent the virus from entering the cell, so ATP6V0C will not be expressed by the group that gets the vaccination but it will be expressed by the control group.

ATP6V0C is a protein with a molecular weight of 16 kDa, with SDS-Page examination its expression can be seen at the bottom approaching the marker region in the 15 kDa region. The ribbon that appears positive in the area is located at well number 9 filled by the control group. The ATP6V0C band was not expressed in all vaccination treatment groups, but was expressed in the control group.

</table>

Table 2 shows that well number 9 containing the control group obtained a ribbon filled in kDa 15.5. This is close to the size of ATP6V0C which is 16 kDa. Whereas in other wells namely the group that got the vaccination, the band that was close to the 15 kDa marker was almost non-existent.

Research conducted by Pavelin et al. proved that ATP6V0C produced almost complete blocks in cytomegalovirus production. This shows that endosome acidification is very important for HCMV replication. Cell viability tests show that the reduction in viral replication is not due to cellular toxicity caused by ATP6V0C knockdown and small transfection of RNA does not induce interferon responses.\(^{22}\)

Targeting ATP6V0C can represent a blocking mechanism in the assembly and release of virions during latent infection. Acidification has been proven to be necessary for efficient signaling by toll endosome residents such as receptors and for efficient class II MHC presentations.\(^{23,24}\) Blocking endosome acidification by targeting ATP6V0C may be an effective way for viruses to interfere with both innate and adaptive immune responses.\(^{27}\)

Another study on flavivirus conducted by Barrows et al. revealed that the endoplasmic reticulum
membrane protein complex facilitated the biogenesis and / or assembly of receptors needed in the plasma or endosomal membrane which had an indirect effect on viral infection, namely the mechanism of virus entry in cells. This shows that ATP6V0C plays an important role in virus replication, so that when ATP6V0C is not expressed due to vaccines, the virus cannot replicate and ultimately the results of virus replication will go down.

**Conclusion**

In this study TIV vaccination has an effect in the form of decreasing viral replication in ferret that have been tested with H1N1 and H3N2 viruses. The results of this study are data about viral replication obtained from hemagglutination tests (HA test) and ATP6V0C expression with SDS-Page.

Changes in Immunological Parameters in Patients Treated Using Direct and Indirect Restorations of the Hard Tissues of the Anterior Teeth in Combination with an Antioxidant

Iryna R. Kumhyr¹, Volodumyr P. Levko¹, Zinovii R. Ozhogan²

¹Associate Professor, ²Professor at the Department of Orthopedic Dentistry, Ivano-Frankivsk National Medical University, 76018, 17 Nezalezhnosti Str., Ivano-Frankivsk, Ukraine

Abstract

The problem of aesthetic restoration of the hard tissue defects in the anterior teeth and the choice of materials for quality restorations, which can include direct composite or indirect ceramic restoration, in particular ceramic veneers, is currently extremely important in clinical dental orthopedics. Currently used composite and ceramic materials are known to have different effects on the conditions of the marginal periodontium and the local immunity in the oral cavity. Therefore, we propose a new approach to treatment, which is the use of indirect ceramic restorations in combination with an antioxidant. The purpose of this article is to increase the effectiveness of treatment in patients with defects in anterior teeth using indirect ceramic restorations with antioxidants. To study the intensity of immune reactivity in patients with existing defects of the coronal part of the anterior teeth, we analyzed the levels of lysozyme and sIgA in the oral fluid. The results of the studies confirm the advantages of indirect ceramic restorations over direct composite ones in the treatment of hard tissue defects in the anterior teeth, taking into account the levels of immunological reactivity and using an antioxidant drug Resveratrol.

Key words: peroxide compounds, bactericidal effects, caries, tooth tissues.

Introduction

With food and air, we consume a significant amount of different types of exogenous bacteria which can cause certain diseases in the body. The first barrier is the surface of the mucous membranes, including the oral cavity. The main specific protective mechanism of these surfaces is the production of lysozyme and secretory sIgA. Protection of the oral mucosa is due to specific and non-specific protective mechanisms. The main factors in the humoral protection of the mucous membranes are sIgA and a number of protein-carbohydrate compounds, which include saliva anti-proteases, lysozyme, lactoferrin and mucus glycoproteins. Antibody deficiency – the main specific immunity factor – is a consequence and integral manifestation of the impaired cellular quantitative composition and their functional characteristics in the process of immunogenesis where the lymphoid and non-lymphoid cells and cytokine regulation play an important part.

The cytokines formed during an inflammatory process damage the tissues of the periodontium and result in the alveolar bone resorption, which is clinically manifested as the symptoms of generalized periodontitis. Therefore, a comprehensive study of the clinical symptoms of periodontal tissue pathology with determination of such local immunity parameters as sIgA and lysozyme levels in the oral fluid seems reasonable.

The immune system, along with the endocrine system, plays a leading role in the relationship between the human body and the environment. This is implemented through nonspecific resistance factors at different stages (barrier – skin, mucous membranes, histogematic barriers; cellular and humoral) and specific immune response (through cooperation among antigen-presenting cells, T and B lymphocytes). The oral cavity shows a wide range of immunological reactions, especially considering constant antigen stimulation by microorganisms. With age and in pathological processes, as well as in cases of various orthopedic and orthodontic structures, immune changes occur, which
are manifested at different levels, first of all, at the level of intercellular interactions.\textsuperscript{7,8,9} The barrier properties of the oral cavity are associated both with the protective mechanisms of the saliva (oral fluid) and structural features of the mucous membranes. The oral fluid has pronounced bactericidal properties. The following factors are the most important: immunoglobulins, lysozyme and other saliva enzymes, leukocytes and leukocyte factors.\textsuperscript{9}

Lysozyme is one of the most important factors in antimicrobial protection in the oral cavity. It shows both antibacterial activity and stimulates immunoglobulin secretion, enhancing their bactericidal activity. There is an association between the amount of lysozyme and immunoglobulins in the oral fluid: in insufficient lysozyme amounts, more immunoglobulins are secreted into the oral cavity. Lysozyme is a necessary component of the local immunity, as in its absence, according to many investigators, the immune response with slgA is impossible.\textsuperscript{6,7,8,9}

The main source of lysozyme in the oral cavity are the salivary glands (80\%) and, to a lesser extent, leukocytes in the oral fluid (20\%). Oral bacteria also produce a part of lysozyme, although their contribution to the total amount of synthesized lysozyme is very small. In the salivary glands, lysozyme is formed in the epithelial cells of the ducts. Total lysozyme activity in the mixed saliva is 4 times higher than its activity in the blood plasma and its secretion increases when salivation is stimulated. Lysozyme activity depends on the acid-base balance in the oral cavity. The optimum activity of lysozyme is observed at pH 5-7. An important stimulus for lysozyme formation and secretion is an increase in microflora in the oral cavity, and vice versa, with a decrease in the number of microorganisms, the amount of lysozyme formed decreases sharply.\textsuperscript{5,6,8,9}

The main class of the immunoglobulins in the oral cavity is IgA. From 50 to 250 mg of IgA are secreted with the saliva, which is 5-10\% of the total amount of Ig of this class. The saliva contains secretory slgA, which consists of two IgA molecules bound to the secretory component (SC). The concentration of immunoglobulins in the saliva does not always correlate with their amount in the blood. IgA enters the oral cavity with the saliva with the highest concentration observed in the secretions of the parotid glands and a 2-fold lower concentration in the saliva of the sublingual and submandibular glands. Secretory IgA has a pronounced bactericidal, antiviral and antitoxic activity. The amount of IgA in the saliva is a factor that determines the occurrence and nature of pathological processes. As for the cariogenic flora, IgA inactivates the enzymatic activity of cariogenic streptococci and reduces the adhesion of microorganisms to the tooth tissues, thus preventing the formation of caries. In addition, slgA prevents the development of inflammatory diseases in the oral mucosa.\textsuperscript{5,7,9}

\textbf{Materials and Method}

Foreign bodies, dental prostheses, are believed to be one of the factors that negatively affect local immunity in the oral cavity. When non-removable precious metal prostheses are used, a rapid normalization of the content of IgA and slgA is observed, which is due to the bactericidal effects of metal ions. The number of microbial antigens in the saliva decreases. This effect is not observed when the prostheses are made of steel or plastic.\textsuperscript{2,5,7,8} Therefore, to determine the effectiveness of treatment with the proposed metal-free dentures, we conducted immunological studies, i.e. lysozyme and IgA levels in the oral and crevicular fluids, during Resverasin administration.

Antioxidants are drugs that can inhibit free radical oxidation processes in the body or eliminate reactive oxygen species and peroxide compounds. During this process, non-toxic products (H2O and CO2) are formed in the body. In dental practice, intensification of free radical oxidation processes is observed in gingivitis, periodontitis, ulcerative stomatitis, and inflammatory processes of the soft tissues and bones.\textsuperscript{8,10,11} The development of free radical lipid peroxidation (LPO) with oxygen can be stopped using the inhibitors that restore free radicals to a stable molecular form that is unable to continue the auto-oxidation chain. LPO inhibition in the body is carried out by an antioxidant system that includes a chain of antioxidants that can inhibit free radicals and a group of enzymes that eliminate reactive oxygen species and peroxide compounds.\textsuperscript{10,12,13,14}

Resveratrol, a phytoalexin, a polyphenolic natural compound that is produced by some plants (grapes, Japanese knotweed, peanut) may become an effective product. Interest in resveratrol increased after an epidemiological study conducted in the 1970s and 1980s, known as the “French paradox.”\textsuperscript{14,15,16} Resveratrol (active substance) has the ability to prolong life, shows powerful antioxidant, anti-inflammatory, cardioprotective, neuroprotective,
antitumor and antidiabetic effects.\textsuperscript{16,17,18,19} Wine extract contains organic acids, polyphenols and minerals such as magnesium, zinc, potassium and manganese. Polyphenols contained in red wine have antioxidant and anti-inflammatory effects, prevent platelet aggregation and improve lipid metabolism. Trace elements contained in wine extract are able to enhance the activity of the body’s antioxidant system via antioxidant enzyme and immune cell catalysis.\textsuperscript{13,14,19}

The initiation of systematic treatment with antioxidants, lutein complexes and vasoactive drugs is able to slow down the progression of dystrophic changes, preserve and improve functions. The use of methyl ethylpyridenol in dental orthopedics for indirect restorations and in studies of immunological parameters shows the effectiveness of this drug, especially in concomitant periodontal tissue diseases.\textsuperscript{16,20,21}

**Results and Discussion**

Thirty six patients, divided into 2 groups, were treated and followed up. The results of the study confirm that indirect ceramic restorations have a number of significant advantages over direct composite restorations. Use of ceramic veneers in combination with Resverasin had positive effects on the immune reactivity in the oral cavity which resulted in a significant increase in the levels of lysozyme and sIgA in the oral fluid, compared to direct light cure polymer restorations. Based on our data immediately after treatment and after 3 and 6 months of follow-up, we can confirm the durability of the structures and a satisfactory aesthetic result, provided the correct assessment of the clinical situation and strict adherence to the stages of veneer production. Therefore, the results obtained justify a significant expansion of the indications for indirect restorations in dental orthopedics.

To study the intensity of immunological reactivity in patients with existing defects of the coronal part of the anterior teeth, we analyzed sIgA and lysozyme levels in the oral fluid. 36 patients were selected for the study and divided into groups as follows: Group 1 – 12 patients aged 18 to 45 years with proposed indirect restorations – ceramic veneers; Group 2-12 patients aged 18 to 45 years with direct restorations performed with Estet X HD light cure polymer materials (Dentsply, USA); and control group – 12 patients aged 18 to 45 years without carious lesions and clinically healthy periodontium.

The method used for the crevicular fluid study is as follows: the area to be examined was carefully cleaned of plaque, isolated with cotton swabs and air-dried. Gum fluid was collected using standard paper pins by immersing them effortlessly in the gingival crevice for 1 minute in the area of the upper and lower incisors. The crevicular fluid was collected prior to treatment, immediately after treatment and 3 and 6 months after treatment.\textsuperscript{9} The analysis of the data obtained in the study groups showed the differences in the parameters and their dependence on the chosen treatment method. As shown in Table 1, the level of lysozyme in the oral fluid increased after treatment, compared to the level before treatment, and was 105.2 + 6.3 μg/mL in Group 1 and 99.4 + 5.2 μg/mL in Group 2 respectively.

<table>
<thead>
<tr>
<th>Table 1. Lysozyme and sIgA levels in the oral fluid in patients with direct and indirect restorations</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Treatment method</strong></td>
</tr>
<tr>
<td><strong>Before treatment</strong></td>
</tr>
<tr>
<td><strong>Veneers (Gr.1)</strong></td>
</tr>
<tr>
<td><strong>Direct restorations (Gr. 2)</strong></td>
</tr>
</tbody>
</table>
Six months later, lysozyme levels in the oral fluid was 91.7 + 6.1 μg/ml in Group 1 following the use of Resverasin and 72.8 + 2.3 μg/ml in Group 2, where treatment was performed using direct restorations, respectively. Changes in immunoglobulins (sIgA) had the following pattern: sIgA level, which was 0.97 + 0.14 g/L in the oral fluid before treatment in Group 1 treated with Resverasin, significantly increased to 1.67 + 0.12 g/L immediately after treatment. In Group 2, the parameters after treatment were as follows: 1.82 + 0.11 g/L in the crevicular fluid and 1.52 + 0.14 g/L in the oral fluid. Three months later, sIgA levels in Group 1 treated with Resverasin were 1.56 + 0.16 in the oral fluid, and after 6 months of follow-up we observed stabilization of the parameters at the level of 1.39 + 0.13 g/L in the oral fluid. Following direct restorations, 3 months after treatment, an increase to 1.42 + 0.15 g/L in the oral fluid was observed, but after 6 months of follow-up, there was a significant decrease in sIgA to 1.12 + 0.11 g/L in the oral fluid, respectively.

Therefore, the analysis of the immune reactivity following the use of direct composite restorations and ceramic veneers in combination with Resverasin for the treatment of patients with hard tissue defects of the anterior teeth showed the superiority of the latter. The use of ceramic veneers for indirect restorations resulted in the increase in lysozyme and sIgA levels in the oral and crevicular fluids immediately after treatment and their stabilization 6 months later, which was not observed after direct light cure polymer restorations.

Conclusions

The study confirms that indirect ceramic restorations have a number of significant advantages over direct composite restorations. Ceramic veneers have no effects on the immune reactivity in the oral cavity and may be a recommended construction of choice in the treatment of the coronal defects in the anterior teeth of carious and non-carious origin. The analysis of immune reactivity in patients with defects in anterior teeth following direct composite restorations and ceramic veneers confirms the advantage of the latter in combination with Resverasin.

The use of ceramic veneers had positive effects on immune reactivity in the oral cavity resulting in a significant increase in the levels of lysozyme to 91.7 + 6.1 μg/ml and sIgA to 1.39 + 0.13 g/L in the oral fluid 6 months after treatment, which was as close as possible to normal, in combination with Resverasin. According to the results of our clinical studies, Resverasin significantly shortens the duration of the adaptation period and increases immune reactivity in the oral cavity, especially in combined pathology, i.e. defects of the hard tissues of the anterior teeth and diseases of periodontal tissues.

Abstract

Objective: Study of morphological changes in the endometrium and fetal membranes during spontaneous abortions in 9-12 weeks of pregnancy to clarify the etiopathogenetic mechanisms.

Materials and methods: Study material was endometrial scrapings with components of fetoplacental tissue obtained after spontaneous abortions (176 cases) in 9-12 weeks of pregnancy, received at the Republican Pathological Bureau from several City Maternity Hospitals of Bishkek (Kyrgyz Republic). The histological sections were stained with hematoxylin and eosin (H&E), and a mixture of acid fuchsin and picric acid. The Periodic acid–Schiff (PAS) reaction was performed.

Results: Of the 176 cases in 80 cases, by the medical reports, pregnant women had concomitant gynecological infectious pathology in the form of chronic endometritis, chronic salpingoophoritis, chlamydia, colpitis, and adnexitis. Histological examination revealed inflammatory changes in the form of deciduitis (24.5% of cases), endometritis (20.5% of cases), villitis (17.3% of cases) in 70% of cases. Pathological changes in the decidual membrane are determined as foci of leukocyte infiltration in 65% of cases, in 30% - foci of necrosis and in 20% - foci of hemorrhage. In 60% of cases, as their combination.

Conclusion: Histological examination of endometrial scrapings and fetal membranes after spontaneous abortions in 9-12 week pregnant women, with a history of infectious inflammatory pathology, revealed the tissue inflammatory changes of varying severity, with the following additional microscopic characteristics: the compact arrangement of endometrial glands, weak vascularization of villus chorion; sclerotic, dystrophic, and necrotic changes with hemorrhages in the endometrium and decidual membrane.

Keywords: Spontaneous abortion, Endometrium, Morphology, Periodic acid–Schiff (PAS) reaction, Fetal membranes.

Introduction

Spontaneous abortions are one of the pressing problems of modern medicine. The number of early abortions varies from 10 to 30% of all pregnancies3 and 80-85% is observed in early pregnancy2. Often, the lack of knowledge and underestimation of the causes of the first spontaneous abortion is the cause of subsequent spontaneous abortions and other gynecological abnormalities. In the development of prevention issues and adequate methods of treating this pathology, along with clinical studies, the study of morphological changes in the endometrium and fetal membranes is essential.
This contributes to a more detailed understanding of the pathogenetic mechanisms of spontaneous abortion at different stages of pregnancy, taking into account etiological factors and concomitant pathology. Although many works exist on the study of various aspects of spontaneous abortion1,4, some questions of the morphological criteria of this pathology at different stages of pregnancy require more detailed clarifications.

**Objective**

Study of morphological changes in the endometrium and fetal membranes during spontaneous abortions in 9-12 weeks of pregnancy to clarify the etiopathogenetic mechanisms.

**Materials and Method**

The Ministry of Health of the Kyrgyz Republic obligates every City Maternity Hospitals to send placental tissues to the Republican Pathological Bureau for mandatory morphological examination. In the present study, study material was endometrial scrapings with components of fetoplacental tissue obtained after spontaneous abortions (176 cases) in 9-12 weeks of pregnancy, received at the Republican Pathological Bureau. Inclusion criteria are confirmed cases of spontaneous abortions between 9-12 weeks of pregnancy and presence of gynecological inflammatory disorder in patient’s previous treatment history. Exclusion criteria are non-confirmed cases of spontaneous abortions (such as induced abortion) and cases of abortions in less than 9 or above 12 weeks of pregnancy. Microscopic examination characterized by the study of histological sections stained with hematoxylin and eosin (H&E), and a mixture of acid fuchsin and picric acid (orange, red, blue colors) used to study the structure of the connective tissue. The Periodic acid–Schiff (PAS) reaction performed to determine neutral and acid mucopolysaccharides. The study area is confined to Bishkek, Kyrgyzstan. The study was conducted for five years (2012-2017).

A histological examination determined the presence and severity of the inflammatory reaction, the severity of angiogenesis, the presence and severity of sclerotic, dystrophic, necrotic, and other changes.

**Results**

The average age of women was 25.7 year-old. Among all the endometrial scrapings examined, we identified 80 cases of spontaneous abortion, where according to the analysis of the medical records, the patients had concomitant gynecological infectious pathology in the form of chronic endometritis, chronic salpingoophoritis, chlamydia, and vaginitis.

The results of histological examination showed that in most of the cases (more than 70%) inflammatory changes were noted with the following rate: deciduitis (24.5% of cases), endometritis (20.5% of cases), villitis (17.3% of cases), and mixed inflammatory changes (37.7% of cases). The mixed inflammatory changes were characterized by a combination of endometritis with deciduitis and villitis. Upon staining with H&E, histologically, changes in the endometrium were characterized as follows: the glands are mainly oval-round in shape, and glands with a sawtooth shape were also found. The lumen of the glands are empty or contains a small amount of homogeneous secretion. There is a slight decrease in the number of endometrial glands - 3-4 in one field of view, which are located compactly. In 30% of cases, partial destruction of these glands is noted. Flattening of the epithelium of these glands is noted in 40% of cases, with nuclei located at the same level. In other cases, the epithelium of the glands is cylindrical with an uneven apical edge. Histological changes in the stroma of the endometrium were characterized by the presence of leukocyte infiltration in 25% of cases (Fig. 1a), in 17% in combination with edema and foci of necrosis expressed to a various extent. In 70% of cases, spiral vessels are determined, which are hyperemic in 86% of cases. In 60–70% of cases, changes in chorionic villi were characterized by their hypovascularization (1 or 2 vessels present). In 30% of cases, stromal edema was noted (Fig. 1b), in 10% - leukocyte infiltration of villi, and in 20% - villous stromal sclerosis. In 50% of cases, varying degree hemorrhages of the intervillous space are noted.
Pathological changes in the decidual membrane are determined as foci of leukocyte infiltration in 65% of cases (Fig. 2A), in 30% - foci of necrosis and in 20% - foci of hemorrhage (Fig. 2B). In 60% of cases, as their combination.

Discussion

In our study, the decidualization of the endometrial stroma is well expressed in almost all cases. Decidual membrane cells have a light cytoplasm with relatively large nuclei. The PAS reaction determined decreased amount of neutral mucopolysaccharides in the epithelium of the endometrial glands.

The most frequent manifestation of mixed inflammatory pathology was the combination of endometritis and deciduitis, less often, there was a combination of endometritis and villitis or a total inflammatory reaction. There is a decrease in the number of endometrial glands with a decrease in the content of neutral mucopolysaccharides in the epithelium.

The objective of our research is to study morphological changes in the endometrium and fetal membranes during spontaneous abortions in 9-12 weeks of pregnancy to clarify the etiopathogenetic
mechanisms. Microscopic examination revealed varying degrees of inflammatory changes in the endometrium and fetal membranes, with the following additional characteristics: the compact arrangement of endometrial glands, sclerotic, dystrophic, and necrotic changes with varying degrees of hemorrhages in the endometrium and decidual membrane.

Although there are many works associated with investigation of different aspects of spontaneous abortions, our study emphasized the morphological aspect of the pathology, describing the morphological changes in endometrial scrapings and fetal membranes.

This study helps to determine the underlying etiopathogenic causes of spontaneous abortions, more specifically the ratio of inflammatory disorders among other causes. Identifying the inflammatory character of the endometrial scrapings can be a strong impact for the development of further prevention issues. Additionally, treatment of the concomitant gynecological infectious pathology during pregnancy may reduce the incidence of spontaneous abortions.

The only limitation of our study is the sample size; further studies with higher samples required to validate our results and receiving precise results are essential. Therefore future research needed using more advanced equipment and methods.

In Conclusion, histological examination of endometrial scrapings and fetal membranes after spontaneous abortions in 9-12 week pregnant women, with a history of infectious inflammatory pathology, revealed the tissue inflammatory changes of varying severity, with the following additional microscopic characteristics: the compact arrangement of endometrial glands, weak vascularization of villus chorion; sclerotic, dystrophic, and necrotic changes with hemorrhages in the endometrium and decidual membrane.

Conflict of Interest: The authors declare no conflict of interest

Source of Funding: This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

The Correlation of Length of Work and Mental Workload with Work Stress at University Lecturers

Kenia Bella Christy1, Noeroel Widajati1
1Department of Occupational Health and Safety, Public Health Faculty, Airlangga University, Surabaya, 2Department of Occupational Health and Safety, Public Health Faculty, Airlangga University Campus C, Mulyorejo Street, Surabaya, 60115

Abstract
The main role of lecturers at Tri Dharma University, namely education, research, and community service. That makes them have certain responsibilities which if it lasts a long time will cause stress. This study aims to determine the correlation between work time and mental workload with work stress on college lecturers in Surabaya. This descriptive study was conducted on 43 active lecturers who teach at a university in Surabaya. The results of this study were analyzed to determine the lecturer’s length of work, the mental workload of lecturers with categories from NASA TLX and their correlation with work stress. The results stated that 22 people had worked for more than 20 years, as many as 25 people had very high mental workloads, and 30 people with mild stress. Most of the lecturers already have a lot of experience and a large number of task demands but are still able to deal with everything well so that work stress does not arise. The correlation value between the length of work and work stress is 0.461, and the correlation value between mental workload and work stress is 0.808. This value states there is no correlation between the length of work and mental workload with work stress. Recommendations are given to universities, lecturers and all those involved in efforts to maintain the atmosphere and work culture to improve comfort for all parties, such as adding green areas in the workspace, providing remuneration for lecturers who excel, and maintaining communication between lecturers.

Keywords: length of work, mental workload, work stress, lecturer.

Introduction
Work stress is a physical and emotional response related to the work, resources, and needs of workers1. All types of work, both related to physical and mental competencies that have the opportunity to cause work stress. The existence of aspirations and dissatisfaction at work can also cause work stress9.

Lecturers are professional educators and scientists with the main task of transforming, developing and disseminating science, technology, and arts through education, research and community service8. Lecturers have three main tasks (Tri Dharma University), namely education, research and also community service as their basis and obligation to carry out their daily activities. The lecturers’ main tasks and the burden of positions on several lecturers causes high work demands that must be completed in accordance with predetermined targets which in turn can cause work stress. There are research results that state that there is a sufficient and direct correlation between workload and work stress4. The length of work is one of the factors characteristic of individuals describing their abilities and experiences in dealing with work problems and can affect the existence of work stress because it provides a different stress response to workers. It has a negative effect if it causes boredom due to monotonous activities, and is positive when it is able to improve its work experience4. Long
working periods and limited work environments can cause boredom and in the end can cause work stress\textsuperscript{10}. There are research results that state that the longer the working period, the lower the perceived stress\textsuperscript{12}. There is also a conclusion that there is no correlation between the length of work with work stress\textsuperscript{2}.

The purpose of this study was to analyze the correlation between the length of work and mental workload with work stress on the lecturers of one of the faculties of a university in Surabaya.

**Material and Method**

This research is a descriptive study to find out the correlation between the length of work and mental workload with work stress on university lecturers in Surabaya. This study uses a workforce analysis approach based on individual data and mental workload using the NASA TLX method. The sample in this study were 43 lecturers with several criteria including active lecturers, were in a healthy condition and were not in the period of consuming certain drugs.

The research design was to collect preliminary data and the number of lecturers. The next step is primary data collection in the form of individual identity, mental workload, and work stress. secondary data needed is a description of the location of the study. This study uses more primary data obtained through questionnaires as research instruments provided to each lecturer. The data collection process takes 3 months.

Data analysis was performed using the Spearman test to find out the correlation between the length of work and mental workload with work stress on university lecturers in Surabaya.

**Findings**

**Lecturer Length of Work Distribution**

Table 1 shows that most of the lecturers are 22 people (51.2% of 43 lecturers) have a service life of >20 years. While other lecturers have varied working periods ranging from <6 years to 20 years. There are 6 people (14%) with a length of work less than 6 years, 3 people (7%) with tenure of 6-10 years, 7 people (16.3%) with tenure of 11-15 years, and 5 people (11.6%) with a service life of 16-20 years. This means that most of the lecturers in one of the universities in Surabaya are senior lecturers who have a lot of relevant experience in their fields.

**Lecturer Mental Workload Distribution**

Table 2 shows that most of the lecturers, 25 people (58.1%) were in the very high workload category, as many as 17 people or around 39.5% with high workloads and 1 person who had rather high workloads. It can be concluded that the workload of university lecturers in Surabaya is dominant in the very high workload category.

**Lecturer Work Stress Distribution**

Based on table 3, it can be concluded that most of the lecturers are 30 people or around 69.8% experience work stress in the mild category, 12 people experience work stress in the moderate category and 1 lecturer experiences severe work stress. It shows that the majority of university lecturers in Surabaya experience mild to moderate work stress.

</tbody>
</table>

Table 4 show that most of the lecturers with a very long length of work have relatively mild levels of work stress. There are lecturers with a working period of >20 years, 16 of whom experience mild work stress and 6 others experience moderate work stress. In addition, there are lecturers with heavy work stress who have worked for 16-20 years. The variation in the level of work stress on lecturers with different lengths of work shows that one of the causes is the adaptability of the lecturer. The value obtained from the statistical test results is 0.461 which is greater than 0.05 (α) concludes that there is no correlation between lengths of work with work stress on lecturers.

The Correlation between Mental Workload and Work Stress

Table 5. Cross Tabulation of Mental Workload and Work Stress of Lecturer at the University in Surabaya in 2019

</tr>
</tbody>
</table>

Table 5 shows that most lecturers or as many as 17 people with very high mental workloads are experiencing mild work stress. Also, there are 12 people with high mental workloads who are experiencing mild work stress and 1 person with a rather high burden also experiences mild stress.

The significant value obtained is 0.808 which means there is no correlation between mental workload with work stress felt by the lecturer. The heavy workload does not always have a high-stress impact on lecturers.

**Discussion**

**Length of Work**

The length of work is individual characteristic that illustrates the length of time the workforce is counted from when it was first entered until now it still works. It is related to experience and understanding because if someone has worked for a long time, the worker will be able to adapt to his work. The length of work will also improve workers’ psychological well-being because they tend to have a mutual need for one another. The positive effect of a long work period if the worker can improve his experience at work, and becomes a negative effect if the length of work can cause boredom to workers. A long work period with a limited work environment will make workers feel bored quickly because of work activities that tend to be monotonous.

The length of work is divided into several categories, namely <6 years, 6-10 years, 11-15 years, 16-20 years, and >20 years. Table 1 shows that most of the lecturers, namely 22 people (51.2% of 43 lecturers) have a working period of >20 years. While other lecturers have varied working periods ranging from less than 6 years to 20 years. This means that most of the lecturers in one of the universities in Surabaya are senior lecturers who have a lot of relevant experience in their fields and have adapted to their work.

**Mental Workload**

Work is a burden for workers that can be a physical, psychological and social burden to meet and satisfy the needs for survival. The workload is the burden experienced by workers due to the work done and has a quite dominant influence on the performance of human resources and can cause negative effects on the safety and health of workers. The weight of the workload can be assessed from the amount of burden with the willingness of time, monotonous activities, fluctuations in workload and demands that overlapping work. Workload analysis uses the NASA TLX to measure mental workload measured in 6 dimensions, including mental demands, physical demands, time demands, performance, business levels, and frustration levels.

Table 2 shows that most of the lecturers (58.1%) are in the very high workload. These results indicate that the mental workload on university lecturers in Surabaya is predominantly in the very high workload. The results of the recapitulation of all scores, the workload of lecturers with high scores are in the dimensions of effort, temporal demand, and own performance. The lowest score is in the physical demand dimension. So, the mental workload on lecturers is more focused on the existence of their business factors in carrying out their main activities within the allotted time and still providing the best performance to make their students become superior human resources and able to compete in the world of work.

**Work Stress**

Work stress occurs because the workload is too much or too little and will disrupt the health of workers both physically and psychologically. Physical health disorders such as headaches, gastrointestinal, etc. While psychological health is mad easily, decreased performance and productivity to cause work accidents. Work stress is measured using a questionnaire that has been submitted for validity and reliability with approval based on effects on individuals including physiological, psychological conditions, changing habits, and changes in conditions in the organization.

Table 3 shows that most of the lecturers, as many as 30 people experienced work stress in the mild category. The overall recapitulation results state that the lowest average score on stress reactions in psychological reactions and the highest average values in organizational relations. This means that the problem of stress in the faculty lot of influence on the psychological reactions such as a decrease in the ability to remember, hard to concentrate, irritability, and less impact on organizational correlations in the workplace.
Correlation between Length of Work and Mental Workload with Work Stress

Older/seniors workers will have the ability and better understanding of their work compared to new/juniors workers because they usually do not have much experience and are still adapting to work so often feel stressed at work and cause stress. As stated earlier, the long work period and the limited working environment lead to worker boredom which can ultimately lead to work stress. Table 5 shows that the majority of lecturers with very long tenure have relatively mild levels of work stress. There are lecturers with a working period of more than 20 years, 16 of whom experience mild work stress.

The significance value of the statistical test that is 0.461 means that there is no correlation between work period with work stress on the lecturer. These results state that both new lecturers and old lecturers have the same opportunity to experience work stress. Other results show that only a small proportion of lecturers with more than 5 years of work experience severe stress because they can adapt to their work. The results of his analysis stated that workers who have not worked long ago are likely to experience work stress because they have to work and learn/adapt many things.

Workload that is too little/too much will cause problems such as boredom, irritability, decreased morale, bad relations between workers, increased mistakes, doubtful at work, decreased ability to remember and so on. Table 6 presents the results of the study which stated that the majority of lecturers as many as 17 people with very high mental workload experienced mild work stress. A small proportion of other lecturers with high to high workloads experience moderate to severe work stress.

The significant value is 0.808, meaning that there is no correlation between mental workload with work stress. So, the weight of the workload does not always have a high-stress impact on lecturers. In contrast to the results of the previous study, some state that there is a strong and unidirectional correlation between mental workloads with work stress which means that the higher the workload the more work stress. The work demands of lecturers in the form of material preparation, conducting research, assisting students in community service activities, and some job assignments. Mismatching physical capacity with so many work demands that can lead to work stress.

Conclusion

The measurement results show that the majority of university lecturers in Surabaya have worked and carried out their profession for more than 20 years, with mental workloads in the very high category and experiencing mild stress. Statistical test results prove that there is no correlation between the length of work and mental workload with work stress experienced by lecturers. So, lecturers with long work periods and high mental workloads do not necessarily experience high work stress. Add green areas in the workspace, provide remuneration for outstanding lecturers, and maintain communication between lecturers to improve work comfort.

Conflicts of Interest: There is no conflict.

Epidemiological Profile of Fatal Poisoning Autopsy Cases Conducted at Gims, Kalaburagi, Karnataka- A Retrospective Study

Khaja Azizuddin Junaidi1, Kashif Ali2
1Tutor, Department of Forensic Medicine, Gulbarga Institute of Medical Sciences, Kalaburagi, Karnataka, 2Senior Resident, Department of Forensic Medicine, Jawaharlal Nehru Medical College, AMU, Aligarh, Uttar Pradesh

Abstract

Background- Pesticide poisoning is a major public health problem worldwide, with thousands of deaths occurring every year, mainly in developing countries. Its usage has been increased in recent past leading its misuse to commit suicide. The aim of this study was to determine the profile of fatal poisoning cases in and around Gulbarga district & to find out its correlates.

Methodology- The present study is a retrospective study of fatal poisoning autopsy cases performed at GIMS, District Hospital, Kalaburagi, Karnataka from January 2018 to December 2018. During this period a total of 647 autopsy cases were conducted of which 85 cases were due to fatal poisoning. Relevant information and subjective data like age, sex, marital status, religion, seasonal variation, type of poison consumed and manner of death have been collected from medicolegal autopsy register, police inquest and treatment history using a predesigned proforma.

Results- A total of 647 cases were autopsied during the year Jan 2018-Dec 2018. Out of 647 cases 85.9% cases were due to unnatural deaths of which 85 cases (13.1%) were due to suspected poisoning. In our study males outnumbered females with 67 cases (78.8%) compared to females with 18 cases (21.2%), maximum number of cases were in the age group between 21-30 years with 36 cases (42.4%). Maximum number of cases were from rural locality with 69 cases (81.2%) & majority of poisoning cases were seen during summer with 42 cases (49.4%). Maximum number of deaths were due to suicide (95.2%) followed by accidental poisoning (4.8%). Majority of poisoning cases were seen in Hindu population (82.3%) and maximum cases were seen in married people (74.1%).

Conclusion- Agrochemical pesticides especially Organophosphorus compounds are responsible for most of the poison related fatalities, which is seen in our present study. Strict legal enforcement in selling and handling of agrochemicals is the need of the hour, and establishment of poison detection centres and early management of poisoning cases at all hospitals, primary health care centres could considerably minimise the morbidity and mortality due to poisoning.

Keywords- Pesticide poisoning, Suicide, Medicolegal autopsies.

Introduction

Poison is a substance that causes damage or injury to the body and endangers one’s life due to its exposure by means of ingestion, inhalation or contact.1 Poisoning is a major public health problem worldwide, with thousands of deaths occurring every year, mainly in the
developing countries. In the last few decades, owing to tremendous advances in the fields of agriculture, medical pharmacology and industrial technologies, there is increase in the incidence of poisoning. Acute poisoning due to accidental and suicidal exposure causes significant mortality and morbidity throughout the world. According to World Health Organization (WHO), globally more than three million of acute poisoning cases with 2,20,000 deaths occur annually. It has been estimated that, in India five to six persons per lakh of population die due to acute poisoning every year.

Organophosphorus (OP) compounds cause most common suicidal deaths in southern, central India. In northern India, Aluminium phosphide causes most deaths. In general, accidental poisoning is more common in young children, whereas suicidal poisoning is more common in young adults. In developed countries, the rate of mortality from poisoning varies from 1 to 2%, while in India the incidence is alarmingly high at 15-30%. The aim of this study is to determine the epidemiological profile of fatal pesticide poisoning in and around Gulbarga district as this part of Karnataka has large agriculture area taking into account demographic data, place of consumption, type of poison involved and the manner of poisoning.

### Material and Method

The present study is a retrospective study of fatal poisoning cases autopsied at the mortuary attached to Gulbarga Institute of medical sciences, Kalaburagi, Karnataka, India from January 2018 to December 2018. Detailed information regarding the circumstances of death was collected from inquest, panchanama, hospital records and medico legal autopsy register. During the study period 647 medico legal autopsies were conducted in the mortuary of district hospital, Kalaburagi of which 85 cases were due to poisoning. Data was compiled and analyzed as per age, sex, marital status, religion, calendar month, residence, & manner of death using a predesigned proforma.

### Results

A total of 647 medico legal autopsies were conducted during the period of 1 year from January 2018 to December 2018. Poisoning cases constituted 85 in number (13.1%). Males outnumbered females with 67 cases (78.8%) compared to females with 18 cases (21.2%). It was observed in the study that the maximum number of cases in both sexes were in the age group between 21-30 years with 36 cases (42.4%) followed by the age group of 31-40 years and 41-50 years [Table 1 & 2].

Discussion

During the study period, a total of 647 cases of medico legal autopsies were performed at District Hospital mortuary, GIMS, Kalaburagi. Out of 647 cases, 85 cases were due to poisoning. The incidence of poisoning in the present study was 13.1%, which is comparable to other studies.10,11,12 Males outnumbered females with 67 cases (78.8%) as compared to females with 18 cases (21.2%) which is similar to studies by Basude et al9, Mrinal Haloi et al13, Srivastava et al.14 This high proportion of poisoning among males might be due to modern life style, cultural patterns in this area, familial, social, psychological and financial problems. These findings are also similar to findings of other studies conducted by Gunnar DG et al15 at Gulbarga which shows that 65.65% of cases were males. According to study of Vinay Shetty16 51.5% of cases were males.

In our study maximum number of fatal poisoning autopsy cases was in the age group between 21-30 years. These findings are in consistency with findings of other authors.10,11,15,16 This age group was the most active one, physically, mentally and socially and therefore more prone to stressful situations in life. In our study commonest manner of poisoning was suicidal with 81 cases (95.2%), followed by 4 cases (4.8%) due to accidental poisoning. Higher suicidal rate was found among males compared to females. The reasons for the suicide in males include lack of employment, poverty, high degree of stress in academic, financial and social sectors. Higher suicidal rate among males than females were similar with other studies done by Sharma et al12 and Dash et al.17

According to this study maximum number of poisoning cases were seen in Hindu population with 70 cases (82.3%) followed by Muslims with 12 cases (14.1%). These findings were in consistence with the findings of Bansude et al.9 This difference is due to majority of Hindu population in our area. Maximum number of poisoning cases were seen in married people with 63 cases (74.1%) mostly due to marital conflicts, extra marital affairs, followed by unmarried with 22 cases (25.9%) which may be due to unemployment, depression and love failure. These findings were in consistence with the findings of Bansude et al.9

In our study we found that Organophosphorus compounds was most common followed carbamates and aluminium phosphide, as organophosphorus pesticides are easily available at a cheap rate in the market. These findings are in consistence with findings by Jesslin et al18 and Jai prakash et al19 except for northern regions of India where Aluminium phosphide is reported as the most commonest type of poison.20 Majority of the organophosphorus pesticides were either easily available at home or purchased from the nearby shops. Maximum number of poisoning cases were reported in summer season with 42 cases (49.4%) followed by rainy season with 25 cases (29.4%). This was similar to the study done by Jesslin et al.18 Water scarcity during summer leads to crop failure and financial loses which indirectly increases the rate of suicide.

Conclusion

Study conducted at Gulbarga Institute of Medical Sciences Kalaburagi, to know the profile of fatal poisoning
autopsy cases during a period of one year from January 2018 to December 2018 comprising a total of 647 medico legal autopsies of which 13.1% cases were due to fatal poisoning. In our study we found that majority of cases were in 3rd decade of life, males outnumbered females, rural residents were more in number, Hindus being majority in number formed bulk of cases. Maximum number of cases were seen in the period between April-June and the most commonest type of pesticide involved was Organophosphorus compounds. Various other socio-economic factors responsible for high incidence of suicidal poisoning need early Government Policies. Agrochemical pesticides especially Organophosphorus compounds are responsible for most of the poison related fatalities, which is seen in our present study. Strict legal enforcement in selling and handling of agrochemicals is the need of the hour, and establishment of poison detection centres and early management of poisoning cases at all hospitals, primary health care centres could considerably minimise the morbidity and mortality due to poisoning. The sale of agrochemicals and other pesticides should be controlled through strict regulations & implemented by the concerned authorities.

Conflict of Interest- None

Assistance in Child Feeding Influences the Nutritional Intake of Stunting Children: *Randomized Control Trial*

Hj. Sukmawati, 1,2 Sirajuddin 2

1 Associate Professor in Nutrition and Dietetics Department of Health Polytechnic of Makassar, Indonesia,
2 Student Doctoral Public Health, Hasanuddin University, Makassar, Indonesia

Abstracts

**Background.** Basic Health Research (BHR) in 2018 noted the prevalence of stunting in Indonesia was still high 30.8%, and around 8.9 million Indonesian children stunted. The Province of South Sulawesi ranks the fourth highest stunting prevalence of all provinces in Indonesia. Nutrition Status Monitoring (NSM) results in the last three years show the percentage of stunting children in South Sulawesi in 2015, 2016 and 2017 was 34.1%, 35.6%, and 34.8%.

**Objective:** This study wants to investigate effect of assistance in child feeding for stunting children to nutrient intake and weight gain.

**Method:** The Randomized Control Trial (RCT). The sample is stunting children aged 2-3 years. There were 30 children (15 as the intervention and 15 as the control group). Study location in the Paccerakang Community Health Center in Makassar City. Statistical analysis used to test hypotheses using Mann-Whitney.

**Results:** an increase in the intake of carbohydrates, protein, vitamin A, z ink higher in the treatment group than the control group (p<0.05).

**Conclusion:** Child feeding assistance significantly influence the nutrition intake of stunting children and also have an effect but not significantly on weight gain of stunting.

**Keywords:** child feeding, food assistance, Nutrient Intake, stunting

Introduction

Stunting is a chronic growth disorder in children due to nutritional deficiencies for a long time, which is based on height index according to HAZ scores index. The Basic Health Research in 2018 noted the prevalence of national stunting was still high 30.8%, meaning that the growth was not maximized suffered by around 8.9 million Indonesian children or one in three Indonesian children and South Sulawesi ranks the fourth highest stunting prevalence of all provinces in Indonesia. in 2015, 2016 and 2017 respectively 34.1%, 35.6%, and 34.8%. The extent and magnitude of stunting under five sufferers in South Sulawesi is a very large impact on the development of human resources in the future. Efforts are needed to prevent the adverse effects of Stunting in infancy, so that its continuation can be prevented both physically and psychosocially.

The Indonesian government is committed to reducing stunting. Medium Term Development Plan National 2015-2019 health sector has targeted a decrease in the number of stunting of children under five years old to 28% in 2019. Specific programs related to improving under-five nutrition are supplementary feeding, provision of nutritional assistance packages such as high-dose Vitamin A supplementation, complementary feeding. In addition, capacity building has been carried out for health workers, implementing activities such as training for nutrition workers, sanitarians, and...
midwives engaged in community health. Funding support from various ministries programs has been carried out in the framework of overcoming and preventing malnutrition and health problems for mothers and children.7,8,9,10

Child feeding is a method that is believed to be able to increase food consumption that meets the child’s nutritional adequacy. The variables are consumption patterns that are influenced by food availability at the family level and food access to the regional level. The ability of the family economically to ensure food availability at the household level is also important to be assessed as an indirect variable related to child development.11,7,12,13

Knowledge and skills of mothers as caregivers of children become important as primary caregivers in the family. The better the mother’s knowledge and skills, the better the quality of her care in child feeding and child health care. Child feeding that is suitable for each stage of growth, is beneficial for children who are stunting to pursue growth retardation.14,15

Method

Design study is Pre Post Test Control Group Design. Data collection was carried out before and after the intervention. Primary data collected were Child Feeding, Child Health Care, Nutrition, Weight (BB), toddler characteristics, and family characteristics. Data on Child Feeding, Child Health Care, obtained from interviews based on questionnaire instruments. BB data was obtained from anthropometric measurements. Prior to the intervention, the Child Feeding and Child Health Care Training was conducted for mothers of children under five. The training was held for 2 days using lecture, discussion and practice methods. The sample of this study was stunting children under the age of 2-3 years in the area of the Public Health Center of Paccerakkang (PHCP) in Makassar City. Based on calculations using sample size formula, j obtained total sample as many as 30 children-where a group of 15 children as a treatment and 15 children as a control group. Respondents are mothers of children under five stunted, and study held April - November 2018.

Results

Subject Characteristics

Sample criteria in this study aged 2-3 years experienced impaired linear growth both short and very short. Determination of the treatment group in the study using simple random sampling. In detail, the characteristics of the sample can be seen in the following table.

<table>

Table 02 shows that there was an increase in carbohydrate, protein, fat, zinc and vitamin A intake in both groups. Significant increasing of intervention than control group for across nutrient intake.

Discussion

The Indonesian Ministry of Social Affairs (2007) explains that mentoring is a process of social relations between facilitators and targets in the form of facilities (facilities) to identify needs and solve problems and encourage the growth of initiatives in the decision making process so that the independence of targets in a sustainable manner can be realized. The responsibility of a mentor when conducting assistance is greatly influenced by the knowledge of the assistant to the function of the implementation of assistance, where, when and for whom the assistance process is carried out.16,17,18,19 The purpose of assistance, the function of assistance is very dependent on the context of the problem being accompanied.

The ability to create behavioral change by assistants in the field becomes a benchmark of success in mentoring. Harmony and the warmth of relationships that establish active participation of assistants to help deal with the problem independently, of course, are inseparable from the emotional ties that have been fostered by assistants and mentors. In this study, the companion is a graduate in applied nutrition who has knowledge in the field of nutrition so that he understands very well about matters relating to feeding children under five who experience stunting. Mother of childrens get maximum assistance about child feeding so that the child’s feeding patterns have improved which is guided by a balanced menu with a sufficient amount in accordance with needs.20,21with a rapid reduction thereafter. We aimed to assess the role of different predictors on stunting reduction over time and across departments, from 2000 to 2012. Methods: We used various secondary data sources to describe time trends of stunting and of possible predictors that included distal to proximal determinants. We determined a ranking of departments by annual change of stunting and of different predictors. To account for variation over time and across departments, we used an ecological hierarchical approach based on a multilevel mixed-effects regression model, considering stunting as the outcome. Our unit of analysis was one department-year. Results: Stunting followed a decreasing trend in all departments, with differing slopes. The reduction pace was higher from 2007-2008 onwards. The departments with the highest annual stunting reduction were Cusco (-2.31%).22

The results of this study explain that child feeding assistance, child health care significantly influence the intake of nutrients (carbohydrates, protein, fat, zinc and vitamin A) stunting toddlers aged 2-3 years. This study is in line with research conducted by Sri Dara Ayu (2008) that the nutrition assistance program increases the mother’s nutritional knowledge, parenting patterns (patterns of child feeding), nutritional status of KEP infants in the 3 months after assistance.

The results of this study are in line with the theory that the mentoring process carried out aims to change risky behavior to be less risky or not risky in this case including behavior in how to feed children. Therefore that need to be considered when a companion conducts an educational intervention to someone in order to change behavior (behavior of feeding children) must go
through several stages, as follows: 1) Providing complete information will be able to increase knowledge. At this stage increased knowledge (awareness). 2) Provision of information that is continuous and more detailed, for example about the existence of several choices that can be considered before deciding to choose the right one for himself (precontemplative). 3) Deciding to choose the right choice for himself, from several options (comptemplative). 4) Make it ready to make its choices (ready to act). 5) They have often /almost implemented safe behavior (action). 6) The phase while still needs to be given support to be able to continue to maintain and carry out safe behavior (support and maintenance). 23,24

The assistance process carried out in this study has increased the knowledge of stunting mothers and toddlers about feeding and child health care in order to increase nutrient intake. After she understands how to feed and how to care for children’s health, then you get the opportunity to choose how to feed children and how to care for children’s health that is good and right. After the mother chooses and believes how to feed the child and how to care for the child’s health is good and right, then the mother will carry out the behavior of feeding and child health care according to the module guidelines. Mother of toddlers need to get support from families, companions and health workers so that they can maintain and carry out child feeding behavior and child health care that is good and right so that it can increase the intake of nutrients, especially carbohydrates, proteins, fats, zinc and vitamin A. Substance intake adequate nutrition both in quality and quantity will improve the growth of children under five years of age especially in stunting.

**Conclusion**

Assistance in child feeding influences the intake of nutrients (carbohydrates, proteins, fats, zinc and Vitamin A) toddler stunting aged 2-3 years.

Determinant of Unmet Need for Family Planning in East Java Province Analysis of 2015 Inter-Census Population Survey Data

Lutfi Agus Salim
Associate Professor in Department Biostatistic and Demography, Faculty of Public Health, Universitas Airlangga, Surabaya, Indonesia

Abstract

One of the government’s efforts to control population growth is the Family Planning (FP) program and one indicator of its performance is unmet need for contraception. Based on 2015 Inter-Census Population Survey Data, East Java is one of the provinces with high unmet need events in Indonesia. Unmet need for contraceptive in East Java is 16.3 percent. This study examines factors that correlate with unmet need in East Java. Chi-square test used to find correlation between independent variables and unmet need. The data used is the 2015 Inter-Census Population Survey Data - East Java Province. The results showed age, area of residence, work status, education, and number of children are related to unmet need events. Interventions that should be undertaken are improving counseling, communication, information and education, fulfilling demand of contraception and making it easier to access family planning.

Keyword: Demographic Characteristics, Unmet Need for Family Planning

Introduction

Unmet need occurs in many countries, especially developing countries. In many developing countries, 105.2 million married women are classified as unmet need, including Indonesia, with 4.4 million women(1). One from ten women of childbearing age in Indonesia who do not want to become pregnant, do not use contraception(2). As a result, many cases of unwanted pregnancy end in abortion. abortion cases in Indonesia are quite high, namely 1,500,000 to 2,000,000 abortions every year(3). sadly, most abortions are performed in an unsafe manner, in an unhealthy environment, and not according to health service standards.

One of the government’s efforts to control population growth is the Family Planning program and one indicator of its performance is the unmet need for contraception. Unmet need is defined as the percentage of women of childbearing age (15-49 years old) who are married who want to spacing or stopping, but do not use contraception(2).

The National Population and Family Planning Board makes unmet need for family planning an indicator of the performance of family planning programs, because the condition for unmet need is a sign that there are couples of childbearing age who want certain types of modern contraception but are not available, so they decide not to use modern contraception. The availability of modern types of contraception is the main key to the successful distribution of contraceptives by the central National Population And Family Planning Board. From contraception providers, they have limitations in providing contraception because of the expiration date in each contraceptive device so that the contraceptive provider cannot make a large amount. In addition, inconsistency of contraceptive users to a type of contraception so that the contraceptive provider cannot predict the need for contraception in the future(3).

The number of family planning needs and uses in Indonesia is quite high. Unmet need trends have increased over the past two decades, namely 17 percent in 1991, 15.3 percent in 1994, 13.6 percent in 1997, 13.2

Lutfi Agus Salim,
E-mail: lutfi.as@fk.unair.ac.id
percent in 2002, 13.1 percent in 2007 and 11.4 percent in 2012. The results of several surveys indicate that lack of knowledge and information about contraceptive methods, health reasons, fear of side effects, low accessibility, rarely having sexual relations, husband or family opposing, customary restrictions, etc. are the causes of women of childbearing age experiencing unmet need\(^4\).

The high case of unmet need will also have an impact on three things: 1) increasing TFR; 2) decrease in the prevalence of family planning; and 3) an increased risk of maternal death because it often causes unintended pregnancies which end in unsafe abortions. The Guttmacher Policy Review report shows that the use of modern contraceptives has reduced many abortion cases in many countries, and will be able to reduce far more abortions if family planning needs are met\(^5\).

Factors that are assumed to contribute to the unmet need are: 1) individual internal factors (social, economic, demographic characteristics); 2) factors related to family planning behavior (family planning knowledge, attitudes towards family planning, family history of family planning use), and 3) factors of family planning services (availability of family planning logistics, ease of accessing family planning services, and family planning staff performance). These conditions can cause maternal and child health problems as well as an increase in the population if efforts are not made immediately to meet the needs of unmet need groups for rational, effective and efficient contraception. Therefore, this study contains information about the description of the condition of unmet need in East Java Province according to socio-demographic characteristics, and the test of the relationship between independent and dependent variables.

**Method**

This research is a cross-sectional study and used 2015 Inter-Census Population Survey Data. Unmarried women and individuals with missing data were excluded from the analysis. After weighed, this study was on 7,534,541 currently married women aged 15-49 years.

According to the definition, a woman is considered as unmet need if she:

1. Married status and still classified as reproductive age (15-49 years)
2. Have physiological and biological abilities to get pregnant
3. Stoping or spacing up to 2 years or more,
4. Not currently using modern or traditional contraceptive methods
5. Pregnant women or newborns from unintended pregnancy or mistimed pregnancy\(^5\).

**Causes of Unmet Need**

Survey research in several developing countries has found that there are a number of reasons that explain why many women want to delay or prevent pregnancy but do not use contraception\(^4\). Some reasons that prevent them from using contraception include:

1. Lack of information and knowledge about contraception;
2. Healthy reasons and fear of side effects;
3. Low accessibility to get quality family planning services (expensive fee, limited resources, far from service facilities);
4. Conflict from individuals, husbands, families, religions, cultural customs; and others, such as rarely having sex, the perceived risk is relatively small to get pregnant.

**Determinants of Unmet Need for Family Planning**

Attitudes toward family planning, social access, access to the type and quality of health services, and access to information have a significant influence on the incidence of unmet need for family planning\(^6\). Husband support also has a relationship with the unmet need for family planning, but there is no relationship between wife’s knowledge and wife’s attitude with the unmet need\(^7\).

Studies in Ethiopia show that unmet need for family planning is influenced by communication between a woman and health workers, women’s age, decisions regarding the number of children, and the type of previous contraception\(^8\). studies in Saudi Arabia show that women who are unmet need are women who are very young and very old, women who have a bad experience of the side effects of using previous contraceptives, women who have certain religious beliefs, and women who are forbidden by their husbands\(^9\).
From some of these studies, determinant factors that influence fertile age couples choose not to use birth control even though they no longer want children are maternal age, maternal employment status, women’s education level, number of children born alive, number of male sex children, and number female child.

Data were analyzed descriptively and using chi-square test for univariate analysis. Statistical analysis were performed using SPSS version 21.0; p < 0.05 indicated statistical significance. There are seven independent variables that are suspected as determinants of unmet need for family planning on married women. The seven variables include: mother’s age, area of residence, maternal work status, women’s education attainment, number of boys born alive, number of girls born alive, and total number of children born alive.

**Result**

Unmet need is the gap between women’s fertility preferences and contraceptive use. This gap is the focus of attention for the government to avoid unwanted pregnancy in the community. The percentage of unmet need will be presented in Figure 1.

![Unmet Need districts/cities in East Java Province](image)

Unmet need for contraceptive in East Java is 16.3 percent. There are 19 districts / cities that have a percentage of unmet need exceeding the percentage of East Java, three of which are three districts / cities that have the lowest CPR, namely District of Bangkalan, District of Sumenep, and City of Blitar. District of Bangkalan was the priority location because the lowest location was using contraception and the highest location was the unmet need, which was 25.5. While the lowest unmet need is District of Probolinggo, which is 7.0.

</table>
Table 1 shows the relationship between mother’s age, area of residence, mother’s education level, mother’s employment status, number of boys born, number of girls born, and total number of children born, with unmet need.

Based on the mother’s age, the cross tabulation results show a unique pattern, namely the older the mother’s age, the greater the percentage of unmet need events, and produces a sig value.<0.001 means that there is a relationship between maternal age and unmet need.

Based on the area of residence and employment status, unmet need is mostly experienced by mothers who live in urban areas and working mothers. This is closely related to the mobility of urban communities. The term city is identified with modern and advanced. Not a few people think that the city is a place to work. The busy work has an impact on the occurrence of unmet need (2).

2015 Inter-Census Population Survey also examined the respondent’s employment status to determine whether differences in urban and rural conditions were caused by work or not. Some of the results of previous studies indicate that the area of residence is closely related to employment status (5).

Women who live in urban areas are less likely to experience unmet need. This can be seen from the percentage of unmet need incidents in urban areas. Easy access to family planning sites and the ease of family planning tools are found, making women living in cities less opportunities for unmet need. Women who work more need contraceptives for spacing or stopping births (6).

Women who work have an impact on income every month. Women who are working have better income. Women who have better income will find it easier to
access information and use family planning, on the other hand, women who have income have the right to manage their income\(^{(13)}\).

Completed education is related to unmet need. It is hoped that the higher the education that is received by the woman, the woman will be better able to understand the physiology of her body, so that the assumptions about when the time of menopause and the ability to get pregnant are known precisely. The data shows that the majority of women who experience unmet need have a low level of education, so even the information available is small. One of them is information about contraception. This increases the chance for them to experience unmet need for family planning\(^{(6,11)}\).

When viewed based on the number of children, unmet need is mostly experienced by mothers who even have more than 2 children. Couples who have many children tend to experience unmet need than couples who have fewer children or do not have children. Couples who already have many children tend not to want more children, but there are other factors such as the choice of kb devices, the availability of tools, and the ease of obtaining kb tools\(^{(14)}\). Couples who already have many children are also more aware to have more children. So they decided to stop having more children\(^{(15)}\). In Indonesia, some residents still believe that if they do not have children of male or female sex, then the family is not yet perfect. This husband and wife has a big dilemma, that they do not want more children with the same sex as those already born, but if they are blessed with children with the opposite sex then they are very happy.

The following are some suggestions that can be used as input for efforts to reduce unmet need cases, especially in east java province.

1. In addition to contraception services, family planning program managers also need to improve the quality of family planning and counseling services for:

   a. Help couples of childbearing age in choosing and using contraception that is rational and suitable to their condition,

   b. Help to reduce women’s fear of contraception by providing clear and accurate information about complaints that are felt in order to fight incorrect beliefs or negative attitudes towards family planning,

   c. Show the target program how to deal with the possible side effects.

2. Increasing access to family planning program targets for adequate contraception and counseling services, for example by increasing the number of cadres, expanding the reach of mobile family planning service units, and the availability of logistical supplies that respondents want. These efforts are expected to:

   a. Accommodate more program target needs for effective and affordable contraceptive services,

   b. Responding to complaints about contraceptive use

**Conclusion**

The Government, in this case National Population And Family Planning Board, must be able to follow the dynamics of community inconsistency choices, as contraceptive users, so that modern contraception can be distributed appropriately, both on target and on time.

Thus, all obstacles for women who do not want to become pregnant to access effective family planning methods in accordance with the conditions themselves and their families can be met. Thus, every pregnancy that occurs is expected to be a pregnancy that is desirable, healthy, and continues with adequate pregnancy care and examination.

Correlation Analysis between Women’s Body Mass Index and Mechanical Low Back Pain

Lydia Handini¹, Andriati¹, Subagyo¹
¹Department of Physical Medicine and Rehabilitation, Dr. Soetomo Teaching Hospital, Faculty of Medicine, Universitas Airlangga, Surabaya 60285, Indonesia

Abstract

Background: Obesity can cause mechanical effects on spine, particularly lumbar spine, thus increased weight will cause spine, tendon and ligament muscle tensions. These problems can change lumbar curve with increased anterior pelvic tilt and hip flexion to maintain normal posture that may eventually cause low back pain. Women may experience weight gain, and it can cause low back pain. However, correlation between increased body mass index and low back pain is still debatable.

Objective: The research aimed to analyze correlation between women’s body mass index and mechanical low back pain.

Method: A total of 12 patients aged 50-60 were the subjects of the research. The subjects’ body mass index, pain scale and lumbosacral axis were measured. The study protocol was approved by the ethics committees of Dr. Soetomo Teaching Hospital (Surabaya, Indonesia). The correlation test was conducted using Pearson’s correlation test (Significant if p<0.05).

Results: The research found no correlation between increased body mass index and low back pain (p = 0.47), while there was a correlation between increased body mass index and lumbosacral axis (p = 0.04). Moreover, there was no correlation between increased lumbosacral axis and low back pain (p = 0.07)

Conclusion: The study found that the more the body mass index increased, the lumbosacral axis also increased, whereas no correlation between body mass index and low back pain.

Keywords: low back pain, obesity, overweight, women.

Introduction

Weight is an expression factor of lifestyle. People with unhealthier lifestyle cannot control their dietary habits and perform their activities, therefore, they will have higher obesity risks. Obesity and overweight are forms of abnormal body mass index that highly correlate with person’s life quality, and it gets worse due to musculoskeletal and systemic impairments. Overweight is a condition of excessive body fat accumulation under skin tissue. Overweight or obesity patients were reported to have medical aid due to low back pain ¹.

Back pain is a clinical syndrome characterized by pain or low spine discomfort and its surrounding. More than 80% of human population have experienced back pain. Although there is a low mortality rate, the morbidity rate due to low back pain shows high value and has a very significant economic effect ². The causes of back pain are multifactorial, such as malignant, aging, infection, musculoskeletal, trauma and psychological processes. A total of 40% of back pain patients have experienced back pain anxiety that will affect the patient’s working ability ³.

Obese women aged 60 or more have a 22% prevalence to experience back pain. A woman will experience weight gain, and it is manifested in increased low back pain due to musculoskeletal changes or body fat that can cause changes in spine’s lumbosacral axis, increased lumbar lordosis and anterior pelvic tilt as well as hip flexion. Some studies found correlations between overweight and low back pain. According to World Health Organization (WHO), an estimated 1 billion people are overweight and 300 million people suffer from obesity. The National Survey conducted in 1996/1997 in capital cities across Indonesia found 8.1% overweight adult male population (≥18 years old; Body mass index (BMI) 22-27 kg/m²) and 6.8% suffered from obesity. Moreover, 10.5% of adult female population suffered from overweight and 13.5% suffered from obesity. The sample group aged 40-49 reached its maximum overweight and obesity at 24.4% and 23% respectively in male population, and 30.4% and 43% in female population. Other risk factors for low back pain are also increased with age, behavior, smoking, lack of activity and heavy work/occupational or psychosocial factors.

The visitation number of new patients with chronic low back pain and abnormal body mass index in Outpatient Medical Rehabilitation Clinic of Dr. Soetomo Teaching Hospital, Surabaya, Indonesia, in the last 3 months (January 2013-Maret 2013) were 1141 patients, consisting of 872 females (76.4%). Therefore, we aimed to analyze correlation between body mass index and mechanical low back pain in women patients at outpatient medical rehabilitation Clinic of Dr. Soetomo Teaching Hospital by assessing plain photo of lumbosacral axis changes in sagittal plane in upright position barefoot.

### Method

The subjects were women patients with back pain and body mass index ≥25 kg/m² who met inclusion criteria at medical rehabilitation unit of Dr. Soetomo Teaching Hospital, Surabaya, Indonesia, in June 2013. The inclusion criteria were women aged 50-60 with back pain, while the exclusion criteria were history of spinal surgery in the last 3 months, kyphosis or scoliosis, ankylosing spondylitis, rheumatoid arthritis or neurologic disease (stroke) and history of delayed spinal surgery. The subjects declared their willingness to become the subject of the study by signing informed consent. The study protocol was approved by the ethics committees of Dr. Soetomo Teaching Hospital (Surabaya, Indonesia).

The research is an observational analytic study with cross sectional, using 12 samples who met the inclusion criteria. The subject characteristics were then recorded that included age, height, weight and body mass index. Each subject was asked to do lumbosacral photography in sagittal plane in upright position barefoot. In addition, each subject was asked to show pain intensity level with visual analog scale. The correlation test was conducted using Pearson’s correlation test using SPSS software (SPSS, Inc., Chicago, IL).

### Results

The subjects were 12 women aged 50-60 with abnormal BMI (>25 kg/m²) and low back pain at outpatient medical rehabilitation clinic of Dr. Soetomo Teaching Hospital, Surabaya Indonesia. We measured subjects’ height, weight, body mass index, lumbosacral axis and Visual analogue scale (VAS) to describe low back pain. The subjects’ demographic characteristics were presented in Table 1. The subjects’ average age was 54.08 (4.00), with minimum and maximum age were 50 and 60 respectively. The subjects’ average height was 153.79 (3.56) cm, with minimum and maximum height were 149 cm and 161 cm respectively. Moreover, the subjects’ average weight was 74.95 (11.32) kg, with minimum and maximum weight were 62 and 93 kg respectively.

### Table 1. Subjects’ demographic characteristics (n = 12)

<table>
<thead>
<tr>

</tr>
</tbody>
</table>
The subjects’ average BMI was 31.52 (3.83) kg/m², with the smallest BMI was 26.4 kg/m² and the biggest was 36.9 kg/m². The subjects’ average lumbosacral axis was 47.16 (4.50) degree, with the lowest and the highest lumbosacral axis were 40 and 54 degree respectively. Moreover, the subjects’ average VAS-described low back pain was 5.08 (1.50), with the smallest and largest VAS values were 3 and 8 respectively.

**Correlation between BMI and low back pain**

The research aimed to obtain correlation data between body mass index and low back pain. The statistical analysis was conducted using SPSS 17 software for Windows with p < 0.05. Pearson’s correlation test showed non-significant correlation between body mass index and low back pain (Table 2), with p = 0.47 (p > 0.05).

**Correlation between body mass index and lumbosacral axis**

Pearson’s correlation test showed significant correlation between body mass index and lumbosacral axis (Table 3), with r = 0.60 and p = 0.04 (p < 0.05). The greater a person’s body mass index, the greater the lumbosacral axis.

**Correlation between lumbosacral axis and low back pain**

Pearson’s correlation test showed a correlation between lumbosacral axis and VAS-described low back pain with p = 0.07 (p > 0.05). All subjects showed non-significant correlation between lumbosacral axis and low back pain (Table 4).

**Discussion**

The research was conducted in 12 patients at
outpatient medical rehabilitation clinic of Dr. Soetomo Teaching Hospital, Surabaya, Indonesia. The eligible subjects were asked to complete informed consent, were interviewed, and the process continued with taking lumbosacral x-ray with upright position barefoot in sagittal plane (at Radiology Unit of Dr. Soetomo Teaching Hospital, Surabaya, Indonesia).

The youngest subject was 50 years old, while the oldest was 60 years old. The subjects’ anthropometry characteristics were height, weight and body mass index. The anthropometry measurement conducted in the study was corresponded to World Health Organization (WHO) criteria, by measuring weight and height. The measurement findings were classified as normal if BMI was 18.5-24.99 kg/m², overweight if BMI was 25.00-29.99 kg/m² and obesity if BMI was >30 kg/m². Figure 5.1 showed 4 overweight subjects with BMI of 25.00-29.99 kg/m², and 8 obese subjects with BMI of >30 kg/m². The prevalence rate of weight gain and low back pain in Italy was 22% in 5724 obese population aged 60.

Obese menopause women aged 51-63 commonly suffered from low back pain (1). Nikolov’s finding suggested that with age, women tended to have weight gain that would cause low back pain due to musculoskeletal changes. Nikolov, in his research, found a correlation between fat accumulation around the stomach and low back pain (1). He suggested that a person had a high risk of having low back pain due to posture changes to maintain upright body position.

Correlation assessment between body mass index and lumbosacral axis

Lumbosacral axis is an axis created by parallel lines in sacrum superior surface and perpendicular axis line. Albert Barnett Ferguson was the first to introduce assessment method using this axis, before he published his study in Journal of Radiology in New York, 1934. The lumbosacral axis above 45 degree is called hyperlordosis, while the axis under 35 degree is called hypolordosis (2). The spinal function evaluation and low back pain assessment used parameters including inclination, lumbar lordosis and lumbosacral axis (14). Weight gain is a world health problem. An overweight or obese person has increased spine burden, discus and other spinal structures. Thus, such heavy loads can lead to a decrease in torso’s joint movement, weak abdominal muscles due to fat accumulation, and lumbosacral axis changes (2). Previous research found a correlation between increased lumbosacral axis and body mass index in female subjects with obesity, osteoarthritis and osteoporosis (15).

From a total of 12 subjects, 33.3% of which suffered from overweight, while 66% of which suffered from obesity. These findings were consistent with the previous studies that showed significant correlations between increased body mass index and lumbosacral axis (p = 0.04). These data showed that the greater the body mass index, the greater the lumbosacral axis degree.

Correlation between lumbosacral axis and low back pain

Lumbosacral is a vital area for spinal mobility and has a function to sustain a person’s weight. The mechanical impairment occurred in the area will cause low back pain, although there are many factors that may affect a person’s lumbosacral axis including age, sex, race, genetic, body mass index, physical activity,
trauma and spinal disease. The present study found no correlation between lumbosacral axis and low back pain \( p = 0.07 \).

This finding was consistent with studies conducted before in chronic low back pain patients, in which they found no correlation between low back pain and increased lumbosacral axis (14). After evaluating radiographic results of lumbar stability and lumbosacral axis based on x-ray screening, it found no lumbosacral axis nor sacral inclusion increment. The results of statistical analysis showed a weak correlation between lumbar stability and lumbosacral axis.

**Conclusion**

The research found no correlation between increased body mass index and increased low back pain as well as increased lumbosacral axis. Moreover, there was no correlation between increased lumbosacral axis and increased low back pain.

**Ethical Clearance:** The study protocol was approved by the Ethical Commission to conduct basic science/clinical research in Dr. Soetomo General Hospital Surabaya, Indonesia. The present study was carried out in accordance with the research principles. This study implemented the basic principle ethics of respect, beneficence, non-maleficence, and justice.

**Conflict of Interest:** The author reports no conflict of interest of this work.

**Source of Funding:** This study is done with individual funding.

Analysis of Health Utilization Services in Worship Place

M L I Ansori1, Aryo Dwipo Kusumo2, D.Y Tandy1, Windhu Purnomo3

1Graduate Student of Policy and Health Administration Department, Faculty of Public Health, Universitas Airlangga, 2Department of Dental Public Health, Faculty of Dental Medicine, Universitas Airlangga, 3Department of Biostatistics and Population, Faculty of Public Health, Universitas Airlangga

Abstract

Background. Good health services will greatly affect health improvement and treatment. One of the health service facilities is the mosque health service. The number of visits to mosque health services from 2016-2018 decreased by 49.1%. Purpose. This study aims to determine the factors that influence the worshipers of the mosque in the utilization of mosque health services in Surabaya Ittihad mosque. Method. This study design used descriptive method with cross sectional research design. Population and samples were the entire worshipers of the Ittihad mosque. The number of samples 123 respondents with sampling techniques conducted by means of purposive sampling. Data was collected by interview using a questionnaire. Data analysis used Chi Square test. Results. This study shows that the sex of mosque worshipers (p = 0.604), age (p = 0.617), education (p = 0.690), occupation (p = 0.243), knowledge about mosque health services (p = 0.999), mosque health service Tariff (p = 0.645), and access to information (p = <0.001). Conclusion. It can be concluded that the factors that influence the utilization of mosque health services are access to information provided by the mosque and mosque health services.

Keywords: Health Services, Access to Information, Utilization.

Introduction

Service is any activity or benefit offered by one party to another party, essentially intangible, and not result in ownership of something1. The basic concept of a service or the quality of a product can be defined as fulfilment that can exceed what customers want or expect (patients). The quality of a service is defined as an overall rating that is equivalent to the attitude of all customer satisfaction factors2. The quality of service obtained is a comparison between expectations and services obtained from suppliers3,4. Thus, if the expectations desired by customers are greater than the performance obtained, customer dissatisfaction will arise5.

Republic of Indonesia Presidential Regulation No. 12 of 2013 concerning health insurance states that health facilities are health service facilities that are used to complete individual health care efforts both promotive, preventive, curative6, and rehabilitative performed by the government, regional government, and / or the community7. Good health services will greatly affect health improvement and treatment8.

The mosque is a place of worship for Muslims. Besides its main function being a place to worship Allah, there are other functions of the mosque; social function, education function, and economic function9. Thus, many mosques create health service centres in order to facilitate mosque worshipers who need health checks. One example of Ittihad Mosque is located on Jl Medokan Semampir K / 1, Sukolilo, Surabaya, East Java.

Ittihad Mosque makes mosque health services with the aim of providing health facilities for mosque worshipers and residents around the mosque. The mosque health service performs health service activities which include promotion (information and education about
degenerative diseases\textsuperscript{10} and curative (examination and treatment\textsuperscript{11}). Types of treatment services provided at mosque health services are general services. The number of patient visits in mosque health services was 1,231 patients in 2016, there was a decrease in visits to 1,023 patients in 2017, and it decreased again to 740 patients in 2018 as well as it can also be seen that the visit of mosque health service patients at Ittihad Mosque tended to decrease by 491 visits patients or 49.1%. Based on these data, this study aims to find out the Factors that Influence Mosque Congregations in Utilizing Mosque Health Services in Ittihad Surabaya Mosque, it is hoped that this study can be used as input and evaluation thus the utilization of mosque health services can be increased.

**Material and Method**

This study was an analytical observational study using quantitative research methods. This quantitative research was a cross sectional design study because the measurement of variables was performed at the same time. Data collection on variables was conducted by using a structured questionnaire with a total of 19 questions in this study. The variables were respondent’s gender, respondent’s age, respondent’s education, whether the respondent’s job was working or not, respondent’s knowledge about mosque health services, the attitude of medical and non-medical staff in mosque health services, support from the closest relatives in using mosque health services, Tariffis on services mosque health and access to information provided from mosque health services. Respondents in this study were 123 people selected based on purposive sampling\textsuperscript{12}. Further data were analysed by using the chi square test to see the relationship between dependent and dependent variables.

**Results**

Based on the characteristics of the respondents in this study, it can be seen that the majority of respondents in the study were 82 women (66.7%) with the most respondents aged over 40 years, such as 88 people (71.5%), the highest level of education was high school, and below as many as 109 (88.6%), and the highest level of work was 66 respondents working (53.7%).

</table>

It can also be seen that most of the mosque’s health services were used as many as 73 respondents (59.3%), as many as 122 respondents (99.2%) have good knowledge about health services the mosque. The attitude of health care workers and social support from the immediate family to use the mosque’s health services included in the good category as many as 123 respondents (100%). Tariff was included in the category 119 respondents were cheap (96.7%), while access to information about mosque health services was not good as many as 67 respondents (54.5%).

The results of the chi-square test analysis as in table 1 showed that gender (p = 0.604), age (p = 0.617), education (p = 0.690), employment (p = 0.243), knowledge about mosque health services (p = 0.999), the attitude of medical personnel, and social support (p = -). Tariff (p = 0.645) was not significantly related to the utilization of mosque health services (p-value > 0.005) while access to information (p = <0.001) was significantly related with the utilization of mosque health services (p-value <0.05).

**Discussion**

Gender and age are among the factors in the utilization of health services as expressed by the Department of Education and Welfare, USA\(^\text{13}\). Female respondents use more mosque health services than men. This study is in accordance with conducted by Supariani (2013) which concluded that there is no meaningful relationship between sex, the use of dental, and oral health services\(^\text{14}\) and contrary to research conducted by Admas (2017) which concludes that there is a sex relationship with the utilization of health services\(^\text{15}\).

Age below 40 years old is more use of mosque health services than age above 40 years old. Age is a variable that is always considered in studies and one of the things that affects knowledge\(^\text{16}\). This study is not in accordance with Pourreza’s study (2009) which concluded that age influences the utilization of health services\(^\text{17}\) and this study also does not fit Yunita’s study (2017) which concludes that there is a relationship between age and the utilization of adolescent reproductive health services in Jayapura City\(^\text{18}\).

This study found that the education factor has no relationship with the utilization of mosque health services. This study was not appropriate conducted by Afolabi (2010) which concluded that in Nigeria, higher education would increase access to ARV12 therapy. However, appropriate study conducted by Kipgen J (2011) concluded that education had no significant relationship with access to health services\(^\text{19}\).

This study is consistent with what was conducted by Amir (2017). There is no employment relationship with the utilization of health services targeted by the healthy Tabalong guarantee program in Tabalong Regency, South Kalimantan\(^\text{20}\). However, this study is not in accordance with what was conducted by Burhan (2013) who concluded that work influences the utilization of health services by women infected with HIV / AIDS\(^\text{21}\).
Good respondent’s knowledge about mosque health services utilizes mosque health services more than respondents’ knowledge which is not good. In this study knowledge does not affect the utilization of mosque health services. This study is not in accordance with study conducted by Fennelly K (2004) which concludes that limited knowledge affects utilization and study by Asih P (2017) which concludes that knowledge has a relationship with health service utilization.

The results also found that the attitude factor of medical personnel made respondents use the mosque’s health services. This study is different from that conducted by Asih P (2017) who concludes that good attitude influences students in the utilization of health services and reinforced by Citra (2016) which concludes that there is a significant relationship between the attitudes of health workers and the utilization of health services.

Social support from family and closest relative serves respondents more to use the mosque’s health services than not to use them. This study differs from what was conducted by Margaret (1995) who concludes that there was a significant relationship between social support for the utilization of health services and also by Nara A (2014) who concludes that family support was significantly related to the utilization of adequate childbirth facilities at Kawangu Health Center.

Tariff is the price in the value of money that must be paid by consumers to obtain or consume a commodity that is goods or services that are in the hospital and known as service facilities and services. It was found that respondents who said tariff is not cheap made respondents use the health services of the mosque in this study. The results of this study are consistent with Mills’s (1990) opinion that one of the factors influencing the demand for health services is the willingness to pay. This study concludes that there is no relationship between Tariff and utilization of mosque health services. This is not in accordance with study conducted by Obiechina (2013), regarding the factors that influence students in the utilization of health services at the University of Oklahoma Nigeria influenced by cost factors.

Access to information is significantly related to the utilization of mosque health services in this study. This is consistent with study conducted by Ogundele (2014) which concludes that there is a relationship between information accessibility to health service utilization and accordingly also by Tey’s study (2013) which shows that media exposure correlates with health service utilization in South Asia and Sub-Africa-Sahara and also in accordance with study conducted by Asih P (2017) which concludes that the ease of information has a relationship with the utilization of health services.

Lack of information received by respondents due to publication or promotion about mosque health services is still low. Marketing efforts that are more innovative and following current trends will attract public interest, through electronic media, print media, and public relations activities such as cooperation and events. Dissemination of information can also be done by providing clear information from service providers to patients so as to increase patient expectations regarding the utilization of health services.

Conclusion

The results of this study indicates that only access to information is related to the utilization of mosque health services. Hence, for mosque health services must pay attention to access information, thus more and more are utilizing mosque health services as is the case through electronic or print media, publication, and promotion not only in mosque health services but also in mosques.

Criminalization toward LGBT Community and its Implementation through the Aceh Qanun in Indonesia

M. Hamdan¹, Eva Syahfitri Nasution¹
¹Lecturer at Faculty of Law, Universitas Sumatera Utara, Medan, Indonesia

Abstract

This paper discussed some Criminal Laws on LGBT community regulated in the Criminal Code and in special legal provisions outside the Criminal Code. It also discussed criminalization toward LGBT people through the Aceh Perda, regulated in the Aceh Qanun and its implementation through the Banda Aceh Sharia Court. In the criminal law stipulated in the Indonesian Criminal Code today and in the legal provisions outside the Penal Code, some of the illegal acts committed by LGBT people are liable to imprisonment. The criminal law stipulated in the Aceh Qanun cleanly regulates the acts of lesbian and gay people as the ones which are strictly prohibited and liable to being punished. Therefore, based on this Aceh Qanun, their acts are considered as criminal acts. Aceh Qanun (which is considered as the Aceh Perda or Government Regulation), has criminalized the acts of LGBT people. In Aceh, committing sexual intercourse of gays and lesbians has been formulated in Article 63 and Article 64 of the Aceh Qanun No. 6/2014. The violation against these Articles has been implemented on the perpetrators who are punished with ‘uqubat’ or whipped 85 times before public as it is found in the Banda Aceh Sharia Court’s Verdict No. 19/JN/2017/Ms.Bna on May 17, 2017.

Keywords: criminalization, LGBT, aceh, qanun, indonesia

Introduction

In Indonesia, criminalization toward LGBT (the acronym of Lesbian, Gay, Bisexual, and Transgender) community is still in pros and cons even though some of their acts have been regulated in the Indonesian Penal Code which originally came from Dutch Criminal Law (Wetboek van Strafrecht). The term, LGBT has been used since the 1990s. Lesbian is the term for a homosexual woman who is led to her sexual orientation with other women or a homosexual woman who loves other women physically, sexually, emotionally, or spiritually. Gay is the term for a man who is led to his sexual orientation with other men or a man who loves other men physically, sexually, emotionally, or spiritually. Discussion on LGBT has been done from various points of view. Several researches reveal that sexual orientation is the enabling factor of discrimination for employment and vocational training.¹ The content analysis shows that trans-individuals experience physical, sexual, and emotional violence, in addition to experiencing discrimination in employment, housing, and healthcare.² Even though some companies do not care about homosexual marriage.³ Besides that, there is another writer who writes about the need for an approach viewed from security point of view toward the LGBT.⁴ In New Delhi, India, the government has decided that the act of LGBT is not a criminal act. In fact, in July, 2009, the Delhi Court ruled that consensual same-sex relations between adults in private could not be criminalized.⁵

This research analyzed two problems. First, it was concerned with law/legal provisions in Indonesia which regulate the criminalization toward LGBT people (not discriminative) in which it was regulated in the Criminal Code (in effect throughout Indonesia), and secondly, it was in specific regulations which were found in the Aceh Qanun (it was specifically in effect in Aceh Province). Therefore, this writing was related to the acts of LGBT people although it was not related to LGBT as individuals or their rights in politics, economic affairs (occupation), etc. Therefore, it was not discriminative toward LGBT as a group of people. It was focused on the regulations on their bizarre sexual behavior.
Regulation on the Acts of LGBT People in the Indonesian Criminal Law

Indonesia as a Unitary State and a Republic consists of several provinces which are divided into districts/towns. One of the provinces is Aceh Province that has the authority to make laws which are based on the Islamic Law as it is stipulated in Law No. 44/1999 and Law No. 11/2006.

In general, the provision on illegal acts (criminal acts) in Indonesia is regulated in the Criminal Code which comes from Dutch Government. Besides that, some criminal acts are specifically regulated outside the Criminal Code as a Special Law which partially regulates certain criminal acts. LGBT is not specifically regulated in the Criminal Code and in the other Special Laws. However, some acts which are related to LGBT (even though they are not indirectly related to it) are regulated in Article 281, Article 292, and Article 293 of the Criminal Code. Besides that, it is also regulated in the Law on Pornography (Article 4 of Law No. 44/2008), Law on Child Protection (Article 76E in conjunction with Article 82 of Law No. 35/2014).

Criminalizing LGBT People Based on the Aceh Qanun

Aceh Province as one of Aceh Special Regions which has been given the authority to regulate and make its Regional Regulation, based on the Islamic Sharia Law, has regulated the case of LGBT specifically in the Aceh Qanun No. 6/2014 on Jinayat Law (law on criminal matters).

The regulation which is regulated specifically in this Qanun is on Lesbians and Gays. Therefore, Aceh has done the process of criminalization toward LGBT people (especially toward Lesbians and Gays), a process to determine an act which has been originally not a criminal act is made and formulated as a criminal act. It is included in the criminal policy as it is pointed out as the science of crime prevention. This criminal policy is through some stages or processes (three stages): formulation policy stage, application policy stage, execution policy stage. In the formulation stage which occurs in the stage of a certain act is determined or formulated in the legal provisions by legislative institution (Law Maker Institution); it is a criminal act which is liable to be punished. The application stage is the stage of law enforcement by judicative institution (Law Enforcement Institution) on any violations against what has been formulated in the previous legal provisions (in the formulation stage). Therefore, when there is an act which has been formulated in law, its perpetrator will be tried to be determined his sentence through the court’s trial. In the execution stage is a stage where the verdict which has been handed down by the court will be executed by the executive institution according to what is read in the court’s verdict.

Formulation Stage in the Acts of LGBT People in the Qanun

The Qanun is actually the regulation in the level of Perda (Regional Regulation) which is in effect only in Aceh Province. The regulation in this Qanun is based on Law No. 11/2006 on The Law on the Governing of Aceh (henceforth abbreviated as LoGA) as it is stipulated in Article 1 of the LoGA. This Qanun cannot be equalized with the Regional Regulations of the other provinces or districts/towns in Indonesia. Therefore, equalizing the Qanun with the other government regulations in the other provinces in Indonesia is basically inaccurate. Qanun constitutes a legal provisions or legislation which content has to be based on the Islamic Sharia and is in effect only in the Special Region of Aceh Province which is, of course, different from the other regions which Regional Regulations are not always based on the Islamic Sharia.

Therefore, Qanun is not the same as Perda because its content has to be based on the Islamic principle or it must not be contrary to the Islamic Sharia. In the case of the hierarchy of laws in Indonesia, according to Law No. 12/2011 on the establishment of legislation, the position of Qanun is equalized with Perda in the other regions.

In the explanation of Article 7, letter f, it is stated that the types of provincial regulations include Qanun which is in effect in Aceh Province, Perdasus (Special Regional Regulations), and Perdasi (Provincial Regulations) in Papua Province and Papua Barat Province.

The position of Qanun is recognized in the hierarchy of the Indonesian legislation and is equalized with Perda. Understanding Law No. 12/2011 on the establishment of this legislation can be accepted in the case of the position of Qanun. This understanding will make easier for the Central Government to supervise and foster Regional Governments, especially those which are related to the establishment of regional policies. Nevertheless, we have to pay attention to the specificity given by the Central Government to Aceh. For example, based on the
specificity given by the Central Government to the Aceh Provincial Government, the House of Representatives of Aceh can validate Qanun on Jinayat or the Islamic Criminal Justice as law of procedure in the Sharia Court. Nevertheless, the Aceh Provincial Government has to fulfill the requirements for the product of Qanun as it is embodied in Chapter XVII of the Islamic Sharia and Its Implementation which is regulated in Article 125 of Law No. 11/2006 on Aceh Provincial Government.

The application stage is the upholding of law by judicative institution to apply legal provisions toward perpetrators who commit criminal acts according to the formulation of the law. One of the examples of the implementation of Qanun No. 6/2014 is the act of homosexual as it is stipulated in Article 63 of the Aceh Qanun No. 6/2014. The act of a gay in the Qanun is called Liwath committed by MT and MH on March 28, 2017 (the indictment was done separately). MT was charged by the prosecutor of having committed Jarimah Liwath as it was stipulated in Article 63, paragraph (1) in conjunction with Article 1, figure 28 of Aceh Qanun No. 6/2014. He was punished with caning sentence with 80 (eighty) times of whipping, reduced by the period of detention. The Judge of the Sharia Court handed down caning sentence of 85 times of whipping reduced by the period of detention as it was handed down in the Banda Aceh Sharia Court’s Verdict No. 19/JN/2017/Ms.Bna on May 17, 2017.

The Banda Aceh Sharia Court’s Verdict No. 19/JN/2017 on May 17, 2017 was executed by the executioner (as the executor) on May 23, 2017, witnessed by about 1,000 people. It took place in the yard of Lamgugob Mosque, Syiah Kuala Subdistrict, Banda Aceh. The execution was done by the executioner with 83 times of caning sentence. The punishment was reduced two times or equal to 2 months of detention which was in accordance with the Judge’s verdict.

**Conclusion**

It is obvious that the Aceh Qanun which becomes the Special Regional Regulation in Aceh Province has clearly stated that the acts of Lesbians and Gays are considered as criminal acts. Therefore, there is criminalization toward the acts of LGBT people in Aceh, based on the Qanun No. 6/2014. Some provisions of the Qanun have been implemented based on the Banda Aceh Sharia Court’s Verdict and have been executed with caning sentences in 83 times whipping.

Counseling Intervention to Reduce Violence and Promote the Psychosocial Well-Being of Women Who Experience Domestic Violence

Maha Mowafy, Dina Shorkry, Heba El Nahas, Asmaa Sayed, Arwa El Shafei

Abstract

Introduction: This study aims to review married women with domestic violence and detecting the effectiveness of counseling intervention on the reduction of intimate partner violence (IPV).

Methods: Phase one of this study was a cross-sectional in which 315 married women living in Al-Badrashin, a slum area in Giza-Egypt, were included and invited to participate in the study and screened for IPV, social support, and psychological status; phase two was an interventional phase in which all abused women detected in phase one invited to participate in the interventional counseling program.

Results: The study revealed that the overall prevalence of IPV among the studied group was (37.7%); the highest form (54.0%) was psychological abuse, followed by physical (52%) one then severe combined abuse including sexual abuse items (48.6%). However; less than one fourth (22.2%) were exposed to harassment. Also revealed the presence of high significant p-value (0.000) reductions in all forms of violence following the intervention program.

Conclusions: Counseling intervention had a positive effect on participants, demonstrating a decrease in violence exposure, improvement of social support and psychological status.

Keywords: Intimate partner violence, Effectiveness, Group counseling intervention, Married women victims.

Introduction

IPV is a very serious social phenomenon. It disturbs all aspects of human life. Its occurrence is increasing rapidly around the world. Inappropriately, many wives blame themselves for IPV due to the male-dominated culture. IPV violates human rights and has always been associated with some physical and mental health problems.

Corresponding author:
Asmaa Ahmed Sayed
AlBadrasheen, Giza, Egypt
E-mail: asmaa.sayed@residents.kasralainy.edu.eg
Assistant lecturer at Family Medicine department, Cairo University

In Egypt IPV is a violation of social and religious values though, fortunately where report on this issue has turned to an issue of community belief instead of being a stigma.

Dealing with the harm imposed by IPV is not an easy task. Most of the intervention studies on IPV victims were performed in domestic violence shelters. However, women living in continuous abuse are similarly need receiving support. IP intervention programs offer counseling which typically includes aiding survivors improve the sense of power and control.
Method

The Study design:

The study had two phases:

1. Cross-sectional descriptive phase in which 315 married women living in a Al-Badrashin (slum area) in Giza were invited to participate in the study and screened for IPV, social support and psychological disorders.

2. Interventional phase in which abused women detected in phase one had involved in the interventional counseling program.

The setting of the study:

This study was conducted in a governmental health center for maternal and child care in a slum area (Al-Badrashin) in Giza-Egypt.

The population of study:

The target populations were any married female, aged above 18 years old, visit Al-Badrashin Health Center for Maternal and Child Care.

Sample size determination:

A number of 315 married women were required to achieve the study objectives (according to the Epi Info 6).

Sampling procedure:

Systematic random sampling technique where every third client aged above 18 years old and met the inclusion criteria of the study were selected and invited to participate in the study.

Inclusion criteria:

- Women aged 18 years or above.
- Married female regardless duration of the marriage.
- Women live with their husbands.

Exclusion criteria:

- A widow or divorced women.
- Women find difficulties in providing informed consent or understanding the content of the study.
- Had experience of trauma unrelated to their abuse within the last year.

Women with serious mental illness.

participants were identified to be abused by their intimate partner, had a total score of 7 or more of the Composite Abuse Scale (CAS), were invited to participate in a group counseling program for IPV victims. Only 21 women were dropped out all through the sessions; meanwhile, the rest of the participants (98) continued until the end of the last session. They were divided into five groups offering each participant suitable days and group to join and attend. Each group consisted of about 20 participants.

The program was implemented over a period of three months. A total of six counseling education sessions took place at weeks (0, 2, 4, 6, 8, and 10), on a biweekly basis for each group and each session lasted two hours. Group members did actively participated in the sessions with a full chance to speak and present themselves.

The counselor started the first session by introducing herself and the objectives of the sessions. Then the pre-test was distributed among participants. For the following sessions, the counselor start with a summary of what occurred in the previous one, followed by the specific subject of the current session, and, at the end of each session, the participants were asked to discuss about the learned outcomes from the session. These sessions included non-judgmental listening, discussion of needs and providing integrated information on IPV.

The Intervention (counseling program for IPV victims as a part of (Spousal Abuse Counseling Program)) was applied for the abused women and aimed to improve the wellbeing of abused women, helping them for rehabilitation and protecting them against continued violence.

Data collection tools: Six tools were used:

1. The participant’s demographic profile sheet: it was used for collecting participant personal data and medical history.

2. The updated Socio-economic status (SES) scale

3. Valid Arabic version of the multidimensional scale of perceived social support (MSPSS)

4. The valid Arabic version of The CAS: Women
were asked to rate how often they experienced abuse in the past 12 months. A 29 abusive forms presented in a six-point format.\textsuperscript{13}

5. The General Health Questionnaire (GHQ-12)\textsuperscript{14} comprises 12 items describing mood.

6. The Arabic version of the Mental Health Checklists of the International Classification of Diseases10 Primary Care (ICD10 PC) version\textsuperscript{15}.

\textbf{Data Analysis}

All analyses were conducted using SPSS version 21 and statistical significance was set at $p \leq 0.05$. Paired sample t-tests were conducted to assess the effect of the overall intervention program.

\textbf{Results}

The mean age of the studied participants was 35.4 ± 9.3 years old; while the mean years of marriage were 13 ± 8.5 years. More than one-third (37\%) of the studied women had experienced exposure to IPV according to the composite abuse scale.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{fig1.png}
\caption{Prevalence of different types of abuse in the studied participants}
\end{figure}

Figure (1) reveals that 119 (37.7\%) of the studied women had experienced exposure to IPV.

\begin{table}[h]
\centering
\begin{tabular}{|c|c|c|c|c|c|c|}
\hline
Total score of CAS Age groups & N Total (315) & Mean & SD & 95\% Confidence Interval for Mean & P value \\
\hline
18-24 & 35 & 23.2 & 22.5 & 15.5 & 30.9 & 0.007* \\
25-29 & 45 & 15.9 & 15.9 & 11.1 & 20.7 & \\
30-34 & 79 & 11.5 & 17.9 & 7.5 & 15.5 & \\
35-39 & 49 & 10.8 & 17.4 & 5.8 & 15.8 & \\
40-44 & 50 & 12.9 & 18.8 & 7.6 & 18.3 & \\
45-49 & 25 & 5.0 & 8.2 & 1.6 & 8.4 & \\
50-55 & 30 & 14.4 & 22.8 & 5.9 & 22.9 & \\
\hline
\end{tabular}
\end{table}

As shown in table (1) young women (<25 years) are more exposed to IPV. It also demonstrates that there is a significant statistical difference between different age groups of participants and violence exposure.

</table>
Table (3) reveals the presence of high significant statistical reductions in all forms of violence following the intervention program (p-value: 0.000). The overall percent of abused women decreased to 68% post-intervention.

**Discussion**

Overall 119 (37.7%) of the studied women had experienced exposure to IPV. The prevalence of violence was less than that of Egypt Demographic Health Survey, 2005 (45.0%), and more than the report of the MOHP/Egypt that stated that 26% of married women aged 15-49 years revealed exposure to IPV at least once in their lifetime; while 14% of the same age group suffered IPV in the last 12 months.

The relationship between educational level and exposure to IPV experience matched the WHO multi-country study on women’s health and domestic violence amongst others which stated that achieving a secondary school education or higher protected against IPV experience. It can be explained that educated women are more aware of information needed for healthier marital life compared to women with lower or no educational level. Secondary education or higher may help women to have a reasonable decision during selecting her partner or not to continue in a violent relationship, and to marry men with matching their levels of education. Furthermore, higher educated women are more valued by their partner and have improved partner communication.

Moreover, the findings demonstrated that SES level is positively associated with violence. Higher SES is mainly protective, supporting theories stating that poverty impacts negatively on levels of IPV.

As regards the psychological status, the results demonstrated that the prevalence of depression in all studied participants was 20%. From the abused women 93% were depressed, Meanwhile; only 7% of the non-abused women were exposed to depression. Also, it presented a significant statistical relationship between depression and exposure to all forms of violence. These findings came consistent with Fanslow & Robinson 2004 who stated that many women exposed to IPV had depression.

Regarding anxiety, The results demonstrated that the prevalence of anxiety in all studied participants was about 83%. From the abused women 31% had anxiety disorder. These results agreed with several studies reporting the presence of an association between exposure to IPV and anxiety.

The percent of abused women decreased to 68% post-intervention denoting effectiveness of the intervention in the reduction of violence exposure. This echo the finding of McBride 2001 whose study targeted 23 female victims of IPV in Canada and evaluated the effectiveness of an 8-week group intervention program, on their cognitive-behavioral.

The women in this study reported an increase in levels of perceived social support after receiving the intervention program. These results matched with Iverson et al., 2009, who reported an increase in perception of social support, after receiving the intervention program, especially in the social support perceived from friends. The intervention created effective outcomes, as other studies had already reported. These findings proof that the intervention met the needs of female victims of IPV, improving their psychosocial well-being.

**Conclusion**

The overall prevalence of IPV was relatively high, it was more prevalent among the young, non-educated and low socioeconomic status. There is a significant relationship between IPV and partners’ levels of education. IPV negatively affects women psychological health. The performed counseling program was found to significantly reduce women exposure to violence, women’s psychological symptoms and improved levels of perceived social support throughout the intervention period.

**Strengths and limitations of the study**

It is the first study conducted in Egypt for assessment of the effectiveness of brief counseling intervention on the reduction of IPV and Promotion of the psychosocial well-being of women who experience IPV. Also, the ability to change the abused women from negative tool to a positive one is a great benefit of the study. However, the program was too lengthy to be applied completely; so the applicable core contents, which suit our culture, were extracted and applied. Invitation of the husband caused a high percentage of women to drop out during the pilot study; so we applied the victim’s group sessions only, ensuring women compliance and safety.

**Recommendations:**
Join the husband to the intervention counseling programs.

Provide follow-up assessments during a period of 12 months to increase the intervention effectiveness.

**Funding:** This research did not receive any fund from public funding agencies, commercial, or nonprofit sectors.

**Ethical Considerations:** This study was approved from the Scientific Research Ethical Committee of the Faculty of Medicine, Cairo University. The approval number is N-122-2018. Informed consent was obtained from each participant before they were enrolled in the study.

Abstract

Objectives: To study the prevalence of osteopenia and osteoporosis (OP) among residents of the Kyrgyz Republic in 3 different age categories (18-39 years, 40-59 years, and 60-79 years), give a comparative assessment of the prevalence of osteopenia and OP depending on gender and based on the results, make proposals for the identification and diagnosis of osteopenia and OP in the Kyrgyz Republic.

Materials and Methods: An Ultrasound bone densitometry (USBD) studied the Bone mineral density (BMD) in a total of 1200 people with 691 women and 509 men of 3 different age categories (18-39 years, 40-59 years, 60-79 years).

Results: In the first group from 18-39 years, normal values found in 55.6% of people, osteopenia in 38.9% of people and OP in 5.5% of people. In the second group, from 40-59 years old, normal values found in 30.9% people, osteopenia in 60.2% people and OP in 8.9% people. Moreover, in the third group, from 60-79 years, normal values were found in 9.5%, osteopenia is seen in 50.2% and OP in 40.3% of older people.

Conclusion: Osteopenia and OP are quite common not only in the older age but even affect people of a younger age. The frequency of detection of osteopenia and OP is the highest recorded in older age groups. Women mostly exposed to OP that has pronounced degrees of BMD affection.

Keywords: Bone mineral density, Ultrasound bone densitometer, Ultrasound bone densitometry Osteopenia, Osteoporosis.

Introduction

Osteoporosis (OP) is a systemic disease of the skeleton, in which bone strength decreases, which leads to an increased risk of fractures¹. Osteoporosis is characterized by a low bone mineral density (BMD) and microarchitectural changes in bones, leading to increased bone fragility². When fractures occur because of OP, the quality of life decreased³. The World Health Organization (WHO) has proposed bone mineral density (BMD) measurements for diagnosing osteoporosis⁴. OP is three times more common in women than men⁵,⁶. WHO experts attributed OP to one of the most common diseases, which, along with myocardial infarction, cancer and sudden death, occupies a leading place in the structure of morbidity and mortality⁷,⁸.

OP is an health burden in both developed and developing countries⁹. According to the International
Fund for Osteoporosis, every three seconds in the world, there is one fracture caused by OP. A modern strategy for organizing care for patients with OP is an early diagnosis with identification of a high risk of fractures and the early appointment of pathogenetic treatment.

The problem of OP in the Kyrgyz Republic remains unsolved and not studied at all. Being in most cases an asymptomatic disease that cannot suspect in the absence of fractures, OP often remains undiagnosed. There are no unified approaches to prevention and treatment, due to the lack of the necessary medical equipment, and there are misconceptions on various aspects of diagnosis.

**Aim:** To perform ultrasound bone densitometry (USBD) in 3 different age categories of people (18-39 years, 40-59 years, and 60-79 years), to identify and study the prevalence of osteopenia and OP.

**Objectives:** To study the prevalence of osteopenia and OP among residents of the Kyrgyz Republic in 3 different age categories (18-39 years, 40-59 years, and 60-79 years), to give a comparative assessment of the prevalence of osteopenia and OP depending on gender and based on the results, make proposals for the identification and diagnosis of osteopenia and OP in the Kyrgyz Republic.

**Materials and Method**

The study was conducted by the Rheumatology Faculty of the Department of Hospital Internal medicine, Occupational Pathology with a Course of Hematology, based in the City Clinical Hospital No. 1, Bishkek, Kyrgyz republic. Ethical clearance taken from Committee on Bioethics, I.K. Akhunbaev Kyrgyz State Medical Academy. The survey included 1200 people, residents of the Kyrgyz republic. Of these, 691 women and 509 men of different age groups (Table 1).

**Table 1. Characteristics of the examined people**

As can be seen from the table 1, the first group consisted of people aged 18-39 years, and the average age was 28.1 ± 1.93 years, the ratio of women to men was 1.1: 1.0. The second group includes people aged 40-59 years, and the average age is 51.2 ± 2.47 years, the ratio of women to men is 1.3: 1.0. Moreover, the third group consisted of older people aged 60-79 years, and the average age was 76.8 ± 2.81 years; the ratio of women to men 1.6: 1.0.

For screening, our study used the SONOST-3000 portable ultrasound bone densitometer, which measures bone mineral density (BMD). This study conducted among university students, medical staff and residents of Bishkek (Chuy region), Karakol (Issyk-Kul region) and Naryn (Naryn region). Senior age groups also recruited among the wards of Bishkek and Nizhne-Serafimovsky social inpatient facilities for the older people and people with disabilities (Chuy region, Kyrgyz Republic).

**Statistical Analysis**

Statistical data analysis and mathematical processing carried out using the Microsoft Excel program, the Statistica Excel application software package, and the Statistica 8.0 application software package. Parametric and nonparametric analysis methods, descriptive statistics with the calculation of the median, 25% and 75% quartiles used. Mutual influence of indicators is determined by, Spearman’s correlation analysis was
used (to determine the relationship between qualitative and quantitative indicators, the Spearman’s correlation coefficient) and Pearson (to determine the mutual influence between the quantitative indicators). Mann-Whitney criteria used to assess the significance of differences between groups. Differences were considered statistically significant at an error level of $p < 0.05$.

**Results**

In our study, the diagnosis of OP carried out based on a decrease in BMD detected by ultrasound bone densitometer, and the following classification used to interpret the results.

USBD in the first group from 18-39 years showed (Table 2) that, in 291 individuals, the T and Z scores were within normal limits to -1.0. In 204 people, the T and Z scores ranged from -1.1 to -2.5, and in 29 people, the T score was 2.9, and the Z score was 3.2. Thus, in the first age group, normal values were found in 55.6% of people, osteopenia in 38.9% of people, and OP in 5.5% of people.

<table>

</tr>
</tbody>
</table>

Note:
* - $p <0.05$ - differences are statistically significant compared with the indicators of the first group
** - $p <0.05$ - differences are statistically significant compared with the first and second groups

The second age group included people from 40-59 years old. In this study group of 121 people, indicators of the T and Z scores were within normal limits to -1.0. In 235 people, the T and Z scores ranged from -1.1 to -2.5. For the remaining 35 people, the T and Z scores were below -2.5. In this study group, normal values found in 30.9% of people, osteopenia in 60.2% of people and OP in 8.9% of people, which is significantly higher than in the first group of the study (Table 2). This shows that, with ageing, osteopenia worsens and the number of people with OP increases.

In the third age group from 60-79 years, as can be seen from table 3, in 27 people the indicators of the level of T and Z scores were within normal limits to -1.0; 143 people had T and Z scores ranging from -1.1 to -2.5, and 115 people had T and Z scores below -2.5. Thus, the USBD detected osteopenia in 50.2% and OP in 40.3% of the older age group. Normal values found in 27 (9.5%) people. Moreover, the normal values of USBD found regardless of the increase in age.

We also analyzed the data of USBD depending on gender (Figure 1). So, out of 691 women, normal values of BMD were in 253 (36.6%) women, osteopenia observed in 331 (47.9%) and OP in 107 (15.5%) of them. Of the 509 men, bone mineral density indicators were normal in 241 (47.3%) people, osteopenia diagnosed in 203 (39.9%) of them, and OP in 65 (12.8%) people.
As can be seen from the figure, the results obtained indicate that the prevalence of osteopenic syndrome and OP in our study is significantly higher in women ($p < 0.05$) than in men.

**Discussion**

Our primary objective was to study the prevalence of osteopenia and OP among residents of the Kyrgyz Republic in 3 different age categories (18-39 years, 40-59 years, and 60-79 years). By USBD, the frequency of detection of osteopenia and OP is the highest recorded in older age groups. At the age of 40-59 years (II group), osteopenia detected in 60.2%, OP in 8.9%, and in the III group of 60-79 years, osteopenia detected in 50.2%, OP in 40.3%.

Our secondary objective was to give a comparative assessment of the prevalence of osteopenia and OP depending on gender. Osteopenia in women was 47.9%, and in men, it was 39.9%; OP in women was 15.5% and in men was 12.8%. By this study, it’s clear that women majorly effected to OP that has pronounced degrees of BMD affection. This type of studies conducted by the Kazakh Academy of Nutrition and S.D. Asfendiyarov Kazakh National Medical University in 2011 (The prevalence of osteoporosis among the population of older age groups according to sonographic screening studies in the Republic of Kazakhstan), but their results differ from our data. So, in their study, both women and men are equally affected by a decrease in the mineral density of bone tissue, whereas in our case, significantly higher numbers in women. The severity of osteopenia in the work of Kazakh colleagues amounted to 74.4%, of which OP was 22.2%, in our study, this indicator is significantly lower.

Our studies clearly showed that with ageing, the situation of osteopenia and OP only worsens. At the same time, osteopenia and OP are quite common not only in the older age, regardless of age, they also affect people of a younger age. In real life, we faced with the fact that often not only society itself, but also the medical community accepts osteopenia and OP as an age-related disease, the lot of older people, and this is the most profound error and mistake that only relaxes vigilance.

The advantages of study are we included all age groups for study, included people from many regions, received good results which may pave the way for future studies. Only one limitation of our study is the sample size; further studies with higher samples required to validate our results and receiving precise results are essential.

**Conclusion**

1. According to USBD, the frequency of detection of osteopenia and OP is the highest recorded in older
age groups. At the age of 40-59, osteopenia detected in 60.2%, OP in 8.9%, and in the age group of >60 years, osteopenia detected in 50.2%, OP in 40.3%.

2. Women most exposed to OP that has pronounced degrees of BMD affection. So, osteopenia in women was 47.9%, on the contrary, in men - 39.9%; OP in women was 15.5%, while in men it was 12.8%.

3. It is necessary to develop and approve a detailed plan and strategy for the prevention of osteopenia and OP acceptable for use by regions of the Kyrgyz Republic, taking into account the study of specific disease risk factors.

Abstract

The objective is to study the epidemiological characteristics and assess the system for establishing a disability in the Kyrgyz Republic.

In establishing disability, a biomedical model of health is used, which does not provide an objective assessment of a person’s condition. This study analyzes data on the disability situation in the Kyrgyz Republic, which indicates a steady annual increase in the disability rate. For children under 18 years of age, the establishment of disability and assignment of the category “disabled child” is biased, since only the state of health and dysfunction of the child’s functional abilities are assessed and, despite the difference in the severity of the condition, the possibility of work capacity and the ability to participate in education is not evaluated.

Key words: Disability, Person with disabilities, Situation on disability, Medical and social expertise, Kyrgyz Republic.

Introduction

Disability is a social phenomenon that no society can avoid, and each state, following its level of development, priorities and opportunities, forms a social and economic policy for people with disabilities¹. Disability is the most crucial indicator of public health and has not only medical but also socio-economic importance. According to the UN, the level of disability in the world is 10%, that is, every tenth inhabitant of the planet is disabled². According to the data published in the “K-News” news feed, in the Kyrgyz Republic, there are currently about 180 thousand disabled people, which makes up 2.8% of the population³.

The problem of disability has enormous socio-medical and economic consequences, due to the withdrawal of a significant part of citizens from the sphere of social manufacture and the considerable state expenditures for organizing social protection of disabled people, provision with medical care, maintaining appropriate social institutions, carrying out activities aimed at the rehabilitation of disabled people⁴.

For many developing countries of the world, the issue of the policy of establishing disability has recently been relevant in the schedule of social policy since the establishment of disability is closely related to the costs of social protection: payments, benefits, services, etc.
Currently, the world standard for disability use WHO-recommended classifications, countries are working to improve disability methods, special needs and the relationship of compensation for needs with services and benefits.

In the Kyrgyz Republic, the old methodology for determining disability is still used. However, it should be noted that since 2013 the country has stepped on the path of reforming the medical and social examination service. In this connection, at this stage, we studied the general situation in a certain number of people with disabilities among adults and children. We also showed the methodology for establishing a disability in our country.

Objective: To study the epidemiological characteristics and assess the system for describing disability in the Kyrgyz Republic.

Materials and Method

The methodology of this study includes an annual analysis of the situation regarding the establishment of disability in the Kyrgyz Republic (Official data of the Republican Center for Medical and Social Expertise under the Ministry of Labor and Social Development of the Kyrgyz Republic).

For the analysis, we studied the reports of government agencies, materials from open sources, information from international and non-governmental organizations, official statistics, and publications on the Internet.

Results and Discussion

According to the National Statistics Committee, in 2019, 6,320,723 residents lived in the Kyrgyz Republic (KR), of which about 168,200 are people with disabilities (PWD), which makes up 2.8% of the total population. The total population of the Kyrgyz Republic is growing annually. So compared to 2000, when their number was 4,898,000 inhabitants, in 2018, the population increased by 1.2 times, and at the end of the year amounted to 6,294,587. With an increase in the number of people, there is an increase in the number of people with disabilities.

So, since 2000, the number of people with disabilities has been steadily growing (Figure 1). If in 2000, PWD totalled 87,314 people, then in 2004, their number exceeded 100,000 people, and in 2005 their number was 106,688 people. As can be seen from the figure, a sharp increase in the number of PWDs has been observed since 2010, when their number amounted to 133,398 people, and compared to 2000, and it increased by 1.5 times. The maximum growth occurred in 2010-2013 when the annual growth amounted to 8500, 9072 and 7218 people, respectively.

Figure 1. Dynamical change in the number of persons with disabilities in the Kyrgyz Republic.
As in previous years, cardiovascular diseases, traumatic injuries of varying localizations, diseases of the sensory organs, diseases of the musculoskeletal system, neoplastic disorders, mental illnesses, tuberculosis and diseases of the nervous system ranked the leading positions in the structure of disability in 2019 (Table 1). All other diseases are classified as miscellaneous nosological forms in Table 1.

Table 1. Disability distribution by nosological forms.

Note: p <0.05 - differences are statistically significant compared to 2016

Under state regulations, depending on the degree of body functioning and social life disruption, citizens of the Kyrgyz Republic are assigned I, II and III disability groups; children under 18 years old assigned the category of “disabled child.”

As for the examination of children, it should be noted that until 2002 the analysis was carried out by the treatment and prevention organizations of the Ministry of Health of the Kyrgyz Republic at the place of registration of the child. Since 2003, the examination transferred to the medical and social examination service under the Ministry of Social Development of the Kyrgyz Republic. An analysis of the situation showed that an annual increase in disability also observed in the category of children from 2000 to 2018 (Figure 2). Moreover, the increase in the number of children with disabilities varies significantly from 135 to 1235 cases per year.
Disability determination for children under 18 years: In the Kyrgyz Republic, all inter-district medical and social expert commissions (MSEC) conduct a mixed reception of children and adults. For children under 18 years of age, when determining disability, the state of health and impairment of functions are evaluated and, despite the difference in the severity of the condition, the category “disabled child” is established. When establishing a disability for children, the opportunities for activity and the ability to participate, special educational needs are not evaluated.

For the assessment of the child’s condition to be more objective, in different countries of the world and the European Union, the levels of ailment are set for children when setting the levels of ailment, WHO recommends that children under 18 years of age should be divided into four groups by age (from birth to 3 years; from 4 to 7 years; from 8 to 14 years; from 15 to 18 years). In the Kyrgyz Republic, WHO recommendations have not been implemented yet.

Disability determination for adults of working age and retirement age: In the Kyrgyz Republic, adults (from 18 years old) are assigned I, II and III disability groups. For people of working age and older people, the disability is determined by a biomedical health model and ICD-10 coding, without separating them by age groups. The identification of disability groups is closely related to benefits, payments, services and other assistance. This methodology for determining disability does not reflect the ability to objectively assess the state of a person of working age, as his ability to perform existing skilled work, acquire new qualifications, or present work that does not require professional skills, as well as other special assistance measures, are not evaluated.

When establishing a disability group in the Kyrgyz Republic, an individual rehabilitation plan should be developed according to regulatory enactments. This provision is declarative since, in practice, medical experts do not have the competence and knowledge to draw up such a program, and the poorly developed links of medical, social and professional rehabilitation do not contribute to this.

In the Kyrgyz Republic, for people with disabilities of working age and people with disabilities of retirement age, the establishment of disability groups does not reflect the situation of an objective assessment of the opportunities and particular needs of people of different ages and the active organization of the necessary rehabilitation, social and financial support.
For PWDs of working age, it is first of all essential to establish the level of working capacity (after all possible treatment and medical rehabilitation measures have been used), and with what rehabilitation measures - vocational and social, you can return PWDs to the labour market.

For people with disabilities of retirement age, the level of work capacity is not relevant. PWD of all age groups has special needs, the satisfaction of which would enable them to live with maximum independence and support in their natural living environment. Such special needs are met, taking into account the economic situation in each country.

Currently, the World Health Organization (WHO) recommends three main international classifications for assessing health status:

1. ICD – 10 - the international statistical classification of diseases and disorders, the tenth revised and supplemented edition (International Classification of Diseases (ICD));

2. ICF - International Classification of Functioning, Disability and Health;

3. ICHI - International Classification of Health Interventions.

The only changes in health, procedures and interventions (interventions) directly classified by ICD-10. The structural basis of this classification based on the etiology, methods and interventions.

ICF – is structured based on a biopsychosocial model of health, in which the restriction of activity and participation is the result of exposure to environmental factors and personality traits. ICF is a standardized language with a unified coding system for health and related conditions.

Both classifications (ICD - 10 and ICF) are recommended for simultaneous use by WHO. Thus, a description of health and related conditions would be complex.

The use of ICF coding in determining disability provides much more detailed and accurate information about human health and its functionality than the use of only ICD-10 coding. ICF essentially defines the state of a person, and not just a disease, as when using ICD-10.

ICD-10 is complete and sufficient for diagnosing diseases, treating patients, but for rehabilitation and other solutions, such as establishing disability, this is not enough. ICF is ideal to describe a person’s condition after treatment.

Guided by the ICF, attitudes towards human diseases and disabilities are changing. The ICF not only helps physicians in physical medicine and rehabilitation cope with disability issues but also requires the public to take responsibility for accepting people with disabilities in society. The ICF, is closely related to human health and health determining factors, helps to choose a profession that is compatible with a health condition and adapt the workplace to a particular PWD while searching for opportunities to integrate PWD into the labour market.

Many countries around the world have begun to use the ICF directly in establishing disability. The United Nations (UN) has adopted the ICF as one of the social classifications and applies it in the fields of insurance, social security, labour, education, economics, and social policy. Countries are actively analyzing ICF and are working on using it, assessing human health, working ability, and disability. Based on the ICF, tools have been created for the general assessment of disability.

In 2011, WHO presented a world disability analysis report prepared following the ICF Convention on the Rights of People with Disabilities. This report provides recommendations to all countries to assess disability using the ICF and the main directions for implementing this classification.

Analyzing the methodology for establishing a disability in the Kyrgyz Republic, a biomedical model of health is used when assessing a person’s condition, when health is determined by medical criteria and is focused on the patient’s body. A physician with specific knowledge of the body is the only expert, and the diagnosis becomes the primary criterion for determining the condition of a person. The biomedical model emphasizes the medical knowledge of the body, ignores the influence of psychological factors on human health and turns social problems into a body problem that essentially remains unsolvable.

In the world, the biomedical model of health is changing the biopsychosocial model, which provides an entirely different concept when health is assessed as the biological, psychological and social well-being of a person. Disability is defined as a long-term deterioration
in health due to disorders of the body structure or functions and the interaction of adverse environmental factors, reduced opportunities for participation in public life and activities. A person with disabilities experiences functional impairment and the influence of the social environment. A person is affected by his social environment, and he becomes the central axis in the health care system and social protection. That is when using the biopsychosocial model of health, and the assessment becomes more objective and comprehensive.

Taking into account the trends in the establishment of disability in the world and comparing the situation of establishing a disability in the Kyrgyz Republic, we must state that in the Kyrgyz Republic the methods of determining disability do not yet comply with international standards and cannot again provide an objective assessment of the state of a person.

**Conclusion**

1. In the Kyrgyz Republic, there is a gradual annual increase in the number of persons with disabilities.

2. In establishing disability, a biomedical health model is used that does not provide an objective assessment of a person’s condition, where a person’s situation is evaluated only by medical diagnosis and the impact of the social environment is not assessed.

3. For children under 18 years of age, the establishment of disability and assignment of the category “disabled child” is biased, since only the state of health and dysfunction of the child’s functional abilities are assessed and, despite the difference in the severity of the condition, the possibility of activity and the ability to participate in education is not evaluated.

4. The Kyrgyz Republic needs the introduction and widespread use of the international classification of functioning in establishing disability.

Akhunbaev Kyrgyz State Medical Academy, Bishkek, Kyrgyz Republic.

Abstract

The objective is to assess the state and prospects of development of the gerontological service and to study the level of the demographic situation in the Kyrgyz Republic.

We studied Legislative, regulatory and legal documents and materials from open sources have studied since 1991. Using the example of Bishkek and Nizhne-Serafimovsk social stationary facilities, the state of health was analyzed, and 442 patients examined. Successes in the development of the gerontology: the Kyrgyz Republic became a member of the AgeNet International gerontological network (2005), the law “On Senior Citizens in the Kyrgyz Republic” (2011) was adopted, and an Action Plan to improve the quality of life of older citizens at 2019-2025. A high frequency of comorbidity revealed: 241 (56.4%) of the wards had from 1 to 3 diseases, 185 (43.3%) from 4 to 6 diseases and in 128 (29.9%) of the departments, seven or more diseases registered. The country needs to create a single coordinating body for gerontological and geriatric services, which will be responsible for its work and development.

Key words: Gerontology, Geriatrics, Old age, Social stationary institution, Kyrgyz Republic.

Introduction

Ageing of the population is one of the relevant problems of modern society. At present, negative medical, demographic processes observed, characterized by an increase in the number of people of older age groups in the general population structure of most countries, including Kyrgyzstan1,2.

According to the UN, the proportion of older people over the age of 65 exceeded 9%, by 2025 there will be more than 800 million people over 65 years old in the world, which will be about 10% of the population, and by 2050 this percentage can reach 16%3,4.

With age, the proportion of acute diseases decreases, and the number of various chronic diseases increases4. The risk of situations that require not only the provision of medical, social and rehabilitation assistance but also outside care increases5.

For Kyrgyzstan, the increase in the proportion of older people is a new phenomenon. Among the many consequences of this phenomenon, there is a need for various types of medical and social assistance. According to studies of the National Statistical Committee of the Kyrgyz Republic6, the older population suffers from multiple severe chronic diseases that occur in conditions of reduced compensatory capabilities of the body. Up to 80% of older people need medical and social assistance, more than 70% of this category have 4-5 chronic diseases of the cardiovascular, nervous, endocrine, hematopoietic, musculoskeletal, respiratory, digestive and others. The incidence of diseases in the older people from 60-74 years is almost two times higher and six
times in the elderly from ≥75 years, compared to young people.

The objective is to study the state and prospects of development of the gerontological service in the Kyrgyz Republic present stage, to assess the level of geriatric care provided to the population of the country, as well as to wards of stationary social institutions of the country.

**Materials and Method**

We studied legislative, regulatory documents, scientific publications and articles from open media sources on the older people, since 1991.

The object of the study was older people, wards of the Bishkek and Nizhne-Serafimovsk social stationary institutions of a general type for older people and people with disabilities (from now on referred to as SSI). We studied medical records of the wards in institutions; there were 506 of them at the time of the study.

Electrocardiography performed in 370 people, echocardiography in 70 people, ultrasound of internal organs in 347 people and ultrasound bone densitometry in 177 people. The following medical equipment of the I.K. Akhunbaev Kyrgyz State Medical Academy was used to conduct these studies: EK12T-01-R-D electrocardiograph, Mindray DP-50 portable ultrasound scanner, and SONOST-3000 portable bone densitometer. The echocardiographic study was carried out by researchers of the Alpine Medicine Department of the M.M. Mirrakhimov National Center of Cardiology and Internal Medicine of the Ministry of Health of the Kyrgyz Republic on the Philips Cx50.

Statistical processing of the results carried out using the program Statistica for Windows, v. 6.0 Data presented as the arithmetic mean ± standard error of the mean (M ± m). The significance of the differences in the frequency values in the observation groups evaluated using the Pearson χ2-criterion, the Student t-test and the Mann – Whitney rank U-test used. The values at p <0.05 were considered statistically significant.

**Results**

About 500 thousand citizens are overworking age or almost every eighth resident of the republic. The number of men over working age (63 years and older) is 4.7%, and the number of women (58 years and older) is 10.8%. The number of women in this age group exceeded the number of men by 2.3 times.

In 2018, life expectancy for men was 67.4 years, for women was 75.6 years. The retirement age of women comes five years earlier (for men at 63 years old, for women at 58 years old).

The solution to the problems and needs of older citizens in the Kyrgyz Republic until 2000 remained without proper attention.

In 2002, the Kyrgyz Republic became a member of the Madrid International Plan of Action on Aging.

In 2005, at the initiative of 22 organizations involved in ageing in Kyrgyzstan, Kazakhstan and Tajikistan, the International Gerontological Network AgeNet International was created. The goal was to help increase the responsibility of the government and civil society in improving the situation of socially vulnerable older people.

In 2011 the Law of the Kyrgyz Republic dated July 26, 2011 No. 133 “On Senior Citizens in the Kyrgyz Republic” was adopted in the country.

In October 2016, the Government of the Kyrgyz Republic decided to form an interagency working group to develop a State national program to improve the quality of life of older people for 2017-2027 years, with the inclusion of six partner organizations of AgeNet International. The recommendations developed by this interagency group formed the basis of the Action Plan to improve the quality of life of senior citizens of the Kyrgyz Republic for 2019-2025, which was approved by the Government Decree No. 442 dated August 30, 2019.

To implement the measures, four priority areas are defined:

1. Equality and non-discrimination;

2. Prevention and promotion of health, increasing the access of senior citizens to quality medical services through improving the health care system and promoting active longevity;

3. Ensuring well-being at all stages of the life cycle of senior citizens;

4. Ensuring the accessibility of senior citizens to state and municipal services by developing the social services market and expanding forms of support, including the private sector.
Geriatrics is a separate medical speciality, the purpose of which is to impact on the physical, mental, functional and social spheres of health and life of the elderly and senile people in acute and chronic diseases during treatment, prevention, rehabilitation and palliative care. The primary health care for the population of the republic provided by 148 medical institutions, 64 family medicine centres, 28 general practice centres, in which 694 groups of family medicine doctors and 1026 Medical- obstetric centres that are part of a system of the Ministry of Health of the Kyrgyz Republic. In the Order of the Ministry of Health of the Kyrgyz Republic No. 387 dated 05/30/2018, the nomenclature of medical and pharmaceutical specialities and the positions of employees with higher medical and pharmaceutical education in healthcare organizations documented the speciality “geriatrics” and the location of “geriatrician”.

There is still no comprehensive training system for geriatric specialists in the country, which should include not only medical personnel at all levels but also social workers. There are no educational programs on geriatrics before and after graduate training. The problems associated with geriatric care: there are no geriatric doctors, no geriatric rooms, no geriatric centres, geriatric medical care is not provided to the elderly, and the wards of stationary social institutions remain not surveyed. Decisive in this direction is the presence and functioning of a hospital for disabled war veterans in the republic, where, along with invalids of the World War 2 and home front workers, who are very few, the older people catered for. The work of stationary social institutions is one of the priority areas that determine the new policy of our state.

The mandatory minimum system includes stationary and semi-stationary organizations. The first contains social inpatient facilities for senior citizens and persons with disabilities. In total, there are 15 institutions in the Kyrgyz Republic, six of which serve for senior retirement and seniors. From table 1, of the six stationary social institutions of the country, the two largest located in the Chuy region, these are the Nizhne-Serafimovsk and Bishkek SSI with a capacity of 308 people and 205 people, respectively. The remaining four institutions situated in the south of the republic. It has Small capacity, designed for 204 beds.

The Nizhne-Serafimovsk SSI founded in 1936 and in 1978, a new 4-storey building, consisting of 3 residential buildings, during the Soviet Union. Currently, the capacity is 325 beds, located in the village of Nizhnyaya Serafimovka, Chuy region. The Bishkek Social Stationery Institution (SSI) was founded in 1961, by Decree of the Council of Ministers of the Kyrgyz SSR No. 99 dated February 15, 1955. The capacity is 205 beds and 83 living rooms, located in the Bishkek.

In our study, a total of 506 people lived in two institutions, of which 442 (87.4%) people of older age health status examined. The remaining 64 (12.6%) of the wards did not fall into the study; these were young and middle-aged people (up to 60 years) with disabilities. Of the 442 wards, men were 248 (56.1%) people, women were 194 (43.9%) people, their average age was 76.1 ± 3.27 years. SSI wards represented by residents of the Chuy region were 194 (43.8%) people, Bishkek were 149 (33.7%) people and Issyk-Kul region were 52 (11.7%) people. The remaining 47 (10.6%) of the wards were representatives of other areas of the republic. Doctors and nurses represent SSI. An average of 6 staff units per institution: a general practitioner, a surgeon and four nurses.

During the research, out of 506 medical observation cards, only 135 observation cards were examined and with the results of laboratory and functional tests. In all these cases, the wards studied in connection with emergency conditions and hospitalization in the clinic. The department staff organized visiting consultations and examination with the involvement of super-specialists from the departments of I.K. Akhunbaev Kyrgyz State Medical Academy.

A comparative analysis in table 2 showed that the percentage of diseases detected for some illnesses in the wards of the Bishkek SSI was significantly higher than in the departments of the Nizhne-Serafimovsk SSI. Summarizing the final figures, six classes of diseases, such as cardiovascular, diseases of the musculoskeletal and connective tissue, nervous and digestive systems, respiratory and visual diseases constituted the disorders that found in wards of SSI.

</table>

Note: p <0.05 - the differences are statistically significant compared with the indicators of the Nizhne-Serafimovsk SSI
A high frequency of comorbidity revealed: 241 (56.4%) of the wards had from 1 to 3 diseases, 185 (43.3%) from 4 to 6 diseases and in 128 (29.9%) of the departments, seven or more diseases registered.

**Discussion**

According to the UN age classification\(^{13}\), if the share of people aged 65 years and over in the total population is below 4\%, then the population of that country is considered young, if, in the range from 4\% to 7\%, the community is on the threshold of old age, if above 7\% aged population. In 2019, 301 thousand (4.7\%) of Kyrgyzstani people were at the age of 65. According to the UN prediction, in Kyrgyzstan, this tendency will manifest itself by about 2030 when the proportion of older people aged 65 years and older will approach 7\%\(^{14}\).

To provide full assistance, a specialist is needed, who knows the theoretical concepts of the functioning of the body over the age of 65.

In our country, the development of geriatric services requires the integration of both medical and non-medical areas. In this case, the primary attention should be paid not only to the fight against ageing but to the prevention and treatment of multiple pathologies, to prevent the pathological and accelerated ageing process of the body. The activities of stationary social institutions in the Kyrgyz Republic can be an excellent example of integration work. But there are also enough issues: institutions are poorly responsive to reforms, and they do not particularly want highly qualified medical intervention.

We can confidently state that the demographic situation in the country today leaves no doubt that caring for people of older age groups is a requirement of the time and a substantial medical and social problem.

**Conclusion**

1. For further study of issues related to the ageing of the population and the development of approaches to organizing geriatric care for the people of the republic, it is necessary to create a coordinating body for gerontology and a network of geriatric centres in the country.

2. For the development of the gerontology service, the achievement of health indicators, the quality of life of older people, the development of cooperative scientific research and the improvement of specialized training in geriatrics are necessary.

3. Coordinated actions by the healthcare and social protection systems are needed to provide the older people and senile population of the country with the highly specialized medical and social assistance they need, affect the extension of their active longevity.

Correlation between the Expression of Melanoma-Associated Antigen-A3 and Cytology Results on Bronchoalveolar Lavage on NSCLC

Mawartih Susanty, Isnin Anang Marhanang

1Faculty of Medicine, Universitas Airlangga, Surabaya Indonesia, 2Department of Pulmonology, Faculty of Medicine, Universitas Airlangga, Surabaya (60131), Indonesia

Abstract

Background: Lung cancer is still considered an alarming health problem, causing a major cause of death in malignant disease. The incidence rate is likely to increase and most of it comes with an advanced stage of diagnosis. To improve the healing rate and life expectancy, the detection of lung cancer should be done early, when it is still small and localized. Bronchoalveolar lavage (BAL) cytology is a method of examination that can be used in lung cancer. The expression of Melanoma-Associated Antigen (MAGE) becomes the marker that is sensitive to certain types of cancer, including lung cancer.

Objective: To analyze the correlation between expression MAGE-A3 and cytology of BAL specimen on NSCLC.

Method: Bronchoscopy was performed on patients with NSCLC lung tumor at pulmonology unit of Dr. Soetomo Teaching Hospital Surabaya Indonesia to collect the BAL. Histologic examination for BAL and MAGE-A3 examination were conducted on patients. Statistical analysis used to determine the correlation between the expression of MAGE A3 and cytology of BAL specimens on NSCLC was fisher’s exact test.

Result: We found that there were 7.14% of subjects with BAL cytology had cancer cells (adenocarcinoma). MAGE-A3 expression was positive only in 28.60% of subjects diagnosed with NSCLC. The result of MAGE A3 expression analysis with cytology of BAL specimen showed p = 0.286.

Conclusion: There was no significant correlation between MAGE-A3 expression and histopathology type. The results of MAGE A3 RT PCR fluid expression examination showed that most of them were in the negative category.

Keywords: MAGE-A3, BAL, NSCLC

Introduction

Lung cancer is still an alarming health problem in the world and is considered the leading cause of death in malignant disease. Its incidence is likely to rise almost worldwide, in developed countries like the United States and in developing countries, including Indonesia. The increasing trend of this case is not only in male but also in female. Diagnosis of lung cancer is 14% of all types of cancer in the world, ranked second after prostate cancer in male and breast cancer in female. Lung cancer in Indonesia ranks the fourth most common of all cancers 1.

Lung cancer type non-small cell carcinoma (NSCLC) is the most common type of lung cancer, with the incidence of 75-80% of all lung cancer. To improve the healing rate and life expectancy, the detection of lung cancer should be done early, when it is still small
and localized. A lot number of research has been done to find the tool for early lung cancer detection; low-dose frequency computed tomography (CT) is able to detect lung cancer that is smaller (less than 1 cm) compared to chest x-ray with is 0.5 cm. However, this procedure has the disadvantage of providing a non-specific mass picture, causing a large false positive rate and increased deaths from unnecessary surgery. In addition, CT scan is costly and repeated CT evaluation scan might increase the risk of adverse side effects of radiation in the patients.

Developments in the field of biomolecular provide an alternative to find an early detection tool for cancer that is not invasive, one of them is tumor antigen. Tumor antigen is one of the tumor makers/biomarkers that provide useful information in patients with developing cancer. Tumor antigens has been widely developed for early detection of lung cancer, being the target of therapy (immunotherapy) and a promising field in the future. However, the specificity and sensitivity of tumor antigens in the diagnosis of cancer might vary.

The gene of melanoma associated antigen (MAGE) belongs to an important group of CT antigens and is grouped according to the expressing tissue and gene structure. It is suspected that the expression of the MAGE gene family can be a marker that is sensitive to certain types of cancer including lung cancer. Overexpression of MAGE gene can be used not only for early diagnosis and screening but also as a target of adjuvant treatment in lung cancer. A study suggests that there is a significant correlation between MAGE expression and histopathology of lung cancer as well as the stage of lung cancer.

Currently, there are already several modalities of molecular detection in determining genetic alterations. One of them is polymerase chain reaction (PCR) that is capable of detecting \(10^{-9} - 10^{-4}\) copies of gene mutation. In addition, PCR helps determine histopathologic classification and detection of specific tumor antigens despite the very few amount of sample. Compared to other molecular modalities, PCR has several advantages that are objective, fast, versatile and cost-effective when applied to small tissue samples. In the context of detecting tumor antigens, the CT antigen of the MAGE family can be detected by RTPCR.

Bronchoscopy is a medical procedure of inserting a pipe into the airway through the nose or mouth. Some types of specimens that can be obtained with bronchoscopy are sweeps, rinses, Bronchoalveolar lavage (BAL), forceps biopsy and transbronchial needle aspiration (TBNA). Fiber optic bronchoscopy (FOB) with BAL is a fairly practical action with moderate risk and is fast and reliable. BAL diagnostic results show a value of more than 50% and it is better than transbronchial biopsy for diagnosis of peripheral lesions that can not be seen through bronchoscopy. In the patients with bronchoalveolar cell carcinoma, the BAL examination has a high diagnostic value.

MAGE-related researchers are still not widely exposed and a previous research reported MAGE expression in lung cancer of 30-50%. In Dr. Soetomo General Hospital Surabaya, Indonesia, there has never been any research or data publication showing the benefits of MAGE expression especially MAGE A3. This study aims to analyze the correlation between the expression of MAGE A3 and the cytology results of BAL specimen on NSCLC.

**Method**

The subjects of the study were lung cancer patients who underwent treatment at Dr. Soetomo General Hospital Surabaya, Indonesia that met the inclusion and exclusion criteria. The inclusion criteria include patients aged 20-70 years with histopathologic results, including NSCLC. Subject exclusion criteria exclude patients with primary tumor in other organs and metastatic lung cancer from cancer of other organs. Subjects who were willing to be involved in this study filled the informed consent in advance.

This study used cross-sectional design and consecutive sampling method to obtain 14 subjects. This study was conducted in the pulmonology unit room of Dr. Soetomo General Hospital Surabaya, Indonesia. Tools and materials used include patients’ medical records, questionnaires containing patient baseline data, CT thoracic scan results, bronchoscopy device, MAGE reagents, real-time PCR, and BAL dosage tubes. Before conducting the research, the we initially underwent ethical test (445/Panke, KKE/VII/2017) at Dr. Soetomo General Hospital Surabaya, Indonesia.

The research procedure includes the diagnosis of lung cancer based on thoracic CT-scan with contrast and histopathology results including NSCLC (adenocarcinoma, squamous cell carcinoma and large cell carcinoma). We performed identification based on subject criteria, followed by examination of MAGE-A3
examination which was the result of BAL liquid sediment examination using primary MMRP-3 & MAGE-A3 with Reverse Transcription (RT) technique of PCR detected in 569 base pairs in the shape of intron ribbon F: 5'-GAAGCCGGCCCAGGCTCG- 3'. The examination performed was BAL fluid cytology as the result of bronchial tumor epithelial cells examination contained in the liquid BAL in the form of adenocarcinoma cells, squamous cell carcinoma and large cell carcinoma. The data used in this study were primary data from thoracic CT scan examination, histopathology result, cytology and MAGE expression examination result from BAL preparation.

The data of measurement results were processed using SPSS software version 20.0 (SPSS, Inc., Chicago, IL). The data were analyzed and presented in tables and descriptions. The data were grouped into two types: numerical and categorical data. The numerical data were presented as mean ± standard deviation and the categorical type data were presented in percentage form. The data on the correlation between MAGE-A3 correlation and cytology results of BAL specimen on NSCLC were analyzed using chi-square test (p < 0.05) if the requirements were met. Otherwise, chi-square test was to be replaced by fisher’s exact test (p < 0.05).

Table above shows BAL preparation was found only in 1 subject with malignant cell result (7.13%). The majority of subjects had BAL preparations in the category of no malignant cells (92.87%). There were BAL preparations with positive MAGE-A3 expression (28.60%) in all study subjects. Most subjects had MAGE-A3 expression in the negative category (71.40%). From the results of the examination, we found 7.14% of subjects who had MAGE-A3 expression with positive category and BAL cytology in the category of malignant cells. Most subjects had MAGE-A3 expression with negative category and BAL cytology in the category of no malignant cells (71.43%).

The samples in this study were all patients with NSCLC lung tumor who underwent bronchoscopy according to inclusion and exclusion criteria in Dr. Soetomo General Hospital Surabaya. The average age of the subjects undergoing bronchoscopy examination and MAGE-A3 RT PCR was 60.07 ± 10.42 years old. The number did not significantly differ between male and female. The subjects had diverse occupations, but most of them were farmers (35.70%), followed by housewives (28.61%). Most subjects were not active smokers and those who smoke had been smokers for 20-50 years. Most histopathologic results are adenocarcinoma lung (85.74%), squamous cell carcinoma lung (7.13%) and large cell ca (7.13%).

The result of statistical analysis shows no significant correlation between MAGE-A3 expression with cytology of BAL (p = 0.286)

**Discussion**

BAL is a standard diagnostic procedure in patients including lung cancer patients, especially in peripheral tumor with a diagnostic value ranging from 33-69%. Cytology preparation with BAL is based on exfoliation cells of malignant lesions of the bronchial epithelium. This BAL fluid component shows inflammatory conditions as well as immune status of the lower airway and alveoli. Adequate cytological dose conditions depend on several factors: the rate of difference in cancer growth, cytological morphology preservation, and operator ability in fluid retention lavage of the bronchi 11. The results of BAL cytology in this study shows preparation with malignant cells, adenocarcinoma. There was no malignant cells found in the other thirteen preparations. This might be due to the number of cancer cells that are expected to collapse with the liquid bronchoalveolar lavage in a few number or none 12.

PCR RT examination is one of the methods used to distinguish different MAGE proteins. With this technique, transcripts of MAGE mRNA activation, expression and aberration are found in many types of cancer, one of which is lung cancer. Some literature mentioned that MAGE expression in lung cancer is 30-50%. The results of RT PCR examination for liquid bronchoalveolar lavage (BAL) shows 4 preparations (28.60%) expressed by positive MAGE-A3 of the 14 examined preparations. This may be caused by the number of cancer cells that fall along with the fluid of bronchoalveolar lavage, in a little amount or none, as well as other MAGE-A types that were not examined in this study. Other MAGE-A which are also expressed in primary lung cancer are MAGE A1, A4, A6 and A10. The type of cancer cells can also be a consideration on the cause of MAGE-A3 expression in this study from adenocarcinoma, large cell ca, squamous cell ca and some adenocarcinoma which indicate a positive MAGE-A3 expression. MAGE-A3 is more often expressed in
NSCLC, especially squamous cell ca. In the preparation study with squamous cell ca there is a preparation with negative MAGE A3 expression results\textsuperscript{13}. However, the result can not be considered inappropriate since there was only 1 preparation with squamous cell ca. More number of subjects with squamous cell ca is required to find out if MAGE A3 expressed more in the cell type of squamous cell ca compared to adenocarcinoma\textsuperscript{14}.

The correlation between MAGE-A3 expression and BAL cytology result showed no significant result. This may be due to the positively expressed MAGE-A3 along with BAL cytology where there was only 1 preparation with malignant cells, whereas the other BAL cytology in the preparation with positive MAGE-A3 expression showed no malignant cells.\textsuperscript{15} Detection of peripheral lung cancer with MAGE A1-6 on bronchial rinse preparations shows that MAGE A1-6 had higher peripheral lung cancer detection capability than conventional cytological examination. MAGE detection on sputum and BAL of lung cancer patients showed that from 23 patients with lung cancer examined by their BAL liquid there were 18 patients (78%) with positive MAGE expression, whereas the cytology result from 23 lung cancer patients showed only 8 patients (35%). BAL fluid cytology preparation and BAL fluid preparation for RT PCR were examined, but on cytological preparation there was only 1 preparation indicating cancer cell, i.e. adenocarcinoma\textsuperscript{2}.

Examination of MAGE expression on the case of lung malignancy was able to detect such malignancy. 70-85% of MAGE expressed in lung cancer tissue, tumor tissue preparations during surgery of patients with early-stage lung cancer. MAGE expressed positively in 59% cytology sputum and 70% in BAL fluid. Percutaneous needle aspiration biopsy was performed on patients suspected of lung cancer and we found MAGE sensitivity of 83% and specificity of 58%.

**Conclusion**

The results of BAL cytology examination showed that no malignant cells the majority of subjects were in the category of no malignant cells. The results of MAGE A3 RT PCR fluid expression examination showed that most of them were in the negative category. In this study there was no significant correlation between MAGE-A3 expression and BAL cytology result.

**Ethical Clearance:** This research involves participants in the process using a questionnaire that was accordant with the ethical research principle based on the regulation of research ethic regulation. The present study was carried out in accordance with the research principles. This study implemented the basic principle ethics of respect, beneficence, non-maleficence, and justice.

**Conflict of Interest:** The authors have not found any conflict of interest related to this research so far.

**Source of Funding:** All of the cost and fees related with this research are paid by the authors only with no sponsorship nor external funds.

Effect of Bosu Pilates on Primary Dysmenorrhea in Adolescent Girls

Mayuri T. Gotpagar¹, Poovishnu Devi²
¹Intern, Faculty of Physiotherapy, Krishna Institute of Medical Sciences Deemed To Be University, Karad, Maharashtra, India, ²Associate Professor, Department of Cardiopulmonary health science, Faculty of Physiotherapy, Krishna Institute of Medical Sciences Deemed To Be University, Karad, Maharashtra, India

Abstract

Background: Dysmenorrhea is a painful menstruation or a cramp labor like pain in the lower abdomen that radiates to upper abdomen, waist and thighs and sometimes accompanied by systemic symptoms like nausea, vomiting, diarrhea and dizziness. Dysmenorrhea can be treated by various pharmacological and non-pharmacological remedies. Incidence rate of dysmenorrhea among Indian girls is found to be 79.67%. It complicates the lives among adolescents females and affect the quality of life of many women. Pilates exercises is safe, non invasive treatment modality to relief pain of primary dysmenorrhea.

Objectives: To study the effect of Bosu Pilates on primary dysmenorrhea in adolescent girls.

Method: Ethical clearance was obtained from the institute committee. 25 women were screen from KARAD aged between 18 to 30 years. They were selected according to the inclusion and exclusion criteria. They were allowed to fill the form given which included the scale which rated the working, location, intensity, days of pain in dysmenorrhea. According to which conclusion was made.

Result: After analyzing the data there was significant effect of exercises like stretching and core strengthening exercises performed on bosu ball which helped to reduce pain status in primary dysmenorrheal adolescent girls seen on Wong Baker scale (p=<0.0001).

Conclusion: The study concludes that there was significant effect of bosu pilates on primary dysmenorrhea in adolescent girls.

Key Words: primary dysmenorrhea, adolescent girls, bosu pilates, menstruation pain.

Introduction

Dysmenorrhea is a painful menstruation or a cramp labor like pain in the lower abdomen that radiates to upper abdomen, waist and thighs and sometimes accompanied by systemic symptoms like nausea, vomiting, diarrhea and dizziness.¹ This disease affects 60% of females with systemic symptoms 60% suffer from headache, 80% from low back pain, nausea and vomiting ,50% from diarrhea ,30% from irritability and 45% dynamic.

Dysmenorrhea can be classified into 2 types:

1)primary dysmenorrhea
2)secondary dysmenorrhea

Primary dysmenorrhea: it’s a cramping like pain with menstruation and physical examination is completely normal.²

Physiological cause for dysmenorrhea include excessive production of uterine prostaglandin and overall production of vasopressin, a hormone which stimulate uterine muscular contraction. Primary dysmenorrhea usually presents during adolescence within 3years of menarche. It is usually for symptoms to start within the first 6months after menarche.³

Affected women experience sharp, intermittent spasms of pain, usually centered in the suprapubic area. Pain may have radiated to back of legs or lower back. Systemic symptoms of nausea, vomiting, diarrhea,
fatigue, fever, headache or light headedness are fairly common. Pain usually develops within hrs. to start of menstruation and peaks as the flow becomes heaviest during the first day or two days of the cycle.4

The pain experienced by adolescents with dysmenorrhea can be very disabling and consequently affect the person’s mood. Previous studies have demonstrated that young population affected by primary dysmenorrhea often is work or school because of discomfort which in turn can have an important social and economic impact.5 An excess of prostaglandins is liberated during menstruation. It is thought that this may be the cause of incapacitating pain, as an excess of prostaglandins may lead to excessive uterine contractions which, in turn, may result in hypoxia and ischemia of the uterus, and lead to the typical pain.6 Non-steroidal anti-inflammatory drugs (NSAIDs) are the pharmacological therapy of choice for patients with PD. However, most patients with PD do not seek medical help, or that of other health professionals.7 Instead, they self-medicate or seek alternative solutions. The continued use of such self-medication without a medical prescription or, at the very least, a professional assessment, can also result in secondary effects.8,9

Conventional therapy:

There has been a major demand for new, complementary or integrative therapies which coexist alongside traditional medicine.

Several studies have proven that different complementary therapies, such as yoga, acupressure or herbal medicine, among others, may contribute towards an improvement in the symptoms of PD and therefore lead to improvements in overall quality of life. 10

As Bosu Pilates is a technique aiming at working, strength, stretching, maintaining physiological body curves with abdomen as the strength center which constantly works during all Pilates exercise on bosu ball, which will help to reduce pain with challenge your stability, balance and core strength. Pilates can manage primary dysmenorrhea through stretching and core strengthening exercise.11,12

JOSEPH HUMBERTUS PILATES has developed a series of exercises based on progressive movements the body is able to make currently called PILATES. Pilates is beneficial for all ages and ability level because it’s a low impact exercise program aiming at core strength, stability, flexibility, and correct alignment of the pelvic and spine.11,12

Each exercise is designed to target a specific muscle and breathing pattern are used to effectively cue the abdominals to support each movement.

Its advantage circulation stimulation and fitness improvement which help to prevent any injuries and provide pain relief with best results.11,12

The effect of Pilates was due to increase in the blood flow and metabolism of uterus during exercises on bosu ball which may affect in reduction in symptoms. Pilates decreases this sympathetic activity and release endorphins substances produced by brain and that raise the pain threshold so symptoms are reduced. Contracted ligamentous is band in abdominal region were causative factor for physical compression of nerve pathway and their irritation and so stretching exercises increase core stability improve the symptoms of dysmenorrhea.11,12

Aim

To find the effect of Bosu Pilates on primary dysmenorrhea in adolescent girls.

Objectives

To determine the effect of Bosu Pilates on primary dysmenorrhea in adolescent girls.

Need For Study

Primary dysmenorrhea is common in adolescent girls as it can be treated by various pharmacological and non-pharmacology remedies. As Bosu Pilates is a technique aiming at working, strength, stretching, maintaining physiological body curves with abdomen as the strength center which constantly works during all Pilates exercise on bosu ball, which will help to reduce pain with challenge your stability, balance and core strength. Pilates can manage primary dysmenorrhea through stretching and core strengthening exercise. The effect of Pilates was due to increase in the blood flow and metabolism of uterus during exercises on bosu ball which may affect in reduction in symptoms. Pilates decreases this sympathetic activity and release endorphins substances produced by brain and that raise the pain threshold so symptoms are reduced. Contracted ligamentous is band in abdominal region were causative factor for physical compression of nerve pathway and their irritation and so stretching exercises increase core
stability improve the symptoms of dysmenorrhea.

Materials and Methods

Materials Required

- Pen
- Bosu ball
- Mat

Methodology

Type of study: - experimental study
Study design: - analytic
Type of Sampling Method: - Simple random method
Sample size: -
\[ n = \frac{4pq}{l^2} \]
\[ 4 \times 50 \times 50 / 20^2 \]
\[ 10000 / 400 = 25 \]

25 women to be screened from KARAD.

Study duration: - 3 months
Place of study: - Karad.

Inclusion Criteria

- Females in age group of 18 - 30 years diagnosed with primary dysmenorrhea.
- Irregular menstrual cycle.

Exclusion Criteria

- Females on medications.
- Performing other type of physical activity like swimming, runner etc.
- Other gynecology disorders.

Outcome Measures

- Wang-Baker scale

Procedure

The study was conducted among rural areas in and around Karad.

The targeted population was medical students; the focus of study was to find the effect of Bosu Pilates on primary dysmenorrhea in adolescent girls.

Subjects were selected for study according to inclusion and exclusion criteria

They were evaluated by using self-made evaluation from diagnosing dysmenorrhea. Selected subjects were trained to see the effect of the structured protocol exercises. Treatment duration was 3 times a day for 3 alternative days in a week for 3 weeks and menstrual days were skipped.

Exercises given were:

- One leg rocker:
  
  Sit up tall on your sit bone and extend your legs out about shoulder width apart. Inhale and stretch out through the side of your back. Exhale and reach forward about shoulder height or touch your toes curling your spine. Release and continue.

- Side leg lift:
  
  Lie down on your right side on bosu ball. Body should be in straight line with legs extended and feet stacked on top of each other. Place your arm straight on the ball or bend your elbows. Place your left hand out front for extra support and let it rest on your leg or hip. As you inhale gently raise your left off the lower leg. Stop raising your leg when you feel muscle flex in your lower back or oblique. Inhale and lower the leg back down to meet the right leg start your feet again.

- Supine leg lift:
  
  Lie supine on the bosu ball with hand resting aside. Bend one knee and ground foot on to the mat. Extend the alternate leg long. This is the start position. Lift the extended leg until it aligns with the bend knee and return back to the start position.

- Opposite arm leg reverse crunches
  
  Lie supine on the bosu ball. Place your hand behind your head supporting your neck with your fingers. Have your abs tucked in and the small of your back pushed against the floor. Lift your knee towards the chest while lifting your shoulder blade off the floor. Rotate to the right bring the left elbow towards the right knee as you extend the other leg in to the air.
Hold period: 1 to 2 sec, inhale and return to the starting position. At one time: 10 repetitions of each exercise was performed. The interpretation of the study was done on the basis of comparing pre and post assessment of Wong Baker scale. Thus statistical analysis was done.

**Statistics**

**Discussion**

This study “effect of bosu pilates on primary dysmenorrhea in adolescent girls” was conducted to see the effect of bosu pilates which included one leg rocker, side leg lift, supine leg lift, heel beats, single leg kicks, opposite arm leg reverse cruches in reducing pain symptom among primary dysmenorrhea girls. Primary dysmenorrhea is common in adolescent girls as it can be treated by various pharmacological and non-pharmacology remedies. As Bosu Pilates is a technique aiming at working, Strength, stretching, maintaining physiological body curves with abdomen as the strength center which constantly works during all Pilates exercise on bosu ball, which will help to reduce pain with challenge your stability and balance and core strength and can manage primary dysmenorrhea through stretching and core strengthening exercise. According to the gate control theory by stimulating large diameter sensory nerve fibres in a dermatomal segment, a blockage or gating affect is established at the dorsal horn level of the spinal cord inhibiting the transmission of pain related impulses. In this way the pain is reduced. So training on bosu ball will help to reduce pain of dysmenorrhea in adolescent girls.

The objectives were to determine the effect of Bosu Pilates on primary dysmenorrhea in adolescent girls. The study was conducted with 25 subjects. Subjects were selected according to the inclusion and exclusion criteria. Inclusion criteria was aged between 18 – 30 yrs, females and with Irregular menstrual cycle. Exclusion criteria was Females on medications and females Performing other type of physical activity like swimming, runner etc and Other gynecology disorders. Prior consent was taken from them. Pre assessment was taken for working ability, location, intensity, days of pain prior intervening with the treatment. The interventions were carried out for 3 days per week for 3 weeks along with 3 times per day.
The outcome measure was Wong-Baker Scale. After 3 weeks post assessment was taken. The results of this study indicate there was significant affect on pain status among primary dysmenorrhea girls. This was confirmed using statistical analysis by using ‘Paired t- test’. Pre and post training there was significant improvement noted with structured protocol for pain status among primary dysmenorrhea (p=<0.0001) on Wong-Baker scale.

Earlier studies was concluded by Shahr jerdy S, Hosseini RS (2012) titled “effect of stretching exercises on primary dysmenorrhea in adolescent girls”. They concluded that there was significant effect of stretching exercises on pain in intensity and duration and reduce the amount of pain killer used in primary dysmenorrhea in adolescent girls.

“A case series on effect of yoga on quality of life and flexibility in menopausal women” was conducted by Mastrangelo MA, Galantino ML, House L (2007) and concluded the effect of pilates was due to increase the blood flow and metabolism of uterus during exercises on bosu ball which made effective in reduction of symptoms. Pilates decreases this sympathetic activity and release androphin substances produced by brain and that raise the pain threshold so symptom are reduced.

“To compare the effect of stretching and core stability exercise in primary dysmenorrhea in young females” by Kaur S, Kaur P, SS, et al (2014) and concluded that contracted ligament is band in abdominal region was causative factor for physical of nerve pathway and their irritation so stretching exercise can increase core stability and improve the symptoms of dysmenorrhea.

RESULT

After analyzing the data there was significant effect of exercises like stretching and core strengthening exercises performed on bosu ball which helped to reduce pain status in primary dysmenorrheal adolescent girls seen on Wong Baker scale (p=<0.0001).

CONCLUSION

The study concludes that there was significant effect of bosu pilates on primary dysmenorrhea in adolescent girls.

CONFLICT OF INTEREST

The author declares that there is no conflict of interest concerning the content of the present study.

Source of Funding: This study is self-funded.

Ethical Clearance: The study was approved by the institutional ethics committee of Krishna Institute of medical sciences deemed to be university, Karad.

Two-Years Corneal Collagen Cross-Linking Outcomes in Patients with Keratoconus

Mitra Zamani1, Asghar Heidarian2, Mohammad Sadegh Mirdehghan3
1Associate Professor, 2Tutor, 3Resident of Ophthalmology, Department of Ophthalmology, Imam Khomeini Hospital
and Infectious Ophthalmologic Research Center, Ahvaz Jundishapur University of Medical Sciences, Ahvaz, Iran

Abstract

Aims: This study aimed to report refractive, topographic, and tomographic outcomes of 2-years corneal collagen cross-linking in patients with progressive keratoconus.

Materials and Method: This prospective study was conducted on 76 eyes of 40 patients with progressive keratoconus and a corneal thickness of at least 400μm. After the baseline examination, cross-linking was performed using riboflavin 0.1% and ultraviolet irradiation (370 nm, 3 mW/cm2) for 30 min. Uncorrected visual acuity (UCVA), best spectacle-corrected visual acuity (BSCVA), manifest refraction spherical equivalent (MRSE), cylinder, keratometric readings, and corneal thickness were evaluated at baseline, 6, 12, and 24 months after corneal collagen cross-linking.

Results: Results showed that at a 24-month follow-up, mean BSCVA and UCV A had significant improvements. Changes in MRSE and cylinder were not significant during the two years of follow-up. At a 2-years follow-up, the mean values of minimum keratometry, maximum keratometry, and average keratometry decreased significantly to 0.75, 0.97, and 0.52 D, respectively, compared to their baseline values. Anterior best fit sphere (BFS) also had significant difference at 24-month follow-up compared to base line evaluation. The central corneal thickness decreased significantly up to 38 μ after 2 years.

Conclusion: Corneal collagen cross-linking is an effective treatment to stop the progression of keratoconus as shown by reduced keratometry and improved vision.

Keywords: Collagen cross-linking, Keratoconus, Ultraviolet, Riboflavin

Introduction

Keratoconus is a bilateral, asymmetric corneal degeneration that causes steepening and thinning of the central corneal tissue, resulting in irregular astigmatism, myopic progression, and reduction of visual acuity.1

The incidence of this disease is usually at the age of puberty,2,3,4 and accordingly, it has a significant effect on the quality of life.5,6 The main causes of biomechanically weak corneas include alteration in the corneal collagen cross-links and higher pepsin activity than normal.7

Chemical and immune histochemical studies of the corneal tissue in normal and keratoconic eyes determined the increased expression of proteolytic and lysosomal enzymes,8,9 reduced the diameter of collagen fibers,8 and decreased the level of protease inhibitors concentration.10 Common options for vision correction in keratoconic eyes include spectacles, rigid contact lens, intra corneal ring segments, and lamellar keratoplasty. Keratoconus is the most frequent cause of keratoplasty in the past three decades.11

Collagen cross-linking was first introduced for the treatment of keratoconic eyes by Wollensak et al. in 2003.12 The purpose of treatment was not only the improvement of visual acuity but also the prevention of the underlying pathophysiologic mechanism of the
disease. The method of corneal collagen cross-linking (CXL) uses the photosensitizer riboflavin 0.1% and after corneal saturation exposes cornea to ultraviolet-A (UV-A) for approximately 30 min. The riboflavin creates new covalent bonds between collagen fibers and improves the biomechanical strength of the cornea.

Confocal microscopy studies indicate the apoptosis of keratocytes in anterior and intermediate corneal stroma and a gradual repopulation of the keratocytes. The stiffening effect of riboflavin and UV-A is approximately 200-300μ in the anterior cornea. Due to the possible increase of corneal endothelial cell damage, CXL is recommended in eyes with a corneal thickness of >400 μm. This study aimed to report refractive, topographic, and tomographic outcomes of 2-years corneal collagen cross-linking patients with progressive keratoconus.

Materials and Method

Population

This prospective, nonrandomized, single-center study was conducted on 76 eyes of 40 patients with progressive keratoconus and a corneal thickness of at least 400 μ. The patients referred to the cornea service of the Ophthalmology Department of Apadana Hospital, Ahvaz, Iran, from December 2013 to December 2015.

Patients who had an increase in maximum keratometry (K-max) of 1.00 diopter in one year, loss of more than 2 lines of best corrected visual acuity, and the need for new contact lens fitting more than once in 2 years were enrolled. The exclusion criteria included corneal thickness less than 400μ at the thinnest point, previous ocular surgery, herpetic keratitis, concomitant autoimmune diseases, pregnancy, breastfeeding, severe dry eye, central and paracentral opacities, and patient with poor compliance. All procedures were performed by a single surgeon.

Preoperative evaluation

Patients with hard lenses and those with soft lenses were required to stop wearing their contact lens at least 3 weeks and 3 days before the preoperative eye examination, respectively. Afterwards, all patients were subjected to the evaluation of slit-lamp and fundus examinations, as well as UCVA, BSCVA, manifest refraction, corneal topography, and corneal pachymetry.

Collagen Cross-linking procedure

The CXL was performed under sterile conditions in the surgical room. After topical anesthesia (tetracaine 0.5% ophthalmic drops, Sina Darou Co, Iran), the central 9mm corneal epithelium was abraded with a surgical blade. Riboflavin with dextran(0.1% riboflavin, 20% dextran, MedioCROSS D-Simovision BVBA, Belgium) was applied in the eye every 3 min for half an hour before the irradiation, which led to the sufficient saturation of the stroma. Using a slit-lamp with the blue filter, the surgeon ensured the penetration of riboflavin into the anterior chamber. Next, an 8 mm diameter of central cornea was exposed to UV-A light at a wavelength light (370 nm; PESCHKE CXL System, System Vision, Germany), and an irradiance of 3 mw/cm2 for 30 min. During the procedure, the riboflavin solution was instilled every 3 min.

Post operation regime

After the surgery, Levofloxacin Ophthalmic Solution 0.5% (Sina darou Co, Iran) was instilled and a soft bandage contact lens was applied until the completion of re-epithelialization. Topical Levofloxacin 0.5% and betamethasone 0.1% (Sina Darou Co, Iran) were administered 4 times a day for a weak. The patients were examined on 3 and 7 days after the surgery to evaluate epithelial healing. Follow-up examinations were performed at baseline, 6, 12, and 24 months after the procedure. At each visit, slit-lamp examination, cyclo refraction, BSCVA, UCVA, corneal topography (TMS-4N, TOMEY, USA) and pachymetry(Bausch & Lomb Orbscan2, Bausch & Lomb Co, USA) recorded.

Statistical Analysis

The analysis of data was performed using SPSS software 20 through paired t-test and repeated-measure ANOVA. P-value less than 0.05 was considered statistically significant.

Results

The mean age of patients was 22±3.54 and 42% of the participants were male.

Vision results

The UCVA and BSCVA data are summarized in Figure1 and Table1. The visual acuity results were reported through the logarithm of the minimum angle of resolution. The baseline mean values of UCVA and
BSCVA were 0.47±0.01 and 0.16±0.14 Log MAR, respectively. During the 24-month follow-up, post-CXL mean values of UCVA and BSCVA were 0.41±0.01 and 0.12±0.10 log MAR, respectively. These improvements in UCVA and BSCVA were statistically significant (P<0.05) after 2-years follow-up, compared to those at the baseline.

UCVA: uncorrected visual acuity; BSCVA: best spectacle-corrected visual acuity; logMAR: logarithm of the minimum angle of resolution; MRSE: manifest refraction spherical equivalent; K-max: maximum keratometry; K-min: minimum keratometry; K-avg: average keratometry; D: diopter; CCT: central corneal thickness; BFS: Best fit sphere.
Refractive results

The baseline mean values of MRSE and cylinder were 5.39±4.23 and 4.95±2.67 D, respectively. There was a mean reduction in MRSE of 0.17 D and a mean reduction in a cylinder of 0.28 D at the 2-year follow-up compared to baseline. There was no significant difference, 24 months after the procedure. The mean value of MRSE improved significantly 6 months after CXL and remained unchanged during 12 and 24 months (Figure 2 and Table 1).

![Figure 2: Changes in (A) keratometric reading based on diopter, (B) cylinder and manifest refraction spherical equivalent based on diopter, (C) central corneal thickness based on micrometer. K-Min: minimum keratometry, K-avg: Average keratometry, K-max: maximum keratometry, MRSE: manifest refraction spherical equivalent, CCT: central corneal thickness.](image)

Topographic results

Table 1 also shows the comparison of the difference between pre-CXL and post-CXL keratometric values, anterior and posterior best fit sphere (BFS) and changes in the irregularity of 3mm and 5mm zones of the cornea at baseline (Figure C), 6 months, 12 months and 24 months respectively. The improvements in the irregularity of 3mm and 5mm zones of the cornea were statistically significant throughout the entire postoperative period, compared to preoperative levels (P<0.05). The baseline mean values of the irregularity in 3mm and 5mm zones of the cornea were 5.11±2.15 and 5.42±2.08, respectively, which decreased to 4.48±1.53 and 4.75±1.78, respectively, after 24 months (Table 1).

The baseline mean values of the surface regularity index, irregular astigmatism index, surface asymmetry index, and keratoconus prediction index and post-CXL follow up (6, 12 and 24 months) changes in these indices were not statistically significant (Table 2).

Discussion

In recent years, CXL has developed as an effective therapeutic modality for the treatment of corneal ectasia and progressive keratoconus. In the past few years, a small number of studies on animals demonstrated that collagen cross-linking significantly increased corneal rigidity in porcine and rabbits cornea. On the basis of the results, BSCVA and UCVA improved significantly to 0.04 log MAR and 0.06 log MAR, respectively, at the 2-years follow-up compared to baseline. Similar results were also reported by Hashemiet al. at a 2-year follow-up. The findings of the previous studies were indicative of a significant reduction in the manifest refraction spherical equivalent and cylinder after cross-linking. The results of the current study during the 24-month follow-up revealed that there was no significant change in the manifest refraction spherical equivalent and cylinder in the course of time. The same results were observed by Viswanathan with a mean of 14.38±9 months. Likewise, in two longitudinal studies performed by Hashemi and El-raggal, there was no significant change in the cylinder five years after the CXL. The reduced values of the corneal curvature and the K-max were important parameters indicating the success of collagen cross-linking. Previous studies have shown a decrease in max-K after the CXL.

Conclusion

According to present study, collagen cross-linking can be combine with procedures, such as rigid contact lenses, ring segments, and surface customized refractive surgery to correct vision partially in keratoconic eyes. In a long term, this therapeutic treatment seems to be much safer compared to corneal grafting with many complications, including infection, glaucoma, cataract, and graft rejection. In addition, cross-linking is a cost-effective and minimally invasive option to the treatment of ectasia compared keratoplasty. No major complications were observed in the current study.

Abstract

Bats are mammal species that have the highest diversity. During the last two decades, various types of infections caused by microorganisms have again become epidemic in many countries, this phenomenon is known as a new infectious disease that arises and re-emerges or Re-Emerging Infectious Diseases (EID/REID). The purpose of this study was to identify EID in bats in the karst area of South Malang. The research method of bat sampling is conducted in the karst area of South Malang, bats are identified by species, taken by blood, prepared and carried out by NGS (next generation sequencing). From the results of the research conducted, obtained 2 types of bats namely fruit-eating bats (*Chiroptera brachyotis*) and insect bats (*Rhinolopus boorneensis*). From the results of the NGS, we get specific viruses and bacteria in bats. The conclusion of this research is that bat in South Malang Karst has potential as a carrier of EID and zoonotic disease.

Keywords: bat, emerging infectious disease, South Malang karst, zoonotic diseases

Introduction

Bats or known as *Chiroptera* have order-level taxon namely Kingdom *Animalia*, Phylum *Chordata*, Mammalian Class, and Superordo *Laurasiatheria*. Bats or Chiroptera are divided into two sub-orders, namely Micro Chiroptera which are generally insectivorous or known as insect-eating bats and Mega Chiroptera which are generally frugivorous or known as fruit-eating bats[1]. In general, bats live in a colony but some live solitary[2,3]. In the world there are 18 families, 192 genera and more than 977 species of bats[4]. In Indonesia, there are 8 families and 72 species of members of the Suborder Megachiroptera and 133 species of members of the Micro Chiroptera Sub-order that more than 50% live in caves[3,5].

Bats carry many diseases that can infect humans, most of which are viruses. In Asia, the Nipah virus, SARS-corona virus, Ebola Reston virus, and the lyssa virus, some are zoonotic viruses that have very high fatality rates, for example 40-80% of humans infected with the Nipah virus have died. Bats infected by the Nipah virus are around 10-30% in each colony, showing signs of previous Nipah infection, and the virus can be excreted through infected bats’ saliva and urine. Research results on bats also found that Lyssa virus (a rabies-related virus) was excreted in saliva, transmitted by bite, and found in bats from Thailand. In addition, evidence of the Ebola Reston virus has been found in bats from the Philippines and Bangladesh, Corona virus related to SARS has also been found in Rhinophid and other bats in China to the rest of the world and many other viruses that have recently been found in bats, but the effect is unknown yet on human health[6]. The purpose of this study was to identify EID in bats in the karst area of South Malang, Indonesia.
Materials and Methods

GPS Garmin 64s SEA, Bat trap, Hanet to catch bats, Caliper, Scalpel blades, DSLR Camera Nikkon D3000, Flakon Bottle, as a preservation place for Syring, Calico bags, Canoe drums, Storage boxes, Formalin 10%, Alcohol 70%, chloroform, for bat anesthesia, DNA and RNA extraction reagents, PCR reagents, NGS (Next Generation Sequencing).

Sample Preparation

The study was conducted in the karst area of South Malang and the Integrated Lab of UIN Sunan Ampel Surabaya, Indonesia. The research period is 6 months from May 2019. 200 microliters of the original sample stored at -70 °C were thawed three times and then centrifuged for 10 minutes. OmniCleave Endonuclease (250U; Madison Epicenter Distributor, WI USA, OC7850K) was added to the supernatant and added 2.5 mM MgCl2, incubated for 1 hour at 37 °C. The genome was extracted from the sample using NucliSENS easy-MAG.

Preparation of NGS

Agilent RNA 6000 Nano Kit (Life Technologies, Waldbronn, Germany) was used to evaluate the total quality of RNA. RNA concentrations were measured using the BR Assay (Life Technologies) Qubit RNA kit. NGS data were processed for NGS sample preparation using the Stranded RNA-Seq Kits SMART (Clontech, Takara Bio Company, CA, USA), Construction for Transcriptom Analysis on the Illumina Platform. The Agilent 2100 Bioanalyzer DNA kit (Life Technologies, Waldbronn, Germany) is used to measure and control the quality of DNA sequencing. NGS was performed using the MiSeq v2 kit (500 cycles) (Illumina, San Diego, CA). After automated clustering in MiSeq, sequencing is processed and genomic sequence readings are obtained.

Computational Analysis of NGS Data

Bowtie 2.032 software is used to filter readings that map the genomes of viruses and bacteria from bats. Data compared to data in the NCBI bank, confirmed again using blastn and blastx, with default parameters.

Discussion

Bat identification refers to the identification key Payne et al. and Suyanto. The first thing to do is catch bats with mistnet, handnet and hanet. Catching this bat is done when the bat returns from foraging. Some of the bats that are caught will be used as samples and the next steps will be taken, while some will be released again after the species has been identified, especially endemic species[2,3]. Bats used as samples were anesthetized with chloroform in a calico bag until dead for 5 minutes (Suhardjono, 1999). Morphometry identification is done based on body measurements. From the results of the study found Chiroptera brachjatis fruit-eating bats and insect-eating bats Rhinolopus boorneensis[7].

Rhinolophus borneensis or prok-bruk Kalimantan has rather small body characteristics with forearm length of 40-44 mm and there is antitragus. Species of the Rhinolophus Genus are characterized by complex nasal leaves, posterior nasal leaves which are triangular in shape, whereas intermediate and anterior nasal leaves are horseshoe shaped[3]. Rhinolophus borneensis has grayish brown hair color. Morphometric measurements on captured samples included Weight (6 gr), Head and Body (48.16 mm), Tail (24.11 mm), Ear (20.62 mm), Hind Foot (5.08 mm), Forearm (39.96 mm), Tibia (15.76 mm). Rhinolophus borneensis is distributed in Java, Kalimantan, Sarawak and Sabah, and Asia (Suyanto, 2001). IUCN status Rhinolophus borneensis is a bat species recorded at IUCN with a Least Concern or LC status[8]. In this study also used NGS (next generation sequencing) in analyzing the EID of the two bat species found. The results of the NGS analysis on Chiroptera brachjatis and Rhinolopus boorneensis can be seen in Tables 1 and 2.

Emerging and Re-Emerging Infectious Diseases (EID/REID) are complex interactions between disease-causing agents, humans, and the environment. In addition, genetic and biological factors from disease-causing agents and humans as hosts are the main contributors to the emergence of EID/REID. Social, political and economic factors also have a role in the process of the emergence of infectious diseases, more specifically, these factors are behavior, demographic status, technological and industrial progress, economic development, land use, trade, travel between countries, and declining quality of the public health system[9,10].

Some countries, especially in the Southeast Asia region are countries that are vulnerable to the emergence of EID/REID[6]. About 60-75% of EID/REID cases are zoonoses, which are diseases transmitted from animals to humans, both livestock or wild animals[5]. Wild animals are considered as a reservoir of several pathogens that were previously unknown to cause infection in humans, one of the wild animals that has the potential to cause zoonosis is bats[11].

Genetic analysis shows that the bat’s immune system evolved along with its flight ability. Bat body temperature when flying can reach temperatures of 41 °C, the same as experienced by mammals when a fever, which is 38-41 °C, conversely, hibernation in bats that live in areas with four seasons has been shown to inhibit the replication of pathogenic viruses and cause some viruses to participate in hibernation. Changes in body temperature is a natural selection of viruses that are thought to increase the diversity of viruses in bats[12]. This results in the co-evolution of viruses and bats which results in the virus being able to survive over a wide temperature range[13,14].

Based on several research results that the number of zoonotic viruses found per bat species is more than rodent[15]. Diversity of virus species in bats is also related to the tendency of different bat species to live in the same ecosystem (sympatry) thereby increasing interaction with each other[11,15]. More than 248 new viruses have been successfully isolated or detected in bats over the past 10 years and some of these viruses have considerable zoonotic potential. In addition, based on the results of research conducted by Sendow et al. found that Henipavirus in bats on Java and Sumatra[16], Wada et al. found gammaherpesvirus in fruit bats[17], Sasaki et al. found alphaherpesviruses[18]. In this study, found more than one virus in both bats using NGS (Next Generation Sequencing) (table 1 and table 2).

In the study also found bacteria in both bats namely Chiroptera brachjatis fruit-eating bats and Rhinolopus Boorneensis-eating bats. Bacteria found in Chiroptera brachjatis fruit-eating bats and insect-eating bats Rhinolopus boorneensis are more than 1 species and have properties that can be transmitted to humans (E. coli, Salmonella)[19]. Based on the results of research conducted by Aminollah found E. coli and Salmonella bacteria in the Pongangan cave in Gresik. Another data published that Sterptobacillus, Streptococcus, Staphylococcus, Shigella and Bacillus in the Menoreh Karst region. The results of this study, the detection of EID in bats in karst of South Malang, Indonesia is
a new discovery and is a source of information both in Indonesia and in the world.

**Conclusion**

In sum, *Chiroptera brachjatis* fruit-eating bats and insect-eating bats *Rhinolopus boorneensis* were obtained. In addition, EID is obtained in bats, so it needs further study, especially on EID in non-bat host (humans and other animals).

Knowledge and Awareness of Bio-Medical Waste Management among Senior Undergraduate and Specialist Dental Students: Cross-Sectional Study

Mohammad Ahmed Qasim Aljunaid1, Aryo Dwipo Kusumo2

1Graduate Student of Dental Health Science, Department Dental Public Health, Faculty of Dental Medicine, Universitas Airlangga, 2Department of Dental Public Health, Faculty of Dental Medicine, Universitas Airlangga

Abstract

Background: There has been a universal rising in knowledge and awareness regarding the bio-medical waste management and the hazards related to it. Purpose: aims to determine and assess the knowledge as well as the awareness towards the management of bio-medical waste among senior undergraduate and specialist dental students in the Faculty of Dental Medicine, Universitas Airlangga, Surabaya - Indonesia. Materials and Method: The study was carried out by using a close-ended survey. The Population of the study consisted of 743 students. However, the taken sample was based on Lemeshow method that includes 130 senior undergraduate and 62 specialist students making a total of 192 participants. Statistical analysis was performed via descriptive statistical analysis and chi-square test. Results: This survey was shown that around 192 questionnaires were distributed of which (86%) returned and analyzed. It was seen that (58.7%) of senior undergraduate students and (87.1%) of specialist students, were having average knowledge of bio-medical waste management system in dental clinics. According to the Chi-square test analysis, it was seen there is a statistically significant P-value (p≤0.05). Conclusion: Within the limitation of this study, we affirmed that there is a good level of knowledge and awareness of bio-medical waste management. In this present study, highly needed for continuing education and training programs to be conducted in dental teaching curricula in the Faculty of Dental Medicine.

Keywords: awareness, dental students, knowledge, waste management.

Introduction

Nowadays, Bio-medical waste is a universal issue1. "Bio-medical waste means any waste, which is generated during the diagnosis, treatment or immunization of human beings or animals or research activities pertaining thereto or in the production or testing of biological or in health camps"2. Healthcare waste (HCW) was defined by World Health Organization (WHO) as the materials that are not treated and discarded from activities health care on human being or animal, having the possibility of transmitting contagious agents to human3.

With the development of science and research work domain4,5, the amount of waste, with bio-hazardous products, is also rising at an alarming rate, leading to instability of the ecosystem6,7. To reduce health problems and eradicate potential risks to people’s health, the services of health care undoubtedly produce a massive amount of bio-medical waste, which creates elevated potentials for infection and injury8. Inconvenient and inappropriate treatment of this waste could have critical public health consequences and a noticeable impact on environment9,10. Due to the random disposal of health-care waste, it has been felt globally in concern about the bio-medical waste in conjunction with the high rise of fatal infections like Hepatitis-B, Acquired Immunodeficiency syndrome (AIDS). As it is not
managed properly, it has been taken into consideration that most of it is hazardous even though only 10–20% is contagious in nature11.

Waste generated in clinics and hospitals of dental teaching is analogous to that generated by other hospitals which include a large component of general waste and a junior proportion of hazardous waste12. Several hazardous wastes that are utilized in dental clinics and hospitals including used disposable items, sharps, mercury-containing wastes, contagious waste (gauze, blood-soaked cotton, etc.), lead-containing waste and chemical waste (spent film fixers, developers, and disinfectants) cause damage to the environment if not managed appropriately. The source of these metals come from the procedures of amalgam filling restoration or removal and the disposal of x-ray fixer solution13. Dental wastes that are generated from several clinical procedures have the possibility to be thrown into the sewage, whilst the majority of the solid type wastes are disposed into landfills and the local trashes sites without the recycling process and separation process14.

The bio-medical and health care waste management is not the same as household and industrial waste management15. Bio-medical waste management is one of the present considerable defies due to the relation to the health of human being16. Knowledge deficiency of information about bio-medical waste will lead the dental specialists to contribute to several environmental deteriorations17. Knowledge is the fundamental criterion that lets for one to allocate between the correct and incorrect, it is a combination of perception, trials, practice, acumen, and skills18,19. The aim of this present study was been to determine and asses the knowledge and awareness of senior undergraduate (BDS) and specialist dental students (SPDS) about bio-medical waste management.

**Materials and Methods**

**Study Type:** This study is cross-sectional20. It is based on a questionnaire survey performed at the Faculty of Dental Medicine, Universitas Airlangga, Surabaya - Indonesia. The self-administered questionnaire was a modification of the work done by Sanjeev et al 18 and Chopra et al21. These questions were categorized into two parts, the first category contained questions on personal and occupational data comprising gender, age, educational qualification, and experience. The second category consists of 13 close-ended questions regarding the assessment of the knowledge, awareness concerning bio-medical waste management. **Sample Size:** The population of our study consisted of 743 students in the Faculty of Dental Medicine, however, the taken sample was based on the Lemeshow method that includes 130 BDS and 62 SPDS making a total of 192 participants in the sample. **Sampling Methodology:** The selection of the sample was according to random sampling techniques (simple random). **Study Duration:** October 2019. The respondents were given sufficient time to fill in the questionnaire and return it on the same day or the next day. **Data Analysis:** All answered questionnaires were coded and descriptively analyzed. The results were displayed in forms of numbers and then each question results were analyzed in percentage forms by the chi-square test also utilized.

**Results**

A total of 192 questionnaires were distributed of which (86%) were received back. The details of participants based on the gender, age, educational qualification and years of experience are shown in. Out of the 166 students, (72.9%) were females and (27.1%) males. The findings show that most of the individuals were undergoing their undergraduate in dental medicine (62.7%) while the specialists were (37.3%). Most of the subjects fell under the group of age 19-23 years (51.2 %). Most of the subjects had 0-3 years of working experience (61.4%).

It had been seen many of the participants (69.3%) had good knowledge about the bio-medical waste management system in dental clinics. P-value were (0.004), (0.000) and (0.010) had been noticed statistically significant in this question within the age, educational qualification, and experience respectively but the gender variable had not statistically significant (0.490). The highest percentage from the whole statistical analysis has been related to the knowledge of important health care waste generation, hazards, and legislations with (98.8%) had been noticed, however, the P-values are not statistically significant in all variables, for instance (94.6%) of the students want the bio-medical waste management to be practiced in faculty dental clinic. However, P-value statistically significant in educational qualification variables (0.025). Also (94.6%) of dental students who need more to know about the management of bio-medical waste, nonetheless P-value had not statistically significant in all variables.
Regarding the answers of the participants, it was found that (94%) of the students know about the importance of dental charts in the dental clinic that helps in guiding disposal of the bio-medical waste, however, the P-value is not significant in all variables. It was noted that regarding the method of how bio-medical waste should be disposed of, (90.4%) of the students’ answers were to be delivered to a bio-medical waste management agency, while (7.8) was throw directly into garbage bins and (1.8%) don’t have the knowledge for waste disposal method. whereas the P-value is not statistically significant in all variables. Nearly, (71.7%) of the students had been aware of color-coding segregation of health care waste. However, the P-value (0.007), (0.050) was statistically significant in the educational qualification, and experience respectively.

P-values are not statistically significant in all variables in related questions that the inappropriate waste disposal can cause health hazards with the result that about (94.6%) of participants knew about it. The related question of the student’s knowledge of the use of puncture-proof Container to discard the needle is available with a percentage of (89.8%). The level of knowledge about destroying the needle before being collected was assessed concerning the qualification of participants, has been shown that (51.6%) in SPDS and (39.4%) in BDS, with no statistically significant P-value in all variable. The lowest percentage was related to the awareness of dental wastewater treatment in a dental clinic (40.4%). Whereas the p-value has been statistically significant (0.038), (0.000) and (0.000) in gender, age, and educational qualification respectively.

Discussion

This study aims to assess the knowledge and awareness of the management of bio-medical waste for BDS and SPDS (Faculty of Dental Medicine, University of Airlangga, Indonesia). The strength of this study is that it made use of a self-administered questionnaire, the coordination pattern of the formatting of the questions, the content of the questions, the analysis, and the response rate. The questions had been designed as close-ended, making the study questions very simple to analyze with quicker response rate, in order to avoid any recall bias. This was assisted by plenty of participants who were covered in a short time.

Interestingly, the participants involved in this study displayed that the knowledge and awareness about the management of bio-medical waste were satisfying. To illustrate, a high percentage of BDS and SPDS (69.3%) had the knowledge and awareness of bio-medical waste management. This supports Saini et al result which showed that the overall awareness of students was high as per the knowledge regarding information of the biomedical waste management and awareness toward its practice.

This study revealed that (92.8%) of the students were aware of regarding the method of segregation into different categories as compared to Charania and Ingle, Bansal et al, Bansal et al, and Sudhir, in which (89%), (86%), and (85%), of dental practitioners, respectively were also aware of the categories of the bio-medical waste.

In the present study, about (71.7%) of the students were aware of the correct color-coding segregation of health care waste. Similar studies conducted by Charania and Ingle, Bansal et al, and Sudhir, in which about (72%) of their participants had information about the color-coding systems.

It is a remarkable observation that about (98.8%) of the participants know the important health care waste generation, hazards, and legislation. These findings are similar to the study done by Pichika et al in which the percentage was (88.8%).

It was reassuring to note that in the present study about (94.6%) of the participants felt that they need the dental college to regulate lectures and a continuing education program to improve existent knowledge about the management of bio-medical waste. A similar study to this one regarded the need for methods to improve the existing knowledge of bio-medical waste management, observation of (97%) of the respondents felt the compulsory need for separate classes and lectures.

It is a significant challenge for deciding the utilization of the resource including methods for diminishing the waste at source and recycling. Consequently, the researchers recommend that there should be a suitable training and concentrated training programs concerning the awareness and practices of waste dumping for the whole staff of the health care and students (BDS and SPDS) with continuous supervision at regular periods. It is mandatory that subjects or lessons about Bio-medical waste management in the curriculum of the faculty of dental medicine should be applied.
Conclusion

Our study revealed that the knowledge and awareness level of bio-medical waste management was good and adequate among senior undergraduate and specialist dental students in the Faculty of Dental Medicine, Universitas Airlangga, Surabaya - Indonesia. Furthermore, the study indicated that there is a need for creating more awareness among dental students regarding bio-medical waste management. Thus, the topic should compulsorily be made as a part of the dental undergraduate curriculum in faculty.

Correlating Schizophrenia with DRD3 Ser9Gly or HTR2 Receptor Gene Variants by using RFLP Method

Mohammed Ayyed Najm1, Zeina S. M. Al –Hadeithi2, Ali Talib Abid Salih3

1Lecturer (Ph.D.) at Faculty of Pharmacy, Al-Rafidain University College, Baghdad-Iraq, 2Lecturer (M.Sc.) at Biotechnology Research Center, Al-Nahrain University, Baghdad, Iraq, 3Lecturer Assistant (M.Sc.) at Forensic DNA Research and Training Center, Al-Nahrain University, Baghdad, Iraq

Abstract

Genetic polymorphism in many candidates associated with psychiatric disorder and Schizophrenia (SCZ). The current research is directed to see if the polymorphisms of Dopamine Receptor D3 (DRD3) or of the 5-Hydroxytryptamine Type 2A (HTR2A) genes is related to SCZ patients. From those admitted to Al-Rasheed Hospital, fifty patients with SCZ (half of them are males and the other half are females), in addition to control group (25 healthy individuals) were included in this study. Blood samples from each individual in both, healthy and control groups were collected, DNA was extracted. Specific primers for exon1 and another for exon 2 have been used to amplify the genes of DRD3 receptor and HTR2A. The data generated in this study indicated significant positive association between T102C polymorphism of HTR2A A1804G transition and DRD3 gene sequence, that resulted in the substitution of Ser9Gly amino acid Iraqi SCZ patients.

Keywords: T102C polymorphism; HTR2A; RFLP

Introduction

Schizophrenia (SCZ) is considered as a neuropsychiatric disease with different etiologies like genetics (1). It is linked to different risks during the life of the patients of about 1% (3). There are a lot of studies took in consideration the SCZ in the members of families, between twins and even those had been adopted, and the results confirmed that the is a strong relation between disease incidence and genetic factors (3).

It has been found that each of the silent mutation T-102C (Ser34Ser) and the A-206G transition (which brought about the substitution of a Ser9Gly amino-acid in the N-terminal of the receptor extracellular domain) in the genetic sequences of 5-HTR2A receptors and of DRD3 receptors; respectively, are genetic polymorphisms used to establish possibility of the psychological disorders (4,5). Furthermore, other studies approved that there is a strong relation between schizophrenia and the variants of C-102 in the polymorphism of the T-102C (6) and also with the increment of homozygosity of the DRD3 polymorphism alleles (7). Oppositely, some studied found there is no correlation, specifically with the Transition of DRD3 Ser9Gly (1,8). The current research examined the connection of HTR2 gene with the genetic susceptibility to SCZ, and the relationship between DRD3 receptor gene and phenotypic expression of SCZ disorder within the Iraqi people.

Material and Results

Sample collection

Approximately 50 blood samples were collected from SCZ patients of both genders (25 female and 25 males with mean age 50.3-39.1) hospitalized at Al-Rasheed Teaching Hospital in Baghdad province by the consultant medical staff. Fifty healthy individuals (25 male and 25 females with mean age 48.2-36.6 years) donated blood samples which served as control group. Samples were preserved at 4C◦ till working on it.

Genes amplification

From the whole blood, genomic DNA has been extracted by using (QIAamp DNA Blood Mini Kit, USA), the DNA concentration and purification were conducted by using the NanoDrop ND-1000 spectrophotometer (NanoDrop Technology) in the Medical and Molecular Biotechnology dept,
Biotechnology Research Center, Al-Nahrain University, Baghdad, Iraq. Conventional PCR was used to amplify the region including the polymorphisms. By using both of F 5’-GCTCTATCTCAACTCTCACA-3’ primer and R 5’-AAGTCTACTCACCCTCGAGTA-3’ primer, a 463 bp fragment of DRD3 exon 1 were amplified according to (Spurlock et al. 1998) (7). A 342 bp fragment of HTR2 of from exon 1, which carries the T102C polymorphic site was amplified with F 5’-TCTGCTACAAGTTCTGGCTT-3’, R 5’-CTGCAGCTTTTTCTCTAGGG-3’ according to (Williams et al. 1996) (6). The PCR amplification master mix /1 reaction was performed by using 25µl volume containing DNA (1.5 µl) ; Taq PCR PreMix (5 µl) (Bioneer, Korea); 10 Pmol (1µl) from each one the primers used; then, by using nuclease free water, the volume was completed to 25 µl. Regarding thermal cycling conditions of DRD3 and HTR2A, they were done as: Denaturation (94 °C ; 7min), then, 35 cycles of secondary denaturation (94 °C ; 35sec), annealing (62°C ; 45sec) & (54°C ; 35sec) respectively & (72 °C ; 35sec) with the final extension (72°C ; 10 min) by using the thermal Cycler (Gene Amp, PCR system 9700; Applied Biosystem).

After that, polyacrylamide gel (30%) were used for the electrophoreses of PCR products, the gel was already stained by using Ethidium bromide to enable the visualization of the product clearly under UV light.

**RFLP analysis**

The genotypes for the T-102C; and also, for A-206G transitions in the genes of 5-HTR2A and DRD3 receptor have been assessed according to (Spurlock et al.1998) (7). The digestion reactions were done (50 µl) volume; (5 µl of 10X CutSmart , 5 µl of 200 ng/ µl amplicons 342 bp, or 463 bp, 0.5 µl of 2.5 U MspI or MscI) (New England Biolabs, USA), incubated for (4hr : 37C). The MscI able to recognize, then to cleave the TGG↓CCA in blunt ends. MspI able to cleave the C↓CGG and leaves 5’ protruding ends. Cleavage of the PCR amplicon (342 bp) by MspI gives a (342 bp) product of the wild-type allele T/T (T-102), & (126 bp & 216 bp) products for the mutant allele T/C (C-102). The MscI digestion resulted in three different fragments size (47bp, 111bp & 305bp) as the products of the wild-type allele A/A Alanine to Alanine (A-206), and four different fragments size (47bp, 99bp, 111bp & 206bp) for mutant allele A/G (G-206). The polymorphisms of the different digested fragments of the DNA have been separated by using a 10% poly acrylamide and 2% Agarose stained with Ethidium Bromide.

Statistical analysis of the present study was achieved by using different statistical programs, X2 test was applied. The tests were considered significant when P value <0.01, compare between control and patients’ group in % of mutation, Chi-square –X2 test was also used to compare the significance between percentage as shown in table 1.

**Results and Discussion**

The HTR2 receptor gene polymorphism results in both healthy and schizophrenia patients

In recent study the conventional PCR amplification resulted two amplicons indicated the DRD3 partial gene (342 bp) and HTR2 (463bp) amplicons gene of SCZ patients, bands are shown in figure 1.

**Figure (1): Electrophoresis (agarose gel) of DRD3 amplicon (342 bp) and HTR2 (463bp) amplicon of SCZ.** The electrophoretic separation of different bands was achieved on a 2% agarose gel (2 h., 5 V / cm, 1X TBE) and then examined by U.V. light after been stained with ethidium bromide. Lane: 1 (M : 100 bp ladder), Lan1 and 2 DRD3 bands sized (342bp). Lan3, and 4 HTR2 bands sized (463bp)

The HTR2 receptor partial gene 342 bp fragments found on the chromosome-13 (long arm) was cleaved with MspI restriction endonuclease enzyme (RE) for detecting the frequencies of allele and their genotypes according to the transition of T-102C in the gene of HTR2. Out of 25 healthy participant 20 (80%) were showed two bands sized (216,126)bp respectively, indicated CC wild type homozygote genotype, and 5(20%) were showed three bands were sized (342,216,126)bp respectively,
indicated TC heterozygote genotype with significant relation between disorder and the allele T-102 (P<0.0001, odds ratio (OR 1.561>1), also the mutant TT genotypes was absent. (Figure 2) in compared with schizophrenia patient’s genotypes according to the digestion result that showed one band sized 342 indicated higher percentage of TT genotypes 36 (72%), in comparison with TC heterozygote genotype 14(28%) that showed three bands (342,216,126) with OR 1.175 and (P<0.0001) less than the control OR considered significant. The allele frequency of C allele in healthy group (0.90) is higher than it in SCZ patient (0.14) but the allele frequency of T allele was found to be more frequent in group of patients (0.86) compare to healthy group (0.10). Table 1 shows the percentages of the frequencies of genotype and alleles of the polymorphism of HTR2 (T-102C).

![Image: Polyacrylamide gel electrophoresis for amplified HTR2A gene (342 bp) of SCZ.](image)

**Figure (2):** Polyacrylamide gel electrophoresis for amplified HTR2A gene (342 bp) of SCZ. The electrophoretic separation of different bands was achieved on 10% gel (3 h., 5 V / cm, 1 X TBE) and then examined by U.V. light after been stained with ethidium bromide.

Lane: 1,7,9,(342,216,26 bp fragment represent T-102/C-102 Heterozygote); Lane: 3, 11, (216,and 126 bp fragment represent C - 102 / C - 102 mutant-type homozygote ); Lane : 2, 4, 5, 10(342 bp fragment represent T - 102 / T - 102 wild-type homozygote), Lane M (100bp ladder).

The results of polymorphism of the gene of DRD3 receptor gene in both healthy & schizophrenia patients

The nucleotide polymorphism (SNP) A-206G transition, which appears in the exon1 of DRD3 receptor was detected by cleaving site of MscI RE of the 463bp amplicon Figure 3. The allele frequency and genotypes are shown in Table 2. It has been observed that; all the control group individuals; 25 subjects (100%), showed three bands (305, 111, 47) bp indicated the AA wild homozygote genotype in comparison with zero of the patient subjects (0%), in addition to that, the appearance of four band sized (206,111,99,47)bp in 35 patient subjects (70%) refers to the higher percentage of the G-206/G-206 mutant-type homozygote, as well as, A-206G genotype heterozygotes in 15 patient subjects (30%). So, all the current findings refer to that there is a strong statically significant association between the G-206/G-206 genotype and schizophrenia (P>0.0001, OR 1.326). Higher A allele frequency in healthy group in compare with patient subjects 0.15 .on the other hand the G allele frequency are rising 0.85 in patients subject study, all data shown in Table 2.

Figure (3): Polyacrylamide gel electrophoresis pattern for amplified DRD3 gene (463 bp) digested with MscI of SCZ. The electrophoretic separation of different bands was achieved on 30% gel (2 h., 5 V / cm, 1 X TBE) and then examined by U.V. light after been stained with ethidium bromide. Lane: 1 and 5 (DNA band pattern of an A – 206 / G - 206 heterozygote); Lane: 2 (DNA band pattern of an A – 206 / A -206 wild - type homozygote). Lane 4 (DNA band pattern of a G - 206 / G-206 mutant - type homozygote).
Discussion

Many candidate genes in the brain, may interact with each other from the monoaminergic pathway, and are related to schizophrenia. Genus, et al., (2009) referred to that 1438 A / G, 102 T / C & His 452 Tyr polymorphisms of the gene of the HTR 2 A were liked with a different cellular change, which resulted in SCZ (9).

The present study indicated a significant positive connection between T102C polymorphism of HTR2A & SCZ. Zhang et al, (2004) found that there was a T102C polymorphism of HTR2A in two Chinese SCZ patients; but no significant positive correlation with all SCZ (10). Polymorphisms of genes of HTR2C and HTR2A are thought to be the result of abnormal metabolism in patients with SCZ who were on olanzapine or clozapine (9). Baritaki, et al, (2004) found that the T102C transitions in the 5HTR2A had a significant association with SCZ, and appeared as an increment in the risk of SCZ for those who carry the T102 allele (11). Najwa Sh, (2014) assumed that the T102C polymorphism of HTR2A is not significantly correlated with SCZ in Iraq patients (12). The findings of the current study conduct that the 1804 A/G SNP of the DRD3 gene is strongly related to the genetic tendency of the incidence SCZ in Iraqi people.

There are conflicting views in the DRD3 Ser9Gly polymorphism gene relationship with the appearance of symptoms of SCZ, as it has been shown in the case control studies which have been gave different results. Some of these results revealed a significant relation between them. Shi et al. (2008) conclude that the DRD3 gene was not nominated to the top seven candidates for predisposition to SCZ (13). Other population study in East Asian (Chinese, Japanese and Korean) suggested that the polymorphism of DRD3 Ser9Gly is not connected to SCZ and Tardive dyskinesia (14). Also, Tee et al. (2001) conducted in their results that DRD3 Ser9Gly polymorphisms and Catechol-O-methyl transferase (COMT) (rs16565) have no significant connection between with SCZ in Malays (15). Furthermore, a study done on Han Chinese population concluded that the polymorphism has no effects on the genetic involvement for SCZ but refers to that variation may play role in exacerbating the symptoms SCZ (16).

Moreover, Talkowski et al.(2006) suggested that the DRD3 Ser9Gly polymorphism has a significant relation with SCZ (17), and Siaz,(2010) reveled that the genetic interaction of SLC6A3 with DRD3, and the DRD2 genetic variations are definitely connected with SCZ (18). Also, Shaikh with his colleagues studied 133 schizophrenic Caucasians patients, and they found that the Ser9/Ser genotype is joined significantly with the allele of DRD3 Ser9 (19).

Conclusion

The present data indicated significant positive association between T102C polymorphism of HTR2A A1804G transition and the genetic sequence of the DRD3, which in turn causes the substitution of a Ser9Gly amino acid in the Iraqi SCZ patients.

Ethical Clearance: A lot of thanks and gratitude to Dr. Mushtaq Talib, a psychologist at Al-Rashad Hospital / Baghdad, for his support for our project and for helping us to obtain the original approvals from the hospital and to collect samples from schizophrenic patients.

Attitude and Knowledge of Medical Negligence among General Population of Ahmedabad City, Gujarat

Mohammed Musaib M. Shaikh¹, Dushyantkumar Barot², Jayjeet Trivedi³, R. S. Bhise⁴
¹Associate Professor, ²Assistant Professor, ³Tutor, ⁴Professor & Head, Department of Forensic Medicine, Dr. M. K Shah Medical College & Research Centre, Ahmedabad Gujarat, India

Abstract

This study explored perspective and knowledge on medical negligence among the general population of Ahmedabad city. 500 people voluntarily participated in the study. People were asked to respond anonymously to a structured questionnaire which dealt with their views, perception, knowledge and attitude towards medical negligence. In the present study, out of 500 participants, 69% were male, 58.4% were aged between 21-40 years & 56.8% were graduate & postgraduate. The majority of people have quite good knowledge about medical negligence, but less knowledge about legal proceedings regarding medical negligence. Educational seminar and awareness programs on this subject may be helpful for them and for medical professionals also.

Keywords: Attitude, Knowledge, Medical Negligence, General Population

Introduction

In ancient Egypt, practice of medicine was subject to legal restrictions. The right to practice was restricted to people of a certain class, and all doctors had to learn and follow the precepts laid down by their predecessors. Obviously, this was the way to protect the public from quackery. If unsatisfactory results followed a course of treatment that had departed from the orthodox, the responsible doctor would be liable to punishment, which could be very harsh. Similar legal restrictions on medical practice were also found in other early civilizations such as Babylon and India¹.

Medical Negligence is defined as absence of reasonable care and skill or willful negligence of medical practitioner in the treatment of patient which cause bodily injury or death of patient². Nowadays allegation & litigation regarding medical negligence is increasing day by day. Many of them may be false allegation & some may be true. But in current situation, attacks on doctors & hospitals in Indian cities are on the increase because of lack of knowledge about medical negligence & its legal proceedings. As medicine is a noble profession but there is also growing anxiety both within the medical profession and in the community regarding increasing trends of complaints and lawsuits against doctors³. Present study was carried out to know perspective and knowledge on medical negligence among general population.

Material and Method

This cross-sectional study was done from January to June 2019. General Population of Ahmedabad City was selected for the study. The study was done with the help of questionnaires specially prepared in vernacular language i.e. Gujarati for the study. After obtaining written informed consent of interested people, questionnaires were given to participants & responses were made anonymously. Incomplete filled forms were excluded from the study. After obtaining the response, some facts of medical negligence regarding the given questionnaires were acquainted and tried to clear their doubts, if any. A total of 500 people participated successfully in the study. The questionnaires consisted of perspective and knowledge of the Medical negligence and legal proceeding regarding medical negligence.
Observation

Questionnaires were distributed among a small group of the general population and obtained a response. A total of 500 respondents successfully participated & included in the study. The data regarding socio demographic characteristics of respondents, response to questionnaire about medical negligence & its legal proceedings obtained, was tabulated and analyzed. The data obtained are shown in Tables 1,2 &3.

(SD = Strongly Disagree, D = Disagree, NS = Not Sure, A = Agree, SA = Strongly Agree)

**Discussion**

There are good numbers of studies available about knowledge, awareness & attitude regarding medical negligence among health care professionals, but very few study available for general population. In the present study, a total of 500 peoples from Ahmedabad city participated, all were aged above 20 years with different educational levels and variable occupational status and quite capable of understanding the subject which we studied. We observed that the knowledge of medical negligence was found to be satisfactory, but the knowledge was poor about legal proceeding regarding medical negligence, our findings are consistent with Parmar P et al & Siddiqui M N.

(A) Knowledge about Medical Negligence

In the present study, 98.4% of respondents agreed upon that, Doctor can be liable for Professional Negligence. But only 59% of people agreed upon that, other hospital staff can also be liable for Negligence, 37.6% respondent disagreed with this.

We observed that 88.2% of people were agreed with that, refusal to admit patients requiring urgent hospitalization is Negligence. 89.8% of people were agreed upon that, if a doctor don’t order proper
investigation according to sign & symptoms is negligence. 88% respondents were agreed upon that Performing any procedure & operation without inform consent is Negligence. It means the general population has sufficient knowledge about the duties of doctors and consent.

All participants were agreed upon that, performing operation on wrong limb is negligence. 69% of respondents knew that, if a doctor does not provide another doctor to a hospitalized patient during his absence is negligence. 71.4% of respondents were of the agreement that giving a premature discharge to a patient who needs further treatment & care is negligence. 75.6% of respondents agreed upon that, failure to inform a patient of the risk of refusal treatment & discharge against medical advice is negligence. It means that peoples are quite aware that, gross absence of skill & absence of due care is negligence.

In present study, 64.8% of respondents were aware that, if disease is not cured after treatment, It is not negligence, but still 32% respondent agreed upon that, if the disease is not cured after treatment, It is negligence. Similarly, 69.8% of respondents knew that if a patient has side effect of prescribed treatment, It is not negligence, but 21.6% of respondents were still believed that if a patient has a side effect of prescribed treatment, it is negligence. The general population is aware of medical maloccurrence, and there is not a 100% guarantee for a cure. But still some people don’t think so; this type of attitude may be harmful to the medical profession.

We observed that 42.8% of respondents were disagreed upon that, a patient without serious Illness die during treatment is negligence, but 51.6% were agreed with this. 49.4% of respondents disagreed that, patient die during Operation, It is always due to negligence, but 48.2% were agreed with this. It means large numbers of people are not aware of the course of illness, risk of operation & anesthetic complications.

B) Knowledge of legal Proceeding regarding medical negligence

In the present study, 99% of respondents were aware that in suspected cases of negligence, you have to file complain in the concerned police station. But 83.6% of respondents were not sure about that, one can file complain in State medical council in a suspected case of negligence.

65.8% respondents were not sure that Medical Board of Government doctors gives a primary report regarding medical negligence, in suspicious case of negligence on requisition of Police.

We observed that 48.2% of participants were agreed upon that postmortem is necessary in case of death due to medical negligence, while 36.8% were disagreed.

78% of Respondents disagreed that Police cannot arrest doctor or lodged FIR without report of medical negligence by medical board in suspicious cases of negligence. We had 14 lawyers in our study, but only 10 participants were agreed on this statement.

Compensation may be given by consumer court for damage due to the negligent act, 73% of participants were agreed with this statement. Still, 27% had no awareness about the consumer protection act.

We observed that 94.6% of participants were agreed upon that death due to the negligence is punishable in court. All participants believed and agreed upon that threaten or attack on a doctor is punishable in court even if doctor is truly negligent.

Overall knowledge about legal proceedings regarding medical negligence was not satisfactory. We have to arrange training sessions & seminars for the general population, lawyers and police.

**Conclusion**

After analyzing the response of participants, we conclude that, the knowledge of medical negligence in context to duties of doctors, consent, gross absence of skill & due care is found to be satisfactory. However, still, there is a false belief about a guaranteed cure and medical malocurrence in some people. We also conclude that knowledge is poor about legal proceedings regarding medical negligence. Medical professionals must obtain informed consent before any procedure and sensitize their patients about medical malocurrence. We have to arrange seminars, awareness programs & training sessions regarding medical negligence & its legal proceedings for the general population, lawyers and police.

Abstract

The social fabric of a population is of utmost importance to know the scenario of HIV/AIDS in that population. This paper highlights vulnerability of women towards the disease based on their socio-economic characteristics. It is a cross-sectional study among the Jaintia tribal women of Meghalaya belonging to the reproductive and vulnerable age group (15-35years). The methods used for data collection are structured interview schedules, participant observation, focussed group discussions and in-depth interviews. The findings revealed that majority of the women are poor and uneducated and as a result, this has an impact on their role and ability to protect them from contracting the disease.

Keywords: social fabric, HIV/AIDS, tribal Jaintia Women, Meghalaya

Introduction

The tribal population is an integral part of India’s social fabric and has the second largest concentration after the African Continent. India accounts for 84 millions of Scheduled Tribes which contributes to about 8% of India’s population and they account for a quarter of the country’s poorest people. Although these groups have seen considerable progress over the years and poverty among tribal groups declined by more than a third between 1983 and 2003 - nearly half the country’s Scheduled Tribe population still remains in poverty, due to their low starting point. A sociological study demands an extensive analysis of the characteristics of the population to be studied. The socio-economic background of an individual plays an important role in acquiring the awareness and the knowledge of the events occurring in society. It also helps in the formation of attitudes, practices and behaviour. The knowledge about the socio-economic profile of the respondents is essential to arrive at the accurate conclusion. Women have different perspective on a particular social problem. Though not wholly and solely, yet responses of the respondents can be explained on the basis of the knowledge of their socio-economic background. It is believed that socio economic condition of any woman can lessen her bargaining power for a safe and healthy physical relation that makes her vulnerable to sexual exploitation. Hence, in order to have a deeper insight into perspective of HIV/AIDS among the tribal Jaintia women of Meghalaya, an attempt has been made to analyse certain important socio-economic variables like age, community, religion, income, occupation, etc.

Methodology

The present cross-sectional study was conducted amongst tribal women of Jaintia Hills, Meghalaya, India, covering East and West Jaintia Hills districts. There are five blocks in both the districts- Thadlaskein, Laskein, Amlarem, Saipung and Khlehriet (Figure 1). For the present study, a total of 20 villages were surveyed covering all five blocks (four villages from each block were randomly selected).
The sample size of 308 was calculated using online sample size calculator http://www.surveysystem.com/sscalc.htm, giving prevalence estimates with 95% confidence level and within 5% confidence interval for a total number of people living with HIV (PLHIV) in Meghalaya, which is 1,541. Structured interview schedules, participant observation and in-depth interviews were used to understand the socio-economic factors related to HIV infection. Data was collected by interacting with the women and building rapport by developing mutual trust with them. This was supplemented with living in the community, participating in their activities and constantly observing what the women actually do in specific situations.

Results

The present study concentrates on the women of Jaintia Hills, Meghalaya. The total number of women (15-35 years of age) under study in East and West Jaintia Hills is 320. Information on socio-demographic profile of the women under study was procured. The data gathered throws light on the background of the respondents.

Demographic Parameters of Women

Geographical Distribution

The geographical distribution of 320 women is represented in Figure 2 (a and b). The present study was conducted covering East and West Jaintia Hills district. There are five blocks in both districts- Thadlaskein, Laskein, Amlarem, Khliehriat and Saipung. From each block 50 women were interviewed except from Thadlaskien as it has a large area, so 120 women were selected from this block.
Community

Community is a group of people living in the same place or having a particular characteristic in common. The major communities under study in Jaintia Hills are Pnar, Biate, Wars and Garo. In the present study, it was observed that majority of the population studied was Pnar (61%) and a small portion belonged to Biate (19%), Wars (14%) and Garo (6%).

· Religion

The present study reveals the religion followed by the women in the study area. Majority of the women were Christian belonging to Scheduled Tribe. Some of the Pnars belong to a religion known as Niamtre. It is the traditional religion in local usage. The word ‘Niam’ means ‘religion’ and ‘tre’ means ‘origin’. Thus, the people who follow the original religion are called ‘Niamtre’. However, over the years a number of the respondents have adopted other religions like Hinduism (16%) and Christianity (49%). At the same time, a significant number of Niamtre (35%) remains and continue the practices of associated rituals and religious practices. The traditional religion does not have any written script, it is based mostly on oral tradition. (Fig. 3)

![Figure 3: Percentage distribution of the religion of the respondents](image)

Age of the respondents is one of the essential features in understanding their perspectives about the specific issue; by and large, age demonstrates the level of development of the people. The broad age group of 15-35 years has been classified into 4 age groups – 15-20 years, 21-25 years, 26-30 years and 31-35 years in order to maintain homogeneity in the age intervals. In view of high prevalence of HIV infection among the women in reproductive and sexual active group and availability of limited information on HIV particularly among the youth population, especially in women, the present study focused on the young women belonging to the age group 15-35 years. The percentage of women in the age group 15-20 years, 21-25 years, 26-30 years and 31-35 years is 16%, 22%, 25% and 37% respectively.

· Education

Education has been distinguished as a conventional social vaccine against contracting HIV, resulting in the more educated less likely to be infected i.e. higher education level is associated with lower level of HIV/AIDS. In the present study, the data shows that there are no respondents with secondary and higher secondary level of education. 33% of the respondents have primary education and 26% of them have middle school education.

![Figure 4: Percentage distribution of education of the respondents](image)

Occupation is an important variable that has direct relation with HIV/AIDS. It has been established that some occupations are called high risk occupations because individuals working in them are more vulnerable to HIV e.g. female sex work, wives of truck drivers, wives of IDUs, etc. The data shows that most of the respondents are engaged in agriculture for a living (66%). Out of 320 respondents, 20% are vendors, 7% are housewives and depend on their families, 5% are health service providers working in the civil hospital, Jowai and 2% are sex workers (Figure 5).
Economic status

Income of a person is an important variable to analyse the socio-economic status of a person. It enables a person to access to good education, maintain good health and provide good future to the children. Lack of income has been found to be related to poor health. The relation between HIV and income is very complex. A number of researcher reported that higher rates of infection are expected among poor. The figure 6 shows that the majority of the women under study belong to the low-income category, i.e., a monthly family income less than Rs. 5000 (n = 320; 56%). Out of the total 320 respondents, 115 respondents (36 %) belong to the category of monthly family income between Rs. 5000 – Rs. 10,000. Another 8 % (n=320) respondent belongs to the category with a monthly family income above Rs. 10,000.

Place of residence

Place of residence plays an important role in creating awareness regarding HIV/AIDS and with regard to treatment. The present findings show that 71% of the respondents belong to the rural areas and 29% belong to the urban areas (n=320). In the rural areas, HIV prevalence is low because of less risky sexual behaviour as compared to urban areas with availability of commercial sex, opportunities for casual sex, and less restriction with regard to sexual relationships. But the virus has moved from urban to rural areas and from high risk to general population, disproportionately affecting women and the youth.

Age at menarche

In both social and medical perspectives, age at menarche is considered as the central event of female puberty, as it signals the possibility of fertility. And with fertility, comes the vulnerability of the respondents towards HIV/AIDS. In the present study, the age at menarche of the women varies from 12 years of age to 15 years of age.

Marital Status

The Jaintias have a unique marriage system. A Jaintia house belongs to a woman and after marriage she stays in her house to be visited by her husband only at night time and this practice continues to remain so long the marriage bond exists. This system is called “Visit Marriage”. The mother has total control of her sons so much so that they belong to her even after their marriage. In the present study, it was noticed that in Jowai among the Niamtres, some of them still follow the traditional ‘night visit’ system, that is, the husbands stayed and ate in their mother’s house while they were sleeping in their wives’ house at night. However, the husbands were found not to share any of their earnings with their wives. The traditional night visit system of marriage was more frequent among the Hindus in Nartiang. It was observed that majority of the Hindus and the Niamtres, both in rural as well as in urban areas followed the night visit system of marriage.

The present study revealed that out of 320 Jaintia women, 19.7 percent married more than once. Higher percentage of women was found to get married more than once in the rural areas (26.2 percent) as compared to that of the urban area (13.0 percent). In the rural areas the percentage of women married more than once
was found to be the highest among the Niamtres (30.2 percent), followed by the Christians (24.4 percent) and the lowest among the Hindus (23.7 percent). However, there was a woman belonging to Hindu religion who was found to get married even seven times. The percentage of women getting married for four times was also found to be the highest among the Hindus. In the urban area women married more than once was found to be higher among the Niamtres (15.5 percent) as compared to that of the Christians (11.2 percent). The various reasons for women marrying more than once were (i) widowhood, (ii) divorce/separation. The reasons for divorce or separation were (a) the husband was drunkard, (b) no child from previous husband/s, (c) no female child from previous husband/s, (d) women fallen in love with another person, (e) husband not helping financially.

The focused group discussions (FGDs) carried out at community/village levels showed that poverty was the most important factor that had an impact on HIV/AIDS infection among the women of Jaintia Hills. Many of the poor young women in the study area were found to having multiple sexual partners as this was the only means of earning a livelihood and maintaining the family. In these situations they become vulnerable to HIV/AIDS not only because they had multiple sex partners but also because they were unable to bargain for safe sex with their partner. Some of the girls were being forced to have multiple sex partners in exchange for money by stepfather/stepmother. Some were sexually abused (more than one time) and then they started having multiple sex partners. There were no Antiretroviral treatment (ART) centre in Jaintia Hills, so, the patients need to go for the treatment to the Shillong Civil Hospital or NEIGRIHMS. The poor had less access to health care and therefore, most of the HIV cases remain unregistered at ART centre and untreated, resulting in further spread of infection. The perceived HIV/AIDS-related problems included malicious spread of HIV/AIDS by some infected people.

Discussion

Worldwide the large proportions of all new HIV infections occur in people under age 35 years. There are approximately four million young women aged 15 to 35 living with HIV globally. The multiple transitions (i.e., biological, psychological) and developmental tasks (e.g., establishing identity) in this period of lifespan of young adults could be the reason for increased risk for HIV. Similarly, in the present study it was found that females belonging to the age group 15-35 years are more likely to be infected with the disease. In a study in Sub-Saharan Africa, it was reported that young women aged 15-24 years have HIV rates higher than their male peers and they acquire HIV infection 5-7 years earlier than their male peers. This gender inequality among HIV prevalence has been reported from the beginning of the HIV epidemic, and partly correlated with biological differences and social inequalities. Their limited access to education and employment status force them to accept situations that put them at risk for contracting sexual infectious diseases especially HIV/AIDS. Other parameters known for contributing to the increased risk of HIV infection includes lack of knowledge and in the present study it can be indicated by rural locality, where young women are not much exposed to larger social networks which may not have led to greater exposure towards the information about sexual health and HIV prevention services, thereby increasing the HIV risk. Previous studies also show that people in rural areas are more susceptible to be affected with HIV. Although, statistically non-significant but most of the women were illiterate or low educated in the study. These findings are consistent with other studies that higher educated women are more knowledgeable yet there is still knowledge deficiencies among the females located in rural areas, however, sometimes the knowledge is not reflected in the sexual behaviors of educated women. Another study also highlighted high level of ignorance about important preventive measure in the sexually active young population in rural areas. A number of socio-economic problems and inequality to health care access are other factors that contribute to the infection among women. Several studies indicate that gaps exist between HIV knowledge and practices regardless of gender, place of residence, education level and socioeconomic status.

Abstract
Epilepsy is a serious disorder of the brain, affects almost fifty million people in the world. About 40% of the patients finally became refractory to epileptic drugs, especially those with temporal lobe epilepsy (TLE). This refractory condition may cause psychosocial decline, including patient’s intelligence. Surgical therapy has an important role in stopping further damage to brain cells caused by repeated seizures. The elimination of the seizure after surgery will hopefully results in better intelligence score. This study aims to find out the effect of surgical therapy in TLE patients after surgery. We were using a Quasi Experimental study with One Group Pre-test and Post-test design. The samples were taken with consecutive sampling method. Subjects were 15 TLE patients who underwent anterior temporal lobectomy and have passed at least one year postoperative period, and also had done an intelligence quotient (IQ) test before surgery. IQ before and after surgery were measured with WAIS and WISC-R method. The statistical tests used were paired t-test. We found the verbal IQ after surgery(98.8±9.88(76-119)) were significantly higher(p=0.01) compared with preoperative verbal IQ(92.7±9.60(77-113)). On the other hand, performance IQ after surgery (98.2±8.64(82-115)) were higher compared with preoperative performance IQ (96.0±9.39(75-116)) but it was not significant (p=0.5). Total IQ after surgery (97.8 ±7.69(81-107)) also higher compared with preoperative total IQ (93.9±9.28(75-115)) but also not significant (p=0.08). Postoperative verbal IQ improvement was found compared with preoperative verbal IQ.

Keywords: IQ, epilepsy, epilepsy surgery

Introduction
Epilepsy is the most frequent serious brain disorder that affects almost fifty million people all over the world. [1] Report from WHO shows the prevalence is 1% of total population in the world, equal value with breast cancer in woman and prostate cancer in man.[2] The incidence rate of epilepsy is still high, especially in developing country, reaching 114 cases in every 100,000 population each year.[3] With its known incidence rate, Indonesia with 220 million in total population has about 250,000 new epilepsy cases each year. Related to the age, the prevalence chart shows bimodal pattern, getting higher in pediatric then come down in early and middle adult, and then rising again in the elderly.[4,5]

Almost 30 to 40 percent of all epilepsy patients will become immune to anti-epilepsy drugs (AED) called refractory epilepsy.[6,7] Complex partial epilepsy is a bulk of this kind of refractory epilepsy.[8,9] In complex partial epilepsy, the epileptic focus mostly located in the side part of the brain. Precisely, it is located in hippocampus area and amygdala body which sometimes involving brain surface area of temporal lobe as well.[8,10]

In every single epileptic spell, brain cells injury or even death will occur. Therefore, when the spell frequently occurs, there will be weakening or death of brain cells, hence, will result in severe declining of intelligence ability.[10-12]

Intelligence has been defined by Wechsler as the aggregate or global capacity of the individual to act
purposefully, to think rationally and to deal effectively with his environment.\textsuperscript{[13]} In general, intelligence is divided into three categories, which are practical ability for problem solving, verbal ability and social competence. Whereas Intelligence Quotient (IQ) is an intelligence score derived from a comparison between mental age and chronology age then multiply by 100.\textsuperscript{[14]}

Since 1999 epilepsy surgery has been performed in Indonesia with terrific post-operative results of seizure attack rate. However, there is no research to date have been conducted that review about the improvement of intelligence ability in post epilepsy surgery patients in Indonesia. This research is conducted to know the possible effect of epilepsy surgery on their intelligence ability, by comparing on their IQ before and after epilepsy surgery.

\textbf{Material and Method}

This research was conducted during March and June 2012 in dr. Kariadi General Public Hospital, Semarang, Central Java of Indonesia. It is Quasi-experimental study one group pre-test and post-test design. The independent variable in this research is epilepsy surgery, whereas dependent variable is IQ.

The target population is the epilepsy patients who had had an epilepsy surgery and already passed a year-time period after operation. Inclusion criteria consist of: a) be declared as temporal lobe epilepsy patient based on preceding clinical examination (EEG, MRI and semiology), b) The patient has the result of IQ examination before surgery. The exclusion criteria: a) Patient who does not have IQ examination before surgery, b) Patient or family refuses to take part in this research, and c) Based on the medical record, there was another abnormality diagnosed which could affect the cognitive function, such as mental disorder. All procedures performed in studies involving human participants were in accordance with the ethical standards of the Medical Faculty, Diponegoro University and Kariadi Hospital ethical committee and with the 1964 Helsinki declaration standards.

Consecutive sampling was used as the sampling method and successfully obtained 15 patients who meet with the criteria. IQ before surgery was collected from medical report whereas IQ after surgery was obtained from the direct test. Paired t-test was used for statistical analysis.

IQ examination after surgery was supervised by the same psychologist who also supervised IQ examination before surgery. The examination was taken place in the installation of Medical Rehabilitation of dr. Kariadi General Public Hospital. IQ was measured by using WAIS method (Wechsler Adult Intelligence Scale) and WISC-R (Wechsler Intelligence Scale for Children) after informed consent was taken.

*Pairet-test: before and after surgery

From the table 1, more than half of sample is male (66.7%). The average age of IQ examination when was taken is 24.3±7.17 with the youngest age is 17 years old and the eldest one is 41 of age. Based on the age of the first experience of epilepsy seizure, the average is 14.0±7.13 years old with the youngest age is two years old and 30 years old is the eldest. Duration of having epilepsy is 7.7±4.70 years with the shortest period is one year and the longest one is 16 years. The time distance between surgery and post-surgery IQ examination is 41.6±29.7 months of average. The shortest is 12 months and 93 months for the longest one. Regarding the surgery side, mostly it is in the non-dominant side (66.7%). Almost in all samples became free of epilepsy seizure state (86.7%). IQ comparison between before and after epilepsy surgery shows in table 2.

From the table 2, verbal IQ after epilepsy surgery shows a better outcome than before surgery and it is statistically significant (p=0.01) (figure 1). The another component of IQ, the performance IQ also shows higher outcome after epilepsy surgery than performance IQ before surgery, however, it is not statistically significant (p=0.5) (figure 2). A better outcome is also found in total IQ after surgery than before surgery although it is not worth statistically (p=0.08) (figure 3).
We found all of IQ components after epilepsy surgery were higher than before surgery. However, it was merely one of IQ component, the verbal IQ that showed an escalation and had significant statistical value. This outcome can be related with part of the brain where the damages occurred. It is in the temporal lobe, part of the brain that has responsibility for language ability, therefore, any manipulation in this part will be affecting on verbal IQ.\cite{15} The performance IQ is slightly affected by the surgery even showing an increased outcome. Total IQ which was a merge result of both verbal and performance IQ showed an increased outcome although not statistically significant.

A research by Anderson, et al. studying the correlation between intelligentsia and brain structure concluded that there is a significant correlation between verbal IQ and total IQ with the volume of temporal lobe both in the right and left side, and also with hippocampus structure. However, no significant correlation found with performance IQ.\cite{15} Their result definitively supports our research and possibly underlies the mechanism of how the verbal IQ increases after epilepsy surgery.

The weakness of this research was not to consider the anti-epileptic drugs. There are some samples who still consume AEDs routinely. In the other hand, several samples have already stopped the AEDs completely. This weakness possibly could affect the IQ examination outcome because AEDs also could influence the cognitive function.

Our research also found a limitation of the total of sample. Not only caused by the time limit but also, our research was conducted only in one center. When the research is conducted multicenter by using cohort method, the obtained sample will be greater in quantity.

Allegedly, one of the factors that possibly affect the increase of IQ in post-surgery epilepsy patient was external stimulation, both by the family and closest friends even from medical practitioners. In the future, we expect the management of epilepsy patient not only stopped after the surgery but also involve proper stimulation therapy for helping stimulation of brain cells activity. Moreover, the doctor has to encourage their family members who have undergone surgery to frequently give stimulation to the patient for increasing the intelligentsia.

IQ of temporal lobe epilepsy patient is increased after epilepsy surgery. This outcome is pointed out from the escalation of verbal IQ after surgery that statistically significant, compared with verbal IQ before surgery. An increase of performance and total IQ are also found, however, they are not statistically significant.

Relationship Between Farmers Weaknesses About Knowledge of Formulation and Feed Technology on Feed Conversion in Alabio Ducks

Muhammad Aftabuddin Rijaluzzaman1, Pudji Srianto2, Chairul Anwar Nidom2, Rini Fajarwati3

1Doctoral Student, Faculty of Veterinary Medicine, Universitas Airlangga, Surabaya, 60115, Indonesia, 2Professor, Faculty of Veterinary Medicine, Universitas Airlangga, Surabaya, 60115, Indonesia, 3Staff, Plantation and Animal Husbandry Agency, Banjar Baru, 70714, Indonesia

Abstract

The study aims to determine and analyze the relationship between breeders’ knowledge about feed formulations and the conversion value of duck feed. The subjects in this study were Alabio duck breeders in Hambuku Raya Village and Putat Atas Village, Hulu Sungai Utara, South Kalimantan Province, Indonesia with observed objects in the form of Alabio duck feed conversion and breeders’ knowledge of feed formulation knowledge and Alabio duck feed technology. The research method used was non-experimental explorative, the researcher did not give treatment to the group of Alabio ducks and conducted a survey by distributing questionnaires to farmers. Observation of feed conversion is carried out for 3 (three) months from February-April 2018 in each group. Observation of feed conversion is carried out starting from Alabio ducks to produce eggs, which are about 6 months old. Testing of feed conversion, normal data using analysis of variance (Anova), if significant continued with LSD. Survey research is the stage of analyzing using SWOT analysis to determine the level of weakness and strength in the framework of the development of Alabio ducks in the Hulu Sungai Utara Regency of South Kalimantan Province. The results of the analysis of feed conversion of the three groups were not significantly different, the group of Putat Atas Ducks for feed conversion an average of 4.51 ducks Hambuku Raya 1 group an average of feed conversion every month 5.30, the ducks of the Hambuku Raya 2 group the average conversion of feed every month 4.75. SWOT analysis value of weakness factor is 1,764, this factor includes one of them is knowledge of farmers about feed formulation. The results of this study are in line with the results of feed conversion in the first stage of research, the value of feed conversion obtained is still relatively high at 4.51-5.30. The conclusion is the SWOT analysis score of weakness factors one of which is the lack of knowledge of farmers about formulation and feed technology affect the high feed conversion.

Keywords: Alabio duck, feed conversion, SWOT analysis

Introduction

Animal husbandry is one of the agricultural sub-sectors that has great potential to be developed because it provides a large enough contribution to the Indonesian agricultural sector. Laying ducks are waterfowl raised specifically to produce eggs. Increased economy and public awareness about the need for animal protein has resulted in an increase in the need for eggs and meat. One effort to meet the needs of animal protein in the community is the livestock business[1]. Sulaiman and Rahmatullah states that in general Alabio duck eggs are very popular, especially for the people of South Kalimantan, who value duck eggs more than chicken eggs[2].

The maintenance of Alabio ducks has a bright prospect along with increasing population and increasing public awareness of the consumption of animal protein from livestock, supported by adequate human resource capabilities[1,2]. Efforts to develop Alabio ducks on an agribusiness scale have promising opportunities and prospects, this is shown by the results of egg sales in the Alabio duck, Hulu Sungai Utara Regency market and increasing consumer demand.
The success of the Alabio duck farm is one of them is the feed factor that meets the quality and quantity requirements. Farmers can use quality feed at a lower price, so the Duck business can provide more appropriate benefits for the business carried out. The high cost of feed is often an obstacle for breeders in fulfilling duck nutrition.

The nutritional needs of ducks that are maintained based on this need an effort to provide technology that is suitable to the needs of farmers at low prices through the utilization of the potential of local feed. Technology is generally defined as ways to carry out the process of activities that produce results or products. Technology is one of the main means to achieve the goals of effectiveness, efficiency and high productivity of business[3].

Feed technology does not only include preservation, but all technologies ranging from the provision of feed ingredients to rations given to livestock[3]. The study aims to determine and analyze the relationship between breeders’ knowledge about feed formulations and the conversion value of duck feed..

**Materials and Methods**

**Object of research**

Subjects in this study were Alabio ducks breeders from the Usaha Maju, Putat Atas Village group, and Maju Bersama, Hambuku Raya Village group, Hulu Sungai Utara, South Kalimantan Province with the object observed were conversion of Alabio duck feed and breeder knowledge about formulation knowledge Alabio ducks and feed technology.

**Research Methods**

The research method used was non-experimental explorative, the researcher did not give treatment to the group of Alabio ducks and conducted a survey by distributing questionnaires to farmers.

**Breeder Profile**

The group of ducks that assisted the research was a group of livestock fostered by the Plantation and Animal Husbandry Office of South Kalimantan Province, located in Hulu Sungai Utara Regency. The herd has been educated and experienced in the field, and has long maintained Alabio ducks.

**Population and Sample**

The population in this study are people who are aware of the development of Alabio ducks in Putat Atas, and Hambuku Raya, Sungai Pandan District, Hulu Sungai Utara Regency. The sampling technique uses Purposive Technique where the deliberate sampling is mainly in determining expert respondents at least 5 people consisting of practitioners namely breeders who have long been breeding the Alabio Duck.

**Research Location Determination Techniques**

The technique of determining the location of the study was determined intentionally, namely in Alabio Duck Farm, a member of the business group Advanced Village Putat Atas, and the Advanced group Together Hambuku Raya Village Sungai Pandan District, Hulu Sungai Utara Regency, South Kalimantan Province. For certain considerations, among others, herds in Sungai Pandan District are herds that are in the central nurseries of Alabio ducks and breeders in the location meet the criteria of the variable studied.

**Observation of Feed Conversion**

Observation of feed conversion is carried out for 3 (three) months from February-April 2018 in each group. Observation of feed conversion is carried out starting from Alabio ducks to produce eggs, which are about 6 months old. Observation of feed conversion is carried out in each flock and recorded every day how much leftover feed is left each day, and recorded every week and every month for 12 weeks.

Hidanah et al. stated that the remaining feed consumption of each treatment unit during the last week of the study was weighed to be calculated on average so that the average consumption data per day per duck was obtained in grams. Feed conversion ratio (FCR) is calculated by dividing the consumption of feed spent in one week (g) with egg production obtained during the week (g). Feed conversion starts from the fourth week after stable egg production[4].

**Data analysis**

Testing of feed conversion, normal data using analysis of variance (Anova), if significant continued with LSD. If the data are not normal then the Kruskal Wallis test is used, if significant it is continued with the Wilcoxon-man whitney test. The test results are significant if P values <0.05 are obtained.
The data obtained were processed and analyzed using the SWOT analysis method\[^5\]. There are three analysis stages namely data collection, analysis phase and decision making stage.

a. Data Collection Stages, namely the classification and pre-analysis stages. At this stage the Internal Strategic Factors Analysis Summary (IFAS) matrix and the External Strategic Factors Analysis Summary (EFAS) matrix are used.

b. The analysis phase (process), this stage, internal and external factors are included in the SWOT matrix model, space analysis matrix, internal-external matrix (IE), space analysis matrix and grand strategy matrix.

c. The decision making stage is determining the alternative priority list for duck development using the QSPM (Quantitative Strategic Planning Matrix) matrix.

**Results**

**Feed Conversion**

Duck group (Putat Atas) feed conversion an average of 4.51, duck group (Hambuku Raya 1) average feed conversion every month 5.30, duck group (Hambuku Raya 2) average feed conversion every month 4.75. p-value = 0.000 > 0.05 so that it can be concluded that there is a significant difference in the average conversion based on the three groups of ducks.

**SWOT Analysis**

The weighting of each internal and external factor is supported by Expert Choice 11 and Microsoft Excel programs, followed by an analysis of internal strategy factors (IFAS) and external strategy factors (EFAS), internal-external matrix analysis (IE), space matrix analysis and decision making stages refer to Yunia\[^6\].

In the preparation of the business plan for Alabio duck breeding in Hulu Sungai Utara Regency, South Kalimantan Province, the steps being referred to are the compilation of strengths, weaknesses, opportunities and threats, weighting and rating on each factor on a scale of four (very strong) up to one (very weak) and four (very strong) times the weights with ratings with values from one to four and scoring.

<table>
<thead>

</tbody>
</table>

**Information:**

1. Strengths include aspects of geographical conditions, availability of seeds, facilities and infrastructure, experienced breeders, farmers joining the livestock group under the guidance of the relevant Dinas, and availability of feed.

2. Weaknesses include aspects, namely limited capital and knowledge of farmers about the nutritional content of animal feed.

3. Opportunities include aspects, namely increasing the power consumption of eggs in the community, developing market demand, the existence of funding from banks.

4. Threats include fluctuations in the price of feed and products from outside entering the local market.

**Discussion**

The results of this study still have high feed conversion values, although these results are slightly lower compared to the opinions of Suswoyo and Rosidi, who reported that the conversion of laying duck feed production periods ranged from 5.84±1.55\[^7\]. When compared with the conversion of laying commercial chicken feed, the conversion of feed in ducks is much worse.

Feed conversion of laying hens between 2.11-2.90\[^8\]. Poor conversion of duck feed is caused by the
eating habits of ducks, including the habit of immediately looking for drinking water after eating. Generally the feed is always scattered/discarded when the duck is moved from the feed to the drinking place or also dissolved in the duck while drinking. Poor feed conversion may also be caused by the inability of ducks to control the amount of feed consumption that is regulated by the amount of energy consumption as can be done by chickens\textsuperscript{[7]}.

Strategy formulation based on the identification of internal and external environment, can be known strengths, weaknesses, opportunities and threats for the company. SWOT analysis can be used to find out what strategies should be implemented by Alabio duck breeding in SouthKalimantan in utilizing market opportunities through analysis of internal and external factors that affect the business of Alabio duck breeding in South Kalimantan.

After the SWOT analysis is carried out, a plan for developing the operational functions of the Alabio South Kalimantan duck business operations will be formulated based on the diagram and table above based on the SWOT calculation. Alabio South Kalimantan duck farms with a S < O score, which is a greater chance than the existing strength, where the direction of the Alabio duck breeding in South Kalimantan is in a stable growth strategy.

The SWOT analysis results obtained positive internal and external factors, meaning that the strength of the Alabio duck breeding in South Kalimantan is relatively superior compared to its weaknesses, while the environmental opportunities currently faced are greater than the threats. The results mentioned above can make, Alabio duck breeding in South Kalimantan have the ability to change the potential into a better yield. The right policy direction for Alabio duck farms in South Kalimantan Province is to increase and enlarge production activities in accordance with their capabilities while expanding their participation in order to take advantage of various opportunities.

SWOT analysis value of weakness factor is 1.764, this factor includes one of them is knowledge of farmers about formulation and feed technology which has a high effect on the high feed conversion.

**Conclusion**

Is sum, one of the SWOT analysis scores from the weakness factor is the lack of knowledge of breeders about formulation and feed technology which has a high effect on the high feed conversion.

Scores Consumption of Functional Foods based on Local Foods in Pregnant Women Buginese in the city of Makassar

Mustamin1, Sirajuddin1,2, Tapriadi3

1Associate Professor in Nutrition and Dietetic Department of Health Polytechnic of Makassar, Indonesia, 2Program Doctor of Public Health Hasanuddin University, Indonesia, 3Associate professor in Nutrition and Dietetic Department of Health Polytechnic of Malang, Indonesia

Abstract

Background Recent evidence is known that functional foods are foods that provide the latest prospects for preventing nutritional problems not only because of their macro and micro nutrient content but their bioactive components that have an effect on the methylation process at the cellular level.

Objective: the purpose of this study was to determine the consumption of functional foods based on local foods in pregnant women in Makassar City

Method: A cross sectional study design. The sample size was 647 pregnant women taken from 41 Puskesmas in Makassar City, except the Sangarrang Kepulauan Puskesmas. Functional food intake was collected using the FFQ method, Macro and micro nutrient intake with Food recall 2 x 24 hours. The data collection enumerators were 21 graduates from Nutrition III / IV graduates. Enumerators are trained for two days.

Results: showed that functional foods consumed by pregnant women based on local foods are sources of fiber, probiotics, Vitamin C, carotenoids, omega 3/9 and folifenol respectively (39.03 ± 36.78), (21.15 ± 7.74), (38.44 ± 30.9), (90.04 ± 50.53), (83.42 ± 60.42) and 166.57 ± 92.66). Conclusion: is that consumption of functional foods based on local foods in pregnant women is good.

Keywords: Score Consumption of Functional Foods, Pregnant Women

Introduction

The most serious nutritional problem in Indonesia is stunting. National stunting prevalence is 36% and South Sulawesi reaches 30.8%1. The impact caused by stunting is low academic potential, high risk of non-communicable diseases, high cost burden on health services and low productivity. Stunting problems must be prevented, because the incidence of stunting from birth is difficult to treat. Prevention of stunting starts from the preconception. This means that starting from pre-pregnancy and pregnancy2,3,4.

Prevention of stunting is most appropriate through the consumption of food with sufficient quality and quantity. Problems faced to meet the quality and quantity of food according to nutritional needs are income, preferences, availability and knowledge of nutrition5,6,7,8.

The fact of the income of the population of Indonesia, South Sulawesi, and Makassar City has an increasing tendency. The availability of local food varies considerably between regions and production centers both in villages and in cities. A change to the diversity of food from local food to fast food. There is a gap between supporting food potential and the emergence of serious nutritional problems in Indonesia, South Sulawesi and Makassar City. The clearest solution is to ensure that pregnant women consume enough food according to their nutritional needs.9,10 The most potential food to be developed is functional food based on local

food, because this intervention is sustainable and has a real impact on improving the health status of mothers and fetuses.\textsuperscript{11,12} The research question is how much the potential for functional food on local food, for pregnant. The objective of this study is to identify scores consumption of functional foods based on local food, for pregnant in the city of Makassar, Indonesia

**Method**

The study design was a cross sectional study approach. The sample is pregnant women in the city of Makassar. Sample size was 647 people by random sampling selected. The sample frame was taken from a cohort of pregnant women available at data base on center of Public Health Offices Biringkanaya Subdistric of Makassar Indonesia. Data collectors by dietisien had been training during 16 hours. Instrument used to Food Frequency Questionaire (FFQ) had been standardized the reliability and validity based on Buginese Ethnicity.

Data of functional food consumption was collected used the FFQ method. The scores of functional foods based on local foods are analyzed for their antioxidant activities. Quality control of data collection by supervisor visiting for all enumerators. Data processing is done by SPSS application, and data analysed by frequency distribution. The study was approved by the Institution Review Board of Health Polytehnic of Makassar and South Sulawesi Province Licensing Service No:18414/s01/PTSP/2019. We obtained written inform consent from the subject.

Based on the results of data analysis, it is known that the highest score of functional food consumption in pregnant women is the source material of polyphenols, carotenoids (90.04 ± 50.34) and Omega 3 + omega 9 (83.42 ± 60.56).

Based on the survey results it is known that the categories of micronutrient intake of Fe, Zinc, Vitamin C and Vitamin A are in the 57.34%, 92.27%, 92.27 and 93.5% categories respectively. This proves that there is still attention to the adequacy of iron sources.

**Discussion**

This survey is intended to describe the consumption of functional food in pregnant women in Makassar City. The results are known that pregnant women have consumed functional foods based on local foods appropriately and this is evidence that the potential of local foods can be increased to support the improvement of nutrition of pregnant women. Functional food has the advantage in containing a very rich source of non-nutritional substances as antioxidants. Consumption of probiotics, symbiotics and probiotics in pregnant women in Makassar is an average of 21.15 ± 7.71 point scores. This is equivalent to consumption of almost four days a week consuming sources of probiotics. A point score of 5 means consuming a source of probiotics once a week so with a score of 21 it is estimated to consume 4 days a week.

Consumption of fiber sources is reaching a value of 39.03 ± 36.78 is included in the category quite good, because every day must consume a source of fiber as a functional food based on local food. Consumption of Vitamin C sources is 38.44 ± 30.96 which means that every day pregnant women consume foods that contain vitamin C sources. Consumption of Omega 3 and Omega 9 sources is very high, reaching 83.42 ± 60.56 which means this that in a week already every day consume sources of omega 3 and omega 9. This generally comes from sea fish. Food consumption of polyphenol sources is the highest among all other food ingredients. This consumption reached 166.57 ± 92.66 point scores.

There is a gap between supporting food potential and the emergence of serious nutritional problems in Indonesia, South Sulawesi and Makassar City. Which way out most obvious is to ensure that pregnant women consume enough food according to nutritional needs and ensure consumption of baby food during the first 1000 days of life.\textsuperscript{8} The most potential food to be developed
is functional food based on local food, because this intervention is sustainable and has a real impact on improving the health status of mothers and children. The results of research on literature reviews conducted in America and Europe provide general guidelines about the causal relationship between food provided and health benefits. Nonetheless, they need to broaden the depth and scope of the guidelines given to companies that want to prove their claims and to provide precise information about functional foods.13

The fiber component consumed by each subject is multi-functional. In research it has been proven that pregnant women consume local food-based analytical functions, one of which is because it is a source of fiber. The emergence of a growing understanding of the structure and function of food fiber, discussed about the concept of resistance to the action of human digestive enzymes. He also said that it is not only carbohydrates (cellulose, hemicellulose, pectin etc.) which are the main components, but lignin which is a type of non-carbohydrate is also included in dietary fiber. The Canadian Ministry of Health (1988) published “Safety Guidelines and Physiological Effects of Fiber Sources and Food Products” and included non-starch polysaccharides from plants as a source of new fiber. Because it’s mentioned that novelty is a source of meaningful fiber. It was only in 2001 when the Institute of Medicine (IOM) expanded the scope of the definition to even isolate and synthesize carbohydrates by categorizing them into three parts namely food fiber, functional fiber and total food fiber (IOM, 2005). In 2009, Codex categorized the definition into three parts, firstly referring to naturally edible carbohydrates, secondly obtained from food raw materials with physical, chemical or enzymatic care and the third including those synthesized artificially.14

Probiotics have significant benefits in improving maternal health. Improving the health status of pregnant women significantly increases the quality of pregnancy and pregnancy output such as the baby’s lag weight and baby’s height status. This is certainly related to efforts to improve the nutritional status of mothers and children. Scientific evidence has been found that fiber and probiotics can prevent damage to epithelial cells during an infection. Improved digestive function and immune system. So it can be believed that mothers who have a source of fiber and probiotic consumption in this research have had direct benefits for themselves and their fetuses.15, used probiotics to prevent diarrhea in all age groups.16. Based on the great benefits of fiber and probiotics, in the food industry the value of probiotics and fiber have become items of concern to producers and consumers alike, including pregnant women.16

Conclusion

The highest consumption of functional foods based on local food is the source of polyphenols.

Ethical Clearance: This study approved ethical clearance from the Committee of Research Ethics of Health Polytechnic of Makassar, Indonesia. Activity of Ethyl Acetate Fraction of *Merremia mammosa* Hall as Anti-Influenza A (H1N1)

Neny Purwitasari¹, Mangestuti Agil², Herra Studiawan³

¹Lecturer and Researcher; ²Professor; ³Lecturer and Researcher; Department of Pharmacognosy and Phytochemistry, Faculty of Pharmacy, Universitas Airlangga, Surabaya, Indonesia

Abstract

The outbreak of influenza A viruses (H1N1 and H5N1) has raised a global concern on the future risk of a pandemic. Oseltamivir, the current neuraminidase inhibitor, could not meet the demand if there is a major outbreak. Thus, there is a need to find alternative treatment for influenza A, especially from natural herbs. The objectives of this study were to determine antiviral influenza A activities of *Merremia mammosa* Hall against influenza A H1N1. People in Madura island, Indonesia used this rhizome to cure tuberculosis. In this research, *Merremia mammosa* Hall rhizome was extracted gradually using n-hexane to remove the non-polar compound. The residue was extracted using ethyl acetate to obtain semi-polar extract. The ethyl acetate fraction of *Merremia mammosa* Hall was subjected to *in vitro* antiviral assay against influenza A (H1N1) virus using Hemagglutinin Assay. This is a method for titering influenza viruses based their ability to attach molecules present on the surface of chicken red blood cell. The virus was incubated in embryonated chicken eggs and treated by ethyl acetate fraction of *M. mammosa* for 3 x 24 hours. Allantoic fluid was harvested and subjected on hemagglutinin assay to measure the titre of virus after treated with the fraction. The ethyl acetate extract of *Merremia mammosa* Hall can reduce the titer of hemagglutinin virus by 97.39% at concentration 1000 µg/mL. In conclusion, *Merremia mammosa* Hall has the potential to be developed as agent of antiinfluenza A infection.

**Keywords:** *Merremia mammosa* Hall, influenza A, H1N1.

Introduction

As 1st August 2010, there were over then 18,449 deaths in more than 214 countries that have reported laboratory confirmed cases of pandemic influenza H1N1 2009, for the period of April 2009 to August 2010. However, WHO stated that the total death (including unreported deaths) from the H1N1 strain was actually higher[¹]. In fact, Dawood reported that the estimate global deaths associated with H1N1 pandemic 2009 influenza were 15 times higher, which were 284,400 deaths[²].

The existed vaccines against seasonal influenza virus to control this disease have been ineffective due to its rapid variable mutation. In the period of pandemic, vaccine supplies would not be adequate[³]. Thus, the development of effective and safe anti-influenza becomes a matter of certainty in drug discovery[⁴]. People in Madura island, Indonesia used the tuber of *Merremia mammosa* (Convolvulaceae) to treat tuberculosis infection *Merremia mammosa* is one Indonesian folk medicine use as treatment of cough and sorethroat[⁵].

However, there is still limited of scientific data can be found about this plant. The chemical component of this plant are Mammoside A and B[⁶]. This plant also contain polyphenol, triterpenoid, terpenoid, and flavonoid[⁷]. It has reported that this plant has pharmacological activity as anti-HIV. *Merremia peltata*, another plant from the same family, has antimicrobial activity and anti-HIV activity by inhibiting HIV-1 reverse transcriptase and gp120-CD4 binding *in vitro*[⁸]. Thus, the objectives of this study were to determine the neuraminidase inhibition (curative) and hemagglutinin inhibition (preventive) influenza A antiviral activities of the tuber of *Merremia mammosa* Hall against influenza A H1N1.
Materials and Method

Chemicals and Reagents

In this study, the solvents used were methanol, n-hexane, n-butanol purchased from Merck (Germany), ethyl acetate and chloroform purchased JT Backer (USA), all the solvent used was analytical reagent grade. Phosphate Buffer Saline (PBS) from Nacalai Tesque (Japan), Penicilline-Streptomycin from Gibco (USA), sterile distilled or deionised H₂O, physiological saline (0.85% NaCl) from Otsuka (Japan). The dimethyl sulfoxide (DMSO) was purchased from Merck. The virus used in this experiment was A/Indonesia/Unair/2011 (H1N1) pandemic strain which was propagated in 11-days embryonated chicken eggs.

Plant Extraction

Merremia mammosa Hall tuber was obtained from Sumenep, Madura, Indonesia. The tuber was cut into slice, dried, and grinded into powder. Dried powder of Merremia mammosa Hall (1900 gr) was subjected on maceration in room temperature using methanol as the solvents (3×5 L). The supernatant was collected and subjected on rotary evaporator to obtain a thick crude extract. The methanol extract was added by deionised water in the same amount and added by non-polar solvent (n-hexane) to obtain non-polar fraction. The mixture of methanol-water and n-hexane was shaken vigorously for 10 minutes. This mixture was allowed to stand for some time to allow a complete separation and formed into two layers (water portion and n-hexane portion). The n-hexane portion was collected. This step was repeated for 3-5 times until the n-hexane layer was clear. The n-hexane portion was concentrated in vacuo, while the water portion was added by ethyl acetate to obtain the ethyl acetate fraction. The ethyl acetate fraction was subjected to in vitro antiinfluenza againsts H1N1 influenza virus.

Toxicity Assay

In order to obtain the MNTD (Minimum Non Toxic Dose), the toxicity test was carried out using the host which was embryonic chicken egg. This assay was aimed to determine the highest concentration of the sample which was not caused the death of chicken embryo. Ethyl acetate fraction was added to PBS solution with final concentration 1000, 500, and 62.5 µg/mL (High, moderate, low). DMSO was added in concentration 2.5% to improve the solubility. In this experiment, the solution of the samples were injected carefully to the broad pole of the 11-days-old embryonic chicken egg. This experiment was conducted in 72 hours, the death of the embryo was a checked every 24 hours. The highest concentration that not caused lethality of chicken embryo is proceed for the next assay. All the experiment were running in triplicate.

Treatment of the Virus

11-days-old embryonic chicken egg were injected with 0.01 MOI of H1N1 virus solution (50 µL). The solution of the sample were injected 30 minutes prior to the virus infection to give chance of the samples to spread to the protein of the egg. Zanamivir 10 µg/mL was used as a positive control and the H1N1 virus without treatment extract is used as a negative control. In each extract solution, 50 mL penicillin-streptomycin were added to avoid bacterial infection. The eggs were then incubated for 72 hours at 37 ºC. Embryo mortality observed every 24 hours. After an incubation period is complete, the eggs stored at 4 ºC for 12-24 hours and allantoic fluid was harvested to be subjected on hemagglutination inhibition activity.

Hemmaglutinin Assay

The first opportunity to prevent influenza virus replication is when the virus attaches to the host cell membrane. Influenza virus hemagglutinin oligosaccharides attached to the host cell membrane associated with sialic acid terminal position. The agents act to inhibit the viral replication by interfering the first attachment step of the virus to the host cell, resulting the reducing of HA titre in culture specimen[9]. Guinea Pig’s whole blood 5 mL+PBS 10 mL, was subjected on centrifuge 1200 rpm for 10 min. The supernatant was removed and this step was repeated until the PBS was clear. 0.75% of RBC was prepared by adding 37.5 μL of RBC+462.5 μL of PBS. To do this assay, U-shaped 96 well of micro-plates were taken. Using a micropipette, 50 µL of PBS (pH 7.2) was added to all wells except first well of each row. Harvested fluid from virus growth inhibition assay (100 µL) was added to the first two wells of each row. Twofold dilution was made by transferring 50 µL from the second well of each column A2-H2 to A3-H3 by using a multi-channel micropipette. This step was preceded until the 12th column and the remaining 50 µL was discarded after the 12th column. Last, 50 µL of 0.75% RBCs was added to all wells and incubated for 30 minutes at 4ºC. Control well was checked for
complete settling of the RBCs. Results were recorded in HA sheet. The dilution also can be done vertically, with the same principle of procedure[10]. The percentage inhibition was calculated by applying the equation below:

\[
\% \text{ HA titer reduction} = \frac{A - BA}{A} \times 100\%
\]

Note: A. Hemagglutinin titer without the treatment; and B. Hemagglutinin titer with the treatment.

(+) means there is no mortality of chicken embryo exposed by the sample. Note: I, II, III = a triplicate experiment.

From this assay, it can be concluded that in the highest concentration, there was no lethality of chicken embryo. Therefore, the next assay will be started at concentration 1000 µg/mL.

### Discussion

*In vitro* antiviral assay was performed using A/Indonesia/Unair/2011 (H1N1) virus which was propagated in embryonated chicken egg. Ethyl acetate fraction was proved to have a specific interaction with HA protein. The reduction of HA titre and 93.75% of H1N1 infectious titre. From the result of the present study, it is possible to suggest that the treatment given was affecting the viral replication especially in the early stage of infection[11]. Ethyl acetate fraction reduced HA titer near to zero in allatoic fluid of embryonated chicken egg specimens and showed high protection against viral infection. Ethyl acetate fraction is rich in flavonoid and terpenoid compounds that has the possibility to inhibit the growth of the virus. In conclusion, ethyl acetate fraction of *Merremia mammosa* Hall is able to inhibit viral at early step of infection especially when giving before the infection.
Conclusion

In sum, *Merremia mammosa* Hall has the potential to be developed as antiviral agent of influenza A (H1N1) infection.

**Abstract**

The aim of this study is to investigate antiviral activity of flavonoid fraction of *Vitex trifolia* leaves towards influenza A viruses H1N1 pandemic-2009 that were propagated in embryonated chicken eggs (ECEs). Fraction that rich of flavonoid compounds was isolated from the crude ethanolic extract using column chromatography, prior to be subjected to antiviral inhibition assay. The assay was evaluated by using hemagglutination (HA) test. The HA titre reduction of the virus was counted after being treated with the flavonoid fraction, compared to untreated one. The result showed that percentage of inhibition of this flavonoid fraction against pandemic-2009 H1N1 influenza A virus are 37.50%, 71.25%, 71.25% at concentration 125 μg/mL, 500 μg/mL, and 750 μg/mL, respectively. In conclusion, the flavonoid fraction of *Vitex trifolia* leaves showed effect to reduce viral hemagglutinine, the enzyme that has a crucial role in the initiating step of virus infection, without possessed any toxicity to ECEs.

**Keywords:** flavonoid, influenza A H1N1 pandemic 2009 virus, Vitex trifolia, hemagglutinin

**Introduction**

Influenza virus is a member of Orthomyxoviridae, one genera of Influenza A with a complex pathogenesis due to its genetic variability. One of the specific mutation of influenza virus is due to the antigenic drift and mutation[1]. The current influenza A subtype H1N1 is a combination from influenza virus gen from swine, bird and human, that has an ability to mutate by the mechanism of antigenic drift and antigenicshift to produce the new resistant influenza virus[2]. However, throughout the world until August 4, 2009, 168 countries reported cases of influenza A H1N1 with 162,388 positive cases, 1,154 of them died. And data on the cumulative number of H1N1 infections in Indonesia up to August 23, 2009 were 1,005 people with 5 of them died. FDA has recommend two types of drugs to cure and to prevent Influenza A, which are M2 inhibitors (Amantadine and Rimantadine) and Neuraminidase inhibitors (Oseltamivir and Zanamivir). Those drugs also can be use for prophilaxis and treatment for seasonal influenza.

The concern about this virus is emergent due to the resistance of the common influenza drug such as oseltamivir due to the mutation of H274T[3,4]. The resistance of adamantane derivatives is also detected due to the substitution of amino acid in the order 26 (LeuàPhe), 27 (ValàAla atau Thr), 30 (AlaàThr atau Val), 31 (SeràAsn atau Arg), and 34 (GàE) in the domain of M2 trans membrane[5]. Thus, the alternative treatment for influenza infection is strongly needed. One of the sources for searching a new potent drug is herbal medicine. One suggestion used for antiviral drugs is chemotaxonomy. In fellow genus *Vitex* studies, extracts and fractions rich in flavonoids from fruits and leaves of *Vitex polygama* Cham (Vebeńaceae) can increase dose-dependent antiviral activity against type 1 herpes simplex virus (ACV-HSV-1). Leaf extract shows...
antiviral activity while the fruit extract has a virucidal effect. Some fractions of ethyl acetate extract can inhibit the virus by blocking HEp-2 receptor cells\(^6\).

In this study, a fractionation method from the methanol extract of the leaves of *Vitex trifolia* was carried out to obtain sub-fractions which contained many flavonoids using ethyl acetate solvents. Ethyl acetate solvents are semi-polar solvents and can dissolve compounds such as flavonoids\(^7\). In addition, one of the flavonoid compounds that has the ability to inhibit viruses with the mechanism of neuraminidase inhibitors is vitexin. Vitexin compound is owned by *Vitex trifolia*\(^8\). Based on these facts it is possible that the sub flavonoid fraction of *Vitex trifolia* also has activity as an antiviral.

**Materials and Method**

The test material used was sub flavonoid fraction of *Vitex trifolia* leaves which was isolated by fractionation using vacuum column chromatography. The fraction that rich of flavonoid compounds was used to the assay.

**Virus and Testing Media**

The influenza virus used was influenza A virus pandemic H1N1 subtype 2009 strain A/Unair-367-2010 and provided by Avian Influenza Research Center (AIRC) Laboratory, Universitas Airlangga, Surabaya, Indonesia. The virus is grown in ECES obtained from Pusvetma, Surabaya, Indonesia. The hemagglutination test (HA) is carried out using guinea pig red blood cells.

**Chemicals and Reagents**

Silica gel GF254, silica gel 60G for thin-layer chromatography, Silica Gel 60, technical methanol (Brataco), Ethyl Acetate (Brataco), n-hexane (Brataco), Chloroform Pa (Fulltime), Phosphate Buffer Saline (PBS) (GIBCO), Dimethylsulfoxide (DMSO) (Merck), Sterile Water For Irrigation U.S.P. (Otsuka), red blood cell (RBC) guinea pig, an antibiotic solution of Penicillin-Streptomycin (Gibco).

**Tools**

Vacuum column chromatography, filter paper, separating funnel, UV scanner (CAMAAG), Analytical scales (Ohaus), Chamber, autoclave (HL-340), Biosafety cabinet (NuAire), incubator, micropipette (Eppendorf), glassware, 96 Centrifuge (Tommy) “U and V” plate, refrigerator 4 °C (Sanyo), -80 °C freezer, Vortex (Barstead Thermolyne), 1 mL injection syringe, Buchner (Schott) funnel, rotary evaporator (Buchi).

**Extraction Method**

The thick methanol extract of leaves of *Vitex trifolia* was weighed 143 g then added with water as much as put in a separating funnel. Prepare as much n-hexane with volume and put it in a separating funnel, shake until homogeneous after that separated between water fraction and n-hexane. The n-hexane fraction is present. This process is repeated until the n-hexane fraction is not dark in color. In this process, the n-hexane fraction is obtained. In the water fraction that is still in the separating funnel, ethyl acetate is added as much, and then shaken until homogeneous, and the ethyl acetate fraction is accommodated. This step is repeated until the ethyl acetate fraction is colorless. Then the ethyl acetate fraction was obtained, the ethyl acetate fraction was subjected to a rotary evaporator at 40 °C until thick ethyl acetate fraction was obtained. The fraction was subjected to vacuum column chromatography. Gradient volume of chloroform and ethyl acetate was used as mobile phase to separate the flavonoid compounds. The sub fraction was diluted in 5% of DMSO and phosphate buffer saline until reach the final concentration 1000 µg/mL, 500 µg/mL, 250 µg/mL, and 125 µg/mL.

**Toxicity test**

Toxicity test and determination of safe concentration of the tested samples on 11 days old ECEs. 15 ECEs then disinfected the outside of the eggs by using 70% of alcohol. Four concentrations of the fractions that have been made 1000 µg/mL, 500 µg/mL, 250 µg/mL and 125 µg/mL each concentration is taken as much as 100 µL+50 µL of penicillin streptomycin solution. Each concentration was injected into the ECEs, replicated 3 times. After entering the fraction+penicillin streptomycin solution, the hole in the egg is covered with tape until it is completely tight. ECEs was incubated at 37 °C incubator for 2 days. Every day the eggs are observed for the embryo. Embryos that die before two days, are removed from the incubator then stored in a refrigerator at 40 °C. After 2 days the non-dead ECE was transferred to the refrigerator at 40 °C for one night. From this process, it can be determined which concentration will be used for the activity test. The virus that will be used for the activity test has a 2\(^12\) titre.

**Control Groups**

a. Inject 100 µL of the pandemic-2009 H1N1
subtype influenza A virus + 100 µL Zanamivir 15 µM + 50 µL Penicillin-Streptomycin solution (10,000U/mL) (positive control; use 3 ECEs).

b. Inject 100 µL of pandemic H1N1 subtype A-2009 virus + 50 µL Penicillin-Streptomycin solution (10,000U/mL) (negative control; use 3 ECEs).

Treatment Group

Injecting 100 µL of pandemic H1N1 subtype A-2009 virus + 100 µL sub flavonoid fraction solution at non-toxic concentration + 50 µL Penicillin-Streptomycin solution (10,000U/mL). ECEs that have been treated are covered with plastic tape. ECEs is stored in an incubator at 37 °C for 3×24 hours. Every 1×24 hours the ECEs is observed using an egg candler. For dead embryos before the third day, they are separated and then stored in a 4 °C refrigerator for one night and harvested with allantoic fluid the next day. Harvested allantoic fluid then centrifuged 3000 rpm for 5 minutes. After being centrifuged, two parts will be formed, namely the part of the supernatant (clear liquid) and the pellet (sediment). Furthermore, the supernatant was taken using a micropipette and carried out the HA test. For the HA test using marmot red blood cells 0.75%, used the “U” shape plate. First, 50 µL PBS is needed in all wells, then 50 µL of allantoic fluid are added to be tested into wells A (1-12, 1 sample / well) and after that serial serial dilution is carried out by taking 50 µL from well A to B and so on until well H, the last one thrown away. Furthermore, each well was given 50 µl of 0.75% marmot red blood cells, shaken to be homogeneous, closed, and incubated in a 4 °C refrigerator for 60 minutes. The HA titre value is the highest dilution of the virus which still shows perfect hemagglutination. HA titers are the opposite of virus dilution.

Data Analysis

For the HA test, it was done to compare the HA titre of samples with controls. The decreasing in the HA titre percentage, showing the ability of the test sample to inhibit the virus. The percentage of antiviral inhibition is calculated by the following formula:

\[
\text{Untreated HA titer} - \text{treated HA titer} \times 100
\]

\[
\text{Untreated HA titer}
\]

Results

Separation of sub flavonoid compounds from 1 to 11 was carried out to obtain good stain separation with chloroform: ethyl acetate gradient volume, using Thin Layer Chromatography (TLC). The flavonoid test was conducted by contacting the TLC plate with ammonia vapor. The presence of yellow colour after ammonia vapor was applied, concluded that the sub fractions contained flavonoids[9]. Results fractions vacuum column chromatography which has been tested in TLC, collected the same stain pattern combined into large fraction.

\[\text{Fraction 5: Fraction from vacuum column chromatography with eluent chloroform: ethyl acetate 60:40}\]

\[\text{Fraction 6: Fraction from vacuum column chromatography with eluent chloroform: ethyl acetate 50:50}\]

The yellow spots were detected using amoniac vapour indicated the presence of flavonoid.

Discussion

Treatment and prevention of influenza can be done through administration of antiviral and vaccination. At present there are 2 classes of influenza antiviral drugs, namely adamantane groups and neuraminidase inhibitors. However, infection control of influenza A virus using antivirals has begun to experience problems due to the emergence of new strains that are resistant to existing antiviral drugs[10]. This study used sub fraction of flavonoids from *Vitex trifolia* leaf with chemotaxonomic approach to determine the effect on the swine flu virus (H1N1 Pandemic 2009).

In previous studies it has been shown that the methanol extract of *Vitex trifolia* leaves can reduce H1N1 virus titers carried out by the hemagglutination (HA) test and in silico through Molegro Virtual Docker (MVD) software based on docking results can be known if vitexin compared to zanamivir have ties hydrogen on Arginine 152 (Arg 152), Arginine 292 (Arg 292), Arginine 371 (Arg 371), Aspartic Acid Asp 151, Tyrosine 406 (Tyr 406). Based on the rerank score, vitexin had a score of -95.6056 kcal/mol and zanamivir -111,423 kcal/mol. The lower (more negative) value of the rerank score, the more stable the receptor ligands interaction. Previous
research also proved that the methanol extract of *Vitex trifolia* leaves can reduce H5N1 virus titers carried out by the hemagglutination (HA) and neuraminidase inhibitor (NAI) tests\textsuperscript{[11]} . To determine the effect of sub-fraction on ECEs as a viral growth medium, a non-toxic dose of sub-fraction in ECEs was tested in several fraction concentrations which are, 125 µg/mL, 250 µg/mL, 500 µg/mL, 1000 µg/mL, 2000 µg/mL. There is no limit in the choice of these concentrations as long as the dose is safe in ECEs\textsuperscript{[12,13]} . ECEs used are free from antibody to fight viruses will be inoculated\textsuperscript{[10]} .

After 72 hours of inoculation, embryonic death was found in concentration 2000 µg/mL and 1000 µg/mL for two ECEs. This can be occured due to individual variations, different egg immunity systems and ECEs used in replication. So, in this study, only concentration of 125 µg/mL, 250 µg/mL, and 500 µg/mL that were used. To determine the growth of viruses in ECEs, can be determined in two ways, namely by observing the embryonic death and testing HA. Based on the results of the observation, embryonic death did not occur at the same time. Individual variations in ECEs greatly affect the ability of the embryo to survive so that hemagglutination tests are carried out to determine the virus titers in ECEs\textsuperscript{[14]} .

The data showed that at concentration of 250 µg/mL and 500 µg/mL, the inhibition oh HA titer is 71.25 %, and indicated a strong inhibition of HA titer. From the previous study, it was also proved that the extracts and fractions of several plants such as *Garcinia mangostana*, *Eurycoma longifolia*, *Tabernaemontana divaricata*, *Brueca javanica*, and *Momordica charantia* had good inhibition percentages at concentrations of 250 µg/mL\textsuperscript{[15]} . In this study, the compound which is suspected to give inhibition for the growth of H1N1 virus is vitexin, one of flavonoid compounds presence in *Vitex* genera. In a similar study, the use of embryonic chicken eggs as a learning model to determine the effect on influenza A H9N2 virus using oseltamivir carboxylate with ten ECEs per replication\textsuperscript{[13]} .

**Conclusion**

In conclusion, the flavonoid fraction of *Vitex trifolia* leaves showed effect to reduce viral hemagglutinin, the enzyme that has a crucial role in the initiating step of virus infection, without possessed any toxicity to ECEs.

Abstract

The phenomenon of teenage pregnancy in Indonesia has increased annually, but only a few studies that indicate its predictors. The present research aimed at analyzing the determinants of teenage pregnancy in Indonesia. The study used secondary data obtained from the Indonesian Demography and Health Survey (IDHS) in 2017. The independent variables are as follows age, wealth status, education, occupation, and marital status. On the other hand, the dependent variable is teenage pregnancy. The data were analyzed using binary logistic regression. It was found that age is a significant determinant of teenage pregnancy. The richest teenager has 0.61 higher possibility of getting pregnant than the poorest. A teenager with higher education is 0.03 times more possible to get pregnant than one that has not gone to school before. Moreover, a working teenager has the possibility to get pregnant higher than that of not working teenager by 1.47 times. The present study empirically proves that marital status is not a determinant of teenage pregnancy. While the four other variables, such as age, lower wealth status, no education, and working have been proven as determinants of teenage pregnancy in Indonesia.

Keywords: teenage, pregnancy, determinants, Indonesia

Background

Teenage pregnancy happens when a young woman aged between 13-19 years old is having sexual intercourse which leads to pregnancy. The number of pregnant teenagers in Indonesia is 58.56%(¹). This evidence from other countries indicates high teenage pregnancy. Most women aged between 20-24 years old in Ethiopia (79.6%) were found pregnant. Every year, Indonesia also reports an increase to the number of pregnant teenagers. Such trend is also true in Malawi(²). The teenage pregnancy in Sub-Sahara Africa shows low utilization of antenatal(³). Moreover, female teenagers in the Midwest, US do not actively search for information related to teenage pregnancy(⁴). Meanwhile, only a few of female teenagers in the Imo Territory of Nigeria are aware of emergency contraception(⁵). A study conducted in South Africa found that women who are pregnant in their teenage period tend to receive negative stigma from their teachers, health service staff, and the community(⁶). Moreover, teenage pregnancy is related to anemia(⁷), low birthweight, premature birth, and hypertension(⁸).

Teenagers in majority have not finished their high school, unmarried, not worked, and financially dependant on their parents. The emotional development of teenagers are not yet stable, making it hard for them to become a young mother. The present study aimed at analyzing age, residence, wealth status, education, occupation, and marital status.

Materials and Method

The research design of this study is correlation, with cross-sectional approach. The research employed secondary data obtained from the Indonesian Demographic and Health Survey in 2017. The research was conducted in 34 provinces of Indonesia. Meanwhile, the analysis unit being researched was women aged between 20-24 years old in Indonesia who has given birth in their < 20 years old. The sampling technique used was stratification and multistage random sampling, thereby obtained 3,350 samples. The 2017 IDHS obtained ethical approval from the National Institute for Health Research and Development of the Indonesian Ministry of Health. All respondents’ identities are unknown from the data, and the respondents gave written consent for their involvement in the research. Permission to use the 2017 IDHS in this study was obtained from ICF International on January 21, 2020, through its website: https://dhsprogram.com/Data/terms-of-use.cfm.

The dependent variable of the study is teenage pregnancy, while independent variables which were analyzed as supposedly predictors, such as: age, type of place of residence, wealth status, education level, currently working, and marital status. Teenage pregnancy in this study was defined as pregnant women aged less than 20 years old. The measurement to obtain the data used two categories, such as yes and no. The age variable was analyzed using the year unit starting from 20 years old to 24 years old in the form of continuous data. More, the definition of type of place of residence refers to the known categories defined by the Central Bureau of Statistics. The measurement was under two categories, such as urban and rural, and for the reference is urban. Wealth status is that of social wealth status of a person indicated by the wealth status. Wealth or wealth status is divided into five classes, such as poorer/lower, middle, richer/higher, richest, and poorest as reference. Education is the level of education of person that is classified into four categories, such as primary, secondary, higher education, and no education, and no education is the reference. Currently working is divided into two classes; working and not working, and not working is the reference. Marital status is categorized into three classifications, such as never in union/no longer living together/separated, married/living with partner, dan Widowed/divorced is the reference. The data analysis followed two steps. First, the study conducted relationship test using chi square for categorical data and t-test for the continuous data. In the final step, the study used binary logistic regression.

Note: *p < 0.05; **p < 0.01; ***p < 0.001.
Table 2 describes the results of binary logistic regression test of teenage pregnancy in Indonesia. The references of the present study is no occurrence of teenage pregnancy. The variable of age is one of the predictors of teenage pregnancy di Indonesia. This result is similar to a study conducted in Ethiopia which found that the chance of giving birth cases in teenagers occurs between the age of 18–19 years old, in which they tend to start having sexual intercourse since 18 years old. Differently, the result of a study in Michigan indicted that age does not affect teenage pregnancy, but the age of the sexual partner does significantly. Age is often correlated with physical maturity and thinking skill. Pregnancy in women younger than 20 years old tends to not develop physically and the pregnant women might not be capable of keeping their pregnancy and having safe birth. Pregnancy with hypertension and anemia, premature birth, and low birthweight are believed to be related with mother’s age when pregnant.

Table 2 also describes the teenage pregnancy seen from the wealth status. Compared with the poorest teenagers, the poorer teenagers have 0.802 times chance higher (OR=0.80; 95% CI 0.67-0.98); Teenagers with middle wealth status have 0.642 times higher chance to get pregnant (OR=0.64; 95% CI 0.52-0.78); while those with the richer wealth status has higher chance by 0.53 times (OR=0.53; 95% CI 0.41-0.67); moreover, teenagers with richest wealth status have 0.61 times higher chance of conceiving pregnancy (OR=0.61; 95% CI 0.45-0.82). This result indicates that the poorest teenagers have the highest chance of conceiving pregnancy. The poorer they are, the higher the possibility to get pregnant in their teenage time. This result is in line with those found in Ghana and Malawi which stated that female teenagers who belong to the lowest wealth status have the highest possibility to have early marriage which will lead to teenage pregnancy. Parents’ poverty is thought to be the underlying justification for their decision to marry their daughters to other people. The negative impact of poverty to teenage pregnancy is that they are more prone to unpleasant condition when being mothers. If their daughters are married, a part of their responsibility will move to their daughters’ husbands. The presence of a son in law within a poor family is also considered an extra help for earning the life. Such family fails to consider possible negative impacts of such early marriage and teenage pregnancy.

Moreover, Table 2 depicts the teenage pregnancy based on the educational level. If compared with teenagers with no education, those with primary education have 0.30 times chance higher (OR=0.30; 95% CI 0.09-0.99); Teenagers with secondary education show 0.13 times higher possibility (OR=0.13; 95% CI 0.04-0.43). Teenagers with higher education perform 0.04 higher chance of conceiving pregnancy (OR=0.04; 95% CI 0.01-0.12). These results show the biggest possibility of conceiving teenage pregnancy. This result confirms the findings of a study in Ghana which mentioned female teenagers who have never gone to school are more likely to get married in their teenage period than teenagers with certain educational level. Similarly, the study in Brazil revealed that daughters of low income family usually do not finish/complete their primary education. Lower length of study is also correlated with planned teenage pregnancy. Education is a process of learning knowledge, skills, and habits. Through education, one develops his/her potentials in order to obtain certain objectives in cognitive and good attitude. The length of study required to finish the secondary school is 18 years. One that has not completed his/her education at least until secondary level might have limited information and life skills. This may lead to the poor consideration on making the decision to get married and conceive pregnancy. The present study has empirically proven that most of teenage pregnancy occurs in marriage. Teenage marriage is therefore assumed to be a way out for female teenagers who do not pursue higher education.

Finally, Table 2 informs about working teenagers who have 1.48 times higher possibility to get pregnant than not working teenagers (OR=1.48; 95% CI 1.26-1.73). This finding indicates that working women are more possible to get pregnant than those who are not working. However, the finding is different from a study in Northern Ethiopia and Brazil who declare that lower monthly income is a predictor to teenage pregnancy. Working women earn their own living. The autonomy in managing one’s own expenses makes a woman more confident in deciding to conceive. They also have broader circles with other people, unlike the not working women. Getting pregnant is thought to be manifestation of self-actualization in a working teenager.

**Conclusions**

Based on the results of analysis, it can be briefly concluded that the four variables are empirically proven
as determinants of teenage pregnancy. The variables include age, wealth status, education level, and working status. These findings could be used as a guidance for the policy makers to lower the number of teenage pregnancy in Indonesia.

Abstract

In the context of globalization of global economy and intense competition and steady increase in population, mortality rates among people with infectious and parasitic diseases are increasing. International organizations are also paying much attention to fighting these problems and their consequences. In particular, the UN Sustainable Development Program up to 2030 emphasizes “issues related to the elimination of immunodeficiency, tuberculosis and malaria epidemics in the period up to 2030, as well as measures to combat hepatitis and other waterborne infections”. Successful implementation of these tasks requires stabilization of nosocheological and nosogeographic situations in arid climates. Medical geographical situation in the regions is one of the most important factors determining the development of society and the way of life of the population. Addressing medical geographical problems and improving public health, reducing morbidity and increasing life expectancy are of vital scientific and practical importance.

Key words: population health, pathological processes, nosogeographic center, nosogeographic range, nosogeographic area.

Introduction

Issues related to medical geographical studies, including the geographical pathology and the territorial structure of diseases, were presented by P.N. Pavlovsky, A.P. Avtsin, K.I. Skryabin, et al.¹ O.B. Ata-Mirzaev, H.T. Tursunov, et al, with close links to the problems in our country, namely from the point of view of economic and social geography. The above research investigates the public health problems, but little has been done on the geographical aspects of this problem in our country. The main purpose of this work is to fill such gaps.²

Traditional zoning is also important in medical geography. Medical geographical zoning is an important result of comprehensive medical geographic research. In medical geographical zoning, nosogeographic centers and ranges are first identified.³ Nozogeographic Furnace – it is the place where the disease is born. From a natural geographical point of view, it is in line with E.N. Pavlovsky’s idea of natural foci of infectious and parasitic diseases.

As a result of medical geographic surveys, a set of thematic cards can be created. Such cards are made at the Institute of Geography of the Russian Academy of Sciences, the Department of Geography of the Academy of Sciences of the Republic of Uzbekistan. In the zoning of the population in terms of its health, the allocated territories differ from each other by the prevalence of various diseases. From this point of view, geography of the population is an important area of social geography as the theoretical and methodological basis of medical geography.

In the study of medical geography, as in other geographical studies, a comprehensive, integrated approach is essential. This implies two distinct meanings: first, the complex, comprehensive, interdisciplinary study of the research object; This is especially true in
the area of healthcare. It is well-known that regional complexes play an important role in economic and social geography and geography in general.4

Nosogeographic Complexes

Nosogeographic complexes are a combination of the spatial combination of various diseases that occur under their influence in a specific natural geographic and socio-economic, social environment (space). This theoretical idea is based on the ideas of Chicago medical scientists about the regional complexes and energy production cycles created in human ecology and socioeconomic geography.

The regional disease complexes are the basis of this, not the nosogeographical region. As the pathological processes are influenced by the landscape, environmental and social geographical factors of the regions, their study is theoretically important. Thus, it is possible to say that a regional set of diseases is a methodology for the analysis and forecasting of nosogeographic regions. Such complexes are usually associated with a specific sociogeographic environment with natural geographical and economic landscapes. In the study of nocogeocomplexes it is necessary to understand first and foremost the effects of their occurrence on each other. Therefore, the process of studying nosogeocomplexes requires extensive practical and theoretical research.

With the passage of time, some types of diseases will diminish, and some new forms will occur. Specifically, in recent years, lethal species of tuberculosis have disappeared. The incidence of infectious intestinal infections, especially amyobiosis and lambliosis, has increased significantly. Nonmaterials can be classified into the following groups: climate-related systems; hydrogen fluxes are recognized as the leading factors in the emergence and spread of diseases of surface water sources, including canals, swamps, rivers or lakes; gene-causing effects of ground water on hydrogeogenic nematodes play a major role, such as kidney and circulatory disorders, metabolic disorders; chemogenic nozzles; biogenic organisms.5

Diseases of the Source and their Spread

The nosogeographic source is the place where the disease is caused.6 The nosogeographic range is the direct spread of a particular disease or the area in which the disease is present, making it the basis of the nosogeographic area.7 If people spend too much time indoors during the winter, they can spread respiratory infections, while wearing warm clothes without personal hygiene will cause an increase in lice and typhoid fever.8

In our view, the nosogeographical condition or condition is characterized primarily by the mortality rate of a population in a particular area or region, including child mortality rates, the average life expectancy and overall morbidity, the presence or origin of certain groups of diseases. In our study, we found it necessary to study the prevalence of brucellosis in the Samarkand and Navoi regions, which is the most common among the livestock population. For the first time, the idea of natural sources of disease was highlighted in the works of D.K. Zabolotny8 in the late 9th and early 20th centuries. The theory of natural sources of disease, the origin and formation of infectious diseases is studied by many fields of science: epidemiology, parasitology, geography of medicine, biogeography, ecology.9 Parasitic systems that play an important role in the study of disease foci.10

It is well known that one of the most common diseases not only in our country, but also in the world today is brucellosis, which is a contagious disease, and is known as Malta, Mediterranean, Cyprus, Gibraltar fever, Traum, Bruce syndrome.11 In Uzbekistan, the incidence of this disease has increased significantly in recent years (Table 1).

Brucellosis is a part of zoonoses, and the main source of the disease is agricultural animals: goats, cows, sheep, pigs, camels. Studies have been conducted mainly on farm animals. For humans, the source of this disease is pets. 70% of the population living in the outbreak is likely to be infected. Microbes enter the body through aerogenic pathways through the upper respiratory tract of wool, dust. Microbes in dust particles enter the body through a conventional mucosa. Professional factors also play an important role in the epidemiology of brucellosis. These activities include animal processing, animal processing and veterinarians, as well as laboratory workers. Seasonality is typical for brucellosis, especially during the spring and summer months.

Navoi region is unique in Uzbekistan on brucellosis incidence. It should be noted that the incidence of a particular disease is not the same in all provinces or in other territorial units (Table 2).

In recent years in the border areas of present-day Samarkand and Jizzakh regions nosogeographic centers of various infectious diseases have been formed, especially Bulungur, Gallaorol and Bakhmal districts. In recent years, great attention has been paid to the prevention of especially dangerous infectious diseases. In particular, anthrax is one such disease. An analysis of the morbidity rate among populations in Uzbekistan with natural fever and zooanthropososis shows a slight increase over the last decade. One of the first medical geographic zoning studies was A.A. Keller. In the 90s of the 20th century B.B. Prokhorov studied the geographical area of Russia and allocated 20 medical and ecological regions. V.Y. Podolyan argues that the essence of medical geographical zoning is a thorough study and evaluation of natural and socio-industrial conditions that have the same impact on the human body and have their own regional features.

Medical Geographical District of Karmana. Navoi Cement Plant, Electrochemical Plant, Navoi GRES, Navoi Mining and Metallurgical Complex and other enterprises have a great influence on the development of pathological processes in urban and suburban areas. The research has focused on diseases associated with air pollution in Samarkand and Navoi, with a slight increase in respiratory, cardiovascular, malignant neoplasms, and nervous systems (Table 3).

Uchkuduk Medical Geographical Region. The main source of pathological processes in the region are dust particles in the form of aerosols rising from the frequent dust storms in the Kyzylkum desert and salt-dust particles from the dried Aral Sea. Changes in pathological processes in these areas are also influenced by air composition and climatic features (Table 4).

Source: Based on data from the Navoi Regional Health Administration.

In general, medical and geographic zoning of the territories of Samarkand and Navoi regions is of great importance in practical terms. However, this process is very complex and complex, along with natural and environmental factors, and their economic and social geographical aspects.

**Geographical Aspects of Pathological Processes Prediction**

We analyzed statistical data on some infectious diseases, including brucellosis in the Republic (Table 5), and developed a forecast for 2021-2031 using extrapolation linear method.

Figure 1. Kidney disease and water hardness functional connection between

Thus, using statistics from 2010-2017, we calculate the number of patients with gallbladder disease in Pastdargom district using the least squares method.

**Conclusions**

In the world geography and medicine, serious research is being conducted to study the main areas of correlation between pathological processes and geographical factors in the environment and human health, and to identify the mechanisms of this linkage, the emergence and optimization of nosochemical and nosogeographic situations. In particular, priority is given to the study of the pathological processes of medical geography and nosogeography as a separate category, to assess the factors influencing them, to determine the range, dynamics and prognosis of the spread of the...
incidence of urinary incidence.

Thus, according to the results of Method 1, we expect that by 2020, the number of cases of gallbladder disease in Pastadargom district will be 897.54. Using the above calculations, we predict and compare the number of cases of gallbladder disease by 2020. In general, medical geographical studies are of vital importance in the assessment of public health in the regions and in the prediction of diseases occurring in them.

**Ethical Clearance:** All procedures performed in studies involving human participants were in accordance with the ethical standards of the institutional and national research committee and with the 1964 Helsinki declaration and its later amendments or comparable ethical standards. Abstract

Development of scientific and practical recommendations on improvement of nosogeographic situation by assessing the impact of nosogeographic situation on the territorial structure of diseases and pathological processes of population in Samarkand and Navoi regions. This includes an analysis of the pathological processes associated with the disease of the population of Samarkand, Navoi regions and their districts; Identification and evaluation of natural, socio-economic geographical factors and nosogeographic situation affecting the health of the population in the regions; medical geographical analysis of some infectious diseases occurring among the population of the regions and their specificity; Determine the main problems in the nosogeographical condition of the regions, the prognosis of the existing diseases among the population. The study identified groups and types of diseases that occur in the regions of the region such as Khatirchi, Qiziltepa, Bulungur. The nosocomial situation was assessed on the basis of a sociological survey method.

Keywords: focal diseases, tuberculosis, malaria, medical geoecological, carcinogenic substances.

Introduction

A number of measures are being taken in the Republic to further improve the health of the population, modernize the healthcare system, reduce the number of disease groups and types of disease, and protect maternal and child health. Item 4 of the Strategy of actions for the further development of the Republic of Uzbekistan in 2017-2021 states: “... decrease of morbidity and life expectancy among the population; health services, above all, aimed at improving accessibility and quality of medical and social services.”

In recent years, many areas of Uzbekistan, including Samarkand region, have been affected by anthropogenic and anthropogenic factors such as pollution of atmospheric air in large cities and villages, various social and environmental problems increase. Anemia, respiratory tract, gastrointestinal tract, kidney (stone), viral hepatitis and malignant neoplasms are among the leading diseases associated with household hygiene and lifestyle. In Samarkand, the pathology of respiratory diseases is mainly due to the pollution of the city’s air with gases emitted by various industrial plants and vehicles, and the polluted air stays in the city streets. Urgut district is the second most common respiratory tract. Like many diseases in the district, the pathology of this disease is mainly tobacco farming in the area. Urgut district provides about 90% of tobacco produced in the Republic. We aim to analyze the emergence and geographical distribution of various diseases within the Navoi region, which species play a leading role in the current environment, and the evolution of the disease, by city and district.
Characteristic of Geoeological Problems in Navoi Region

In our research we studied the geoeological problems and their impact on human health in the Navoi region. Navoi region is one of the most well-developed regions in the mining, chemical, electro-energy and animal industries. The growth of industrial enterprises and motor vehicles, the intensive use of arable land will lead to further environmental pollution in the area of agricultural chemicalization and so on. In most regions of Uzbekistan, including Navoi region, there is an increasing incidence of various diseases due to origin and other adverse events.

According to the Department of Ecology and Nature Protection of Navoi region, it can be seen that some of the chemical compounds released into the atmosphere from industrial enterprises in the city are higher than the permissible limits (REM). In particular, from the atmospheric air analyzes in Navoi, in January, source No. 3 of NIES reported that NOx nitrogen oxide was 14.89 g/s and was 0.11 times higher than REM. One of the most common diseases among the population of the region is malignant neoplasms. All the factors that cause tumors are classified into two types: exogenous and endogenous. These include: dietary habits and types of food, 35%, tobacco and nasvay 30%, sunshine 5%, alcohol consumption 3%, industrial waste 18%, and radiation 5%.

The survey was conducted by the author in two months in 2018 (January-February) in Samarkand (Nurabad and Bulungur) and Navoi (Khatirchi and Qiziltepa) regions. A total of 912 respondents from these areas differed in their natural, environmental conditions, demographics, geographical location, economy, and the daily rituals of the people in these districts. Bulungur, Nurabad, Samarkand and Khatirchi and Qiziltepa districts of Navoi region were selected for the study. The Bulungur district of Samarkand region is located on the large transport and highway in the area adjacent to Jizzakh region.

As it is known, Navoi city is one of the largest centers of chemical, mining and construction industries in the country. This city is distinguished not only in this region, but also in the country, in terms of maternal mortality rates, births with congenital malformations, and morbidity of the population with malignant neoplasms.

The main toxic chemicals of tobacco that have a negative impact on human health are the nicotine they contain. It often causes malignant tumors in the mouth, throat, bronchi, esophagus and lungs of the human body. For this reason, tonsils, allergic rhinitis are common in tonsils, chronic bronchitis, asthma, and allergic rehydration, which are allergic to respiratory diseases. In particular, the total incidence of respiratory diseases in Pakhtachi district was 8747.1 in 2005, 15,329.4 in 2010 and 18,652.0 in 2015. We compared the districts in the eastern and western parts of the province to this disease. The most common districts are those of Samarkand, Taylak, Kattakurgan and Akdarya districts.

Samarkand and Taylak districts are specialized in agriculture, horticulture and various pesticides are used in fruit and vegetable growing. They are mainly used by spraying. As a result, it causes inflammation of the upper respiratory system and the development of various allergic diseases. One of the most common diseases among the population of the region is diseases of the digestive system. The incidence of such diseases was 252.4 in 1997, it increased by 364.7 in 2000, in 1045.3 in 2005, and by 14,223.9 in 2010, and in 2015 it increased to 15,839.2.

Another common disease among the residents of Kushrabad district, which is rare in other districts, is the gastrointestinal tract. The prevalence of gallbladder disease is caused by the high levels of calcium, sodium, potassium in the drinking water sources and high water hardness. In Kushrabad district infectious parasitic diseases are among the lowest in other districts. In large cities, where there is a high density of public transport, crowded parks, theaters, and stadiums, the prevalence of infectious diseases (hepatitis A, and flu) is linked to human factors. In addition, migration has a significant impact on the incidence of infectious diseases.

Analysis of the Results of a Sociological Survey

The analysis shows that in recent years, though overall mortality rates, including infant and maternal mortality rates have been declining slightly, overall morbidity rates are increasing. Taking into account this process, the survey was conducted in the slightly ecologically unfavorable areas of these regions. In the present study, it was necessary to cover 15 questions directly related to the research topic from the 20 questions included in the sociological survey.
1. First of all, through the questionnaire, the respondents were defined as provincial and district citizens, their age and sex. The results of the table show that the respondents in each of the four provinces had different ages (Table 1). The study was conducted at the central district hospitals, as well as with the staff of sanitary-epidemiological centers and rural health centers located in these areas.

Table 1. Birth and sex of the respondents (as a percentage of total)

3. In the questionnaire, “What’s the biggest impact on the health of the population in your area?”, high levels of air pollution in the Kiziltepa district were taken into account as the main cause of illness. Also, 47.7% of respondents in the district stated that drinking water is the main source of many diseases.

4. The question “What infectious diseases are common in your area?” Most respondents in all three districts emphasized TB. In the Kiziltepa and Bulungur districts, response sheets show a relatively high TB rate of over fifty percent, in Khatirchi district 37.1 percent, and in Nurabad, about 31.0 percent.

5. Participants were also asked whether the air pollution in your area is harmful to human health. This question allows us to think more fully about the environmental situation of these areas. Kiziltepa district (59.2%) had the highest number of answers “Yes, it does”. This indicator is slightly lower in Bulungur (46.8), Nurabad (27.5) and Khatirchi districts (23.9). In the Khatirchi district, on the contrary, the “no” answers are common. There are also many who cannot comment on this question.

6. In four districts, the question “How are the people in your area provided with health facilities?” has received a very interesting answer. Kiziltepa district (22.3%) had the highest “negative” answers – 15.1% in Khatirchi district, 12.4% in Nurabad district and 9.7% in Bulungur district.

7. When respondents were asked: “What do you think is the main cause of maternal mortality in your area?”, most respondents mentioned anemia, childbirth, and death due to cervical and breast cancer. Especially in Kiziltepa district due to severe environmental conditions, the number of malignant tumors among mothers is growing. It should be noted that maternal mortality in 2017 was 93.5 per 100,000 live births, which is several times higher than the national average (Table 3).

8. The question “What illnesses are most common among children in your area?” has also given controversial results. It is well known that the most common group of children and their deaths are respiratory diseases. In all four districts surveyed, infant mortality rates are close to the national average, but the incidence and morbidity rates vary widely (Table 4).

</table>

Source: the table is based on the results of a sociological survey.
9. The question “Where do you usually get drinking water from your household (from a well, from a river, canal or ditch, from other areas)?” is also included in the questionnaire. However, in many regions of the country, access to these sources remains one of the most pressing problems. As a result of the research, we have received the following answers: most of the wells used as the main water source came from Nurabad district, as well as the majority of river, canal or arable water users. The majority of household water users were identified by Khatirchi district respondents. But its share was only 9.8%. In Nurabad district, the indicators are the lowest (0.6 percent).

10. The question “How do you assess the medical, hygienic, and environmental quality of the population in your area?” was given by the respondents: The majority of the respondents rated this situation as “poor” (19.3%) (Table 5). It can be concluded that in each of the four districts surveyed, some negative results were reported in Kiziltepa district and in Bulungur district.

Source: the table is based on the results of a sociological survey.

In general, the results of such a survey of the population in the regions of medical geographical surveys provide reliable information on the nosogeographic situation of these regions and serve as the basis for the implementation of the necessary measures.

**Conclusions**

As a result of many years of research, based on the evaluation of natural, socio-economic factors influencing the nosogeographic situation in the regions, the public health problems and recommendations for their solution were developed; revealed that the epidemiological source of some infectious diseases is associated with economic specialization and epizootic situation, i.e. the range of brucellosis and other diseases is related to livestock.

The results of the research show that the types and types of diseases that occur in the population differ sharply in urban and rural areas. In fact, Samarkand and Navoi, the largest cities, have a high incidence of respiratory diseases and malignant neoplasms, nervous system, allergic diseases. The main reason for this is that the cities, in particular, have some negative aspects of the nosocomial situation in Navoi. Most of the industrial facilities in the city are not equipped with modern technical equipment and require repair and high level of modernization. At the same time, the incidence of the outbreak is very high in the regions.

Abstract

Background. Pharmacy professionals, as the most available members of medical team, have an important role in educating patients about Cutaneous Adverse Drug Reaction (CADR). Our aim was to evaluate pharmacists’ knowledge of the cutaneous drug reaction, and their recommendations under hypothetical situations, through a written questionnaire. Methods. Based cross-sectional study was conducted among community pharmacists working at the private sector of the rabat-salé-zemmour-zaer region using a structured interviewing questionnaire. Results. Ninety-eight pharmacists completed the questionnaire (response rate 48%). The mean overall score was 52.87 ± 23.19% correct answers. The majority of pharmacists (66.32%) estimated that they view more than a Patient with CADR each month, and only forty-seven pharmacists underwent CADR related training during the year preceding the survey. Pharmacists obtained the highest correct scores on the true/false statements inquiring about Cutaneous reaction due to drugs definition, classification and the most common medication classes implicated in Cutaneous reaction due to drugs. Overall, the true/false questions were relatively easier to address, compared with the multiple choice questions (63.60 ± 13.15% vs. 51.18 ± 24.12%, respectively; p < 0.01). Only 14 pharmacists were familiar with Cutaneous reaction due to drugs such as (Drug Reaction With Eosinophilia, contact dermatitis, Nail Disorders, bullous pemphigoid). Longer time since training completion was associated with a lower total score (38,77 ± 9% vs. 61,22 ± 11% for the pharmacists who were in practice 5 years or less and those with longer time in practice, respectively; p < 0.05). Conclusion. Pharmacists were knowledgeable regarding some aspects of CADR. However, our study, as in previous studies among health care professionals, identified some gaps in knowledge. These findings indicate the need for better education of pharmacists regarding CADR and its supported.

Keywords: Cutaneous Adverse Drug Reaction, Pharmacists, Knowledge, Questionnaires

Introduction

Any unintended harmful reaction to a medicine or drug is known as an adverse drug reaction (ADR) according to the definition by the World Health Organization. The term Cutaneous Adverse Drug Reaction (CADR) is used for dermatoses with involvement of the skin, mucosas, and/or skin appendages, caused by the effect of a substance, usually a drug, which comes into contact with the organism by a range of pathways. Serious cutaneous drug reactions are immunemediated events that are classed as unexpected ADR.

They are the cause of hospitalization in dermatology services for about 1.5% of patients in France, 4.11% in Tunisia, 27% in Togo, 10.40% patients in
Guinea [6] and have a high degree of semiological variability. Two per cent of these can be severe, with severe sequelae or life threatening [7]. They can occur in all individuals without distinction of age; however, they are less frequent in children with an incidence of 0.9% in the Thiesen et al series in England [8].

Nowadays, consumers’ demand on CADR information is very high and pharmacists, if knowledgeable, are in an ideal position to address this demand. They are the third largest regulated healthcare professional groups in the world [9]. A 2012 report conducted in 90 countries stated that 55% of pharmacists were working in community pharmacies [10].

To our knowledge, few studies have been published on diseases pharmacists’ knowledge, in particular in the past few decades [11,12]. This study was therefore intended to assess the knowledge regarding CADR in a low-income country setting. The findings will support the design of educational programs and objectives by pharmacy schools and professional organizations.

**Materials and Method**

§ Study Design

This was a cross-sectional study conducted from January 2018 to March 2018, among community pharmacists in the private sector of the rabat-salé-zemmour-zaer region. Data were collected by the authors during the day time working hours and mostly in the morning.

§ Study Tool

A questionnaire was developed by three clinical pharmacists from the coauthors.

The questionnaire consisted of four sections.

The first section collected demographic data of the respondents such as gender, age, the number of years practicing as pharmacist, highest qualification related to pharmacy, Country of academic studies, Estimated number of Patient with CADR /month view in the pharmacy and CADR training over the past year.

In the second section, respondents were questioned about definition of ADRs and CADR, the different categories of CADR and the most medication classes implicated in CADR. The answer in this section was from true/false reponse.

In the third section, respondents were questioned about the pharmacists’ possible actions in theoretical situations involving the different types of Cutaneous adverse drug reaction such as Definition, Pathogenesis, Clinical Manifestations: (Onset, Symptoms, Signs), Diagnosis: (Clinical Diagnosis, Differential Diagnosis), Prognosis, Treatment: (Definitive, Symptomatic, Prevention).

In the last section entitled “comments” respondents are invited to add comments about Cutaneous adverse drug reaction.

Then, a pilot survey of the questionnaire was carried out with pharmacy department staff. Finally, necessary modifications were made based on the comments received from the pilot survey.

§ Data collection

The questionnaire was presented to pharmacists in the private sector of the rabat-salé-zemmour-zaer region. Fifteen minutes were allotted to complete the questionnaire. Pharmacists were not supposed to consult any information resources when they were taking the quiz. We could not validate that the other pharmacists did not use information resources. No financial incentives were offered to encourage participation. However, a document containing detailed answers to the study questions was prepared and distributed among members of the organizations participating in the study.

§ Data analysis

The final score was expressed as the percentage of correct answers of each pharmacist. The option “I don’t know” was considered a separate category, and included in the estimation of the score per question as a wrong answer. Responders were grouped into one of two categories of duration since graduation from training (five years or less and longer than five years) and of countries in which the Pharm degree was obtained (Morocco, other). Descriptive statistics were obtained for the various variables. Response patterns were evaluated using the two-tailed Mann–Whitney test, the Kruskal–Wallis test, and the Pearson correlation (SPSS software. 10 at the Laboratory of Biostatistics and Clinical Research of the Faculty of Medicine and Pharmacy of Rabat), as appropriate. The results are reported as mean ± standard deviation (SD), unless otherwise indicated. A p-value ≤ 0.05 was considered significant.
Results

A total of 98 pharmacists completed the questionnaire. The response rate was 48%. The compiled demographic data are presented in **Table 1**.

</tbody>
</table>
Pharmacists obtained the highest correct scores on the true/false statements inquiring about CADR definition, classification and the most common medication classes implicated in CADR. Only 14 pharmacists were familiar with CADR such as (Drug Reaction With Eosinophilia, contact dermatitis, Nail Disorders, bullous pemphigoid). Across all questions and all study participants, the option “I don’t know” was selected in 5.0% of cases. Across all questions and all study participants, the option “I don’t know” was selected in 2.04% of cases.

Longer time since training completion was associated with a lower total score (38.77 ± 9% vs. 61.22 ± 11% for the pharmacists who were in practice 5 years or less and those with longer time in practice, respectively; p < 0.05). In contrast, the total score was not affected by the setting in which the questionnaire was distributed, gender, the country in which the Pharm degree was obtained (Morocco vs. others); whether they underwent some form of training about CADR over the year prior to the survey (p > 0.05; data not shown). In addition, the total score was not associated with the number of Patient with CADR seen monthly by the pharmacist (p > 0.05) and did not correlate with the responders’ age (r =-0.1596, p > 0.05).

Nineteen of the pharmacists included in this study added comments under the “Comments” sections of the questionnaires. Four comments related to lack of the responder’s knowledge, two stated the need for more extensive education, six referred to the availability of data sources, and the remainder of comments were related to the wording of the statements or the answers.

**Discussion**

Pharmacists constitute a valuable source of information for patients and prescribers. As such, they should be familiar with various aspects of CADR, including actions taken in theoretical situations involving CADR therapy, and be able to consult patients.

Unfortunately, CADR patients’ knowledge regarding their illness and its treatment is unsatisfactory. Furthermore, pharmacists can be the first to recognize conditions in which the physician should be contacted as soon as possible. Yet, our study found significant knowledge gaps among pharmacists, including those who see Patient with CADR frequently; the mean score of surveyed pharmacists was only 52.87%. Several responders checked the “I don’t know” option or commented that they don’t know the answer, implying that they were able to admit that they have gaps of knowledge.

Pharmacists obtained the highest correct scores on the true/false statements, in fact pharmacists in this study had good baseline knowledge of definition of ADRs and CADR, the different categories of CADR and the most medication classes implicated in CADR. These elements are very interesting because they facilitate the pharmaceutical management of CADR afterwards.

The duration since professional training completion and a PharmD degree were the only predictors associated with overall score. Longer duration since graduation could be associated with the absence of updated knowledge about CADR. In addition, there was a partial overlap between shorter duration since graduation and a PharmD degree.

The majority of Moroccan pharmacists with a PharmD degree graduated over the past four years from a single Faculty of pharmacy, in which personalized medicine has been an important component of the curriculum. Thus, for both comparisons, the greatest gaps were detected in questions related to Drug Reaction With Eosinophilia, contact dermatitis, Nail Disorders, and bullous pemphigoid. Interestingly, there was no relationship between larger numbers of Patient with CADR seen each month and scores. This is may be explained by reliance on computerized resources and minimal time for interacting with patients and actually consulting them. The setting in which the questionnaire was presented, and therefore the time allowed for their completion and the percentage of practicing pharmacists among the participants, did not affect the scores. Intriguingly, recent training about CADR was not shown to increase performance in completing the questionnaire, although the type of training was not detailed. It is necessary to consider the optimal type of education that may efficiently improve pharmacists’ knowledge and actions. The major limitations of our study are related to potential selection bias, to the partial validation of the questionnaire. The majority of our participants were pharmacists who attend meetings and training courses, who may be more knowledgeable than other pharmacists. Among those who attended the university diploma in pharmacovigilance at the poison center of Morocco, low response rate may further increase the bias towards those who may be willing to answer the questionnaire because they felt more comfortable with
their degree of knowledge. Yet, participants pointed out that the questionnaire was difficult, and that the given options in the situation-related multiple choice questions did not fully reflect the possible options the pharmacist encounters at work as described above. The limited response range also reflects another limitation of the study: asking a clinical question via a multiple choice question.

However, no significant differences were found between the scores of participants in the various settings of the study. Therefore, our work may be of wider relevance to the healthcare professionals involved in the management of Patient with CADR.

**Conclusion**

Pharmacists were knowledgeable regarding some aspects of CADR. However, our study, as in previous studies among health care professionals, identified some gaps in knowledge. These findings indicate the need for better education of pharmacists regarding CADR and its supported.

Abstract

Introduction: Brushing teeth is an important thing to do since it is one of the factors that affect oral hygiene, especially to remove plaque on the teeth.¹ The ability to brush teeth properly and correctly is a fairly important factor in maintaining dental and oral health, especially in adolescence.⁵ The purpose of study to explain the differences in plaque scores before and after toothbrushing training using Bass technique in adolescents

Method: The sample were 100 students aged 12-15 years old in grades 7, 8 and 9. This study design was experimental quasi and using a pre-test and post-test after 7 days to determine the difference in plaque scores before and after the training. The plaque index method that used to examine oral hygiene was Patient Hygiene Performance (PHP). Comparison between plaque scores before and after training evaluated using Wilcoxon test. Result: Examination of PHP index before training shows 81 samples (81%) in poor criteria, then most subjects undergoes improvement after training. There were 94 samples (94%) experienced decrease or improvement in plaque score whilst 6 samples (6%) did not show improvement after training. Median of plaque score before training was 4.3 (0.2-5 (SD=0.502)) afterwards improved to 2.2 (0-4.8 (SD=0.496)). Wilcoxon test obtained a value of p<0.05 which was 0.000. Conclusion: There were significant differences in plaque scores before and after toothbrushing training using Bass technique.

Keywords: dental plaque, toothbrush, bass technique, oral hygiene

Introduction

Brushing teeth is an important thing to do since it is one of the factors that affect oral hygiene, especially to remove plaque on the teeth. Dental plaque is a bacterial biofilm with highly variable structural entity consisting of micro-organisms and their products concurrently resides in their environment.¹ The soft layer of plaque consists of 80 percent water, and the remaining of 20 percent are other components, such as proteins, lipids and minerals, calcium and phosphorus.² Bacterial deposits on uncalcified plaques accumulate above the surface of the teeth and other objects in the oral cavity, such as restorations, dentures and dental calculus that are firmly attached to this surface. Dental plaque can only be removed by mechanical cleansing, one of which is by brushing teeth.³

The right knowledge about brushing teeth in the community includes the frequency of brushing teeth, the method of brushing teeth, and the shape of a toothbrush. Brushing teeth can be a preventive measure for dental caries and periodontal disease, especially in adolescence.⁴

The ability to brush teeth properly and correctly is a fairly important factor in maintaining dental and oral health, especially in adolescence. The skill of brushing teeth must be taught to children of all ages, especially school children because at that age it is easy to accept
Based on the results of national basic health research (riset kesehatan dasar/Riskesdas) in 2007 and 2013, oral health problems increased from 23.2 percent to 25.9 percent. The prevalence of oral health problems based on the 10-14 years age group in 2007 was 20.6 percent, increasing in 2013 to 25.2 percent, and in the 15-24 years age group it increased from 21.5 percent to 24.3 percent. There was also an increase in the proportion of provincial oral health problems in DKI Jakarta province of 6.1 percent, from a value of 23 percent in 2007 to 29.1 percent in 2013. Whereas, the national percentage of toothbrushing every day was 94.2 percent in 15 provinces below national prevalence. There was a decline in correct toothbrushing behavior from 7.3 percent in 2007 and decreased to 2.3 percent in 2013.6,7

The purpose of this study was to explain that there were differences in plaque scores before and after toothbrushing training in adolescents aged 12-15 years at An-Nuqthah Islamic Boarding School, Cipete, Tangerang.

Material and Method

The independent variable was toothbrushing training and dependent variables was the score of plaque. This study was conducted at An-Nuqthah Islamic Boarding School, Cipete, Tangerang, Banten, Indonesia in 2018. The population in this study were adolescents in the An-Nuqthah Islamic Boarding School, Cipete, Tangerang and the sample in this study were 100 students aged 12-15 years old in grades 7, 8 and 9 in An-Nuqthah Islamic Boarding School.

The type and design of the study used was experimental quasi, which is an experimental study that controls the research situation using non-random methods that have a function to determine the impact of interventions. This study used a pre-test and post-test design to determine the difference in plaque scores before and after the training of toothbrushing using Bass technique.

Data collection was done using interviews, questionnaires and examination of plaque scores with disclosing agent solution. The plaque index method used was Patient Hygiene Performance (PHP). Data processing was carried out after the data was collected from school. Furthermore, data processing stage was carried out as follows: editing data, encoding data, and data entry (computerization). Data that had been collected and processed using the SPSS 17 computer program were then tested for its hypothesis using Wilcoxon test.

Research Results

1. Plaque Score Before Toothbrushing Training Using Bass Technique (Pre-Test Plaque Score)

Distribution of PHP index criteria on 100 samples before toothbrushing training using Bass technique shows very good criteria in 0 sample (0%), good criteria in 1 sample (1 %), moderate criteria in 18 samples (18%), and poor criteria in 81 samples (81%).

3. Comparison of Plaque Scores before and after Toothbrushing Training using Bass Technique

There was plaque score improvement in 100 sample after toothbrushing training using Bass technique, in which 94 samples (94%) experienced a decrease in plaque score after training. Whereas, 6 samples (6%) did not experience plaque score changes.

The median, minimum, maximum, and standard deviation values of the plaque score after toothbrushing training using Bass technique were lower than before training. Wilcoxon test obtained a value of p<0.05 which was 0.000. It can be concluded that there were differences in plaque scores before and after toothbrushing training using Bass technique in adolescents.

**Discussion**

This study was conducted to determine and explain the differences in plaque scores before and after toothbrushing training using Bass technique of adolescents aged 12-15 years. This study was conducted on 64 female and 36 male students taken randomly of grade 7, 8 and 9 in junior high school students at An-Nuqthah Islamic Boarding School, Cipete, Tangerang who had fulfilled the inclusion and exclusion criteria. The measurement of plaque scores was carried out before and after toothbrushing training using Bass technique.

Bass technique is sulcular (or crevicular) technique that aims to clean the crevicular part or gingival sulcus. If this technique is used correctly, cleaning the gingival sulcus area can be very effective.\(^3\),\(^8\),\(^11\) The time taken by researchers to measure plaque scores before and after toothbrushing training was 7 days, same as in the study conducted by Choirunnisa \(^5\),\(^8\) et al and Sari \(^2\).

The distribution of samples based on gender can be seen from total sample (n = 100). The number of female samples was more (64) compared to the number of males (36). This was in accordance with previous study conducted by Sari \(^2\) et al at At-Taufiq Lakarsantri Islamic School in Surabaya in June 2012, with a sample of 34 people, in which the number of female samples was more (24) compared to the number of males (10).

There was decrease of plaque score in most samples after training. Found 94 samples (94%) experienced improvement or decrease in plaque score and 6 samples (6%) did not show improvement (Table 3.1). The distribution was as follows: 60 samples (63.8%) were female and 34 samples (36.2%) were male who experienced improvement in plaque scores. Whereas, as many as 4 female samples (66.7%) and 2 male samples (33.3%) did not experience changes in plaque scores. This was in line with a study conducted by Sari \(^2\) et al. In 34 samples, 33 samples (97.1%) experienced improvement in plaque scores and 1 sample (2.9%) did not experience changes in plaque scores. The distribution was as follows: 23 samples (95.8%) were female and 10 samples (100%) were male who experienced improvement in plaque scores. Whereas, as many as 1 female sample (4.2%) and 0 male sample (0%) did not experience changes in plaque scores.\(^5\)

The habit of brushing teeth twice or more in one day was quite high, which was equal to 91%. However, the plaque score was still high as evidenced by 81% of total samples having poor criteria (value 3.5-5) before training (Table 1.1). This can be caused by toothbrushing technique being used is not correct. This was stated in a study conducted by Park S, Cho S and Han J in Department of Peridontology, Hanyang Medical Center, Seoul, South Korea in 2018, conducted on 124 samples also used the intervention of toothbrushing method using Bass technique. Park \(^9\),\(^15\),\(^16\) et al suggested that the effectiveness of toothbrushing techniques could be a solution for removing plaque on teeth.\(^9\),\(^15\),\(^16\)

Based on the research that has been done with Wilcoxon test (p<0.05), the value was 0.000. It means there was significant difference before and after toothbrushing training using Bass technique (Table 3.1). This study is in line with a study conducted by Rizkika \(^14\) et al which showed that plaque scores decreased after toothbrushing training using Bass technique with mean plaque score was 4.1 before training and 2.2 after training. The difference of mean value before and after toothbrushing training using Bass technique was 1.8.

These results also consistent with a study conducted by Rizkika N, Baehaqi M and Putranto RR in Purwosari Kudus Special Elementary School in 2014 which
examined the effectiveness of toothbrushing with Bass technique on changes in plaque scores in mentally retarded children. In their research, Rizkika et al found that brushing teeth with Bass technique could reduce plaque scores, from the mean value of plaque score as much as 3.88 before intervention to 3.03.17,20

From the results of the study (Table 1.2) it can be seen there was a decrease in plaque scores after toothbrushing training using Bass technique. This proves if this technique is done correctly, cleaning the gingival sulcus area can be very effective.15,17,22 In addition, toothbrushing is one of the ways to control plaque mechanically which is quite effective in removing plaque attachment on the surface of the tooth. Plaque control is a basic procedure for maintaining oral hygiene.3,21,23

Brushing teeth is important to do since it is one of the factors that affect dental and oral hygiene, especially in removing plaque on the teeth. Plaque on the teeth can cause a reduction in the quality of oral and dental health. Plaque is one of the etiological factors in caries and periodontal disease. Plaque will form a smooth, strong surface in the form of a deposit on the surface of the tooth. Therefore, plaque on the tooth surface must be removed by brushing teeth.5,10,24

**Conclusion**

There were significant differences in plaque scores before and after toothbrushing training using Bass technique. Bass brushing technique is quite effective in removing plaque deposits on the tooth surface, and is quite easy to apply in daily life.

Family Background and Parenting Characteristics of Young People with Methamphetamine Use Disorder in Northeastern Region of Thailand

Pinet Tatiwechakul¹, Varisara Luvira², Akarapat Tayarajakul³, Wannaporn Phachantasein⁴
¹Doctor, ²Assistant Professor, Department of Community Medicine, Faculty of Medicine, Khon Kaen University, Khon Kaen, Thailand, ³Doctor, Thanyarak Khon Kaen Hospital, Khon Kaen, Thailand, ⁴Nurse, Thanyarak Udon Thani Hospital, Udon Thani, Thailand

Abstract

Background: Drug abuse is an important medical problem which affects both the patient and society. This problem is rather common among young people in Thailand which family upbringing is one of the risk factors especially in the Northeastern region where prevalence of parental migration is the highest.

Objective: The objective of this study was to examine family background and parenting characteristics of young people with methamphetamine use disorder as well as the association between factors related to family upbringing and the onset of substance use in these young people.

Materials and Method: This cross-sectional descriptive study of young people between 18 and 24 years of age with methamphetamine use disorder who visited outpatient clinics in Thanyarak Udon Thani Hospital and Thanyarak Khon Kaen Hospital. 145 subjects were included to complete self-answer questionnaire that included demographic information, details on substance uses, family background and parenting characteristics.

Results: The results showed 88.3% were male and the mean age of 21.22 years. The prevalence of parental migration during childhood was 30.34% (95%CI: 23.14, 38.61) while parental absence was 16.6%. Primary caregivers during childhood were either father or mother in 70.34% of the subjects. Data analysis found that having neither of parents as primary caregivers was associated with the onset of methamphetamine use before age of 18 years (p<0.5).

Conclusion: Having one or both parents as childhood primary caregivers could reduce the risk of methamphetamine abuse among adolescents.

Keywords: parental migration, family, methamphetamine use, young people, youth

Introduction

Drug abuse is recognized as a major public health problem in many countries¹, since it affects not just the users but also the society². Amphetamine-type stimulant use was first reported in Thailand during 1980s³. According to the national household survey, 3.5 million individuals between age of 12 and 65 years had ever used illicit drugs and 590,000 people had been using the drugs within 12 months⁴. The problem is becoming rather common and is still rising in young people⁴-⁷, while studies had shown its associated with inappropriate parenting and family backgrounds⁸-⁹.

Thailand has been facing with concentrated industrialization which results in mass migration of working population into these industrialized areas. Consequently, rural areas are left with children and...
elderly, obliging the grandparents to look after their grandchildren instead of the migrating parents. Children living apart from parents due to this pattern of internal migration is very common particularly in the Northern and Northeastern regions of Thailand, due to poverty and misconception; believing that it is better for the children to be raised by their grandparents\(^{10}\). Even thought, internal migration seems financially essential for the families, many studies had shown that children who experienced parental migration had higher risk of delayed development\(^{11}\), negative mental health\(^{12-14}\), poor academic outcomes, low living condition satisfaction, and alcohol use\(^{15}\). Still, the association between parental migration and substance abuse has not been well examined especially in Thailand. We assessed family background and parenting characteristics that might associate with early age onset of substance abuse among young people who lived in Northeastern region of Thailand.

**Material and Method**

This cross-sectional descriptive study assessed patients with methamphetamine use disorder who visited outpatient clinics in Thanyarak Udon Thani Hospital and Thanyarak Khon Kaen Hospital from September to November 2019. The patients aged from 18 to 24 years, had no communication and reading difficulties, were not intoxicated from any substances, had negative urine drug tests, and were not in a medical emergency. The subjects were asked to fill in a self-answer questionnaire that included demographic information, information on substance use, family background and parenting characteristics.

Statistical analyses were performed using IBM SPSS 19; nominal variables using frequency and percentage, numerical variables using mean and standard deviation. All statistics were two-sided and a p-value of 0.05 was considered statistically significant.

In this study, “parental migration” was defined by subjects reported migration for employment of father and mother during childhood but not time-specific, whereas “parental absence” was when the migration lasted at least 1 year. Young people were usually referred to the subjects, aged 18 – 24 years, of this study.

**Results**

1. **Demographics**

The study included 145 subjects, 88.3% of the subjects were male, with the mean age of 21.22 years (S.D. = 2.06 years), 64.1% graduated from junior high school or lower, 69% were unemployed and 74.5% were unmarried.

2. **Information about substance use**

The earliest age onset of methamphetamine use was 11 years and the mean age onset was 15.86 years (S.D. = 2.01 years). The most common place where subjects used the substance was their home (61.1%) and the rate of multiple substance use, other than methamphetamine, was 93.79%; with smoking as the most co-occurring substance (66.2%).

3. **Family background and parenting characteristics**

Parental migration rate was 30.34% (95%CI: 23.14, 38.61) which mostly lasted longer than 2 years (43.18%). 60 subjects (41.38%) reported of either paternal or maternal migration, with higher rate of paternal migration. It was found that all subjects who reported of maternal migration longer than 2 years also reported of paternal migration longer than 2 years (Table 1). Parental absence was reported in 24 subjects (16.6%).

Primary caregivers during childhood were mostly either father or mother in 102 subjects (70.34%); with more on the mother side. In 45 subjects (31%) both father and mother were the primary caregivers. There were 43 subjects (29.66%), whose primary caregivers were neither father nor mother, who were left in care of mostly maternal grandparents (Table 2).

Subjects reported rate of past family conflict was 24.8% and domestic violence was 18.6%. As for the present family conflict was 15.9% and domestic violence was 12.4%.

4. **Factors from family background and parenting characteristics that might associate with age onset of methamphetamine use**

The study found that subjects with neither parents as primary caregivers were associated with the age onset of methamphetamine abuse before 18 years old, while having both parents as the primary caregivers, parental migration, and parental absence were not associated with the early age onset (table 3).

* P < 0.05 level of significance

**Discussion**

The study found that the rate of parental migration was 30.34% among young people with methamphetamine abuse in Northeastern region of Thailand. When compared with the earlier study of parental migration in 2012, among Thai children age between 0 and 4 years, the rate of parental migration was lower at 21%\(^{(16)}\). Bear in mind that our study was done in Northeastern region, where the rate of parental migration was the highest, as well as the subject age group of 18 to 24 years, when parental migration could occur after 4 years of age. Our study was done in subjects or families who, without court-mandated, sought treatment for methamphetamine abuse which might imply that these subjects were more attentive and taken care by their family members. The attentiveness could obscure the real number of parental migration/absence among young people with methamphetamine abuse who might had never sought medical care or been recognized by their family members. Paternal migration was more common than maternal migration which was consistent with earlier studies\(^{(16,17)}\). Maternal migration had been shown to negatively impact the children\(^{(18,19)}\) as consistent with our study showing any maternal migration lasted longer than 2 years would always co-exist with paternal migration also lasted longer than 2 years.

The earliest age onset of methamphetamine use was 11 years which was reported by two subjects. Similarly, the two subjects did not have their parents as primary caregivers while one subject reported of parental absence. In Thailand, 18 is the age of majority and when taking this into account we found that the age onset of methamphetamine abuse before 18 was associated with having neither of parents as primary caregivers. This could assume that by having neither of parents as primary caregivers could problematically affect the children as consistent with the study that showed negative impacts on children from maternal migration\(^{(18,19)}\) as well as...
from paternal migration in the other study\(^{20}\).

This was the first study ever assessed the issue of parental migration on young people with methamphetamine use disorder in Northeastern region as well as in Thailand. Interestingly, we found that maternal migration that lasted longer than 2 years would always occur with paternal migration that also lasted longer than 2 years. In terms of substance abuse, this study suggested that adolescents would be better off under the care of either one or both parents, since unavailability was associated with the age onset of methamphetamine abuse before 18. However, the subjects from this study were those who voluntarily sought medical care rather than subjected to compulsory treatment order and the hospital settings were specialized drug addiction treatment centers that could not represent patients from general hospitals. Other limitation was that this study was based on a self-answer questionnaire; being a retrospective study, the results might not be as impactful as prospective studies.

**Conclusion**

Young people with methamphetamine use disorder who sought medical care, without compulsory treatment order, in the drug addiction treatment hospitals in Northeastern region of Thailand were found that the rate of childhood parental migration was 30.34% and the rate of parental absence was 16.6%. In every case of maternal migration that lasted longer than 2 years, paternal migration would always co-exist and also lasted longer than 2 years. Family conflict and domestic violence, either in the past or present, were reported in one out of four or five subjects. Primary caregivers during childhood were either father or mother in 70.34% of the subjects; mother was the majority. By having neither of parents as primary caregivers was associated with the age onset of methamphetamine abuse before 18.

Heatstroke due to Vehicular Entrapment: An Autopsy Case Report

Razuin R1,2, Julina M. N3, Nurquin F. S.2, Amirul A. H.2

1Centre for Pathology Diagnostic & Research Laboratories, Faculty of Medicine, Universiti Teknologi MARA, Selangor, Malaysia, 2Department of Forensic Medicine, Hospital Sungai Buloh, Ministry of Health Malaysia, 3Department of Emergency Medicine, Faculty of Medicine, Universiti Teknologi MARA, Selangor, Malaysia

Abstract

Heatstroke is defined as severe heat illness with elevated body temperature greater than 40.6°C associated with central nervous system dysfunction. In children, heatstroke as a result of vehicular entrapment is commonly encountered. We report a case of a six-year-old boy who was accidentally left in a school van under scorching hot afternoon for several hours. Upon discovery, he was rushed to a hospital where he was pronounced dead. His body temperature taken at the Emergency Department was 40.3°C. The body felt warm in spite of apparent presence of post mortem changes such as rigor and livor mortis. His clothes were drenched in sweat. A medico-legal autopsy was performed. On general examination, his body was pale and the lips were also parched and pale. Internally, there was subdural haemorrhage and petechial haemorrhages on the lungs and the epicardial surface of the heart. The cause of death was given as heatstroke as a result of vehicular entrapment. We wish to emphasize and appeal to the public that this tragic incident is preventable. Public and private sectors should help creating awareness of dangers in leaving a child unattended in a car.

Keywords: Heatstroke; Hyperthermia; Automobile; Paediatric; Autopsy

Introduction

Heatstroke is a life-threatening condition which is characterized by an elevated core body temperature above 40.6°C accompanied by central nervous system dysfunction, multi-organ failure and potentially result in death.1,2 Hyperthermia causing heatstroke as a result of excessive metabolic heat production usually during exercise is known as exertional heatstroke.3 Another type of heatstroke which is known as classical heatstroke is a result of poor heat dissipation which occurs in the event of heat waves or entrapped in a vehicle.4,5

In young children, heat related deaths are mostly caused by vehicular entrapment, intentionally or unintentionally.6,7 The National Highway Traffic Safety Administration (NHTSA) of the United States recorded 793 deaths of entrapped children between 1990 and 2016, with an average of 37 deaths per year.8,9 In Malaysia, data of vehicular entrapment cases were obtained from local newspaper reports, showing much lesser incidence of approximately one case per year. In many instances, the events include caretaker forgotten about the child in a vehicle or the child gaining access to the vehicle without the parents or guardians knowledge. In short, lack of adult supervision was determined as the most common contributing factor worldwide.

The diagnosis of heatstroke relies heavily on the history of circumstances of death. At autopsy, findings of heatstroke may be subtle and non-specific. Internal examination may demonstrate cerebral oedema, pulmonary oedema and internal organs congestion.2,6,10 Typical autopsy findings in adult or children with heatstroke include diffuse petechiae and haemorrhages as well as pulmonary involvement.4 Therefore, in the absence of good anamnesis, heatstroke as a cause of death could have been inadvertently missed.

We report a case of a child who was accidentally left in a school van on a scorching hot afternoon for a
few hours. He was found unconscious and immediately rushed to a hospital where resuscitation efforts were commenced, to no avail. The aim of this case report is to describe the pathology findings of an autopsy performed on a child who died of heatstroke as a result of vehicular entrapment. We also wish to highlight that this tragic incident is entirely preventable.

Case Report

In mid-August 2017, a six-year-old boy was found unconscious and unresponsive in a school van. He was picked up from home to attend a preschool in a hot sunny afternoon. After dropping off the children, the van driver proceeded to a restaurant nearby for lunch. About two and a half hours later, he returned to the van in order to pick up the children from school and send them back to their homes. This was when he realized that one child never actually alighted off the van. He immediately rushed the child to a nearby clinic which subsequently referred him to a hospital.

At the Emergency Department (ED), the child was noted to be warm and the rectal temperature measured was 40.3°C. Rigor mortis was present as evidenced from the fixed flexion of both arms and legs. Cardiorespiratory resuscitation (CPR) was commenced while the patient was in an ambulance en route to the hospital and continued for several minutes upon arrival. He was eventually pronounced dead and a police order for medico-legal autopsy was issued.

Autopsy examination showed a well-nourished and appropriately built male child measuring 107 cm in length and 39 kg in weight. The clothes were drenched in sweat. The lips were parched and pale. Bluish discolouration was noted on the nail beds, indicating cyanosis. Rigor mortis was present in spite of the relatively warm body. Internal examination of the head and neck revealed cerebral oedema, minimal subdural haemorrhages and markedly congested cerebral blood vessels. Examination of the lungs revealed subpleural petechial haemorrhages, pulmonary oedema and blood vessels congestion. Froth was also present on the trachea, in keeping with pulmonary oedema. Petechial haemorrhages were also observed on the epicardial surface of the heart. Sago-spleen like appearance was observed.

Tissue samples from the brain, heart, lungs, liver, kidneys and adrenal glands were obtained for microscopy examination. On histology, the organs showed dilated and congested blood vessels. The cause of death was concluded as heatstroke as a result of vehicular entrapment. The mechanism of death was hyperthermia leading to neurological dysfunction and cardio-circulatory failure.

Discussion

Children are vulnerable to heatstroke due to their under-developed thermoregulatory system, hence impairing the body’s ability to dissipate heat effectively. Their small body size also contributes to large surface area, resulting in high rate of heat absorption. On top of that, their small blood volume restricts the potential for heat conductance, thus resulting in higher heat accumulation. Eventually, their small physique also means smaller sweat glands, lower metabolic capacity and lower sensitivity of sweating mechanism to thermal stimuli.

Autopsy findings in fatal hyperthermia include widespread haemorrhages, pulmonary congestion and oedema. In both children and adults, the features of heatstroke are relatively similar, regardless of the circumstances leading to it. Essentially, these findings are non-specific and could be attributed to other causes such as sepsis, burn injuries, barotrauma and electrocution. Therefore, history of the case which includes detailed police investigation and relevant witness statement will be of ultimate key evidence leading to heatstroke diagnosis.

In children, vehicular entrapment is the most common cause of fatal heatstroke. Studies have shown that the interior of a closed vehicle heats up very quickly. Within 15 minutes, the interior of a parked vehicle may reach the maximum temperature of 51-67°C, from the ambient temperature of 36.8°C. Within 5 minutes of closing the doors, 75% of the maximal value could be reached.

In our case, the child has most probably fallen asleep during the short journey to school causing him to fail to alight from the van. When he was discovered two and a half hours later, he was already deceased as rigor mortis had already set in. Meteorological report showed that on the fateful day, the sunny afternoon temperature fetched 33°C. As the school van was parked in an open area and under direct sunlight, it is hypothesized that the interior temperature of the van could have gone up to almost 70°C in less than 15 minutes. Hyperthermia may cause death when the body temperature reaches 41.7°C. As
the temperature inside the van reached more than 60°C in short period of time, heatstroke and death could have occurred in short period of time too. A study by Walter and Carrareto has found that hyperthermia with body temperature of 38.8°C, cognitive impairment may occur in one to two hours after insult. In a case of vehicular entrapment, the excessive high temperature in the vehicle will remain until the doors are opened. Therefore, the core body temperature will also rise within the relatively similar time frame. We postulated that death occurred in less than one hour of entrapment, in keeping with acute and extreme temperature elevation inside the school van. At the early stage, heat-regulating mechanisms such as excessive sweating, rapid breathing and fast, weak pulse were in place, as evidenced by his sweat-drenched clothes. Eventually, the body’s thermoregulation became overwhelmed, the blood pressure dropped as the heart attempted to maintain adequate circulation to the vital organs. Decrease in blood pressure and vasoconstriction resulted in pale appearance of the body. At the ED, the body was pale and warm despite presence of rigor mortis. Another key finding in this case is rigor mortis, as it is not only an indication of death, but also, a sign of death associated with hyperthermia.

A study by A Guard found that almost three quarters of the cases were actually children who were left by adults. More than 50% of these cases resulted from adults who forgot or unaware that they were leaving the children inside the vehicle. About 13% of these cases involved childcare providers and drivers. In our case, the van driver was a replacement driver who happened to be on his first day at work. While he himself was a youth, inexperience and lack of proper guidance imparted to him about the job have resulted in a lifetime of regret.

**Conclusion**

Heatstroke fatality resulted from vehicular entrapment is an entirely preventable tragedy. Parents, caregivers including school van drivers should be regularly reminded to take heed of important tips such as looking at the backseat before exiting and checking the vehicle before locking the doors. Increased public awareness could help averting the tragic incident from claiming life of another child.

Cardiac Haemorrhage: An Extreme Presentation of Leptospirosis

Razuin R1,2, Nurquin F. S2, Nur A. R. P.2, Julina M. N.3

1Centre for Pathology Diagnostic & Research Laboratories, Faculty of Medicine, Universiti Teknologi MARA, Selangor, Malaysia, 2Department of Forensic Medicine, Hospital Sungai Buloh, Ministry of Health Malaysia, 3Department of Emergency Medicine, Faculty of Medicine, Universiti Teknologi MARA, Selangor, Malaysia

Abstract

Introduction: Leptospirosis is a worldwide disease with significant morbidity and mortality. The severe form of the disease may present with cardiac and pulmonary involvements resulting in multi-organ failure. Cardiac manifestations of leptospirosis include arrhythmia, cardiomegaly, petechial haemorrhages, pericarditis and myocarditis. Case report: We report a case of a 10-year-old boy who was having shortness of breath and collapsed at home. At the emergency department, he was having refractory hypotension with electrocardiogram (ECG) showing sinus tachycardia. The liver and cardiac enzymes were markedly raised. The full blood count showed leukocytosis. It was concluded that he was in septicaemic state with acute multi-organ failure of unknown cause. He succumbed to the illness approximately 8 hours after the hospital admission. At autopsy, the lungs, liver and spleen were markedly congested. Pericardial effusion was noted. The heart showed extensive areas of petechial and confluent haemorrhages involving almost the entire epicardial surface of the right and left ventricles. Massive subendocardial haemorrhage was also observed upon sectioning of the left ventricular chamber. Histopathology examination corroborated that haemorrhages were present in the heart, lungs and the liver. Laboratory investigations revealed positive Leptospira IgM antibody, confirmed by positive Leptospira PCR. The cause of death was concluded as cardiac and pulmonary haemorrhages secondary to leptospirosis. Conclusion: Cardiovascular involvement in leptospirosis may manifest as rapidly deteriorating illness with clinical evidence demonstrable from the ECG changes and raised cardiac enzymes. Recognizing these signs early may help to improve outcomes.

Keywords: Leptospirosis; Myocarditis; Pulmonary haemorrhage; Autopsy; Cardiac haemorrhage

Introduction

Leptospirosis is a worldwide zoonotic disease caused by pathogenic spirochetes of the genus Leptospira.1,2 Transmission primarily occurs from direct contact with infected animals, or water contaminated with urine of infected animals, commonly rodents.3,4 The clinical manifestations include simple febrile episodes, classified as self-limiting anicteric febrile disease to complex clinical features known as Weil’s disease.2,5 A severe and fatal form of this illness may present with cardiac and pulmonary involvement, renal failure, liver failure or a combination of multi-organ involvement with haemorrhagic diathesis.3,6

Cardiac manifestations of leptospirosis include arrhythmia, cardiomegaly, petechial haemorrhages, pericarditis and myocarditis.2,7,8 Studies have shown that cardiac involvement occurred in 20% to 93% of the cases.7,9 At autopsy, petechial haemorrhages and myocarditis are the most common presentations indicating cardiovascular involvement in leptospirosis.2,7,9

We report a case of a 10-year-old boy who appeared to be slightly unwell, collapsed at home and passed away approximately 8 hours after the hospital admission. He was diagnosed with acute multi-organ failure and sepsis of an unknown cause. At autopsy, massive cardiac

haemorrhages were observed. *Leptospira* IgM antibody and polymerase chain reaction (PCR) were positive. In this case report, we wish to highlight that fatal leptospirosis may have very minimum presentations, thus, high index of suspicion is needed in order to improve outcomes. We also wish to describe an extreme cardiac presentation associated with leptospirosis.

**Case Report**

A 10-year-old boy was brought to a hospital after he was found collapsed in a bathroom at home. According to the parents, he appeared slightly unwell and less active for two days. At the emergency department, he was unresponsive with Glasgow Coma Scale (GCS) of 3/15. His heart rate was 180/min, blood pressure of 110/40, SpO2 99%, and temperature was 38.4°C. The electrocardiogram (ECG) showed sinus tachycardia. He also had cool peripheries. Blood investigations revealed normal haemoglobin (15.5 g/dL), high total white cell count (38 x 10⁹/ L) and mild thrombocytopenia (149 x 10⁹/ L). Cardiac enzymes such as troponin I, creatine kinase (CK), aspartate aminotransferase (AST) and lactate dehydrogenase (LDH) were all raised, at 15439 ng/ml, >42670 mml/L, 995 U/L and 2904 U/L respectively. The creatinine level was 309.7 mg/dl, indicating acute renal failure. The liver function test showed increased alanine aminotransferase (232 U/L).

Computed tomography for the brain was performed, showing no evidence of intracranial bleed or space occupying lesion. The working diagnoses at this point were severe sepsis with acute multi-organ failure. He was promptly intubated and resuscitated. Shortly after the admission, his blood pressure began to show a downward trend. Systolic pressured ranging from 50-60 mmHg and diastolic pressure 30-40 mmHg. His blood pressure remained low despite maximum inotropic supports and multiple fluid boluses given. Eventually, he succumbed to the illness approximately 8 hours after the admission. A medico-legal autopsy was performed to ascertain the cause of death.

Autopsy examination showed an obese and appropriately built male child measuring 146 cm in length and 85 kg in weight. The lungs, liver and spleen were markedly congested. Detailed gross examination of the cardiovascular system showed pericardial effusion amounting to 55 ml. The heart showed extensive areas of petechial and confluent haemorrhages involving almost the entire epicardial surface of the right and left ventricles. Massive subendocardial haemorrhage was also noted upon sectioning of the left ventricular chamber (Fig. 1). The serial cut sections showed softening of the cardiac parenchyma associated with transmural petechial haemorrhages, mostly prominent at the antero-septal region of the left ventricle. ‘Shock’ kidneys appearance was observed, exhibiting pale cortex with dark medulla. The spleen was also congested, soft and friable.

![Fig. 1](image.png)
Representative tissue samples from the heart, lungs, liver, spleen and kidneys were obtained for microscopy examination. On histology, the heart shows extensive transmural haemorrhages involving both the right and left ventricles. Occasional acute inflammatory cells are present and contraction band necrosis is also observed, in keeping with ischaemic changes (Fig. 2 a&b). Haemorrhages are also present on the liver and lungs sections. The spleen shows massive neutrophilic infiltration and central necrosis of the white pulps. These features are in keeping with septicaemia. The kidneys show features of acute tubular necrosis, corroborating the high creatinine level from the blood investigation. Myoglobin globules are observed in the kidneys, which, in combination with the markedly raised creatine kinase, confirming presence of rhabdomyolysis in this case (Fig. 2d). The lungs show oedema, congestion and massive intra-alveolar haemorrhages (Fig. 2c). An area showing pulmonary infarction is also observed. In summary, the histology examination confirmed that the deceased was having an acute multiple organ failure, cardiac and pulmonary haemorrhages, as well as severe rhabdomyolysis.

In view of the physical examination, laboratory investigations results and autopsy findings, a diagnosis of leptospirosis was suspected. Several post mortem blood samples were obtained for infectious disease screening. Serological analysis revealed a positive *Leptospira* IgM antibody. A subsequent confirmatory test by PCR was performed, the result was positive. Therefore, the cause of death was concluded as cardiac and pulmonary haemorrhages secondary to leptospirosis. The mechanism of death was septicaemia in combination with multiple organ failure.

Fig. 2 (a) The myocardium showing multiple foci of haemorrhages (arrows). (b) Scattered intraparenchymal haemorrhages and contraction band necrosis of the myocardium (arrows). There is no inflammatory cell infiltrate observed. (c) The lung section shows thickened alveolar walls with red blood cells in the alveoli sacs. (d) Masson’s trichrome stain of the kidney, showing myoglobin globules in the distal convoluted tubules (arrows).
Discussion

Cardiovascular involvement in leptospirosis has variable degrees and potentially life threatening. Presentations such as arhythmia, pericarditis, myocarditis, congestive heart failure and cardiogenic shock are well documented in studies before. Clinical evidence is frequently demonstrable from cardiac enzymes assays, ECG and echocardiography (ECHO). Manifestations such as refractory hypotension, AV conduction block and sinus tachycardia are the most common ECG findings in leptospirosis. Raised cardiac enzymes may be an indication of myocarditis and an important prognostic marker. In our case, the child presented with refractory hypotension and sinus tachycardia on ECG. All the cardiac enzymes were markedly raised. We hypothesized that the child was having cardiogenic shock when he was admitted to the hospital.

At autopsy, cardiac manifestations in leptospirosis include cardiomegaly, petechial haemorrhages, inflammation of the cardiac muscles and complications such as congestive cardiac failure. Microscopically, interstitial myocarditis with predominant lymphocytes and macrophages infiltrations with some degree of myocardial injuries such as degeneration or necrosis are commonly observed. In our case, massive haemorrhages were observed affecting almost the entire epicardial surface and all layers of the heart. On microscopy, the cardiac parenchyma generally showed evidence of haemorrhages with minimum inflammation. Therefore, our case illustrates an extreme and unusual form of cardiac presentation where the heart was essentially having severe bleeding, instead of inflammation as commonly observed in leptospirosis.

Another highlight of the case is rapid deterioration of a patient with cardiovascular involvement. Retrospectively, the parents only noticed his reduced activity for two days, as he was lying down and taking nap a little longer than usual. Still, he did not complain of feeling ill or appear very sick. However, the fact that paracetamol and salicylate were present in the blood suggested that the child did have fever and myalgia. According to the parents, the boy was quite independent and most probably had taken the medications by himself. As he came in with acute multi-organ failure with sepsis, the rapid worsening of his conditions baffled the attending clinicians. Unfortunately, leptospirosis was not suspected to be the cause.

Contact tracing revealed that he was most probably infected during a recreational activity at a waterfall. Two weeks prior to his death, the family went to a waterfall for picnic and swimming. A week later, he probably began to have fever as further checks showed that he bought some fever medications at a convenient store near his home. However, all this while, he appeared well and was able to carry out his daily activities including going to school and playing football in the afternoon. A day prior to his demise, he appeared slightly unwell, as he spent longer nap in the afternoon and did not go out to play football. His final symptom was difficulty in breathing amid the high fever. Observing the sequence of events, we hypothesized that after a week of contracting the disease, he began to have fever as a manifestation of the first phase of leptospirosis. The first phase is usually associated with high fever, headache, myalgia, abdominal pain, nausea and vomiting. Subsequently, the child went into the second phase which is characterized by jaundice, renal and liver failures and pulmonary haemorrhages. When he was brought to the hospital, two weeks after contracting leptospirosis, he was having cardiogenic shock, multiple organ failure and septicaemia.

Conclusion

Cardiovascular involvement in leptospirosis may manifest as rapidly deteriorating illness with clinical evidence demonstrable from the ECG changes and raised cardiac enzymes. Despite a vague medical history, leptospirosis should always be kept in mind as early identification and appropriate treatments may help to improve outcomes.

Abstract

Background. Changes in community structure from argument to industry and lifestyle changes, socio-economic societies are suspected as a backdrop to the increasing prevalence of non-communicable diseases, so that the incidence of non-communicable diseases varies greatly in epidemiological transitions. One of the epidemiological problems that often arises is the problem of child nutrition. Street children nutrition is very concern in Makassar City. Street children in Makassar city are increasing every year. This was seen in 2014 the number of street children was 220, in 2015 there were 250 children, while in 2016 it increased to 305 street children. Street children are at risk of suffering from nutritional disorders. The nutritional status of street children is very dependent on mobility, streetism, mobility, and social cohesion. The study was conducted with the aim of analyzing the nutritional status of street children based on the perspective of streetism, mobility and social cohesion in Makassar. The benefits of this research are expected to be able to develop theories and concepts regarding the nutritional status of street children based on epidemiological studies. Material and Methods The type of research used was an observational method in a cross-sectional study design. The sampling method uses simple random sampling. The study was conducted in September-January 2020. The number of sampling was 90 people. The population and research sample are street children in Makassar City. The data analysis technique used in this study is Chi-square. Results. There is an influence of streetism and social cohesion on street children in Makassar. The results of the analysis of the relationship between streetism, mobility and social cohesion with the nutritional status of street children found that streetism p (0,000) < p (0.05), mobility p (0,075) p > (0,05), kohesi social p (0,075) p > (0,05). Conclusion. Streetism has a very significant influence on the status of street children in Makassar. It is recommended that the social service and health office work together with halfway houses to provide information on nutrition to street children so that they understand about nutritious food, healthy eating patterns.

The nutritional status of street children is very dependent on mobility, streetism, mobility, and social cohesion. The study was conducted with the aim of analyzing the nutritional status of street children based on the perspective of streetism, mobility and social cohesion in Makassar City. The benefits of this research are expected to be able to develop theories and concepts regarding the nutritional status of street children based on epidemiological studies.

Street children who leave home, either voluntarily or because they are forced to live on the streets, become a risk for street children. Their living and living conditions are faced with risks related to nutrition, health, deviant sexual behavior, drug and alcohol abuse, threats of physical and psychological violence. Determination of the health status and nutritional status of street children is closely related to the mobility of street children, social cohesion, streetism in solving problems faced. Streetism contains an understanding of how street children live their lives on the road.

**Material and Method**

**Material and Methods** The type of research used was an observational method in a cross-sectional study design. The sampling method uses simple random sampling. The study was conducted in September-January 2020. The number of sampling was 90 people. The population and research sample are street children in Makassar City. The data analysis technique used in this study is Chi-square.

**Results**

Data on street children collected as many as 90 people spread across all roads in the Makassar City area were then measured for nutritional status. The results of these measurements can be seen in the following table.

**Table 1** Effects of Streetism on the Nutritional Status of Street Children

Table 3 explains that the social cohesion variable obtained p (0.047) p > (0.05), does not have an effect on the nutritional status of street children

### Discussion

Table 1 explains that the variable streetism is obtained p (0.000) p < (0.05), giving an influence on the nutritional status of street children. This is related to several factors such as income, choice of food, free lifestyle and others. Street children are children who spend most of their time doing daily life activities on the streets such as making a living and or wandering, in other public places. Street children have their own characteristics such as age between 5-10 years, carrying out activities on the streets, mostly dull appearance, neglected clothing, and high mobility. [3]

Streetism is a term that describes the desperate situation of children, who are forced to spend most of their time outside the home, often sleeping on the street and engaging in activities to generate low income. [3], [4]

Streetism arises in urban areas such as Makassar, where children who come from suburbs or slums in the city, who do not get attention and are not taken care of by their parents, are on the road forcefully or with their own awareness to fulfill their basic needs, especially food sufficiency. Streetism is related to freedom of life on the streets, freedom of family problems, work to fulfill basic life needs, not bound by regulations, limited housing and home facilities as well as physical and non-physical violence.

Streetism conditions have an impact on the nutritional status of street children. Adequate nutrition of street children is related to their daily food consumption. Healthy and nutritious food can be fulfilled by buying processed foods or food ingredients that are processed into food. Street children buy food from the work of begging, busking, parkers, porters or laborers, and various other jobs.

Freedom as a sign of streetism has an impact on the nutritional status of street children. Street children who are bigger and have a higher income, will spend their money on non-food needs. As part of street children buying cigarettes and smoking to show freedom and non-attachment to rules. Some of them have even begun to try coplo pills or alcoholic drinks, which are widely available on the streets and easy for them to access.

Isbach et al. reported as many as 63.2% of street children who spent 4-8 hours per day on the road with very thin nutritional status. The energy used to work on the streets is not proportional to the food they consume. The same was reported by Hakim et al., 66.67% of street children underweight and 33.33% of normal body weight who worked on the streets of Bangladesh. [5], [6]

Patriasih, et al. in Lembang City, Bandung, West Java, found that from 324 street children samples, 80.4% had underweight and were obstructed. Common diseases suffered by street children are diarrhea as much as 22.7% and diseases as much as 18.4%. Research conducted by Nur’aini in the city of Bandung, shows that most street children work as singers, spending 4-8 hours a day and...
4-6 days a week. The average level of energy and protein adequacy of children is in the category of mild deficits, iron and vitamin C in the low category and vitamin A in the sufficient category. [7], [8]

Rathod et al reported that a survey of children in Mumbai, India, where 56 of them were women. About 77 percent of the total children are malnourished. Of the total number of malnourished children, 43 percent of children are obstructed, 38 percent are underweight and 19 percent are wasted. About 36 percent had a fever and 17 percent had diarrhea in the past year. [9]

Sehra, RN., Conducted a nutritional status assessment and identified general health problems among street children in Bikaner, Rajasthan, India, stating that 41.5% of children have normal nutritional status, while 59.5 suffer from lack of energy protein (KRP). Likewise, Meshram et al. Reported on the nutritional status of street children in India, that the prevalence of anemia was still high in street children. [10], [11]

Table 2 explains that the variable social morbility obtained $p (0.075) > (0.05)$ did not influence the nutritional status of street children. This can be due to the mobility of the area or migration of the population, which is the driving factor that makes the community leave the region of origin and the pull factor that makes the community come to the area, will not immediately change its economic capacity.

Regional mobility occurs around Makassar City such as Kab. Gowa, Kab. Maros, Kab. Takalar and Kab. Jenneponto or other regions in South Sulawesi and influenced by four important factors, namely factors that can drive the migration process, which are issued by the area of origin and are likely to be negative, migration process, factors that are in the migration channel area, individual factors of the population migrating. [12], [13]

People who come to Makassar for economic and employment reasons, but do not have sufficient education, skills and abilities to work, will eventually live in slums with work as laborers, coolies, or other informal sectors. The work is not enough to provide a living to finance the needs of his family. The child from the family then becomes a street child, a child who spends most of his time on the road working as a beggar, buskers, scavengers, parking attendants, coolies or laborers.

Mobility in the Makassar City itself also does not have an impact on nutritional status, because mobility does not directly improve consumption patterns and fulfill the food needs of families and street children. Street children who work as scavengers, have high mobility, but instead become thinner because of the large amount of energy used to carry out physical activities on foot or pedal the garbage collection wheels.

Research conducted by Goodmana et al., Assessing household and maternal factors associated with child street migration in Kenya, shows no significant relationship between increasing maternal childhood difficulties and child street migration. [14]

Literature study mainly from three continents (Africa, Asia, and Latin America) and observing economic, political, social, and environmental versions, carried out by Alem et al., Informs that the majority of road occupants are categorized as children working on the street in Africa, while in Asia some of them are left from their homes. Children who come to the streets may be driven by factors such as coercion by families, lack of access to education, and the existence of an unpleasant life in Africa. Children in Asia are encouraged by families to work as laborers and street vendors, as a source of family livelihood. [15]

Table 3 explains that the social cohesion variable obtained $p (0.047) > (0.05)$, does not have an effect on the nutritional status of street children. This can be due to several factors such as high integrity and quality of life as part of the results of social cohesion. Social cohesion is an order that has shared values and interpretations, which reduces wealth and income disparities, and generally enables people to have a sense of involvement in a community, face shared challenges, and have a perception of shared community. [16]

Social cohesion occurs because the values held in common and then build a community to face common challenges, and have a perception of community similarity. Social cohesion is based on quality of life, scope of life and integrity. integrity as a part of forming community social cohesion has not been able to improve the nutritional status of street children. Although there is a sense of unity and harmony and solidarity among street children, but what will be distributed or assisted to other street children is still limited.

Quality of life is still low, especially in food availability and food consumption patterns. Even
though the availability of sufficient food will provide an opportunity for every family member to meet their food needs. Likewise, the level of education as a determinant of quality of life, will cause the families of street children, namely mothers and fathers, lack adequate knowledge about healthy and balanced food, so that street children who still go home will get food that is not nutritious enough.

Hakim, RL, conducted research on energy intake and infectious diseases with the nutritional status of street children in the city of Semarang. The research sample of 90 street children with cross-sectional study design. The results of the study concluded that there is a relationship between energy intake and infectious disease with the nutritional status of street children. [17]

Cumber et al. Stated that street children are at risk of carrying a greater burden of disease. The lifestyle of street children is more vulnerable to risk and health problems than children who live at home, when street children roam the streets looking for food and money. The street child sleeps in half-destroyed houses, abandoned basements, under bridges and in the open air. Street children usually work in poor conditions, are dangerous to their health, and starve for several days. [18]

**Conclusion**

Streetism has a very significant influence on the status of street children in Makassar. It is recommended that the Social Service and Health Office work together with halfway houses to provide information on nutrition to street children so that they understand about nutritious food, healthy eating patterns

Changes in ARB Sputum Positivity, BMI and TNF-α Levels of Pulmonary TB Patients with ARB Positive During One-month Intensive Treatment

Samsuri¹, Helmia Hasan¹

¹Department of Pulmonology and Medical Respiration, Faculty of Medicine, Universitas Airlangga, Surabaya (60131), Indonesia

Abstract

Background: TNF-α plays a role in the occurrence of anorexia and weight loss in pulmonary tuberculosis (TB) patients. Evaluation of treatment response can be done with clinical, microbiological and radiological evaluation. In patients without cough, Body Mass Index (BMI) and TNF-α levels can be used to evaluate clinical treatment response.

Objectives: The aim of the study is to measure the Acid Resistant Bacteria (ARB) sputum positivity decrease, TNF-α levels and increased BMI after 2 weeks and 4 weeks intensive treatment of pulmonary TB patients with new case of ARB positive.

Methods: The sample size was 14 people with ARB positive pulmonary TB cases, consisting of 9 men and 5 women. It was done sputum smear, BMI and TNF-α examination before treatment, at week 2 and week 4 of intensive phase treatment

Result: At the end of the second week, TNF-α levels decreased significantly compared to baseline TNF-α levels with p = 0.015. There was a non significant increase of BMI at the end of the second and fourth week with p = 0.309 and p = 0.270 respectively. The decrease in ARB sputum smear positivity at the end of the second week compared to the fourth week was not statistically significant with p = 0.157. There was a strong correlation between TNF-α and IMT levels before treatment with negative correlation, r = -0.702 and p = 0.005.

Conclusion: Levels of TNF-α at the end of the second week decreased significantly compared to baseline TNF-α levels. There was a strong correlation between TNF-α levels and BMI prior to treatment.

Keywords: Acid Resistant Bacteria Sputum, Body Mass Index, TNF-α levels, pulmonary Tuberculosis, new cases, intensive phase

Introduction

Tuberculosis (TB) is an important public health problem worldwide. It is estimated that about one-third of the world’s population has been infected by the Mycobacterium tuberculosis. The WHO data 2012 stated that Indonesia takes the fourth place in the world with the number of 0.40-0.50 million people with tuberculosis after India (2.0-2.5 million sufferers), China (0.9-1.1 million sufferers) and South Africa (0.40-0.60 million sufferers)¹.

Body weight loss due to TB is caused by pro-inflammatory cytokines TNF-α produced by dendritic cells and macrophages. TNF-α is known as cachectin that works in the hypothalamus by suppressing the eating desire center causing anorexia and cachexia. At the onset of OAT treatment, there was an increase in TNF-α levels, whereas longitudinal studies concluded that TNF-α levels fluctuated during OAT treatment. Other studies reported an increase in TNF-α levels in TB patients although not significant ².

Body Mass Index (BMI) is the result of weight (kg) divided by height (m) squared. BMI is a simple method to monitor adult nutritional status. BMI is very sensitive to sudden changes in the body for example due to
infectious diseases or decreased appetite. Evaluation of weight gain can be used to assess the clinical treatment progress of TB patients.

The number of ARB germs declines rapidly after OAT treatment begins, 80-85% of pulmonary TB patients become non-infectious after about 2 weeks of treatment. It is estimated that more than 50% of TB sufferers remain infectious after 2 weeks of treatment. The best assessment of the OAT therapy response is the TB bacilli eradication of sputum. Some researchers have found ARB decreased after receiving OAT therapy for approximately 2 weeks.

Surgery, OBG, ENT Eye Disease Sciences are not rare getting a case with surgical indications in a patient who simultaneously suffers from ARB positive pulmonary TB. The Pulmonology and Respiratory Medicine is often consulted in such cases. Should the operation be delayed and wait until the intensive phase is complete (sputum conversion has occurred)? And the answers given are often different. From the description above, it is necessary to examine the decrease of ARB sputum positivity, TNF-α level and BMI increase after 2 weeks and 4 weeks of intensive treatment to determine the relationship between the sputum positivity level of BTA and BMI, as well as the relationship between decrease in ARB sputum positivity and TNF-α after 2 weeks and 4 weeks of intensive phases.

**Method**

The subjects were pulmonary TB patients who met the inclusion and exclusion criteria. Inclusion criteria were male and female, aged 15-60 years, positive new case of pulmonary TB, and willing to seek treatment at DOTS Unit of Pulmonology Department, Dr. Soetomo General Hospital Surabaya, Indonesia. Exclusion criteria were DM, malignant and AIDS / HIV disease, patients could not excrete sputum spontaneously, did not get standard OAT 4 FDC, there are major side effects of OAT.

This was analytical observational study. The study procedure included interview, physical examination, TNF-α level examination, and ARB smear sputum examination. Interviews included anamnesis about Diabetes Mellitus (DM) symptoms, malignancy and HIV/AIDS risk factors. Physical examination included general examination, weight, height, tension, pulse, breath frequency. Physical examination was also intended to look for signs of malignancy and HIV/AIDS more specifically.

Examination of TNF-α levels was performed by taking venous blood with a syringe of 5 cc, then centrifuged for several minutes. The serum was taken, then put into the tube and stored in the refrigerator with a temperature of -70°C. Measurements of TNF-α levels were performed by ELISA. The steps of TNF-α examination were as follows (1). Reagents preparation, samples and standard solutions as controls (2). Add 100 μl standard solution or sample, incubate for 2.5 hours at room temperature (3). Add 100 μl biotin antibody, incubate for 1 hour at room temperature (4). Add 100 μl of Streptavidin solution, incubate for 45 minutes at room temperature (5). Add 100 μl of One-Step Substrate TMB reagent, incubated for 30 minutes at room temperature (6). Add 50 μl Stop Solution and read immediately on 450 nm wave.

Sputum smear of ARB examination was done by taking spontaneous sputum of patients into 2 sputum pots. Sputum taken for examination was spontaneous sputum and morning sputum. Spontaneous sputum was labeled with name, age, register number, date of specimen taking then sent to Microbiology Unit for sputum painting examination by Ziehl Nielsen method. Ziehl Nielsen painting results were read on an IUALTLD scale.

The data were recorded and collected, then analyzed using the SPSS computer statistical program (SPSS, Inc., Chicago, IL). Sputum positivity rate of ARB, BMI and TNF-α levels were presented in tables. The correlation between sputum positivity level of ARB and BMI, between sputum positivity of ARB and TNF-α level was tested using Pearson correlation test with p <0.05.

**Result**

Respondents Characteristics

Smear sputum results of ARB according to IUALTLD score at the time of pulmonary TB diagnosis were 2 ARB scanty sputum (14.28%), 6 ARB sputum 1+ (42.86%), 4 ARB sputum 2+ (28.57%) and 2 ARB sputum 3+ (14.28%). At the end of second week of treatment, 9 patients (64.29%) converted to negative, 4 patients (28.57%) with ARB smear sputum 1+ and 1 patient (7.14%) with ARB smear sputum 2+. At the end of the fourth week of treatment, there were 11 patients (78.57%) converted to negative, 2 patients (14.28%) with ARB smear sputum 1+ and 1 patient (7.14%) with...
ARB smear sputum 2+ (Table 1).

**Analysis Results**

Paired sample t test was used to determine the significant difference of BMI in the fourth week and preliminary condition, second week and preliminary condition, fourth week and second week of treatment. The result of paired sample t test of BMI was $p = 0.309$, 0.107 and 0.270. TNF-α in the fourth week compared to preliminary TNF-α was $p = 0.015$ while second week compared to preliminary TNF-α was $p = 0.026$. The TNF-α in fourth week compared to second week was $p = 0.990$ (Table 2). The Wilcoxon statistical test was used to compare the decrease in the ARB sputum positivity in the fourth week and second week. The result was $p = 0.157$ (Table 3).

Before conducting a correlation test, there should be a significance test among decreased ARB sputum positivity, BMI and TNF-α levels at the end of the second and fourth week (table 4). The significant test of TNF-α and initial BMI obtained $p = 0.005$, thus it could be concluded that there was a significant difference. Pearson correlation was performed to determine the correlation between TNF-α and initial BMI (table 5). The correlation between TNF-α and initial BMI obtained $r = -0.702$ (table 6).

Discussion

Nutritional status is one of the factors that determine the body system function including the immune system. The immune system is needed by humans to protect the body against infection. When the immune system is weak, *M. tuberculosis* germs easily enter the lungs, multiply and spread throughout the body through blood vessels or lymph nodes. People infected by *M. tuberculosis* germs does not always suffer from tuberculosis, depending on the immune system. When the immune system is strong then the germ remains asleep in the body (dormant) and will not develop into a disease. When the immune system is weak, germs will develop and cause tuberculosis.

Body Mass Index (BMI) can be used to assess the patient’s nutritional status. BMI is a simple and sensitive way to determine adult nutritional status. BMI is defined as body weight (kg) divided by height (m) squared. There are several levels of nutritional status based on BMI that is very thin (<17 kg/m²), thin (17.0-18.4 kg/m), normal (18.5-24.9 kg/m²), overweight (25.0-26.9 kg/m²), fat (27-28.9 kg/m²) and obese/very fat (≥29 kg/m²). A person is said to be malnourished if BMI <18.5 kg/m².

In this study, 9 (64.29%) of 14 patients had been converted at the end of second week of OAT treatment.
This was due to many died M. tuberculosis germs because of OAT. The conversion rate in the second week was 50%. Tuberculosis is an infectious disease that is often accompanied by nutritional and metabolic disorders. Response to infection is associated with increased energy expenditures and tissue damage levels.

Energy expenditures needed to fight through M. tuberculosis infection. Characteristics of patients characterized by loss of appetite and weight loss. Complex changes occur in macronutrient metabolism such as proteins, carbohydrates and fats. Increased protein breakdown leads to reduced muscle mass in patients with tuberculosis. Tuberculosis patients also experience loss of protein (nitrogen), which is the result of impaired absorption of diarrhea, fluid loss, electrolytes and other nutrient reserves.

Sputum of ARB is an important thing that should be evaluated in pulmonary tuberculosis patients. According to the Health Department, ARB sputum evaluation is done at the end of the second month, fifth month and sixth month of treatment. This study reported decreased ARB sputum quantitatively and qualitatively at the end of the second week and the fourth week of treatment. Quantitatively, 4 (28.57%) patients still had ARB positive at the end of second week and 3 (21.43%) at the end of the fourth week. At the end of the fourth week, there was a conversion of ARB sputum as much as 11 (78.58%) from 14 patients. ARB declined rapidly after starting OAT treatment, 80-85% of pulmonary tuberculosis patients became non-infectious after 2 weeks. The sputum conversion after four weeks was 52%. This study obtained the conversion rate at the end of second week by 64.29% and the fourth week of 78.58%.

In the intensive phase, mycobacterium was killed quickly within 2 weeks thus the infectious patients became non-infectious and had clinical improvement. The result of patient’s sputum is influenced by various things such as the ability of the sufferer for adequate cough, small sputum volume (ideally 5-10 ml), sputum consistency (mucoid or purulent). The ARB sputum conversion is strongly influenced by appropriate drug, appropriate dosage, regular drug taking, nutritional status and immune status.

Weight loss due to tuberculosis caused by TNF-α produced by dendritic cells, T lymphocytes and macrophages. TNF-α is known as cachectin that works in the hypothalamus by suppressing the appetite center causing anorexia. Increased TNF-α can be detected in the MN-cell supernatant of peripheral blood of pulmonary tuberculosis patients. Immune response pulmonary tuberculosis patients is active before and after treatment, and reporting an increase of TNF-α levels during treatment although not significant. Recent studies reported significant increases in TNF-α levels after recognition of the muramyl dipeptide bond (MDP). Alveolar macrophage activity was significantly associated with TNF-α.

At the onset of OAT treatment there was an increase of TNF-α. Longitudinal studies reported that TNF-α levels fluctuated during treatment. The TNF-α in tuberculosis patients before treatment were significantly higher than in healthy controls (23.19 ± 12.78 vs 14.22 ± 7.17 pg/mL, with p <0.05). After standard OAT treatment for 6 months, TNF-α levels in both groups were similar. It could be concluded that there was correlation between TNF-α and weight.

**Conclusion**

It could be concluded that TNF-α levels at the end of the second week decreased significantly compared to baseline TNF-α levels. There was an increase BMI by the end of the second week and the fourth week. There was no significant different of ARB sputum positivity at the end of the second week compared to the fourth week. There was a strong correlation between TNF-α levels and BMI prior to treatment with negative direction.

The Relationship between Frequency of Prayer and Death Anxiety in Cancer Patients

Negar Ranjbar Hajabadi1, Roya Ebrahimi1, Sakine Farhadi2, Hojjati Hamid3, Mahboubeh Tabrsa4
1Research Scholar, Department of Nursing, Urmia Branch, Islamic Azad University, Urmia, Iran, 2Research Scholar, 3Assistant Professor, Department of Nursing, Aliabad Katoul Branch, Islamic Azad University, Aliabad Katoul, Iran, 4Instructor Young Researchers and Elite Club, Aliabad Katoul Branch, Islamic Azad University, Aliabad Katoul, Iran

Abstract

Introduction: Cancer is a chronic and fatal disease. In advanced stages of cancer when patients notice their impending death, they become increasingly afraid of death. Meanwhile, having faith and resorting to prayer act as non-medical treatment and palliative care. This study aimed to investigate the relationship between praying and anxiety of death in cancer patients.

Method: This descriptive-correlation study was conducted on 96 cancer patients who had been referred to the Food and Drug Administration of Golestan province in Iran to receive agonist drugs. Templar and Marioliga’s standard questionnaire was used as data collection tool. Data were analyzed by logistic regression test.

Results: Pearson’s correlation test showed a significant but reverse relationship between prayer and death anxiety (P<0.2, r=-0.24), so that with increase in prayer, death anxiety reduced.

Conclusion: According to chronic nature of cancer and prolong treatment that it acquires, non-pharmacological methods such as religion can be effective in improving mental health and reducing anxiety of dying patients.

Key words: Prayer frequency, Death anxiety, Cancer.

Introduction

Cancer is one of the major health problems in the world with high mortality. Cancer is the second leading cause of death in developed countries and the fourth one in developing countries. Research and observations indicate that cancer diagnosis creates many psychosocial problems, And also requires the types of vascular access. In the advanced stages of cancer, when the cancer patients are informed about their imminent death, they will become overwhelmed by the fear of death. Thinking about death is scary, and most people prefer not to think about it, because anxiety and fear of death are unpleasant and common in humans. The closer a cancer patient gets to death, the greater level of fear, anxiety and suffering she/he will experience. Therefore, it can be stated that one of the problems of cancer patients is the fear and anxiety of death.

Death anxiety is a multidimensional concept and difficult to define. It is often defined as the fear of dying, because patient is concerned about pain, treatment and what happens after death. In other words, anxiety of death involves predicting own death and fear of dying. Death anxiety is more common in patients with advanced cancer or conditions, which often cause psychosocial problems in them.

Religious is one of the most important and effective factors in health. Spirituality plays an important role in the acceptance of illness along with religious
practices such as prayer[^5^, ^13^]. Many psychologists and psychiatrists have found that remembering, praying to, and paying close attention to God wholeheartedly assist people in dealing with life’s problems and negative thoughts, reduce anxiety and fear, and create calmness and relaxed state of mind[^14^]. It is also believed that in religion, calling divine names and religious words can reduce anxiety and increase mental health[^15^], because prayer is human’s communication with God, who is capable of all things and is closer to man than his neck vein. God delivers if being asked, so the best way to reduce anxiety and concern is to pray to God almighty[^16^]. On the other hand, some other studies have shown that religious people have more emotional distress than non-religious people, and this causes high level of death anxiety in them[^17^]. Religious therapies can have both negative and positive effects on patients[^18^, ^24^]. For instance, prayer and spiritual attitude can have positive effects on heart diseases[^19^]. Accordingly, this study was conducted to investigate the relationship between prayer frequency and death anxiety in cancer patients, with the assumption that prayer frequency has a link with death anxiety.

**Method**

To collect data, after approval of project by the Research Council of Aliabad Katoo branch of Azad University and obtaining necessary permission from the Food and Drug Administration of Golestan University of Medical Sciences, the researchers attended the desired cancer center on the days when cancer patients were coming to collect their agonist drugs. The research team explained the objectives of study to the potential participants and assured them about confidentiality of their information. The participants were also informed that, participation in the study is voluntarily and they can withdraw from the study at any time with any reason without any consequences. Then, oral informed consent was obtained from them. It took 15 to 20 minutes to complete the questionnaire during which, the researchers were present and answered potential questions in case of ambiguity.

Templer Death Anxiety Scale (TDAS) designed by Professor Donald Templer in 1970 has been used for about 40 years as a valid questionnaire to measure death anxiety, and its validity and reliability have been confirmed in many countries and articles. TDAS has been analyzed and validated in Iran, and translated in Farsi. It consists of 15 questions with the correct and incorrect answers. In this questionnaire, 9 items out of 15 items with the correct answer are given the score of 1, and 6 items with the wrong answers are given the score of one. Total score of the questionnaire ranges from 0 to 15, with higher scores indicating higher level of death anxiety.

**Validity and reliability of the tool:**

Reliability assessment: The TDAS is a standard questionnaire and has been used repeatedly in various studies around the world to measure death anxiety. Aghajani and Valiei (2010) used the internal reliability method to measure the reliability of TADS and calculated its correlation coefficient to be 0.86 using Richardson’s code formula[^8^]. Masoudzadeh, Sattar Mohammadpour and Kurdi (2008) also reported a correlation coefficient of 0.95 for this questionnaire[^17^]. The scoring system of TDAS is as follow: It consists of 15 items from which, 9 items with the correct answer are given the score of 1, and 6 items with the wrong answer are given the score of one. In other words, patient gives the score of 0 or 1 to each item, depending on the answer being correct or wrong (score of 1 if the patient’s response indicates death anxiety and score of 0 if the patient’s response indicates lack of death anxiety).

After collecting data and removing incomplete questionnaires, data were entered into SPSS-16 statistical software to be analyzed using descriptive statistics (table, mean, standard deviation) and inferential statistics (independent t-test, analysis of variance, Schiffer’s post-hoc test) at the significant level of 0.05. The data normality was determined by Kolmogorov–Smirnov test.

**Findings**

Results of this study showed that, the mean age of subjects was 54.6 ± 14 years and they had been diagnosed with cancer for an average of 5 years. Most of the participants 59% (n=57) were male and 41% of them (n=39) were female. Also, 80% of the samples (n=77) were married and 20% of them (n=19) were single. In terms of occupation, 31.2% of the participants (n=30) were housewives, and 6.4% of them (n=6) were shopkeepers. Also, 65.6% of the participants (n=66 =) had a history of chemotherapy and 34.4% of them (n=34) were currently receiving chemotherapy.

In this study, the frequency of prayer with the
mean and standard deviation of 171.0 ± 32.0 was above average. Also, level of death anxiety with the mean and standard deviation of 8.3 ± 2.4 was above average. Pearson’s correlation test showed a significant but reverse relationship between prayer and death anxiety (P<0.2, r=-0.24), so that with increase in prayer, the death anxiety was reduced. No relationship was found between the frequency of prayer and demographic characteristics such as sex (p<0.09), age (p<0.17), education (p<0.68), marital status (p<0.15), occupation (p<0.06) and diagnosis time (p<0.82).

There was also no relationship between the frequency of prayer and demographic characteristics such as sex (p<0.49), age (p<0.67), education (p<0.16), marital status (p<0.13), occupation (p<0.66) and diagnosis time (p<0.69).

Discussion

Results of present study showed that frequency of prayer reduced death anxiety. Religious belief becomes more important at the time of illness than at any other time, and helps people to understand the life events, especially those that are painful and create anxiety. It also brings about heartwarming joy and happiness in people’s life\[20\]. Various studies have shown that patients who suffer physical injuries tend to turn to religious beliefs, because religion helps them to endure the suffering and pain caused by their illness\[21\]. Positive thoughts and tolerance are both components of prayer therapy and are related to health and stress resistance. Religious psychology refers to the remembrance of God as the main therapy for underlying psychiatric disorders, including anxiety and stress. It brings peace and reassurance to people throughout their ups and downs and during the time of pain and suffering\[22\].

Many people, even those who are not familiar with the Arabic language and do not understand the meaning of Quran, find comfort in hearing it. This is due to the physiological effect of prayer on the nervous system\[23\].

In the religious book it is said that, when a human being is harmed, he calls upon his Lord and returns to him. At the same time, performing religious practices such as prayer as a defense mechanism can lead to better adaptation, self-worth and hopefulness\[20\].

Conclusion

Considering the attitude of Iranian people who believe in the effectiveness of prayer, prayer therapy should be used as a complimentary therapy along with other therapies. However, in Iran, this treatment is still unknown to some. Also, to implement any new approach, it should be tested first and its effectiveness should be institutionalized in the health care delivery system. Thus, further studies on the effectiveness of prayer are recommended, especially in chronic patients such as cancer, hemodialysis, thalassemic and cardiac patients. Considering the high costs, side effects, and stress of treatments such as surgery, chemotherapy, and injections, prayer therapy can be used as a low-cost, natural, and stress-free approach or a complementary treatment. One of the limitations of present study was that, the researcher had no control over recent events in the patient’s life. It is hoped that these limitations will be mitigated in future studies.

Abstract

Tuberculosis (TB) is one of the major global health problem which affects millions of people each year. For the routine diagnosis of TB, microscopic technique is used but it has lower sensitivity and specificity. This study was carried out to evaluate the efficacy of loop mediated isothermal amplification (LAMP) over smear microscopy to detect *Mycobacterium tuberculosis*. Out of 84 processed samples processed in this study, the diagnostic tests showed varying results. Using smear microscopy, 16(19.05%) and with the LAMP assay, 17(20.24%) cases were found positive for *M. tuberculosis*. The sensitivity of the LAMP assay (87.5%) was greater than that of microscopy (82.35%) while the specificity of both methods was comparable (>95%). Being more sensitive than microscopy, LAMP assay is more likely to show the positive result and solve the errors in diagnosis of the TB cases. Thus, LAMP assay can be an important and cost-effective tool for appropriate and timely diagnosis of TB patients. This can further assist to implement intervention programs against TB.

Key words: Tuberculosis, Global health problem, LAMP, Diagnostic tool, Microscopy

Background

Tuberculosis (TB) is an age old disease and one of the major global health problems. Deterioration of public health programs aimed at preventing tuberculosis and encouraging completion of drug therapy for treatment of the disease is cited as a reason for the increasing rate of TB. Globally, approximately 10 million people are affected by this disease each year. As per the report from the last five years, the causative agent of this disease has been a leading cause of death from a single infectious agent, ranking above HIV/AIDS. This is despite the fact that, with a timely diagnosis and correct treatment, most people who develop TB disease can be cured. More than 95% of deaths due to TB occurred in developing countries out of which 50% were recorded from India, China, Indonesia, Pakistan, and the Philippines. In Nepal, about 45% of the total population is expected to have TB infection and the number of deaths due to tuberculosis is 5,000 to 7,000 people every year.

In most developing countries, microscopic examination of sputum is the widely available tool for routine diagnosis of TB. But the reliability of this method has been challenged because of lower sensitivity and specificity. The lack of standardized procedures and trained microscopists on reading acid-fast bacilli (AFB) sputum smears present further drawbacks to finding cases in such countries. Culture, the gold standard diagnostic method, is highly sensitive but the slow multiplication and difficulty of selective cultivation often limits the culture based diagnosis. Thus, new technologies with higher sensitivity and specificity are urgently needed to confirm the clinical diagnosis and help reduce TB transmission.
The loop-mediated isothermal amplification (LAMP) assay – a nucleic acid amplification technology – was first proposed by Notomi\(^6\). Under isothermal condition, LAMP can amplify DNA with high specificity and efficiency using six sets of primers that recognize eight distinct regions on the target sequence. Unlike PCR, LAMP reaction does not require a denatured DNA template and relies on auto cycling strand displacement DNA synthesis by a \textit{Bst} DNA polymerase\(^7\). LAMP produces extremely large amounts of amplified products which enables simple visual detection and thus eliminates the need for electrophoresis.

Although bacterial culture is the gold standard for TB diagnosis, it is an expensive and slow technique and so, cannot be used for routine diagnosis. The LAMP assay, however, can be a simple, inexpensive and reliable choice for the TB diagnosis as this test combines rapidity of microscopy and sensitivity of bacterial cultural methods\(^9\). In the context of Nepal, the purpose of this study is to assess whether the LAMP assay can be a better and efficient method than microscopy. Additionally, the findings of this research can provide us a greater understanding of the prevalence rate of TB in terms of sex and age.

**Material and Method**

**Sample collection and evaluation**

In this study, a total of 84 samples were collected from the participants (February 2017 to October 2017) who were referred for a LAMP test and processed at Healthy Nepal, Balkhu. Informed consents were taken from the participants prior to the study. The study was approved by the Institutional Ethical Committee.

Sputum and different extra-pulmonary samples (urine, abscess, pleural fluid, peritoneal fluid, CSF and pericardial fluid) were the target samples of choice in this study. A series of at least three single specimens were collected initially (preferably on different days) from TB patients. First one on the spot, second early morning and third once again on the spot in which patients were instructed to take a deep breath and coughed deeply and vigorously\(^10\). Specimens were clearly labeled with patient’s information and date of collection in a sterile plastic container.

**Digestion, Decontamination and Concentration of Specimen**

All other samples, except cerebrospinal fluid (CSF), pleural, peritoneal and pericardial fluid were decontaminated and homogenized with NALC-NaOH solution. Furthermore, for the purpose of digestion, decontamination and concentration of specimens, the protocols of Chatterjee et al were followed\(^11\).

**Acid-fast microscopy**

The smear was heat fixed by placing the slide over flame three or four times with the smear on upper position and allowed to cool before staining. Further, smears were stained with Ziehl-Neelsen (Z-N) stain and examined for acid-fast bacilli (AFB) by microscopy. The positive organisms appeared as bright red against blue background.

**DNA Extraction**

DNA was extracted from the concentrated samples by alternate boiling and freezing method. Samples were heated at 95\(^\circ\)C for 10 minutes and freezed at -20\(^\circ\)C for 30 minutes for three times\(^13\). Thus, extracted DNA was stored in deep freeze until analysis.

**LAMP Reaction**

Altogether, six primers i.e. outer primer (F\(_3\) and B\(_3\)), a forward inner primer (FIP), a backward inner primer (BIP) and loop primers (loop F and loop B) were used. They recognize eight distinct regions on 16S rRNA gene of the target DNA. LAMP was performed in a total volume of 25 \(\mu\)l reaction containing LAMP buffer, Betaine, MgSO\(_4\), Primer mix (F\(_3\), B\(_3\), BIP, FIP, loop F, loop B), dNTPs (2.5 mM each), Bst DNA polymerase (8 units/ml), 0.1% methyl green dye, DNA samples and distilled water. Constituents of master mixture (25\(\mu\)l/tube) were 16.5\(\mu\)l LAMP premix (LAMP buffer, Betaine, MgSO\(_4\), primer mix), 1.5\(\mu\)l dNTPs (25mM), 1.0\(\mu\)l 0.1% Methyl green, 1.0\(\mu\)l Bst DNA polymerase and 5\(\mu\)l sample DNA. The whole reaction was performed at isothermal temperature (64\(^\circ\)C for one hour)\(^14\). A positive and negative control was included in each reaction. All the reagents, primers, and solutions required for LAMP were provided by Eiken Chemical Co. Ltd, Japan.

**LAMP result**

LAMP amplicons of positive organisms in the reaction tube were directly detected with the naked eye by observing the change in color of the solution containing reaction mixture with methyl green which stains DNA and in large amount of amplicons give
distinguished blue green color.

**Disposal and Decontamination**

The waste materials were first treated with 0.5% Sodium hypochloride and then autoclaved at 121°C temperature for 15 minutes before disposal.

**Statistical Analysis**

All data obtained was statistically analyzed by using statistical package for social science version 20 software. Sensitivity and specificity were compared using Chi-square test.

**Results**

**Distribution of infection by microscopy and LAMP**

Out of 84 clinical specimens processed, 19.05% (16/84) were microscopy positive, however, the same specimens were 20.24% (17/84) positive with the LAMP assay.

![Fig: Distribution of infection by microscopy and LAMP](image)

**Sex-wise distribution of cases**

In the sex-wise distribution of cases, 52 were male participants while 32 were female participants. Under microscopy and LAMP methods, male participants showed varying results while female participants had similar incidence of TB. With microscopy, 19.2% (10/52) male cases had positive infection while the rate was 21.1% (11/52) using LAMP. Similarly in the case of female participants, the incidence rate was 18.7% (6/32) for both microscopy and LAMP.

**Age wise distribution of positive cases as detected by Microscopy and LAMP**

The age-wise microscopic results shows that the infection was highest in the age-group 31-40 years 31.25% (5/16), while lowest in the age-group <10 years (0%). With the LAMP assay, age-wise infection rate was highest in the age-group 31-40 years (29.4% (5/17)) and lowest in <10 years (0%).
Evaluation of LAMP with reference to microscopy

This showed 14 samples were positive by both microscopy and LAMP. With the LAMP assay, three microscopically negative cases were positive. Also with microscopy test, two LAMP assay negative cases were positive and 65 cases were negative by both tests. Sensitivity and specificity of the LAMP assay was 87.50% and 95.59% respectively. The predictive values of both of the tests were under the confidence interval.

Discussion

The main finding of this study shows that the LAMP assay can be a better and efficient method for tuberculosis diagnosis in Nepal. In this study, sensitivity of LAMP (87.5%) and microscopy (82.35%) are within in confidence interval. Similarly, specificity of LAMP (95.6%) and microscopy (97.01%) are also within the confidence interval. The sensitivity of the LAMP assay is consistent with other studies, but the lower specificity in contrast to microscopy (95.59% < 97.01%) might be due to human error during the laboratory process as most of the previous studies had recorded higher specificity of the LAMP assay16,17,18. In a similar study in Nepal, the sensitivity of MTB-LAMP in culture-positive samples was 100% (96/96)19. In some other studies, the LAMP assay had lower sensitivity but high specificity19,20. The limitation of this study is lower sample size. This is because the subjects who were referred for a LAMP test (over a period of six months) were not many in number.

In our study, we found 20.24% (17/84) of the cases had positive infection. In Nepal, previous studies have also reported high prevalence of infection i.e. 27.98% (585/2091) in thirteen districts21. Also, studies in Western Nepal22 showed a positive rate of TB around 10%. From these studies, we can infer that TB prevalence differs in Nepal depending on places and also sample size. Again, our study does not show a significant difference (not shown) in sex-wise prevalence (male=21.1% and female=18.7%). This means that both males and females may be equally exposed to the risk factors. Age-wise study showed people above 10 years are at higher risk of TB infection. In a similar study by Jaiswal et al24 conducted in Western Nepal, they found 37.9% of TB infection in the age-group 15-35 years. Use of tobacco products25 and extensive travelling by people (age>10 years) may expose them to TB infection.

According to the finding of our study, the LAMP assay provides a reliable and accurate choice for TB diagnostic testing in resource limited settings or where advanced PCR or cultural methods are not available. Being a rapid, inexpensive and technically not demanding diagnostic tool, this method can be used as a routine diagnostic tool. Furthermore, this can bring down the costs of diagnosis with complicated cases. This can also pave the way for clinicians in Nepal to prescribe
the right TB cases for DOTS program. Additionally, researches using this diagnostic test would increase the credibility and relevance in the context of Nepal.

When we compare the values of sensitivity, specificity, positive and negative predictive values of either test, it indicates microscopy can still be appropriate as a primary test. But the results of microscopy cannot be always relied upon. In this condition, application of the LAMP assay would greatly assist in the detection and confirmation of positive cases. In recent years, Nepal has been facing a lot of challenges to bring down the TB infection rate. The emergence of new cases often threatens the anti-TB program. The records of national tuberculosis programme also shows increasing incidences of TB in the country. One challenge for this may be inefficiency of the diagnostic methods being used. NTP has adopted END TB Strategy and aims to make TB control program accessible to people who need timely diagnosis and treatment for TB so that the epidemic condition of TB can be ended by 2030.

Appropriate and timely diagnosis of TB victims is a must to implement intervention programs against TB.

**Conclusion**

In conclusion, this study showed that the LAMP assay could be better tool than microscopy for the diagnosis of tuberculosis. Microscopy can diagnose TB cases but cannot be a confirmatory test. The LAMP assay, however, could be a sensitive, fast and reliable tool and can be a confirmatory test for most of the cases. Thus this would help clinicians and health officers to prescribe the right TB cases for anti-tuberculosis drugs.

Characteristics Nanoparticle of Propolis Ethanol Extracts with Variations of Chitosan-Sodium Alginat

Santi Sinala1,4, Marianti A.Manggau2, Sartini2, Rudy Hartono3,4

1Lecturer at Department of Pharmacy, Makassar Health Polytechnic, Indonesia, 2Lecturer at Department of Pharmacy, Hasanuddin University, Indonesia, 3Associate Professor in the Department of Nutrition, Makassar Health, Polytechnic, Indonesia, 4The Center of Excellence in Urban Health at the Makassar Health Polytechnic, Indonesia

Abstract

Nanoencapsulation technology has many advantages, which include important roles in drug delivery and protection of bioactive components that have perishable stability, one of which is polyphenol compounds. Propolis which contains high levels of polyphenol compounds has been used as an antioxidant for various diseases. By making nanoparticles from propolis, it can maintain the stability of polyphenol compounds from propolis and increase the effect of treatment through optimal delivery. Nanoformulations containing ethanol extract of propolis were absorbed by chitosan-sodium alginate using an ionotropic pre-gelation method. Optimization is carried out at various concentrations of chitosan, namely 0.05%; 0.075%; 0.1% and 0.125%, with the use of the same sodium alginate concentration which is 0.0063%. Testing of nanoparticle characteristics includes particle size and morphology and adsorption efficiency (EE) consisting of total flavonoid and total polyphenol values. The increase in chitosan polymer is directly proportional to the increase in particle size, but does not occur in the absorption efficiency value. The 0.05% chitosan formula showed the absorption of polyphenol compounds at 99.41% with particle sizes of 259.12 nm.

Key words: Propolis, Nanoparticles, Chitosan-Sodium Alginate, Absorption Efficiency

Introduction

Nature has prepared ingredients that contain substances that have the potential as antioxidant agents. One of them is propolis. Propolis is a resin material collected by bees mixed with saliva. Propolis is used by bees as a defense for survival. Propolis contains many secondary metabolites that can be used as antioxidants including polyphenols (flavonoids, phenolic acids and esters), terpenoids, amino acids and steroids. This polyphenol content can inhibit specific enzymes, stimulate several hormones and neurotransmitters, fight free radicals and prevent the growth of microorganisms.

In drug delivery systems, nanoencapsulation acts as a carrier by absorbing, encapsulating, or attaching the drug in the matrix to protect bioactive components (polyphenols, micronutrients, enzymes, and antioxidants). Through the encapsulation of these molecules in nano carriers, the solubility and stability of the drug can be increased and can control the release of the drug in the workplace. Small-sized nano-encapsulation materials, which are around 50-500 nm, can overcome biological barriers that help permeate and diffuse in achieving cellular recapture.

Several studies have been conducted on nanoencapsulation technology including who conducted tests on mice and reported increased effectiveness and reduced toxicity from cancer treatment of the head and neck when using nanoencapsulation as a drug carrier. Radovic et al. (2012) reported that nanoencapsulation containing antibiotics can kill bacteria because of high doses in the workplace and sustained release.

One ingredient in making nanoencapsulation is chitosan and sodium alginate. Chitosan, a polysaccharide consisting of glucosamine units and acetylglucosamine...
units. Chitosan is biocompatible, biodegradable and non-toxic when used as a drug carrier orally. In addition, chitosan also prolongs the contact time of active substances with epithelial tissue and expands absorption by opening the tight junction of the epithelium. Chitosan here acts as a polycation polymer. While sodium alginate will act as a crosslinked polyanion polymer, which will eventually form nanoparticles.

Based on the background above, the problem that arises is how does the effect of chitosan concentration with sodium alginate in the formation of nanoencapsulation of ethanol extract of propolis

**Materials and Materials**

The tools used are a set of maceration tools, analytical scales, rotary evaporators, water baths, sonicators, a set of freeze drying tools, homogenizer, centrifuges, scanning electron microscopy (SEM) 10 MA EVO, UV-Vis spectrophotometer, and Particle Size Analyzer (PSA) While the ingredients used are propolis, n-hexane, acetic acid, 70% ethanol, aqua destillata, Folin reagent - Ciocalteau, 96% pa alcohol, Na₂CO₃, Quercetin, AlCl₃, gallic acid, Sodium acetate, chitosan, sodium alginate, CaCl₂.

**Sample 1**

Raw material of propolis is put into the freezer until it freezes. After freezing, propolis is cut into small pieces and pollinated, then extracted by multilevel maceration. The pollinated propolis was weighed as much as 300 g and then extracted by maceration with one liter of n-hexane for 10 x 24 hours with the help of a magnetic stirrer. The filtrate is then evaporated with a rotary evaporator until a thick n-hexane extract is obtained and dried in a desiccator vacuum. The residue from n-hexane extraction was macerated with 70% ethanol as much as 500 ml for 6 x 24 hours with the help of a magnetic stirrer. The filtrate is then evaporated with a rotary evaporator and then dried in the freeze dryer to obtain a thick extract.

**Sample 2**

Determination of total polyphenols was carried out by weighing 0.25 g of ethanol extract of propolis and dissolved with 50 ml of 80% ethanol (5000 µg / ml). 0.3 mL was taken from the dilution of the extract, then put in a 10 ml volumetric flask, added 96% pa ethanol as much as 1 mL and added Folin - Ciocalteau reagent (1: 1) as much as 100 µL and stirred. After that Na₂CO₃ solution is added 7.5% and homogeneous stirring, then each volume is up to 5 mL. The mixture is left for 3 minutes and the solution is measured absorbance at a wavelength of 641.5 nm. The concentration is calculated from the regression equation for standard gallic acid solutions.

**Sample 3**

Total Flavonoid Test where e ethanol extract of propolis was weighed 0.25 g then dissolved in a flask measuring 50 ml with 80% ethanol. From the stock solution carefully piped 0.3 ml then added 1 ml of 96% ethanol and added 100 µl of AlCl₃ 10% and 100 µl Sodium acetate 1. The final volume is sufficient to 10 ml in a flask. After incubation for 25 minutes at room temperature, absorbance was measured at a wavelength of 422.5 nm. Concentration was calculated from the regression equation for standard quercetin solutions.

**Sample 4**

**Nanoencapsulation testing**

1. Observation of Size and Shape of Vesicles

The particle size was analyzed using the Particle...
Size Analizer (PSA) tool and the surface morphology was measured using scanning electron microscopy (SEM).

2. Determination of Absorption Efficiency (EE)

Determination of Concentration

1. Total Flavonoid Levels

Piped 5 ml of the supernatant solution resulting from centrifugation then added 1 ml of ethanol p.a, 100 µL of AlCl₃ 10% and 100 µL of sodium acetate 1 M. The volume was sufficient to 10 mL and left for 25 minutes. After being allowed to stand, the absorbance is measured at a wavelength of 422.5 nm.

2. Total Polyphenol Levels

Piped 5 ml of the supernatant solution resulting from centrifugation then added 1 ml of ethanol p.a, 100 µL of Folin-Ciocalteau (1: 1) and 100 µL of Na₂CO₃ solution 7.5% . The volume is sufficient to 10 mL and left for 3 minutes. After being immobilized, the absorbance is measured at a wave length of 641.5 nm.

b. Calculation of Absorption Effectiveness (EE)

The percentage of gallic acid absorption is calculated from the following formula:

\[ EE = \frac{Qt - Qs}{Qt} \times 100\% \]

Qt is the amount of gallic acid in the ethanol extract of propolis added, Qs is the amount of gallic acid detected in the supernatant.

Findings

In this study the active substances contained in propolis are withdrawn by means of multilevel maceration, where propolis is macerated with n-hexane several days until it is clear to attract non-polar substances such as fat and tannins which are mostly found in propolis. After that, the residue was first released from n-hexane, then macerated with 70% ethanol to attract polar compounds in the form of flavonoids and phenolic compounds.

The results of extraction in the form of rendamen and total flavonoid test and total polyphenols can be seen in table 2. From table 2, the data obtained for the weight of n-hexane extract as much as 145.80 grams, with a rendition of 48.6% and 70% ethanol extract as much as 45.06 grams with a rendition of 15.02%. The ethanol extract obtained is brown and has a distinctive odor.

Discussion

The method of making nanoparticles used in this study is the ionotropic gelation method (polyelectrolyte coaservation or complexation method). In the ionic gelation method, polysaccharides (chitosan) are dissolved in a weak acid medium, then added dropwise with constant stirring in solutions containing other counterions. The basis of this method is the nature of chitosan which experiences a liquid-gel transition due to ionic interactions with polyanion. This interaction occurs between positively charged chitosan ammonium groups with a crosslinker. Nanoparticles are formed by constant stirring at room temperature.

Electrostatic interactions between crossing anions and chitosan determine the nature of the nanoparticles produced. This interaction depends on the molecular structure of anions, surface charge and molecular concentration, pH of chitosan solution, and physical properties of chitosan. The physical properties of chitosan include molecular weight and degree of deacetylation.

The advantage of the ionic gelation method is that it can be carried out under mild conditions, does not require organic solvents, can increase drug loading capacity, and form nanoparticles with a hydrophilic environment. Chitosan used in this study is medium chain chitosan (200-800 cps) because it has the best encapsulation efficiency.

Sodium alginate is a negative anion used to stabilize the formed nanoparticles. Before sodium alginate is reacted with chitosan, sodium alginate is first mixed with calcium chloride solution. Calcium ions from calcium chloride will react with guluronic acid units from alginate to form an ‘egg-box’ structure. This shows that nanoparticles can be formed by wrapping negatively charged calcium alginate complexes in a pre-gel state with cationic polymers such as chitosan, and it is the pre-gel state that is very important to allow ionic interactions between alginate, calcium, and cationic polymers such as chitosan to form nanoparticles.

The results of making nanoenkapulsiation powder from chitosan-alginate can be seen in Figure 1. Figure 1 shows brown chitosan-alginate nanoparticles powder with fine and light powder. This brown color comes from the color of propolis ethanol extract.
The results of testing nanop powder in the form of particle size and adsorption efficiency can be seen in table 3.

While the results of nanoenkapulation particle morphology can be seen in Figure 2. From the results of nanoparticles with differences in the concentration of chitosan to sodium alginate 0.0063 mg and measurements obtained data that the smallest particle size of the four is formed by chitosan with a concentration of 0.05% with 99 absorption efficiency, 47% with a size of 259.12 nm. This is supported by the results of SEM measurements that show the morphology of nanoparticle powder with a symmetrical sphere shape. The resulting morphology of powder is not significantly different from the morphology of nifedipin chitosan- sodium alginate powder which is also in the form of sperm. The location of the difference is in the particle size produced, where the particle size of nifedipin chitosan-alginate ranges from 20-50 nm, while the particle size in this study is around 200-500 nm. This is due to differences in the tools used in making nanoparticles. However, this result is not much different when compared with the results of research from Chopra et al. (2012) which produced particle size of streptomycin-chitosan-alginate ranging from 300-700 nm.

From the particle size data, it can be seen that the greater the concentration of chitosan, the greater the size of the particles produced. This is because more chitosan wraps the polyphenol compounds of propolis so that the particle size gets thicker and bigger.

There are two data in obtaining absorption efficiency that is based on the total content of flavonoids which is equivalent to quasarsetin and the total content of polyphenols which is equivalent to gallic acid. The measurement of absorption efficiency obtained total flavonoid data with negative absorbance values so that the absorption efficiency cannot be calculated. This shows that 100% quasaretin equivalent flavonoids are absorbed in chitosan-alginate nanoparticles. While the absorption efficiency for the total polyphenols on the four formulations obtained chitosan data 0.05% with EE value = 99.47%, chitosan 0.075% with EE value = 97.66%, chitosan 0.1% with EE value = 98.04% and chitosan 0.125% with EE value = 98.71%. These results indicate that 0.05% chitosan has the best EE among the four formulas. Because the total polyphenol data can be calculated, the total polyphenols are then used in the next calculation.

**Conclusion**

Chitosan at a concentration of 0.05% has a particle size of 259.12 nm with adsorption efficiency of 99.47%.

**Conflict of Interest:** There is no conflict between researchers and subjects in this study.

**Source of Funding:** The study was independently funded by each researcher.

**Ethical Clearance:** Research ethics were obtained from the Makassar Health Polytechnic Health Research Ethics Committee by No. 292/KEPK-PTKMKSVII/2019.

Abstract

Elderly people is someone who has the age of 60 years or more. In old age physiological functions decrease due to degenerative processes (aging), resulting in many non-communicable diseases. Non-communicable diseases in the elderly include hypertension, stroke, diabetes mellitus and arthritis or rheumatism. The prevalence of hypertension and diabetes in the district of Gresik is quite high. The aims of this community service was to find out the profile of blood pressure and blood glucose levels of the elderly in “Y” Village, Gresik District. This study was a descriptive study with a cross-sectional design. The sampling method uses accidental sampling technique, which is 60 elderly people who come at the health examination. Sixty elderly people measured blood pressure and blood glucose level. The measurement results showed that the elderly blood pressure in Y village had 50% blood pressure in the hypertension stage 1 and 2, 23% in the pre-hypertension category, and 27% had normal blood pressure. While the results of measuring 22% of blood glucose levels had blood glucose level in the Diabetes Melitus category which is ≥200 mg / dl, 58% have blood glucose levels in the category of 90-199 mg / dl and 20% had normal blood glucose levels. This study concludes that most of the elderly in Y Village are suffering from hypertension and having non-DM blood glucose level. Conclusion of this research is elderly people in Y Village has hypertension and blood glucose level in the category of not yet diabetes.

Keywords: blood glucose level, diabetes, elderly people, hypertension

Introduction

Elderly people are individuals with the age of 60 years and above. The rise of life expectancy in Indonesia is an indicator of successful country development in several aspects, including health. The rise of life expectancy is linear with the rising number of elderly people. Indonesia should be aware of the possibility of triple burden: the rise of birth rate, disease burden (infectious or non-infectious) and burden of productive age group towards the non-productive age group. Most of the elders are belonged to non-productive group and have experienced degradation in physical, social, and psychological qualities. Age development causes decrease in physiological function due to degenerative process which triggers non-infectious disease among the elderly. The common infectious diseases among the elderly include hypertension, stroke, diabetes mellitus, and rheumatism. The prevalence of hypertension and diabetes among the elderly in Gresik is quite high. Based
on the health profile of East Java in 2017, the percentage of hypertension patient in Gresik reached 35.36%. In addition, according to Basic Health Research in 2018, Gresik ranked in the 5th position with highest patient of diabetes in East Java1.

World Health Organization (WHO) classified elderly into several age groups. Middle age: 45–59 years old; elderly: 60–74 years old; old: 75–90 years old; and very old: >90 years old. Physiological changes in the cell rate, organ, and organ system are experienced by the elderly2. Based on the results of Basic Health Research in 2013, the most common disease in old age is non-communicable diseases which include hypertension, arthritis, stroke, Chronic Obstructive Pulmonary Disease (COPD) and Diabetes Mellitus (DM)3, 4.

Alteration in cardiovascular system is one of the causes which increase the hypertension risk among the elderly. Old-age group tends to have higher blood pressure. Aging process caused changes in the connective tissues of artery, vein, and myocardium and caused degradation in elasticity. Aging process also increase nerve enhancement and norephinephrin rate, thus increasing the risk of arteriolar constriction and blood vessel resistance5. Hypertension is the increase of systolic blood pressure higher than 140 mmHg and diastolic blood pressure higher than 90 mmHg in rest condition. Increase in blood pressure for long period and uncontrollable manner may lead to liver failure, heart coronary disease, and stroke without early detection and sufficient treatment6, 7.

Age is one of the risk factors for diabetes mellitus. Metabolism disturbance in blood glucose is caused by the damage in insulin secretion by beta cell and the increase of insulin resistance. It resulted in the increase of blood glucose5. Hyperglu Hyperglycemia is the increase of blood glucose above the normal limit. The normal range of blood glucose level is 80-200 mg/dl. Hyperglycemia is a common sign of DM besides other typical symptoms such as polyuria, polydipsia, and polyphagia6.

Hypertension and diabetes are untreatable diseases which can be controlled. Therefore, examination of blood pressure and blood glucose level should be done regularly. In general, people will ask for health examination only when they experience health disturbances. In addition, the health workers have little knowledge on the prevalence of diabetes in Y Village. The activity of blood pressure and blood glucose level examination is conducted to obtain the data about the blood pressure and blood glucose level for early detection of hypertension and diabetes among the elderly in Y Village, Gresik. The examination did not require payment to attract more people to check their health. The examination data is then given to the village health workers to let them know the condition of the blood pressure and blood glucose level among the elderly in that village.

Y Village is one of the villages in Gresik with 31 Neighborhood Association and 8 Citizen Association and divided into three hamlets. Based on the Data of Village Profile of 2014, the number of elderly inhabitants in Y village made up 9% of the total 3,000 population9.

Based on the background, this research is aimed at discovering the profiles of blood pressure and blood glucose level among the elderly in Y Village, Gresik. The result of this research will provide information about blood pressure and blood glucose status to the subjects to increase their awareness on the importance of checking their health regularly. In addition, the examination results given to the health workers in Y Village can be followed up by the regional government to design a promotive, preventive, and curative program for hypertension and diabetes especially for the elderly people in Y Village, Gresik.

**Method**

This study is a descriptive research with cross-sectional design. Sample is taken using accidental sampling technique by involving 60 elderly people who check their health at the examination program. The research is conducted in Y Village Community Building, Gresik on July 2019.

Blood pressure is measured using aneroid tensimeter and stethoscope. The data of blood pressure examination is classified using JNC VII criteria10. On-time blood sugar level is measured using glucometer (smart check blood glucose meter) in capillary blood. The data of on-time blood sugar examination is classified using the criteria issued by Perkeni8. The collected data is processed using Microsoft Excel. The data is analyzed with descriptive approach to explain or describe the characteristic of each research variable. The analysis produce frequency distribution and percentage of each variable.
Results And Discussion

Respondents’ Characteristics

Table 1. The Distribution of Respondents’ Age and Sex in Y Village in 2019

</table>

The observation produced the data of blood pressure and blood sugar examination of 60 elders. Samples’ characteristics based on age and sex are described in Table 1. Based on Table 1, most respondents belonged to the 60–74 age group, with the number of 52%. The number indicated that the elderly population in Y Village is generally healthy because they were still able to attend the health examination program. 45–59 years old people is counted for 45%. This group is classified as productive-age group. The members of this group in Y Village are still active and productive, so they still pursuing their career. Lastly, there were 3% belonged to the 75-90 years of age.

Based on the sex classification, most of the respondents were female, counted for 87%. The number of male elders is counted for 13%. The proportion is in corresponds with the data issued by The Ministry of Health of the Republic of Indonesia in 2015 that there are more female elders than male which indicate higher life-expectancy among female elders.

Blood Pressure Profile

Normal blood pressure is indicated by systolic pressure of <120 mmHg and diastolic pressure of <80 mmHg. Blood pressure is categorized as pre-hypertension with systolic pressure of 120-139 mmHg or diastolic pressure of 80-89 mmHg. Meanwhile, first-degree hypertension is shown by systolic pressure of 140-159 mmHg or diastolic pressure of 90-99 mmHg. Second-degree blood pressure is indicated by systolic pressure of ≥160 mmHg or diastolic pressure of ≥100 mmHg.

Table 2. Distribution of Respondents’ Blood Pressure in Y Village in 2019

<td>20</td>
</tr>
<tr>
<td>≥160/≥100</td>
<td>18</td>
<td>30</td>
</tr>
</tbody>
</table>

Table 2 shows that 50% elders are suffered from hypertension, 20% with first-degree hypertension and 30% with second-degree hypertension. Meanwhile, 23% of the elderly were having pre-hypertension; and 27% others have normal blood pressure. The diagnosis of hypertension can be stated if the measurement shows systolic blood pressure of ≥ 140 mmHg and/or diastolic blood pressure of ≥ 90 mmHg in the repeating examination. Systolic blood pressure is the main indicator in deciding the diagnosis of hypertension.

Table 3. The Distribution of Blood Pressure based on Respondents’ Age in Y Village in 2019

<table>

</tr>
<tr>
<td>≥160/≥100</td>
<td>6</td>
<td>22</td>
<td>10</td>
</tr>
</tbody>
</table>
Based on Table 3, the number of patients with first-degree and second-degree hypertension in 45–59 age group is 41% and 22%, respectively. Meanwhile, the number of patients with first-degree and second-degree hypertension 60–74 age group is 41% and 22%, respectively. In 75-95 age group, 50% were suffering from first-degree hypertension and 50% were suffering from second-degree hypertension. Age is one factor which influence blood pressure. Older the age, higher the risk of hypertension.

The mean of systolic blood pressure and diastolic blood pressure in 45–59 age group is 127 mmHg and 83 mmHg, respectively. The mean of systolic blood pressure and diastolic blood pressure in 60–74 is 128 mmHg dan 83 mmHg, respectively. The mean of systolic blood pressure and diastolic blood pressure in 75–90 age group is 135 mmHg dan 90 mmHg, respectively.

The above results are in corresponds with Basic Health Research published in 2013, the prevalence of hypertension among the elderly is rising along with the increase in age. In age group of 55–64, the prevalence of hypertension is 45.9%; 65–74 is 57.6%; and among 75 years above, the prevalence is 63.8%.

The grouping of blood glucose level is based on the criteria issued by Perkeni. The criteria are used to measure on-time blood glucose level in capillary blood. 20% of the respondents showed blood glucose level less than 90 mg/dl or normal level as long as the subject does not experience hypoglycemia. 58% of the respondents showed blood glucose level of 90–199 mg/dl. The blood glucose level is categorized as DM. The group needs further identification for symptoms and risk factors to prevent increase in blood glucose level, known as hyperglycemia. Blood glucose level above 200 mg/dl fulfills the criteria of DM diagnosis. Research results showed that 22% of the elders belonged to DM criteria. It is due to the fact that 50% of elderly people experience increase in blood glucose level caused by disturbance of glucose metabolism.

**The Profile of Blood Glucose Level**

<td>13</td>
<td>48</td>
<td>22</td>
</tr>
<tr>
<td>≥200</td>
<td>8</td>
<td>29</td>
<td>4</td>
</tr>
</tbody>
</table>
Based on Table 5, from 27 individuals belonged to age group of 45–59, 22% respondents showed non-DM blood glucose level; 48% showed uncertain-of-DM blood glucose level; and 29% showed DM blood glucose level. From 31 individuals belonged to age group of 60–74, 16% respondents showed non-DM blood glucose level; 70% showed uncertain-of-DM blood glucose level; and 12% showed DM blood glucose level. Meanwhile, among 31 respondents belonged to 75–90 age group, 50% respondents showed non-DM blood glucose level and 50% respondent showed DM blood glucose level.

The mean of blood glucose level in 45–59 age-group is 160 mg/dl with the lowest level of 53 mg/dl and highest level of 453 mg/dl. The mean of blood glucose level in 60–74 age-group is 136 mg/dl, with the lowest level of 62 mg/dl and highest level of 337 mg/dl. The mean of blood glucose level in 75–90 age-group is 163 mg/dl, with the lowest level of 73 mg/dl and highest level of 253 mg/dl.

Diagnosis of diabetes can be stated if the measurement of on-time plasma glucose showed the level of ≥200 mg/dl with common symptoms such as polydipsia, polyphagia, and decrease in body weight with unknown reason. Diabetes patients are mostly belonged to the age-group of 55–64 years and 65–74 years. The data is in correspond with the research result as most of the DM-categorized blood glucose level found in the range of 45–59 years and 60–74 years. There is a differnt in the age category. Age is one of the risk factors which increase the rise of blood glucose in infodatin diabetes in 2018. The prevalence of diabetes is increased as the age developed. Disturbance in blood glucose setting is due to homeostasis disorders or disruption in the production of beta cell in the pancreas and the rise of insulin resistance. Insulin resistance can be caused by changes in fat composition in elderly body in the form of low muscle mass and high fat tissue due to bad diet.

CONCLUSION AND SUGGESTION

This study concludes that the profile of blood pressure among the elderly in Y Village is 50% showed blood pressure categorized as first-degree and second-degree hypertension, 23% categorized as pre-hypertension, and 27% showed normal blood pressure. The profile of blood glucose level among the elderly in Y Village is 22% showed blood glucose level categorized as DM, 58% categorized as non-DM, and 20% showed normal blood glucose level. The data indicates increase in blood glucose level for most of the elders and specific intervention is needed to control diabetes mellitus in Y Village.

Acknowledgment: The authors would like to deliver our gratitudes for the Regional Government and Health Workers in Y Village and LPPM Universitas Airlangga for providing us the chance to conduct community service for the community with the 60th KKN-BBM Tematik program in Y Village.

Is Parity a Predictor of Neonatal Death in Indonesia? Analysis of the 2017 Indonesia Demographic and Health Survey

Ratna Dwi Wulandari¹, Agung Dwi Laksono²

Abstract

One factor that is thought to have a close relationship with neonatal deaths is parity. This is a problem for Indonesia which has the cultural characteristics of a large number of children is something positive. The study used the 2017 IDHS data. With stratification and multistage random sampling, 36,548 women aged 15-49 years with live births in the last 5 years were sampled. The final analyzed using a Binary Logistic Regression test. Multiparous women in Indonesia have a higher percentage of neonatal deaths than multiparous women. But the difference in parity between primiparous and multiparous was found not to be a predictor of neonatal death in Indonesia. Three other variables were found to be proven, predictors. Women who were not employed were 0.576 times more likely than women employed for neonatal death (OR 0.576; 95% CI 0.407-0.814). Women who did antenatal care ≥4 times were 2.332 times more likely than women who had ANC <4 times to experience neonatal death (OR 2.332; 95% CI 1.519-3.578). Women who did not experience a complication during delivery were 0.457 times more likely than women who had a complication during delivery for neonatal death (OR 0.457; 95% CI 0.317-0.659). The study concluded that parity was not a predictor of neonatal death in Indonesia. Other variables that were proven to be predictors are employment status, antenatal care, and complications during pregnancy.

Keywords: neonatal death, mother and child health, parity.

Background

The neonatal period, or the first twenty-eight days of life, is the most vulnerable time for a child’s survival. Data collected by WHO from various countries found that in 2018, 47% of all under-five deaths occurred in the neonatal period¹. Unicef 2018 data recorded a global average of neonatal mortality of 18 deaths per 1,000 live births².

Neonatal mortality is an important indicator that reflects the quality of newborn, prenatal, intrapartum and neonatal care. Early neonatal mortality is more closely related to factors related to pregnancy and maternal health, whereas late neonatal mortality is more related to factors in the newborn environment².

The majority of neonatal deaths are concentrated on the first day and week, with around 1 million dying on the first day and almost one million dying within the next six days. Current trends, more than 60 countries will lose the opportunity to achieve the SDG target to reduce neonatal deaths to as low as 12 deaths per 1000 live births by 2030. About half of them will still not reach the target until 2050. These countries carry about 80% of the neonatal mortality burden in 2016¹.

Neonatal mortality in Indonesia is still high. The results of the 2017 Indonesia Demographic and Health Survey report show 15 neonatal per 1000 live births. This figure is higher than the figures achieved by the countries in the region³.

One factor that is thought to have a close relationship with neonatal deaths is parity⁴. Such a situation is a problem for a country like Indonesia, which has a culture with a large number of children with cultural characteristics which is positive⁵. It is important to prove

Statistically, parity is a predictor of neonatal deaths in Indonesia, to focus more on efforts to prevent neonatal deaths based on parity. Based on the background, this study is aimed at analyzing parity as a predictor of neonatal death in Indonesia.

**Materials and Method**

This study used data from the 2017 Indonesian Demographic Data Survey (IDHS) as analysis material. The 2017 IDHS sample was determined through stratification and multistage random sampling. The unit of analysis in this study was women in childbearing aged, 15-49 years old, who had given birth in the last 5 years. A number of 36,548 women were sampled.

The 2017 IDHS has passed ethical tests from the National Institute for Health Research and Development of the Indonesian Ministry of Health. The respondents’ identities have all been deleted from the dataset. Respondents have provided written approval for their involvement in the study. The use of the 2017 IDHS data for this study has received permission from ICF International through its website: https://dhsprogram.com/data/new-user-registration.cfm.

Parity is the number of living children whose births are born to a woman. In this study parity was divided into two, namely primiparous (<2 children), and multiparous (≥2 children). Socioeconomic was the wealth status of respondents compiled based on the index of goods ownership quintile stated by the respondent. The five categories were the poorest (quintile 1), poorer (quintile 2), middle (quintile 3), richer (quintile 4), and richest (quintile 5). Complications during pregnancy were the respondent’s acknowledgment of complications experienced during pregnancy until delivery. These problems consist of: prolonged labor, vaginal bleeding, fever, convulsions, baby in the wrong position, swollen limbs, faint, breathlessness, tiredness, and others. Problems during delivery were the respondent’s acknowledgment of problems experienced during childbirth.

Variables analyzed included: parity, age groups, educational level, wealth status, employment status, place of residence, antenatal care, complication during pregnancy, a problem during delivery, childbirth assistance, and place of delivery. Statistical analysis using chi-square was carried out to select the variables. Estimates were performed using Binary Logistic Regression because of the nature of the dependent variable. All statistical analyses were carried out using SPSS 19 software.

**Findings**

Table 1 was a descriptive statistic of neonatal death and related variables in Indonesia. Table 1 showed that multiparous women have higher neonatal deaths than primiparous women.

Table 1 shows that multiparous women have a higher neonatal death than multiparous women. Statistical test results show that there are significant differences between the two. Table 1 shows that all variables to be tested as predictors proved to be significant, and could be continued to the next stage.

Table 2 describes the results of the binary logistic regression test for neonatal death in Indonesia. The results of his analysis show that although primiparous women have lower odds ratios than multiparous women, the difference in parity between primiparous and multiparous is not a predictor of neonatal death in
Indonesia. The results of this study are different from other studies, which found that parity is one of the determinants of neonatal mortality\textsuperscript{6,7,8}.

Note: *Significant at level 95%
Table 2 shows that there are three significant variables as predictors of neonatal death in Indonesia. The three variables are employment status, antenatal care, and complication during pregnancy.

Table 2 shows that women who were not employed had a probability of 0.576 times compared to women employed for neonatal death (OR 0.576; 95% CI 0.407-0.814). This means that employed women have a higher chance of having neonatal death than those who are not employed. A study in Ethiopia found similar results. Employment status was found along with other demographic factors that contributed to neonatal mortality. Paradoxically, it was found that women who did antenatal care ≥4 times were 2.332 times more likely than women who did ANC <4 times to experience neonatal death (OR 2.332; 95% CI 1.519-3.578). Research in Nigeria and Southern Ethiopia shows different results. Verbal/social autopsy results show that lack of antenatal care has proven to be a factor affecting mortality in both countries. The analysis results in this study also contradict the results of research in Brazil which found that an early diagnosis during pregnancy that was performed during antenatal care can prevent infant mortality. It is predicted that 35.3% of infant deaths can be prevented by early diagnosis.

The paradoxical research results as in this study were also found in a study in Ethiopia. Analysis in Ethiopia found that childbirth performed at home actually has a better chance and protects the infant from death. Table 2 shows that women who did not experience a complication during delivery were 0.457 times more likely than women who had a complication during delivery for neonatal death (OR 0.457; 95% CI 0.317-0.659). This means that women who have a complication during delivery have a higher chance of having neonatal death than those who do not have a complication during delivery. This result is in line with research in China and the United States. Several studies recommend strengthening early identification of obstetric complications and immediate interventions to prevent neonatal death.

The results of this analysis indicate the possibility that although women in Indonesia perform antenatal care more frequently, experience complications during pregnancy, they may have a higher chance of experiencing neonatal death. Another possibility is the availability of health services which are still uneven in some parts of Indonesia. The geographical condition of Indonesia, which has more than 16 thousand, could also be another factor affecting neonatal death, including the still thick local cultural customs that make Indonesian women choose to give birth at a traditional birth attendant.

Conclusions

Based on the results of the study it can be concluded that parity was not a predictor of neonatal death in Indonesia. Other variables that were proven to be predictors were employment status, antenatal care, and complications during pregnancy.

Abstract

Damage to liver function is the most common cause of patients or doctors stopping treatment. Anti-tuberculosis (OAT) drug-induced hepatotoxicity is mainly caused by oxidative stress caused by drugs and metabolites. Subchronic toxicity is one of the conditions for testing long-term used drugs such as OAT. The research aims to determine the potential of miana leaf extract (EDM) as a hepatoprotector and prevent toxicity due to OAT administration. The study used 5 groups of Wistar rat test animals namely K1 (normal mice given placebo); K2 (OAT-induced mice given placebo); K3 (OAT-induced mice given Makassar EDM); K4 (OAT-induced mice given EDM Kupang); K5 (OAT-induced mice given Silymarin). Tests on mice were carried out after 30 days of treatment with parameters SGOT, SGPT, total bilirubin, creatinine and liver histopathology. The results showed that EDM has the potential as a hepatoprotector by preventing an increase in SGOT, SGPT and total bilirubin so as to avoid liver damage due to OAT induction. EDM has the potential to prevent toxicity due to the administration of OAT with creatinine parameters.

Keywords: miana leaf extract, OAT, hepatoprotector, toxicity

Introduction

The first-line treatment of tuberculosis according to tuberculosis prevention guidelines (6) is the use of anti-tuberculosis (OAT) drugs such as isoniazid, rifampicin, pyrazinamide, streptomycin and ethambutol. The most common factor in the treatment of tuberculosis is the side effects of OAT against damage to liver function such as hepatitis, hypersensitivity reactions, nausea, and vomiting (Gautam, 2012). Drug-induced hepatotoxicity and metabolites such as OAT are mainly caused by oxidative stress (18).

Prevention of drug induced liver injury (DILI) has been carried out using chemical compounds or natural ingredients. The effect of n-acetylsysteine hepatoprotector in preventing damage to liver function due to administration of OAT (4). Singh (18) have compared the effects of hepatoprotector n-acetylsysteine, silymarin and curcumin. The results can reduce hepotoxic HepG2 cells during OAT administration with parameters of survival, morphology, mitochondrial respiration and cell cycle. Krisnansari (11) proved the hepatoprotective potential of propolis against white mice induced by CCl4 (carbon tetra chloride). Propolis is proven to provide a significant difference in IL-6, superoxide dismutase, body weight and histopathology of rat liver. Huda proved the formulation of polyberbal sharbat chylosin as a hepatoprotector against total bilirubin, ALT, AST, ALP and rat liver histopathology (8).

Research assumes that the hepatoprotective effect is related to the antioxidant properties of plant extracts. Shehab investigated the antioxidant capacity of Fagonia indica Burn extract, Calotropis procera RBr and Salsola imbricate Forssk as potential hepatoprotectors for CCl4-induced mice, because they can reduce ALT, AST and
serum bilirubin levels (17). Phenolic compounds from plants such as quercetin and rosmarinic acid have the potential as antioxidants that can counteract oxidative stress as a pathophysiological mechanism of DILI (21).

Plants that have potential as antioxidants and hepatoprotectors become therapeutic mechanisms so that it is important to be given as a complementary in the treatment of tuberculosis such as: meniran, miana, mangosteen, temulawak, rosella, kencur, kedondong forest, garlic, brotowali (13,14). Al-Snafi has identified 45 medicinal plants in Iraq that contain secondary metabolites that are antioxidants (3). In India found 4167 species of medicinal plants that have been used for the treatment of liver disorders, filariasis and diabetes mellitus (16). Verma has reviewed 15 plants as hepatoprotective in Iranian folk medicine (19). Kumar identified the antioxidant properties of herbs as a hepatoprotector with oxidative mechanisms against toxic chemicals (10).

The use of plants even as hepatoprotectors need to consider the subchronic toxicity caused. Especially for long-term use such as complementary tuberculosis treatment. Rachmawati and Ulfa examined the toxicity of yellow wood extract to the liver and kidneys with parameters of SGOT, SGPT, histopathology of the liver and kidney (15).

This study aims to determine the toxicity and hepatoprotective potential of EDM in OAT-induced white rats. The hepatoprotector function was tested based on the parameters AST / SGOT, ALT / SGPT, histopathological features of white rat liver. Toxicity prevention function based on white rat bilirubin and creatinine.

**Material and Method**

**Test material** are EDM originating from Makassar City and Kupang City, OAT, Sylimarin and Sodium CMC as placebo. The extract was prepared based on maceration method. The dosage of the test material consisted of Rifampicin 25 mg / kg BW rat / day; INH 25 mg / kg BW rat / day; Placebo Na CMC 1%; EDM from Makassar 250 mg / kg rat / day; EDM from Kupang 250 mg / kg body weight / day; Sylimarin 25 mg / kg BW rat / day.

**Test sample** is white rat (*Rattus norvegicus*) Wistar strain; male, healthy, 2-3 months old, body weight 150-200g.

**Procedure for testing.** White rats were grouped in 5 groups with 7 rats for each treatment group. Every day the rats were fed and drank ad libitum. Every day rats get different treatment for each group. K1 (control group animals were given placebo (sodium CMC) orally once a day for 30 days). K2 (negative control group was given OAT and Placebo orally once a day for 30 days). K3 (treatment group given OAT and EDM from Makassar orally once a day for 30 days). K4 (treatment group given OAT and EDM from Kupang orally once a day for 30 days). K5 (positive control group given OAT and silymarin orally once a day for 30 days). OAT given is a combination drug of rifampicin and INH. Administration of OAT and EDM or Silymarin is done 1 hour apart to prevent drug interactions. After the end of treatment the dieuthanasia rats were then dissected to take specimens for testing. Specimens taken were rat blood for AST / SGOT, ALT / SGPT testing, total bilirubin, creatinine and complete blood. Mouse liver organ specimens for histopathological testing of the liver. Maintenance and treatment of samples was carried out in the animal laboratory of the Faculty of Medicine, Airlangga University (FKUA). Blood sample testing is carried out in the Dr. Chemistry clinical laboratory laboratory. Soetomo Surabaya. Histopathological testing was performed with HE staining preparations in the anatomic pathology laboratory FKUA Surabaya.

**Finding and Discussion**

**Finding**

The potential of EDM as a hepatoprotector for tuberculosis treatment is based on the results of rat blood sample testing according to the following table
Table 1. Test results on the number of SGPT, SGOT, Bilirubin and Creatinine in white rat test animals after OAT induction and treated with test material

Discussion

The results of phytochemical screening from EDM and antioxidant testing proved that EDM contains flavonoid compounds that have potential as antioxidants (13). Liver damage is also caused by free radicals released by cells that are induced by OAT so that the antioxidant function of EDM in this case can prevent malfunctioning and liver damage. In this case Airaodion have proven the hepatoprotective effect of Parkia biglobosa in rats induced by oxidative stress with parameters AST, ALT, LDH, LPO, CAT, SOD and GSH. Then it can be stated that EDM which contains antioxidants has the potential to be a hepatoprotector with its antioxidant mechanism (2). In accordance with research Shehab which shows the relationship of phenolic content in several herbal medicines as antioxidants and hepatoprotectors with the parameters of reducing the amount of ALT, AST, CAT, GSH, SOD and TBARS and proving that the flavonol content of quercitrin and rosmarinic acid play a role in reducing DPPH free radicals (17). Airaodion have proven the hepatoprotective effect of Parkia biglobosa in rats induced by oxidative stress with the same parameters (2).

Symptoms of hepatotoxicity in patients receiving tuberculosis treatment are based on an increase in serum alanine aminotransaminase in both ALT / SGPT and AST / SGOT amounts that appear after OAT administration such as rifampicin and INH. Increased serum 3-5 times the normal value accompanied by symptoms of hepatitis (5). Grouping of test animals was done to compare the effect of Na CMC (K2) test material; EDM from Makassar (K3); EDM from Kupang (K4) and silymarin (K5). The hepatotoxic parameters tested after administration of OAT are: an increase in the normal value of AST and / or ALT; an increase in total serum bilirubin and an improvement in liver function after stopping OAT. While creatinine testing is done to prevent toxicity. The parameters tested are in line with studies that test kidney toxicity including creatinine and BUN, while liver function includes SGOT, SGPT, HDL, LDL, total cholesterol, total protein, albumin, and triglycerides (5,7).

The test results showed an increase in SGOT and SGPT in K2 compared to K1 by (22%) and (128%). Based on the analysis there was a decrease in the number of SGOT and SGPT towards K2, namely in K3 (25%) and (86%); K4 (27%) and (41%); K5 (39%) and (41%). The Mann Whitney test showed that K3 and K4 were not significantly different from K1 for the SGOT and K3 parameters because they gave the largest and significant decrease in SGPT with other treatments for the SGPT parameter. Based on the results of research on the effect of giving EDM as a hepatoprotector with parameters of the amount of SGOT, SGPT, total bilirubin and histopathological features of the liver, the relationship between these variables is the mechanism of hepatoprotector that occurs in OAT induced rats. In the study, it was proven that mice induced by OAT on K2 showed an increase in the amount of SGOT, SGPT and total bilirubin compared to K1, which means that there has been impaired liver function due to OAT administration. Other studies have shown an increase in SGPT due to 7.5-fold OAT-induced hepatotoxicity in patients with HIV / AIDS and 100% of subjects given 600mg rifampicin experienced hepatotoxicity due to increased SGOT and SGPT (12).

The test results showed an increase in total bilirubin and creatinine from K2 to K1 (31.57%) and (24.94%). However, there was a decrease in K2 from K3 (17.56%)}
and (11.2%); K4 (6.63%) and (22.53%); K5 (14%) and (29.97%). Mann Whitney analysis shows the amount of creatinine K3, K4 and K5 is not significantly different from one another. Total bilirubin can be used to detect hepatobiliners, hepatitis, cirrhosis and other liver diseases. Likewise, Huda and Mosaddik have proven the hepatoprotector effect of herbal medicine formulas by comparing silymarin based on decreasing the amount of ALT / SGPT, AST / SGOT, ALP and total bilirubin(8).

Histopathological picture of liver showed damage occurred in K2 rat’s liver compared to other groups, because necrosis had occurred with the characteristics of the discovery of picnosis, karyoreksis and karyolysis. Although in general in all samples congestion occurs in the central vein but in K2 congestion is accompanied by hyalinization. Whereas in K3, K4 and K5 only found a few congestions in the observation of the entire microscopic field of view. In the triad portal lymphocyte infiltration and bleeding occurred in all treatment groups. But in K2 it turns out to be hyalinized, so it can be stated that K3 and K4 have potential as hepatoprotectors based on the rat liver damage picture. According to Zachary and McGavin in the case of acute cell damage, the process is that at first the cell nucleus undergoes picnosis (damage to the cell nucleus so that the cell contents thicken) and then chromatin in the cell nucleus will dissolve (karyolysis) followed by a breakdown of the cell nucleus (karyoreksis)(21). The hepatoprotective function of herbal medicines such as propolis, yellow wood and 15 other types of herbs has been proven based on histopathological features (11,15,19). In line with the results of the study of the potential of EDM as a hepatoprotector Ahsan also proved the potential of herbs as hepatoprotector with the results of reducing SGOT, SGPT and total bilirubin and showing differences in the histopathological picture of CCl4 induced rat liver(1). Yani and Singh also reported the hepatoprotective effect of N-Acetylcysteine in preventing DILI due to OAT so it was recommended to use hepatoprotector in OAT treatment to avoid the occurrence of hepatotoxic in patients who were given rifampicin and INH treatment(20). The results of this study support the function of EDM not only as a preventive, complementary curative tuberculosis (14) but also functions as a hepatoprotector and prevents toxicity due to treatment.

Conclusion

1. EDM has potential as a hepatoprotector by reducing the number of AST / SGOT and ALT / SGPT OAT induced white mice

2. EDM has the potential to prevent OAT toxicity based on improved histopathology of the liver and is able to maintain the amount of OAT induced white rat bilirubin and creatinine

The Performance of Elastographic Diagnostic of Breast Tumor in Dr. Soetomo Teaching Hospital Surabaya

Shinta Rosalina1, Nifa Koesmarsono Wahid1, Anggraini Dwi Sensusiatı2

1Student of Department of Radiology Medical Faculty Universitas Airlangga, Dr. Soetomo Teaching Hospital Surabaya 60285, Indonesia, 1Lecture of Department of Radiology Medical Faculty Universitas Airlangga, Dr. Soetomo Teaching Hospital Surabaya 60285, Indonesia, 2Lecture of Department of Gynecology and Oncology, Medical Faculty Universitas Airlangga, Dr. Soetomo Teaching Hospital Surabaya 60285, Indonesia

Abstract

**Background:** Elastography in breast cancer cases has not become a routine examination that is conducted in the radiodiagnostic unit in Dr. Soetomo Teaching Hospital Surabaya. These last few years, elastography has been an addition examination modality which is promising to assess breast lesions that are detected by an ultrasound. **Objective:** The aim of the present study is to observe the performance of elastography in breast tumor cases. **Method:** This cross-sectional study was conducted in Dr. Soetomo Teaching Hospital Surabaya. The elastography is applied in 65 females (the average age is 49.1 years old) and it was found 66 lesions with a definitive diagnosis (34 benign tumors, 32 malignant tumors) which was proved through a fine-needle aspiration biopsy. The grayscale result is classified into benign and malignant categorizations with examining five descriptors including shape, margin, orientation, echo pattern, and posterior features. **Results:** The elastography score showed that the sensitivity is 87.5%, the specificity is 94.1%, and the accuracy is 90.9%. The strain ratio showed 93.8%, 94.1%, 90.9% in sequence. On the other hand, the grayscale result showed 96.9%, 91.2%, and 95.5%. The combination of elastography and grayscale showed a better performance with the 97.1% of sensitivity, 94.1% of specificity, and 93.8% of accuracy. There was a significant correlation between the lesion size and the quality of elastography result (P = .034) while there was no correlation with the lesion depth (P = .624). **Conclusion:** The combination of elastography and grayscale have a better diagnostic performance in distinguishing benign breast tumor with malignant breast tumor.

**Keywords:** Breast Tumor, Elastography Score, Strain

---

**Background**

Elastography is a non-invasive imaging technique that can be applied to describe the strain of a tissue as a response to a given mechanical power. The basic of elastography is still developed, so the implementation in the clinical practice has become a debate in the scientific community and its functions remain unknown1. This technique is initially addressed to differentiate between the benign lesions and malignant lesions. However, it is implemented to assess ‘probably benign lesion’.

Several studies reported that the elastography did not give any additional information to the ultrasonografi (USG) diagnosis of breast cancer, in which the accuracy of the diagnostic is similar to the USG of grayscale3. However, other studies revealed that this method can only be applied to the lesions which are no more than 2 cm4. On the other hand, several other studies asserted that elastography could give additional information regarding the elasticity (strain) that cannot be achieved through the routine imaging modalities. It can also increase the specificity in the (USG) of grayscale so that it can decrease the biopsy number in benign lesion cases through the dubious grayscale USG and it can be postponed for one year5,6,7,8.

The elastography application in the imaging elastographic properties of tissues was proposed in one study. A conducted study categorized in a static method and based on the facts that a hard tissue has a small strain\(^1\). On the other hand, one of the conducted study referred to the dynamic method and based on the fact that a hard tissue has a high velocity of propagation\(^9\). There was a scoring system called Tsukuba Elasticity Score (TES) based on the diagnosis of more than 100 breast tumor cases in 2006. This scoring system categorizes the color scheme of the breast tumor elasticity into five classes, from benign (score 1-3), to malignant (score 4-5), and BGR score for cystic lesions\(^5\).

Thus, this method is not applied to replace the conventional USG to diagnose a breast tumor but as a complementary by giving information about the strain of a tissue which is not obtained in other imaging modalities. So far, there has been no data related to the use of elastography in breast tumor cases in radiodiagnostic unit Dr. Soetomo Teaching Hospital. Therefore, the present study aims to understand the elastography functions in diagnosing a breast tumor in radiodiagnostic unit of Dr. Soetomo Teaching Hospital. In addition, it also aims to recognize the elastography variations in breast tumors and explore the factors that can affect the elastography result.

**Method**

The independent variable was used for the elastography result and the related variable was used for the FNAB result. The present study conducted an examination hosted by the radiology residents that has been through an ultrasound stage for 5 months and supervised by the technical appliance and used Hitachi machine type Hi-Vision Avius with probe EUP-L74M 5-13 MHz.

All notes were submitted next to do a tabulation of data and statistic analysis. The present study also used a statistic analysis by calculating the sensitivity, specificity, and accuracy of the Chi-Square method. The trust limit that was used is 95% (95% CI) with the value of p is considered significant if it is <0.05. The statistic calculation was conducted with the assistance of SPSS software. Ethically, the researcher has received ethical clearance permission from Medical Research Ethics Commission Dr. Soetomo Teaching Hospital Surabaya.

**Results**

**The Subject Characteristic of the Study**

In this study, 66 samples are obtained aged between 32-80 years old with the mean 49.1 ± 8, 94 years old in which the most age group are 40-49 years old. The age average in the group with the benign cytology is 45.94 ± 7.32. However, the age average in the group with the malignant cytology is 52.41 ± 9.29.

From the first elastography examination, it is found that SE means in the group with benign cytology is 2. On the other hand, the SE mean in the malignant cytology group are 4. Secondly, from the SR assessment is found the SR mean in the benign cytology group is 3.03 ± 1.28. The elastography score is range from 0 until 5. In score 0, it is obtained 17 persons (25.8%) with benign tumors. In score 1, it is found 5 persons (7.6%) with benign tumors. Score 3 found 8 patients (12.1%) with benign tumors. Score 4 obtained 18 patients (27.3%) with malignant tumors. In score 5, there are 10 patients (15.2%) with malignant tumors. The strain ration ≤ 4.5 are 34 patients (51.5%) with benign tumors and 2 persons (3%) are the malignant tumor patients. On the other hand, the strain ratio ≥ 4.5 are 32 persons with 2 patients with benign tumors (3%) and 30 patients with malignant tumors (45.5%).

The results of the gray scale in benign tumor and FNAB in the benign tumor are 33 persons and the score of elastography in benign tumor and FNAB in the malignant tumor are 3 persons. The results of the gray scale in malignant tumor and FNAB in the benign tumor are 1 persons and the score of elastography in malignant tumor and FNAB in the malignant tumor are 29 persons. The sensitivity result of the diagnostic performance of SE is 90,6%, the specificity is 97,1%, the accuracy is 93,9%, PPV is 96,7%, FP is 3,3%, NPV is 91,7%, and FN is 8,3%.
Discussion

This study revealed that there are 2 lesions with FNAB-FCC result. Theoretically, FCC must result in the benign elastography. However, this study is obtained 1 case with malignant elastography (SE = 4; SR = 4.61). After analyzing it, it is indeed found that the lesion location, in this case, is deep (depth +/-1,1 cm) compared to the other FCC that has been diagnosed accurately. As Thomas et al stated, the depth of lesion location which is more than 1 cm cannot be evaluated adequately with elastography. However, from the data analysis of the study, it is obtained that there is no false positive/negative in the lesion with 1,5 cm deep.

This study revealed that 3 lesions with FNAB-BEH result and all of them have atendency to benign elastography. However, two of them have the grayscale result that tends to be malignant. In accordance with the study conducted by Barr et al., the BEH case had a grayscale result and malignant elastography.

This study found 22 cases with FNAB-IDC and two cases with FNAB-ILC result. There are 3 cases such as (2 IDC, 1 ILC) with the benign elastography result (SE = 2.3; SR = 3.20), but the grayscale result tends to be malignant. The false negative is also reported in the two conducted5,10. IDC and ILC are categorized as “hard carcinoma” compared to other malignant tumors11. IDC/ILC low grade and intermediate usually related to the intensified esmoplastic process. So it will appear as a hard lesion. On the other hand, IDC high grade is related to the high rate of mitosis and necrosis area so that it appears to be a mild lesion. Thus, it causes the false negative result.

This study found 3 cases with FNAB mucinous ca and 2 cases with NST result. Mucinous ca and NST are categorized as “soft carcinoma”11. It is usually related to thecystic component or a collection of mucin so that it appears to be soft. Based on the result of this study. It is found mean SE and SR for lower mucinous compared to IDC/ILC. This study revealed that one case with malignant round cellca result (referred to NHL). The result of elastography and grayscale tend to be benign (SE = 3, SR = 3,46. Similar to the previous studies conducted by Thomas et al. dan Barr et al., there are 2 cases of false negative which are lymphoma.

On the other hand, the result of this study tends to be benign. It referred to the facts that the discovery of conventional radiography does not usually assist in distinguishing the primary lesion with metastatic. We found that the cutoff value is SR 5.1. As a comparison, a conducted study found that the SR value in breast cancer diagnosis was 3.0812. In addition, a study found that the SR value is 4.5 as it is used to be the standard in this study13. However, previous conducted study found that the SR value is 2.814.

In this study, SE possesses the sensitivity of 87.5 %, 94.1 % of specificity, the accuracy is 90.9 %, the false positive is 6.7 %, the false negative is 11.1 %. While, SR possesses 93.8 % sensitivity, 94.1 % of specificity, 93.9 % of accuracy, 6.3 % of false positives, and 5.9 % of afalse negative. While grayscale has 90.6 % sensitivity, 91.2 % specificity and 90.9 % accuracy. If it is all combined with the grayscale sensitivity, specificity, and accuracy, it obtains 90.6 %, 97.1 %, 93.9 %. From the results above, it can be concluded that the elastography can increase the specificity of grayscale. It is in accordance with the results of some studies5. Some previous studies found that asserted that elastography could increase the specificity in breast tumor diagnosis12.

There is a significant correlation between the tumor size and the result of elastography (P = .034. The result of this study is in accordance with the two related previous studies (Itoh, et al. 2014), (Rizzatto 2001). However, there is no significant correlation between the depth of tumor and the result of Elastography (P = .624). It Is Not In Accordance With The Two Conducted Studies 15,14.

However, there is no significant correlation between the depth of tumor and the result of elastography. The breast tumor with 3 scores are not considered as the benign one but it is considered as indeterminate and suggested to do biopsy.. All tumors with 3 scores underwent a biopsy to minimalize the findings of a false negative, because it would increase the sensitivity in 2007. However, this study still suggests that biopsy must be undergone by considering the result of gray scale USG first.

Conclusion

Ethical Clearance: This study protocol was approved by ethical clearance Dr.Soetomo Surabaya, Indonesia teaching hospital research.

Abstract

Background: It is recognized that social capital plays an important role in health, including mental health. However, there are only a few studies that explain the role of social capital in the mental health of older adults in Aceh, Indonesia. This study aims to assess the relationship between social capital and the mental health of older adults.

Method: This study used cross-sectional design by involving 483 respondents aged 60 or above, which are retrieved by using multistage random sampling in Aceh Barat District. Data collection was conducted for four months in 2019. SPSS Version 21 was used to analyze the data through a logistic regression test.

Result: The result shows that the average age of respondents is 69.76 years and female respondents are 68.9%. The result of logistic regression analysis to conclude the relationship between social capital and mental health resulted in confidence level (p=0.044), social cohesion (p=0.021), social network (p=0.001), and social participation (p=0.119).

Conclusion: The result indicates that social capital includes a social network, social cohesion, and trust are significantly relevant to the mental health of older adults.

Keywords: mental health, social capital and older adults.

Introduction

Mental health is crucial to overall health and prosperity. Mental health is also recognized to be equally important to physical health, including the older adults⁴. They are recognized as a group that has a higher risk of experiencing mental health problems⁵. There are several plausible reasons that older people have a higher risk of experiencing mental health problems, including illness, lack of independence, weakness, isolation, separation, and their age ⁶.

The proportion of older adults who experience mental health problems may increase as the growth of the aging population continues to happen in this era.

Globally, it is estimated that adults aged 60 years or more suffer from mental and neurological disorders by 20% ⁷. In developed countries like America, it is estimated that in 2017 there were 46.6 million adults who experienced mental, behavioral, or emotional disorders, and 13.8% occurred in adults aged 50 years or more⁴. While in Indonesia, it was found that among 2,929 people aged 60 years or above, there was 16.14% who experienced symptoms of moderate and severe depression⁵.

Mental health problems harm sufferers, families, and the government. In patients with, for example, disruption of mental health impacts on the decrease of productivity, decrease of life quality, social problems, and additional health problems. Families who have members with mental health problems can experience economic problems such as a decrease in household income because they cannot work optimally due to caring for family members who suffer from mental
health problems. These conditions can increase the risk of household poverty. More broadly, the adverse effects of mental health problems are experienced by the government, where the national economic burden increases, and globally this can hamper international public health efforts. WHO states that higher disability and death rates are found in people with mental disorders. For example, the chance of dying prematurely in people with major depression and schizophrenia is 40% -60% compared to the general population².

As with other aspects of health, mental health can be influenced by various factors, including individual attributes, social, cultural, economic, political, and environmental factors². In this study, we only highlight the important role of social capital in mental health, which is part of social factors. As a construct, social capital has been popular for the last decade⁷. Most researchers divide social capital into two complementary forms, structural social capital, and cognitive social capital. Structural social capital are social contact, the compactness of social networks and social participation, while the cognitive social capital are trust, social cohesion and perceived social support⁸,⁹.

Social capital has been used in recent years to explain health disparities⁹, including mental health. The positive significant relationship between social capital and mental health has been proven through several studies conducted in developing countries¹⁰ and developed countries, such as Japan¹¹ and Finland⁸.

Although the study of social capital relationship with mental health has been conducted, according to the WHO, knowledge which specifically highlights the process of aging and mental health is still limited². Such conditions also occurred in Indonesia, and this is a challenge that needs to be answered with more research efforts. This study was conducted to examine the relationship between social capital and mental health of older adults in Aceh, Indonesia.

Materials and Method

Design and sample

The study design used was cross-sectional. Data collection was conducted from June to October 2019 through a survey of 483 respondents. Respondents in this study were people who were 60 years of age or above. Sampling was carried out by using multistage random sampling in the Aceh Barat District, Aceh, Indonesia. 6 out of 12 sub-districts in Aceh Barat District are randomly selected. Then, each of the three sub-districts was chosen randomly as a sampling place. Samples taken are respondents who meet the following criteria: 1) can be invited to communicate; 2) willing to become a respondent by signing a statement of consent to be a respondent; and 3) respondent is not in a condition of serious illness or treated in the health services unit during the data collection period. During data collection, researchers were assisted by several trained enumerators.

Mental health measurement

The instrument used to measure mental health is the geriatric depression scale (GDS) developed by Yesavage and Sheikh with 15 question items. The 15 questions were translated into Indonesian. The answer to each question item has two choices, “yes” or “no”. A zero score (0) is given for each answer, indicating low mental health, and a score of one (1) is given for each answer indicating good mental health. The higher the composite score obtained by the respondent, the better the mental health of the respondent.

Social capital measurement

Social capital is assessed through four variables, including trust, social participation, social cohesion, and social networks. Cronbach’s alpha scores for trust (0.9), participation (0.8), social cohesion (0.8) and social networks (0.9). All question items are in positive form using a Likert scale (four choices of the answer) includes strongly disagree (score 1); disagree (score 2); agree (score 3), and; strongly agree (score 4). The higher composite score shows better social capital.

Statistic Analysis

Logistic regression using IBM SPSS v.21 was conducted to determine the relationship between several variables of social capital and mental health.

Results

The results of the descriptive analysis in Table 1 about the demographic characteristics of the respondents showed that the average age of respondents was 69.76 years (standard deviation: 8.41) or more than half were aged 60-69 years (56.5%), more women (68.9%), unemployed (58.2%), no income (41.0%). An overview of mental health showed that there are more healthy older adults (65.8%) than the unhealthy ones (34.2%). While several social capital variables are known that
trust, social cohesion, social participation, and social networks are more in the medium category with the percentage of each is trust (67.7%), social cohesion (59.4%), social participation (58.0%) and social networks (67.7%).

Abbreviations: B = Beta coefficient, SE = Standard Error, CI = Confidence Interval, Adj OR = Adjusted odds ratio, * = significant p-value

The results of logistic regression test stage 1 (Table. 2) between social capital and mental health variables show that trust is significantly related to mental health of older adults (p=0.044), social cohesion is significantly related to the mental health of older adults (p=0.021), social network is significantly relevant to the mental health of older adults (p=0.001). Social participation is the only variable that is not related to mental health (p=0.119). Since social participation has a value of > 0.05, it was taken out of the model, and logistic regression stage 2 was conducted.

Abbreviations: B = Beta coefficient, SE = Standard Error, CI = Confidence Interval, Adj OR = Adjusted odds ratio, * = significant p-value

In the logistic regression test stage 2 (Table. 3), it was found that trust, social cohesion, and social networks significantly related to the mental health of older adults with a p-value of each is p = 0.011, p = 0.002, and p = <0.001 respectively. The relationship between the three variables with mental health is positive, and social networks have the strongest relationship with mental health.

Discussion

The result of our study shows that trust and social cohesion as forms of cognitive social capital have a significant and positive relationship with the mental health of older adults. This finding indicates that older adults with a high sense of trust in their community have better mental health than older adults with a lower sense of trust. Likewise, social cohesion, where older adults with high social cohesion have better mental health compared to older adults with low social cohesion.

Previous studies have proven the link between cognitive social capital and mental health in older adults. Formans et al. reported from the results of their study that cognitive social capital through mistrust was significantly related to psychological distress among older adults in Finland\(^8\). A study in China found a correlation between trust and depression in older adults\(^7\). In Indonesia, the results of the Tampubolon and Hanandita study also prove that social trust is positively related to mental health in people aged 15-65 years\(^10\). Although the study does not specifically address the older adult population, it could support the result of our study in proving the relationship of trust with mental health. The study of social cohesion was carried out in older adults in the Czech Republic, Russia, and Poland with
a prospective approach. The results of the study showed that the symptoms of depression increased among older adults with lower levels of social cohesion\textsuperscript{12}.

In addition, the results of our study found that social networking as a form of structural social capital was positively related to the mental health of older adults. It means that older adults with good social networking have better mental health compared to older adults with bad social networking. The social network is the variable of social capital that has the most significant relationship with mental health compared to the other two variables (trust and social cohesion). For social networks, we focus more on the close relationships of older adults with family or other relatives, their close relationships with friends and neighbors, and the close relationships of older adults with village officials where they live. This is important to assess as a part of an individual’s social capital because one of the essential mental health resources is the social individual capital of older adults\textsuperscript{8}. Older adults who feel close to family members, relatives, friends, neighbors, or the community around their residence may feel more calm and comfortable in living than those who have a less close relationship. If they have a problem, some close people can be invited to share and find solutions to the problems encountered. The condition is likely to have a positive influence on the psychology or mental of older adults so that they are mentally healthier. This finding is supported by the results of previous studies on the relationship between social networks and mental health of older adults\textsuperscript{7}.

Of the four social capital variables examined, we do not find any relationship between social participation and mental health in older adults. A study conducted in China by Cao et al. in people aged 60 years or above found the same result, in which social participation is not correlated with geriatric depression\textsuperscript{7}.

From the previous description, it can be concluded that mental health problems in older adults cannot be underestimated, as the notion of some people who consider the problem as an inevitable part of the aging process\textsuperscript{13}. Whereas mental health problem is a critical aspect of health problems, especially in older adults\textsuperscript{3} and social capital is one factor that plays an important role. The results of this study can be one of the evidence that proves positive social capital can improve and maintain the mental health of older adults. The increase of knowledge and awareness about social capital can be considered as one of the health promotion program strategies to increase and maintain the mental health of older adults. Health promotion of the importance of social networks is the first thing that needs to be done by public health practitioners. Finally, because this study is only cross-sectional, the results of this study cannot be concluded as a causal relationship. For this reason, further longitudinal studies need to be conducted by future researchers.

**Conclusion**

The conclusion that can be drawn from the results of this study is that three social capital variables are positively related to the mental health of older adults, including trust, social cohesion, and social networking. Social participation is not positively related to health. The social network is the variable that has the strongest relationship with mental health compared to the other variables.

Analysis the Role of Management for Achieving of Public Health Coverage Programs at Public Health Care in Bengkulu

Syaiful Anwar Ab1, Henni Febriawati1,2, Lizar Alfansi1, Effed Darta Hadi1

1Program Doktor of Management Science University of Bengkulu, 2Faculty of The Science of Health Muhammadiyah University Bengkulu

Abstract

Background: Public Health Care is a primary public health service center. It is also as a promotive and preventive service provider with a target group and community to maintain and improve health and prevent disease. In the implementation of the health program the management function in the public health center is called planning (P), Mobilizing implementation (MI), Supervision Control Assessment (SCA). The purpose of conducting a public health care management analysis is Planning (P), Mobilizing Implementation (MI), and Supervision Control Assessment (SCA) on the achievement of public health care performance indicators in Bengkulu City.

Study Design: The research design used is exploratory or non-experimental research for qualitative methods and analytic research designs are cross sectional observational approaches for quantitative methods with hypothesis testing. Informants in this qualitative study were carried out by means of purposive sampling, namely by conducting interviews with all the Head of Public Health Center. The sample in this study amounted to 80 samples consisting of the head of the Public Health Center, the person in charge of the program and the implementer of the Public health care program/activity.

Results: There is a relationship between Management functions (planning, mobilizing implementation, controlling assessment control) to the achievement of the performance of the Environmental Health, Nutrition, Prevention and Disease Control program at Bengkulu City Health Center;

Conclusion: The implementation of management functions (Planning, Mobilizing Implementation, Supervision Control Assessment) influences the Environmental Health, Nutrition, Disease Prevention and Control program in Bengkulu City Health center.

Keywords: Planning function, Mobilizing Implementation, Supervision Control Assessment and indicator program.

Introduction

Public health care can be divided into two categories, namely: first, as a primary public health service center as a promotive and preventive service provider with a target group and community to maintain and improve health and prevent disease. Second, the public health care as the center for primary individual health services. Public health care can provide comprehensive health services namely preventive, promotive, curative and rehabilitative.

Public health approach that focuses on population and risk factors for personal symptom or diseases is important for achieving the goals of promoting health and preventing disease, overcoming underlying factors, determining health and increasing the effectiveness and efficiency of the health system. The purpose of conducting a Public health care management analysis is (P), (MI), (SPA) on the achievement of Public health care performance indicators in Bengkulu City.
Material and Methods

The research design used is exploratory or non-experimental research for qualitative methods and analytic research designs are cross sectional observational approaches for quantitative methods with hypothesis testing. Quantitative methods determine the role of Public health care management in achieving performance indicators.

Informants in this qualitative study were conducted by means of purposive sampling, namely by conducting interviews with all the Head of Public health center Bengkulu City. Based on interviews were conducted by the Head of the Health Center, the person in charge of individual health efforts and those responsible for public health efforts in all Bengkulu City Health Centers. Samples for management hypotheses (planning, mobilizing implementation, controlling assessment controls), Community Health Efforts (CHE) and Individual Health Efforts (CHE) towards the achievement of performance indicators and program indicators are the Head of the Public health center and IHE and IHE Program Holders in the Public health center. Sampling uses purposive sampling.

Result

Planning

Public health care managers carry out their duties and functions in an integrated manner in all promotive, preventive and curative programs. Public health center as a first-level health facility (CFLHF), has the function of increasing the degree of public health through promotive and preventive services. The results of interviews with the head of the Public health center, all informants said the planning was prepared based on an analysis of the situation, national targets and local policies, prepared integrated with the IHA-FG and indicators of performance commitment, as said by the informants can be concluded based on the results of the interview:

.... Public health center compiles plans based on situation analysis, national programs, local and most diseases and the participation of the community will produce an effective and efficient planning of activities to be able to reduce the illnesses suffered and improve public health. Planning based on situation analysis and community participation is an initial concept that can guarantee the implementation of activities according to their needs and goals. Good planning will produce maximum objectives and can be used as a model for Public health center planning.

Mobilizing Implementation

The implementation of the management function of the implementation in the form of a meeting forum is known as Mini Workshop. The general objective of the Mini public health center workshop is to improve the function of public health center through the promotion of cross-program and cross-sectoral teamwork and the activities of the Public health center in accordance with planning.

Based on the interview results with those responsible for public health efforts in all public health center, it can be concluded that the public health center has been driving the implementation of It’s activities. In accordance with the results of an interview with the person in charge said:

In the mini-workshop, socialization of activities, problems based on evaluation results, identification of solutions with all staff, to develop a specific plan (Specific) to achieve targets that have not been achieved based on the results of the evaluation; move across sectors so that city is healthy, in mobilizing the community, if it has not been achieved yet do a home visit (Informant F2)

The management function of the planned program / activity implementation can be carried out according to the schedule, goals and objectives of each activity. Activator through mini public health center’s workshops and cross-sector workshops to carry out activities planned as a management model by optimizing the mobilization and implementation management functions.

Supervision Control Assessment (P3)

Targets that have not been achieved at the set time, the Public health center makes special efforts, or re-planning, are discussed at the monthly mini workshop, according to the results of interviews with informants:

.... Supervision Control Assessment is carried out routinely during monthly mini workshops, indicators
that have not yet been reached are formulated, evaluated, corrected and followed up with Plan, Do, Check, Action (PDCA) prepared together with officers and relevant stakeholders (Informant A1). ...

Improving the results of activities by redesigning, re-implementing, supervising and following up on the re-implementation of an activity. The Plan, Do, Check, Action (PDCA) process of the Plan, Execute, Check and Follow-up activities are a problem-solving process with four creative steps commonly used in quality control for the continuous improvement of all activities in the Public health center.

Supervision is carried out by the head of the Public health center and the person in charge of the activities including administrative aspects, resources, achievement of program performance and technical services. If any discrepancies are found based on plans, standards, and various obligations that must be applied, coaching is carried out in accordance with the guidelines for implementing activities.

Management function with the Achievement Program

Results of Planning Relations, mobilizing Implementation (MI), Supervision of assessment Control (SCA) with the Achievement of the Environmental Health Program in Table 1.

Source: Analysis data (2018)

The results of the analysis of the relationship between P, MI, SCA (obtained from numerical data (ratio) of answers to questions then categorized in ordinal form) with the achievement of the prevention and control of public health center disease programs seen from the target and program achievements if the achievements of more than 80% of the targets are categorized as good, 50-79% of the moderate target and less than 49% are categorized as less. The analysis shows the relationship between P, MI, SCA with the achievement of prevention and control program of Public health center disease in Bengkulu City is partly being with the achievement of prevention and control program of disease. So there is a relationship between P, MI, SCA with the achievement of the prevention and control program of Public health care in Bengkulu City.

Discussion

Planning (P)

Program and performance commitment indicators. The management of the Public health center shows a systematic sequence which is implemented to optimize management functions which are carried out in an interrelated and continuous manner. The planning function can improve the achievement of Public health center performance. The leadership of the Public health center has developed a plan that involves human resources and optimizes available resources, this is in line with several studies. De Waal and Heijden’s research (2015) states that planning affects employee performance. Employee performance is also influenced by coordination between leaders and leaders and employees so that optimal performance is realized.

Management recommends reviewing regulations at the service level at the Public health center, capacity building, supervision and quality assurance, redefinition and strengthening the role of gatekeepers, availability of regulations and strengthening of patient referral policies, staff motivation in customer service.

According to Ashton (2015) compiling a framework of performance and integrated incentives by providing new performance measurements for the health system in New Zealand consisting of namely; a) build and combine existing performance measurements; b) national policies...
and shifts to integrated services; c) combining incentives for quality improvement and (d) performance-centered. Integrated planning of all existing and new Public health center indicators, improving performance outcomes.

The quality management center of the Public health care is a series of ongoing routine activities, which must be monitored regularly and regularly, monitored and controlled at all times. The Head of the Public health center guarantees that the quality management cycle runs effectively and efficiently, setting up a Public health center management team that functions as the person responsible for the quality of Public health center management.

**Mobilizing Implementation**

The function of mobilization implementation is integrated starting from the internal mini workshop program conducted by Public health center every month and cross-sector which is conducted every three months to discuss program achievements, causes of problems and solutions. The results of the study concluded that the mobilization and implementation of the Public health center plan began with situational leadership, professionalism and incentives that were implemented, optimal resource empower would improve performance outcomes. This is in line with several studies. The development of health organizations is directly proportional to the process of leadership, professional management, incentives and adequate resources in a progressive manner of service achievement. Health service organizations must be understood as a dynamic system that by complexity is able to produce strategic and professional health managers, so that they can fight obstacles and promote diversity, to generate new ideas that can help improve the health service process.

The mobilization in the effort to prepare for the implementation of activities, began by conducting a mini Public health center workshop to draw up a plan for the current year’s activities, to gather strength in Public health center. The mobilization of Public health center is also carried out to mobilize resources outside the Public health center through cross-sector workshops which are held 4 (four) times in one year.

**Supervision Control Assessment (SCA)**

The main principles of evaluation of health services and indicators can be successfully modified for the purpose, based on demographics and public health needs by ensuring flexibility and adaptation to the context. This is in line with several studies. Concludes that effective supervision determines a Public health center management so that supervision, training, administration of health services, is related to the performance and motivation of workers.

The results of Adindu’s study (2010) show that monitoring and evaluation of primary health care cannot be separated. Monitoring ensures that primary health care programs are according to plan, while evaluations ensure they are on the right track according to the plan and the impact is set.

Planning, mobilizing implementation, of Public health center are management functions carried out in an integrated and interrelated way. Implementation of the Planning Function, mobilization implementation, Supervision Control Assessment contribute to the achievement of service commitment indicators. Stakeholders will be able to play a role after knowing and understanding the objectives of the program. Need to improve the functions of planning, mobilizing implementation, supervision, control assessment of Public health center at Public health center in Bengkulu City.

Results based monitoring and evaluation systems must be considered as work in progress. Continued attention, resources and political commitment are needed to ensure the continuity and sustainability of the system. Building and maintaining a results-based monitoring and evaluation system requires time and effort, there is no perfect system and there are many different approaches, but the journey is worth the effort and the results can be many.

**Conclusion**

Public health care in carrying out its functions as: The implementation of Community Health Efforts (CHE) and Individual Health Efforts (IHE) in the working area, effective and efficient Public health center management functions can increase influence on the achievement of Public health center performance indicators in Bengkulu City. Provincial and district/city governments can establish policies by increasing the role of Public health care management functions in promoting and preventive efforts at Public health care.

Eruption Pattern of Permanent Molars among School Children in Chennai

Daniel Rajendran T
1Department of Forensic Medicine and Toxicology, Sree Balaji Medical College and Hospital

Abstract

Background: Estimation of the age of an individual is essential investigation in medicolegal cases, especially involving children and adolescents. Among the various factors used for age estimation, eruption of permanent teeth is one of them. Several factors influence the eruption of teeth, including genetic, nutritional and hormonal. This study was carried out to analyze the pattern of eruption of permanent teeth among school going children in urban Chennai.

Method: This cross sectional study was carried out among 983 school children between the age group of 4-14 years. Two schools, one belonging to the lower socioeconomic status and the other belonging to the higher socioeconomic status were taken up for this study. Eruption of permanent teeth were examined clinically.

Results: Majority of the first molars erupted by 7-7.5 years of age (95%) while majority of the central incisors erupted between 8-9 years. Lateral incisors were completely erupted between 9.5-10 years and first premolar were completely erupted between 12.5-12.9 years. Both second premolar and canine erupted by 13.5-13.9 years.

Conclusion: The visual observation of eruption of permanent teeth is a non invasive procedure and does not require any special machines like that of radiography. This method of assessing the age of the individual is considerably easier, economical and safe. Hazards of exposing the individual to radiation can be prevented.

Keywords: Chronological age, eruption of permanent teeth, medicolegal issues, anthropometry, nutritional status.

Introduction

Estimation of the age of an individual is of utmost importance in medicolegal cases, especially in populations where records are not well maintained. Medically, age of an individual can be estimated based on the eruption of teeth, ossification of bones, presence of secondary sexual characteristics and various other physical features. Among these methods, assessment of dentition is one of the most widely used techniques, given the fact that they are simple and feasible methods. Moreover, eruption of teeth is fairly constant in all races and ethnic groups, and are specific to narrow age range. The three types of human dentition (deciduous, mixed and permanent) follow a periodic sequence which is useful for determining accurate estimation of the age. There are two methods currently available for assessment of dentition, namely the clinical examination and radiological assessment. With the help of radiographic methods, it is possible to follow the formation of crowns and roots of the teeth and their calcification. However, clinical method is more suitable as it is simple, feasible and economical.

Keywords: Chronological age, eruption of permanent teeth, medicolegal issues, anthropometry, nutritional status.
especially in the low socioeconomic status population. Studies have shown linkages between delay in the eruption of the permanent teeth and protein energy malnutrition in children and stunting among adolescents. [3] There are however, no registries maintained in India to document the eruption of permanent teeth with respect to age and socioeconomic status. A study focusing on dental eruption, clinical assessed at school level will go a long way in documenting the pattern of maturation, in addition will serve as a proxy measure for evaluating the nutritional status of these school children.

**Objectives**

This study was carried out to analyze the eruption pattern of permanent dentition among school going children.

**Methodology**

**Study setting and participants**

This study was carried out as a cross sectional study among the school children of the urban field practice area of our medical college in Chennai. This study was carried out for a period of three months between July to September 2019.

**Sample size and sampling technique**

All the schools in the urban field practice area of our medical college were approached for permission to carry out the study. Two schools – one government and one private school consented for the study. Since there was no literature available regarding the eruption patterns, all the children aged between four and fourteen years studying the above two consented schools were taken up for the study. The participants were selected by purposive sampling. A total of 963 children participated, of which 490 were from government school and 473 were from a private school within the field practice area.

**Ethical approval and informed consent**

Approval was obtained from the institutional ethics committee prior to the commencement of the study. Written consent was obtained from the principals of both the schools. Each participant was explained in detail about the study. Informed consent was obtained from both the parents and the participants prior to the commencement of data collection.

**Data collection**

A structured clinical proforma was used to obtain information regarding demographic characteristics like age, sex, etc. Oral examination was carried out by the principal investigator to evaluate the dentition pattern among the study participants.

**Data Analysis**

Data was entered and analyzed using SPSS ver. 20 software. The pattern of eruption of the permanent teeth was expressed in percentages. Independent sample t test was used to evaluate the association between eruption and background characteristics. A p value <0.05 was considered statistically significant.

**Results**

This study was carried out among 963 school students in the field practice area of our tertiary teaching institution. Majority of the participants were aged between 4-7.5 years (41.4%) and were males (64.4%). (Table 1)

It was observed that central incisor had erupted in 31.1% of the participants followed by first molar (29.6%). Lateral incisor and second molar had erupted in 22.2% of the participants. (Figure 1)

The age wise comparison of the eruption of permanent teeth is given in table 2. It was observed that first molar and central incisors were the earliest to develop as early as 4-4.5 years. Majority of the first molars erupted by 7-7.5 years of age (95%) while majority of the central incisors erupted between 8-9 years. Lateral incisors were completely erupted between 9.5-10 years and first premolar were completely erupted between 12.5-12.9 years. Both second premolar and canine erupted by 13.5-13.9 years. (Table 2)

On comparing with the gender, central incisors erupted in 23.7% of the males followed by first molar (22.4%) and lateral incisor (17.8%). Among females, central incisor erupted in 44.6% followed by first premolar in 43.7%. (Table 3)

On comparison with the socioeconomic status, among the low income group, central incisor erupted in 42% followed by first molar (40.4%) and first premolar (30.6%). Among the high income group, central incisor
erupted in 19.9% followed by first molar (18.4%) and first premolar (17.3%). (Table 4)

**Discussion**

On analyzing the eruption of individual teeth from the above tables, it is clearly understood that some individuals have early eruption from six months to two years. However, there was no correlation between early eruption ad socio economic status. The early shedding of primary teeth advances the emergence of the permanent teeth.[4] This could be the reason for early eruption of the permanent teeth. In addition, it was found that some individuals have late eruption from 6 months to 2 years. Root resorption of the primary tooth sometimes does not follow their routine procedure, with the result that the permanent tooth cannot emerge which may bring about the prolonged retention of deciduous tooth. This could be the reason for late eruption.[5]

The emergence of permanent teeth, whether it is primarily in the mandibular or maxillary regions was not a part of this study as the emergence of teeth in any of the quadrants were taken as the corresponding age group of the individual but in the majority of the cases it was noted that the mandibular teeth erupts earlier than the maxillary teeth.

It was stated that from the day of eruption of the permanent first molar till the day of eruption of last permanent canines there would be both temporary and permanent teeth in the jaws, referred to as the period of mixed dentition. In addition, it was stated that there would not be any deciduous teeth above 12 years.[6] The available data was analysed for this and it was found that in about 11% subjects between 12 to 14 years even after the eruption of permanent second molar, deciduous canine is still present. There was mixed dentition even after the eruption of permanent second molars.

This study observed a wide deviation from the early eruption to late eruption for each permanent tooth for both males and females. It was found necessary to arrive an average or mean period of eruption by clubbing males and females together for each permanent dentition. The mean period for each permanent dentition in the present study is almost corroborative with the earlier studies. A very few in the literature have shown mean age group for each permanent dentition but there was no mention of standard deviation. This study has clearly arrived at a standard deviation of eruption of each permanent tooth irrespective of the sex.

*Schour and Massler* have described the formation of the permanent teeth in 1940 as occurring in three clusters. The first cluster consists of the first molars, the central incisors, the lateral incisors and the cupids, which begins formation during first year. The second cluster being the second molar forms during 2 to 4 years and the third cluster being the third molar forms during 5 to 6 years.[7] This clearly shows that there was simultaneous eruption of differing permanent teeth and this was observed in the present study. Overlapping or simultaneous eruption of two differing permanent teeth whose eruption schedule is close to each other is observed. This overlapping tooth eruption corroborates with the first group of cluster formation and the second cluster with canine.
Dental age can reflect an assessment of physiological age comparable to age based on skeletal development, weight or height. In addition, it was stated, when forming, the crowns and roots of the teeth appear to be the tissues least affected by environmental influences (nutrition, endocrinopathies etc) and dentition may be considered to be single best physiological indicator of chronological age in juveniles.\cite{8}

This study has clearly shown that eruption of permanent teeth has no correlation with the socioeconomic status of the individual during the mixed dentition period and is mainly inheritable based on genetic factors unless the tooth is affected by caries or severe malnutrition. Since the eruption of permanent teeth is least affected by the socio economic status of the individual as well as by nutrition, it can be taken as the best indicator for assessment of physiological age in the juveniles. However, while giving the age of the individual, it should be given as a range by adding or subtracting the standard deviation for that tooth.

**Conclusion**

The visual observation of eruption of permanent teeth is a non invasive procedure and does not require any special machines like that of radiography. This method of assessing the age of the individual is considerably easier, economical and safe. Hazards of exposing the individual to radiation can be prevented.

Effectiveness of Tailored Reaction Time Training Drills in Addition to Warm-Up Sessions on Performance Parameters in Recreational Cricket Players

Tanishk Choksi1, S Anandh2
1Intern, Faculty of Physiotherapy, KIMS “Deemed to Be University” Karad, Maharashtra, India, 2Professor, Department of Community Health Sciences, Faculty of Physiotherapy, KIMS “Deemed To Be University” Karad, Maharashtra, India

Abstract

Background: In the game of cricket, the players need very good reflexes to react to the situation. The players who play very rarely (recreational players) end up with more injuries compared to elite players due to improper training session and warm-ups. The recreational players in over enthusiasm often end up with injury during the match. So to improve the performance of the recreational cricket players their reaction time should be improved. Thus recreational players need appropriate training and awareness of such therapeutic reaction time training drills like Ball Drop Drill, Reactive Gear Drill, Shuffle Reaction Ball Drill, Ball Catch Drill, Run Shuffle Drill, T-Drill, Multiple Slinger Drill and Mountain climber to Sprint along with regular warm up sessions are necessary for preventing injuries as well as improving the performance parameters of the cricket players.

Objective: The objective of this study was to compare the effect of conventional and tailor made Reaction Time Training Drills sessions for recreational cricket players.

Method: In this study, 26 individuals who played cricket for recreation (all male) were taken. They were equally divided into two groups i.e. Group A and Group B. Individuals in the age group of 19-30 years were included in this study, out of which 13(50%) players were in group A and 13(50%) were in group B. This consisted of those who played recreational cricket and did not have any training or experience in professional Cricket. Pre intervention and post intervention reaction time testing were taken. Group A received conventional training while Group B received Reaction Time Training Drill.

Result: There was a significant effect of reaction time training on individuals of group B compared to conventional training in group A (p <0.0001).

Conclusion: The tailored Reaction Time Training Drills are effective in improving performance and preventing injuries in recreational cricket players.

Key Words: Reaction Time Training Drill, Reaction Time Testing, Cricket, Recreational players.

Introduction

Cricket has always been the sport of choice for most of India.1 From young children to the old, everybody has played cricket for a good part of their life. However, most of the individuals have played cricket only for recreation.2 They have generally played only for their schools, colleges or local cricket organisations in their area of residence.

This makes them vulnerable to a vast variety of problems. The most common of this being injuries. All of these players at least once in their lifetime have sustained an injury while playing cricket. Common cricket injuries include hamstring strain, ankle sprain, groin pull, shin splints, tennis elbow etc.3,5,6 Most of these injuries occur due to the player failing to catch the ball, hit the ball while batting or due to stumbling while running.
These injuries again vary according to the role of the player in the sport. Batsmen usually suffer from ankle sprain while running between the wickets, Groin pull while trying to run to score a run, getting hit by the ball due to slow reaction time etc.\(^5\)\(^6\)

Bowlers suffer from Shoulder injuries while throwing. The wrist and well as the elbow are also involved.\(^7\) Fielders get injured due to a delay in catching the ball and in turn getting hit by the ball or because of stumbling while running to catch a ball.\(^8\)\(^9\)

From the above mentioned injuries, it can be said that these injuries have mainly occurred due to a slow reaction time of the players.\(^10\) Reaction time is the minimum time taken by an individual to react to a certain stimuli. This is extremely important for cricketers as the entire game is based on reacting to the stimuli, i.e. the throw of a ball within time. Any slowing of reaction time will greatly hamper their performance.

Recreational players generally focus on improving their strength and endurance. They train at the gym frequently to build up their strength. Before playing they run a few rounds around the ground and perform a few basic stretches. At time most, they’ll perform some simple agility drills.

It is very important to improve the awareness about the concept of reaction time among these players. Focus needs to be put on teaching them on how to assess the speed of their own reflexes and try to improve them. A little increase in reaction time of these players will immensely improve their overall performance in the sport.\(^11\)\(^12\) Thus, we are conducting this study to facilitate their progression in the sport.

**Methodology**

An approval for the study was obtained from the Protocol committee and the Institutional Ethical Committee of KIMSDU. 32 individuals were approached of which 26 were selected according to the inclusion criteria. The procedure was explained and written informed consent was taken. Exercises were explained thoroughly. Training was given half hour before the game for 3 matches. Pre and post assessment of reaction time testing (Reaction Ruler Test)\(^4\) were taken and average was calculated in Milli seconds.

**Interpretation:** Table no.5 shows that, the association between reaction time test scores of Group A and Group B before intervention, according to unpaired t-test, had a p-value of 0.6979(NS) with a t-value of 0.3929. After intervention, paired t-test had a p-value of <0.0001(ES) with a t-value of 4.814.

**Discussion**

In the game of cricket, the players need very good reflexes to react to the situation. The players who play very rarely (recreational players) end up with more injuries compared to elite players due to improper training session and warm-ups. The recreational players in over enthusiasm often end up with injury during the match. So to improve the performance of the recreational cricket players their reaction time should be improved. Thus recreational players need appropriate training and awareness of such therapeutic reaction time training drills like Ball Drop Drill, Reactive Gear Drill, Shuffle Reaction Ball Drill, Ball Catch Drill, Run Shuffle Drill, T-Drill, Multiple Slinger Drill and Mountain climber to Sprint along with regular warm up sessions are necessary for preventing injuries as well as improving the performance parameters of the cricket players.

The aim of this study was to find the effectiveness of Reaction Time Training Drill in addition to warm-up sessions on performance parameters in recreational cricket players.

The objectives of this study were to find out the effect of conventional training in addition to regular warm-up on recreational cricket players, to find out the effect of Reaction Time Training Drills in addition to...
The objective was also to compare the effect of conventional and tailor made Reaction Time Training Drills sessions for recreational cricket players.

In this study, 26 individuals who played cricket for recreation (all male) were taken. They were equally divided into two groups i.e. Group A and Group B. Individuals in the age group of 19-30 years were included in this study, out of which 13(50%) players were in group A and 13(50%) were in group B. This consisted of those who played recreational cricket and did not have any training or experience in professional Cricket. The mean age for players in group A was 21.38 years and that for players in group B was 22 years.

The players were distributed according to their roles in the sport. Out of the 13 players in group A, 6 (46.1%) were batsmen-fielders, 4(30.7%) were bowler-fielder and 3(23.07%) were all-rounder. Out of the 13 players in group B, 4(30.7%) were batsmen-fielders, 4(30.7%) were bowler-fielder and 5(38.46%) were all-rounder.

In Group A, the subjects were given only conventional training along with regular warm-up session for improving reaction time before 3 matches individually and in Group B, the subjects were given reaction time training drills along with regular warm-up session before 3 matches individually. Reaction time testing was done for all the players before and after the training session respectively. The mean reaction time test scores for players in group A, pre and post intervention were 149.9ms and 148.8ms respectively. For group B the mean scores were 145.7ms and 104.84ms respectively.

Statistical analysis of the reaction time testing scores pre and post intervention was also done between both the groups i.e. inter group analysis was done to confirm that the difference between the pre and post measurements is significant. Unpaired t-test was used. The comparison for pre intervention scores of group A and group B was found to have a p-value of 0.6979(NS) which was not significant and post intervention scores of group A and group B was found to have a p-value of <0.0001(ES) which was extremely significant.

This shows that there was a considerably significant difference in the scores of both the groups thus showing that the improvement in group B was significantly more than that of group A.

This study will also improve the postural stability of players and by performing the drills before every match will give them habit of having controlled movements which is very much required in the game of cricket. Thus, there was a significant improvement in their performance parameters. This will also improve their confidence and in turn their performance.

This knowledge will help us to improve the training administered by the coaches at small institutions thus improving the performance of these players greatly. This will in turn improve their chances of participating in esteemed tournaments all over the nation.

**Conclusion**

On the basis of the results of the study, there was significant difference in the reaction time testing (Reaction Ruler Test) score of group B than that of group A which shows that Reaction Time Training Drills is effective in improving performance of recreational cricket players.

**Conflict of Interest:** There were no conflicts of interest in this study

Abstract

In veterinary practice, at present, specialists often have to deal with pathology of the prostate gland in dogs. The reason for this is that the pathological process in the tissues of the prostate gland can occur asymptomatic and for a long period of time, subsequently leading to organ hypertrophy. An increase in the volume of the prostate gland most often has a benign character, which is generally accepted to be diagnosed as prostatic hyperplasia. The disease is often detected at a late stage, which complicates the treatment and worsens the prognosis. Hyperplasia, as a medical condition, is an indicative term used to describe the abnormal increase in the number of cells in any organ, in this case the prostate gland. This article describes the main symptoms, diagnostic methods and differential diagnosis proceeding from practical veterinary experience.

Key words: reproductive system, secretion, seminal plasma components, pathologies.

Introduction

The prostate gland (prostate) is an important part of the male reproductive system, producing a fluid that contains simple sugars, citric acid, calcium and a number of enzymes that are involved in the balance and protection of seminal fluid, contributing to the survivability and motility of sperm and increasing its ability to fertilize the ovum. The prostate gland is the only accessory sex organ in dogs that plays an important part in the secretion of seminal plasma components. This is an oval-shaped bicuspid exocrine gland located in the pelvic cavity of adult dogs, through which pass the urethra and deferens ductus, where sperm is transferred to the urethra. The prostate communicates with the urethra through several holes along the entire prostatic urethra through which the seminal plasma is released. Pathologies of the prostate gland are extremely common in dogs, therefore their study is of great importance for a better understanding of these conditions.¹

Benign prostatic hyperplasia (BPH) is a condition of enlarged prostate gland. This is the most common prostate disease observed in intact male dogs, less common in cats. The word “hyperplasia” means increased size.² Medium and large breeds are prone to the development of BPH. This condition is associated with proliferation (hyperplasia) and an increase in cell volume (hpyertrophy) of prostate tissue. Benign prostatic hyperplasia begins as glandular hyperplasia and subsequently passes into cystic hyperplasia with the formation of many small cysts in the parenchyma of the caudal part of the abdominal cavity; from this age on, during puberty, the prostate is located in the pelvic cavity. After reaching puberty, the organ increases in size, extending cranially into the abdominal cavity. Prostate hyperplasia in dogs is a pathological age-related change in the form of a painless increase that manifests itself in two phases: glandular and complex. The glandular phase is characterized by an increase in the number of cells and a symmetric increase in the gland. The complex phase is characterized by glandular hyperplasia, glandular atrophy, the formation of small cysts, chronic inflammation, including squamous metaplasia of the epithelium.
prostate gland. The aetiology of BPH is understudied, but it is known that dihydrotestosterone (DHT) plays a key part in the pathogenesis. The function of the prostate depends entirely on the testosterone produced by the testes, which significantly affect its function and size. Since the balance of hormones in a dog’s body changes with age, the prostate tends to increase as a result of excessive production of sex hormones. Clinically manifested benign prostatic hyperplasia predominantly affects older dogs. On the other hand, a structural change in the glandular epithelium begins already at the age of two years and eventually leads to multiple, small intraprostatic cysts, which are filled with a vitreous yellowish fluid. These cysts can also protrude above the surface of the organ at an advanced stage. It is estimated that approximately 50% of intact males will develop BPH at the age of 5 years, 60% – at the age of 6 years, and 95% – at the age of 9 years. BPH is a condition observed only in intact (unesterified) male dogs.

Unlike humans, dogs have an enlarged prostate gland that usually does not cause problems with urination, but can sometimes cause changes in bowel function. An increase in the volume of prostate gland can put pressure on the colon and reduce its diameter. When the prostate enlarges, it expands backwards in four-footed animals, that is, to the spine. If there is a significant increase, it can cause stress during bowel movements, constipation, and even faecal exposure. Faeces can be flat or ribbon-shaped. From time to time, an enlarged prostate pushes forward as against backward, pressing on the urethra. This can cause the dog to strain while urinating.

### Materials and Method

Using the analysis method, other diseases that cause an enlargement of the prostate gland or similar clinical signs were identified:

- prostatitis is a bacterial infection of the prostate gland. The prostate is usually painful on palpation;
- abscess is an insulated pocket of infection containing white blood cells, bacteria and cell debris;
- paraprostatic cysts are fluid-filled sacs that are connected to the prostate by a thin stem;
- prostate neoplasia (cancer). Prostate cancer can closely mimic other types of prostatomegaly, but usually dogs with prostate cancer have an asymmetric increase in one of the prostate lobes. Animals with prostate neoplasia are also usually systemically ill and have a history of weight loss;
- squamous cell metaplasia. Squamous metaplasia is a change in the prostate gland due to elevated levels of oestrogen in the blood.

The main diagnostic tests carried out in patients with suspected prostate disease include general clinical tests, including haematological and biochemical tests of blood and urine, palpation of the gland through the rectum, microscopy of prostate secretion. The studies were conducted during 2019 in the Veterinary Centre “Krokodil” in the city of Petropavlovsk-Kamchatsky. During the study period, 260 dogs with suspected benign prostatic hyperplasia were examined.

![Figure 1. Clinical signs of prostatic hyperplasia](image1)

![Figure 2. Physical examination (palpation of the prostate): 1 – penis; 2 – bladder; 3 – prostate gland; 4 – rectum; 5 – testis](image2)

In the process of diagnosis, the following research methods were used: gathering of medical history and clinical examination (Fig. 1); palpation of the gland through the rectum (Fig. 2); cytological and microbiological examination of the secretion of the prostate gland by obtaining ejaculate; X-ray examination, general urine analysis; biochemical and clinical blood
Results and Discussion

Rectal examination showed an increase in the size of the prostate gland in the animals under study; upon evaluation of the results of a general urinalysis, minor inflammatory changes were noted in 10 animals. A cytological evaluation of seminal fluid showed the presence of tumour cells that are large, irregular in shape, and react well to haematoxylin-eosin technique (Fig. 3).

On radiographs, the prostate is visible either in the pelvic canal or in the caudal part of the abdominal cavity, somewhat more cranial to the pubic tubercle. With an enlarged prostate, the colon can be pushed up and squeezed, while the bladder can be pushed further into the abdominal cavity (Fig. 4). Abnormal calcification of the prostate gland is easily visualized radiologically and sometimes correlates with the tumour process. Infection can also cause these changes.8

Ultrasound of the abdominal cavity, performed to evaluate the texture and consistency of the prostate gland, including its size and shape (Fig. 5). A smooth capsule with a symmetrically enlarged gland is noted. Small cystic areas can be observed, which are usually well defined and have smooth edges.

The advantages of ultrasound are high information content, speed of obtaining results, non-invasiveness. In veterinary practice, an ultrasound frequency of 2 to 10 MHz is used. A certain echographic picture appears depending on the structure of the organ. Ultrasound of the prostate can be performed using abdominal and rectal sensors. Transabdominal ultrasound is a simple and quite informative method of research. The location of the prostate provides easy access for ultrasound
examination, allows to evaluate the shape, size, presence or absence of structural changes in the gland.9

Ultrasound is a common imaging technique used to examine the dog’s prostate gland, which has proven successful in diagnosing many clinical conditions. While B-mode ultrasound is useful for evaluating the prostate, there are apparently significant differences in the emergence of certain pathological conditions, although some experienced ultrasound doctors often have a high ability to make the correct diagnosis.10 Aspiration in the tissue of the prostate gland allowed to obtain small samples for histological analysis. Fine needle aspiration is useful upon collecting fluid from cysts or obtaining small samples of cells from prostate tissue. A biopsy provides the nucleus of the tissue for histopathology (microscopic examination of the tissue), and usually gives more accurate information on the pathology of the prostate gland, as more tissue can be evaluated.3

According to the studies, the following results were obtained. In 134 males, slight increases in size and a change in the structure of the prostate gland were detected. Proceeding from the studies, 67 dogs were diagnosed with benign prostatic hyperplasia (adenomas) and prostatitis was diagnosed in 28 dogs. 31 dogs had a suspicion of prostate adenocarcinoma, which was confirmed in 8 dogs subsequent to an additional histological examination.

Conclusions

Upon diagnosing benign prostatic hyperplasia (adenoma) in dogs, it is necessary to use a comprehensive approach involving several research methods for the differential diagnosis of this pathology: gathering medical history, palpation of the gland through the rectum, cytology of prostate secretion, x-ray, cytological and microbiological examination of prostate secretion, ultrasound, histological examination upon aspiration or percutaneous biopsy. General urinalysis, biochemical and clinical blood tests constitute non-informative research methods for diagnosis clarification with given prostate pathology in dogs.

Abstract

Background: Prenatal substance use is a public health problem deserving the highest priority of attention because it poses devastating risks of maternal and fetal consequences. Situational analysis of current substance use in pregnancy and its risk factors is essential for effective preventive strategies for maternal and child health. This study explored the prevalence of risky substance use (caffeine, alcohol, and tobacco) along with associated factors patterning among pregnant women in the middle zone of Northeastern Thailand.

Method: This cross-sectional study was conducted in 58 district hospitals located in the middle zone of northeastern Thailand. The participants were 944 pregnant women attending antenatal clinics chosen based on consecutive sampling. Data collection used a questionnaire, and data analysis used multiple logistic regression.

Result: More than two-thirds of the pregnant women (70.1%) reported current substance use, including caffeine (61.6%), alcohol (20.7%), and tobacco (3.3%). Risk factors such as family caffeine use (AOR=2.83, 95%CI: 2.02-3.97) and couple relationship (AOR=1.58, 95%CI: 1.07-2.33) were found to be associated with caffeine in use risk, while marital status (AOR=2.53, 95%CI: 1.11-5.77), couple relationship (AOR=2.27, 95%CI: 1.05-4.91), and family alcohol use (AOR=3.54, 95%CI: 1.49-8.42) were those associated with alcohol in use risk. It was notable that while family tobacco use (AOR=3.85, 95%CI: 1.05-14.06) was associated with tobacco in use risk, age was found to be its protective factor (AOR=0.31, 95%CI: 0.10-0.95) among those in the tobacco use risk group.

Conclusion: Currently there is strong evidence about the risky substance use during pregnancy. Modification solutions for suitable consumption behavior should targeted pregnant women with family substance use, poor couple relationships, single status and more than 20 years, old.

Key words: caffeine, alcohol, tobacco, risk factors, pregnancy, Thailand

Introduction

Substance abuse is a worldwide problem. In 2014, an estimated over 29 million people who use drugs suffer from drug use disorders. Moreover, 43.5 per million deaths are drug-related (¹). According to the UNODC’s World Drug Report, women are particularly affected by this kind of substance use (²,³); substance use in pregnant women has been widely recognized as a challenge to public health concerns in many countries. Women with substance abuse during pregnancy are at significant risk of adverse obstetric and perinatal outcomes with their children (⁴,⁵). Consumption of caffeine, a psychoactive substance during pregnancy is associated significantly with spontaneous abortion and fetal loss (⁶,⁷) .

A national survey conducted in the United States among pregnant women found that 8.5% drink alcohol and 15.9% smoke cigarettes (8). A similar pattern of this substance use has been seen in many countries (9-11). In Thailand, there is little available evidence on the extent of substance use among pregnant women. Recently, substance use (alcohol and tobacco) during pregnancy in Northern and Southern Thailand was reported (12-14).

However, there have been no studied of substance use in Northeastern Thailand in particular patterns of legal substance use in women during pregnancy. These substance uses are easy to assess, and there are no restrictions among pregnant women. Therefore, this study presents a cross-sectional survey of the patterns of substance use and the associated risk factors among pregnant women in the middle zone of Northeastern Thailand.

Materials and Method

This cross-sectional study was conducted during December 2016 to May 2017 in 58 antenatal care clinics of secondary care units in four provinces (Khon Kaen, Kalasin, Mahasarakham, Roi Et) in the middle zone of Northeastern Thailand. A consecutive sampling technique was used to select participants. The sample size was calculated using the formula for sampling for proportions. (15) The final sample size was 944 pregnant women.

The self administered questionnaire was composed of 2 parts, (1) Demographic and obstetric characteristics and (2) Current substance use behavior, developed from AUDIT (Alcohol Use Disorders Identification Test) Thai version (16). There are 10-items for each substance use, which covers the domains of caffeine consumption, drinking alcohol and smoking tobacco. Scores can range from 0 to 40, (score 0-7 indicates low risk, 8-15 indicates hazardous use, 16-19 indicates harmful use and 20 or more indicates dependence). The cut-off point for identifying a potential substance use problem is more than 8. The content validity index of this questionnaire was 0.93. Cronbach alpha co-efficient were 0.85.

The descriptive and analytical statistics were analyzed using IBM SPSS statistics soft-ware Version 26.0. Respondent characteristics were described by frequency and percentage. Factors independently associated with substance use in risk level were assessed by multiple logistic regression. The results were considered statistically significant when p < 0.05.

Results

Among the 944 pregnant women who volunteered for this survey, 25.5% were adolescents. The mean age was 24.9 years (SD = 6.71). Most (91.8%) of the pregnant women had completed a lower bachelor’s degree, and 66.5% were employed.

Current substance use was found in 624 pregnant women (70.1 %). The women with substance use were caffeine use 61.6%, alcohol use 20.7% and tobacco use 3.3%. Pregnant women at risk of substance abuse were 236 individuals (35.6 %): caffeine use risk 44.9 %, alcohol use risk 22.6%, and tobacco use risk 63.6%.

Risk factors significantly associated with caffeine risk use were family caffeine use (AOR=2.83, 95%CI: 2.02-3.97) and poor couple relationships (AOR=1.58, 95%CI: 1.07-2.33). Risk factors associated with alcohol risk use were being single (AOR=2.53, 95%CI: 1.11-5.77), having poor couple relationship (AOR=2.27, 95%CI: 1.05-4.91) and family alcohol use (AOR=3.54, 95%CI: 1.49-8.42). The risk factor associated with tobacco risk use was family tobacco use (AOR=3.85, 95%CI: 1.05-14.06), while age was a protective factor (AOR=0.31, 95%CI: 0.10-0.95).

Discussions

This is the first report on patterns of caffeine, alcohol and tobacco use by pregnant women, and substance risk use factors in Northeastern Thailand. Seventy percent of pregnant women reported current use of substance, with caffeine being the most commonly used, followed by alcohol and tobacco. These finding indicate high use of legal substances during pregnancy in these areas.

That three out of five pregnant women currently using caffeine was similar to previous studies by Vitti et al. (17), but less than Jarosz, Wierzejska and Siuba (18) who found 98.4% of pregnant women using caffeine. The percentage of pregnant women was higher than sixty percent in many countries because this substance use was thought to have little effect, although use can cause fetal loss. (19–20) Current alcohol use was one in five in pregnancy; this finding was higher than other studies (21,22) because Thai alcohol purchase rules and related...
regulations do not cover the pregnancy group.\(^{(23)}\) The pregnant smokers in this study were similar with report in Northern Thailand that pregnant women smoke \(^{(12,13)}\) but lower than USA\(^{(24)}\), Canada\(^{(25)}\) and India \(^{(11)}\).

There were many risk factors associated with substance use in risk level in pregnant women. The results with confounders adjustment showed that family member use of each substance (caffeine, alcohol and smoking) was associated with pregnant use risk. This risk factor correlates with the study by Hans et al. \(^{(26)}\) that showed that substance-abusing pregnant women often have family histories of factors of substance abuse.

Couples having poor relationships were associated with more chance of risk use in two substances (caffeine and alcohol). Moreover, pregnancy while being single was associated with increased alcohol use during pregnancy; this finding was similar to the study by Foitier, 1993\(^{(27)}\) that women without a partner had higher substance use. Higher social support was associated with risk of drinking during pregnancy. A higher score for social drinking motivation increased the likelihood of drinking during pregnancy.\(^{(28)}\)

Interestingly, pregnant women with age over/equal to twenty years were the protective factor of pregnant smokers, corresponding to the Drake et al study \(^{(29)}\), as smoking prevalence reduces along with the age of pregnant women, but different from Singh et al. study \(^{(11)}\) in which pregnant women aged above 25 used tobacco during pregnancy.

**Conclusion**

The high legal use of substances during pregnancy in these areas could potentially be harmful to maternal and fetal health. Modification solutions for suitable consumption behaviors should be targeted at pregnant women with family substance uses. Specific solutions should be targeted to strengthening good couple relationships for caffeine use risk individuals, and to couple relationships and marital status for those with alcohol use risk. All result should be used- to find substance use preventive strategies for maternal and child health.

Criminal Legal Protection Against Doctor Malpractice in Indonesia

Tongat
Associate Professor, Universitas Muhammadiyah Malang, Indonesia

Abstract
One of the Human Rights elements that must be achieved in accordance with the ideals of the Indonesian people is the Health aspect, the profession as a doctor devotes his/her knowledge to the public interests, has freedom and independence which is oriented to human values in accordance with the code of ethics. In implementing the code of medical ethics, it as much as possible avoids the occurrence of medical error. The error can occur in the diagnostic stage such as error or delay in diagnosis, not implementing the appropriate examination, using an examination method that is no longer used or does not act on the examination or observation result, etc. The risk that occur if it is not carried out thoroughly and carefully, is that it will result in a fatal error. The method used in this research is the normative juridism method, namely the addition method by holding on to the applied norms or legal rules. The result in this research is the liability’s manifestation of the doctor who performs medical malpractice as a form of criminal legal protection in Indonesia, it is basically based on intentional or unintentional mistakes or negligence. If it results in the victim’s death, it is equal to murder, and if the victim does not die it is called an act of persecution with the sanction of persecution.

Keywords: Criminal, Legal Protection, Malpractice, Doctor

Introduction
Health is element of Human Rights which must be realized in accordance with the ideals of the Indonesian people, the general welfare of national goals. To achieve the ability to live healthy for each people in order to realize an optimal degree of public health. The profession as a doctor devotes his/her knowledge to the public interests, it has freedom and independence which is oriented to human values in accordance with the code of ethics.(\textsuperscript{1}) This code of medical ethics aims to prioritize the interests and the safety of patient, to ensure that the medical profession must always be carried out with noble intention and use the right way.\textsuperscript{(2)}

In implementing the code of medical ethics, it avoids the occurrence of medical error as much as possible,\textsuperscript{(3)} namely a failure of a medical action that has been planned to be completed resulting in not as expected, an error of action or wrong planning to achieve a goal. The error that occured will result in an unexpected injury to patient, it can be in the form Adverse Event (KTD). This is very detrimental and dangerous; the patient can experience bad things and the action giver can also be exposed to Article of law violation.\textsuperscript{(4)}

Near Miss (NC) is an event resulting from carrying out an action or not taking the action that should be taken, which can injure the patient, but serious injury does not occur because of luck. This can be seen from the number of actions taken that are dangerous but can be prevented before they occur or are handled before they cause effects, for example, the patient receives a contra indication medicine but there is no drug reaction occurred, prevention of a medicine with an overdose will be given, but other staff know and cancel it before the medicine is given, and relief of a medicine with an overdose is given, it is known early and then given the antidote. Adverse Event (KTD) is an event resulting in an unexpected injury to the patient due to an action or not taking the action that should be taken, and not

Corresponding Author:
Tongat, Universitas Muhammadiyah Malang, Bendungan Sutami Street No.188, Malang City, Indonesia. Email: tongat_umm@yahoo.co.id
because of the patient’s condition.(5)

The error can occur in the diagnostic stage(6) such as error or delay in diagnosis, not implementing the appropriate examination, using an examination method that is no longer used or does not act on the examination or observation result.(7) In the treatment stage, such as error in treatment procedures, therapy treatment, drug use method, and delay in responding to the result of improper care checks; in the preventive stage, such as not providing provilactic therapy as well as inadequate monitor and follow-up; or in other technical matter such as communication failure, device or other systems failure.(8)

The risk occurred in human is so vulnerable to an action. If it is not carried out carefully and thoroughly, it will result in a fatal error. The existence of medical risks, both those that have been detected previously and those that were not detected before or unexpected at all before, in the implementation of health services is only an adequate information.

Even so, in carrying out their professional duties, health workers are normatively obliged to remain cautious, to comply with the medical standard, to carry out the professional standard of expertise, and to respect the patient rights. This is done in order to obtain legal protection for them.

In this normative definition of a worker, it raises the definition that health worker who carries out the professional duties has a special legal position, it means that in carrying out their professional duties, they are exposed to high medical risk. Based on these explanations, it needs a criminal legal protection against doctor malpractice in Indonesia.

**Research Method**

This research used library research which is a research method that is carried out by reading and studying theories relevant to the subject matter. The data collected was then processed using data processing method which consists of: Normative juridism method, namely the addition method by holding on to the applied norms or legal rules. This discussion method is used in accordance with its need to produce an acceptable discussion both in juridical and scientific terms.

**Discussion**

A jargon that reads *errare humanum est* (error is humane), seems need to be contemplated. A theory of respectable minority rule which states that a doctor is not considered negligent if he/she chooses one of the many ways of treatment that is recognized by the medical world. Basically, a doctor will be brought before a court if there has been a loss to the patient. The loss arises as a result of a breach of obligation in which an agreement had been previously made. Even though the doctor’s obligations are not detailed in the therapeutic contract, but the doctor’s obligations are not covered by the medical services standard. While the medical services standard is made based on the rights and obligations of the doctor, both those regulated in the Code of ethics and those regulated in statutory regulation.

Legal protection for the implementation of the doctor’s duty and authority who has medical risk in the Criminal Code is formulated in Article 359 and 360, the action that causes others to be seriously injured or die which was done inadvertently. As for the elements of Article 359 and 360, there are the negligence element (culpa), the existence of certain form of action, and there are serious injuries or death of others, and the existence of a causal relation between the form of action with the result of that other person death.

Elements of medical risk and medical malpractice are as follow, in the medical risk is found the negligence element, while in the medical malpractice it is clear that there is a negligence element. In addition, specifically in health services, negligence is also associated with services that do not meet or below the medical services standard which in its practice also needs to be used to distinguish between medical risk and medical malpractice. If upon the patient, it has been performed procedures according to the medical services standard, but the patient ends up seriously injured or dead, this is a medical risk. Whereas for patient who has suffered serious injury or death as a result of doctor performing services below medical standard, this means that there is a medical malpractice.

In order to avoid misunderstanding about the emergence of risks that are detrimental to the patient, it is necessary to have clear and complete information by the doctor in a language that easily understood by the patient and by remembering where the communication is carried out. This is where the importance of a health interview is, so that in the end the patient is willing to give consent for the medical action to be taken by the doctor in the effort to cure his illness in a therapeutic
transaction.

It means that the negligence element is very instrumental in determining whether a doctor is convicted or not and negligence in the medical field is very closely related to the implementation of doctor professional standards. Not only the negligence element in medical risk, it also means that both Article 359 and 360 of the Criminal Code cannot be applied to the doctor’s action that has medical risk, because one of the elements of Criminal Code Article 359 or 360 is not fulfilled in medical risk.

In the case of medical accident, there is a judge’s decision to adjudicate a case that in Indonesia it indeed requires that a doctor must act carefully on every action taken. But we cannot just regard it as a negligence act for something that is actually an accident. Regarding the mistake of clinical examination, it is actually also understandable because after all, as a human being a doctor cannot escape from the possibility of making a mistake.

In addition, the doctor’s action toward patient also has justification reason as mentioned in Criminal Code Article 50 and Article 51 paragraph 1. Meanwhile, for the conviction of an error that can be interpreted as liability in criminal law, it must meet 3 elements, namely: the ability to be responsible for the action, the inner connection between the actor and the action that can be intentional (dolus) or negligence (culpa), and there is no forgiving or erasing reason.

Thus, to make sure that a medical action is not against the law, the action must be performed in accordance with the medical profession standard or carried out legeartically, as reflected by: The existence of medical indication in accordance with the concrete treatment goal, performed according to the standardized medical procedures standard, fulfilled the patient’s rights regarding informed consent.

We need to realize that doctor’s medical actions sometimes indeed produce undesirable consequences both by the doctor and the patient, even though doctor has tried their best. Because almost all medical actions are essentially persecution justified by the Constitution, especially those related to acts of anesthesia and surgery. So that the possibility of the risk of injury or even death is very difficult to avoid. Based on the analysis, the criminal law adheres to the principle of “no criminal without error”. Furthermore, in Article 2 of the Criminal Code mentioned, “criminal provisions in Indonesian statutory regulation are applied to everyone who commits an offense in Indonesia”.

The formulation of this article determines that every individual who is in the Indonesian legal territory, can be held liable for criminal liability upon the mistakes he/she made. Based on that provision, the doctor profession is inseparable from the provision of the article. Moreover, a doctor in his daily work is always involved in the acts regulated in the Criminal Code. Even though the criminal law recognizes the abolition of criminal act in the health service, namely justification and forgiving reasons as well as those contained in the jurisprudence, it does not necessarily mean the justification and forgiving reasons abolish a criminal offense for the doctor profession.

One of the jurisprudences that contains justification reason and forgiving reason in health services is the jurisprudence. This jurisprudence contains “informed consent” as a criminal offense omission. However, this does not mean that the doctor profession is freed from all criminal liability, because the justification reason and forgiving reason for the doctor’s action is only in a certain exception.

Legal protection toward doctor’s legal liability can be distinguished between liability that is not related to the implementation of his/her profession and legal liability related to his/her profession. The implementation of the doctor profession in Indonesia can still be distinguished between responsibility for professional provisions, namely the Indonesian Code of Medical Ethics (KODEKI) contained in the Decree of the Minister of Health No. 434/Men.Kes/SK/X/1983 and responsibility for legal provisions covering the administrative law, the criminal law and the civil law. Action or behavior of doctor as legal subject in their performance in society can be distinguished between daily actions that are not related to his/her profession.

There are special factors in Medicine that are not found in general applicable law, for example medical accident or risk of treatment. Some basis for the omission of penalties or special error in medicine, namely: Risk of treatment, Medical accident, Non-negligent error of judgment, *Volenti non fit iniura* and Contributory negligence.

Criminal law in Indonesia in the implementation of certain medical act, there is always a risk inherent in the medical act (inherent risk of treatment). If the doctor
performs the medical treatment carefully, with the patient’s permission and based on the Medical Service Standard (SPM), but it turns out that the risk persists, for example if there is an unexpected allergic reaction, as well as complications that cannot be predicted beforehand (for example, there occurs amniotic water embolism during labor), then the doctor cannot be blamed.

Article 44 of Constitution on Medical Practice as an official explanation is determined as follows, “service standard” is a guideline that must be followed by doctor or dentist in carrying out medical practice. “Service facility level” is the level of service in which the standard of personnel and equipment are in accordance with the capabilities provided. Attitude and action that must be carried out by doctor are regulated in various standards. The profession has at least 3 kinds of standards, namely: Competency standard, Behavior standard, and Service standard.

Constitution No.36 of 2009 concerning Health has formulated the criminal threat, hence the criminal threat against the error or the negligence committed by doctor resulting in patient suffering from disabilities or injuries, no longer refers solely to the provision of Article 359, 360, and 361 of the Criminal Code. The threat is contained in Article 198 of Constitution No. 36 of 2009 concerning Health. The arrangement of doctor’s legal liability towards patient in the event of malpractice, the Indonesian health law does not officially mention the term Malpractice, but only mention error or negligence in carrying out the profession (listed in Articles 54 and 55).

Thus, the malpractice term is a legal term used in Articles 54 and 55 mentioned above. Error or negligence in carrying out the profession is listed in articles 54 and 55 of Constitution No.36 of 2009 concerning Health. Article 54 and 55 stated that the sanction on medical malpractice is the imposition of disciplinary action determined by the Medical Disciplinary Council to doctor who based on the judgment of the Council have committed negligence. Whereas the compensation that must be fulfilled by the doctor concerned is carried out in accordance with the applicable statutory regulations.

Criminal offenses are listed in Article 80, Article 81 and Article 82, while criminal violation is listed in Article 84. If in the relation between a doctor and a patient in a therapeutic transaction based on the agreement of both parties, there is an inadvertent or uncareful action by the doctor, so as to cause disability or death of the patient, then the consequences are regulated in criminal law.

Indonesian law gives full rights to its people to obtain justice and to obtain it, it is done by submitting application, complaint, and lawsuit. Both in civil, criminal or administrative cases. Therefore, as a legal protection for Indonesian people, they will be tried through a free and impartial judicial process, which referred to legal procedures that guarantee an objective examination by honest and fair judge. The sanction in criminal law is basically sanction in the form of torture or restriction of freedom against the perpetrator of criminal act. With the hope that after undergoing the criminal sanction, it will cause a deterrent effect on the perpetrator or there is a preventive element against others (the society).

Conclusion

Criminal legal protection against doctor malpractice in Indonesia in the Criminal Code can not be applied to the doctor’s action who has medical risk. This is because at the medical risk, there is one element that cannot be fulfilled, namely the negligence element. However, if the negligence element from a doctor’s action can be proven, then according to the Criminal Code, the doctor can be imposed on committing act that cause serious injury or loss of patient’s life. Besides that, based on the basis of doctor’s mistake omission, namely the justification reason (treatment risk) and forgiving reason (accident occurs in difficult operation). The liability’s manifestation of the doctor who performs medical malpractice is basically based on intentional or unintentional mistake or negligence. For intentional mistake, if it results in the victim’s death, it is equal with murder, and if the victim does not die it is called an act of persecution with the sanction of persecution.

Relationship of Family Support with Vegetable and Fruit Consumption Behavior

Untung Halajur
Department of Nursing, Polytechnic of Health, Ministry of Health, Palangka Raya Indonesia

Abstract

The family approach is the development of a home visit by the public health center effort. One of the activities is community management support system in supporting a culture of healthy living in the family. Family support is needed to behave in the consumption of vegetables and fruit every day. Clean and healthy living behavior in the household or family structure is one of the goals in clean and healthy behavior. There are 10 indicators of clean and healthy behavior in family settings, one of them is the consumption of vegetables and fruit every day. This study aims to analyze the relationship between family support and the consumption of vegetables and fruits in children. The research design used in this study is research cross sectional. The research sample is Golden Christian School elementary school students. The time of the study was in May and June 2018. The results showed that there was no significant relationship between emotional and assessment support for vegetable and fruit consumption behavior in children. There is a significant relationship between instrumental support and information support with vegetable and fruit consumption behaviors in children, respectively p-value 0.015 and 0.041. It is recommended that the school provide knowledge to parents whose children are vulnerable not to consume vegetables and fruits in order to support the healthy Indonesia program with a family approach.

Keywords: family support, behavior, consumption, vegetables, fruit

Introduction

Health development is an effort carried out by all components of the Indonesian nation to increase awareness, willingness, and ability to live a healthy life for everyone in order to realize the conditions of Indonesian people who have optimal health degrees. The healthy Indonesia program is the main health development program which was later planned to be achieved through the Ministry of Health Strategic Plan for 2015-2019.

The Ministry of Health’s strategic plan 2015-2019 confirms the healthy Indonesia program through the family approach (PIS-PK) in support of the healthy living community movement (GERMAS). The family approach is one of the ways the public health center can increase the reach of targets and increase community access to health services by visiting families.

Healthy Indonesia program through the family approach is implemented by public health center with the following characteristics such as the main target is the family, prioritizing promotive-preventive efforts, accompanied by strengthening community-based health efforts, active home visits by public health center to increase outreach and total coverage, and life cycle approach.

The family approach is one way for the public health center to increase the reach of targets and improve access to health services in the working area by visiting families. The public health center does not only provide health services inside the building but also exits the building by visiting family in the working area. The family as a focus on the approach of implementing the health Indonesia program because there are five family functions, one of which is the health care function (The

Health Care Function). The function of health care is to maintain the health condition of family members so that they continue to have high productivity. This function is developed into a family task in the health sector, while family tasks in health care are recognize the health development disorder of each family member, make decisions for appropriate health measures, provide care to sick family members, maintaining a favorable home atmosphere for the health and personality development of family members, maintaining mutual relations between families and health facilities.

The family approach is the development of home visits by the public health center and an expansion of the community health care effort, which includes several activities, one of which is the utilization of data and information from the family health profile for community empowerment and public health center management, because the family is one support system in supporting the culture of healthy living in the family. So that family support is needed to behave in the consumption of vegetables and fruit every day. Clean and healthy life behaviour in the household or family structure is one of the targets of the order in clean and healthy life behaviour. There are ten indicators of clean and healthy life behaviour in family settings, one of which is the consumption of vegetables and fruit every day.

**Materials and Method**

This research uses quantitative methods with a cross-sectional design. The study was conducted at the Golden Christian School of Palangka Raya in May-June 2018. The sample used was 42 children from grades V and VI. Family support is defined by emotional support, assessment support, instrumental support, and information support. Vegetable and fruit consumption behavior are expressed by ever consuming fruit vegetables ≥ 1 time per week and never consuming vegetables and fruits. Analysis of the data used is the statistical test chi-square because the data is categorical with 2 levels.

Adolescent or adolescence is a critical period of transition from child to adult. Genetic, nutritional and other environmental factors are considered to play a role in puberty. Physical changes that occur in this period of puberty are also followed by emotional and physical anxiety. Psychosocially, adolescent growth is divided into 3 stages: early, middle, and late adolescent. Each stage has its own characteristics. Everything that interferes with the process of physical and hormonal maturation in adolescence can affect psychological and emotional development so that a good understanding of the process of change that occurs during adolescence from all aspects. Adolescence is the beginning of someone in adopting dietary behavior that tends to be settled in the future. Current adolescent diets tend to consume less vegetables and fruit. Consumption of vegetables and fruit in adolescents can be influenced by various things. As many as 61.1% of adolescent boys ever consumed vegetables and fruit more than equal to 1 times a week and 54.2% of adolescent girls had consumed more than 1 times a week of vegetables and fruit. Teenage boys in this study had a higher percentage of consuming vegetables and fruit than teenage girls as was the case with Anggraeni and Suadiarti’s research in 2018 showing that male teenagers preferred to consume vegetables and fruits.

The results showed no relationship between sex with vegetable and fruit consumption behavior. There is no relationship of gender with vegetable and fruit consumption behavior \( p\)-value 0.941. There is no significant relationship between sex and vegetable and fruit consumption \( p\)-value 0.435. Adolescent girls have poorer dietary habits than male.

Favorite food or termed food preference is whether or not someone likes a food that is influenced by various factors. Food preferences are considered as a determining factor in consuming foods including vegetables and fruit. The love of fruit and vegetables has a direct relationship to the consumption of vegetables and fruit in adolescents, similar things expressed by other studies that state the taste and liking for a food is closely related to a person’s consumption behavior, including vegetables and fruits. The results of statistical analysis showed no relationship between food preferences or favorite foods with vegetable and fruit consumption behavior. Most of the respondents chose other food preferences such as cooked chicken, steak, noodles, fried rice, potatoes. There was no significant relationship between food preferences on vegetable and fruit consumption behavior.

</table>
The family is the smallest social unit in society and can have a major influence on the social changes and the child’s closest environment. The role of the family environment is one of the pillars of the dam shape the good and bad of the human person so that it develops well. One of the roles of the family is in fulfilling children’s nutrition. Good parental knowledge will be very helpful in directing children to consume vegetables and fruits. The role of fathers and mothers is very important for the growth and development of children and the formation of children’s character including in consuming food.

Information support from the family in this case is expressed by supporting information in the form of the content and benefits of vitamins in vegetables and fruit. The role of the family as an information provider is a form of implementation for children to consume vegetables and fruit. Families who introduce various types of vegetables and fruits and always provide information related to the importance of consumption of vegetables and fruit can stimulate children to increase consumption of vegetables and fruit to the recommended.

The results showed that there was a significant relationship between information support and vegetable and fruit consumption behavior. The same thing was shown by the results of the Afif and Sumarmi research in 2017 that there was a significant relationship between the role of the mother as an educator and initiator of the consumption of vegetables and fruits (p-value=0.003). 

Appraisal support can be used as subjective norm, subjective norms are individual perceptions about whether others will support or not the realization of actions or behavior. Subjective norms can also be interpreted as a result of one’s beliefs about what other people or groups think, combined with their motivation to adjust. An individual will intend to display a certain behavior if he perceives that other important people think that he should do it. Suppose someone believes that a person is considered important as a parent wants that person to consume fruits and vegetables or vice versa. Then in addition to trust, this person must have the motivation to follow what the person desires that was considered important earlier, to consume fruit and vegetables. Parents have a role in providing social support to children. as a form of support for children to carry out healthy behaviors, the role of parents includes providing rules, discipline, gifts and support that influence the interaction between parents and children.

This study shows that there is no significant relationship between assessment support and vegetable and fruit consumption behavior. There is no significant relationship between subjective norms in the form of assessment support with vegetable and fruit consumption behavior.

One of the roles of the family in instilling behavior of eating vegetables and fruit is to take advantage of the yard by growing vegetables and fruit and provide vegetables and fruit every day at home, does not have to be expensive, easy to find and affordable prices. The results showed there was a relationship between instrumental support and consumption of vegetables and fruit. Family instrumental support is expressed by providing different vegetables and fruits every day.

In the study of the availability of vegetables and fruit at school is positively related to the consumption of vegetables and fruit in adolescents. Even though food preferences are low, if the availability of fruits and vegetables is good enough, consumption will increase. The types of food that are available have more opportunities to be consumed, while the types of food that are not available will not be consumed by people. So efforts to provide more vegetables and fruit can increase consumption of these foods.

Parents play a role in providing emotional support so that the process of approaching healthy habits, such as healthy eating behavior will be created properly. This support is perceived by the child as an effort to form behaviors that are appropriate to the child and the environment. Parental support has a positive correlation with eating behavior, nutritional status and psychological development of children. the attitude of parents gives an indirect effect on children in having preferred foods, as well as children’s eating habits. For example, children will choose different types of food when being watched by parents.

The results of this study indicate there is no relationship between emotional support and vegetable and fruit consumption behavior.

**Conclusion**

The results of this study showed 42.9% of adolescents did not consume vegetables and fruits. The love of fruit and vegetables has a direct relationship to the consumption of vegetables and fruit in adolescents, similar things expressed by other studies that state the
taste and liking for a food is closely related to a person’s consumption behavior, including vegetables and fruits. The results of statistical analysis showed no relationship between food preferences or favorite foods with vegetable and fruit consumption behavior. Most of the respondents chose other food preferences such as cooked chicken, steak, noodles, fried rice, potatoes. The results showed that there was a significant relationship between information support and vegetable and fruit consumption behavior. The results showed there was a relationship between instrumental support and consumption of vegetables and fruit. Family instrumental support is expressed by providing different vegetables and fruits every day.

The Relationship Between Qor-40 Questionary Value And Pupillary Pain Index As Assessment Of Recovery Quality On Post-Operating Patients Treated By Multimodal Analgesia (Parasetamol + NSAID + PCA OPIOID)

Wayan Dhea Agastya¹, Arie Utariani², Dedi Susila²
¹RSUD Dr. Soetomo Surabaya, Department of Anesthesiology and Intensive Therapy, Faculty of Medicine, Airlangga University Surabaya, Indonesia, ²Department of Anesthesiology and Intensive Therapy, Faculty of Medicine, Airlangga University Surabaya, Indonesia.

Abstract
This study analyzes the correlation between QoR-40 questionnaire value and the Pupillary Pain Index as an assessment for the quality of recovery of postoperative patients receiving multimodal analgesia (Paracetamol + NSAID + PCA Opioid) in Dr. Soetomo Hospital. An observational analytic study with cross-sectional design was conducted on patients aged 18-60 years who underwent elective surgery with general anesthesia at Dr. Soetomo Hospital Surabaya and receiving multimodal analgesia therapy, which includes intravenous paracetamol 4 x 500 mg, intravenous ketorolac 3 x 10 mg, and intravenous fentanyl via PCA. Recovery quality checks were performed at 12 and 24 hours postoperatively. Retrieval of data in the form of a QoR-40 questionnaire and pupillary pain index examination using algiscan® pupillometry. Both parameters will be analyzed by correlation test. The total need for fentanyl and PCA demand dose was also evaluated for use within 24 hours postoperatively. From 46 samples, obtained characteristics of study are widely distributed in terms of age, sex, anthropometry, and preoperative physical status. The average total fentanyl PCA requirement is relatively small at 0.28 mcg / kg / hour. The correlation formed between QoR-40 and pupillary pain index is significant. It can be concluded that Pupillary Pain Index can replace the QoR-40 questionnaire as an alternative assessment of the quality of recovery of patients after surgery.

Keywords: QoR-40 Questionnaire, Pupillary Pain Index, Quality of Postoperative Recovery.

Introduction
Uncontrolled postoperative pain can have various consequences including increased morbidity, delayed recovery, and a high incidence of chronic pain. Postoperative pain affects the quality and duration of the patient’s postoperative recovery period and will affect his quality of life. The postoperative recovery that has been developed and specifically designed for multimodal perioperative care pathways that will be aimed at obtaining rapid healing after major surgery with preoperative support of organ function and exacerbating the stress response caused by surgical trauma¹.

In the United States, more than 80% of patients undergoing surgery experience acute postoperative pain and approximately 75% report moderate, severe or extreme pain ². Based on the Ministry of Health survey data, more than 80% of surgical patients reported experiencing moderate pain and 31-37% of patients experiencing severe to very severe pain³. Inadequate pain control has a negative impact on quality of life, risk after surgery, and risk of postoperative persistence².

Multimodal analgesia is the use of more than one type of analgesia drug and technique which targets different mechanisms of action in the central and / or peripheral nervous system (which can be combined with non-pharmacological interventions) that allow for synergy or addiction effects and are more effective in relieving pain than with a single capital intervention².

The selection of tools to check pain and the quality of recovery also needs to be considered in the form of
pain scores such as the Numeric rating system (NRS) and Visual analogue Scale (VAS) or questionnaire. The recovery quality questionnaire (QoR-40) is a tool used to assess the quality of recovery after surgery through questions relating to 40 items related to 5 domains. However, QoR-40 has limitations, which requires a long time and good understanding from sufferers to be able to obtain the quality of postoperative pain.

Objective parameters of pain and quality of recovery can be evaluated using biomarkers and tools. Studies on pain biomarkers do not have very significant results and are considered not cost-effective. Recent research reveals, evaluation of pain and quality of recovery can use tools that utilize a variety of body responses due to pain or discomfort, one of which is Pupillary Pain Index (PPI) which can be assessed by interpreting the response of dilated pupils to the presence of pain or discomfort. PPI is considered more practical, non-invasive, does not require a long time and is inexpensive in evaluating the objective parameters of pain and its relation to the quality of postoperative recovery. Studies that have evaluated the quality of postoperative recovery with subjective and objective parameters in the provision of multimodal analgesia have never been done, this study tried to analyze the relationship of recovery quality as measured by a QoR-40 questionnaire and PPI using the pupillometry.

Materials and Method

This type of research is an observational analytic research using Diagnostic Test intended to find the relationship between QoR-40 questionnaire and PPI using the pupillometry so that it can determine that PPI can replace the QoR-40 questionnaire as an evaluation of quality recovery postoperatively. This research was carried out at the recovery room at the Dr. Soetomo Hospital Surabaya in September-October 2019. The study samples were aged 18-60 years who underwent elective surgery with general anesthesia. With the inclusion criteria are patients with physical status ASA (American Society Anesthesiologist) 1-2, can communicate well, not deaf, not mute, not mentally retarded and not senile. The sampling technique in this study was conducted with judgment sampling. Patients who entered the inclusion criteria will be examined preoperatively 1 day before surgery, including history, physical examination, laboratory and radiological examination. Patients will receive multimodal analgesia therapy, which includes intravenous paracetamol 4 x 500 mg, intravenous ketorolac 3 x 10 mg, and intravenous fentanyl via PCA (Patients-Controlled Analgesia). Recovery quality checks were performed at 12 and 24 hours postoperatively. Retrieval of data is in the form of a QoR-40 questionnaire and pupillary pain index examination using pupillometry. Parameters will be analyzed by correlation test. The total need for fentanyl and PCA demand dose was also evaluated for use within 24 hours postoperatively. Data analysis is divided into 2 parts, descriptive statistical analysis, and correlation analysis of two variables.

Results

There were 46 patients was taken in the Recovery Room of Dr. Soetomo Hospital Surabaya during September to October 2019. Following are the characteristics of the research subjects:

Evaluation of the patient’s initial pain scale using WBFS (Wong Baker Faces Scale) prior to anesthesia and surgery. From the data table below, there were no patients with moderate or severe pain scale at the beginning of the preoperative examination.

In this study, the use of modalities used for postoperative pain relief therapy is multimodal analgesia with PCA fentanyl. Provision of the amount of fentanyl need for pain relief through PCA was measured for each patient in this study. There are 2 parameters of PCA fentanyl requirements that are evaluated, namely total fentanyl and total demand dose within 24 hours of administration.

The quality of recovery of postoperative patients evaluated in this study includes 2 things, namely from the subjective parameters of the patient using the self-reporting method using the QoR-40 questionnaire and also from the objective parameters using the pupillary pain index which is examined by digital pupillometry. Quality recovery checks were performed in 2 times, namely at 12 hours postoperatively and 24 hours post surgery. This study uses a cut-off point 142 as a clinical interpretation of good and poor quality of recovery, following previous study. While in the PPI assessment, the range of values is between 1 and 10, where the smaller the value, the better the quality of recovery well.

Examination of the quality of recovery of patients after surgery when compared between the 12th hours to the 24th hour on both parameters. It showed a significant difference with p <0.01.

Correlations analysis between the quality of recovery of postoperative patients based on QoR-40 and PPI is drawn according to the graphs in Figure 1 and Figure 2.

![Figure 1](image1.png)
Discussion

This broad distribution of types of surgery shows that the results of the correlation analysis between QoR-40 and PPI, apply in all types of operations. It showed that the number of fentanyl PCA requirements can be seen according to table 4. In this study, Fentanyl can be used as a single modality for postoperative analgesia with a continuous dose ranging from 0.5 to 0.75 mcg / kg / hour. The dose of fentanyl continuous infusion as a mild-moderate postoperative opioid analgesia is 0.4-0.6 mcg / kg / hour. This shows the number of fentanyl needs of patients is low.

The concept of multimodal analgesia can be given at a smaller dose than a single administration of the drug. In this study the provision of multimodal analgesia was clinically effective, because with the combination of paracetamol and ketorolac the amount of PCA fentanyl requirement was relatively small at 0.28 mcg / kg / hour. According to the study, the administration of therapeutic regimens through PCA can be tailored to individual needs for improving the quality of healing and care.

According to a study, the quality of patient recovery at 12 hours postoperatively is unsatisfying because it has a mean value QoR-40 is below the cut-off point. Further, from 46 samples, 28 patients (60.8%) had a QoR-40 questionnaire value of less than 142. Only 39.2% of patients who had a QoR-40 score of 142 and above, or clinically had good recovery quality at 12 o’clock after surgery. But in evaluating the quality of recovery at 24 hours postoperatively, the Qor-40 questionnaire value of the sample patients in this study had a statistically significant improvement compared to 12 hours (p < 0.01). The mean QoR-40 at 24 hours was 161.06 ± 24.56, exceeding the cut-off point of 142. Most, 37 patients (80.4%), had good recovery quality (QoR-40 more than 142) 24 hours postoperatively. Only 9 or 19.6% of patients had poor recovery quality (QoR-40 value < 142) at 24 hours.

Several things can cause the lack of quality postoperative recovery at 12 hours based on the QoR-40 questionnaire. The quality of recovery in QoR-40 is assessed based on 5 dimensions: patient support, patient comfort, patient emotions, physical independence, and pain. The provision of multimodal analgesia dealing with pain and comfort for patients, but support, emotional, and independence factors are more subjective and cannot be controlled with multimodal analgesia in the acute phase, less than 1 day after surgery. Maybe, the patient does not feel pain, but emotionally does and his physical independence is still lacking. This causes the quality of recovery at 12 hours is unsatisfying.

In evaluating the quality of recovery using objective parameters (PPI), the value at 12 hours postoperatively varies from 1 to 10. While at 24 hours, the value of PPI variations 1 to 6. In contrast to QoR-40, quality assessment recovery using PPI has the opposite interpretation. In PPI, the higher the value the clinical patient feels very painful or uncomfortable, while the smaller the value, the better the quality of recovery. There is no cut-off point for PPI values that can be used as a clinical interpretation in the classification quality of recovery.

When compared between the 12th hour PPI value and the 24th hour, there was a statistically significant difference (p < 0.01). At the 12th hour postoperatively the PPI mean value was 4.39 ± 1.94, while at the 24th hour there was a decrease in the PPI mean value of 2.82 ± 1.33. In the sample data of this study, there were 36 patients (78.2%) who experienced a decrease in PPI values from 12 to 24 hours. There were 7 patients (15.2%) who had the same PPI values at 12 and 24 hours, and only 3 patients (6.6%) experienced an increase in PPI values from 12 to 24 hours.

Based on the analysis of the relationship between QoR-40 and PPI, it can be concluded clinically that PPI
evaluation can be used as a substitute for QoR-40 in assessing the quality of recovery of patients after surgery. This is in accordance with a study conducted by Rollins et al., that the characteristics of pupils and pupillary dilation reflex (PDR) can be used as an objective response to discomfort or pain in postoperative patients. Comfort and pain are also factors that influence the quality of patient recovery directly, this causes PPI to have a significant relationship and can be used to replace QoR-40 as an assessment of the quality of recovery of patients after surgery.

Clinically, the use of PPI when compared to the QoR-40 questionnaire is more practical and effective. PPI examination with pupillometry is an objective measurement of pain, the same as pain biomarkers such as cortisol, IL-6, TNF-alpha and others. But studies of pain biomarkers do not have very significant results and are considered not effective. On the other hand, evaluation of pain and quality of recovery can use tools that utilize a variety of body responses due to pain or discomfort, one of which is PPI which can be assessed by interpreting the response of dilated pupils to the presence of pain or discomfort. PPI is considered more practical, non-invasive, fast and inexpensive in evaluating the objective parameters of pain and its relation to the quality of postoperative recovery.

Conclusion

The QoR-40 questionnaire has a significant correlation with the Pupillary Pain Index as an assessment of the quality of recovery in postoperative patients (p <0.01). Pupillary Pain Index can replace QoR-40 as an alternative assessment of the quality of recovery of patients after surgery.

Coal Dust Exposure and Gingivial Lead Line in Coal Miners

Widodo1, Sahdhina Rismawati1, Eko Suhartono2, R. Darmawan Setijanto3

1Department of Dental Public Health, Faculty of Dentistry, Universitas Lambung Mangkurat, Banjarmasin, Kalimantan Selatan, Indonesia, 2Department of Medical Chemistry/ Biochemistry, Faculty of Medicine, Universitas Lambung Mangkurat, Banjarbaru, Kalimantan Selatan, Indonesia, 3Department of Dental Public Health, Faculty of Dental Medicine, Universitas Airlangga, Surabaya, Indonesia

Abstract
Coal dust contains less than 1% lead (Pb). This dust can enter the body through breathing, mouth and skin. Lead contained in coal dust can react with Sulfur and form gingivial leadline. The study was an observational study with cross-sectional design. The research subjects were coal miners in Sambung Makmur Sub-District, Banjar District, amounting to 100 people. The number of samples was calculated by the Slovin formula and obtained 80 people as samples and determined by simple random sampling technique. The sample obtained then determined the value of the gingivial lead line score as done by Sudibyo. The degree of gingivial lead line is assessed based on the score as follows: 0 = no gingivial lead line; 1 = gingivial lead line found in 1-2 marginal gingival anterior teeth labial surface; 2 = gingivial lead line found at 3-4 marginal gingival anterior teeth labial surface; 3 = gingivial lead line at>4 marginal gingival anterior teeth labial surface. In addition, age, working period (tenure), and smoking habits are the variables measured in this study. The data obtained were analyzed using the chi-square test with a = 5%. The conclusion is the incidence of gingivial leadline of coal miners was related to age, tenure, and smoking habits.

Keywords: gingivial leadline, lead, coal dust, coal miners

Introduction
Kalimantan Selatan is one of the provinces in Indonesia which has the largest coal mining with locations spread throughout the region. One of the problems arising from mining is the issue of coal dust which can have an impact on health. This is due to the metal content found in coal dust, namely Fe 36.9%; Si 17.9%; Mo 15%; Al 10%; Ca 8.67%; S 4.7%; Ti 3.65%. Some heavy metal content of less than 1% includes K, V, Cr, Mn, Ni, Cu, and Pb.1

Coal dust containing metals can enter the body through breathing, mouth and skin. Furthermore, metals contained in coal dust, especially Lead and Sulfur will accumulate in gum tissue through systemic and local processes, namely direct absorption by the oral mucosa. Lead and Sulfur produce lead sulfate which is deposited in the basement membrane of gum.2 These deposits provide a picture of the lead line in the gums. Various factors that are thought to influence the occurrence of gingival lead line, such as working period, age, use of personal protective equipment (PPE), smoking habits, etc.3

The working period (tenure) affects the incidence of gingivial lead line, because the working period shows the length of time someone is exposed to coal dust. The longer the exposure time, the incidence of gingival lead line will be more severe. Likewise, increasing age causes the detoxification rate to slow down, resulting in a buildup of lead from coal dust. This incident gingivial lead line will be more severe.4

Corresponding Author:
Widodo,
Department of Dental Public Health, Faculty of Dentistry, Universitas Lambung Mangkurat, Jl. Veteran No. 128B Banjarmasin - Indonesia, email: dodowident@gmail.com
Previous research has revealed that the working period has a relationship with the incidence of gingivial lead line in traffic police.\(^4\) Other studies have also revealed that the workshop workers have a risk of gingivial lead line because every day they are exposed to fumes that contain lead.\(^5\) Coal miners are a group at risk of developing gingivial lead lines. This is due to his daily exposure to coal dust containing lead and sulfur. However, not many studies have revealed this. Therefore in this study we will examine the relationship of working period, age, and smoking habits to the incidence of gingivial lead line of coal miners.

**Materials and Method**

The study was an observational study with cross-sectional design. The research subjects were coal miners in Sambung Makmur Sub-District, Banjar District, amounting to 100 people. The number of samples was calculated by the Slovin formula and obtained 80 people as samples and determined by simple random sampling technique.

The sample obtained is then determined by the value of the gingivial lead line score as done by Sudibyo.\(^6\) The degree of gingivial lead line is assessed based on the score as follows:

- 0 = no gingivial lead line
- 1 = gingivial lead line found in 1-2 marginal gingival anterior teeth labial surface
- 2 = gingivial lead line found in 3-4 marginal gingival anterior teeth labial surface
- 3 = gingivial lead line at>4 marginal gingival anterior teeth labial surface

In addition, age, working period, and smoking habits are the variables measured in this study. The data obtained were analyzed using the chi-square test with \(a = 5\%\).

**Findings and Discussion**

This study involve 80 male who were willing to be sample in the study. The lowest age is 19 years and the highest is 45 years. The existence of gingivial lead line can be seen in Figure 1.

![Figure 1. Normal gum looks reddish (a) and gingivial lead line (b)](image)

Gingivial leadline, also called Burtons’s Line, is a pigment in the form of gray-blue lines at the border between teeth and gums.\(^7\) Leadline occurs due to a reaction between lead and sulfur ions released by the bacterial oral cavity, leading to lead sulfid at the tooth and gingivial surface.\(^8\)

**Relationship between age and gingival lead line**

The relationship between age and the gingival lead line is presented in table 1. Gingivial lead line is found in>4 marginal gingival anterior teeth labial surfaces. It is found more at the age of 30-45 years.
Table 1. Relationship of Age with Gingival Lead Line

<table>
<thead>
<tr>
<th>Age (years)</th>
<th>Gingival Lead Line Score</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>0</td>
</tr>
<tr>
<td>15-30</td>
<td>15%</td>
</tr>
<tr>
<td>30-45</td>
<td>7.5%</td>
</tr>
</tbody>
</table>

Based on the results of the chi-square test obtained $p = 0.005$ ($p < 0.05$), it was concluded that age was associated with the incidence of gingival lead lines in coal miners. The relationship between age and gingival lead line caused by in the young age more sensitive to lead activity. It is closely related to organ development and function are not perfect. In the old age the sensitivity is higher, this is caused by the activity of the biotransformase enzyme decreases with increasing age and the resistance of certain organs decreases to the effectsof coal dust containing lead. The older the person, the higher the amount of lead accumulated in the body tissues.

On the other hand, the activity metaloprotein (metal-binding protein) in the oral cavity will slowly decrease the activity. This causes lead contained in coal dust can not be transported optimally by metalloproteins. As a result, lead reacts with sulfur in the oral cavity and leadline is formed. The results of this study are in accordance with the study by Vera$^9$, which states that the age of street vendors in the city of Semarang affects the incidence of gingival leadline.

<table>
<thead>

<td>1.25%</td>
</tr>
</tbody>
</table>

Based on the results of the chi-square test obtained $p = 0.000$ ($p < 0.05$), it was concluded that the working period of coal miners was related to the incidence of gingival lead line. The working period shows the length of exposure to coal dust containing lead. Lead as the cause of many lead lines accumulates in gum tissue through systemic processes or local processes, namely direct absorption by the oral mucosa. This lead will only form a lead line after reacting with sulfur ions produced by anaerobic bacteria in the oral cavity.$^{10}$ The results of
the reaction are lead sulfate compounds which are then deposited on the gum basement membrane. These deposits provide a picture of the lead line in the gums. Thus, it can be concluded that indirectly the Oral Hygiene Index (OHI) and Gingivitis Index (GI) are important factors that determine the quality of lead line formation because these two factors are closely related to the presence of bacteria in the oral cavity.\textsuperscript{11}

**Relationship between smoking habit and gingival lead line**

In table 3, the relationship between smoking habits and the incidence of gingival lead line is presented.

<table>
<thead>
<tr>
<th>Smoking habit</th>
<th>Gingival Lead Line Score</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>0</td>
</tr>
<tr>
<td>Not a smoker</td>
<td>7.5%</td>
</tr>
<tr>
<td>Smoker</td>
<td>15.0%</td>
</tr>
</tbody>
</table>

Based on the results of the chi-square test obtained $p = 0.158$ ($p < 0.05$), it was concluded that the smoking habits of coal miners were not related to the incidence of gingival lead lines. The standard of cigarettes taken from tobacco, in the handling process often uses pesticides which also contain basic ingredients of lead (Pb).\textsuperscript{12} Thus, research subjects who had a smoking habit of Pb levels increased the amount of Pb exposure both from the contents of the cigarette and from coal dust were also sucked. This can worsen the incidence of gingival leadline.

**Conclusion**

The results of this study concluded that the incidence of gingival lead line in coal miners was significantly related with age, working, and smoking habits. Thus, a comprehensive effort is needed to improve dental and oral health.

**Ethical Clearance:** This research has gone ethical feasibility testing by the Ethical Research Commission of the Faculty of Dentistry, University of Lambung Mangkurat and declared as ethical: no. 28 / KEPKG-FKGULM / EC / IX / 2017.

Abstract

Background: Child nutritional status needs to be assessed accurately so that early and appropriate management can be carried out. Indonesia has launched child growth standards in 2005, known as Growth Diagrams of Indonesian Children (GDIC), while the WHO 2006 child growth standards (WHO-CGS) is currently use as standards to assess growth of Indonesian children.

Aim: This study aims to analyze differences in the interpretation of nutritional status between 2006 WHO-CGS and 2005 GDIC.

Method: This is a cross sectional study. 1162 children aged 0-60 months in five selected villages in a public health center in East Java, Indonesia were included in this study. Interpretation of growth was categorized into weight-for-age, length/height-for-age, and weight-for-length/height based on two growth assessment standards; 2006 WHO-GCS and 2005 GDIC.

Results: 2005 GDIC detected underweight, stunted, wasted, and obese children fewer than the 2006 WHO-CGS. There are significant differences in the interpretation of weight-for-age in girls aged 0-50 weeks (p<0.001) and length/height-for-age in children aged 0-60 months (p<0.001). While weight-for-length/height showed significant differences in boys aged 0-60 months (p=0.008) and aged 6-36 months (p=0.027).

Conclusion: 2005 GDIC detects fewer children with malnutrition than 2006 WHO-CGS. The significant difference on interpretation between two growth charts was particularly found in height-for-age.

Keywords: 2006 WHO child growth standards, 2005 Growth Diagrams of Indonesian Children, malnutrition, children 0-60 months

Introduction

Malnutrition is one of the important public health problems, affecting more than 900 million people worldwide. It is responsible for the highest death rates in children and has long-term physiological impacts. Malnutrition in children has been linked to poor mental development and school performance as well as behavior disorders. 1 Children’s height for 2 years of age is the best predictor of human capital, therefore malnutrition is associated with lower human capital. Damage suffered early in life leads to permanent decline and may also affect future generations. Malnutrition prevention might bring important health, educational, and economic benefits. Chronic diseases are especially common in malnourished children who gain rapid weight gain in their growth. 2 Cooperation of all stakeholders is needed to act to overcome malnutrition. 3

The prevalence of underweight children under five years old with in the world in 2011 is estimated at 16% (101 million) and has shown a decrease from 1990 with 159 million. The prevalence of stunted and very stunted toddlers in the world in 2016 was 22.9% (155.8 million). But this data has shown a decrease compared
to 2011 which was 26%.\textsuperscript{4} The 2018 national prevalence of underweight and stunted children is higher than the world prevalence (17.7% and 30.8%, respectively), but it shows lower prevalence than 2013 national data (19.6% and 37.2% respectively).\textsuperscript{5} Those prevalence rates were obtained from interpretations of nutritional status using the 2006 WHO child growth standards (2006 WHO-CGS).

Large number of malnutrition prevalence becomes national priority program and concern in daily clinical management. Nonetheless, several studies have concluded that the interpretation of nutritional status using the WHO child growth standards results in overestimation of malnutrition prevalence rate.\textsuperscript{6-10} Those studies were conducted to compare interpretation between the 2006 WHO-CGS growth chart and the national growth charts of each country. This suggests that specific factors play a role to affect child growth in each country.

Indonesia has developed 2005 growth diagrams of Indonesian children (2005 GDIC), even though it has not been widely used.\textsuperscript{11} This research will analyze the different interpretations between 2006 WHO-CGS and 2005 GDIC, and also underline the importance of using national growth charts to measure nutritional status more accurately.

**Method**

This study was cross sectional study conducted on October-November 2017. Secondary data were obtained from medical record of five selected villages in the working area of Berbek community health center in East Java, Indonesia. A total of 1162 boys and girls aged 0-60 months who took part in the routine Pos Pelayanan Terpadu (posyandu)/integrated healthcare center in their respective villages on August 2017 were included in this study. Patients with congenital anomalies, chronic diseases, or patients taking long-term corticosteroids were not included in the study.

The selection of five villages from nineteen villages was chosen used simple random sampling. Children were divided into boys and girls, and each sex group were divided into three age groups; 0-5 months, 6-36 months, and 37-60 months. Anthropometric data was collected, both weight (kg) and length/height (cm). The data were plotted based on its nutritional status using two growth charts, the 2006 WHO-CGS and 2005 GDIC. The nutritional status is categorized into weight-for-age, length/height-for-age, and weight-for-length/height. The data were statistically analyzed through comparison test using the Wilcoxon Signed-rank Test. p<0.05 was considered significant.

**Results**

Table 1 shows the sample characteristics of children. From a total of 1162 children under five the majority of children were male (53.4%) and their age were 6-36 months (55.5%). Measurements using the two growth charts cannot be done in all age groups because the weight-for-age diagram of 2005 GDIC is only available for children aged 0-50 weeks and weight-for-length/height diagrams of 2005 GDIC is only available for children with length/height <60 cm. Of about 1162 children, only weight-for-age of 374 children were measured using those 2 standards, and only weight-for-length/height of 1094 children were measured using those 2 standards. However, length/height-for-age can be measure in every sex and age groups. The total prevalence of underweight, stunted, wasted, and obesity among children was smaller when interpreted using 2005 GDIC growth chart.

Most of children have normal weight-for-age, both according to 2006 WHO-CGS or 2005 GDIC. 2005 GDIC detects fewer underweight children in both sexes and fever obese boys than 2006 WHO-CGS. The difference of weight-for-age interpretation was significant only for girls (p<0.001). Most of children have normal weight-for-length/height, both according to 2006 WHO-CGS or 2005 GDIC. 2005 GDIC detects fewer both wasted and obese children than 2006 WHO-CGS. The difference of weight-for-length/height interpretation was significant only for boys aged 0-60 months (p=0.008) and boys 6-36 months (p=0.027).

Weight comparison on male subject aged 0-50 weeks old (p=0.439), Weight comparison comparison on female subject aged 0-50 weeks old (p<0.001), Height interpretation based on age comparison on male toddlers 0-60 Months old, 0-5 Months old, 6-36 Months old, 37-60 Months old (p<0.000), BW/BH interpretation comparison on male toddlers aged 0-60 Months old (p=0.008), 0-5 Months old (p=0.157), 6-36 Months old (p=0.027), 37-60 Months old (p=0.371) and WHO Curve dan GDIC Curve comparison in BW/BH interpretation of female toddlers aged 0-60 Months old (p=456), 0-5 Months old (p=0.059), 6-36 Months old (p=0.841), 37-60 Months old (p=0.782).

**Discussion**

Abnormalities of child growth either under-nutrition or over-nutrition are associated with morbidity and mortality as well as long term impacts in adulthood, such as cardiovascular and metabolic disease. Therefore, precise measurement of growth is important to monitor child health and prevent malnutrition.

This study shows that both growth charts mostly detect normal growth in our study participants. Prevalence of national under-five underweight, stunted, and wasted children were higher (17.7%, 30.8%, 10.2%, respectively), but obese children was fewer (8.0%) than prevalence found in this study. However, prevalence of stunted children in this study was higher than world prevalence in 2016. 4
2006 WHO-CGS detects more underweight, stunted, wasted, and obese children than 2005 GDIC. However, significant differences were only found in weight-for-age of girl, height-for-age of all age and sex groups, weight-for-length/height of 0-60 months boys, and 3-36 months boys.

This indicates that Indonesian children are lighter and shorter than the population standard used to develop the 2006 WHO-CGS. Previous study also suggest that the nutritional status of Indonesian children according to weight-for-length/height tends to be the same as the population of American children because Indonesian children are lighter and shorter. 11

Weight-for-age interpretation was only significantly difference in 0-50 weeks girl, and weight-for-age interpretation was only significantly difference in 0-60 months boys and 3-36 months boys. This suggests that gender plays an important role in child growth. Genetic expressions that affect body weight appear to be significantly higher in girls starting at 9 months compared to boys. 14

Racial factor is thought to be associated with child growth difference between Indonesian and American populations. But the influence of race in child growth is still controversial. Despite differences in race, WHO Multicentre Growth Reference Study Group (2006) found similar child growth rate among their subjects. It is thought that environmental factor such as nutrition have more impact on child growth, because poor nutrition and infection can increase risk of stunted children. 15 Previous review also indicate that application of specific racial and ethnic groups growth chart is not recommended because child growth are more affected by environmental factors rather than genetic factors. 16 Therefore, WHO recommends to use only one growth chart for all child populations in the world. 17

However, some studies show that the interpretation of height-for-age using WHO chart shows different result than interpretation using height-for-age national chart of some countries. 18 Racial difference in child growth is a fact but this phenomenon is caused by inequality in environmental factors such as economics, psychosocial, and cultural factors that affect minority groups. However, previous study has shown the biological influence on child growth. Hong Kong Chinese children is shorter than WHO growth standards as a result of epigenetic constrains on growth rather than environmental factors
