Summary and Conclusion

Mucin histochemistry of normal endocervical glands was undertaken in the department of Anatomy at Krishna Institute of Medical Sciences University, Karad from 2010 to 2012.

In the present study, special histochemical methods were applied.

- Special stains such as PAS, PAS-Diastase, and PAS-Phenyl hydrazine were used for confirmation of neutral mucins.
- Alcian blue pH 2.5 was used to assess acidic mucin. Further categorization of acidic mucins into sulpho and sialomucins was carried out by Alcian blue pH 1 and Aldehyde fuchsin.
- Combined stains such as AB-PAS, AF-AB and PAS-Phenyl hydrazine were used to differentiate between neutral and acidic mucins.
- In the present study the results were compared with various other studies and the results correlated with them.
- The varied heterogeneity of acidic mucins was indicated by a mixture of sulpho and sialomucins.
- In the present study mucin histochemistry of normal endocervical glands showed mixture of mucosubstances, both neutral and acidic. Acidic mucins were more in amount than neutral. In acid mucinssialomucins were predominantly seen.

The present study correlates with workers like, Lapertosa G et al17 V. Misra et al18 Zhao and Shumei et al19 in the histochemical study of normal endocervix

Ethical Clearance: Taken from institutional ethics committee, KIMSDU, Karad.

Abstract

Background: Personal identification has an important role in forensic sciences. Lip print and thumb print can be used for personal identification since they are unique for individuals and do not change during the life of a person.

Objective: To analyse predominant patterns of lip print in females and males, To analyse predominant patterns of finger print in females and males, To identify if there exists any correlation between lip prints and finger prints.

Material and Method: A cross sectional study was conducted in Sathyabama Dental College among 500 individuals (250 females and 250 males) between age group of 18-40 years. Fingerprint and lip print of all the subjects were collected and compared, and the results were analyzed based on Micheal Kucken classification system for fingerprints and Suzuki and Tsuchihashi classification for lip prints. Descriptive and inferential statistics were carried out. Level of significance was set as 0.05.

Result: Reticular lip print pattern was found in majority (36.4%) of the males, whereas vertical grooves (29.6%) and branched grooves (29.6%) are common in females. Finger prints showed that loop pattern is more common in both males and females. This study showed a significant correlation between lip prints and thumb pattern in males while females showed no significance.

Keywords: Lip Print; Finger print; Sex determination; Cheiloscopy; Dermatoglyphics.

Introduction

Every human being is distinct and discernible in that they exhibit their own pattern of characteristics¹. Personal identification is one of the key areas in the forensic sciences. The common techniques which are employed to ensure fast and secure identifications were DNA comparisons and finger print analyses, but there are certain crime scenarios where other supplemental aids like lip prints, palatal rugae pattern, bite marks, etc, are used². However, personal identification by physical appearance and visual examination may play a role in adjunct mode rather than confirmatory. One such physical evidence for personal identification in forensic scene is lip print analysis and finger print analysis³.

Lip print and thumb print can be used for personal identification since they are unique for individuals and do not change during the life of a person. It has been verified that lip prints recover after undergoing alterations such as minor trauma, inflammation and herpes and that the disposition and form of furrows does not vary with environmental factors⁴.

Lip prints are a characteristic pattern formed by the wrinkles and grooves on labial mucosa and is unique to one person except in monozygotic twins. The study of lip print is known as “Cheiloscopy”. Unique set of minute raised ridges seen on the volar pads are called the fingerprints, the study of which is called “Dermatoglyphics”.

Due to the immense potential of fingerprints and lip prints as an effective method of identification an attempt has been made in the present work to investigate whether the lip prints are unique to any fingerprint in the population under investigation based on gender and to see if this association will help forensic odontologists in
the personal identification of the person at the scene of crime and in solving crimes.

**Methodology**

A cross sectional study was conducted after obtaining ethical clearance from the Institutional Ethical Committee Sathyabama Dental College [Ref No: Sathyabama university/ IHEC/study no 011] among 500 individuals (250 females and 250 males), who had morphologically healthy look, devoid of congenital or developmental abnormalities. The study procedure was explained to the participants and a written consent was obtained from each individual before the start of the study. Analysis of lip prints and finger prints was done as follows

*Lip print analysis:*

The lips of the individuals were cleaned. A thin coat of dark coloured lipstick was applied uniformly on the lips by a lipstick applicator brush starting at middle and moving laterally. The sticky side of the cellophane tape was placed over the lip in resting position and pressed uniformly. Tape was then gently removed from the lip without distorting the lip print and then stuck to the chart sheet. The Lip prints were interpreted using magnifying glass. While studying the various types of Lip prints, the lips were divided into 6 compartments. Lip prints was studied on all the compartments and the type of pattern which was prominent was observed based on Suzuki and Tsuchihashi classification.

According to this classification, the lip print pattern is divided as; Type I: Clear cut vertical grooves that run across the entire lip; Type I’: Similar to type-I but do not cover the entire lip; Type II: Branched grooves; Type III: Intersecting grooves; Type IV: Reticular grooves; Type V: Grooves that do not fall in any of the pattern.

*Finger print analysis:*

For recording finger print, the imprint of the left thumb was recorded using an ink pad on chart sheet, after cleaning and drying the hand. The primary patterns of the finger prints was observed using a magnifying glass and interpreted using Michael Kucken classification as Loop pattern, Arch pattern and Whorl Pattern.

*Statistical analysis:*

The data collected was compiled in Microsoft excel sheet and transferred to version 20 SPSS software. Descriptive and inferential statistics were carried out. Level of significance was set as 0.05.

**Results**

Table 1 and 2 shows there is a statistically significant difference among male and female considering lip prints and finger prints. Majority of the male population shows Reticular pattern whereas vertical grooves and branched grooves are common in females. Finger prints showed that loop pattern is more common in both males and females. Table 3 shows there is a significant correlation among males in lip pattern and finger print with r value of -0.133 and there is no correlation among females in lip print and finger print with r value of 0.081.

Discussion

Lip prints and thumb print are unique for any individual and hence its being used significantly in the field of forensic sciences for individual identification. The Klein’s zone, in the lips is the area which is usually concerned for identification and is covered with wrinkles and grooves that forms a unique characteristic pattern. The primary dermal ridge in the fingerprint formed during 12-13 weeks of intrauterine life is fixed throughout the life of an individual. The size and shape may vary with age but the basic pattern remains permanent. This study was undertaken to identify whether certain lip prints are unique to any fingerprint in the population under investigation.

The present study reports predominant lip pattern in males is reticular grooves and in females, branched and vertical grooves running across entire lip is equally predominant. This study is in accordance with studies done by Vahanwala et al9 and Krishnan RP et al.10 In contrast, Nagasupriya et al11, Negi A et al12 reports branch pattern predominant in males. Loop pattern is common in both males and females followed by Whorl pattern in this study. This finding is similar to other Indian studies conducted by Srilekha N et al (2014)13, Nagasupriya A et al (2011)14 and Mutalik VS et al (2013)15.

This study shows a significant correlation between lip prints and thumb pattern in males while females shows no significance. This is similar with the findings of Naik R et al (2017)15 and Nagasuriya et al(2011)14 who found significance of finger pattern and lip prints in males and not in females. However, it is observed that the associated finger pattern and lip print in both studies
are different. Naik R et al (2017) suggests Intersecting grooves in lip prints and whorl type of thumbprint in males are significant, whereas, Nagasupriya et al(2011) suggests branching type of lip print and arch pattern in finger prints are significant.

From this study, it can be concluded that the reticular grooves is commonly seen lip print in males. Branched and vertical grooves running across entire lip is equally predominant lip print in females. Loop pattern is finger pattern is common in both males and females. There is a significant correlation seen between lip print and finger pattern in males.

Abstract

Objectives: Low back pain in postnatal women is a major issue. So, lumbar curvature is a key feature to maintain core strength for which it has to be assessed. The individual variations in spinal curvature and lordotic pattern signifies the bio mechanics of the spine and it responds according to the load / activities. To find out the pre-test measures of flexibility, functional capacity and discomfort level related to lumbar spine in the subjects with postural dysfunctions. To find out the post-test flexibility, functional capacity and discomfort level in the subjects with postural dysfunctions. To analyze the difference between the pre-test and post-test values. People should also have awareness about the posture maintenance. So, early assessment is necessary. Also secondary factors like the type of shoes wear, Occupation and Lifestyle can influence the spinal curvatures which can be dealt with easier with the outcome of the research.

Methodology: In this experimental study, 29 people with age group of 25 to 60 years who have chronic low back pain. Their lumbar spine flexibility, functional capacity, and discomfort level was measured pre-test and post-test. Results were obtained and compared.

Result: The average mean value of lumbar spine flexibility pre-test measured with schober test was 1.81 while post-test was 2.08. Average mean value of VAS for lumbar spine was 6.06 while post-test was 3.24. Average mean value for pre-test functional capacity measured with 6 min walk test was 647.58 while post-test was 665.17.

Conclusion: On comparing summary score of lumbar spine flexibility, VAS, and functional capacity, the differences showed were 0.27 cms, 2.82, 17.59 metres respectively.

So, we can conclude that there was a significant difference in the improvement of lumbar spine flexibility, functional capacity and also decrease in pain after the treatment.

Key Words: Lumbar spine flexibility, VAS, functional capacity, schober test, 6 minute walk test, low back pain, postural dysfunction.

Introduction

Low back pain is a leading cause of disability. It occurs in similar proportions in all cultures, interferes with quality of life and work performance, and is the most common reason for medical consultations. Few cases of back pain are due to specific causes; most cases are non-specific. Acute back pain is the most common presentation and is usually self-limiting, lasting less than three months regardless of treatment.¹ Chronic back pain is a more difficult problem, which often has strong psychological overlay: work dissatisfaction, boredom, and a generous compensation system contribute to it. Among the diagnoses offered for chronic pain is fibromyalgia, an urban condition (the diagnosis is not made in rural settings) that does not differ materially from other instances of widespread chronic pain²,³. Although disc protrusions detected on X-ray are often blamed, they rarely are responsible for the pain, and surgery is seldom successful at alleviating it. No single treatment is superior to others; patients prefer
Manipulative therapy, but studies have not demonstrated that it has any superiority over others.  

Some activities—such as jogging and running on cement roads rather than cinder tracks, heavy lifting, and prolonged sitting (especially in cars, trucks, and poorly designed chairs)—can provoke back pain. Nevertheless, strong psychological factors do play a role.

The following measures to be included in all studies to be reported (but not necessarily for consultations by individual patients):

- Appropriate history and physical examination—functional capacity.
- Modified Schober test of spinal mobility
- Measurement of pain on a visual analogue scale.

Bed rest, supportive corsets, and braces, which used to be prescribed almost routinely, are no longer advocated for back pain, as they are thought to prevent the muscles from providing the necessary structural support. “Back schools”—in which posture, exercises, and other training for the back are taught—have limited value, especially for chronic pain, but they do have a potential role in education.

Two of the most common causes of lower back pain in older adults include osteoarthritis and spinal stenosis. Degeneration of joints in the lumbar spine is a common cause of back pain in older adults.

The lumbar spine supports the upper body and transmits the weight of the trunk with upper body to the pelvis and lower limbs. Lumbar spine consists of 5 vertebrae. The normal resting position of the lumbar spine is in S shaped and is midway between flexion and extension. Lumbar spine plays an important role for posture and stability providing the strength needed for stability especially utilized in static and dynamic postures.

Lumbar lordosis: The anterior concavity in the curvature of the lumbar spine as viewed from the side.

Or

An abnormal increase in lumbar curvature.

Methodology

An approval for the study was obtained from the Protocol committee and the Institutional Ethical Committee of KIMSDU. Individuals were approached and those fulfilling the inclusion criteria were selected. Total 29 individuals were selected. The procedure was explained and written informed consent was taken from those willing to participate.

Demographic information of the subjects was taken. The individuals were explained about the purpose of the study. Also, they were informed about the procedure. Each of them was assessed for the lumbar spine flexibility, VAS, functional capacity.

In this experimental study, 29 women with age group of 25 to 60 years who have chronic low back pain. Results were obtained and compared.

Data was documented and statistical analysis was done.

Data Presentation, Analysis And Interpretation:

1. Comparison of Pre-Test And Post-Test In Lumbar Spine Flexibility With Schober Test:

<table>
<thead>
<tr>
<th>LUMBAR SPINE FLEXIBILITY (MEAN) PRE-TEST</th>
<th>LUMBAR SPINE FLEXIBILITY (MEAN) POST-TEST</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.81</td>
<td>2.08</td>
</tr>
</tbody>
</table>

2. Comparison of Pre-Test And Post-Test In Functional Capacity With 6 Min Walk Test:
TABLE NO 2- COMPARISON OF PRE-TEST AND POST-TEST IN FUNCTIONAL CAPACITY WITH 6MWT.

<table>
<thead>
<tr>
<th>6MWT Distance (MEAN)</th>
<th>6MWT Distance (MEAN)</th>
</tr>
</thead>
<tbody>
<tr>
<td>PRE-TEST</td>
<td>POST-TEST</td>
</tr>
<tr>
<td>647.58</td>
<td>665.17</td>
</tr>
</tbody>
</table>

3. COMPARISON OF PRE-TEST AND POST-TEST IN VAS:

TABLE NO 3- COMPARISON OF PRE-TEST AND POST-TEST IN VAS:

<table>
<thead>
<tr>
<th>VAS (MEAN)</th>
<th>VAS (MEAN)</th>
</tr>
</thead>
<tbody>
<tr>
<td>PRE-TEST</td>
<td>POST-TEST</td>
</tr>
<tr>
<td>6.06</td>
<td>3.24</td>
</tr>
</tbody>
</table>

Interpretation:

From the above data, it is clear that there is significant difference between pre-test and post-test values with a positive result that is improvement in the condition of subjects.

Significant difference

1. Differences In The Pre-Test And Post-Test Values:

TABLE NO. 4: DIFFERENCES IN THE PRE-TEST AND POST-TEST VALUES:

<table>
<thead>
<tr>
<th></th>
<th>PRE-TEST</th>
<th>POST-TEST</th>
</tr>
</thead>
<tbody>
<tr>
<td>Schober test (in cms)</td>
<td>1.81</td>
<td>2.08</td>
</tr>
<tr>
<td>6MWT (in m)</td>
<td>647.58</td>
<td>665.17</td>
</tr>
<tr>
<td>VAS</td>
<td>6.06</td>
<td>3.24</td>
</tr>
</tbody>
</table>

**Result**

The average mean value of lumbar spine flexibility pre-test measured with schober test was 1.81 while post-test was 2.08. Average mean value of VAS for lumbar spine was 6.06 while post-test was 3.24. Average mean value for pre-test functional capacity measured with 6 min walk test was 647.58 while post-test was 665.17.

**Conclusion**

After analyzing the data, it was found that the mean value of VAS is 6.06 Pretest and 3.24 Posttest.

Pretest schober test value (in cms) was 1.81 while posttest it was 2.08.

Pretest 6MWT (in m) value was 647.58 while posttest it was 665.17.

On comparing summary score of

1. VAS, significant difference of 2.82 was noted.
2. Schober test, significant difference of 0.27 cms was noted.
3. 6MWT, significant difference of 17.59 metres was noted.

Thus concluding that there is an improvement in the functional capacity, flexibility, and VAS of an individual in the post test results.

Prevalence of Piriformis Tightness with Relevance of Sitting Duration in Bankers

Vaishnavi S Desai, S. Anand

1 Final year student, Faculty of Physiotherapy, KIMS “Deemed To Be University” Karad, Maharashtra, India,
2 HOD and Professor, Department of Community Health Sciences, Faculty of Physiotherapy, KIMS “Deemed To Be University” Karad, Maharashtra, India

Abstract

Objectives: Piriformis tightness is one of the potential cause of pain, discomfort and dysfunction in community. However the ergonomic risk factors, pain (type, intensity, precipitating factors), physical anthropometrics specific to piriformis tightness were unclear. Hence the attempt was made to find the data and trends in piriformis tightness and its prevalence in bankers.

Methodology: Study was conducted by approaching 36 banks in Karad taluka. Total 260 subjects (M:162; F:98) were included in the study who were assessed for their piriformis tightness by piriformis stretch test. There demographic data, no. of working years, pain (type, intensity, precipitating factor), chair height, chair width, cushion support were also documented.

Result: Prevalence of piriformis tightness in bankers was 51.92%. Out of 135(M:93; F:42) bankers having tightness, 44 were having only right side involved, 22 were having left side involved and 69 were having bilateral tightness. Prevalence was more in people with BMI between 25-29kg/m² (pre-obese) and in fourth decade of life.

Conclusion: Out of 260 subjects 135(51.92%) bankers were having piriformis tightness. There is increasing risk of getting piriformis tightness with increasing BMI, Age. There is not significant relation between the chair height, Chair weight and Cushion support on the chair and the piriformis tightness. There was increasing pain in sitting position (after maintaining for long time) and is relieved by rest.

Key Words: Demographic data, ergonomic risk factor, physical anthropometrics, piriformis stretch test, Piriformis tightness, precipitating factor, physical anthropometrics.

Introduction

Technology and physical activity are inversely proportional to each other that is as the technology progresses physical activity decreases which turn out to be the reason for sedentariness.1 People are spending most of the time in the environment which make them confined of sit at one place like in home, work place.2,3

Correspondence:
Dr. S.Anandh
Department of community health sciences,
Faculty of Physiotherapy, KIMS “Deemed To Be University” Karad, Maharashtra, India, Pin:415110

Email id: vaishnavidesai13@gmail.com

Sedentary life style comes hand in hand with poor health and mortality.4 According to survey, in India the average working time of bankers is 6-7 hours per day , so from this we come to know that bankers are at high risk to get musculoskeletal problems related to sedentary lifestyle. Sitting constantly for 6-7 hours per day means sitting is forward flexion position of sagittal plane which can lead to muscle imbalance. One of the most common condition resulting due to physical inactivity is LBP. 52.4% bankers suffer from LBP.5 It is documented that 6.5% LBP worldwide is due to Piriformis tightness.6

The three joint muscle below gluteal muscle is piriformis.7 It is one of the important and powerful
muscles in the pelvis. If the hip flexion is 60° or less than it act as external rotator and above 60° it acts as internal rotator. It is reported that during sitting position piriformis muscle is constantly under low grade contraction. Piriformis Syndrome is a neuromuscular disorder that take place when sciatic nerve is pinched and inflamed by piriformis muscle. This causes pain, altered sensations in buttocks all the way of sciatic nerve course from low back to thigh and down the leg. The pain location described by the patient is vague, the describe pain as is the hip, tailbone, buttocks and groin or radiating down back the leg.

According to one survey conducted on patient in Adam malik General hospital, Quality of life correlates with the intensity of pain in patient with low back pain especially on the grounds of physical function, litigation due to emotional problems, vitality, social function and feeling of pain and general health.11

Types of Piriformis Syndrome:12
1. Primary Piriformis Syndrome
2. Secondary Piriformis Syndrome

Primary Piriformis Syndrome has an anatomic cause, such as a split piriformis muscle, split sciatic nerve or an anomalous sciatic nerve path.12

Secondary Piriformis syndrome occurs as a result of 12:
1. precipitating cause,
2. macrotrauma
3. microtrauma
4. ischemic mass effect
5. local ischemia

Physical findings of Piriformis Syndrome13:
1. Tenderness over the sciatic notch
2. Isolated atrophy of gluteus maximus ani chronic stage
3. Dysesthesia in the posterior aspect of thigh
4. Tenderness over the rectal wall

Signs specific to piriformis syndrome are 12:

Delayed Diagnosis of piriformis tightness may lead to pathological conditions of the sciatic nerve, chronic somatic dysfunction and compensatory changes and it may cause pain, paraesthesia, hyperesthesia and muscle weakness. In extreme cases, misdiagnosis of piriformis syndrome-related back pain with “sciatica” as prolapsed intervertebral disc may lead to unnecessary surgery. Prevalence of piriformis tightness with relevance with sitting duration is scarce in the literatures. Therefore the present study to find the prevalence of piriformis tightness with relevance to the sitting duration is necessary so the proper corrective and preventive measures can be taken in time which may reduce the rate of low back pain because of piriformis tightness.

**Methodology**

An approval for the study was obtained from the Protocol committee and the Institutional Ethical Committee of KIMSDU. Individuals were approached and those fulfilling the inclusion criteria were selected. Total 260 (M:162; F:98) individuals were selected. The procedure was explained and written informed consent was taken from those willing to participate.

Demographic information of the subjects was taken. The individuals were explained about the purpose of the study. Also, they were informed about the procedure. Each of them was assessed for the Piriformis tightness using Piriformis stretch test. Piriformis stretch test was performed with the patient positioned in supine, the tested leg was placed in flexion at hip and knee so that the foot of the tested leg rests on the table lateral to the contralateral knee (the tested leg was crossed over the straight non-tested leg. The angle of hip flexion was maintained at 60°. It was ensured by measuring goniometer Therapist was standing beside the plinth at the test side to stabilize the no-tested side ASIS by one hand to prevent the pelvic motion during the test. The knee of the test side was pit in to adduction, to place stretch on the piriformis muscle. If the adduction ROM
was limited and the patient recorded discomfort posterior to the tested greater trochanter tested side piriformis was considered tight (positive). Pain assessment was done by the Visual Analogue Scale (VAS) which is taken of Rest and On Activity. Chair width and chair height was measured of each subject using inch tape, presence or absence of cushion was noted.

Data was documented and statistical analysis was done

Data Presentation, Analysis And Interpretation:

1. Right side Piriformis Tightness in the study

<table>
<thead>

</tbody>
</table>

Table no. 7: Association between Age and Pain Due to piriformis tightness:

Interpretation: From the above table out of 135 bank employees present with pain due to piriformis tightness 40 subject were in the age group of 31-45 years and 95 were in the age group above 46 years. Association between age and pain due to piriformis tightness was calculated by the Chi-square test which found out to be 59.869 with the p-value of <0.001 which is significant.
Result

In this study, 260 (M:162; F:98) bank employees were taken. It was found that 135 bank employees had piriformis tightness out of which 44 subjects had only right side tightness of piriformis muscle, 22 subjects were having tightness if left side piriformis muscle and 69 subject had bilateral piriformis tightness. Prevalence of piriformis tightness in bankers was found out to be 51.92%.

The study stated that there is significant risk of having piriformis tightness as the age increases as most of the subjects with positive piriformis stretch test were in have the age above 45 years. The reason for this might be the more amount of time spent in sitting positions.

All the subjects with positive piriformis stretch test were screened for the pain patterns at rest and on activity by the use of VAS scale. The average pain on rest of the subject present with piriformis tightness which was calculated on VAS scale was 5.5 cms and the average pain on activity of subjects positive with piriformis stretch test is 1.82 cm.

The study also documented other demographic variable of the subjects such as the BMI and gender. The study also stated that BMI and piriformis tightness are directly proportional to each other that is as the BMI increases the risk of getting piriformis tightness also increases and this is clear as most of the subjects (76 subjects) with piriformis tightness were in the BMI category of 25-29.9 (pre-obese).

The risk of piriformis tightness is more in males than in females. From the study it is also clear that as the working years of the bankers increases the chances of them getting piriformis tightness are high.

Now talking about the ergonomic risk factors, from this study we get to know that there is not a significant relation between the chair height, chair width, and the cushion support on the chair and the piriformis tightness.

According to the study there is 51% prevalence of piriformis tightness in the bankers which if not treated can compress the sciatic nerve passing just beneath the muscle which will lead to piriformis syndrome which has variety of disturbing symptoms like radiating pain from the buttock to the back of the thigh with the association of the tingling sensation.

So to prevent the tightness of this small triangular muscle of the buttock it is necessary to implement stretching and change in activity so that it will not strain the piriformis muscle much.

Conclusion

On the basis of the result of the study, it was concluded that there is prevalence of 51.92% of piriformis tightness in bankers. There is increases in risk of getting piriformis tight with increase in BMI, with male gender, with increases in age. And there is not any significant relation between the chair height, chair width, and the cushion support on the chair and the piriformis tightness.

Conflicts of Interest: There were no conflicts of interest in this study

Abstract

Background of the study: Proper guided brushing technique improves the oral health status especially among diabetic individuals who are more susceptible for periodontal disease. Aim and objective: To find the outcome efficacy of modified design special tooth brush with beat sound by evaluating oral hygiene status among diabetic individuals. Material and methods: The present observational study included 25 study participants irrespective of age and gender divided and categorized as 13 non-diabetic (control) group and 12 belong to diabetic (study) group. All the study participants were educated to use modified special tooth brush with beat sound regularly for a period of 1 week and their oral hygiene status were evaluated by using Oral hygiene index simplified (OHI-S), periodontal index (PI) and Gingival index (GI) at regular intervals on 1st, 3rd, 5th and 7th day. Results: It was observed that all the study participants showed significant improvement in oral health status at the end of 7th day. It was also observed that diabetic individuals showed superior OHI-S (P=0.002), PI (P=0.0001) and GI (P=0.0004) scores with greater significance (p<.05) than non-diabetic individuals. Conclusion: From the above results it can be concluded that the modified special tooth brush with beat sound used in the present study can reduce the burden of periodontal disease status by improving oral health among diabetic individuals.

KEYWORDS: Modified Special Tooth Brush, Gingival Index, Plaque, Bleeding, Diabetes.

Introduction

Oral health is often ignored by this age group due to poor oral health care practices, nutritional habits and exposure to illegitimate practices that adversely affecting the quality of life [1]. Dental plaque or calculus is the major etiological factor in the causation of gingivitis which subsequently left untreated leads to periodontitis [2]. Mechanical control using tooth brush for removing of the deposits is the gold standard in its prevention or progression of disease process however; it is insufficient in the interdental areas [3]. According to a study in 2010 conducted on the basis of consumer usage, almost half of the population of India did not use toothbrush to clean their teeth[4].Therefore, Effective Oral hygiene practices such as proper brushing technique, appropriate use of brushes; use of adjunctive oral hygiene aids, interdental aids like interdental toothbrushes, toothpicks and floss along with tooth brushes is often recommended. These practices play a vital role in maintaining a good oral health thereby preventing gingival or periodontal diseases[5]. In addition to professional care, successful management of periodontal disease depends on the capacity of patient’s oral self-care [6].

The presence of systemic conditions such as diabetes mellitus, hypertension, cardiovascular disease, respiratory disorders, endocrine disorders, etc. can individually or collectively attribute to tooth loss.
According to the Diabetes Atlas (2006), published by the International Diabetes Federation, the number of people with diabetes in India currently around 40.9 million is expected to rise to 69.9 million by 2025 unless urgent preventive steps are taken [7]. Low levels of insulin to achieve adequate response and/or insulin resistance of target tissues, mainly skeletal muscles, adipose tissue, and to a lesser extent, liver, at the level of insulin receptors, signal transduction system, and/or effector enzymes or genes are responsible for these metabolic abnormalities [8]. Studies establishing the relationship among diabetes mellitus, periodontal health and subsequent tooth loss have been broadly reported (Campus et al 2005 [9]; Khader et al 2008 [10]; Furukawa et al 2007 [11]; Taylor and Borgnakke 2008 [12]). Individuals with diabetes tend to have higher values for indices of plaque, dental calculus, and gingival inflammation, and deeper periodontal pockets. They are frequently in greater need of periodontal treatment and prophylactic procedures [13]. Various studies have shown abrupt periodontal destruction and more severe periodontitis in individuals with uncontrolled diabetes compared to individuals with well controlled blood glucose level. The patients with poorly controlled diabetes are at greater risk of developing periodontal disease. It starts with gingivitis and then with poor glycaemic control it progresses to advanced periodontal disease [14, 15].

The present study was aimed to evaluate the oral health status among diabetic individuals and to find the outcome efficacy of this method by modified design special tooth brush with beat sound.

**Materials And Method**

The present observational study included 26 random study participants categorized as two groups among which 13 were non-diabetic (control) group and 12 belong to diabetic (study) group irrespective of age and gender. All the study participants were given modified design tooth brush which is designed in such a way to guide proper brushing technique by presence of beads in the shank portion capable of producing beat sound (Figure 1). The beads are placed in a regular interval for effective movement of the handle in the direction of vertical along with circular motions hence by producing noise only at the time of proper brushing technique. The instructions were given and study participants were educated to use modified special tooth brush regularly twice a day for a period of 1 week and not to use any other oral hygiene aids.

Oral hygiene status was evaluated by using Oral hygiene index simplified (OHI-S) given by John C Greene and Jack R Vermillion (1964), Periodontal index (PI) given by Russell A L (1956) and Gingival index (GI) given by Loe H and Silness J (1963) at regular intervals on 1st, 3rd, 5th and 7th day. Indices scores were recorded. All the data collected was tabulated. Statistical analysis was performed by using SPSS software version 21.0 (SPSS V21.0 Illinois, Chicago).

**Findings**

All the score were validated and compared for evaluation by chi-square test and One-Way ANOVA. Among the non-diabetic individuals interrelation within the group OHI-S scores showed f-ratio value of 12.99911 (Table 1), PI scores showed f-ratio value of 13.73005 and GI scores showed f-ratio value of 17.58903 with p-value is < .00001. All the three indices showed significant at p < .05. Similarly Among the diabetic individuals interrelation within the group OHI-S scores showed f-ratio value of 63.6499 (Table 2), PI scores showed f-ratio value of 121.582 and GI scores showed f-ratio value of 261.30 with p-value is < .00001. All the three indices showed significant at p < .05. Pearson’s correlation coefficient was used to evaluate the efficacy of present technique on oral health status among diabetic and non-diabetic individuals. A moderate positive correlation was found with OHI-S index which means there is a tendency for high diabetic variable scores go with high non-diabetic variable scores (and vice versa). The value of R is 0.5868. This is The P-Value is .002047. Similarly a moderate positive correlation was also observed with PI indices scores with R value of 0.6848 and P-value of .000159 and with GI indices score with R value of 0.6504 and P-Value of .000432. All these results were significant at p < .05 among the three indices a greater correlation was observed with periodontal indices than other indices used in the present study (Table 3).

**FIGURE 1:** Photograph showing the modified tooth brush with presence of beads in the shank portion capable of producing beat sound

**Discussion:**

Periodontitis is the most common multifactorial oral disease often associated with systemic conditions such as Hypertension, Diabetes Mellitus, Cardiovascular diseases, smoking. Over the years numerous epidemiological studies were carried out to confirm that diabetes is a substantial risk element for periodontitis, and the risk of periodontitis is greater if glycaemic levels are poor or less controlled[16].
Accumulation of dental plaque and calculus is usually caused by improper toothbrushing techniques, failure to carry out interdental cleaning and irregular dental visits. This accumulation probably results in gingival inflammation. Faulty tooth brushing techniques, improper use of oral hygiene aids involving excessive pressure may not efficiently or effectively remove plaque but also considerably increase gingival recession and loss of tooth substance by mechanical abrasion [17].

In the present study it was observed among the diabetic individuals interrelation within the group on OHI-S scores, PI scores and GI scores showed significant at p < .05. The present study is similar to the study by Toda et al [18], Lee et al [19] who also observed patients with diabetes are likely to have more severe periodontitis in terms of average plaque index (PI), average gingival index (GI), and clinical attachment loss (CAL), but exhibit the same extent of periodontal disease. This could be attributed to the fact that duration of the disease process play a role in the increasing magnitude of periodontal disease, 1 week follow up was made in the present study in contrast to their studies this may explain the apparent contradiction to the study by Emrich et al [20].

The results of the present investigation revealed that the diabetic patients exhibited significantly higher levels of gingivitis, periodontitis and bone loss than the non-diabetic patients. The above findings are in agreement with the studies by Collin et al [21], Taylor et al [22] and Sznajder et al [23]. However, the reduction of gingival or OHI-S Index may not have been greater due the age group of selected patients and for the low quality of brushing technique that they presented previously. Hence a higher significance was present with the periodontal status of an individual especially on diabetic group.

In a study by Rohit et al on severity of scores of periodontal index, gingival index, oral hygiene index simplified and bone loss score showed no significant difference in their severity [24] where as in the present study a moderate positive correlation was found with OHI-S index, PI indices scores and with GI indices score that explained by the fact that Bass technique was followed producing beat sound emphasizes the sulcular placement of the bristles, removing the plaque not only from the gingival margin but also with the cleaning efficiency can reach a depth of 0.5 mm subgingivally [25].

Ueno et al in a community based study observed the outcome of periodontal disease seemed to be influenced by the diabetic state to some degree, but a clear association between diabetes and oral health status was not found in the study [26]. In contrast, our study showed a moderate positive correlation which means there is a tendency for high diabetic indices variable scores go with high non diabetic indices variable scores (and vice versa). Differences in types of subjects (i.e., race, gender, and age) and degree of diabetes or using more rigorous and systematic study by evaluating CPITN index, Plaque Index on a large population, will be necessary to confirm the current observations which might have produced these conflicting results.

**Conclusion**

Within the limits of this study and based on clinical implication of the obtained results when comparing diabetic and non-diabetic individuals, it can be concluded that modified special tooth brush with beat sound technique show effectiveness on the plaque control by improving the overall oral health indices score in patients especially in individuals with good diabetic control. Further studies may be important to confirm these findings by long term follow up of patients to demonstrate the effectiveness of this method on the periodontal tissues health and also in improving the overall health status of an individual.

Age Estimation by Dental Eruption in Schoolchildren of 14-16 Years Age Group

Vijay Kumar AG1, Suresh J2

1Associate Professor, Department of Forensic Medicine & Toxicology, Adichunchanagiri Institute Of Medical Sciences; 2Associate Professor, Department Of Forensic Medicine & Toxicology, J.J.M Medical College, Davangere

Abstract

The estimation of age is an important and is commonly carried in medico legal area. Assessment of age is often required while administering justice to an individual involved in the civil and the criminal litigation. Teeth are known to aid in personal identification and age estimation as they are highly durable and resist putrefaction, fire, chemicals etc. Objective: To study the status of dental eruption in schoolchildren of age group between 14- 16 years. The study was carried out involving 100 students of age group of 14-16 years from BGS High School, B G Nagara, Mandya District. Out of 100 subjects, 50 males and 50 females constituted the study population. In the present study, Upper jaw, on both right and left sides, there was no space behind 2nd molar tooth in 14 years males while space was present in one female of same age group. Only 1 male and 1 female of 15 years age group had developed space behind 2nd molar tooth. Considering the Lower jaw, space behind 2nd molar tooth was developed in 7 cases right side and 8 cases left side in case of 14 years boys. In case of girls of 14 years age it was present in 12 cases on right side and 9 cases on left side. In case of boys of 15 years, it was present in 18 cases on right side and 19 cases on left side. In case of girls of 15 years, it was present in 18 cases on right side and 20 cases on left side. The dental system is an integral part of the human body, its growth and development can be studied in parallel with other physiological maturity indicators such as bone age, menarche and height.

Keywords: Age Estimation, Dental Eruption, 14-16 Years of Age group.

Introduction

The estimation of age is an important and is commonly carried in medico legal area. Assessment of age is often required while administering justice to an individual involved in the civil and the criminal litigation. Teeth are known to aid in personal identification and age estimation as they are highly durable and resist putrefaction, fire, chemicals etc. Dental age estimation in the living is mostly based upon non-invasive methods, which evaluate the timing and sequence of defined growth stages of the developing dentition and the sequence or modification of traits in the mature dentition and the surrounding tissues. Eruption of teeth is one of the changes observed easily among the various dynamic changes that occur from the formation of teeth to the final shedding of teeth. The times of eruption of teeth are fairly constant and assessment of age of an individual by examination of teeth is one of the accepted methods of age determination. This fact can be made use of in ascertaining the average age of eruption of the tooth.1

It is well accepted by several authorities that the principal methods that enable one to give a fairly accurate range regarding the age of an individual are on the basis of appearance of secondary sexual characteristics, eruption of teeth. As determined by various studies so far in India, it is well known that there exists considerable variation in ossification of bones and teeth eruption in different regions of the country. So also there is divergence in the pattern of appearance of secondary sexual characteristics in various regions of our country and in different socio-economic groups.

Examination of teeth is very important in medico-legal cases as it helps in identification and age estimation of living as well as dead since the teeth resist putrefaction for a long time. From eruption of 20 temporary teeth, one can estimate approximate age from 6 months to 30 months. Temporary or deciduous teeth are replaced by 32 permanent teeth in later life which starts around 6th year. From eruption of first permanent molar until eruption of all the four permanent canines, it is called as period of mixed dentition. Teeth eruption is affected by climatic, racial, geographical factors. Also nutritional deficiency status and some diseases either delay eruption of teeth or may cause premature dentition.2,3

**Objective**

To study the status of dental eruption in school children of age group between 14-16 years

**Methodology**

The study was carried out involving 100 students of age group of 14-16 years from BGS High School, B G Nagar, Mandya District. Out of 100 subjects, 50 males and 50 females constituted the study population.

**Results**

**Table 1: Space behind Second Molar Tooth**

In the Upper jaw, on both right and left sides, there was no space behind 2nd molar tooth in 14 years males while space was present in one female of same age group. Only 1 male and 1 female of 15 years age group had developed space behind 2nd molar tooth.

Considering the Lower jaw, space behind 2nd molar tooth was developed in 7 cases right side and 8 cases left side in case of 14 years boys. In case of girls of 14 years age it was present in 12 cases on right side and 9 cases on left side. In case of boys of 15 years, it was present in 18 cases on right side and 19 cases on left side. In case of girls of 15 years, it was present in 18 cases on right side and 20 cases on left side.

**Discussion**

In the present study, Upper jaw, on both right and left sides, there was no space behind 2nd molar tooth in 14 years males while space was present in one female of same age group. Only 1 male and 1 female of 15 years age group had developed space behind 2nd molar tooth.

Considering the Lower jaw, space behind 2nd molar tooth was developed in 7 cases right side and 8 cases left side in case of 14 years boys. In case of girls of 14 years age it was present in 12 cases on right side and 9 cases on left side. In case of boys of 15 years, it was present in 18 cases on right side and 19 cases on left side. In case of girls of 15 years, it was present in 18 cases on right side and 20 cases on left side.

Kumar and Sridhar studied a total of 1008 individuals in between 5 years – and 14 years of age residing in Tirupati, Andra Pradesh. This study was community based on eruption times of permanent teeth to establish age of the individual. The median age of the eruption was computed based on the concept of “Ex” which is defined as the age at which specified percent of individuals shows eruption of a given permanent tooth. The median age “E50” was computed by transforming of percentages to probits and plotting a graph between age and probits. The individual’s age can be computed according to E50 value of permanent tooth, which erupted last. Given individuals probability being above or below the assessed age can be estimated by referring to graph and probit transformation table.1

Helm and Prydso recorded permanent emergence of mandibular third molar at an early age of 14 years in 235 Danish Medieval skulls, 52 of whom were in various stages of mixed dentition. They argued that assessment of age at death could be made fairly accurately for the age group 5 to 30 years.4
Kaul et al. studied deciduous teeth emergence of 312 children aged 4 months to 31 months with Punjabi parenthood. For calculating medium age of tooth emergence, they used probit analysis. They found earlier tooth emergence in females than their male counterparts. In comparison with other population, it was found that in general, mean number of emerged teeth in Punjabi children is more at most ages and with lower medium age of eruption for most teeth. Variability in the eruption time was highest in 16-17 and 20-21 months. Thus, their study suggests that the number of teeth can be used as a parameter for estimation of age.\(^5\)

Foti et al. studied for age determination both in living and dead children with the help of linear regression. The equation can be applied based on the number of erupted teeth and tooth germs detected during the clinical examination and radiograph. This equation helps in age estimation until 20 years of age.\(^6\)

**Conclusion**

The dental system is an integral part of the human body, its growth and development can be studied in parallel with other physiological maturity indicators such as bone age, menarche and height. Several authors have shown that dental parameters are more suitable for age estimation in children because the variability is lower since calcification rates of teeth are more controlled by genes than by environmental factors. Rate of formation of the permanent teeth is not affected by premature loss of the primary teeth. Gingival emergence also called tooth eruption represents only one stage in the continuous process of dental eruption.

A Retrospective Study of Fatal Road Traffic Accidents on Autopsies done at Madurai Medical College and Hospital

T. Selvaraj¹, R. Uthayakumar²

¹Professor and HOD, ²Assistant Professor, Department of Forensic Medicine, Department of Forensic Medicine,, Madurai Medical College, Madurai, Govt.Thoothukudi Medical College,Thoothukudi, Tamil Nadu

Abstract

Aims: To study the demographic and injury profile in autopsy cases with an alleged history of RTA.

Design: It is a retrospective observational study.

Setting: Department of Forensic Medicine and Toxicology, Madurai Medical College, Madurai.

Subjects and Method: All autopsies of RTA victims which were performed between January 2018 to June 2018, were analysed for sex, age, time of RTA, type of vehicle, position of victim during RTA, nature of injury, and cause of death.

Exclusion Criteria: None

Statistical Analysis: All parameters were expressed in percentage.

Results: A total of 568 RTA victims were referred for autopsy during the period of January 2018 to June 2018. 301 (53%) victims were between 21-30 years of age, males constituted 71% of the total victims. Injuries involving limbs constituted 31% of the total injuries, followed by injuries involving head, thorax, abdomen, pelvis and spine. Among head injuries, fractured skulls occurred in 67%, Subdural Haemorrhage in 78%, Subarachnoid Haemorrhage in 62%, Extradural Haemorrhage in 49% and Intra-cranial injuries in 22%. Head injury accounted for 67% of deaths, and haemorrhagic shock for 27% of deaths.

Conclusion: Various preventive measures like speed control, helmet use, no driving under alcohol influence etc., enforcing road safety regulations, and improving emergency medical services could be used to control the increasing toll of deaths due to RTA.

Key Words: RTA, Autopsies, Injury profile, Demographic profile, Road safety

Introduction

Each year, road traffic injuries take the lives of 1.2 million people around the world and seriously injure millions more[1] The death rate is highest, and still growing in low and middle-income countries, where pedestrians, motorcyclists, cyclists and passengers are especially vulnerable[1] Moreover, estimated costs of road traffic injuries are between 1% and 2% of GNP per annum in these countries, and accounts for a loss of approximately US$ 65 billion every year; almost twice the total development assistance received worldwide by developing countries[1] India accounts for about 10 percent of road accident fatalities worldwide, 85% of all road accident deaths occur in developing countries, and nearly half in the Asia-Pacific region[1] According to the World Health Report 2002, 30.3% morbidity and 28.7% mortality occurred in the South-East Asia Region due to injuries[2]; Road traffic injuries are predicted to rise from ninth place in 2004 to fifth place by 2030 as a contributor to the global burden of diseases[3]; The purpose of the present study is to describe the demographic and injury profile in autopsy cases with an alleged history of RTA, thereby drawing public attention and awareness in order
to prevent/control Road traffic accidents.

**Material and Method**

The present retrospective study was conducted on 568 autopsy cases brought to the Forensic Department of Madurai Medical College during the period between January 2018 to June 2018 with an alleged history of RTA. For the purpose of the study, a RTA was defined as an accident which took place on the road between two or more objects, one of which must be any kind of a moving vehicle. Various study variables analyzed were sex, age, type of vehicle (light vehicle like two wheelers, three wheelers, car, jeep etc. and heavy vehicle like truck, bus, train, tractor) and position of the victim during RTA (occupant/ pedestrian/ driver), nature of injury, and cause of death. The data sources were statements of patient (dying declaration), history from relatives and friends, and police investigation reports. A detailed proforma for the purpose of recording history, epidemiological data and the details of injuries etc. was prepared for the filling observation of the present study. All the parameters were expressed in percentage and numbers.

**Observation and Results**

A total of 568 RTA victims were autopsied during the period of January 2018 to June 2018. The highest number of victims 301 (53%) belonged to age group of 21-30 years. If we considered age group of 21-40 years, it showed more than 3/4th of total RTA victims (73%). The males outnumbered the females in totality and male to female ratio was 3:1. Two wheelers were involved in 42% of RTA. Head injuries constituted 27% of the total injuries, followed by injuries involving limbs, thorax, abdomen, pelvis, and spine [Table 3]. Among the head injuries Subdural Haemorrhage was most common.

**Discussion**

In the present study, males constituted 71% and females constituted only 29% of the total victims. Moreover, age between 20-40 years was found to be more vulnerable to RTA. Similarly, in a study from South India, there were 83% males and 17% female accident victims. Among the motorized vehicles, two wheeler drivers were more (42%) involved in accidents. Being knocked down was the common mode of accidents. However, in our study, a majority of victims were pedestrians (58%). Previously a study from Delhi reported 69% injuries in the age group of 15 to 35, and males were four times more affected than females.

In a study from Maharashtra, maximum cases of RTA were among males (83.20%), and in the age group of 20 to 39 years (51.20%) [5]. Banerjee K.K. from Delhi reported 81.80% victims of thoraco-abdominal injuries all of which were in males, and all of, 40% were in the age group of 21-30 years [6]. A study from Nepal also reported 16-30 years as commonest age-group involved in RTA. Males sustained craniofacial injuries about 4 times more than females in this study [2]. A few studies reported pedestrians as the majority of victims involved in RTA, as reported in our study [5, 7]. In our study, limb injuries constituted 31% of the total injuries, followed by injuries involving head, thorax, abdomen, pelvis and spine. Among head injuries, fractured skulls occurred in 69%, Subdural Haemorrhage in 78%, Subarachnoid Haemorrhage in 63%, Extradural Haemorrhage in 47%, Intra-cranial injuries in 23%, and Contusion and Lacerations in 32% of the victims. In an earlier study from India, head was the commonest site to be injured in RTA, and Subdural Haemorrhage was the commonest haemorrhage. Laceration of brain tissue was highest among all brain tissue injuries, as reported in our study [5].

In a study from Nepal, 39% of medicolegal cases that were brought to the emergency department, were of craniofacial trauma (in 70% cases, cause is RTA [2]. Ganveer GB and Tiwari RR also reported in their study that out of total 423 subjects, 363 (85.8%) were males, while only 60 (14.2%) were female subjects, and a majority of the victims (75%) were in the age group 18-37 years [8]. Moreover, in the above study, two wheelers and LMV were the most common vehicles involved, and fracture of the bones was the common injury afflicted in accidents, as reported in our study [8]. In the present study, head injury was the major cause of death (67%), as reported earlier by Chaudhary B L, et al [5].

Conclusion

RTA is one of the major causes of disability and death all over the world and continues to be a growing menace, incurring heavy loss of valuable human resources, along with wastage of potential economic growth. Every 4 minutes, a person killed or injured in India due to RTA[1] Behaviour of the road user, vehicle characteristics, and traffic environment, coupled with human errors, have been cited as the main causes. The All India road data shows that 83.5% of the accidents were due to the driver’s fault. Other contributory factors were: mechanical defects in vehicles, pedestrian fault, fault of the passenger, bad roads, and bad weather[9]RTA is the third major preventable cause of all deaths[8]. Various preventive measures like avoiding high speeding and driving under the influence of alcohol; promoting the use of helmets, seat belts and other restraints, ensuring that people walking and cycling are more easily visible, improving the design of roads and vehicles, enforcing road safety regulations, and improving emergency medical services, could be used to control the increasing toll of deaths due to RTA. More importantly there should be legislation and stringent punishment against drunken driving. Society should be involved in implementing many campaigns such as Motorcycle Helmet Campaign, Anti-Drunk-Driving Campaign etc. In addition setting speed limits, separate lane for bicycles, proper pavement for pedestrians in vehicle congested areas and over bridge or subway in national highways crossovers is an effective strategy that minimises the risk of fatal road traffic accidents.

Identification of Sex from Facial Index in Western Maharashtra Population

Umang P. Patel1, Makandar UK2, Karkhyle Md layeeque3, Kailash Balkund2
1Assistant Professor Department of Forensic Medicine and Toxicology, 2Professor, 3Associate professor, Department of Anatomy Vedantaa Institute of Medical Sciences Dhundalwadi DahanuPalghar (Dist), Maharashtra

Abstract

Background: Facial Index anthropometry has well known, implications in health-related fields, identification of person in Forensic Medicine, Plastic Surgery, Orthodontics, Archaeology, hair style design and examination of differences between races and ethnicities.

Method: 120 (60 Male and 60 female) adults aged between 25 to 45 were studied. Facial height is divided by Breadth of Zygomatic arch and multiplied by 100. The Measurement were taken from Nasion to Gnathion and distance between two zygoma by asking the volunteers to sit in upright position, spreading calliper used for measurement of two zygoma and sliding calliper for Nasion to Gnathion.

Results: The man value of Male Facial Index was 92.1 (SD±0.40) female was 89.2 (SD±0.19), t test value was 1.97 and p value was highly significant (P<0.01) and anthropologically obtained values belong to Leptoproscopic Index.

Conclusion: The present study of western Maharashtra will be useful for medico legal expert, anthropologist to differentiate from other parts of country and abroad as well. Moreover, it would be useful to orthodontics plastic surgeons for reconstruction of face.

Key words: Spreading calliper, Sliding calliper, Ethnic, Medico-legal, Volunteers.

Introduction

The pioneer to measure the Facial Index was William.R. Leonard Professor of Anthropology from North-western university in 1987 from Evanston to study the ethnicity and race. The face is the body part that, epitomises a human person. The face is required for identification of individuals in the passport, driving license and other documents yet human face is an anatomical entity that arise through biological processes during the course of human evolution and its structure is regulated by same embryological, anatomical and physiological mechanism that form all other parts of the body thus the facial parameters have scientific identity.

Slight Modifications in the structural elements of the face (bones, muscle, cartilage) allow individual features or facial morphology to be interposed over the general, modern human face pattern. These variations in the facial morphology arise through differential growth and create an individual face that allow us to distinguish one person to another. These variations are controlled by multiple factors like hormonal, genetic, environmental and nutritional factors. Hence attempt was made to study the facial index in western Maharashtra people.

Material and Method

60 adult Males and 60 adult females regularly visiting Vedantaa hospital of Medical sciences were studied.

Inclusive Criteria: 60 Males, 60 Females normal Facial Index well-nourished volunteers aged between 25 to 40 years volunteers were selected for study.
Exclusive Criteria: Patients had history of mandibular fracture or fracture Normafacials, malnourished or any bone diseases was excluded from the study.

Method The volunteers were asked to sit in upright position. The facial Index was measured with the help of spreading calliper and sliding calliper.

Facial Height – is measured straight distance between Nasion to Gnathion (Measured by sliding calliper)

Breadth of zygomatic Arch – It was measured straight distance between twozygoma (Measured by spreading calliper).

Facial Index =Facial height X 100

Breadth of zygomatic arch

Measurements were taken as

1) Nasion – The point at Nasal root intersected by Midsagital plane (Nasal root is a depression of Nose) but at the Naso-frontal suture which can be felt by slightly probing the root of the Nose.

2) Gnathion – is the lowest point jaw intersected by the Mid Sagital plane. This point can be palpated on the lower jaw slightly another to chin.

3) Zygoma – is the most laterally placed point on zygomatic Arch.

Duration of study was about 2 years.

Statistical analysis – The obtained values of males and females were compared by ‘t’ test by using SPSS 2007 software.

Observation and Results

Table – 1: Mean values Male Facial Index was 92.78 (SD±0.40) and female Index 89.1 (SD±0.19) t test was and P value was P<0.0.

Table – 2: present Facial Index was compared with anthropological Index.

Table-3: The present study was compared previous workers.

Discussion

In the present study of Facial Index in western Maharashtra population. The mean value of Male facial Index was 92.1 (SD±0.40) and female was 89.2 (SD±0.19) t test value was 64.5 and p<0.000 (p value was highly significant) (Table-1). As per the anthropological Index both obtained values fall under Leptoprosopic anthropological Index. (Table-2). The present values were more or less in agreement with previous studies. (3)(6)(7)

The obtained anthropological values were due to nutritional, genetic and environmental factors.8 Harmony and disharmony of the face depends on the relationship between individual measurements of craniofacial Index. It was also observed that, variations of facial Index in new born and adults. Moreover, it was concluded that, facial anthropometry can change with age due to re-absorption of cranial bones including mandible.9

In addition, this bone being mesoderm origin is more plastic tissue after blood hence it adapts with environmental and nutritional changes.10 Moreover dates of fusion are usually delayed in normal individuals of short stature and accelerated in tall individuals. The factors which determine. The time of ossification is obscure. Different times of ossification of bones of skull ossify earlier. Functional and morphological factors may be involved in such cases.11 It is established fact genes became active if they get proper nutrition otherwise, they are called as silenced genes, which retard the biomechanical functions of the body.

Summary and Conclusion

The present study of Facial Index in western Maharashtra population in both sexes will be useful to medico – legal expert, anthropologist, Oral Maxillofacial surgery, plastic surgery, but this demands further genetic, hormonal, nutritional, anthropological study because exact morpho-metric values of Mesodermal derivatives are still un-certain.

Abstract

Introduction: Obesity is associated with significant global morbidity and mortality. The prevalence of obesity is on the rise, especially in low- and middle-income countries and there is a need for a tool for the prevention of this disease. As per the available pieces of evidence, dermatoglyphics can be utilized for this purpose to some extent. Dermatoglyphics is a study of configurations of epidermal ridges on certain body parts, namely, palms, fingers, soles, and toes. The term is derived from ancient Greek: derma = skin, glyph = carving. Dermatoglyphic patterns begin to develop in the 10th week of gestation and are complete by the 24th week.

Aim: The primary objective of this study was to investigate the correlation of the “atd angle” (a dermatoglyphic parameter) with the body fat distribution (or obesity).

Methods: This cross-sectional study was conducted in the department of anatomy, Maharishi Markandeshwar Institute of Medical Sciences and Research, Mullana (Ambala). It included 400 participants (200 males and 200 females) from students and employees of the college. All demographic and anthropometric parameters along with the hand imprints were obtained using standard procedures. For determining statistical significance of difference among various variables qualitative data was analyzed by Pearson’s Chi square test and quantitative data by student’s independent t-test and one way ANOVA. P-value of < 0.05 was considered significant. All analysis was done using SPSS version-20.

Results: Overall 24% of subjects (32% of males and 16% of females) were found to be obese (BMI≥25kg/m²). A statistically significant difference was observed in the values of both right and left hand “atd angle” for the comparison of obese and non-obese subjects (p=0.009 and <0.001, respectively). A statistically significant positive correlation of left hand “atd angle” was observed with BMI.

Conclusion: Dermatoglyphics can potentially be used as a tool for the prediction of obesity.

Recommendations: A large-scale study with a well-defined protocol is required for establishing dermatoglyphics as a screening tool for obesity.

Key Words: Obesity, Dermatoglyphics, BMI, anthropometric parameters, axial triradii, digital triradii

Introduction

Obesity is derived from a Greek word that means ‘overeating’ and is defined as abnormal or excessive fat accumulation that may lead to impaired health. Body mass index (BMI) is a simple and widely used parameter for the classification of overweight and obesity. According to
World health organization (WHO), people with BMI ≥25 are termed as overweight and those with BMI ≥30 are termed as obese. In 2016, about 39% and 13% of the world’s adult (individuals ≥18 years of age) population, which corresponds to 1.9 billion and 650 million adults, were overweight and obese, respectively. The prevalence of obesity has increased three-folds in 2016 when compared with that in 1975. Obesity is considered a major risk factor for the development of various non-communicable diseases such as cardiovascular diseases, diabetes mellitus, musculoskeletal disorders, and a certain type of cancers. As common hypothesis obesity occurs when caloric intake is greater than the energy expenditure. However, with the developments in our knowledge about obesity, it is now considered to be an inheritable disorder that is caused by a complex interaction of genetic, environmental, and behavioral factors. Previously regarded as an epidemic of the western world, obesity is now a major concern for low-and middle-income countries like India. Presently, identification of individuals at high risk of obesity and related co-morbidities is an important goal for healthcare providers worldwide.

Due to increase awareness about the management of obesity, various researches are being carried out to invent methods for preventing this chronic disease. Dermatoglyphics, a term derived from two Greek words: ‘derma’ meaning skin and ‘glyphic’ meaning carving, is the study of epidermal ridges and their arrangement on the volar aspect of the hand, finger, feet, and toe. Abnormal dermatoglyphics pattern arises when any disturbance occurs in the growth of the fetus during early stages of fetal life. Arches, loops, and whorls are the three basic patterns found in hand. Dermatoglyphics has proved to be helpful in the prediction of various genetic disorders and in diagnosing certain congenital malformations. Many studies have indicated the role of dermatoglyphics in the prediction of different diseases like hypertension, diabetes mellitus, asthma, rheumatoid arthritis and schizophrenia. The researchers have proposed that there might be some genetic abnormality involved in the occurrence of these diseases, which can be predicted from the analysis of dermatoglyphic parameters. For the management of obesity, it would be really helpful to have a handy tool like dermatoglyphics to predict the probability of having obesity later in life. This will help in saving many lives and resources.

Certain studies have reported that evaluation of centralized obesity (measured using anthropometric indices such as waist circumference, hip circumference, waist-to-hip ratio, and waist-to-height ratio) is a method for predicting co-morbidities associated with obesity compared with the evaluation of BMI alone. Hence, the objectives of the current study were: 1) To study the prevalence of disordered anthropometric indices in the study population;

2) To explore the correlation, if any, between body fat distribution (or obesity) and the “atd angle”, a dermatoglyphic parameter.

**Material and Method**

The present cross sectional study was conducted in the Department of Anatomy, Maharishi Markandeshwar Institute of Medical Sciences and Research, Mullana (Ambala) after ethical clearance from IEC (Institutional Ethics Committee vide Project No: IEC-1087). The study included 400 participants (200 males and 200 females) from students and employees of the college. Prior informed consent for the study was obtained from all the subjects in both English and vernacular. No personal information was retained or published without the prior consent of the individual. Subjects with age above 18 years and below 40 years were included in the study. Subjects who had a problem in standing erect, with postural defects or those confined to a wheel chair, with skin diseases like eczema, leprosy involving finger/palm, or with any inflammation, trauma, anomalies of hand were excluded. All demographic and anthropometric parameters such as age, gender, body weight, height, waist circumference, hip circumference, and BMI were collected for the study population. For assessing the prevalence of obesity, the study participants were grouped in the following 4 categories based on the BMI values:

<table>
<thead>
<tr>
<th>Categories</th>
<th>BMI (kg/m²)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Underweight</td>
<td>&lt;18.0</td>
</tr>
<tr>
<td>Normal</td>
<td>18.0 to 22.9</td>
</tr>
<tr>
<td>Overweight</td>
<td>23.0 to 24.9</td>
</tr>
<tr>
<td>Obese</td>
<td>≥25</td>
</tr>
</tbody>
</table>

For collecting the dermatoglyphic parameters, the entire palm of all the subjects was covered with ink and hand imprints for both the hands were taken on a pair of white paper sheet placed on a flat surface with a foam
pad underneath. The subject’s wrists were placed on the bottom of the paper and palms were pressed firmly so that the center is printed without any white space. Digits were printed separately and it was reviewed that the entire pattern on each digit is printed. For the purpose of the present study following landmarks of the handprints were considered: a) digital and axial triradii must be present; b) no space present in the center of the palm; c) all the fingertip area must be present and digital wrist creases can be located. The following observations were made in case of palm prints: Axial and digital triradii were observed in the palm. The obtained palm/digit prints were examined with the help of a magnifying glass. By drawing the lines connecting triradii (a, t to d), “atd angle” was measured using a goniometer.6-21
**Statistical Analysis:** For determining statistical significance of difference among various variables qualitative data was analyzed by Pearson’s Chi square test and quantitative data by student’s independent t-test and one way ANOVA . P-value of < 0.05 was considered significant. All analysis was done using SPSS version-20.

**Results**

A total of 400 study subjects comprising of 200 males and 200 females were included in the study. The results obtained for the prevalence of obesity among the study participants are shown in Table 1. The obesity was statistically significantly more prevalent among males compared with females (chi-square value = 26.584, p <0.001).

<table>
<thead>
<tr>
<th>BMI (Kg/m2)</th>

<td>32 (16%)</td>
<td>96 (24%)</td>
</tr>
</tbody>
</table>

The results for the “atd angle” measured for both left and right hands for the entire study population are presented in Table 2. The right hand “atd angle” was statistically significantly higher than the left hand “atd angle” for the entire study population ( p-value <0.001). Also, males had statistically significantly higher right and left hand “atd angles” compared with females (p = 0.011 and 0.004, respectively).

<table>
<thead>
<tr>
<th>Atd angle</th>
<th>Entire study population (n=400) Mean ± SD</th>
<th>Males (n=200) Mean ± SD</th>

<td>38.07 ± 2.81</td>
<td>37.18 ± 3.24</td>
<td>2.919</td>
<td>0.004</td>
</tr>
</tbody>
</table>

Results of the left hand “atd angle” were statistically significantly different among subjects in different BMI categories for obesity (p <0.001). A statistically significant difference was observed in the values of both right and left hand “atd angle” for the comparison of obese versus non-obese subjects (p = 0.009 and <0.001, respectively) (Table 3 and Table 4). Interestingly, a numerically higher mean value for both the right and left hand “atd angle” was observed in the obese subjects compared with that of normal subjects.

Discussion

The current study indicates that a higher value of “atd angle”, especially that of the left hand can be predictive of the risk of obesity in north Indian adults. Results obtained in the current study are in-line with those obtained in earlier studies, that is, the dermatoglyphic parameter such as “atd angle” is positively correlated with the occurrence of obesity. In the past, a few studies have been conducted and data have been published for the correlation between dermatoglyphic parameters including the “atd angle” and obesity in different age, geographic, and ethnic groups. Bhardwaj N. Et. Al. conducted a study to explore the association of the dermatoglyphic patterns with obesity in 370 school-going children of both sexes. An increase in the number of arches in thumb, mainly right thumb, was observed in 42% of the obese children. An increased “atd angle”, abnormal endings of the main palm lines, additional triradii, and reduced line were observed in 29%, 21%, 17%, and 11% of obese children, respectively. Alberti A et al. conducted a study in 2172 children and adolescents aged 10 to 19 years to explore the relationship between dermatoglyphic parameters and obesity in the center-west region of Brazil. The results suggested that a greater number of lines in the left hand finger two, a higher frequency of the radial and ulnar loop pattern can be considered the predictive marker of obesity in the study population. Dermatoglyphic characteristics are influenced by nutritional status of children and adolescents. Sharmila. D conducted another study to assess the correlation between dermatoglyphic patterns and obesity in 300 children. Results showed that an increased number of arches can be used as a predictive marker for obesity in children. Oladipo et al. conducted a study to assess the link between dermatoglyphic features and obesity in subjects from the Ibibio ethnic group in Nigeria. It was reported that subjects with obesity had a high percentage of arch pattern and a significantly higher value of “atd angle” compared with the normal subjects.

Conclusion

Dermatoglyphics could be proved a vital tool for the prediction of various diseases with a genetic link. Despite the positive correlation observed in the current study it is not yet established whether we can use any of the dermatoglyphic parameters to precisely predict obesity, due to limitations of these studies. Thus, large-scale studies with a well-defined protocol are required to be conducted with the involvement of regulatory bodies for establishing the importance of dermatoglyphics as a screening tool for obesity.

A Vignette on the Trend of Medicolegal Cases in a Tertiary Care Hospital in South India

Yogesh C1, Amirthvarshan2, Paranthaman2, Priyanka2
1Associate Professor, Department of Forensic Medicine, Velammal Medical College Hospital & Research Institute, Madurai, Tamil Nadu, 2 Undergraduate, PSG Institute of Medical Sciences and Research, Coimbatore, Tamil Nadu

Abstract

Introduction: Profiling of medico-legal cases is an important aspect for the prevention of preventable casualties in future and to study the genuine crime in the area which contributes a substantial workload in casualty department.

Objectives: The aim of the study is to measure the incidence of medicolegal cases recorded in a tertiary care hospital in South India in one year.

Method: A retrospective analytical content based analysis was made on 776 medicolegal cases recorded in a tertiary care hospital in South India in one year from June 1st 2017 to May 31st 2018 and the results were tabulated.

Results: Of the 776 cases, 545 were men and 231 were women with RTA constituting 70.74% (549 cases) of the cases and poisoning with 10.69% (83 cases) of the cases forming the majority of the case profile.

Conclusion: The study concludes that road traffic accidents are the major causes of medicolegal cases recorded in a tertiary care hospital in South India. Preventive measures of better traffic control and road safety are to be instituted at the earliest. More number of medicolegal profiling should be conducted in every region for further measures.

Key words: Medicolegal profile; RTA; Road safety; Casualty Department; Documentation.

Introduction

A medico-legal case is a case of injury or illness where the attending doctor, after eliciting history and examining the patient, thinks that some investigation by law enforcement agencies is essential to establish and fix responsibility for the case in accordance with the law of the land1. Common medico-legal cases include alleged cases of assault, road traffic accidents, burns, poisoning, snake bite, insect bite, industrial accidents, alcoholic intoxications etc.

The casualty department is backbone of every hospital because almost all cases of medical emergencies reported first to Casualty Department of hospital, and also Casualty Department also deals with the medico legal cases more frequently than any other department of hospital and so medico legal cases constitute substantial proportion of workload. A medico-legal register should be maintained in the casualty of every hospital and details of all medico-legal cases should be entered in this register, including the time and date of examination and the name of the doctor who is dealing with the case. This would be of immense help for future reference, when the patient through the court/the police, requests for a copy of the medicolegal report. A case may be registered as an MLC even if it is brought several days after the incident2.

The reporting of medico-legal cases is imperative to recognize the burden of medico legal cases, calculate
their risk and for the avoidance of preventable casualties in future. The idea is to initiate legal proceeding at the earliest so that maximum evidence can be collected to study the crime pattern in the area. The mortalities and morbidities from all medicolegal causes has been increasing at an alarming rate in our country and also throughout the world, yet to be controlled effectively; by the year 2020 mortality from injury will be more than those from communicable diseases. Despite this documentation, injuries are still not well recognized as a major public health problem in our country.

Profiling of medico-legal cases is an important aspect for the prevention of preventable casualties in future and to study the genuine crime in the area. In spite of recent advancement of technology in the field of medical sciences, death and deformities due to all causes, are yet to be controlled successfully; rather incidences of road traffic accidents has been increasing at an alarming rate throughout the world. Not all medicolegal cases are being recorded as many of them remain unnoticed even after thereoccurs a death of an individual. Hence, this study aims to find the profile of various medicolegal cases that was recorded in a tertiary care hospital in South India, most probably covering the data of south Indian population.

### Method

A total of 776 medicolegal cases were studied that was recorded in one year from June 1st 2017 to May 31st 2018 in a tertiary care hospital in South India. It was a retrospective analytical study with secondary data obtained from the Medical Records Department in the hospital. It was a based on content analysis where a proforma was formed related to the nature and details of the medicolegal cases that was used to obtain the data.

All age group registered with medicolegal cases and treated in the hospital were included in the study. Unregistered medicolegal cases and cases that were sent for further referral from the hospital were excluded from the study. The data was analysed and results were tabulated using simple tables and pie charts. Percentage calculations were made for better statistical reporting.

### Results

Of the 776 cases analysed, 545 cases were males and 231 were females accounting for 70.2% and 29.8% respectively. Of all the 776 cases, 99.36% (771 cases) were alive and discharged post treatment and 0.64% (5 cases) were dead in spite of adequate medical care and all of them were due to severe RTA.

With regard to nature of medicolegal cases, 549 cases were due to road traffic accidents forming 70.7% of the total medico-legal cases. There are 30 cases of burns which contributes to 3.87% and 12 cases of assault which amounts to 1.54% of the total cases. 41 cases are due to fall from height constituting 5.28% of the total cases collected.

38 cases are due to occupational injuries which is about 4.89% of the total cases. 10 cases of snake bite and 3 cases of scorpion sting were collected constituting about 1.3% and 0.38% respectively . 6 cases of hanging and 4 cases of self-inflicted wound accounting to 0.77% and 0.51% respectively were collected. A total of 83 cases due to various poisoning were noticed resulting in 10.69% of all the cases. The details of each poisoning are given in the Table 1. Pie charts 1 and 2 are given to depict the sex distribution and the nature of medicolegal cases respectively.

Discussion

Medico-legal case is an integral part of medical practice that is frequently encountered by medical officers working in emergency department. For such patients, not only treatment, but exhaustive documentation is also mandatory. It is the responsibility of a registered medical practitioner to judge each and every case properly and in doubtful cases, it is mandatory to inform the police as required by law. This saves the doctor from unnecessary and needless allegations later.

Injuries account for 10.1% of the world burden of disease in 2013. In 1990, 5 million people died due to trauma and injuries. The number is expected to rise to 8.4 million by year 2020. Road traffic accidents will be the second most common cause of disability in the developing world. In a retrospective study profile of medico-legal cases in the casualty department of Sri Aurobindo Medical College and PGI, Indore for a period of 1 year, from 1st June 2016 to 31st May 2017, Majority of cases about 57.70% were of road traffic accident (RTA). In our study that was done exactly one year after, 70.74% were RTA.
showing the increasing trend of RTA year after year due to various factors like the increasing high speed vehicles, poor traffic control and adventurous mindset of the people especially youngsters.

Earlier reports demonstrated that everyday almost 700 people die from poisonings around the world and for every person that dies, several thousands more are affected by poisoning\textsuperscript{15,16}. It has been estimated that, in India five to six persons per lakh of population die due to acute poisoning every year\textsuperscript{17}. Pattern of poisoning in a region depends on various factors which include availability and access to the poison, socioeconomic status of an individual, cultural and religious influences, etc. In India, as agriculture is the main occupation, insecticides and other agrochemical fertilizers are used to a greater extent and the poisoning with such products are more common\textsuperscript{18}. This was similar to our study where total poisoning cases were found to be 10.69\% (83 cases) of which cow dung (25.30\%) and OPC along with rat killer poison (12.04\%) constituting the bulk of the poisoning proving the fact they are more commonly used, available and easy to handle by the population.

One year retrospective study was carried out between 1\textsuperscript{st} July 2012 to 30\textsuperscript{th} June 2013 from the in the causality data of Government Medical College, Akola which revealed that Burns - 21.87\% (449 cases) constituted majority of medico legal cases\textsuperscript{19} , comparable to our study which has 3.87\% (30 cases) of cases. The decrease in percentage may be attributed to better fire safety precautions and easy availability of fire service on call.

Considerable amount of occupational injuries were recorded which amounts to 4.89\% (38 cases) of total cases. In a study of 173 medico-legal cases reported to the casualty department of Sri Siddhartha Medical College, Tumkur during the period from 1\textsuperscript{st} January 2012 to 31\textsuperscript{st} August 2013, 21 cases were recorded for occupational injuries\textsuperscript{20}. The rise may be due to rapid industrialisation in the past five years engaging more people in hazardous activities.

10 cases of snake bite were recorded in our study – a very lesser number because of the high industrial oriented occupation and less field related work and also better protective measures in houses and fields. The treatment of snake bite cases have gone a far way better in the recent decade with appropriate clinical management and anti-venom availability since there were no deaths among the 10 cases. This was similar to the study done in tertiary care hospital in Bengaluru during the period of January 2013 to June 2013\textsuperscript{21}.

Other cases such as assault and fall from height contributed to 1.54\% (12 cases) and 5.28\% (41 cases) respectively. The fall from height were mostly seen in young children mostly due to accidental slip and fall as a result of lack of attention. Overall, the medicolegal profile reflected on the alarming rise in RTA and a considerable amount of poisoning which may indicate the stress and depression level of the population though accidental poisonings have to be ruled out. Road traffic accidents and poisoning cases continue to be a growing menace, incurring heavy loss of valuable man-power and human resources in the form of death and disability along with a corresponding drain of potential economic growth\textsuperscript{22}. There should be a road-safety program in which all the cities of our country must be ranked on the basis of various criteria like standard of roads, functioning of traffic signals, obeying of traffic rules by the citizens etc. Despite the weight of evidence, the importance of preventing and treating injuries in low and middle income countries has yet to be embraced by global public health community\textsuperscript{23}. Poison prevention strategies can be implemented at various levels such as strict implementation of pesticide act, so that import, manufacture, sale, transport, distribution and use of pesticides can be under the supervision of the government and controlling access to dangerous pesticides and follow secure storage practice\textsuperscript{24}. Health education to adolescents at school and college level about poisoning and its first aid treatment and strict implementation of anti-dowry law, marriage counselling and women empowerment will help in decreasing the day to day tension in married life and decrease the incidence of poisoning among house wives.

**Conclusion**

The study concludes that road traffic accidents are the major causes of medicolegal cases recorded in a tertiary care hospital in South India followed by poisoning. The basic principles of injury prevention are education, engineering, uniform enforcement of law \& order, pre-hospital care and the evaluation. Proper education, training for safety standards and behaviour modification are interlinked; and are required to be implemented in the community to prevent all kind of injuries including domestic violence. Injury related research should be increased; and improvement in health
care facilities and posttraumatic care should be worked on. Further large number of prospective studies should be carried out that would assist various organizations to set various causative risk factors, circumstances, chain of events; and the preventive measures accordingly to bring down the incidence of not only RTA but all medicolegal cases and shaping the future generation and society more towards being more humane and reaching the goal of World Peace.

Abstract

Introduction: RTA is the public health issue and cost a lot to individuals, families, communities and nations as injuries and deaths due to road traffic accidents (RTA) are a major public health problem in developing countries.

Objectives: The present study was carried out with the objective to find out the profile of RTA cases in a tertiary care hospital in South India in one year.

Methods: A retrospective analytical content based analysis was made on 549 RTA cases recorded in a tertiary care hospital in South India in one year from June 1st 2017 to May 31st 2018 and the results were tabulated.

Results: Of the 549 cases, 409 cases were males and 140 were females of which head injury with 182 cases (29.50%) forms the majority of the injury followed by orthopaedic injuries with 163 cases (26.04%).

Conclusion: This study thus analyses various aspects of RTA with head injury being the most common and and its various confounding factors which shows that there is clearly a need for road safety education particularly targeting student community.

Key words: RTA; Head injury; Epidemic; Students; Road safety.

Introduction

Globalization has led to the expansion in the road network along with rise in motorization of vehicles. Simultaneous population explosion and rapidly increasing use of motor vehicles has led to rise in the number of road traffic related accidents, road accident injuries and fatalities¹. Death from road traffic accidents (RTA) and in particular Motor vehicle Traffic Accidents have been characterized worldwide as a hidden epidemic which affects all sectors of society². RTA is the public health issue and cost a lot to individuals, families, communities and nations.

Injury and deaths due to road traffic accidents (RTA) are a major public health problem in developing countries where more than 85% of all deaths and 90% of disability-adjusted life years were lost from road traffic injuries³. The statistical profile reflects a global estimate of 5.1 million deaths in 2000, which was due to injuries that accounted for 10% of deaths due to all causes. Out of this a quarter of injury-related deaths occurred in the South-East Asian region⁴.

As a developing country, India is no exception. Not a day passes without RTA happening in the roads in India in which countless number of people are killed or disabled. The data for fatal accidents presented to the Parliament by the Ministry of Road Transport and

Corresponding author:
Associate Professor, Department of Forensic Medicine, Velammal Medical College Hospital & Research Institute, Madurai, Tamil Nadu. Email: dr.c.yogesh@gmail.com. Phone: 9980025510
Highways for year 2008 shows that 119,860 people perished in mishaps that year and the national and state highways accounted for nearly half of all road accidents. Deaths due to road accidents in 2009 were reported to be 126,896 and in 2010 it increased to 133,938 which is about 5.5% over and above the previous year’s deaths

The reasons for the high burden of road traffic injuries in developing countries are increase in the number of motor vehicles, poor enforcement of traffic safety regulations, inadequacy of health infrastructure, and poor transport facility. Road crashes deserve to be a strategic issue for any country’s public health and can lead to overall growth crisis, if not addressed properly. In spite of recent advancement of technology in the field of medical sciences, death and deformities due to all causes, are yet to be controlled successfully; rather incidences of road traffic accidents has been increasing at an alarming rate throughout the world. If the current trends continue, the number of people killed and injured on the world’s roads will rise by more than 60% by 2020. Hence, this study aims to provide an insight into the road traffic accidents reported to a tertiary care hospital in South India, probably covering the data from south Indian population.

**Method**

A total of 549 RTA cases were studied that was recorded in one year from June 1st 2017 to May 31st 2018 in a tertiary care hospital in South India. It was a retrospective analytical study with secondary data obtained from the Medical Records Department in the hospital. It was a based on content analysis where a proforma was formed related to the nature and details of the RTA cases that was used to obtain the data.

All age group registered with RTA cases and treated in the hospital were included in the study. Unregistered cases and cases that were sent for further referral from the hospital were excluded from the study. The data was analysed and results were tabulated using simple tables and pie charts. Percentage calculations were made for better statistical reporting.

**Results**

Of the 549 cases, 409 were males and 140 were females accounting for 74.49% and 25.51% respectively. With regards to age distribution, 33 cases (6.01%) under 15 years of age, 170 (30.96%) cases from 16-30 years of age, 141 (25.68%) cases from 31-45 years of age, 135 (24.59%) cases from 46-60 years of age and 70 (12.75%) cases over 60 years of age.

With regard to time of incident, 60 cases (10.92%) occurred before 8am, 220 cases (40.07%) from 8am-4pm and 269 cases (48.99%) from 4pm-12pm. Various injuries that occurred in the RTA cases are tabulated in Table 1. The duration of hospital stay was divided into 3 categories: 238 cases stayed less than 5 days, 170 cases stayed between 6-10 days and 100 cases were hospitalised more than 10 days.

The time lapse between incident and admission in hospital is tabulated in Table 2. Among the 549 cases, 544 were alive and 5 were dead due to treatment failure and 9 cases discharged against medical advice. On the grounds of occupation, 67 cases (12.20%) among professionals, 92 cases (16.75%) among labourers, 81 cases (14.75%) among housewives, 155 cases (28.23%) among students, 42 cases (7.65%) among retired, 61 cases (11.11%) among unemployed, 51 cases (9.28%) among children under 15 years of age were reported. Pie charts 1 and 2 are given to depict the sex distribution and the occupational distribution of poisoning respectively.

DISCUSSION

William Haddon (Head of Road Safety Agency in USA) has pointed out that road accidents were associated with numerous problems each of which needed to be addressed separately. Human, vehicle and environmental factors play roles before, during and after a trauma event. Accidents, therefore, can be studied in terms of agent, host and environmental factors and epidemiologically classified into time, place and person distribution.

In our study, there was a male preponderance similar to the study done in Delhi and it is due to greater male exposure on urban streets and predominance of male drivers in Indian roads. Also maximum number of cases were recorded in the age group of 16-30 years- the most active and productive years of life similar to a study done by Henricksson et al. Tendency of this age group to show scarce attention to traffic rules and regulations and nonuse of safety devices such as helmets, seatbelts, restraints, and so on, can be a possible explanation for the same. This reveals that the most active and productive age group of population are affected in RTAs, which poses a serious economic loss to the community.
This is in accordance with higher incidence among students in our study (155 cases) similar to an epidemiological study done in South India\textsuperscript{14}. The road accidents are happening most often due to the reckless and speedy driving of the vehicles, not obeying or following traffic rules\textsuperscript{15} and the adventurous nature of the youth are the main factors behind rise in RTA among student population. The next major affected group is labourers- the reason may be that the labourers travel in trucks carrying bricks, sand and other heavy materials. It is interesting to note that among the type of motorized vehicles trucks were involved in the highest number of accidents, and labourers often travelled in the truck as part of their work\textsuperscript{10}. Housewives are affected as they most often travel as pillion riders with their spouse.

Most number of cases occurred post 4pm which is similar to study done by Nilambar et.al\textsuperscript{16}. These hours are the busiest as commuters go to and return from the schools, offices, factories and business place. Among the injury profile, head injury remains the most common injury similar to study done in Mangalore\textsuperscript{17} which shows the lack of awareness of safety equipments like helmet or wearing a seat belt in a car etc. This was followed by fractures in limbs (163 cases) more commonly seen with two wheeler riders as they tend to fall outwards and stretch their arms or legs. Facial injuries are almost always grievous injuries which may require the treatment of plastic surgery. Minor injuries like abrasions, sprains, contusions are treated with bandages and simple medications.

The time lapse is crucial in RTA because the first hour is crucial in trauma management as cases reaching more than one hour are subjected to more severe morbidity and mortality\textsuperscript{18}. Majority of cases were addressed with a time lapse of 1-6 hours (342 cases) in our study. A positive linear trend as well as logarithmic trend was observed with delay in admission to the hospital and severity of outcome\textsuperscript{19}. So an effort should be made to provide timely and proper medical services to RTA victims via mobile emergency services, quality trauma centers and proper rehabilitation services. This was evident in our study as 5 cases died due to late admission in the hospital. 9 cases were discharged against medical advice due to lack of adherence, affordability, disbelief in the treatment of the doctor etc.

Human factor contribute significantly to increasing number of road accidents in India. Most drivers continue to be acting like maniacs in a tearing hurry and error in judgment often leads to major accidents. Reckless driving, over speeding, decline to follow traffic rules, and drunken driving are main reasons for road accidents. Small bars along the Indian highways are of prime concern to control drunken driving. India has laws to check the drunken driving but its effective implementation is still to be worked upon.

Realizing this serious Public Health Issue happening globally, the WHO in 2004 came out with a theme of “Road Safety is No Accidents” to highlight the urgency to tackle the issue on a priority basis\textsuperscript{20}. Prevention of RTA is a responsibility of various agencies and a multi-disciplinary approach will effectively reduce the incidence of RTA and reduction in injuries and deaths on the roads. “Road Safety Week” is observed throughout the country every year in the month of January in order to highlight and emphasize the need for safe roads by taking up activities to promote the concept\textsuperscript{21}.

Measures promoting safe driving behavior such as mobile usage, eating, inadequate attention, fatigue, negligence; maintenance of vehicle condition; adequate protection including abs, helmets, safety, and others; promoting licensed vehicle and coping skills when integrated with efficient and effective legislation of traffic regulation and maintenance and implementation by legislation (whose absence has been the influencing factor for increased number of RTA among youths) are bound to have a more pronounced positive effect. Protection is needed for three main vulnerable groups—pedestrians, who in urban areas constitute up to 70% of the fatalities; passengers commuting on buses, trucks, and minibuses, who constitute the next largest population group affected; and cyclists. Addressing the risks of these three groups will require multiple policy initiatives\textsuperscript{22}.

**Conclusion**

This study thus analyses various aspects of RTA with head injury being the most common and and its various confounding factors which shows that there is clearly a need for road safety education and it should be directed towards road users, who are frequently involved and injured in RTAs (e.g. students). India’s Motor Vehicles Act lagging far behind the needs of a fast-motorizing society is painfully evident from its road safety record. the Bill for creation of a statutory National Road Safety and Traffic Management Board must be speeded up- such an agency is vital to set standards...
for road design, inspect existing roads, and investigate accidents scientifically. But strict implementation of traffic rules and stringent punishments alone will not solve the persisting crisis. Change in the mind set of riders and drivers and road users realizing their responsibilities alone will bring about a change. Further large number of prospective studies should be carried out that would assist various organizations to set various causative risk factors, circumstances, chain of events; and the preventive measures accordingly to bring down the incidence of not only RTA but all medicolegal cases and shaping the future generation and society more towards being more humane and reaching the goal of World Peace.

Prevalence of Non-Strabismic Binocular Vision Dysfunction in A Hospital based Population

Rajib Mandal¹, Rajesh Kamath²

¹Principal, Netra Jyothi Institute of Allied Health Sciences, Udupi, Karnataka, ²Assistant Professor, Prasanna School of Public Health, Manipal Academy of Higher Education, Manipal, Karnataka, India

Abstract

This study was aimed towards finding the prevalence of non strabismic binocular vision dysfunctions (NSBVD) in the Indian population presenting with different symptoms pertaining to binocular vision disorders. **Method:** This retrospective study included one hundred and sixty one patients who presented to the out- patient department with symptoms of binocular vision dysfunction, during a period of one year. Patients were in the age group of 18 ±6.93, with 71 males and 90 females. Their binocular vision dysfunction was assessed via several diagnostic modules/tools designed for binocular vision assessment. **Results:** Results indicate that the most common binocular vision anomalies in this studied population are fusional vergence dysfunction with accommodative infacility (40.38%), convergence insufficiency with accommodative infacility (24.36%), Fusional vergence dysfunction (7.05%). Convergence Insufficiency and Accommodative infacility showed the same prevalence of 7.7%. **Discussion:** Accommodative and non-strabismic binocular vision dysfunctions are commonly underdiagnosed/undiagnosed in clinical practice. These disorders affect academic performance, sports activities and general quality of life. An appropriate detailed orthoptic examination and accurate diagnosis is necessary to manage these binocular vision dysfunctions.

**Keywords:** Headache, Incidence, Non strabismic binocular vision disorders, Orthoptic evaluation, Focusing problem, accommodative insufficiency, fusional vergence dysfunction.

Introduction

Binocular vision anomalies are the most common visual disorders. Patient complaints include decreased vision, headache, eyestrain, watering, blurred vision while doing near tasks, double vision (diplopia), a lack of concentration, difficulty focusing at near to far or vice versa and poor reading comprehension. These symptoms have a negative impact on academic performance.¹²³

Purcell et al. established an indirect comparison figure for symptomatic binocular dysfunction. They reviewed the records of 120 patients at an optometry college clinic. The patients were between 25 to 35 years of age without strabismus, amblyopia, eye pathology or current contact lens wear. In addition to refractive error they found there were 30.8% patients were with the symptoms (ex: headache, eye strain, watering, redness, photophobia and double vision ) of NSBVD who needed vision therapy treatment with prism, bifocals, or near point lenses. Other studies have established the correlation of accommodative and non-strabismic binocular dysfunctions to learning difficulties.²³⁴⁵⁶ Successful treatment lead to a significant improvement in the quality of life of this group of patients.

These dysfunctions are generally missed out unless a complete orthoptic and binocular vision examination is performed. Vision therapy is a very useful treatment for these conditions with the help of lenses and prisms. In India, such epidemiologic studies on non-strabismic binocular dysfunction are lacking. We believe this is the first study in India providing valid epidemiologic information about the prevalence of non-strabismic binocular disorders in a clinic population.

Methodology

It is a retrospective single centre study including patients presenting with symptoms of binocular vision anomaly at Karthik netralaya, Super-specialty Eye Hospital, Bangalore, India during the period of one year (January 2014 to January 2015). One hundred and sixty one (n=161) patients between the age group of 18 ±6.93 were screened. Exclusion criteria included strabismus, amblyopia, nystagmus, contact lens users, best corrected visual acuity < 6/6 in each eye, cataract, ocular pathologies, neurological and myogenic disorders, psychological disorders and previous ocular surgeries which could affect the accommodation-vergence relationship. All patients underwent comprehensive ocular examination and were enrolled for detailed orthoptic evaluation. Findings and diagnosis were documented into excel spreadsheet. Visual acuity assessment was done for near (at patient’s functional distance) and distance with Jaeger’s Chart and Snellen’s chart respectively. Objective refraction was done with the help of retinoscope (Welch allyn retinoscope) followed by subjective refraction with phoropter. Assessment of binocular vision disorder was performed by a standardized protocol which included detailed history of ocular symptoms, sensory evaluation of binocular vision for near distance with Worth 4 dot test at 40 cm and 6 meters respectively, Cover test with accommodative targets for near and distance, prism bar cover test, AC/A ratio, MEM retinoscopy, assessment of near point accommodation and near point of convergence, amplitude of accommodation, negative and positive fusional vergence and vergence and accommodative facility. The result of each of the tests were compared first with the population norms, derived from Morgan’s data.

Results

Only symptomatic subjects with abnormal clinical findings were included. Of the 161 subjects screened, 90 were females and 71 were males. Mean age was 18 ±6.93 years. 156 were diagnosed with Non strabismic binocular vision disorder.

Fig 1: Graphical presentation of total patients male vs. female.

The most prevalent symptoms were frontal headache or asthenopia after prolonged near work (50.31%), followed by blurring of vision and difficulty in focusing when looking from near to far (20.50%). 9.31% had skipping lines or words while reading followed by blurness of vision (6.21%). 3.72% showed eyestrain while reading. 6.21% were not comfortable with spectacles and the remaining 3.72% presented watering, intermittent diplopia and loss of concentration. (see figure 2)
The prevalence of non-strabismic binocular vision disorder detected in this age group was as follows:

Fusional vergence dysfunction with accommodative infacility (40.38%), convergence insufficiency with accommodative infacility (24.36%), fusional vergence dysfunction (7.05%). Convergence Insufficiency and accommodative infacility showed the same prevalence of 7.7%. Excluding these, other binocular dysfunctions have less prevalence, as shown in table no 1.

Discussion

This retrospective study was done using standard diagnostic criteria according to the population norms derived from Morgan’s data. According to comprehensive optometric evaluation of the adult population in India, non strabismic binocular vision dysfunction was prevalent. Being a clinical population study, the prevalence of the dysfunction was expected to be higher than a general/normal population study, which was a limitation for this study. In this study fusional vergence dysfunction with accommodative infacility and convergence insufficiency with accommodative infacility had higher prevalence (40.38%). The ability of change of accommodation of eye at various distance with enough speed and accuracy to maintain normal visual function is called as accommodative facility.

This can be measured as monocularly or binocularly. To measure this usually the accommodative object (a small target depends on the best corrected visual acuity) fixate alternately through plus and minus lens, which are interchanged as soon as the target appears clear. The operation is repeated many times and results are commonly present in cycle per minute (one cycle indicates that both plus and minus lens have been cleared). This disorder is commonly associated with asthenopia. With accommodative infacility there is no over-action of accommodation, ciliary spasm, or spasm of the near reflex. There is normal amplitude of accommodation. However there is difficulty in clearing -2.00D and +2.00D with accommodative flipper, monocularly and binocularly. Positive and negative relative accommodation may be below normal value (PRA ≤1.25 D and NRA ≤1.50 D), as per results obtained in this study.

Convergence insufficiency can be described as a condition with near exophoria (greater than distance), receded near point of convergence with low AC/A ratio and reduced positive fusional vergence. In literature, the frequency of convergence insufficiency in pediatric clinical population differs greatly, with scheiman et al. reporting 4.6% Rouse et al. reporting 6.0%, shin et al. reported 28%, dwyer reporting 33%, though all these reports show significant prevalence. Our study shows similar data with 7.7% convergence insufficiency and 24.35% of convergence insufficiency with accommodative infacility. Our study also supports all these study by showing the prevalence of convergence insufficiency 7.7% and convergence insufficiency with accommodative infacility 24.35%. But all these above mention studies mainly focused on the pediatric age group while this study involved the young adult age group.
Prevalence of fusional vergence dysfunction was 7.05%. Fusional vergence dysfunction is a sensory motor disorder of the visual system characteristic by reduced PFV (positive fusional vergence) and NFV (negative fusional vergence) measured at near and distance for at least one of three –blur, break, and recovery. Minimum normative NFV is ≤9/17/8 for blur, break and recovery and minimum normative PFV is ≤12/15/4 for blur, break and recovery. As per textbook definition accommodative spasm or excess is a clinical state of excess accommodation (lens focusing); spasm of near reflex is the tired of excess accommodation, excess convergence and excess miosis. This condition often triggered by stress or prolonged reading.14 In a study Esteban Porcar et al. showed that accommodative and non-strabismic binocular vision problems were prevalent (32.3%) in a population of university students. Accommodative excess was the most common dysfunction detected (10.8%).15 But our study did not support this study result. In this study we got a lower prevalence of accommodative excess (2.56%). Accommodative and non-strabismic binocular vision dysfunctions are commonly under-diagnosed / undiagnosed in clinical practice. It is already proved that these disorders affect academic performance, sport activities and general quality of life. Findings of our study suggest that an appropriate detailed orthoptic examination and accurate diagnosis is necessary to manage these binocular vision dysfunctions.

Non strabismic binocular dysfunctions have a significant prevalence in society and have a bearing on the quality of life. Hence these disorders need detailed evaluation and appropriate management by clinicians. Data presented in this study has a relatively small sample size; and a large scale epidemiological study will further reflect the status of binocular dysfunctions in the Indian population.

Determination of Stature From Index and Ring Finger Lengths in South Indian Population

Jayanth SH¹, Basappa S Hugar², S Praveen³

¹Asst Professor, Basappa S Hugar, ²Associate Professor, ³Professor Dept of Forensic Medicine, MS Ramaiah Medical College, MSRIT PO, MSR Nagar, Bangalore

Abstract

Introduction: Personal identification is an important role of forensic experts during mass disasters like earthquakes, tsunamis, and plane crash etc. Stature determination is an important factor in establishing identity in forensic practice. Forensic anthropometrists use various anthropometric techniques to determine stature from such dismembered body parts. These techniques aim to derive equations from various body measurements that could estimate stature in males and females.

Aim: The aim of present study is to correlate index and ring finger lengths and stature in both sexes and to derive linear regression equations to estimate stature.

Materials and Method: The study was conducted in the Department of Forensic Medicine & Toxicology, M.S. Ramaiah Medical College Bangalore in the year 2019. The material consisted of 150 young and healthy students (66 males and 84 females) in the age group of 20-21 years after taking informed consent to participate in the study. Subjects of south Indian origin were selected based on their mother tongue. The data obtained were computed and analysed using Statistical Package for Social Sciences (SPSS, version 25.0) computer software.

Results: In the present study, mean stature, index finger length and ring finger length were significantly higher in males than females. Statistically significant correlation was observed between stature, index finger length and ring finger length in right and left hands. Correlation coefficient was higher among males than females. Among males left ring finger length and in females right index finger length showed more correlation with the stature.

Conclusion: Sex specific linear regression formulae were derived for estimating stature from index finger length and ring finger length. Study concludes that stature can be estimated from the index finger length and ring finger length with a reasonable accuracy among South Indians.

Key Words: Forensic Science, Stature, Index finger length and Ring finger length, Identification, Anthropometry

Introduction

Establishment of the identity of the deceased is of the greatest significance to the forensic expert in situations where bodies are badly mutilated. Identification of victims from dismembered human remains has always been a challenging medico-legal investigation. Such a scenario is commonly encountered in mass disasters or in homicides where deceased bodies have been dismembered to suppress the identity of the murdered. Stature estimation from skeletal remains and body parts is based on the principle that height of an individual has a definite and linear relationship with various body parts and long bones of an individual.

Estimation of stature is more accurate and reliable using long bones than any other part of the body. Studies on the estimation of stature from finger length and phalanges are limited in literature when compared to studies for estimation of stature from upper and lower
extremities.

Dimensional relationship between body segments and the whole body has been the focus of scientist, anatomist and anthropologist for many years. For this purpose, many sets of regression equation have been developed, and the better known are Karl Pearson, Trotter and Glesser from western countries and Pan (1924), Singh and Sohal (1952), and Mehat and Thomas were from India. Multiple methods need to be applied in different scenarios for a positive identification.

The present study was carried out to correlate index and ring finger lengths with stature in both sexes specifically for population of South India.

**Material and Method**

The study was conducted in the Department of Forensic Medicine & Toxicology, M.S. Ramaiah Medical College Bangalore in the year 2019. The material consisted of 150 young and healthy students (66 males and 84 females) in the age group of 20-21 years after taking informed consent to participate in the study. Subjects of south Indian origin were selected based on their mother tongue.

Sliding calipers was used to measure both index and ring finger lengths. Measurements were taken from the midpoint of the proximal crease at the base of the fingers to their tips.

Stature is the vertical distance from vertex to the floor with the head of the subject held in the Frankfurt Horizontal plane. It was measured with the help of an anthropometer rod.

**Inclusion criteria**

1. Medical students above 20 years of age and less than 21 years of age studying in M.S. Ramaiah Medical College, Bangalore

2. Subjects of south Indian origin using mother tongue (Tamil, Telugu, Malayalam, and Kannada etc.) as a criteria for origin.

**Exclusion criteria**

1. Subjects having any skeletal deformity and other disorders which could have affected the general or bony growth.

**Statistical Analysis**

The data obtained were computed and analysed using Statistical Package for Social Sciences (SPSS, version 23.0) computer software. Correlation coefficient was calculated and the correlation between the stature and index and ring finger length was drawn. Regression formulae were derived for stature estimation from index finger length (IFL) and ring finger length (RFL) in males and females keeping stature as the dependent variable and index finger length and ring finger length as an independent variable. P-value of less than 0.05 was considered as significant.

**Results**

The stature ranged from 153.3-186.0 cm in males and from 136.5-177.8 cm in females. Mean stature was significantly larger in males (Table No. 1). Mean IFL on right and left sides respectively was 7.41 cm and 7.38 cm in males and 6.79 cm and 6.72 cm in females. RFL was greater than IFL in males and in females RFL was greater only on the left side. The mean RFL on right and left sides respectively was 7.52 cm and 7.61 cm in males and 6.77 cm and 6.83 cm in females. Finger length measurements (IFL, RFL) were significantly larger in males than females in both hands.

Descriptive statistics of stature, IFL and RFL in both hands are shown in Table No. 1 and 2. Statistically significant correlation was observed between stature and finger lengths (IFL, RFL) in right and left hands (Table No. 3). Pearson correlation (r) for stature and finger lengths was higher among males (ranging between 0.384 for the right IFL and 0.538 for the left RFL) than females (ranging between 0.432 for the left IFL and 0.506 for the right IFL). Among males and females, correlation coefficient was higher for the ring finger length than the index finger length except for females on the right hand. In males the correlation was higher between left ring finger and stature (r=0.538) while in females the correlation was higher between right index finger and stature (r=0.506).

Linear regression models derived for reconstruction of stature in males and females are shown in Table No. 4. Coefficient of Standard Error was determined to find the predictive accuracy of linear regression models for stature estimation from IFL and RFL. The Coefficient of Standard Error in stature estimation from IFL and IFL using linear regression models ranged between +/- 1.57 to +/- 1.7 among females and between +/- 1.56 to +/- 1.86 in males. IFL and RFL showed a significant correlation with the stature in males and females. Left RFL in males and right IFL in females appear to be the better predictors of stature.

**Discussion**

Stature is one of the primary characteristics of identification. Estimation of stature of an individual is an important aspect of medico legal examination. Ratio in size of different parts of the body to one another and to the stature varies considerably in different individuals as also in different races. Studies have shown that no two individuals are exactly alike genetically; even identical twins differ in some aspects, and the variability is strongly influenced by genetic and environmental factors. (5)

Studies where stature can be estimated from finger lengths are few. Hence the present study was conducted to correlate index and ring finger lengths (IFL & RFL) with stature in both sexes specifically for population of South India. Amongst the study sample, mean stature was significantly larger in males (172.67 cm) than in females (158.39 cm). The mean RFL on right and left sides respectively was 7.52 cm and 7.61 cm in males and 6.77 cm and 6.83 cm in females. Finger length measurements (IFL, RFL) were significantly larger in males than females in both hands.

Statistically significant correlation was observed between stature and finger lengths (IFL, RFL) in right and left hands. Pearson correlation (r) for stature and finger lengths was higher among males (ranging between 0.384 for the right IFL and 0.538 for the left RFL) than females (ranging between 0.432 for the left IFL and 0.506 for the right IFL). In males the correlation was higher between left ring finger and stature (r=0.538) while in females the correlation was higher between right index finger and stature (r=0.506).

Tyagi et al studied the subjects from Delhi and found positive correlation between stature and finger lengths and have suggested that index finger was best for the prediction of stature in both males and females. (6) Jasuja et al had studied the hand and four phalange lengths in 60 subjects belonging to Jat Sikhs community. The researchers had observed correlation coefficient that ranged from 0.215 to 0.681 and concluded that stature could be estimated from studied parameters. (7) Rastogi et al estimated stature from middle finger and noted a positive correlation that ranged from 0.504 to 0.696 between middle finger length and stature while studying the north and south Indian population. (8) Varghese et al studied in Mysore, India and found that best finger to predict the height in case of males was left thumb and in females it was right thumb. (9)

In a study by Manirul Islam, hand length showed a positive correlation with stature. (10) Habib and Kamal (11) and Jasuja and Singh (12) in their studies on reconstruction of stature with measurements of hand and phalange lengths have reported a similar observation. The correlation coefficients between stature and all the measurements of hands were found to be positive and statistically significant. (13)

Linear regression equations derived in the present study would help in estimation of stature with less error. The results of a study show that the extent of error of estimate inherent in estimation of stature by regression analysis is less than that of multiplication method. Hence, confirming that the stature estimation is more accurate and reliable with regression analysis method. (14)

**Conclusion**

The present study shows significant and positive correlation between stature and finger lengths (LIF, LRF, RIF and RRF) in males and females. Left RFL in males and right IFL in females appear to be the better predictors of stature. This study also shows that the stature can be predicted from the index and ring finger lengths with a reasonable accuracy.

Determination of Sex From Adult Clavicle – An Autopsy based Regional Study

Levis Vaseem Moorkhan1, Prajith Thekke Madathil2
1Assistant Professor, Department of Forensic Medicine, Govt. Medical college Manjeri, Malappuram, Kerala, 2Assistant Professor, Department of Forensic Medicine, Govt. Medical college Kozhikode, Kozhikode, Kerala

Abstract

Background: Studies on “identification of the sex from clavicle bone alone” are carried out by various workers all over the world. But, it is well known fact that the racial and geographical differences exist in the metrical measurement of all the bones including clavicles, as the determination of sex is a population specific phenomenon. Materials and Methodology: This study was conducted on 100 male clavicles and 100 female clavicles collected from identified corpses brought for medicolegal autopsy at Department of Forensic Medicine Govt. Medical College Calicut. Measured the various parameters and compared with previous studies. RESULTS: In the present study, the length, midclavicular circumference and weight of male clavicles were more than female clavicles. The female clavicle has its length around 86% of male clavicle and mean MCC around 83% of the male clavicles. Robustness index also calculated, mean robustness index was 23.11, and could identify only 76% males and 64% females by this. CONCLUSION: In order to establish the anthropometric standards, and for the evaluation of the same from time to time, the continuance of such studies in defined geographical areas over a particular period of time is needed.

Key Words: clavicle, sex determination, midclavicular circumference, Robustness index and autopsy.

Background

Identification of an individual is based on various physical features and biological parameters, which are unique to an individual. Question of identification arises in everyday medico legal practice in both civil and criminal cases. The features such as birthmarks, scars, tattoo marks, malformations, assessment of age and sex determination, race, stature, anthropometric measurements, fingerprints etc. are usually taken for the same.

Since bone resist putrefaction and destruction by animals, they contribute to the determination of age, sex, race and stature of an individual. Sex being one of the cardinal features of establishing the identity, its estimation is of greater importance and requires special attention in cases, where bodies are found decomposed, mutilated or only fragmentary remains are discovered.

Determination of sex from the skeletal remains of an individual by the examination of a single bone (except hipbone) is considered to be almost an impossible task. Even in cases where entire human bony pelvis and skull are available, more than 95% of accuracy cannot be achieved (Krogman, 1962).

On the whole, the bones of male skeleton are heavier, larger and markings of muscular attachments are more pronounced than females. Human clavicle is a long bone (Troter&Peterson 1953); it extends horizontally with a double curve across the root of the neck, laterally towards the point of shoulder.

Studies on “identification of the sex from clavicle bone alone” are carried out by various workers all over the world. These studies include that of Peterson in England (1916), Terry in USA(1932) and in India study has been conducted by Jit I &Singh in Amritsar zone(1966), Singh and Gangrade in Varanasi zone(1968), Jit I &SahniD in...
Chandigarh zone (1983). However, major pioneer studies about the subject have been lacking from southern India.

But, it is well known fact that the racial and geographical differences exist in the metrical measurement of all the bones including clavicles, as the determination of sex is a population specific phenomenon.

**Objectives**

This study attempts to identify the sex of an individual from measurable characteristics of clavicle.

1. To assess the difference in measurements of various parameters and indices such as length, mid clavicular circumference, and Robustness index in male and female clavicles.
2. To compare the results with previous studies.
3. To establish standardised formula for determination of sex from clavicle.

**Materials and Method**

This is a descriptive study based on 100 clavicles from males and 100 clavicles from females collected from cadavers of Calicut Medical College mortuary, selected from cases in which the consent has been obtained.

**Selection Criteria:**

1. Left clavicle (for uniformity) of adult humans of known age (>25 years) and sex.

**Exclusion Criteria:**

1. Unidentified bodies, or wherever the exact age and sex could not be determined.
2. Cases showing any deformed, diseased or fractured (including old healed fracture) clavicles, and that showing any pathologic lesion, which may hamper the study.

**Measurements:**

1. Maximum length in millimetres; measured from the sternal end to the acromial end with the help of a Vernier caliper, ignoring the curves of the bone.

2. Circumference of the clavicle at the middle of the bone in millimetres; The middle point of the length of the clavicle is marked and taken as the point where the mid-shaft circumference was measured with the help of a measuring tape and recorded in millimetres.

After the measurements were taken, they were subjected to statistical analysis using SPSS software for windows. On applying ROC curve, decided the cut-off values for each parameter.

**Observations**

The present study includes a total of 100 adult clavicles from males and 100 clavicles from females of known age and sex.

**Length**

Table 1 shows that, the length of male clavicles ranges from 130 to 167.80 mm, with a mean of 147.97 mm and standard deviation 11.61 mm, and the length of female clavicles ranges from 116.22 to 143.20 mm, with a mean of 127.4 mm and standard deviation 6.9 mm.

<table>
<thead>
<tr>
<th>Sex</th>

<tbody>
<tr>
<td>Male</td>
<td>88%</td>
<td>12%</td>
</tr>
<tr>
<td>Female</td>
<td>16%</td>
<td>84%</td>
</tr>
</tbody>
</table>

Table 2 shows that, for the male clavicles, the length >88% of them lies above the cut-off, that is 132 mm (on applying ROC curve), and only 12% of the length of male clavicles, falls below the cut-off. In the
case of length of female clavicles, only 16% of them falls above the cut-off and > 84% of the length of female clavicles falls below the cut-off point 132mm.

**Midclavicular circumference**

**Table 3: Statistical analysis of the male and female clavicles of both sexes in relation to MCC**

<table>
<thead>
<tr>
<th>Sex</th>
<th>Range(mm)</th>
<th>Mean(mm)</th>
<th>SD</th>
</tr>
</thead>
<tbody>
<tr>
<td>Male</td>
<td>30.8-45.8</td>
<td>36.37</td>
<td>4.3</td>
</tr>
<tr>
<td>Female</td>
<td>24.8-33.8</td>
<td>29.23</td>
<td>2.39</td>
</tr>
</tbody>
</table>

Table – 3 shows that, the MCC of male clavicles ranges from 30.8 to 45.8mm, with a mean of 36.37mm and standard deviation 4.13, and the MCC of female clavicles ranges from 24.8 to 33.8mm, with a mean of 29.23mm and standard deviation 2.39.

**Table 4: Probable Sex determination using cut off values for the clavicles with MCC**

<table>
<thead>
<tr>
<th>sex</th>
<th>&gt;Cut off</th>
<th>&lt;Cut off</th>
</tr>
</thead>
<tbody>
<tr>
<td>male</td>
<td>84%</td>
<td>16%</td>
</tr>
<tr>
<td>female</td>
<td>8%</td>
<td>92%</td>
</tr>
</tbody>
</table>

Table – 4 shows that, for the male clavicles, the MCC > 84% of them lies above the cut-off value (on applying ROC curve), that is 32, and only 16% of the male clavicular MCC falls below the cut-off. In the case of female clavicular MCC, only 8% of them falls above the cut-off and > 92% of the female clavicular MCC falls below the cut-off point.

**Table 5: Probable Sex determination using cut off values for the clavicles with Robustness index**

<table>
<thead>
<tr>
<th>sex</th>
<th>&gt;Cut off</th>
<th>&lt;Cut off</th>
</tr>
</thead>
<tbody>
<tr>
<td>male</td>
<td>76%</td>
<td>24%</td>
</tr>
<tr>
<td>female</td>
<td>36%</td>
<td>64%</td>
</tr>
</tbody>
</table>

Table – 5 shows that cut off value of robustness index for sex determination of clavicles as 23.11 (on applying ROC curve). Thus table – 11, shows that for the male clavicles, the robustness index > 76% of them lies above the cut-off, that is 23.11, and only 24% of the male clavicular index falls below the cut-off. In the case of female clavicular index, only 36% of them falls above the cut-off and > 64% falls below the cut-off point 23.11mm.

**Discussion**

In the present study, the clavicle has been compared in relation to its morphometric parameters with the studies in the past.

1. **LENGTH OF CLAVICLE**

In the present study, mean length of male clavicle is significantly higher than that of female clavicle. It is clear from table that, present study similar to studies of Padeyappanavar et al\(^2\) (2009), and Jit I and Sahni D\(^3\); thus the present study observed statistically significant difference between length of male and female clavicles (\(p<0.001\)). In the present study, mean length of male clavicle (147.97mm) is comparable with the studies of Jit I & Singh S\(^4\) (157.59), Singh and Gangrade\(^5\)(144.18mm) and Padeyappanavar KV et al\(^2\) (143.5mm), and Jit I & Sahni D\(^3\). But it is lower than the studies of Terry RJ\(^6\) for USA white (154.10mm) and Negroes (155.86mm) and Singh S\(^7\) for USA white (153.7mm) and Negroes (157.32mm).

The mean length of female clavicle in present study (127.4mm) is comparable with most of the studies except Jit I and Sahni D\(^3\) (134mm), Terry RJ\(^6\) for USA Negroes (141.8mm) and Singh S\(^7\) for USA Negroes (140.80mm) which are higher than the meanvalue of present study.

The fact that American Negroes and Whites and North Indians are taller and well-built than South Indian population, this difference in length is appreciated.
Sexual difference: According to Olivier (1951)\(^8\), the length of the female clavicle is 89.7% of that in a male clavicle, and other authors give the proportion varying from 88.2% to 93%. In the present study, the average North Malabar female clavicle is 86% of male clavicle. This is similar to the study results of Arvinder Pal Singh Batra, Anupama Mahajan, Seema 12 (2010), and Jit I and Singh S (1966)\(^4\). As there is overlap between the length measurements of male and female clavicles, the sex of the clavicle could not be determined in every case, 88% of male and 84% of female clavicle could only be sexed correctly. This result is also similar to the results of study done by Frutos and Rios L\(^9\) (2002), Kaur K, Sindhu SS, Kaushal S, Kaur B\(^10\) (1997). The prediction of correct sex can still be increased by including length in multivariate analysis along with mid-shaft circumference, weight and volume of the clavicle.

2. Mid-Shaft Circumference:

The mid-shaft circumference of the clavicle had been calculated in several races by different workers and this is the most popular clavicular parameter used for sex identification. Oliver G\(^8\) has provided a table giving finding of various workers in this regard.

Mid-shaft circumference in the present study is statistically highly significant (p<0.001) in differentiating the sex of male and female clavicles, which is similar to the studies of Padeyappanavar et al\(^2\), Jit I and Sahni D\(^3\).

Mean mid-shaft circumference in male (36.37mm) and in female (29.23mm) of present study is comparable with all the studies except with Terry RJ\(^6\), Oliver G\(^8\), Jit and Singh S\(^4\) and mean RI of female clavicle (23.03mm) is also comparable with other studies.

Sexual difference: It is agreed by most of the previous workers that female clavicle has a smaller circumference than male and this difference is statistically highly significant and varies from 3.7 to 7.8mm. Shamer Singh & Inder Jit\(^11\) found difference to be 8mm for males and 6mm for females. In the study by Terry RJ\(^6\) (1932), the circumference of Negro female bone was about 5mm shorter than that of Negro male.

Oliver G\(^8\) (1951) found the difference to be 6.8mm in French bones. Jit and Singh S\(^4\) (1966) found the difference to be 6mm - 7mm. In the present study, the difference is about 6.42–7.14mm. This shows that, mid-shaft circumference is an extremely useful data by which a fairly large number of clavicles can be sexed without any difficulty. The probable prediction of sex by mid-shaft circumference alone is 84% in male and 92% in female clavicles. These results are similar to results of Jit and Singh S (1966)\(^4\) and Padeyappanavar KV et.al\(^2\) (2009).

3. ROBUSTNESS INDEX:

In the present study, mean RI of male clavicle is more than that of female clavicle. This is in accordance with all other workers who agree that the robustness index is greater in males than in females. But their reliance to be put on this index as a parameter useful to identify the sex of clavicle has not been worked out. The figures in this study prove that this index is significantly greater in male compared to female and this difference is statistically significant (p<0.001). This is similar to the studies of Jit I and Singh S (1966)\(^4\) who also found that RI values are statistically significant for sex differentiation.

In the present study, mean RI of male clavicle (24.65mm) is comparable with the results of Terry RJ\(^6\), Oliver G\(^8\), Jit and Singh S\(^4\) and mean RI of female clavicle (23.03mm) is also comparable with other studies.

Sexual difference: Robustness index of male and female clavicles as given by other authors vary from 0.4 to 2.8mm, but in the present study, it is 1.62mm. As the values of robustness index of clavicle in both sexes show significant overlapping, the robustness index of clavicle alone is not sufficient to sex each clavicle. Thus, the prediction of sex of clavicles by robustness index alone is 76% male and 64% female, which is having much less prediction of sex as compared to taking individual characteristics like length, weight or mid-shaft circumference for sex estimation.

Conclusion

Present study on determination of sex of adult human clavicle by metric parameters showed some difference with respect to the same results of the studies done by various workers in the past.

In the present study, the length of male clavicles was more than female clavicles. The female clavicle has its
length around 86% of male clavicle. On applying ROC curve, in case of length, the clavicle could be sexed, with some probable predictions. For males could be sexed in 88% of the cases and females in 84 %, also the same prediction is applied with some overlapping.

The mean mid-shaft circumference of male clavicles was more than that in females, and the female clavicle has its mean MCC around 83% of the male clavicles. The probability of prediction of sex of clavicles by mid-shaft circumference alone was 84% for males and 92% for females, with some overlapping.

Robustness index also calculated, mean robustness index was 23.11, and could identify only 76 % males and 64% females by this. There was considerable overlap between male and female clavicular measurements and their indices. This overlap may be due to genetic, nutritional and socio economic difference in the individual or may be due to hypo-muscularity in the male clavicles and hyper-muscularity in the female clavicles. Hence it is not possible to determine the sex of each and every clavicle by any of the parameter alone.

The present study helps to know the changing trends in the metric measurements if any. In order to establish the anthropometric standards, and for the evaluation of the same from time to time, the continuance of such studies in defined geographical areas over a particular period of time is needed.

Profile of Medico-legal Cases at JSS Hospital, Mysuru – a Two Year Prospective Study

S.Prasanth Kumaran¹, H.V.Chandrakanth², Arun.M³, Smitha Rani⁴

¹Assistant Professor, Dept of Forensic Medicine and Toxicology, Sri Lakshmi Narayana Institute of Medical Sciences, Pondicherry, ²Professor, ³Professor and Head, ⁴Assistant Professor, Dept of Forensic Medicine and Toxicology, JSS Medical College, JSS Academy of Higher Education and Research, Mysore.

Abstract

This Prospective study was conducted to do profiling and analysis of Medico-legal cases attending the JSS Medical College and Hospital, Mysuru for a period of two years. Total 2033 Medical-legal cases which were registered during the time period were analysed. Analysing the pattern of such unnatural events, would provide a vital data for healthcare professionals, civil administrators, investigating agencies of state and judiciary to devise and implement appropriate and adequate strategies so as to reduce such incidences from happening. Majority of the cases were RTA, followed by poisoning. Among all the admitted cases, majority of the cases recovered and discharged. The mortality rate is low among the admitted cases, only 9.9% of cases were hospital deaths.

Most of the cases occurred during the time period of 12.01pm to 6pm followed by 6.01pm to 12am.

The age group of 21-30 years are the most frequently affected. Majority of the victims were males.

Suicide by hanging is more frequent among females compared to males, despite of predominant male population among the MLCs.

Key Words: Medico-legal case, Medicolegal expert, pattern

Introduction

Medico-legal cases constitute a substantial proportion of workload in the casualty and such patients not only merit treatment, but their exhaustive documentation is mandatory.¹

Cases of Road Traffic Accidents (RTA), suicide by poisoning, burns, hanging, drowning, alleged history of assault, criminal abortions, industrial accidents, sexual offences, animal attacks, unnatural suspected deaths, custodial deaths, dowry deaths are considered as medico-legal cases. Among them RTA, suicide by poisoning constitute the majority of medico-legal cases. Injuries from RTA is the third most common cause of universal disability. The risk factors for RTA include speeding, alcohol impaired driving and violation of traffic rules. The spectrum of medico-legal cases presenting to the emergency medicine department would highlight the social, economic, educational aspects of the society and in broader sense highlights the value system, ethics and morality prevailing in that particular geographical habitat.

A medico-legal case is a case of injury or illness where attending doctor after eliciting, listing and examining patient is of opinion that some investigation by law enforce agencies is essential to establish and fix responsibility for the cases in accordance with the law of the land².

Injury is defined under section 44 IPC (Indian Penal Code) as any harm whatever illegally caused to
Medico-legal case is a medical case with legal implications or a legal case requiring medical expertise.

In recent days, medico legal cases are on the rise. This may be attributed to the following factors like: increased vehicular traffic density, un-employment, high income disparities, substance abuse, insurance compensations etc.

Inspite of recent advancement of technology in the field of medical sciences, death and deformities due to all causes, are yet to be controlled successfully, rather incidences of road traffic accidents has been increasing at an alarming rate throughout the world.

**Aims and Objectives**

1. To determine the socio-demographic profile of medico-legal cases reported to JSS Medical College and Hospital during the study period.
2. To determine the mortality rate
3. To study the profile of different medico-legal cases in the hospital.
4. To recommend this study as a standard for Medico-Legal work in casualty.

**Materials and Method**

This is a prospective study which is conducted in the casualty of Jagadguru Sri Shivarathreeshwara hospital from October 2016 to September 2018.

The medico-legal register of casualty department is the main source of this study which comprises of information regarding various parameters. The data was analysed and results were derived with the help of SPSS version22, Microsoft Excel and R software.

Inclusion criteria: all cases brought to the JSS Hospital casualty with known history of medico legal implications.

Exclusion criteria:

1. The cases with inadequate details or missing data-all the cases for which any of the details regarding age, sex, date and time of incident, was not mentioned, or unavailable in the records.
2. The cases referred from other hospitals or clinics.
3. The cases which have received treatment or first aid in other centres.

**Observations and Results**

A total of 2033 Medico-legal cases were registered during the time period according to the inclusion criteria. Only the medico-legal cases which reported first to Jagadguru Sri Shivarathreeshwara Medical college & Hospital, Mysore were included in the study. Referred cases and other cases which reported or received first aid in any other hospital or clinic were excluded. The analysis of the various parameters of the cases, revealed the following observations:

**Figure 1: Distribution of the cases with respect to age group:**
With regards to age, the cases are categorized into nine different age groups of ten years range. Majority of the cases (595 cases) belonged to the age group of 21-30 years which accounts to 29.3%.

**Sex wise distribution of cases:**

With regards to sex, male preponderance is observed: 1480(72.8%) cases were males and 553(27.2%) cases were females.

![Fig 2: Distribution of cases with respect to type of case](image)

Profiling with respect to type of case revealed that: RTA constituted majority of the cases(1242 cases, 61.1%) followed by poisoning(374, 18.4%), assault(116, 5.7%), brought dead with unknown history(64, 3.1%) respectively.

**Manner wise distribution of cases:**

The manner of injury for majority of the cases is accidental (1533 cases, 75.4%), followed by suicidal (316 cases, 15.5%) and homicidal (120 cases, 5.9%). The manner is unknown for 64 cases(3.1%), which were brought dead cases with unknown history.

**Table 1: Distribution of cases with respect to time of incidence:**

<table>
<thead>
<tr>
<th>Time of incidence of unnatural event</th>
<th>Frequency</th>
<th>Percent</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.01am to 6.00am</td>

<td>697</td>
<td>34.3</td>
</tr>
<tr>
<td>Total</td>
<td>2033</td>
<td>100.0</td>
</tr>
</tbody>
</table>
According to the time at which the unnatural event had occurred, the 24 hour time period in a day is divided into four different groups of 6 hour time intervals. Most of the cases occurred during the time period of 12.01pm to 6pm(746 cases, 36.7%) followed by 6.01pm to 12am (697 cases, 34.3%).

**Table 2: Distribution of the cases with respect to conscious condition when reporting to the hospital**

<table>
<thead>
<tr>
<th>Consciousness/ condition</th>
<th>Frequency</th>

<tr>
<td>Brought dead</td>
<td>108</td>
<td>5.3</td>
</tr>
<tr>
<td>Total</td>
<td>2033</td>
<td>100.0</td>
</tr>
</tbody>
</table>

Majority of the cases (1820 cases, 89.5%) were conscious when reporting to the casualty. Only 105 cases (5.2%) were unconscious. 108 cases (5.3%) were brought dead to the casualty.

**Distribution of cases on outpatient/ inpatient (admission) basis:**

Profiling of cases on inpatient, outpatient basis revealed that: majority of the cases (1451 cases, 71.4%) were treated and managed on outpatient basis compared to only 582 cases (28.6%) which were treated on inpatient basis (admitted).

**Table 3: Distribution of the cases on the basis of final outcome:**

<table>
<thead>
<tr>
<th>Final outcome</th>
<th>Frequency</th>
<th>Percent</th>

</table>

The above table shows that, RTA and poisoning are 1st and 2nd most frequent cases among both males and females. The one peculiar finding in this study is that the number of hanging cases is significantly more among females when compared to males, despite of male predominance among the total cases.

### Distribution of the cases with respect to locality:

With regards to locality, majority of the cases were from urban background (1458 cases, 71.7%) compared to rural background (575 cases, 28.3%).

### Discussion

The results of our study were analysed and compared
In the present study, male preponderance was observed: 1480(72.8%) cases were males and 553(27.2%) cases were females. This finding is consistent with most of the other studies done by Atul Saxena et al, Yatoo GH et al, SN Hussaini et al. This could be due to greater involvement of males in outdoor activities like travelling on roads, working in construction areas, industries etc making them more prone to accidents and injuries.

Profiling with respect to type of case revealed that: RTA constituted majority of the cases which is consistent with other studies done by Atul Saxena et al, Mahesh M Trangadia et al and Garg Vishal et al. The predominant incidence and reporting of RTA cases could be attributed to rapid urbanization and increase in the number of vehicles, poor road conditions, ignoring the traffic rules and absence of safety policies. The one contrary finding in our study is that the number of hanging cases is significantly more among females when compared to males, despite of male predominance among the total cases. This is in contrast to studies done by Mathew J Martin et al, Derya Azmak et al where males were the predominant victims of hanging.

The second most frequent cases in this study were poisoning cases(18.4%).Only two cases of strangulation were recorded during this study period and both were accidental in manner, both were females. The third most common among the MLCs were assault cases accounting to 5.7% of the total cases.

It was observed in the present study that most of the cases belonged to the age group of 21 to 30 years of age. This could be due to the fact that individuals of this age group are more active, violent and are predominantly involved in activities.

In the present study most of the cases occurred during the time period of 12.01pm to 6pm (746 cases,36.7%) which is consistent with studies done by Mahesh M Trangadia et al and Vishal Garg et al. Because this is the peak time period during which most of the people are active in addition the other factors like peak transportation traffic density in the evening hours. This is closely followed by 6.01pm to 12.00am time period during which 34.3% of cases occurred.

The incidence of MLCs were least during the time period of 12.01 am to 6 am. This could be attributed to the profound inactivity as most of the people prefer to sleep during this time period.

Among the admitted cases, majority of the cases (385 cases, 66.1%) recovered and discharged. This is consistent with other previous studies done by Mahesh M et al and Garg Vishal et al. This can be attributed to the timely admission, effective treatment and management in the hospital. The second most frequency of cases (137 cases, 23.5%) developed complications like motor or sensory impairments or organ dysfunctions, 58 cases (9.9%) were hospital deaths and only 2 cases were referred out to other hospitals. Out of the total 582 admitted cases only 67cases (11.6%) were DAMA.

Majority of the cases were brought to the hospital by relatives or friends (1793 cases, 88.3%). This could be due to the presence of relatives or friends nearby the victim at the time of occurrence of unnatural event and due to the communication of information to the family members, relatives or friends about the injured victim. Self reporting was done by 134(6.6%) cases. This could be due to sustaining minor injuries which were not severe, that made the victims to report to the hospital on their own without any company from others. Very few cases(106 cases, 5.2%) were brought by strangers to the hospital. This could be due to sustaining serious or life threatening injuries by these victims rendering them unconscious or unable to seek first aid on their own, such that strangers had to help them by accompanying them or transporting those victims to hospital.

**Conclusion**

Majority of the cases belonged to the age group of 21-30 years. Male preponderance is observed.

With regards to demographic locality, majority of the cases were from urban background.

Profiling with respect to type of case revealed that: RTA constituted majority of the cases followed by poisoning.

Most of the cases occurred during the time period of 12.01pm to 6pm followed by 6.01pm to 12am.

Among all the admitted cases, majority of the
cases recovered and discharged. The mortality rate is low among the admitted cases, only 9.9% of cases were hospital deaths.

Majority of the cases were brought to the hospital or accompanied by relatives or friends.

Suicide by hanging is more frequent among females compared to males, despite of predominant male population among the MLCs.

The present study shows that the predominant cause of injuries are road traffic accidents and are accidental in nature. Public health officials should develop and implement preventive strategies with a comprehensive approach to reduce the incidence and deal with day to day morbidity and mortality. The basic principles to be followed to prevent injury are education, engineering, uniform enforcement of law & order, pre-hospital care and the evaluation. Proper education, training must be delivered for safety standards. Rules and regulations are to be strictly implemented in the community to prevent all kind of injuries. Further large number of prospective studies should be carried out that would facilitate various organizations to set various causative risk factors, circumstances, chain of events; and the preventive measures accordingly.

To prevent or reduce the incidence of suicides, regular awareness programs, counselling should be delivered to all the individuals who are prone to stress (especially students, medical professionals and individuals involved in professional jobs) from time to time. Proper counselling to manage and cope with stress and failures and for developing positive attitude should be facilitated and promoted especially among youths.

Due to the higher incidence of RTAs, poisoning and assault cases, hospitals should have availability of such medico-legal experts in sufficient number throughout day and night, 24/7 to deal effectively with such cases.

Medico-legal cases must be handled with proper attention. Timely intimation to police, proper documentation, thorough investigations and management are essential on the part of medical professionals, especially Casualty medical officers.

For the better handling and dealing of medico-legal cases, awareness programs, and adequate proper training regarding MLCs should be given to the undergraduate students, interns and medical officers. Also during internship, a brief period of posting in Forensic Medicine Department is essential for imparting better knowledge about MLCs and their management.

Abstract

\textbf{Background:} To explore the various perceived causes and solutions for substance abuse among the nursing students in Mangalore, Karnataka, India.

\textbf{Methods:} Group of nursing students belonging to the second year participated in the study. A method of free listing and pile sorting was employed to discover the causes and solutions for substance abuse.

\textbf{Conclusion:} The primary cause of substance abuse was found to be peer pressure with a salience value of (0.945) followed by enjoyment (0.614), family problems (0.486). Cognitive mapping revealed the causes of being grouped under three major headings: psychological imbalance, adaptation to modern lifestyle, and unhealthy family environment. The solutions suggested by the students were counseling and rehabilitation with the highest salience value (0.751), awareness about the adverse effects at an early age (0.637). Cognitive mapping portrayed the solutions grouped into headings like therapies and treatment, external sources, family care, and support. Factors such as peer pressure, academic pressure, and easy availability of drugs can be looked into by external institutions to root out the evils of substance abuse

\textbf{Keywords:} drug abuse, nursing students, substance abuse

Introduction

Substance abuse disorder is one of the significant concerns globally. World health organisation (WHO) defines the term substance abuse as “Persistent or sporadic use of a drug inconsistent with or unrelated to acceptable medical practice” \textsuperscript{1}. Substance abuse indicates the use of dangerous psychoactive substances such as tobacco, alcohol, and other drugs like heroin, amphetamine, and cannabis \textsuperscript{2}. Use of substance has caused intolerable sufferings in terms of mortality and financial crisis causing menace to social life around the world \textsuperscript{3}. The initiation of drug abuse is observed in the period of adulthood, which significantly increases the probability of more severe drug problems later in life \textsuperscript{4}. Globalization, urbanization, deteriorating cultural values, conflicts, and violence force young adults to use substances \textsuperscript{5}. Studies conducted to determine the prevalence of substance abuse among the various streams, including the medical stream, were found

Research shows that indulgence in substance abuse can be a result of exposure to violence and post-traumatic stress. The prevalence of substance use among health care students ranges from 5% to 67% with higher percentages (67%) being reported in developed countries like the United States. Among developing countries such as Iran, Ethiopia, Nepal, and India, substance use among health care students varies from 5% to 48%.

Taken together, there is a strong need to assess substance use among health care students as they hold greater responsibility in society. The present study was undertaken for the qualitative exploration of perceived causes of substance abuse and possible solutions for the same among nursing students from selected nursing colleges of Mangalore.

**Methodology**

The present qualitative study was done among 15 second-year students from selected nursing colleges of Mangalore, Karnataka. The sample size of 15 was reached after applying the rule of saturation for the qualitative study. Study was conducted after obtaining the ethical clearance from the institutional ethics committee. Permission was obtained from the heads of the nursing institutes, and consent was taken from the nursing students before the commencement of the study. A method of free listing and pile sorting were employed to discover the perceived causes for initiation of substance abuse and possible solutions to address these problems among students of nursing colleges in Mangalore.

Free listing: For the free listing, students were asked two probe questions:

1. In your opinion, what do you think are the causes for substance abuse among your age group of students in your field?
2. Suggest the possible solutions to eradicate the use of substance abuse among this age group of students in your field?

Students were asked to provide a list of various perceived causes and possible solutions for substance abuse individually. Statistical program ANTHROPAC was used to compute Smith’s Saliency Index and frequency for free list data. Smith’s saliency index refers to the “importance, representativeness, or prominence of items to individuals or the group. Twenty responses as causes and fifteen solutions were taken for pile sorting. Obtained results were subjected to analysis using Visual Anthropac.

**Pile sorting:** First, the identified salient items were written on cards with their respective numbers. Participants were then allowed to group; selected perceived reasons and solutions based on their own criteria. Participants were asked to explain the reason for piling. Successive pile sorting was done with similar causes and solutions, followed by items with less similarity. Process continues until all the groups are clustered into a single pile.

**Results & Discussion**

Table 1 shows the perceived causes of substance abuse among nursing students. The most predisposing factor for substance abuse is peer pressure with the highest salience value of 0.945, followed by just for temporary enjoyment with the salience value of 0.614.

Figure 1: Cognitive map-causes of substance abuse among nursing students:

1 peer pressure, 2 just for enjoyment, 3 family problems, 4 socio-economic status, 5 parental influence, 6 stress, 7 breakup, 8 loneliness, 9 curiosity, 10 easy accessibility, 11 anxiety, 12 emotional trauma, 13 ignorance, 14 social media influence, 15 temporary happiness, 16 inadequate parental supervision and care, 17 adapting to modern lifestyle, 18 social gathering, 19 migration from rural to urban area, 20 depression
Pile 1 includes causes like anxiety, depression, emotional trauma, loneliness, breakup, stress, and curiosity, which were piled up under the title psychological imbalance.

Pile 2 - Students classified reasons such as peer pressure, temporary happiness, just for enjoyment, easy accessibility, media influence, social gathering, adapting to modern lifestyle, migration from rural to urban areas, and socioeconomic status as social factors tempting the students towards drug abuse.

The rest of the causes, such as ignorance, parental influence, family problems, inadequate parental care, and support were assorted under pile 3 with headings like family influence, lack of parental support, care, and unhealthy family environment.

From the assorted groups in figure 1, it is observed that the major reasons for substance abuse are psychological imbalance, curiosity, and environmental factors such as peer influence and other social factors.

</table>

Solutions enumerated by nursing students are depicted in Table 2 in the order of decreasing salience value. It is observed from Table 2 that counselling, rehabilitation centres, awareness about the side-effects at an early age, parental support, and care were commonly suggested solutions. Students also stated that trying out therapies such as behavioural therapy, diversional therapy, and socializing with the right people will help in preventing the use of substances.

Cognitive map - solutions for substance abuse suggested by nursing students: Figure 2
Figure 2 portrays the cognitive mapping of the solutions given by the nursing students.

Nursing students assorted reasons such as diversional therapy, behavioral therapy, rehabilitation centre, counseling, proper treatment, extracurricular activities and identify the cause and treat accordingly into Pile 1 named therapies and treatment, diversion from substance abuse. Solutions like limiting the availability of drugs near college institutions, awareness about the side effects at an early age, socializing with the right people, self-control, and choosing the right friends were grouped into Pile 2 under the headings self-help best help, help from an external source and social remedies.

Pile 3 consists of two solutions, emotional support and parental care and support, which were grouped under the title family care and support.

From Figure 2 it is evident that recreational activities, surrounding yourself with right and positive people, parental care and supervision, and limiting the availability of drugs to students can emerge to be of immense aid to reduce the prevalence of drug abuse among the students.

The present study shows that the predominant perceived cause for substance abuse among nursing students is peer pressure. The present finding is consistent with the study conducted in Nepal by Bimala Panthee et al. (2017) among the health care students. Cognitive mapping depicts reasons such as peer pressure, social media influence as the current trend in the modern era. Few nursing students reported that they used substances for pleasurable purposes in a study conducted by Jashmid Ahamdi et al. (2004). It was also observed that parental influence and inadequate parental support and care were major governing factors in substance abuse initiation. The study conducted by Gouri Kumari Padhy et al. (2014) supports this reason. Family problem was found to be a determining reason for drug abuse. Study conducted by Mohan D (1980) reveals that students belonging to nuclear families had the least prevalence of drug abuse.

In addition to this, easy accessibility to drugs was found to be a major cause. It was reported that heavy alcohol drinking and cigarette smoking were the significant predictors of substance use among Nepalese health care students. In the present study, students opined that curiosity is also one of the factors to indulge in alcohol abuse. Peer pressure, academic stress, and
social media influence were also found to be the main reasons for initiating drug use in a few published studies. 98% of substance abusers were aware of the adverse effects of substance abuse but were continuing the same. This showed carelessness towards self-health and a lack of proper health education. Previously published studies show that the college environment favoured substance abuse since many have initiated the use of drugs after joining medical colleges. The most common reasons reported in the present study for using such substances were a relief from psychological stress, occasional celebration followed by to reduce tiredness, peer pressure, easy availability, experimental use and community acceptance.

The majority of the students believe indulging in extracurricular activities and exploring your hobbies alleviate stress levels and help them choose healthier options over drugs, which was consistent with the previously published study. The nursing students had suggested therapies such as diversional therapy and behavioural therapy. They also agreed that parental care and attention, healthier family relations would decrease the use of substance abuse, as reported in other studies. Other possible solutions suggested by the students were choosing the right friends circle and attending counselling sessions. Other predominantly stated solutions were limiting the availability of drugs near college institutions and spreading awareness about the toxic effects of substance abuse at an early age. Benegal. V et al. (1998) conducted a study that depicts the commonly reported solutions as similar to these.

Present qualitative study explores the causes of substance abuse among the health professional students. Psychological imbalance and stress due to various external factors forced the students to use various forms of drugs. In addition to this, easy accessibility to drugs was found to be an essential factor in substance abuse initiation. Solutions enumerated by the students include parental support and guidance, help from private organisations, having self-control, indulging in various co-curricular activities, and choosing the right friends. Limiting the availability of drugs near college institutions is a commonly reported solution.

**Conclusion**

The present qualitative study explores the causes and solutions for substance abuse among nursing students through a method of free listing and pile sorting. It is clearly evident that the most predisposing factor is peer pressure. Limiting the availability of drugs near college institutions was a commonly reported solution. In addition to this, students suggested therapies like diversional therapy and behavioral therapy.

Assessment of Oral Health Related Quality of Life and Patient Satisfaction after Complete Denture Therapy- An Observational Study

MR Athira1, Shenoy VK 2, Mehendale A3, Kamath M4, Zaheer A5, Rodrigues S6

1Post graduate Student, Department of Prosthodontics, AJ Institute of Dental Sciences, Mangalore, 2Professor and Head, Department of Prosthodontics, AJIDS, Mangalore, 3Reader, Department of Prosthodontics, AJIDS, Mangalore, 4Assistant Professor, Department of Prosthodontics, AJIDS, Mangalore, 5Associate Professor, Department of Public Health Dentistry, Azhar Dental College, Idukki, 6 Professor, Department of Prosthodontics, MCODS Mangalore, Manipal Academy of Higher Education, Manipal, Karnataka

Abstract

Objective : To assess the oral health related quality of life (OHRQoL) and patient satisfaction after complete denture therapy.

Methodology : Participants in the study included 60 first time complete denture wearers. OHRQoL was assessed using Oral Health Impact Profile-Edentulous(OHIP-EDENT) questionnaire; denture quality and patient satisfaction was assessed using denture quality evaluation parameters and patient satisfaction questionnaire respectively. Paired t test was used to analyse pre and post change in OHRQoL and Pearson Correlation coefficient was used to assess the co-relation between various parameters.

Results: There was a statistically significant change in the mean OHIP score of patients before and after rehabilitation (p<0.001). Across the seven domains used for measuring the denture quality, stability and retention of mandibular denture showed statistically significant reduction after one month. Significant correlations were observed between the patient satisfaction parameters and the denture quality as well as OHRQoL (p= 0.001, p=0.001 and p= 0.01).

Conclusion: OHRQoL improved significantly in first time denture wearers.

Keywords: Complete denture, Quality of life, patient satisfaction, denture retention

Introduction

Oral health is an essential and integral part of systemic health.1 Edentulism considerably influences the OHRQoL in the elderly people as it leads to disability, impairment and handicap.2,3

Despite the various rehabilitation modalities, a considerable number of patients, out of necessity or choice, receive conventional complete dentures. Complete denture therapy has been the most accessible treatment for edentulism for many decades, owing to its cost effectiveness, esthetic appeal, and easy maintenance.4 Also, edentulousness and the wearing of complete dentures can affect the quality of life and patient satisfaction.5

The OHRQoL determines the degree to which oral health affects an individual’s daily life and social functioning.6,7,8 The most preferred tool to measure the patients OHRQoL is by using the OHIP questionnaires.7,9,10-13 The original OHIP comprises

E-mail: vidsk@rediffmail.com
of 49 questions and a shortened version of this OHIP-EDENT specifically for the edentulous patients has been developed.

Patient satisfaction is one of the important objectives to achieve after complete denture treatment and is influenced by socioeconomic status, age, gender, number of post-delivery appointments, previous experience, oral condition and patient-dentist relationship. However, patients’ expectations can sway their satisfaction with the prostheses.

Further, little is known about the consequence of conventional complete dentures on OHRQoL and patient satisfaction in first time denture wearers. Thus, the current study was to planned to assess the impact of complete dentures on OHRQoL and patient satisfaction in first time denture wearers attending the Prosthodontic Department in a Dental School in India. Also, the correlation between denture quality parameters, patient satisfaction and OHRQoL was explored.

The null hypotheses of the study was complete denture therapy has no influence on the OHRQoL in first time denture wearers.

**Method**

The study involved 60 completely edentulous subjects, who were first time complete denture wearers. All study related procedures were approved by institutional ethics committee.

Participants included were edentulous patients who satisfied class I prosthodontic diagnostic index, no previous history of complete denture wear, no significant medical history, those who were able to respond to test questionnaires.

Old denture wearers, those who opted for tooth/implant supported overdentures, those with symptoms of temporomandibular disorders, xerostomia, orofacial motor disorders, severe oral manifestations of systemic diseases, psychological conditions, cognitive disturbance, neurological disorders and unwilling to participate in the study were excluded. Informed consent was obtained from all the participants.

The pre-treatment OHRQoL was evaluated using a shortened version of the OHIP questionnaire -OHIP-EDENT. The OHIP-EDENT consists of 19 questions belonging to the same seven conceptual domains i.e. functional limitation, physical pain, psychological discomfort, physical disability, psychological disability, social disability, handicap. All questions were responded on Likert scale: 0 = never, 1 = hardly ever, 2 = occasionally, 3 = fairly often, 4 = very often. Lower scores represented a better OHRQoL. The response codes for each of the items were calculated within each of the seven domains to give seven subscale scores. Higher OHIP-EDENT summary scores indicated OHRQoL impairment.

The rehabilitation of patients with conventional complete dentures was performed by post graduate students under the faculty supervision. During the denture insertion appointment, denture quality was evaluated by two prosthodontists using ‘denture quality evaluation parameters’ consisting of 7 criteria i.e esthetic lip support, esthetic lower lip, stability of maxillary denture, stability of mandibular denture, retention of maxillary denture, retention of mandibular denture, occlusion. All the clinical parameters were described precisely and evaluated on a dichotomous scale [satisfactory=1 and unsatisfactory=0]. Post-treatment review was scheduled one month later. At this visit, the subjects were asked to repeat the OHIP-EDENT instrument.

Patient satisfaction was assessed using patient satisfaction questionnaire with the use of 100mm Visual Analog Scale. General satisfaction, ability to masticate, ability to speak, ease of cleaning, stability, retention, esthetics and comfort were selected as evaluation items for the prosthesis. The satisfaction rate for each item were recorded by drawing a vertical line on a 100mm VAS for each item of the questionnaire. Each horizontal line in this questionnaire represented “very satisfied” (100) at the extreme right and “very dissatisfied” (0) at the extreme left. All the data were analysed using SPSS v.22 software package.

**Results**

A total of 60 edentulous subjects were included in the study with the mean age of 65.57 years.

A comparison was made between the OHIP scores for all subjects before and after treatment. Paired t test was used to analyse the change in OHRQoL in patients before and after complete denture therapy. The results
indicated that in all domains there were significant improvements in the OHIP scores with the new complete dentures (p<0.001) (Table 1).

Paired t test was used to analyse the change in denture quality parameters before and after complete denture therapy and the mean scores for the denture quality parameters were 0.926 and 0.892, respectively. However, there was no statistically significant difference (Table 2). Statistically significant reduction was seen in the stability and retention of mandibular denture (p<0.047 and p<0.07 respectively) after a month.

An improvement in the overall patient satisfaction level was observed post one month of the complete denture therapy, with mean total 84.75(Table 3). The mean values of the evaluation items such as comfort (90.88) and easiness to clean (90.85) was higher than the other items evaluated.

Pearson Correlation coefficient was used to assess the co relation between the technical quality of the denture and the general patient satisfaction. Statistical significance was set at p<0.05 and p<0.001. Significant correlations (Table 4) were observed between the patient satisfaction domains of denture stability, retention, easiness of clean and denture quality after one month (p=0.001, p=0.001 and p=0.01). There was a positive correlation between all the domains of patient satisfaction and OHRQoL (Table 4).

Discussion

The findings of the present study allowed the rejection of the null hypothesis. The OHIP-EDENT was used because it is a validated questionnaire specific for edentulous patients. High OHIP-EDENT scores were verified before the treatment. Usually, loss of all the teeth compromises the chewing, speech, sleep, emotional and social stability of patients. Oral health related quality of life improved significantly after the complete denture treatment probably due to the replacement of teeth which improved the function, esthetics, comfort and self-esteem of the person.

With regard to the general patient satisfaction, the patients reported improved satisfaction with the dentures. This indicates new complete dentures had good fit and adapted well to the oral tissues, reducing functional restrictions that happen as a consequence of pain.

There was a statistically significant co-relation between the denture quality parameters and patient satisfaction domains and the results agree with the previous studies.

There was a positive correlation between general patient satisfaction and the OHRQoL. Stable conventional complete dentures improve chewing capacity, thereby have a positive effect on their quality of life. Therefore, stability and retention takes precedence over other factors while fabricating the complete dentures. Biomechanical factors like muscle tonus, neuromuscular coordination, tongue, cheeks, lips, saliva may help to achieve adequate denture stability and retention in cases of severe residual ridge resorption.

In general, patient satisfaction and denture related OHRQoL depends more on acceptance of denture limitations than functional accuracy of their dentures. What is accepted as a normal level of discomfort or handicap to one patient, may be unbearable to another.

When conventional approach fails to achieve optimum retention and stability in cases of ridge resorption dental implants are an alternate option. Evidence also suggests that implant supported overdentures is a feasible and predictable treatment option that can result in high levels of patient satisfaction. However, this treatment modality may not be feasible as a result of morphological, psychological or socioeconomic factors.

The use of a validated denture quality evaluation parameter and denture satisfaction scale, the high inter-examiner and intra-examiner agreement, add to the scientific rigor and external validity of this research. However, long term follow up studies are needed to confirm these results.

Finally, patients’ perception regarding the experience with their complete dentures is inherently unique and highly subjective. Therefore, a certain level of discomfort or handicap may be acceptable to one patient and unbearable to another. Beyond the technical quality of the dentures, variables like oral health status, the patient’s personality and psychological state, and neuromuscular adaptation are to be considered. However, the available scientific literature does not provide conclusive evidence about this issue. Therefore, it is prudent for clinicians to establish good clinician-patient rapport.

Conclusion

There was a significant improvement in OHRQoL in first time denture wearers after rehabilitation with complete dentures. There was also a marked improvement in the general patient satisfaction.

Abstract
Children, one of the most vulnerable part of the population, face unusually high health risks as they grow. Children are the promise and future of every nation and the core of development. But it has been observed that even after so many efforts by governments of developing countries we are far behind to achieve hundred percent health care utilization by under-five population. Keeping this in view, this study was conducted to find out any correlation in-between child mortality of under-five years of age with health care utilization and place of residence. using verbal autopsy as a tool in Dehradun.

Methodology: The survey was done on all the houses of the deceased children residing in our field practice areas by visiting their houses.

Results: Among the 83 deaths reported, 38 received no treatment, 10 were treated by quakes, 19 and 16 under five – children were treated in government and private hospital respectively.

Conclusion: Our study shows that by utilization of health care facilities we can remarkably reduce under five mortality.

Keywords: MDG-4, deceased children, mortality rate, health care, under-utilized

Background
India is one among the 60 LMICs where reduction of child mortality rate has not progressed steadily towards achieving MDG-4. In India, infant mortality rate (IMR) and under-five mortality rate (U5MR) were 50 and 64 respectively per 1000 births during the year 2009 according to sample registration system (SRS) in India. One of the reasons for slow decline in child mortality in India could be unequal distribution of healthcare resources and difficulties in access to health care. One of the reasons for slow progress in achieving MDG-4 in many LMICs is the socioeconomic inequities existing in these countries. These inequities may also affect access to and utilization of available health care services and time taken in seeking of medical care as well as selection of appropriate health care provider for acute childhood illnesses. Studies from various countries suggest that health care seeking is inappropriate and health services are often under-utilized during childhood illnesses. Studies have reported that high cost of treatment is a major deterrent to seek care. Mothers’ perceptions about symptoms and their severity, mother’s beliefs about childhood illnesses and mothers’ ability to recognize the danger signs are some important factors determining health care-seeking behavior or utilization of health care services. Studies on utilization
of health services during childhood illness have reported that a significant proportion of children are not taken for medical care\textsuperscript{16}.

**Material and Method**

The study was undertaken for one year in the field practice areas of department of community medicine HIHT Dehradun after taking approval of institutional ethical committee. The total population registered under Rural Health Training Centre (Rajeev Nagar) & Urban Health Training Centre was 12,588 and 12,930 respectively out of which under five children were 1297 at RHTC and 1325 at UHTC.

All deaths except still births registered with Rural and Urban Health Training Centre were included in the study. When a child died, the mother or the respondent was questioned in detail about the health care utilization and place of residence of children prior to death. A drafted questionnaire (English version) developed by WHO, was modified suitably, as well as certain variables were added to find out any relation in-between under five children death and health care facility utilization with place of residence\textsuperscript{17}. The information so collected, was first coded and then entered in the computer. The analysis was done by using SPSS software. Appropriate statistical methods (proportion and chi – square test) were applied as per requirement.

(X^2 =0.754; df=3 ; p>0.05)

Present study shows that in rural area out of 39 deaths, 19(48.7 %) children were not treated for their illness whereas 5 (12.8 %) were shown to a quack,3(7.7%) children were seen by a private practitioner,9( 23.1 %) children were taken to government hospital while only 6 (15.4 %) children were taken to private hospital. Thus in the rural area, majority of children (48.7 %) received no treatment whereas only 15 (38.5%) children were taken to government hospital. In urban areas, 19 (43.2 %) children were not treated for their illness whereas 5 (11.4 %) were taken to a quack, 10 (22.7 %) were taken to government hospital and 12 (22.7 %) were taken to private hospital. Reasons for not seeking treatment were, either the illness was not considered serious in most of the cases, or there was financial constraints and lack of time or long waiting period. There is need for better health care delivery system and that too within reach of general population.

A Study done by Garg et al (1993) 18 on neonatal mortality in Meerut district found that 42.8 % of neonates who died did not receive treatment for an illness before their death. 11.9 % of neonates who died but received some treatment, were treated in hospital. A study done by Kumar et al (1982) 19 found that doctors (RMP) and qualified Doctor of Modern Medicine were consulted in 30.7 % babies. In 48.8 % both health workers and doctors were consulted for the treatment of terminal illness. No health worker was consulted in 19.7 % cases. Only in less than half of the cases a consultation was obtained from a health facility available close to home like sub center or a primary health center. Only 8.8 % of infants were taken to Tehsil, District or teaching hospital, so need to strengthen health care at home is greater during the neonatal period because 73.8 % of newborns were never shown in a health Centre or hospital. Study done by Awasthi and Panda (1996) 20 found that urban slums preferred those health care providers who so ever is the closest one available. Most often the parents take
the child to a non-governmental dispenser who may not be qualified Practitioner. Whereas Bhandari N et al (2002) 21 reported in his study that the first week deaths commonly (61 %) occurred within 24 hours of recognition of illness which might have been to a short time for effective interventions by care providers. Only six of 45 neonates were advised by primary health care providers for hospitalization. Similarly, 25 (41%) of 61 older infants who had severe malnutrition, sepsis, meningitis, diarrhoea or pneumonia or other illness were referred to hospital.

Conclusion

Our study as well as studies from different parts of globe especially developing countries came to this conclusion that maximum utilization of health care facilities can remarkably help in reducing under five children mortality and moreover, we should make our health facilities more efficient and patient friendly.

Study of Death among Children below five Years of Age and Its Relationship with Person Conducting Delivery and Place of Residence. Using Verbal Autopsy as a Tool in Dehradun

Sushil Dalal¹, Kiran Pande², Neetu Pippet³

¹Associate Professor dept of Community Medicine MMU Amballa, ²Assistant Professor dept of OBG MMU Mullana Ambala, ³Additional SMO State Headquarter Ayushman Bharat, Panchkula, Haryana

Abstract

Substantial reduction in child mortality has occurred in low income and middle income countries in the late 20th century but more than ten million children younger than five years still die every year, one of the important factor which has been observed in under five mortality is the person conducting the delivery. Keeping this in view, this study was conducted to find out relation in-between child mortality of under-five years of age and its relation with person conducting delivery and place of residence. using verbal autopsy as a tool in Dehradun.

Methodology: The survey was done on all the houses of the deceased children residing in our field practice areas by visiting their houses.

Results: Among the 83 deaths reported most of the deaths were conducted by daies and relatives.

Conclusion: Our study shows that delivery conducted by qualified personnel greatly help in reducing the under-five mortality rate.

Keywords: Qualified personnel, deceased children, mortality rate, Millennium development goal, untrained dai.

Background

In India about 2.1 million child deaths occur every year, which is the highest with in a single country worldwide¹. There has been a substantial decrease in child mortality in the past two decades in India. The reduction being more marked in the 1980’s than in 1990’s. despite these impressive gains. India compares poorly in the pace of child mortality reduction to several other countries in South and South-East Asia, including Bangladesh. More disturbing are the data which indicate that the decline in the child mortality rate is slowing in India². According to UNICEF estimates, child mortality rates have been reduced by around 12 percent over the period 1990 – 2002. Given the average annual rate of reduction of 1 percent, the pace of progress needs to be increased significantly to achieve millennium development goal MDG – 4³. Appropriate delivery care is crucial for both maternal and perinatal health and increasing skilled attendance at birth is a central goal of the safe motherhood and child survival movements. Skilled attendance at delivery is an important indicator in monitoring progress towards Millennium Development Goal 5 to reduce the maternal mortality ratio by three quarters between 1990 and 2015⁴. In addition to professional attention, it is important that mothers deliver their babies in an appropriate setting, where life saving equipments and hygienic conditions can also help reduce the risk of complications that may cause death or illness to mother and child (2006)⁵. One of the resent change which has been observed in government policies is emphasis on institutional deliveries in respect to home deliveries.

Material and Method

The study was undertaken for one year in the field practice areas of department of community medicine HIHT Dehradun after taking approval of institutional
ethical committee. The total population registered under Rural Health Training Centre (Rajeev Nagar) & Urban Health Training Centre was 12,588 and 12,930 respectively out of which under five children were 1297 at RHTC and 1325 at UHTC.

Discussion

In the present study most of the deliveries in rural area i.e. 59% was conducted by untrained dai or relatives while in the urban slum 39.7 % was conducted by untrained personnel. Overall 48.2 % of delivery in the study area was conducted by trained personnel. The delivery conducted by trained personnel and the delivery conducted by untrained personnel do presents risks to newborn. However the difference between delivery conducted by and place of residence was found to be statistically insignificant. According to NFHS – 3 survey done Uttarakhand 7, almost half 48 % of births was assisted by trained personnel in last 5 years and as per NFHS – 3 India, 47 % of birth in last 5 years were assisted by health personnel while 37 % was assisted by TBA. In a study done by Katz et al (2003) 8 while analyzing the risk factors for early infant mortality in Sarlahi, Nepal found that only 2.8 % women delivered in hospitals and 1.8 % were delivered by a doctor, most women delivered at home with the help of family or untrained birth attendant. Another study done by Garg et al (1993) 9 shows in their study on neonatal mortality in Meerut district, that 90.5 % of these were home deliveries, 45.3 % were delivered by an untrained birth attendant and 30.9 % were delivered by TBA. 11.9 % were delivered by a family member.

Haque A (1996) 10 also found in his study done in urban slum of Dhaka that over 75 % had deliveries performed by an untrained attendant. 8 % delivered the infant themselves. And 3% had a doctor assisted deliveries. Adamson PC (2012) 11 observed the increase in cesarean section rates suggests that more women are being identified with pregnancy complications through institutional delivery, the increase in community NMR indicates the continued delivery of high risk or complicated cases in home births. Caste disparities continue to exist, with women of lower castes continuing to have higher rates of home birth. Maternal complications during delivery have been reported as a key factor in neonatal mortality in India Kumar et al.(2014) 12. Titaley et al. (2012) 13 also concluded that in urban areas, infants of mothers with delivery complications who were delivered at health care facilities had a reduced risk of death. Study done by De Costa et al. (2014) 14 also stresses on the same approach as Gujarat government’s emphasis on promoting institutional delivery among BPL or ST mothers is a step in the right direction, not just for maternal death reduction but also for NMR reduction. Study done by Lawn (2005) 15 also came to this conclusion that maternal complications in labor carry a high risk of neonatal death. Recent study done by Fink (2015) 16 also states that Facility deliveries have the potential to reduce early neonatal mortality in developing countries.

Conclusion

Our study as well as studies from different parts of globe especially developing countries came to this conclusion that person conducting a delivery has a great role in decreasing under five mortality especially neonatal mortality. And if we go for institutional deliveries then both neonatal mortality as well as maternal mortality can be reduced extensively.

Profile of Pediatric Deaths in Bellary District

Gururaj Biradar1, Pavanchand Shetty H2, B Suresh Kumar Shetty3, Haneil Larson Dsouza2, V Yogiraj4, Charan Kishor Shetty5

1Assistant Professor, Department of Forensic Medicine, VIMS Bellary, 2Associate Professor, 3Professor, Department of Forensic Medicine Kasturba Medical College, Mangalore, MAHE Manipal, 4Professor and Head, Department of Forensic Medicine, VIMS Bellary, 5Assistant professor and Unit head, department of Forensic Medicine, University Sultan Zainal Abidin( UniSZA) Malaysia

Abstract

Study was conducted in VIMS bellary on cases brought for autopsy. The data was collected from the postmortem report of the body brought for autopsy. The study done on 607 pediatric deaths in retrospective manner. In this study it was found out that male mortality was higher in comparison to females. The vulnerable or susceptible age group among the studied sample was 12 to 18 years. Road traffic accident was found to be one of the major killers

Key words. Paediatric death, Autopsy, Road traffic accidents

Introduction

To improve maternal and child health it is important to find the cause of death and the quality of health services in that particular area. Infant and child mortality being a major concern in our country government is trying its best to take adequate measures. Initial 18 years of life is considered as childhood. The measures can only be effective if it is supported by adequate statistical data. To improve child health and get reforms in the health care sector proper static is required to know the scenario existing in the health system. Understanding of various causes of death in this age group will help in implementing various preventive methods and its effectiveness. The present study was a retrospective study numbered 607 which was studied and classified under various categories.

Materials and Method

In the present study the information was collected from the postmortem reports of the autopsy done in the VIMS bellary mortuary. The study is a retrospective study and the data collected was processed and analyzed. In this study 607 pediatric death cases were studied and various parameters were collected and analyzed.

Results

In the present study most of the victims were male in comparison to females. Male preponderance was found to be more in this study (Table 1). The age wise distribution of deaths showed that maximum deaths were seen in the age group of 12-18 years and minimum was less than 1 year( Table 2 ). Road traffic accident was found be one of the main cause of death followed by poisoning( Table 3 ).

Table no. 1. YEAR WISE

<table>
<thead>
<tr>
<th>Year</th>
<th>Male</th>

</tr>
</tbody>
</table>
Accidental deaths were more common than other manner of death. Suicidal and accidental deaths were predominant in males in comparison to females.

**Discussion**

In this study mortality was more in the age group of 12 to 18 years. The most common mode of death being road traffic accident. This study gives an insight into the particular sex being more vulnerable and the problem of road traffic accident affecting the younger age groups. The male population being more vulnerable might be due to aggressive nature and risk taking behavior among male population. In this study it was found out that 12 to 18 years age group was most vulnerable. In the study conducted in Virginia state similar findings were seen. Males were more in number compared to females because of the risky activities and aggressive nature they are prone to causalities and similar findings were observed by Cekin et al. and Vali et al. Death due to drowning is due to activities of children’s in water bodies like swimming, bathing and other recreation activities which was also found in study by Ahmed et al.

**Conclusion**

This study gave an insight into the pattern of death in pediatric population. The study showed that male are affected more and most vulnerable age group is between 12 to 18 yrs. This study also brought into notice the road traffic accident affecting younger population. The study results bring into focus the various problems and dangers affecting younger population which can further guide us in taking some preventive strategies in preventing mortality.

Prevalence of Knee Dysfunction in Mallakhamb Players in Karad

Arundhati V. Nimbalkar¹, S. Anandh²

¹Final Year, ²Professor, Department of Community Health sciences, Krishna college of Physiotherapy, Krishna Institute of medical sciences deemed to be university, Karad, Maharashtra

Abstract

Background: Mallakhamb is combination of Yoga, Gymnastics and Martial Arts. There is various types of mallakhamb such as pole, rope, hanging, niradhar(without support), on cane, on floating platform, mallakhamb with weapons etc. but at competitive level only pole, rope and hanging mallakhamb are being performed by mallakhamb player.In the sport, knee is common injury site. Knee dysfunction leads to long absence from sports and are one of the main causes of permanent sports disability. Common cause of musculoskeletal pain is hypermobility. In mallakhamb players knee dysfunction is diagnosed with the help of KOOS scale. Conservative management is important to correct knee dysfunctions in mallakhamb players. This study has been undertaken to check the prevalence of knee dysfunction in mallakhamb players.

Objective: To find out the prevalence of knee dysfunction in mallakhamb players.

Method: An observational study was carried out using a cross sectional study design. The study conducted in and around karad, Maharashtra. The samples were chosen using the simple random sampling method. The participants in this study were both males and females who were played state and national level mallakhamb game more than 6years. Subjects who played only national level mallakhamb game and subjects who were not willing to participate in mallakhamb were excluded from this study. Study was conducted using a sample size of 84 mallakhamb players (n= 4pq/L² ) for a period of 6 months. The materials was used in this study includes paper, pen, data collection sheet, consent form.

Results: On the basis of statistical analysis there was significant knee dysfunction in mallakhamb players.

Conclusion: After analyzing the data, it was concluded that there is a prevalence of knee dysfunction in mallakhamb players.

Keywords: Mallakhamb players, hypermobility, knee dysfunction, KOOS.

Introduction

Mallakhamb is combination of Yoga, Gymnastics and Martial Arts. There are various types of mallakhamb such as pole, rope, hanging, niradhar(without support), on cane, on floating platform, mallakhamb with weapons etc. but at competitive level only pole, rope and hanging mallakhamb are being performed by mallakhamb player¹. At competitive level, gymnast has to perform a set of elements transitional movement satisfying the requirement of ‘Code of Mallakhamb Federation of India².’

Mallakhamb is the game which is played against the gravity. It requires agility, quickness of reflexes, coordination of different muscles, strength, flexibility to execute turn and twist which stretch and maintain balance on the pole during practice or competition.
In the sport, knee is common injury site. Knee dysfunction leads to long absence from sports and are one of the main causes of permanent sports disability[4].

Most common factor during this practice is hypermobility which leads to musculoskeletal pain which further leads to knee injuries[9].

Being a traditional sport, the absence of proper physio and medical care results in increased incidence of knee dysfunction. Joint hypermobility is a feature of several disorders that results in joint laxity which can cause dislocations, subluxations and sprains[6].

Knee dysfunction was defined as any orthopedic conditions of the knee that contributed to a decreased level of function as perceived by the individual[11,12].

There are various outcome measures which are used to quantify knee injuries in athletes specifically in Mallakhamb players but KOOS is very easy to determine, with no any equipment or technology involved, and is validated for clinical and research use. A 2010 systematic review found that subjects categorized as hypermobile were at a significantly increased risk for sustaining knee injuries, but not ankle injuries, compared to their non-hypermobile peers[12].

This study has been undertaken to check the prevalence of knee dysfunction in mallakhamb players.

**Methodology**

An observational study was carried out using a cross sectional study design. The study conducted in and around Karad, Maharashtra. The samples were chosen using the simple random sampling method. The participants in this study were both males and females who were played state and national level mallakhamb game more than 6 years. Subjects who played only national level mallakhamb game and subjects who were not willing to participate in mallakhamb were excluded from this study. Study was conducted using a sample size of 84 mallakhamb players (n= 4pq/L²) for a period of 6 months. The materials used in this study includes paper, pen, data collection sheet, consent form.

**Procedure**

An approval for the study was obtained from the Protocol committee and Institutional Ethical committee of KIMSDU. Individuals were approached and those fulfilling the inclusion criteria were selected. The procedure was explained and written informed consent was taken.

Demographic information of the subjects was taken. Individuals were thoroughly explained about the procedure. If any word or terminology in the questionnaire was not familiar to them, it was explained to them. A thorough and necessary assessment were taken. The intensity of pain and knee dysfunction of each individual was noted. The score was calculated and data was recorded. Later statistical analysis was done.

**Findings**

Discussion

Mallakhamb is the combination of yoga, gymnastics and martial arts. There is various types of mallakhamb but at competitive level only pole, rope and hangingmallakhamb are being performed by players. Gymnasts has to perform a set of elements transitional movements which is against gravity. The performers to execute turning and twisting, stretching movement and balance exercises on mallakhamb during training and competition. In this game, hypermobility is one of the factors which can cause musculoskeletal pain. Lack of proper physio and medical care results in increased incidence of knee dysfunction in this game. Therefore, consequent negative impact on players.

This is a prevalence study of knee dysfunction in mallakhamb players. There is generalised ligament laxity in this player which leads to joint hypermobility resulting in increased incidence of knee injuries such as pain, dislocation, subluxation and sprains. Movements in mallakhamb game such as turning, twisting, locking, jumping, sudden jerk and landing which also cause of risk of knee injuries.

This study was done in 6 months of duration with sample size 84 and age 12-28 years. Later this group were divided into pre-operative and post-operative subjects. Subjects were selected as per inclusion and exclusion criteria. Consent from was taken from subjects and assessment were done.

According to SAYALI DHURI, DR SAJEER USMAN, conducted a study on prevalence of hypermobility in traditional gymnasts and its comparison with normal population. This study shows that mallakhamb players have more generalized hypermobility than same age normal children. So due hypermobility increases the incidence of knee injuries in mallakhamb players.

After that pain assessment were done with the help of VAS score and then ask to fill KOOS questionnaire, which includes 5 dimensions were scored separately: pain(9 items), symptoms(7 items), ADL(17 items), S/R(5 items), QOL(4 items) and their total score were calculated.

Table no.1- shows that mean of VAS score at rest is 2.17 and on activity is 5.2 in pre-operative subjects.

Table no.2- shows that mean of pain is 49, symptom is 59, ADL is 59.7, S/R is 42.1 and QOL is 43.5 (KOOS Score) in pre-operative subjects.

Table no.3- shows that mean of VAS score at rest is 1.8 and on activity is 4.33 in post-operative subjects.

Table no.4- shows that mean of pain is 74, symptom is 72.9, ADL is 75.7, S/R is 67.1 and QOL is 63.7 (KOOS Score) in post-operative subjects.

According to articles and this study proved that there is increase incidence of knee dysfunction due to hypermobility in mallakhamb players which consequent negative impact on players and on knee joint. so the findings suggest that therapist should consider the factors that impact on plassyers and with the help of this study can concentrate on knee dysfunction in mallakhamb players for future training and red alerts.

Conclusion

On the basis of the results of the study, it was concluded that there is significant knee dysfunction in mallakhamb players. After analysing the KOOS score it was found that in pre operative patients KOOS score is less which means they have extreme knee problems while in post operative patients KOOS score is more which means they had less pain or knee dysfunction.

Acknowledgement: I sincerely thank the management of KIMSDU for allowing me to conduct this study by providing me the necessary requirement. I thank Dean and my guide Dr.S. Anandh for his support and helping me in my research. I take this opportunity all those who have been directly and indirectly involved for smooth conduction of this study.

Conflict of Interest: There were no conflicts of interest in my study.

Source of Funding: Funding is given by Krishna Institute of Medical Sciences, “ Deemed to be” University, Karad.

Ethical Clearance: The Institutional ethics committee has hereby given permission to initiate the research project titled, “PREVALENCE OF KNEE DYSFUNCTION IN MALLAKHAMB PLAYERS IN KARAD”.

Bipolar Disorder: A Major Setback in Substance Abuse

Jeetendra Kumar Gupta
Institute of Pharmaceutical Research, GLA University Mathura, Uttar Pradesh, India

Abstract

Substance abuse refers to harmful or precarious use of psychoactive substances, including alcohol, cannabis and illicit drugs. It is directly and indirectly responsible for millions of morbidities each year. It is a crucial snag of present generation. Illegitimate use of psychoactive drugs can lead to lunatic illnesses. The prevalence of psychotic disorders among patients with substance abuse has attended noticeable magnitude. This study indicates that bipolar disorder is more likely to occur in patients with substance abuse. Chronic substance abuse can lead to down-regulation of concerned receptors as well as erosion of gray matter in the prefrontal cortex of brain. Hence, it would be imperative to address bipolar disorder from the perspective of potential and progressive adverse effect of substance abuse. The observation of study indicates that bipolar disorder is more prevalent in cannabis, alcohol and cocaine abuse cases. Drug abuse disorders are associated with impaired outcome of manic depression maladies that brings severe high or low moods, thinking and behavior.

Key words: Bipolar, Mania, Hypomania, Depression, Substance abuse.

Introduction

Bipolar disorder is a mental condition that causes marked plunging of mood, energy and ability to think clearly. It is a state of mental illness in which mood reversals achieve emotional highs (mania or hypomania) as well as emotional lows (depression) at two distinct periods of time. It is observed that bipolar disorder is partly caused by an underlying complication with discrete brain circuits and the functioning of brain neurotransmitters. According to a scientific study, bipolar disorder is a severe and often chronic psychotic sickness touching almost 2% to 5% of population. It exists in two forms: bipolar I and bipolar II. The difference between these two subtypes lies in the severity of the manic episodes. In bipolar I disorder, the manic episode is full blown, while a person with bipolar II will experience hypomanic episode without any characteristic change in depressive phase. Factors that may influence the risk of developing bipolar disorder for the first episode include – consanguinity, drugs and alcohol abuse tendency and major life changes such as nervous breakdown. These factors may cause certain imbalance in the normal level of dopamine, norepinephrine and serotonin. These neurotransmitters have influential roles on mood swings (figure 1). Among the all factors, drug abuse and alcoholism are wide spread factors especially in adolescents and youth. It has been observed that bipolar disease is more facile in youth as compared to old individuals.

Substance abuse is habitual intake of illegal drug or substance for the purpose of psychostimulation or euphoria. Substance abuse can lead to drug-dependence. The term drug-dependence refers to a state arising from repeated intake of an abusive substance on regular basis. It is capable of altering mood and feelings. The person suffering from drug dependence has either psychological or physical dependence, addictions or habituation in order to acquire euphoria, retraction from reality or for the purpose of social adjustment. Drug addiction is complex condition, a brain disease which is characterized by compulsive substance use despite many

Bipolar disorder is one of the serious upshots which is frequently observed in substance abuse cases. This article emphasizes on bipolar disorder as a major setback in substance abuse cases.

**Bipolar Disorder and Drug Abuse**

The cases of substance abuse are growing up day by day, especially in younger population due to the lack of knowledge and awareness. Teenagers are more susceptible to this vicious katzenjammer, since they are less cognizant with the pros and cons of those felonious substances. Drug abuse has become a significant public health issue of present time. Prior studies have suggested that psychotic illnesses and cognitive impairments are the most noxious adverse effects of this malign habit. There is an intense relation seen between drug abuse and bipolar disorder. Although it has not been seen that bipolar disorder makes people more likely to abuse drugs, but drugs such as cannabis and alcohol often make the symptoms of bipolar disorder worse. Imbalance of neurotransmission in brain as well as certain genetic complicity can also cause bipolar disorder. Traumatic brain injury is also a risk factor for this illness. People with bipolar disorder perceive drastic shifting of mood between intense emotional highs and depressive phase. There are four major ordeals that a person can experience with substance abuse linked bipolar disorder. Those are manic or hypomanic episodes with depression or mixed episodes. Manic episode is a state of emotion mainly characterized by elevated mood with exaggerated state of well-being. Hypomania is a lenient configuration of mania. Mania or hypomania can occur in bipolar disorder that ranges from depressive lows to manic highs.

Cannabis and cannabis products are highly lipid soluble substances. They contain plethora of chemicals. Tetrahydrocannabinol (THC) is one of them which indirectly triggers dopamine release in brain. Hence, it can affect brain’s reward system also. Similarly, alcoholism and other abusive substance like...
cocaine and amphetamine etc have also intense impact on dopaminergic system\textsuperscript{15}. The fervent reward sensation of drug abuse creates a strong feeling of pleasure. This experience instigates high and more frequent drug intake in order to get more pleasure of the reward response over and over. As a result, craving of the rewards linked with the drug abuse continue to occur, which leads to provocation of repetitive and compulsive use. On the other hand, long-term continued drug abuse results in reduction in the number of dopamine receptors in brain in order to maintain homeostasis for the elevated level of dopamine\textsuperscript{16}. This reduction in dopamine receptors leads to giant impact on addiction. Firstly, due to less dopamine receptors, a state of reduction in pleasure response is created which is known as ‘anhedonia’ and secondly, this depressive feeling of anhedonia drives the user to administer stronger dose of the substance which leads to acute toxicity\textsuperscript{17}. Long term substance abuse has diabolical impact on the user. Chronic use of abusive substance starts to erode gray matter in the prefrontal cortex of the recipient. This erosion in prefrontal cortex leads to organic damage. Drug abuse and addiction causes change in the brain that leads to bipolar disorder\textsuperscript{18}. Even the recipients who were mentally healthy before can develop bipolar disorder due to their substance abuse nature.

**BIPOLAR DISORDER TEST AND SCREENING**

Although there is no any specific blood test or brain scan technique to diagnose bipolar disorder, but certain tests such as thyroid function test and urine examinations can be carried out in order to identify the aggravating factors\textsuperscript{19}. These tests can help in diagnosing the problem if other factors such as drug abuse, habituation or addiction are laissez-faire in the pathogenesis. However, most of the cases of bipolar disorder have a close association with substance abuse (figure 2). Comorbid bipolar disorder with substance abuse is frequently observed and has highest rate of dejections including cardiovascular disorders, respiratory disorders and sleep apnea\textsuperscript{20}. People with substance abuse disorder have highest incidences of mania and hypomania amongst the total patients. The prevalence of substance abuse linked bipolar disorder was observed in the patients of Indian hospitals after scrutinizing the data of 6000 patients (from January to December, 2019), which was further segregated on the basis of radix amongst 243 patients of bipolar disorder. The occurrence of substance induced bipolar was noticed in 102 patients (42%). Amongst these, 56 patients (23%) were suffering from cannabis abuse and addiction, while 43 patients (18%) were observed with chronic alcoholism. There were only three patients who were affected with cocaine linked bipolar disorder. Out of the total cases of manic depression, 76 patients had family history of psychiatric illnesses, while 65 patients had no reason for this malady. Although the consumers of alcohol are very high in the population, but the incidences of substance abused disorders were not seen in those people who were occasional drinker and don’t violate the guidelines of safe drinking.

![Figure 2: Basal demographic and clinical perceptions of bipolar disease](image-url)
Conclusion

Drug abuse has become a significant public health concern of present time. Hassle of bipolar disorder and substance abuse are frequently related. The sufferer of substance abuse, addiction and habituation are more likely to have bipolar disorder. During the screening test, almost 243 patients were assessed and explored for bipolar which were approximately 4% of the entire cohort. It was found that the two subtypes of bipolar disorder have nearby similar prevalence in substance abuse cases. Cannabis linked bipolar disorder was in the largest subgroup, at 23%, followed by chronic alcoholism induced 18% and other drugs induced bipolar disorder at 1%. In chronic substance abused patients, the average age of onset of bipolar disorder was 21.2 years, while 26.5 years of mean age value was seen in those without substance abuse. Influential role of family history was also seen in about 31% of the total patients. The mechanism behind substance abused manic depression lies in the imbalancing of neurotransmitters such as dopamine, norepinephrine and serotonin. Long term continued drug abuse results in reduction of dopamine receptors as well as erosion of gray matter in the prefrontal cortex area of brain. In addition to illicit substances, several ‘over the counter’ drugs as well as prescription medicines have also been involved in the outbreak of bipolar disorder. The cardinal feature of drug or substance induced bipolar disorder is the onset of symptoms in context to abuse, intoxication or withdrawal.

Discussion

The co-occurrence of bipolar disorder is high with substance abuse cases, but the mechanism of pathogenesis has not been explored adequately till date. Evidences suggest that drug addiction has very tenacious consequences and a number of other complications have also been reported in the management and clinical therapeutics. Psychosis is an umbrella term that covers many mental illnesses, in which bipolar psychosis occupies an inclusive spectrum. It is a relapsing mood disorder characterized by mania as well as depression. Delusion may be associated in both depressive and manic phase. In mania, the person may be crabby, overactive or grandiose, while in depression the person may have symptoms like unipolar disorder.

Drug addiction has become a can of worms for youth and teenagers. People with substance abuse have higher percentage of mania and depression than normal population. Reduction in or curtailment of substance abuse sensitization is likely to increase therapeutic benefits in bipolar disorder and other concerned psychotic episodes. Certain environmental factors, such as stress or trauma may cause genetic changes that can propagate down through progeny and may come up with certain psychiatric illnesses or substance use disorder. Bipolar disorder is often labyrinthine by co-occurrence of substance use, and there has been very little studies available particularly targeting the co-morbid population. Thus, an effective as well as substantial focus is required targeting intensive therapeutic interventions so that the rogue ailment could be controlled in due course of time.

Tunica Vaginalis Flap Versus Inner Preputial Dartos Flap as Waterproof Layer for Proximal Staged Hypospadias Repair: A Comparative Study

Zakaryia Yahya Moosa¹, Yousuf Mohammed Al-hallak²
¹ M.B.Ch.B., Medical city, Baghdad, Iraq, ² M.B.Ch.B. F.I.C.M.S. F.E.B.U. FRCS, (Glasg) (Consultant Urologist), Medical city, Baghdad, Iraq

Abstract

Background: Hypospadias is an abnormality of anterior urethral and penile development in which the urethral opening is ectopically located on the ventral aspect of the penis proximal to the tip of the glans penis, which, in this condition, is splayed open.¹ The urethral opening may be located as far down as in the scrotum or perineum. The penis is more likely to have associated ventral shortening and curvature, called chordee, with more proximal urethral defects.

Aim: To compare the outcome of using tunica vaginalis flap to dartos flap in proximal two stage hypospadias repair in reducing post-operative complication (dehiscence and fistula).

Materials and Methods: In the defined period of January 2015 to June 2018, 47 male patients with clinical diagnosis of penoscrotal hypospadias, The age of the patients range from 2 years to 10 years, All these cases were managed in 2 stages repair with buccal mucosal graft, with either tunica vaginalis flap (group A) (25 cases) , or preputial dartos flap (group B)(22 cases) as a second cover over new tubularized urethra. We compared between these two groups regarding complications rate.

Result: we observed that tunica vaginalis flap was better than dartos flap (although it was statistically non-significant p value 0.214 > 0.05) specifically in fistula formation.

Conclusion: we observed that tunica vaginalis flap had excellent outcome when used as a second layer over the neourethral suture line in term of decrease the fistula rate and wound dehiscence because of its good vascular features.

Keywords: Comparative study, preputial dartos flap, waterproof layer

Introduction

The word “hypospadias” is derived from the Greek words hypo, which means below, and spadon, which means rent or hole. Hypospadias is the most common congenital anomaly of the penis.¹ A spectrum of abnormalities, including ventral curvature of the penis (chordee), a hooded incomplete prepuce, and an abortive corpus spongiosum, are commonly associated with hypospadias. Surgery is indicated where deformity is severe, interferes with voiding, or is predicted to interfere with sexual function. [2,3] More than 150 methods of corrective surgery for hypospadias have been described. Currently, many urologists perform one-stage repairs with foreskin island flaps and incised urethral plate. It now appears that buccal mucosa grafts are more advantageous than others and should be considered the primary grafting technique when indicated. [4]

So we need five basic steps for successful; orthoplasty, urethroplasty, meatoplasty and glanuloplasty,scrotoplasty, and skin coverage. [4]

Diagnosis includes clinical description of the local findings; position; shape and width of the orifice,presence for the atretic urethra and division of corpus Spongiosum,appearance of preputial hood and scrotum, with determination size of the penis, and curvature of penis on erection. diagnostic evaluation also includes an
assessment for the associated anomalies, such as undescended testis and inguinal hernia.

The using of protective intermediate layer is still evolving, Durham Smith (1973) de-epithelialization, Snow (1986) described the use of Tunica vaginalis wrap, Retik (1988) was the first to use dorsal subcutaneous flap from the prepuce, Motiwala (1993) described the use of Dartos flap from the scrotum, and Yamataka (1998) reported the use of external spermatic fascia flap.

Aim of this Study

To compare the outcome of using tunica vaginalis flap to dartos flap in proximal two stage hypospadias repair in reducing post-operative complication (dehiscence and fistula).

Patients and Methods

In the defined period of January 2015 to June 2018 a total of 47 male patients of proximal hypospadias were operated on in ghazi alhariri surgical specialties, medical city hospital, Baghdad.

The age of the patients range from 2 years to 10 years. All these cases were planned to be managed in 2 stages repair with buccal mucosal graft, with either using preputial dartos flap or tunica vaginalis flap as a second cover over new tubularized urethra.

All patients and their family were given special formula included written informed consent for participation. The demographic data of all cases were recorded. Antenatal, postnatal and family history were taken. Local and general examination were done in all patients including examination of scrotum to exclude undescended testis. Penile anthropometry was documented in case sheet. Routine investigations were performed (CBC, RFT, virology, CXR) in addition to renal ultrasound, and karyotyping to exclude intersex, operative details (anesthesia check list, notes of the surgeon, time of surgery, any complications), early postoperative examination (wound infection, seroma formation, hematoma formation, penile skin necrosis, wound dehiscence) and follow up data at 1,3,6,12 months (fistula, meatal stenosis, urethral stricture or diverticulum, testicular ascent or atrophy, penile torque). All patients were kept fasting for 6 hours before surgery.

Inclusion criteria was penoscrotal hypospadias with good graft intake and successful chordoplasty. While exclusion criteria were previous circumcised patient, poor taking or retracted graft, unsuccessful chordoplasty, and bilateral orchiopexy.

In the 2nd stage which was usually happened 6-9 months from the 1st stage, after tubularization of new urethra, we divided the patients into two groups: Group A (25 cases) those who underwent tunica vaginalis flap as a second waterproof layer, and Group B (22 cases) for whom we used preputial dartos flap as a second waterproof layer.

Figure1: (A) dissection of testis and spermatic cord and mobilization to surgical field, (B) harvesting TVF, (C) fixation of TVF over neourethra, (D) penile skin closure.

Silicone catheter or stent were removed on average 7 days post operatively then we followed the patients sequentially for up to 6 months, Outcome was assessed at Day 7 after removal of the stent and at first follow up visit.

During follow up visit, we concentrated on any urine leak from the wound and examined the wound to ensure good healing. The maximum follow-up is up to 2 years for earlier operated patients.

Statistical Analyses

Statistical analyses were performed using SPSS statistical package for Social Sciences (version 20.0 for windows, SPSS, Chicago, IL, USA). Data are presented as mean ± SD, and number and percentage for qualitative
variables. Qualitative relations were evaluated using Chi-square test. P value of <0.05 was considered statistically significant.

Discussion

The hypospadias surgery is permanently developing. Actually, the hypospadias field need good imagination, excessive delicateness.

In the present study, we enrolled 47 patients with mean age of 4.9 years most of them from 2-4 years, then we divided them in two 2 groups ; group (A )for whom we applied tunica vaginalis flap as a second waterproof layer and group (B) for whom we used preputial dartos flap as a second water proof layer . Regarding to the age and the number of the patients, our study was comparable to the jiwan et al. [5] Usually we deal with penoscrotal hypospadias as two stages procedure, which was well accepted in many literatures. [6,7,8] in the 1st stage our target to straight the penis by complete degloving with or without dorsal plication ( in our study 5/47 (10.63%) needed dorsal plication which is comparable to Castagnetti and co-worker study (5%), [9] as well as to Yogender and his co-worker study.[10] In our study we achieved 100% success result of graft intake, these results are similar to johal et al. [11] and Faure et al. [12] Snow et al [13]. in 1995, were the first to announce the use of tunica vaginalis flap, the fistula rate reported was 9%. In his recent experience, Snodgrass in his new series reduced the fistula rate to 0% with the use of tunica vaginalis flap. [14] we recorded rate of fistula (0%) in TVF group which is better than Yogender et al[10] who reported (9%) fistula rate and also better than Shankar et al.[15] and Handoo et al.[16] Both report same fistula rate of (11%),but its comparable to Chatterjee et al.,[17] who recorded (0%) fistula rate.

we recorded no testicular ascent, wound dehiscence or testicular abscess (0%) which were comparable to Yogender et al [10],in the tunica vaginalis flap group patients, no body develop meatal stenosis (0%) which is better than Kamyar et al.[18] who reported (14%) meatal stenosis. In TVF group scrotal swelling developed in one case (4%) which resolved spontaneously after one week and its less or comparable to Yogender et al[10] who reported (4%) scrotal hematoma ,by the way he put scrotal drain in all his patients ,unlike in our study the scrotal drain used only in one case. In group (A) one case developed acquired chordee which is by examination felt as a cord like structure at the penoscrotal junction which tethered the proximal penis causing (penile torque) (4%), it’s also recognized in many studies like Palabras et al.[19] which need reoperation for release of this tethered tissue.in group B, we used preputial dartos flap. This flap need meticulous separation of dartos from the skin and underlying bucks fascia with support of loupe magnification with avoidance of excessive cauterization to preserve minute blood supply in this
flap. Out of the 22 cases, 2 cases developed primary urethrocutaneous fistula which represented (9%) of total cases, this results was much less than most of the results of other similar studies about penoscrotal hypospadias repair like that which was done by Basavaraju et al (22%) [20], in Chatterjee et al. [17], (12%) in Dhua et al [20] while (66.67%) in Jiwan et al. [5] this high worldwide rate of fistula in dartos flap is due to Structural amendments of the hypospadiac patients. The prepuce is insufficient in most proximal hypospadias cases to provide enough waterproof layer added that Çağrı Savaş et al. [21] Examined microvascular intensity of prepuce in hypospadias cases and found it to be greatly less. Soyer et al [22] established that there is decrease in the level of vascular endothelial growth factor in prepuce of hypospadiac patients and this subsequently cause impairment in the wound healing and recurrent complications after reconstruction. Also Pichler et al. [23] did a quantitative measurements of androgen receptors in prepuce of hypospadias and found androgen receptors mRNA (P = 0.013), and androgen receptors protein (P = 0.014) was significantly elevated. All these evidence suggested that dartos flaps of prepuce might not be the perfect tissue due to vascular, neural, and immunological alterations. 1 out of 22 of dartos group developed meatal stenosis (4.5%). This was possibly due to relatively loss of favourable anatomical feature of glans and urethral plate, which may resulted in a relatively tight closure of the glans over the dartos flap. Jiwan et al [5] reported (16.6%) meatal stenosis in proximal hypospadias repair with dartos flap in both groups we didn’t report skin necrosis (0%), urethral diverticulum (0%) or wound dehiscence (0%), this result was better than Jiwan et al [5] who reported (30%) skin necrosis in dartos group and (0%) in tunica vaginalis flap group. In addition, he recorded (16%) urethral diverticulum in both groups, wound dehiscence (7%) in dartos group and (3%) in tunica vaginalis flap group. Although both tunica vaginal flap and dartos flap had excellent outcome and our results were in favor of in comparison with counterpart recent studies and we observed that tunica vaginalis flap was better than dartos flap.

**Recommendation**

Apply the procedure on larger patients groups. we need longer follow up time for urinary and sexual issues we recommend use the tunica vaginalis flap as a second layer in all cases of proximal hypospadias and in different age groups.

**Financial Disclosure:** There is no financial disclosure.

**Conflict of Interest:** None to declare.

**Ethical Clearance:** All experimental protocols were approved under the ghazi alhariri surgical specialties, medical city hospital, Baghdad and all experiments were carried out in accordance with approved guidelines.

Association of HLA-DRB1 Gene Polymorphism in Rheumatoid Arthritis Patients in Babylon Province, Iraq

Bariaa A. Aljoboury¹, Abdulsamie H. Alta’ee², Sabah J. Alrubaie³

¹Ph.D. Student, College of Medicine, ²Prof. Dr., College of Medicine, ³Prof. Dr., Hammurabi Medical College, University of Babylon, P. Code 51002, Hilla PO Box 4, Iraq

Abstract

Background: The heritability of rheumatoid arthritis (RA) is approximately 40% to 65% for seropositive RA and 20% for seronegative RA. The risk of developing RA has been associated with human leukocyte antigen HLA-DRB1 alleles: HLA-DRB1*04, HLA-DRB1*01, and HLA-DRB1*010 in deferent ethnocentrism. These HLA-DRB1 alleles contain a stretch of conserved five amino acid sequence, the shared epitope (SE), in the third hypervariable region of their DRB1 chain, which has been associated with the risk of developing RA.

Aim of the study: to study the possible association of HLA-DRB1 gene polymorphism of Arabic ethnocentrism PA patients in Babylon Province, Iraq.

Patients and methods: The present case control study was conducted on sixty one patients (18 males and 43 females) of Arabic ethnocentrism RA patients admitted to Rheumatoid Unit in Merjan Teaching Medical City, Babylon Province, Iraq, as well as 127 apparently healthy control subjects (41 males, 86 females) as control group.

Results: The risk of HLA-DRB1*01 allele was assessed through calculation of odds ratio (OR) which was estimated to be 1.95 (95 % confidence interval of 1.03 to 3.70). The risk of HLA-DRB1*04 allele was assessed through calculation of odds ratio (OR) which was estimated to be 4.46 (95 % confidence interval of 2.32 to 8.55). The risk of HLA-DRB1*010 allele was assessed through calculation of odds ratio (OR) which was estimated to be 3.12 (95 % confidence interval of 1.39 -7.00).

Conclusion: The current study documented that RA is significantly associated with the locus HLA-DRB1* and allelic groups HLA-DRB1*01, HLA-DRB1*04 and HLA-DRB1*010 in Iraqi patients with RA.

Key words: HLA-DRB1 Gene Polymorphism, Rheumatoid Arthritis, Babylon

Introduction

Rheumatoid arthritis (RA) is a systemic autoimmune disease characterized by inflammatory arthritis and extra-articular involvement. RA with symptom duration of fewer than six months is defined as early, and when the symptoms have been present for more than six months, it is defined as established ¹⁻³. Twin studies have shown a concordance rate of 15% to 30% among monozygotic twins and 5% among dizygotic twins. The heritability of rheumatoid arthritis is approximately 40% to 65% for seropositive rheumatoid arthritis and 20% for seronegative rheumatoid arthritis. The risk of developing rheumatoid arthritis has been associated with HLA-DRB1 alleles: HLA-DRB1*04, HLA-DRB1*01, and HLA-DRB1*010. These HLA-DRB1 alleles contain a stretch of conserved five amino acid sequence, the shared epitope (SE), in the third hypervariable region of their DRB1 chain, which has been associated with the risk of developing RA ⁴⁻⁶.

In several twin studies, the heritability of RA was estimated to be approximately 60%, pointing towards a substantial influence of genetic risk factors on the development of RA disease \(^7\). Recent genome-wide association studies (GWAS) have identified 101 single nucleotide polymorphism (SNPs) in total, showing the highest contribution of the \(HLA-DRB1\) gene to the development of RA \(^8^{-11}\). \(HLA-DRB1\)-encoded proteins are components of human leukocyte antigen-DR (HLA-DR) molecules and together with HLA-DQ and HLA-DP, they represent the major determinants in the induction of adaptive immune responses. They are expressed, amongst others, by antigen-presenting cells (APCs) and are able to present peptides to CD4\(^+\) T cells. In the 1970s, HLA-Dw4 was shown to be present in the majority of the RA patients which was confirmed by serological HLA-typing identifying HLA-DR4 and HLA-DR1 in association with RA \(^12\). Nowadays, the list of HLA alleles conferring increased risk for RA development is largely known albeit with altered nomenclature. The predisposing HLA-DR alleles were found to have a particular sequence in common, located in the beta chain (HLA-DRB1) at positions 70–74 \(^12\). This has later become known as the shared epitope sequence and as such, the HLA-DR alleles carrying this particular sequence were designated as ‘Shared Epitope alleles’ (SE-alleles). In 2005, it was discovered that the genetic contribution of the HLA locus did not apply to RA as such, but rather to ACPA-positive RA only \(^13\). These data are important as they indicate that ACPA-positive and ACPA-negative RA represent different disease entities with a different underlying pathophysiology. More recently, positions 11 and 13, which are also part of the peptide-binding groove, have been implicated in the association between HLA and RA \(^14\). However, as these positions are the most polymorphic in the HLA-region, these two positions most likely represent the best proxy for the predisposing HLA molecules explaining their association with RA in statistical terms. Because of significant controversy about HLA DRB1 gene polymorphism in association with RA and due to the rarity of Iraqi studies on people living in Babylon province with this regard, the current study was justified and conducted.

### Patients and Method

The present case control study was conducted in Department of Biochemistry, College of Medicine, University of Babylon, and Rheumatoid Unit, Merjan Teaching Medical City, Hilla City, Babylon Province, Iraq. The duration of current study was extended from September 2018 to July 2019. Sample size was determined according to sample size equation. Sixty one patients (18 male and 43 female) with RA clinically diagnosed by specialist physician attended to out clinic of Merjan Teaching Medical City, Hilla City with mean age of (47.43 ±11.34 years), as well as 127 apparently healthy control subjects (41 males, 86 females) with mean age of (48.94 ±12.36 years). Disease severity score of RA patients was determined by use DAS-28. DNA was isolated from white blood cells (WBCs) and (HLAD-RB1) gene promoter polymorphism was determined by Polymerase chain reaction with sequence-specific primers (PCR-SSP).

### Results

The genetic study in the current study involved the assessment of the frequency of HLA-DRB1 allelic frequency in patients with RA and contrasting the results to that of comparable healthy subjects serving as control group. These HLAD-RB1 alleles included HLAD-RB1*01, HLAD-RB1*04 and HLAD-RB1*10. HLAD-RB1*01 allele was identified in 26 (42.6 %) patients and in 35 (27.6 %) control subjects; the difference was statistically significant (\(P = 0.039\)); the allele frequency being higher in patients group. The risk of HLA-DRB1*01 allele was assessed through calculation of odds ratio (OR) which was estimated to be 1.95 (95 % confidence interval of 1.03 to 3.70). This indicates that persons with HLA-DRB1*01 allele are at approximately 2 times the chance to have RA that persons lacking this allele. The etiologic fraction (EF) of HLA-DRB1*01 allele in association with RA was 0.21, as shown in Table 1.

HLA-DRB1*04 allele was identified in 36 (59.0 %) patients and in 31 (24.4 %) control subjects; the difference was statistically highly significant ($P < 0.001$); the allele frequency being higher in patients group. The risk of HLA-DRB1*04 allele was assessed through calculation of odds ratio (OR) which was estimated to be 4.46 (95 % confidence interval of 2.32 to 8.55). This indicates that persons with HLA-DRB1*04 allele are at approximately 4.5 times the chance to have rheumatoid arthritis that persons lacking this allele. The etiologic fraction (EF) of HLA-DRB1*04 allele in association with rheumatoid arthritis was 0.42, as shown in Table 2.

HLA-DRB1*010 allele was identified in 16 (26.2 %) patients and in 13 (10.2 %) control subjects; the difference was statistically highly significant ($P = 0.004$); the allele frequency being higher in patients group. The risk of HLA-DRB1*010 allele was assessed through calculation of odds ratio (OR) which was estimated to be 3.12 (95 % confidence interval of 1.39 - 7.00). This indicates that persons with HLA-DRB1*010 allele are at approximately 4.5 times the chance to have rheumatoid arthritis that persons lacking this allele. The etiologic fraction (EF) of HLA-DRB1*010 allele in association with rheumatoid arthritis was 0.37, as shown in Table 3.

Discussion

In the current study, HLA-DRB1*01 allele was identified in 26 (42.6 %) patients and in 35 (27.6 %) control subjects; the difference was statistically significant ($P = 0.039$); the allele frequency being higher in patients group. The risk of HLA-DRB1*01 allele was assessed through calculation of odds ratio (OR) which was estimated to be 1.95 (95 % confidence interval of 1.03 to 3.70). This indicates that persons with HLA-DRB1*01 allele are at approximately 2 times the chance to have rheumatoid arthritis that persons lacking this allele. The etiologic fraction (EF) of HLA-DRB1*01 allele in association with rheumatoid arthritis was 0.21. In the current study also, HLA-DRB1*04 allele was identified in 36 (59.0 %) patients and in 31 (24.4 %) control subjects; the difference was statistically highly significant ($P < 0.001$); the allele frequency being higher in patients group. The risk of HLA-DRB1*04 allele was assessed through calculation of odds ratio (OR) which was estimated to be 4.46 (95 % confidence interval of 2.32 to 8.55). This indicates that persons with HLA-DRB1*04 allele are at approximately 4.5 times the chance to have rheumatoid arthritis that persons lacking this allele. The etiologic fraction (EF) of HLA-DRB1*04 allele in association with rheumatoid arthritis was 0.42. An association between RA and HLA-DRB1–shared
epitope (SE), including DRB1*04 and DRB1*01 alleles, has been reported. HLA molecules with specific shared epitopes (SEs) are considered to constitute about 30% to 40% of the genetic risk for RA. However, a positive trend was observed with this allele in RA subjects compared to the control group, implying that a survey on DRB1*04 in larger-population samples of both RA patients and healthy people can assist in arriving at a more reliable conclusion on this commonly noticed allele. Further, analysis of the sub-alleles of DRB1*04 can shed more light on the role of this allele with regard to RA association. In addition to a positive association between RA and the presence of HLA-DRB*01 (OR=3.5) and HLA-DRB1*04 (OR=4.0), there was also a positive association between RA and HLA-DRB1*10 (OR=4.4). In our patients, we have established the absence of the DRB1*10 allele group. In the population of Finland, the association between RA and presence of HLA-DRB1*04 was confirmed. Similar results for DRB1*04 were found in studies conducted in Slovakia and Hungary. Research on the distribution of HLA-DRB1 locus conducted in Turkey showed that HLA-DRB1*04 is present in high frequency (46.2%) in RA patients, in comparison to healthy subjects (20.9%); OR=3.24. Analysis of the population from the area of northern Italy showed a weaker correlation between RA and HLA-DRB1*04 and an increased frequency of HLA-DRB1*01 in RA patients (24%), and in the control group, respectively (16%), accompanied by a relative risk of 1.5.

Parents’ Perception of Rehabilitation Services for their Children with Special Healthcare Needs in Helena Center in Erbil City

Zainab Abdulrahman Abdullah¹, Kareem Fatah Aziz²

¹ M.sc., Student, Community Health Nursing, College Of Nursing, Hawler Medical University, ² Assistant Professor, College of Nursing, Hawler Medical University

Abstract

Objective: First, to determine the socio-demographic characteristics; second, to identify parents’ perception of rehabilitation services; and third, to find out the relationship between socio-demographic characteristics and parents’ perception of rehabilitation services.

Methods: A descriptive cross sectional study was carried out. The data were collected from May 2019 to September 2019. A non-probability convenience sampling was used, and sample size of 335 parents who attending to Helena center for rehabilitation and operation children with special needs in Erbil city was calculated.

Results: The majority (around 80% or more) of the parents had positive attitudes toward the rehabilitation services provided in the center.

Conclusion: Parents of children with special health care needs in Helena Center perceived services provided to their children as family-centered.

Keywords: Rehabilitation, Children, Special Healthcare

Introduction

The Maternal Child Health Bureau (MCHB) defines children with special health care needs (CSHCN) as “those who have or are at risk for a chronic physical, developmental, behavioral, or emotional condition and who also require health and related services of a type or amount beyond what is required by children generally”¹. Rehabilitation defined as “a set of measures that assist individuals who experience, or are likely to experience, disability to achieve and maintain optimal functioning in interaction with their environments”. The goal of rehabilitation is improvements in individual performance - for example, by improving the ability of a person’s to eat and drink independently. Rehabilitation therapy means improving performance by diagnosing and treating health conditions, reducing disabilities, and preventing complications ². The main focus of Tertiary prevention in health care is to limit or reduce the consequences an existing health condition, by rehabilitation services and interventions that aim to prevent activity limitations and to promote independence ³. Remedy is involved with restoring and compensating for the lack of functioning, and preventing or slowing deterioration in functioning in each area of a person’s existence. Therapists and rehabilitation workers encompass occupational therapists, orthotists, physiotherapists, prosthetists, psychologists, rehabilitation and technical assistants, social employees, and speech and language therapists. Therapy measures include exercises, and compensatory techniques, education, assist and counseling, changes to the environment, provision of resources and assistive technology. There are three main types of rehabilitation therapy are occupational, physical and speech. Each type of rehabilitation serves a unique purpose in helping the person to reach full recovery, but all have one goal is to help the patient to return to a healthy and active lifestyle ⁴. Family-centered care is the preferred service delivery model in pediatric physical therapy. Family-centered care approaches affirm the importance of parent involvement in their child’s health and rehabilitation
services. This service submission model promotes parent-provider partnerships to facilitate communication, care coordination, and access to services. The origin of the word “therapy” is the Hebrew word refua (healing) (Origin of English word therapy, 2015). Rehabilitation therapy, a main ingredient of the Physical Medicine and Rehabilitation curing process, has an extended history. Millenary of years ago the old Chinese utilize Cong Fu, a motion therapy, to reduce pain; the Greek physician Herodicus defined an particular system of gymnastic practice for the preventing and treatment of illness in the 5th century BCE, and the Roman physician Galen described interference to rehabilitate martial injuries in the 2nd century CE. through the midst ages, the philosopher-physician Maimonides confirmed Talmudic rules of sanitary exercising habits, in addition regimen, as preventive medication in Medical proverbs, posted between 1187-1190; and in 1569 the philologist-physician Mercurialis promoted gymnastics as each a preventive and a rehabilitative mode within the art of Gymnastics. In the eighteenth century, Niels Stenson discovered the biomechanics of human movement and Joseph Clement Tissot’s 1780 Medical and Surgical Gymnastics advanced the worth of movement as an alternate to bed rest for patients recuperating from operation, going through neurological situations, and recovering after strokes. In the 19th century, the idea of neuromuscular re-schooling was suggested by means of Fulgence Raymond (1844-1910).

Methods

Design of the study

A descriptive cross sectional study was carried out to identify parents’ perception of rehabilitation services for their Children with special healthcare needs in Helena center in Erbil city.

Setting of the study

The study was carried out in Helena center for rehabilitation and operation children with special needs in Erbil city which was established since 1992.

Time of the study

The study was conducted during the period March 2019 to the November 2019. The data were collected from May 2019 to August 2019.

Sample of the study

The sample size was calculated using Epi Info-7 computer program issue. These criteria were used for sample size calculation: Population 2613, significant level 95%, prevalence of perception and satisfaction 50%, absolute precision 5%. Accordingly the sample was 335 parents who attending to Helena center for rehabilitation and operation children with special needs in Erbil city. The study sample was chosen by non-probability convenience sampling.

Inclusion Criteria

1- Parents who agree to be involved in the study.
2- Both genders (male and female).

Exclusion Criteria

1- Parents who refused participation in the study.

The Study Instrument

In order to collect the proper information of study, a questionnaire was designed and modified depending on extensive review of relevant literature.

Rating Scales and Scores

In order to measure the previous items accurately and statistically in part two and three, each item has been scaled by five levels of Likert scales and scored respectively as follow:

The scale is out of 100 (20 questions X 5 scores = 100). So 1 = 20, 2 = 40, 3 = 60, 4 = 80, and 5 = 100, so the category of 1 and 2 (never and rarely less than 60), sometimes (60-79), and often or always => 80

Data collection method

The data collection process has been carried out from May 2019 to August 2019. An interview technique was used, it took about 25-30 minutes for each parents. All participants were informed that the information will be kept confidential and used just for a scientific purpose.

Results

It is evident in Table 1 that the majority (around 80% or more) of the parents had positive attitudes toward the rehabilitation services provided in the center. They felt that the health care providers cooperate with the parents and pay great attention to the children without discrimination between a child and another. They answer the questions of the parents and teach them what to do at home. The only weaknesses were unavailability
of health education booklets or videos, and the other thing is that the health care providers didn’t provide advice on how to contact other parents.

</table>

It is evident in Figure 1 that the largest proportion of the couples (78.8%) scored between 60-79 % in the total perception score, and only 16.1% scored ≥ 80%.

![Figure 1. Overall parents’ perception of rehabilitation services](image_url)
Table 2 shows no significant association between the parents’ perception with age of the child (p = 0.163), and presence of other child with special care need (p > 0.999). The table shows that the fathers and mothers of a female child had better perception scores than those with a male child (p = 0.025). Regarding the child disability, 25% of those with a child with food deformity had good perception, and 20.7% of those with a child with developmental dislocation of the hip had good perception while fewer rates were detected for the other types of deformities. It is evident in the table that 18.8% of the couples whose child was on physical therapy had higher perception scores compared with 12.6% when the child was on occupational therapy (p = 0.025).

*By Fisher’s exact test.
†Insufficient computer memory to calculate the p value by Fisher’s exact test.
Discussion

One aspect of parent satisfaction is the perception of the processes of care, which is focused on the actions of health care providers and their interaction with clients rather than the specific techniques they perform King (2004). The aim of the study was to obtain the overall perceptions of parents attending therapy services at Helena center. The results of this study suggest that most parents perceive that aspects of care relating to respectful and supportive care, coordination of care occur frequently which is similar to previous research was done in western countries Van Schie (2004). Parents report a lack of information in various forms booklet, video, etc. Similar findings have been reported in other studies. Good information is necessary as a basis for FCC, provision must be sensitively tailored to parents’ individual needs and capabilities. Similar to previous research, parents in our project were satisfied with services. The result of present study reveals that there is no significant statistical relationship between the parents’ perception with socio-demographic regarding fathers and mothers, also there is no significant statistical relationship between the parents’ perception with age of the child which is consistent with the results of Arnadottir (2012)

Conclusion

The overall results obtained in this study are important in understanding the current status of services as seen by parents. As concluded from parents’ responses, there is some issues appear to be in need of improvement such as Provision of information where some parents expressed a desire for more child-specific and general information. The results also showed that parents need additional opportunities to interact with other parents. In general Parents’ perceived that the services provided to their children are family-centered.

Assessment of Patient’s Knowledge Regarding Hemodialysis Therapy at Imam Hussein Medical City in Holly Karbala Governorate

Hussam Abbas Dawood

Ph.D., Lecturer, Adult Nursing Department, College of Nursing, University of Babylon, Iraq;

Abstract

Background: Descriptive and analytical study in which evaluation approach applied in order to achieve the objectives of the study mentioned at the beginning of the search. The study began in 2 April 2016 to 21 June 2017. The research was conducted in order to identify hemodialysis patients knowledge regarding hemodialysis therapy at Imam Hussein medical city in holly Karbala Governorate.

Objectives: to assess hemodialysis patients knowledge about hemodialysis therapy, To find out the relationship between hemodialysis knowledge and some variables such as: age, gender, level of education.

Methods: This Descriptive and analytical study was conducted at Imam Hussein medical city in the province of Karbala, Iraq, from 1 October 2017 to 1 April 2018, use to to identify hemodialysis patients knowledge regarding hemodialysis therapy. SPSS 21 was used for statistical analysis.

Results: shown on Results of the study that Highest percent of the study samples was samples age (50 or more) years old, According to the gender, the study sample were male and female, equal percent and number was (50-50%), Most of the study sample low educational levels, Most of them had married, Finally the general knowledge level of Imam Hussein medical city regarding hemodialysis therapy is High.

Conclusion: Highest percent of the study samples was samples age (50 or more) years old, According to the gender, the study sample were male and female, equal percent and number was (50-50%), Finally the general knowledge level of Imam Hussein medical city regarding hemodialysis therapy is High.

Keywords: hemodialysis patients knowledge, hemodialysis.

Introduction

Kidney failure, also known as renal failure or renal insufficiency, is a medical condition in which the kidneys fail to adequately filter waste products from the blood. The two main forms are acute kidney injury, which is often reversible with adequate treatment, and chronic kidney disease, which is often not reversible. Kidney failure is mainly determined by a decrease in glomerular filtration rate, which is the rate at which blood is filtered in the glomeruli of the kidney. The condition is detected by a decrease in or absence of urine production or determination of waste products (creatinine or urea) in the blood. Depending on the cause (National Institute of Diabetes and Digestive and Kidney Diseases, 2013). Dialysis is the artificial process of eliminating waste (diffusion) and unwanted water (ultrafiltration) from the blood. Healthy kidneys do this naturally. Some people, however, may have failed or damaged kidneys which cannot carry out the function properly - they may need dialysis. Dialysis is the artificial replacement for lost kidney function (renal replacement therapy). Dialysis may be used for patients who have become ill and have acute kidney failure (temporary loss of kidney function), or for fairly stable patients who have permanently lost kidney function (stage 5 chronic kidney disease) (Medical News Today, 2015). If kidneys are damaged the waste product is removed from the human body by hemodialysis procedure. Without dialysis the amount of waste products in the blood would increase and eventually reach levels that would cause coma and death.
Methodology

A descriptive analytic study was designed to identify hemodialysis patients' knowledge regarding hemodialysis therapy at Imam Hussein medical city in holy Karbala, Iraq. The study has been conducted on hemodialysis patients at Imam Hussein medical city in the province of Karbala, Iraq. The data were collected through the use of questions put in the questionnaire and data collection done through used the self-administration techniques. Study population was using purposive selection sample technique, 100 samples from hemodialysis unit at Imam Hussein medical city in the province of Karbala, Iraq.

Instrument

Measure which was built by researchers, who used contain 34 question divided into two sections: Demographic knowledge, Patients’ knowledge of kidney failure and hemodialysis: Knowledge relate to kidney failure, Knowledge relate to causes kidney failure, Kidney and hem dialysis, Problem happen through hem dialysis process, Knowledge must be done after hem dialysis process. The first section of the questionnaire was the participants background; (age, gender , educational level, marital status, duration of kidney failure.

Second section: Patients’ knowledge of kidney failure and hemodialysis.

Rating and scoring

Some question consists of (2) alternative responses, and only one of these alternative responses was considered a correct response. To achieve the purpose of the present study, the responses of emotional distress questionnaire were scored as (3) never and (2) sometimes and(1) always.

(Cut of point) x100 / (No. of scale).

Low = (less than 75), Moderate = (75.1-87.5), High = (87.6-100), these calculated according to the following formula (100-75) /2 =12.5, then this score was added to (75+ 12.5=87.5) moderate level, (87.5+12.5=100) high level (Al-maliky, 2010).

The instrument was validity by a panel of (9) expert from the Karbala university, college of nursing, and (1) from hemodialysis unit at Imam Hussein medical city.

Pilot study:

A pilot study was conducted on a purposive sample of (10) patients which was selected from hemodialysis unit from the period 25 December 2018 to 26 December, 2018. The pilot study sample was excluded from the original sample of the study.

Reliability assessments according to the internal consistency of the studied questionnaire was (75.5%) by using Cronbach Alpha test.

Data analysis:

Statistical analyzes were conducting by using the statistical package for social science (SPSS) version 23. Data analysis was employed through the application of descriptive and inferential statistical approaches which were performed through the computation of the following:(Frequencies(F),Percentage(%),Cumulative percentage ,Means of score(M.S),Standard deviations(SD) and Relative sufficient.

Results of the Study

This chapter present results of the study with correspondence to the study objectives.

...
in the Table (1) represented the sociodemographic characteristics of the sample patients that the most sample was (36%) of the samples age (50 or more) years old, while the lowest percent (12%) were at group (20 or less) years old. According to the gender, the study sample were male and female, equal percent and number was (50-50%), the educational levels, most of the studied sample had low educational levels, since 20 number and percent(40%) of them were primary school graduates and, while the lowest percent (12%) were University or more in percent (4%). With respect to the marital status most of the studied sample was married in percent (66%), The last section of demographic Characteristics is medical history or duration of renal failure, that the (2-4 yrs) was the most sample present (48%).

| 1 | Age | 20 or less | 6 | 12.0 | 12.0 |
| 1 | Age | 21-30 | 6 | 12.0 | 24.0 |

Table 6: Knowledge must be done after hemodialysis process, The results showed that hemodialysis patient had average high knowledge, where knowledge was high in questions (1,2,4,5,6,7) And their average was moderate responses to questions (3,8).

Discussion

This chapter presents a systematically, organized, interpretation and reasonably derived discussion of the results with a support of the available literatures and related studies.

Part one: Discussion of the patients’ demographic characteristics:

In this study, we assessed the knowledge hemodialysis patients knowledge regarding hemodialysis therapy at Imam Hussein medical city in holy Karbala, Iraq, as a results we found in the table (1) represented the sociodemographic characteristics of the sample patients that the most sample was (36%) of the samples age (50 or more) years old, while the lowest percent (12%) were at group (20 or less) years old. this result was agreement
with studies done by (Sharman et al.,2006) and (Levey, et al., 2005).

According to the gender, the study sample were male and female, equal percent and number was (50-50%), this result was disagreement with study done by Nasrin (2014).

According to the educational levels, most of the studied sample had low educational levels, since 20 number and percent(40%) of them were primary school graduates and, while the lowest percent (12%) were University or more in percent (4%), this result was agreement with study done by Tawfiq (2006).

With respect to the marital status most of the studied sample was married in percent (66%), this result was agreement with study done by nurten (2015).

The last section of demographic Characteristics is medical history or duration of renal failure, that the (2-4 yrs) was the most sample present (48%), this result was agreement with study done by 4. In Table (2,3,4,5,6) shown the mean of score, standard Deviation and the relative sufficiency of participant’s in assessment of the level of knowledge regarding hemodialysis therapy that was High.

**Conclusion**

In conclusion, According to the present study finding the researcher has been able to conclude the following: Highest percent of the study samples was samples age (50 or more) years old, According to the gender, the study sample were male and female, equal percent and number was (50-50%), Most of the study sample low educational levels, Most of them had married, Finally the general knowledge level of Imam Hussein medical city regarding hemodialysis therapy is High.

**Financial Disclosure:** There is no financial disclosure.

**Conflict of Interest:** None to declare.

**Ethical Clearance:** All experimental protocols were approved under the College of Nursing and all experiments were carried out in accordance with approved guidelines.

Nurses Competence with Regard Congenital Heart Diseases in Cardiac Care Unit of Pediatric Hospital in Sulaimani City

Banw Azad Mohammed 1, Aso Faeq Salih2

1 Assistant Lecturer University of Sulaimani College of Nursing, Iraq, 2 MBchB, DCH, FIBMS, Higher diploma (pediatric cardiology), Assistant Professor University of Sulaimani College of Medicine, Iraq

Abstract

The activities of the nurse performing duties at a haemodynamic facility is characterized by the need to be able to field a high degree of specialisation. It is absolutely essential that he/she has bases of knowledge and skills also in the field of intensive care and cardiac resuscitation that are adequate for the high complexity of the diseases and procedures that are treated.

Method: Quantitative design with descriptive study was carried out with assessment approach and it was conducted on nurses in cardiac care unit of pediatric hospital in Sulaimani city/Kurdistan region from 1st July 2017-1st May 2018. Non-probability sampling was performed, a purposive sample of (35) nurses, all males and females. Data were shown and tabled in frequencies and percentage, and mean of scores was calculated from ordinal data in five level (5, 4, 3, 2, 1). In the present study the highest mean of score indicates the highest level of practice regarding nursing management. The P-value at 0.05 level indicates the degree of significance. Independent T-test and ANOVA have been utilized to find out the significant relationship of nursing care management with socio-demographic characteristics, and nurse’s skill and experiences.

Result: socio-demographic profile of participants presented. Out of 35 participants studied 21 (60%) were from age group 20 – 30 years, with mean age of 30.4 years. Majority of participants studied 77.1 % were female. Majority of the nurses were graduated for institute 16 (45.7%) and 10 (28.6%) were hold university certificate. According to working experience and skills. Out of 35 participants studied, only 19 (54.29%) attended training session regarding Pediatric Intensive Care Unit (PICU). Around 74.29% of participants were not familiar with PICU drugs. Around 74.29% of participants were not familiar with PICU drugs however, 88.6% of participants were familiar to PICU doses. 80% of the total participants did not attend the periodic educational program and conference/symposium. 97.14% of the participants did not study the books regarding CHD. The right to practice in manner that is suitable for fulfilling the obligations was reported as never by 48.6% of nurses. Regarding perception of ethical practice in work environment major participants 88.6% reported sometime.

Keywords: Congenital heart diseases, Nurses competence, cardiac care unit

Introduction

Competence is defined as knowledge and performance combined with psychomotor and clinical problem-solving skills and a responsive attitude.

Competence of nurses is a complex combination of knowledge, function, skills, attitudes, and values. Delivering care for patients in the Intensive Cardiac Care Unit (ICCU) requires nurses’ competences. The concept of competence has been described by many authors, Meretoja et al. (2004) defined nursing competence in terms of three dimensions, i.e., the nurse’s ability to function professionally, knowledge and skills for collaborating within real-world practices with a degree of understanding, affection, and psychomotor skills, and professional development and the willingness to acquire...
more skills. The activities of the nurse performing duties at a haemodynamic facility is characterized by the need to be able to field a high degree of specialisation. It is absolutely essential that he/she has bases of knowledge and skills also in the field of intensive care and cardiac resuscitation that are adequate for the high complexity of the diseases and procedures that are treated. The set of skills should therefore also include good knowledge of anatomy and cardiovascular pathophysiology, working knowledge of electro-medical equipment, technical skills and knowledge of electrocardiogram monitoring and other highly specialized techniques. In addition, the nurse must know how to relate to others and have the skills needed for performing the process of care, capacity of observation, planning, judgment and decision-taking. Neither should he/she lack the ability to properly interpret information and communicate in a comprehensive way. Continuous updating of the nursing staff is very important in order to constantly increase their professionalism, obviously including constant participation in courses and conferences in order to facilitate cultural and experiential exchange with other situations and at international level.

Method and Materials

Design of the study:
Quantitative design with descriptive study was carried out with assessment approach and it was conducted on nurses in cardiac care unit of pediatric hospital in Sulaimani city from 1st July 2017-1st May 2018. The study carried out to evaluate nursing management regarding children with congenital heart diseases.

Setting of the study:
Pediatric Intensive Care Unit selected as setting of the study which located at Kurdistan region/Sulaimani/Iraq. Most of serious pediatric patient admitting in this unit in order to performing better caring and services. The most critical cases includes: Congenital heart diseases, Pneumonia, Nephrotic syndrome, Sever dehydration, Bleeding, Sepsis, Convulsion, Croop, live fail, and encephalitis.

The sample of the study:
Non-probability sampling was performed, a purposive sample of (35) nurses who were employed in pediatric intensive care unit, and were performed nursing management for (105) pediatric patient with congenital heart diseases.

The inclusion criteria for sample selection:
All nurses who work at cardiac care unit, with both gender (male and female) and all nurses who work at both shifts (morning and evening).

Tools:
The study tool include two parts. First are three section. Section one regarding nurses socio-demographic data (age, gender, years of employment, experience, Level of education, and marital status). Section two consist of information related to pediatric intensive care unit which include supportive activities like training session, educational programs, conference and symposium. Also in section two Self-education and learning is an other item which consist of availability of books and references, time for reading and nurses information regarding scientific web cite and articles, and availability of PICU equipment is also involved in section two, consist of information regarding nurses familiarity with drugs, drug doses, the ways of O2 supply, and equipment like (monitor, ventilator, ECG).

Regarding part two is the observational check list scale includes (40) items concerning practice and activities that should be provided from the nurses to the children with CHD in Pediatric Intensive Care Unit.

Method of data collection:
Data collection method were throw the using of adopted and constructed questionnaire, interviewing technique, and observational technique. Data were collected from (1st July 2017 - 1st April 2018).

Rating scales and scores:
In this study using 3 types of rating scales:

Two points likert scale (Yes and NO)

Three points likert scale (Always, Some time, and Never) is used in the section three of part one.

Five point likert scale:
Poor (1), Fair (2), Good (3), Very good (4), Excellent (5)
Five is the highest score regarding nursing management in the (observational check list part) performed to the children with congenital heart disease in Pediatric Intensive Care Unit.

To make understanding scoring system more clearly, mean of nursing care management were calculate for each subscale, then the score of each subscales have been unified in (0-100).

Statistical analysis:

Descriptive statistics:-

Data were shown and tabled in frequencies and percentage, and mean of scores was calculated from ordinal data in five level (5, 4, 3, 2, 1). In the present study the highest mean of score indicates the highest level of practice regarding nursing management. The P-value at 0.05 level indicates the degree of significance.

Inferential statistics:-

Independent T-test and ANOVA have been utilized to find out the significant relationship of nursing care management with socio-demographic characteristics, and nurse’s skill and experiences.

**. Correlation is significant at the 0.01 level (2-tailed). r: Pearson Correlation,
Nurse’s satisfaction with the nursing rights were taken as the indicators of nursing care management in this study. This study has found that nurses who lesser perceived to work in environmental support and ethical practice had significant high practice in nursing care management. This finding could is considered to be a negative out-come. while, in contrast to that nurses who more perceived to advocate for themselves and their patient, and those who feel to right to safe environment to nurses and patient practice were provide better nursing care management. This finding was observed in other study, it was observed that, the nurse’s right they would improve patient experiences of the quality of nursing care, clinically competent nurses. And the collaborative working relationships, autonomous nursing practice, adequate staffing, control over nursing practice was addressed as the reasons for better practice of nursing care (Kieft et al. 2014). There is many promotion courses for nurturing nursing skill and for providing better nursing performance. Nurses attending academic activities and training course are considered to provide good nursing care management. For instance, in developing countries low academic and educational program for staff lead to poor providing care for patients with CHD and it becomes a substantial challenge for health care. Several patients, who have initial heart conditions, have ended up with secondary irreversible damage or death (Jivanji, 2019). In this study attending academic activities and training were taken as one determinate for nursing care management. The current study has shown that there was not a significant association between attending academic activities and nursing care management. However, those nurses who attend the training, educational program, and search website regarding CHD had provide better nursing care management. Education program in developing countries have significant effect on nursing care management, quality of health care, and impact of the CHD. Different kinds of certificate had made impact on quality of nursing care management, and patient’s out-come. In this concerning, many kinds of certification, courses and training are introduced in the US. The courses such as Cardiac-designated ICUs, Mixed PICUs Academic teaching hospital, American Nursing Certification Center Magnet Recognition, American Association of Critical Care Nurses Beacon Designation have a significant relationship with the nursing care qualities and patient out-come. From another side this study found the relationship between nursing care management (nursing assessment and nursing intervention), and nursing care management with and child period hospitalization. There was a positive weak association of nursing assessment and nursing intervention. And the weak negative relationship of nursing care management was found with child period hospitalization. In some study, the reasons for long hospitalization have been determined, while the relationship of long hospitalization and the nursing care practices have not been studied. According to those study, the cases which stay long in hospital have need to more nursing care and advance skill for clinical assessment and intervention. And it has mentioned that the complexity and complication of CHD such as tetralogy of fallot and respiratory infection (due to respiratory syncytial virus) mostly are determined as the reasons for long hospitalization.

Conclusions

The nurse’s academic background and experience were not good qualified. Most of the nurses had more working experience while working experience in the ICU was less. The nurse’s education background was considerably less by considering developed countries, since only few of them were college graduated nurse. Regarding to training, only (54 %) nurses attended training session regarding Paediatric Intensive Care Unit (PICU). Most of the cases were male, and diagnostic with cyanotic congenital heart.

Assessment of Mother’s Practice among Using Oral Rehydration Solution for their Children with Diarrhea in Babylon City

Abdulmahdi A. Hasan
Assistant prof, Ph.D., pediatric & Mental Health Nursing, College of Nursing, Babylon University

Abstract

Objectives: A descriptive study that aimed to find out demographic characteristics of mothers like age, level of education, occupation and resident area, to find out demographic characteristics of child regarding age, sex and birth order of the child and kind of feeding breast feeding and to assess the mother practices among using oral rehydration solution.

Methodology: The study was carried out at Child and Maternal Babylon Hospital, study period extended from December(2016) to end of the February(2017). Anon-probability sample was selected from Child and Maternal Babylon Hospital and al-Hashemia Hospital, the sample consisted (100) mothers.

Results: showed that (64%) of mothers their age between (20-30) years. also results reveal that (56%) of mothers graduate from primary school, and show that (93%) of mothers were unemployed.

Keyword: mothers, rehydration, child, diarrhea.

Introduction

Diarrhea is a clinical manifestation of a variety disorders of infants and young children and is one of the main causes of morbidity among them in most parts of the world, were crowding and lack of sanitary facilities present a major public health problem, as many infectious agent have been known to cause diarrhea such as bacteria, parasites and viruses. Also diarrhea can readily be produced through physiological and nutritional disorders in the complete absence of any enter pathogens, it is classified according to its severity into three degree, Mild, Moderate and sever. Diarrhea leads to dehydration which cause death in children that before the application of Oral Rehydration Therapy, all children with diarrhea were admitted to hospital for the replacement of fluid by intravenous rout, but no a days after the application of Oral Rehydration therapy the number of admitted cases in hospitals are reduced. ORT is considered as an effective tool in controlling dehydration in children as a result of diarrhea and many Mild diarrheal become moderate or sever due to improper mothers knowledge and practices to treat diarrhea, Oral Rehydration Therapy administration of dextrolytes by mouth to prevent or correct the dehydration that is a consequence of diarrhea it consists of the following sodium chloride 3.5 gram/liters, potassium chloride 1.5 gram/liters, Trisodium citrate dehydrate 2.9 grams/liters and glucose 20 grams/liter. Oral Rehydration Solution(ORS) represents the clinical application of some of the most basic concepts of cellular physiology. It offers a therapy that is inexpensive and simple with very few potential complications. In Iraq diarrhea is considered to be an important cause for infant morbidity and rates bacterial diarrhea contributes to about one third of the total cases of diarrhea in infancy and early childhood. So, we choose the study about this problem because during our practice in the hospital and we found that most of children attending in the hospital with the gastroenteritis (D.V.D) when we spoke with the mothers about how they can manage it at home we found that they have less practices about the ORS, so we interesting to do this research.

Methodology

1. Design of study: descriptive study

2. Setting of study: the study was carried out at Child and Maternal Babylon Hospital.
3. **Time of the study**: the study period extended from December (2016) to end of February (2017).

4. **Ethical Consideration**: Data collection is done by researchers, who kept the confidentiality and anonymity of the data. The form for data collection was applied without mentioning the name of mothers, their address, and taking a verbal agreement were obtained from participants in the study.

5. **The sample of study**: Anon-probability sample was selected from Child and Maternal Babylon Hospital and al-kawthar Health Center, the sample consisted (100) mothers. The questionnaire was used as a mean of data collection, questionnaire concerning mothers’ practice regarding oral rehydration therapy.

6. **Validity**: Validity of the study instrument was determined initially through the panel of experts’ responses were positive toward the study questionnaire, changes and modification were made in respect to experts’ suggestions and recommendations.

7. **Statistical analysis**: Data were analyzed through frequency, percentage, the item were rated according to point type rating scale Yes (1) and No (0).

</table>
Table (1) The table stated that majority of mothers (62%) they prepared 1 liter of boiled cooled water, while (22%) of them prepared by 1 glass of boiled cooled water and (15%) of them they do not known, shows that (45%) of mothers they knew that Oral Rehydration Salt should be used within 6 hours, while (15%) of 1 them they knew with 24 hours, and (25%) of mother used within 12 hour, Regarding the frequency of giving Oral Rehydration Salt (48%) of mothers giving after each stool pass, while (19%) of them they do not known. Also the table show that (66%) of mothers knew that Oral rehydration Salt replaced electrolytes and water lost from the body, and (21%) they do not known. Regarding Oral Rehydration Salt available (49%) of mothers knew are available at Health center. And (11%) they do not known. Also the table shows that (29%) of mothers store it in a cool dry place in closed conditioner and (16%) they do not known. Also the table shows that (45%) of mothers using usual amounts of fluid, while using ORS. Also the table shows that (26%) of mothers given during ORS. The table shows that (56%) of mothers giving to the child Rice water with salt, while (30%) of them giving soups, only (21%) of them given Home available fluid. Table (1) shows that (64%) of mothers their age between (20-30) years, while (1%) of mothers their age between (41-50) years, this result is similar to the finding of (Makkia, 2004) who found that (70%) of mothers their age between (20-30) years. Also table (1) shows that (56%) of mothers graduate from primary school and (5%) of them graduate from institution and university, this result disagree with the study done by (United Nations Children’s(2002)) who found that the high percentage of mothers their level of education read and write. Also the table (1) according to the occupation that (93%) of mothers were unemployed, this result disagree with the study done by (Makkia, 2004) who found that (45%) of mothers unemployed. Table (2) shows that (48%) of child their age less than one year, this results agree with the study done by (Enzley (1997)) who found that in his study regarding diarrhea the majority of the child their age less than one year. also the table (2) shows that (65%) of child male and (35%) of them female this result opposite of the study done by (WHO (2002)) who found in this study (60%) of them female, regarding birth order of the child (34%) of child their birth order second and (24%) of them order are first. also the table shows that (52%) of child artificial feeding this result agree with the study done by (WHO (2002)) who found that in this study (70%) of child have diarrhea they on artificial feeding. Table (3) show that (62%) of mothers prepared ORT by 1 liter of boiled cooler; water this result disagree with the study done by (Snyder, Merson(2000)) who found that majority of mothers do not known who to prepared ORT, and the table shows that (46%) mothers they knew that oral rehydration salt should be used with 6 hours this result disagree with the study done by (WHO (2002)) who found that (60%) of mothers prepared with the 24 hours. Regarding the frequency of giving oral rehydration salt (48%) of mothers giving after each stool pass, this result agree with the study done by (Snyder, Merson(2000)) who that (< 55%) of mothers giving oral rehydration salt after each stool pass. Also the table shows that (66%) of mothers knew that ORT replaced electrolytes and water lost from the body this study agree with the study done (Claeson (2006)) who stated that in their study the majority of mothers knew that ORT replace fluid in child body Also table (3) shows that (49%) of mothers knew that ORT are available at health center, this result disagree with the study done (Santosham (2002)) who found that in their study the majority of mothers knew that ORT are available at hearth center. Also the table shows that (29%) of mothers store it in a cool dry place in dosed conditioner this result agree with the study done by (Bern (2000)) who found that most of mothers store ORT in a cool dry place. Also our results shows that (45%) of mothers using usual amount of fluid while using ORS and (26%) of them increased fluid this study disagree with the study done by (Martines(2000)) who found that the majority of mothers they give ORT only without any others kind of fluid Also our results shows that (56%) of mothers giving to the child Rice water with salt, while (30%) of them giving soups, this results agree with the study done by (United Nations Children’s(2002)) who found that (60%) of them giving Rice water with salt.

Conclusion

According to Interpretation and discussion of the study finding the following conclusion were driven:

- (64%) of mothers their age between (20-30) years.
- (56%) of mothers graduate from primary school.
- (93%) of mother were unemployed.
- (48%) of child their age less than one year.
(52%) of child were artificial feeding.

(62%) of mothers prepared ORT in 1 liter of boiled water.

(48%) of mothers giving ORS after each stool pass.

(29%) of them store it in a cool dry place.

**Recommendations:** Based on the results of present study, the researchers recommended the following:

1. health education should be done regarding preparing of oral rehydration therapy.

2. mass media should play a role in educating the family.

3. further study should be done in a large group.

**Financial Disclosure:** There is no financial disclosure.

**Conflict of Interest:** None to declare.

**Ethical Clearance:** All experimental protocols were approved under the F College of Nursing and all experiments were carried out in accordance with approved guidelines.

Isolation and Identification Bacteria Species and Study Epidemiological Features to Burns Patients in Al- Yarmook Teaching Hospital

Faraj, H. Johni 1, Abdulla L. Jiad2

1Ph.D. Physiology, Technical medical institutes/Baghdad, 2Assist. prof., Technical medical institutes/Baghdad

Abstract

The present study was conducted to identify the correlation between some epidemiological and bacterial characteristics of burn patients and their complications for the period from October to March 2018 for patients who were visiting or staying at AL- Yarmook hospital. One hundred patients were randomly selected after being examined and diagnosed by a specialist. The pre-prepared questionnaire for the epidemiological features of each patients, which included sex, age, marital or economic status, location of residence and the nature of the work of the patients was filled. While the bacterial side included the collection of skin swabs from areas exposed to burns (skin) and to all patients under sterile conditions and under the supervisions of the doctor supervisor the treatment of infected cases. Samples were transferred to the laboratory to complete bacterial laboratory test. Samples were planted on the special and general culture, and bacterial growth was observed followed by final diagnosis of isolates. The results showed that the rate of infection was high in females compare males (63% to 37%) respectively. While the incidence of burns was high in patients aged (16-30) 52%. The rate of infections was also high in patients with poor families (54%) while those living in rural areas had high rates of infection (41%).

The results of primary bacterial transplantation gave a high positive result (78%). The total isolates obtained from all initial transplant samples were 92% isolates and a percentage (117.9%), a high and satisfactory rate. Gram negative bacteria isolates showed a higher frequency than gram positive (73.9) and (26.06%) respectively.

It was noted that Pseudomonas spp was very high (48.9%) compared with rest of the positive or negative bacteria isolates, where the frequency presence of Klebsiella spp, Staphylococcus spp, Streptococcus SPP (25%), (18.4%), (7.6%) respectively. The results of the present study include the importance of epidemiological aspects in the cases of burns, whether as factors that assist or are ready to be injured or accelerated in the healing of the infected cases, in addition to the importance of early bacterial diagnosis of infection to control the complications of secondary infection of bacteria in cases of burns and thus easy medical treatment.

Keywords: bacteria, epidemiological features, burns, patients

Introduction

The most common burns and damage to body tissue which causes the immune system inhibition of the injured body, making it vulnerable to the various complications that causes various types of pathogens 1. High mortality was noted in cases of burns and associated bacterial infections 2. Burns destroy skin tissue responsible for protecting the body from the pathogenic and bacterial pathogens, which become an important and appropriate medium for the growth and reproduction of pathogenic bacteria, leading to various diseases 3. Burns occur for different reasons as well as different ways and means. Burns in children under the age of eight year are often burns, hot water or boiling water vapor 4. Burns caused by direct burning fire are the second most common cause of burns after water, liquids or hot steam 5. Other types of burns occur as a result of exposure to heat centrally and for a very short period such as burns caused by
incendiary gases such as propane, butane, oil purification gases, alcohols and other combustible liquids. Burns also occur as a result of direct contact with hot metals, liquids plastics, hot gases. Chemical burns are known to be burns caused by the exposure of the human body to chemical solution concentrated or containing chemical composition of burning materials such as caustic side, it has been observed that most of these burns are very influential on the tissues of the body of the patient, leading to the formation of thrombocytopenia of the skin and epithelial tissues and muscles lining and very quickly before removal. The burning skin tissue attacks several types of bacterial pathogens due to the severe damage caused by burns to the body tissues or to the self-immunity of the patient with burns, leading localized infections which increase with time, local sepsis, and septicemia cases which complicate burns and delay treatment or recovery which sometimes lead to death of the patient. It was noted that Pseudomonas and Klebsiella are among the most important bacterial pathogens that are contaminated or associated with burns which cause significant damage to the infected cases, some of which may lead to death, while studies indicate that Staphylococcus bacteria and Streptococcus are also Gram positive bacteria responsible for injuries associated with burns which have somewhat lower effect than the factors first mentioned in the severity of the impact or damage.

Aims

The present study aims at identifying some of the epidemiological characteristics of cases of burns related to patients such as sex, age, marital or economic status, location or place of residence, as well as the nature of the work of the person suffering from burns. The study also isolates and diagnosis some of the most common pathogenic bacterial pathogens (usually secondary infections or burns) to burn patients at Al- Yarmook teaching hospital and during six months research period only.

Patients and Methods

1- Patients : the study examined 100 randomly selected patients (males and females), between the age of (4-45) years who were visiting or staying at Al-Yarmook teaching hospital (burns division) for the period 10 October to 30 March 2019. where they examined and diagnosis clinically by the specialist doctor as all of them cases of burns due to various causes and the various degree of disease and the quantity and quality of burns (whether flame or burning with warm water) and range or intensity degree burns between 15-75%.

2- Epidemiological aspects: A questionnaire was developed in the research to identify some characteristics or epidemiological profile of burn cases, which include information on patients with burns. It was filled by the researchers and supervised by the treating physician for each case. The questionnaire included sex, age, marital or economic status, place of residence (place, nature of work of the injured person).

The study sample was divided by age into three groups:

<table>
<thead>
<tr>
<th>First age group</th>
<th>The age of patients with burns range 5-15 years</th>
</tr>
</thead>
<tbody>
<tr>
<td>Second age group</td>
<td>The age of patients with burns range 16-30 years</td>
</tr>
<tr>
<td>Third age group</td>
<td>The age of patients with burns range 31-45 years</td>
</tr>
</tbody>
</table>

The study classified the living or economic situation into three categories of agencies:

* Good quality: the families whose average monthly income exceeds above five hundred thousand dinars

** Average class: for families whose average monthly income ranges from two hundred and fifty thousand to five hundred thousand dinars.

*** Poor category: for families whose average monthly income less than two hundred and fifty thousand dinars.

While the studied cases of burns according to the location of housing by distance from the city of Baghdad to:

1- Rural housing: for families living in the countryside surrounding the city of Baghdad which are often cases of the arrival of Baghdad.

2- Civil housing: for the families who living in the city of Baghdad and nearby cities of the civilian nature of housing.

3- Rural housing –civil: for families living in areas...
that mix the rural civil character of living.

While the nature of the work of the patients was mainly male, which is often free work irregular in the state departments, in addition to some cases of disease for females, which was explained in the results, which were also due to the work of females outside the home, which is almost limited.

4- Bacterial side: for the purpose of identifying some of the bacterial cases associated with burns, swabs were taken for burns from the patients and they were removed from the burns and administrated by medical staff supervising the treatment in the hospital. The cotton swabs where the placed in sterile test tube containing a buffer solution to maintain intact bacterial pathogens. Test tube were transferred steriley to the laboratory (11).

in vitro samples were cultured on blood agar, Mac Conkey agar and nutrient agar, and incubated for 24-48 hours at 37 c., (12). The isolates as follows:

1- Macroscopic appearance: the examination included identification of the shape, size, color, nature of the outer edges of the colony as well as its texture.

2- Microscopic appearance: the isolates were examined after staining by gram stain.

3- Biochemical tests: several tests were used to diagnosis or differentiation to arrive at the final diagnosis (13).

Results and Discussion

The present study indicates that the number of cases diagnosis as burns was 37 cases in males while 63 cases were in females. All cases studied (100) were the same percentage of cases as shown in table (1). The number of infection and their percentage in females is 63% compared to 37% in females respectively. The nature of house work and their preoccupation with household matters, especially with regard to cooking or near sources of burns such as direct fire, hot steam during the day (14). The results of this study agree with the findings of, Mayhall, 2003, (15) that the incidence of burns affects females more than males because of the nature of work of females work in cooking and direct contact with the source of fire. Table (1) showed distribution of burns according to age group of (16-30) years had a high incidence of infection at 52% while the age group (5-15) years with a lower accidence of burns, 30%. The infection rate in the age group (31-45) years was the lowest in the infection which reached 18%. The results indicate that the third group had the lowest rate of infection, which may be due to the effect of age in the injury in which the person at this age is more mature and aware and experience to enable it keep away or reduce the chance of burns. The injuries were very high (52%) in the middle age group (16-36) which may be due to this age is working in various household or work matters, wither male or female (16), while the injuries in the first group (5-15) years were 30%, and this percentage reflect the relationship between burn and age. Especially children they are more susceptible to burns for different reasons (12). The results of the current study indicated in the table (2) that the cases of burns diagnosed clinically were distributed in varying degrees in terms of the living or economic situation where the incidence of burns in the family members of the vulnerable category was 54% while the rate of infection in individuals or families of the middle class 29%, while at a slightly lower rate was 17% in the good category. It is noted from the proportions of the distributions of status that the living conditions associated with the general income families play an important role in the creation of the means of or tools, devices or equipment that may ensure the individual to move away or reduce the sources of exposure to burns and this conclusion is consistent with the findings of many researchers (17).

The results of the first implantation of the skin lesions samples from burned skin areas which occurred more than 24 hours and less than ten day ago, showed that the number of cases of bacterial transplantation (containing bacterial growth) was 78 cases out of a total of 100 studied cases (78%) while 22 did not give positive results for the first bacterial transplant. These results are consistent with the (19) incidence of skin lesions of burns with a recurrence rate of 86.5% for the first bacterial transplant, as well as for (20) of the number of skin
lesions that give a negative result of bacterial cultures in his research was 18% (table 3). Bacterial growth rate (78%), which gave 14 single bacterial growth (bacterial isolates of one bacterial species) was 17.9% while the combined bacterial growth (each containing more than one bacterial strain) was positive 53% and 67.9% respectively. The bacterial isolates obtained from all Petri dishes showed 92 bacterial isolation and 177.9% (table 3). After bacterial isolating observed that the primary cultures media and carrying out isolation and identification of bacteria, frequency of gram positive bacteria isolates was 24(26.06%) while the frequency or recurrence of Gram negative bacteria isolates 68 (73.9%) which confirm that we have indicated that Gram negative bacteria is highly susceptible to infection and invasion of tissues exposed to burns, and occupied Pseudomonas spp. The highest incidence was 45(48.9) while the presence of Klebsiella spp. At a lower rate than the previous 23 (25%) table (4), while types of Gram positive bacteria were 17 (18.4%) and 7(7.6%) for Staphylococcus aureus and Streptococcus pyogenes. The results of isolation and diagnosis agree with, Muir, 1987, he was found Gram negative bacteria is more presence or recurrence in cases of burns for their ability to produce large amounts of factors and enzymes in infected tissues in addition to toxins that affect on skin tissues which helps in the poisoning of the body (generalized septicemia). The present study also agreed with its findings, Maitra, 2003 that pseudomonas spp the most frequent cases of burns because they are opportunistic bacteria which find tissues infected burns a good medium for growth and reproduction, as well as being one of the most important bacterial species that causes nosocomial infection which transmitted easily. Klebsiella spp is one of the Gram negative bacteria which is infected burns and existed 23 (25%) and this percentage agreed with, Bowler, 2001.

The results of isolation and diagnosis showed that the positive bacterial species were found somewhat lower than those of Gram negative bacterial according to nature and requirement of this type of bacteria. Presence of Staphylococcus ssp more than Streptococcus ssp (18.4%) and (7.6%) respectively, and these results are agreed with, Emmerson, 1994. Staphylococcus aureus is still one of the most of Gram positive bacteria contaminated for hospitals and causes sever skin sores damage. With regard to streptococcus infection is similar to Staphylococcus for nutritional requirement and reproduction, which is often attributed to 20% of septic episodes of skin burns in patients.

**Financial Disclosure:** There is no financial disclosure.

**Conflict of Interest:** None to declare.

**Ethical Clearance:** All experimental protocols were approved under the Technical medical institutes and all experiments were carried out in accordance with approved guidelines.

Critical Care Nurses’ Knowledge about Pulmonary embolism in Respiratory Care Unit in Baghdad Teaching Hospitals

Massara Abdullah Najm¹, Aqeel H. Jassim², Tahseen R. Mohammed²

¹ Assistant Instructor. ² Instructor, Department of Adult Nursing, College of Nursing, University of Baghdad, Iraq

Abstract:

Aim of the study: To assess the nurses’ knowledge about pulmonary embolism

Methodology: A descriptive design study was carried out for the period of November 18th 2018 up to the 20th of April 2019. Anon-probability (purposive) samples of (60) a nurse work at respiratory care unit in Baghdad Teaching Hospitals from different educational levels, both sexes (males and females), were selected. The instrument questionnaire tool consists of two parts, First part consist of (6) items included, age, gender, level of education, number of years of employment in hospital, number of experience in the respiratory care unit and training course about pulmonary embolism. & second part consist of (4) domains which included Nurses knowledge concerning definition and causes of disease, signs and symptoms, diagnostic test, treatment of pulmonary embolism. The data have been analyzed through the application of: descriptive and the inferential analysis, and the researcher used the SPSS version 20 to analysis of data.

Conclusion: The study recommend that the critical care nurse have moderate level of knowledge and there were significant association between level of education and the nurse knowledge at p > 0.05 level.

Keywords: Nurses’ Knowledge, Pulmonary embolism, Baghdad Teaching Hospitals.

Introduction

Pulmonary embolism is a common complication of hospitalization and contributes to 5 to 10 percent of deaths in hospitalized patients, making it one of the leading causes of preventable hospital deaths ¹,². Despite it being an enormous health problem, the true incidence of pulmonary embolism is uncertain. The diagnosis of cyst venous thrombi and pulmonary emboli can be difficult and requires specialized imaging techniques that are not available in all hospitals or healthcare settings ². The diagnosis of pulmonary embolism (PE) is missed more often than it is made, because PE often causes only vague and nonspecific symptoms. pulmonary Embolism is an extremely common and highly lethal condition and that is why it is a leading cause of death in all age groups. Risk factors for venous thromboembolic disease include increasing age, prolonged immobility, surgery, trauma, malignancy, pregnancy, congestive heart failure, and diseases that alter blood viscosity⁴. Pulmonary embolism (PE) is a life threatening condition with the potential to masquerade as a variety of common disorders, and no single test exists for its definitive diagnosis. Clinically, PE is categorized into acute massive PE, acute medium / small PE, & chronic PE. It is the third most common acute cardiovascular disease, after myocardial infarction & stroke ⁵.
diagnostic test, treatment of pulmonary embolism. The instrument develop constricted by researcher through reading textbox and review of literature. The content validity of the instrument format is established through a panel of (8) experts. They are (9) faculty members from the College of Nursing /University of Baghdad. These experts have more than 10 years of experience in their specialist with a mean (18) year, and (SD=11.4). They were asked to review the questionnaire whether they multiple choice questions (items). Data were collected through using a constructed questionnaire and Self reporting through an interview technique with the nurses as means of data collection. The self-report of the questionnaire and interview took approximately 10–15 minutes for each nurse. The 0.5 the level of significance was used as a standard to determine if there was a significant difference in the nurses’ knowledge according to (age, gender, level of education and years of employed in hospital) Each items students knowledge was ranked according to the following scale as follow: know = 3, uncertain= 2, do not know=1. Data are analyzed through the use of the statistical package of social sciences (SPSS) version 20.0.

Results and Discussion

The analysis of socio-demographic characteristics in table (1) The findings show the majority of the study were male who accounted for (63.3%) of the total participants. The results supported by6, they noticed that the (54%) of nurses in sample study were male. Most of the study participants (55%) were ages between 20 and 26 years old. These findings agreed with study done by7, stated That the majority of the sample in their study was college and post educational graduated. A high percentage of them were most of them (34.3%) were for (1-5) years were employment in nursing, majority of them (58.3%) were for (1-5) years, have experiences in RCU and finally majority of nurses (58.3%) have no training session in Respiratory care unit. These results similar with study done by, who reported that (27%) of participants hasn’t taking any training session (71%) of the study sample have experiences in (1-5) years in EM. It is supported by8, study done by9, who reported Majority of the respondents (41.2%) were of age group 25-29 years. Nearly half of them (45.9%) had completed certificate nursing and were working as staff nurse (87.1%). Majority (22.4%) were working in ICU. About 39% of them had been working for less than 5 years in the institution. Table 2.A,B,C,D depicted that nurses had a low level in Nurses knowledge concerning definition and causes of disease in (8) and,(13) items, nurses had a low level in Nurses knowledge concerning signs and symptoms of pulmonary embolism in item (3 and 8) items and, diagnostic test in item(6) and, concerning treatment of pulmonary embolism in item (1 5 and, 8) item(drink plenty of fluids in the traveling for a long time, to prevent formation of pulmonary clots. These results agree with supported by study done in Rwanda by10, who found that nurses working in ICU had poor knowledge and bad attitudes towards pain assessment and management. Table 3 demonstrates the association between sociodemographic and nurses knowledge score was explored. There are association between level of education and studied sample knowledge at p value 0.05 and also illustrate that no relationship found with rest of studied variables which are (age groups, gender and years of employment in RCU at p value 0.05. These finding is supported by 11, who that founds the majority of the respondents were black, married, from the Free state province only 38 (11.0%) knew the three main clinical manifestations associated with chronic disease. Level of school education, race and language were statistically significantly associated with knowledge level where as age and marital status were not. The findings of present study shows that there were not significant differences between gender and nurses knowledge about PE at P ≤0.05 value.

Pulmonary embolism occurs due to circulate blood clots to the lungs from the legs.

Pulmonary embolism is a dangerous condition that can cause permanent damage to the lungs. The causes of pulmonary embolism are accurately not known. Cancer tumors is not a cause of pulmonary embolism. Air bubbles are one of the factors contributing to pulmonary embolism. Fatty deposits that enter the blood vessels when a fracture occurs in the bones are one of the factors contributing to pulmonary embolism. Amniotic fluid embolism is one of the causes of pulmonary embolism. Smoking cannot cause pulmonary embolism. The genetic factor is one of the factors contributing to pulmonary embolism.

df. =degree of freedom, F=frequency, Sig. =significance

This table indicate that there is a significant differences between level of education and nurses knowledge, and no significant association between age , gender, years of experience and nurses knowledge.
Conclusion

Results revealed that the majority of the study were male who accounted for (63.3%) of the total participants while female constituted (36.7%). Most of the study participants (55%) were ages between (20-26) years old. A high percentage of them were having Nursing college and above (46.7%). Majority of them (58.3%) were employee (1-5) years in respiratory care unit. Majority of nurses’ (58.3%) have not training session about PE in RCU. Nurses’ knowledge concerning PE in RCU had moderate knowledge level, with respect to the total mean of score (MS) which was (50). There is a significant association between level of education and studied sample knowledge at p value 0.05.

Abstract

Background: Helicobacter pylori (H. pylori) is amongst the most infectious and almost half of the country’s population is affected by a chronic bacterial infection. H. pylori evoke an inflammatory reaction of the host epithelium, leading to induction of immune cells which exhibit as gastritis. There is little knowledge of how H. pylori remain in the host’s antimicrobial agents, such as calprotectin (CP), which is found through an immune response. Objective: The purpose of this study was to evaluate the role of fecal calprotectin (FC) in subjects with gastric ulcer and correlation of it with H. pylori.

Methods: 25 patients with gastric ulcer and 25 healthy controls were included in a prospective study. Samples of blood are taken IgG antibody H pylori and stool specimen for measured of calprotectin level.

Results: All gastric ulcer patients infected with H pylori. From a total of 25 patients participating in this study 8 were man and 17 women with the mean age 40.6±15.8. There was a statistically meaningful difference between the groups analyzed (p=0.0001) dependent on the calprotectin level. Also found significant association between sex and calprotectin level according to the positivity of H pylori.

Conclusion: There’s a significant statistical between fecal calprotectin level and H. pylori infection in gastric ulcer patients.

Key words: Gastric Ulcer, H. pylori, Fecal Calprotectin.

Introduction

Gastric ulcer is one of the most frequent chronic gastrointestinal diseases characterized by a serious mucosal barrier defect. The gastrointestinal mucosa is covered by a single layer of epithelial cells accompanied by precarious elements of loose connective tissue laid under a thin layer of smooth muscle fibers. The gastric epithelium is not only exposed to its own acidic and enzymatic secretions in many people, but also to duodenal bile, highly prevalent Helicobacter pylori (H. pylori), frequently used non-steroidal anti-inflammatory drugs (NSAIDs) and alcohol intake. Gastric ulcers grow as a consequence of an inconsistency between harmful factors and gastric mucosa defense mechanisms. A stomach ulcer is a localized deep necrotic lesion affecting the entire thickness of the mucosa and the muscle is mucosa. Therefore, gastric mucosal damage is very common and can arise in so many patients as gastric ulcers. H. pylori are a widespread bacterial pathogen in the worldwide responsible for significant gastrointestinal morbidity. Helicobacter pylori is optimal for living in the stomach’s harsh, acidic environment. These bacteria have the ability to change their environment and reduce their acidity so they can survive. Whereas infections usually have no symptoms, they can proceed to other diseases, such as peptic ulcers and gastritis. Helicobacter pylori gastritis induces a combined acute and chronic inflammatory reaction that activates neutrophils and eosinophils, mast and dendritic cells. Calprotectin is a protein produced from endothelial cells following neutrophil inflammation and activation or attachment of the monocytes to endothelial cells. Calprotectin is an essential antimicrobial inflammatory factor, which is also an element of the host innate immune system. Calprotectin accounts for about 50% of the cytoplasmic protein content of the neutrophil and is a critical component of the host nutrient. Calprotectin plasma level is an important marker of inflammation. This protein is responsive to bacterial enzymes and
intestinal protease and can be used as a marker of inflammation of the gastrointestinal tract \(^5\). Calprotectin is bacterial deterioration resistant and stable in fecal samples for up to one week \(^11\). In the gastrointestinal tract, some inflammation improves the mucosal permeability, resulting in large amounts of calprotectin being released into the stool. There is a significant correlation between fecal calprotectin levels and inflammation or infection severity \(^5\), therefore this research was just to determine calprotectin levels in patients with gastric ulcer infected with Helicobacter pylori.

**Method and Patients**

This case-control study applied on (50 subjects was divided in to 25 patients complain from gastric ulcer and 25 healthy control). Totally, 25 individual had gastric ulcer infected with H. pylori were diagnosed by specialists’ physicians in the Imam Hussein Medical City in Karbala. Two ml of blood sample has been taken from gastric ulcer patients and healthy control for examined the H pylori antibody. H pylori antibody was performed by rapid chromatographic method according to leaflet that provides with kit (CTK) Company. Stool samples collected from study group participants to assess the calprotectin level. Fecal calprotectin was evaluated by using a commercially available rapid chromatographic method according to the procedure that provided with kit (CerTes Biotec Spain) Company. Obtained data of present research were analyzed statistically by using the SPSS version 18. The chi-square test was used for calculated mean, standard deviation and p value at 0.05 levels of data and compared between the studied groups.

**Results:**

The study population included 21 males and 29 females (gastric ulcer 8 males and 17 females, while males were 13 and females12 for the healthy group) with the age range15-71 years for the gastric ulcer patients, whilst healthy controls were 18-70 years. Statistically, there was no significant difference between patients and healthy control groups according to the sex and age as illustrated in table (1), also no found any association between positivity of calprotectin level and age group of patients, whereas there was significant difference in patients according to positivity of calprotectin level and gender (P value= 0.0001) as in table (2).

Interestingly, in patients with gastric ulcer, the value of fecal calprotectin was increased compression with healthy control group. Likewise, the present study was revealed the level of calprotectin was positive in 15 cases infected with H. pylori and the remainder had negative results for calprotectin. There was a highly significant correlation between patients and healthy dependent on the levels of fecal calprotectin (P- value= 0.01) see in table (1).

Discussion

There are few studies in patients with gastric ulcer that assess the relationship between calprotectin and H pylori infection. The current study examined the level of calprotectin and determination the relationship between level of it and H pylori infection in patients suffering from gastric ulcer. Calprotectin is a calcium-binding neutrophil granulocyte protein that, when measured in feces, is well correlated with neutrophil infiltration of the intestinal mucosa, has antimicrobial activity and is resistant to both in vivo and in vitro enzyme degradation (Jellema P.et al, 2009) Calprotectin is an important regulatory protein in inflammatory reactions (Wang L.et al,2013 ; Eva Källberg. et al,2012)

Many Studies were performed on pediatric and adult patients with different gastrointestinal disorders have demonstrated a relation between fecal calprotectin concentrations and the severity of mucosal inflammation (Schoepfer AM. et al, 2009; Kolho KL. et al ,2006). Recently, Several studies found that FC levels in gastrointestinal disorders are statistically significantly higher compared to control (including gastritis, gastric ulcer, gastric carcinoma, duodenitis, ulcerative colitis, Crohn’s disease, colorectal carcinoma, colorectal polyps and another bowel diseases) (Shaodong Wang.et al,2013 ; Burak ÖzGeker.et al,2016). This study correspond with recent work done by Pedram (Pedram Ataee .et al, 2017) who found that the fecal calprotectin level higher in patients with colonization of H. pylori were compared in those without colonization. On the other hand, there was one study carried out by Montalto et al in 2010 (Montalto M.et al,2010). The current study concluded that the infection of H. pylori bacteria leads to increases in the fecal Calprotectin level. In addition, we believe the Calprotectin level can be useful for monitoring patients with H. pylori after its extirpation.

Knowledge and Awareness among Mothers Regarding Exclusive Breastfeeding in Holy Karbala City / Iraq

Maytham Salim Al-Nasrawii 1, Ali Neamah Hasan Al-Aaragi 2, Ali Abd Al-Latif G. Mohammed 2

1 Lecturer, 2 Assist lecturer, Community Health Department, Technical Institute of Karbala, AL-Furat Al-Awsat Technical University, Karbala/Iraq

Abstract

Background: World Health Organization (WHO) and United Nations Children’s Fund (UNICEF) “Exclusive breastfeeding (EBF)” is explained as “the infant receives only breast milk, no other liquids or solids. Its recommended for the first 6 months of life, and then complementary feeding should be started. EBF helps to reduce child morbidity and mortality from several diseases such as diarrhea, respiratory and / or ear infections and other infectious diseases, shielding lactation women from breast and ovarian cancer. In addition to offers societal economic and environmental benefits, The objective of this study was to assess the knowledge and awareness of exclusive breast feeding among mothers with a child < 2 years of age.

Method: A descriptive cross-sectional study was carried out in Health Directorate of Holy Karbala city. The study consist of (487) mothers how attendant to six Primary Health Care center (PHC). The collected data was done by direct interview with mothers and using a questionnaire form that designed based on the study objectives according to WHO criteria. Data were analyzed by SPSS “ Statistical Package for the Social Sciences”, the descriptive statistics included numbers (N) and percentage (%), and the inferential statistical test was done by using Chi-Square test ($\chi^2$), P-value (Probability of chance ) was equal or less than 0.05 considered as statistically significant to find for any association between the results variables.

Result: A total of 487 participants were included in the study and the rate of response was 92.7%. The highest percentage (66.3%) of study sample were full in the age group (21-30) years, and more than three quarters were lived in urban area. Nearly half of the study sample 47% had primary education and 60% those housewives, and the main source of information being family and friends (84.4%). As an overall assessment, 61.8% of the study sample had good knowledge and awareness about exclusive breastfeeding, with highly significant differences to education level, occupation residence of the mother.

Conclusion: Over half of the subjects had good knowledge and awareness of exclusive Breastfeeding. And, on the other hand, there was a very significant difference between education level, occupation and mother’s residence with a level of knowledge.

Keywords: knowledge, Awareness, Exclusive breastfeeding, Karbala city.

Background

Breast milk has the full nutritional requirements for health advancement that a baby needs. Additionally, it is safe and contains antibodies that help protect infants and boost immunity (1). Consequently, breastfeeding contributes to reduced infant morbidity and mortality due to diarrhea, respiratory or ear infections and other infectious diseases(2-4), and for mothers, breast and ovarian cancer risk is reduced (5). In addition, breastfeeding offers societal economic and environmental benefits (6). WHO recommends that children be exclusively breastfed for the first six months of life to achieve optimum growth, development, and health. Children should then obtain complementary foods that are nutritionally adequate and healthy when continuing to the breast for up to two years or more (6). According to WHO and UNICEF “exclusive breastfeeding” is explained as “the infant receives only breast milk, no other liquids or solids are given – not even water – with the exception of oral rehydration...
solution, or drops/syrups of vitamins, minerals or medicines”. Its recommended for the first 6 months of life, and then complementary feeding should be started. Whereas, breastfeeding should continue for 2 years age or beyond (7,8).

The aim of this study was to assess the knowledge and awareness towards exclusive breast feeding among mothers had a child aged < 2 years and find out any association between mothers and knowledge and awareness and some demographic characteristics.

Methods

We obtained the ethical and administrative approval on study from the research ethics committee in Karbala Health Directorate. After that, a verbal consent was taken from each mother prior to interview. A cross-sectional study was conducted to achieve the aim of the study. A total of 487 mothers of infants aged (1-24 months) was selected by simple random sampling and direct interviewed during the Period of the study with a response rate of 92.7%. The sample consist of, the mothers who attended six of primary health care (PHC) from Karbala City. Data collected by direct interview with mothers and using a questionnaire form that designed based on the study objectives. The collected data were analyzed by SPSS. The descriptive statistics included numbers (N) and percentage (%) and the inferential statistical test was done by Chi-Square test, P-value was equal or less than 0.05 considered as statistically significant used to test for any relationship between variables with the results.

Results

Table (1) displayed mother age distribution, the highest percentage (66.3%) was in the age group (21-30) years. Regard to the distribution the type of delivery, this table shows that (80 %) of the study sample was vaginal delivery; on the other hand, the distribution of residence, education level and the occupation of the respondents, the majority of readings were (76 %), (47 %) and (63 %) in the urban area, primary school and housewife respectively.

Figure (2), show the main source of information about EBF. The most efficient source of information was family and friends (84.4%), while the internet, posters and booklets, workshops, local satellite channels, and school curriculum were less than (50%).

Figure (2): Distribution the sources of information of study sample.

Discussion

It is very important for all members of the community to understand the importance of EBF for every mother and her baby, for that we assess the knowledge and awareness towards exclusive breast feeding among mothers had a child aged <2 years in Karbala city.

In table (1) that illustrate the distribution the mother demographic characteristics, 66.3% were in the age group (21-30) years, it’s the same percentage in age group by Adrawa, A. P et al in Adjumani district 89.9% and Alamirew, M.W. et al in Ethiopia 66.9% (8,9).

Regarding the distribution the type of delivery, more than three quarters of the sample 79.3% had vaginal delivery “ Normal delivery “ that similar to AL-Abedi, N. et al in AL-Najaf City 74% (10), on the other hands regarding residency, education level and occupation of the participates, most of the results 76%, 47%, and 63% were from urban area, had primary school and housewife, respectively, that also agreed with AL-Abedi, N. et al (2016) and Joshi, S. in Navi Mumbai, Where they recorded their results as 28.7%, 30% and 94%, 70% for primary school and housewife (10,11).

Concerning to knowledge of mother about exclusive breastfeeding, table 2 showed that differences of answered as correctly about the questions, 94% of mothers answered correctly about the definition breast milk and 92% having good awareness towards initiation of exclusive breastfeeding this was similar to other reported study in Navi Mumbai (11) and Sana’a City (2018) by Dallak, A. et al (12). This table also indicates that more than three-quarters of participants were fully aware of exclusive breastfeeding through, decrease hemorrhagic after delivery, helps mothers return to their pre-pregnancy weight and prevent pregnancy for at least one year after delivery. While there was defect ( incorrect answers 58.3 %) of study sample knowledge towards reducing the death rate from the breast and ovarian cancer. As overall assessment, figure (2) reveal 61.8% of the objects had good knowledge, its agreement with the study done by AL-Abedi, N. et al 71% (2016) and Mbada, et al., (2013) “ they reported that overall assessment was good “ (13).

Result in (Table3) refers to an important relationship between mother’s awareness and occupational status that is could be due to, housewives are more committed
to breastfeeding than female employees, its disagrees with Maryam, et al.,(2014); Mahmud, (2011); Al-Asadi, (2011), all of them stated that a non-significant difference among mother’s occupations and the knowledge level (14),(15),(16).

For the educational level, there was a highly significant relationship with EBF, its match with the study done by Al-Hially (17), (2010), who reported that there is a significant relationship between mother’s education and awareness for breastfeeding , this might be that the “educated mother has better knowledge about breastfeeding more than an uneducated mother”.

Mentions that there was a significant correlation between knowledge and delivery type, this can be because natural births are more likely to produce breast milk than cesareans, this result was similar to AL-Abedi, N. et al (10). On the other hand, there was a non-significant relationship with Age groups, its disagree with AL-Azzawi, etal.,(2010), who stated that was a significant indicator between age of the mother and knowledge about EBF (18).

Finally, figure (2) reveals the source of information of the study sample about EBF, the study indicates that the highest percentage 84.4% of participates in this study were received education about exclusive breastfeeding was from family and friends, “Since the majority of participated mothers had primary education, these low educational levels make them incapable to understand and comprehend the educational information in pamphlets, posters, and advanced media. So, they need to be educated about breastfeeding directly from family, friends or health workers, this means that the family plays an important role in successful breastfeeding”; its approved with the result do it by Dallak, etal.,(2016), who reported that “the majority of the study sample educated by family and friends for exclusive breastfeeding” (12).

Conclusions

There is an urgent necessity to provide accurate prenatal education that focuses on methods and long-term benefits for breastfeeding because mothers don’t have inadequate awareness of exclusive breastfeeding from where (initiation, colostrum benefits, and breast and ovarian cancer incidence reduction). The study found a highly significant relationship between mother’s knowledge and that residence, education level and occupation.

Recommendation: In spite of good mother Knowledge toward of EBF, but health education programs for breastfeeding promotion should be well planned and address the factors which reinforce and enable breastfeeding and health team members should be properly trained in breastfeeding essentials and communication skills with the mothers especially in this critical period (child aged < 2 years ) in Karbala city.

Effectiveness of an educational program on Nurses’ Knowledge towards Nursing Management of Patients with Transurethral Resection of the Bladder Tumor at Hilla Teaching Hospitals

Basim Hasson Hussein¹, Halima Yusuf Al-Rubaiyee ²

¹ Academic Nurse Specialist, Lieutenant Colonel, Ministry of Defense), ² Professor, Dr. Adults Nursing, Collage of Nursing/ Baghdad University- Iraq).

Abstract

Bladder cancer is the fourth most prevalent tumor in men and eighth in women. Approximately 50,000 new cases are diagnosed annually in around the world. The study aims at: assess nurse’s knowledge regarding management of patients who undergo the transurethral resection of the bladder tumor. A descriptive study is conducted during the periods of July 29th 2018 to December 25th 2019. The study conducted in Hilla Teaching Hospital and Al’imam Alsadiq Teaching Hospital were the designated site for data collection. By non-probability “purposive sample” of (51) nurses, data were collected for pre-post test and analyzed a descriptive and inferential statistical data analysis approach. Results of the study depicts that age of the nurses ranged from 20- 43 years, (60%) of nurses in the control group, there were somewhat less female nurses (45.2%) than male nurses (54.8%) in the study group and (32%) were female and (68%) nurses male in the control group, (80.6%) were married in the study group and (22) (88%) were married in the control group, education was from a secondary nursing school and institute degree (35.5%) for each degree in the study group, and (48%) institute degree in the control group, (1-5) years was (67.7%) in the study group and (68%) in the control group. Nurses knowledge in the study group has increased from (M.S. 1.3026) in the pretest time to (M.S. 1.6787) in post test time for the control group, this score has slightly increase from pre test (M.S. 1.2985) to post tests (M.S. 1.3343). There were concluded improving in nurses’ knowledge after post-test for study group for educational program concerning management of patients with transurethral resection of the bladder tumor. While control group did not present any improvement in their knowledge concerning management of patients with transurethral resection of the bladder tumor at pre and post-test. It is need to be encouraging nurses to be enrolled in training sessions to improve their knowledge to keep them up to date toward management of patients with transurethral resection of the bladder tumor.

Key words: Effectiveness, Knowledge, Transurethral Resection.

Introduction

Cancer is the main cause of death worldwide and is creating a significant burden on society as a result of population growth and aging. Accurate information regarding cancer incidence is important for clinical decision making and appropriate cancer control [1]. Bladder cancer is the most common malignancy of the urinary tract[2]. Bladder cancer is the fourth most common noncutaneous malignancy in men and the incidence of bladder tumors is increasing in industrialized and developed countries [3]. In men, it is the fourth most common cancer after prostate, lung, and colorectal cancers, accounting for 6.2% of all cancer cases. In women, it is the eighth most common cancer, accounting for 2.5% of all cancers [4]. Its occurrence is strongly associated with cigarette smoking and the use of certain chemicals [5]. Symptoms are relatively specific, and what is more important are very obvious, haematuria is the presenting symptom in 85-90% of the patients with bladder cancer gross or microscopic,
Irritative voiding symptoms seem to be more common in patients with CIS [6]. Transurethral Resection of the Bladder Tumor under regional or general anesthesia is the initial treatment for visible lesions and is performed to remove all visible tumors and to provide specimens for pathological examination to determine stage and grade [7]. According to the American Cancer Society, bladder cancer will be responsible for 5% of all cancer diagnosed in the United States in 2017, with 79,030 patients expected to be diagnosed with the disease and 16,870 expected patient deaths from bladder cancer [8,9]. The majority of newly diagnosed patients with bladder cancer are male, which is thought to be related to an increased rate of smoking and occupational exposure [8].

Methodology

The study has been conducted in order to assess nurse’s knowledge regarding management of patients who undergo the transurethral resection of the bladder tumor.

Study design: A descriptive study is conducted during the periods of July 29th 2018 to December 25th 2019. The study conducted in Hilla Teaching Hospital and Al’imam Alsadiq Teaching Hospital were the designated site for data collection.

Study Sample: A non-probability “purposive sample” of (51) nurses who are working at surgical wards. The total number of nurses working in surgical department in Hilla Teaching Hospital and Al’imam Alsadiq Teaching Hospital were (76) nurses. (41) nurses in Hilla Teaching Hospital and (35) nurses in Al’imam Alsadiq Teaching Hospital.

Study Instrument: To evaluate the effectiveness of education program on nurses knowledge toward management patient with TURBT, the researcher constructed a questionnaire format in order to reach the aims of the study, consisted of (2) parts

Part I: Self-administered questionnaire sheet related to demographic characteristics of the nurses.

Part II: Self-administered questionnaire sheet related to nurses knowledge toward management patients with TURBT.

Statistical analysis: The statistical data analysis approach by using (SPSS-ver.20) is used in order to analyze and evaluate the data of the study. A descriptive statistical data analysis approach used to describe the study variables: Frequencies, Percentages, standard deviation, and mean of score. Inferential statistical data analysis approach: used by application of the analysis of variance (ANOVA).

</table>

This table represents the distribution of the nurses their demographic characteristics in terms of frequencies and percentage (control versus study). Age of the nurses ranged from 20-43 years, revealed that the majority 17 (54.8%) of nurses in the study group are within the age (26-31), while 15 (60%) of nurses in the control group, there were somewhat less female nurses (45.2%) than male nurses (54.8%) in the study group and (32%) were female and (68%) nurses male in the control group. The majority of nurses 25 (80.6%) were married in the study group and 22 (88%) were married in the control group. The most common educational education was from a secondary nursing school and institute degree (35.5%) for each degree in the study group, and (48%) institute degree in the control group. In relation of years of experience in nursing ranged from (1-5) years was 21 (67.7%) in the study group and 17 (68%) in the control group. Most common showed that he years of experience in surgical wards ranged from (1-5) years was 27 (87.1%) in the study group and 20 (80%) in the control group. Concerning training course in nursing in Iraq 17 (54.8%) of nurses in the study group and 14 (56%) of nurses in control group hadn’t training courses in nursing. Most common showed that the duration of training in the study group between (1-15) days was (35.4%), and (28%) in the control group. Statistically, there is no significant difference between study and control groups related age,
gender, educational level, years of experience in nursing, years of experience in surgical wards, and training course in nursing.

Reveal that score of participants knowledge in the study group has increased from (M.S. 1.3026) in the pretest time to (M.S. 1.6787) in post test time for the control group, this score has slightly increase from pre test (M.S. 1.2985) to post tests (M.S. 1.3343).

**Discussion**

**Nurses Demographic Data**

The sample consists of 51 nurses who were purposive allocated to either a control group (n=25) and a study group (n=31). Our findings reveal that the most of nurses in the study and control groups are male, it constituted (54.8% and 68.0%) respectively. As well as, both of study and control groups share a highly range of ages group (26-31) years old, due to the nature of the nursing profession, male nurses were accounted for most of the nursing staff, and all nurses who work in surgical word need to be young to cover all duties in this units. Also, this may be due to the fact that males cover night duties while females does not.

This results come in the same line with study has been conducted in AL-Jamhuree Teaching Hospital and AL-Salam Teaching Hospital in Nineveh Governorate during the period from 10th September 2013 up to 10th March 2014.. Their results reported that the age of nurses who work in surgical wards and participated in this study ranged from 20 -29 years was (43.4%) in study group and (46.7%) in the control group. and concerning gender of nurses in study most common male nurses in both study and control group was (56.7%) [10].

**Nurses Knowledge**

Nurse’s knowledge questionnaire items towards management of patients with transurethral resection of the bladder tumor, which classified in four axis (main domains), such that “ anatomy and physiology of urinary bladder, general information about bladder tumor, TURBT, and complication of TURBT”, using MCQ questionnaire’s items technique which were classify in to two categories responses, such as “ False, and True” along studied (Pre, and Post) periods due to application an educational program for study group, as well as controlled group are chooses for comparisons significant. Results of testing significant with reference of questionnaire’s items are reported mostly highly significant differences at P-value <0.01, which assigned effectiveness of the studied educational program through raising knowledge grades regarding nurse staff in study group, and that be enable to confirms importance or
successfulness of applying the suggested program.

The deficit knowledge pretest in both study and control groups regarding transurethral resection of the bladder tumor might be due to several reasons; the nurses do not develop and update their knowledge continuously, most of nurses who work in health institutions quit book reading so they do not follow up and only indulge in nursing practices, consequently they became unable to remember some information particularly the knowledge that related to transurethral resection.

Our findings come in the same line with effectiveness of educational program on nurses’ knowledge regarding pre and post-operative nursing management. Measurement of effectiveness for educational program carried out through the use of knowledge test that include (40) items test-retest. The results of the study show that the effectiveness of educational program about nurses’ knowledge regarding pre and post-operative nursing management is positive and evident. It also shows that there is a good development with highly significant differences in study group between pre and post-test in all items related to pre and post-operative nursing management [11].

It is important to note the importance of the nurses’ knowledge in the workplace which is confirmed study deals with nursing implications from the operating room to discharge: therapy following transurethral resection of bladder tumors. It’s confirmed that oncology nurses, who have a unique knowledge of safe handling and patient care, can improve staff safety and patient outcomes in several areas of healthcare organizations, as well as reduce the mortality and morbidity of urinary bladder cancer by learning more about the disease and intravesical antineoplastic therapy [12].

Also, a narrative review in caring for patients with prostate cancer, they emphasized that nursing knowledge in care procedures for men with prostate cancer should begin at the time of diagnosis, when patients should participate in determining the best course of treatment. During the period of prostatectomy, care includes preoperative preparation, which is essential to achieve healing and adaptation to postoperative sequelae. Its concludes that the role of a clinical nursing specialist in the care of men with prostate cancer is broad and necessary, but new interventions and strategies for care need to be knowledge development assessment in a continuously through well-designed clinical studies [13].

In another manual, a cross-sectional study has been aimed at identification of nursing actions in the preoperative period and in preparing prostatectomy patients. Has been identified weaknesses in care delivery for prostatectomy patients, particularly in nurses education, nurses knowledge or education in those area very important [14].

Moreover, a descriptive cross sectional study was conducted among nurses in private tertiary care hospital Peshawar. The study result was alarming to know that the nurses had low knowledge, and poor practices about infection control in the use of urethral catheter. This indicates that nurses need to be educated and trained more on infection control in the use of urethral catheter [15].

Conclusions

There were improving in nurses’ knowledge after post-test for study group for educational program concerning management of patients with transurethral resection of the bladder tumor. While control group did not present any improvement in their knowledge concerning management of patients with transurethral resection of the bladder tumor at pre and post-test. It is need to be encouraging nurses to be enrolled in training sessions to improve their knowledge to keep them up to date toward management of patients with transurethral resection of the bladder tumor.

The Children with Attention-Deficit/Hyperactivity Disorder (ADHD) More Likely Creates to Irritable Bowel Syndrome

Abdul AL-Kareem Hamza
College of Health and Medical Technologies/Baghdad

Abstract

The research aimed study the children with attention-deficit/hyperactivity disorder (ADHD) more likely Creates to irritable bowel syndrome at Ibn-Rushd Psychiatric Teaching Hospital in Baghdad city, find out the relationship between demographic characteristic, irritable bowel syndrome and Attention-Deficit/Hyperactivity disorder patients. A purposive (non-probability), the sample included (100) patients, from (3-11) years old. A descriptive study carried out from December 10th 2018 to the February 25th 2019, from family Attention-Deficit/Hyperactivity Disorder outpatients of Ibn-Rushd Psychiatric Teaching Hospital in Baghdad city. A questionnaire was constructed for the purpose of the study, which was a consisted of (2) part. The 1st part included the demographic characteristics and the 2nd part included the items related with irritable bowel syndrome. Data were analyzed through descriptive statistical approach (frequency and percentage) and inferential statistical approach (correlation coefficient). Scores, Perpson, lycart scale analysis that include, t-test, and stepwise multiple regression. The result of the study confirmed that the mean of score for the age of sample was (7.1) year, most of them male urban, low score for socio-economic status, strong positive to irritable bowel syndrome.

Key Words: Attention-Deficit/Hyperactivity Disorder (Adhd) And Irritable Bowel Syndrome

Introduction

The children with attention-deficit/hyperactivity disorder (ADHD), which is a brain disorder marked by an ongoing pattern of inattention and/or hyperactivity-impulsivity that interferes with functioning or development, neurodevelopmental disorder characterized by impaired social interaction, verbal and non-verbal communication, and restricted and repetitive behavior [1]. Attention-deficit/hyperactivity disorder is a widespread chronic disorder affecting children’s well-being and success in life. The historical understanding of ADHD has changed over the years [2]. ADHD was defined in the Diagnostic and Statistical Manual of Mental Disorders (DSM)-III-R in 1987 as a disorder with a specific diagnostic checklist and three subtypes primarily inattentive, primarily hyperactive, and combined. According to the American Psychiatric Association in the DSM-V, to be considered ADHD, a child must have symptoms before the age of 12, for at least six months, and affecting two domains of life. The prevalence of the three subtypes of ADHD are primarily inattentive (20–30% of diagnosed population), primarily hyperactive-impulsive (less than 15%), and combined subtype (50–75%) [3]. The prevalence of ADHD in the US among children is estimated at 11%. ADHD is very common among children and adolescents, consisting of about 50% of children psychiatric diagnoses [4]. One of the most significant contributing factors in the children with Attention-Deficit/Hyperactivity Disorder (ADHD) appears to be undesirable foods and chemicals that come from parents who’ve noticed vast improvements in their children after changing their diets [5]. The strongest direct evidence of foods linked to attention-deficit/hyperactivity disorder involves wheat and dairy, and the specific proteins they contain namely, gluten and casein. These are difficult to digest and, especially if introduced too early in life, may result in an allergy. Fragments of these proteins, called peptides, can have big impacts in the brain.

Methods and Patients

A purposive (non-probability) sample of (100) patients with a diagnosis of ADHD, from (3-11) years old, who were selected from Ibn-Rushd Psychiatric Teaching Hospital in Baghdad city, had been chosen.
The study was conducted in order to correlation between ADHD patients and irritable bowel syndrome through the period from December 10\textsuperscript{th} 2018 to the February 25\textsuperscript{th} 2019, from family ADHD outpatients of Ibn-Rushd Psychiatric Teaching Hospital in Baghdad city. For the purpose of the present study, a questionnaire was constructed by the researcher to study the variable for ADHD patients and irritable bowel syndrome. Data were analyzed through descriptive statistical approach (frequency and percentage) and inferential statistical approach (correlation coefficient) Scores, Pereson, likert scale analysis that include, t-test, and stepwise multiple regression.

A questionnaire was constructed for the purpose of the study. It was composed of (2) major parts, and overall items, which were included in the questionnaire, were (29) items. Part I consist of (10) items related with demographic data for ADHD children which consisted of age, gender, body mass index, the age of child during diagnosis/year, the number of children in his family, and demographic data for ADHD children family which consisted of age of parents, gender, residential area, the age of mother during labor and socio-economic status. Part II consist of (19) items which included the symptoms of irritable bowel syndrome for child with ADHD. Reliability was determined through a pilot study. The data was analyzed through the application of the descriptive statistical, (Frequency and Percentage) and the inferential statistical data analysis approach Chi-square, Person correlation coefficient, all the patients under treatment and diagnosis by psychiatrist.

**. Correlation is significant at the 0.01 level (2-tailed).

*. Correlation is significant at the 0.05 level (2-tailed).

Discussion

Table (3) shows that the mean of scores for irritable bowel syndrome is a highly significant in all items expected itemes (4, 6 and 16) was significant, and the items (12, 18) was non significant. The table also shows the association between dietary pattern and attention-deficit/hyperactivity disorder. The table shows that there was a significant association between irritable bowel syndrome and attention-deficit/hyperactivity disorder. Recent research shows that more than 50% of children with attention-deficit/hyperactivity disorder have GI symptoms, food allergies, and maligestion or malabsorption issues. It’s obvious from talking to parents that GI problems are a major concern in children with attention-deficit/hyperactivity disorder. Listservs dealing with attention-deficit/hyperactivity disorder have discussions on GI issues all the time. Antifungal use, both prescription and alternative remedies, is a common topic. Parents have tried “anti-yeast” diets, prescription drugs and natural remedies, but nothing seems to be “the answer” to the chronic microbial problems these kids face \[19\]. Altered intestinal permeability was found in 43% of attention-deficit/hyperactivity disorder patients, but not found in any of the controls (Harvard University). Intestinal permeability, commonly called “leaky gut”, means that there are larger than normal spaces present between the cells of the gut wall. When these large spaces exist in the small intestine, it allows undigested food and other toxins to enter the blood stream. When incompletely broken down foods enter the body, the immune system mounts an attack against the “foreigner” resulting in food allergies and sensitivities. The release of antibodies triggers inflammatory reactions when the foods are eaten again. The chronic inflammation lowers IgA levels. Sufficient levels of IgA are needed to protect the intestinal tract from clostridia and yeast. The decreasing IgA levels allow for even further microbe proliferation in the intestinal tract. Vitamin and mineral deficiencies are also found due to the leaky gut problem \[20\]. Table (4) indicated that there was strong positive relationship in cell (20, 25, 26, 31, 33, 41, 3, 9, 12, 15, 16, 18, 19, 22, 23, 27, 32, 36, 39, 4, 5, 7, 11, 13, 14, 21, 24, 28, 30, 1, 8, 10, 17, 35, 38 and 42), positive relationship in cell (4, 2, 34, 37, 6, 40, 44 and 43). Unusual eating behavior occurs in about three-quarters of children with attention-deficit/hyperactivity disorder (ADHD), to the extent that it was formerly a diagnostic indicator. Selectivity is the most common problem, although eating rituals and food refusal also occur, this is appear to result in malnutrition, although some children with attention-deficit/hyperactivity disorder also have gastrointestinal (GI) symptoms \[21\]. In a healthy intestinal tract the small intestine and stomach are not inhabited by bacteria. When the flora balance in the colon is lost, the microbes can migrate into the small intestine and stomach, which hampers digestion. The microbes compete for nutrients and their waste products overrun the intestinal tract. One of the toxins produced by yeast is actually an enzyme that allows the yeast to bore into the intestinal wall. The yeast also produces other toxins such as organic acids, which can also damage the intestinal wall \[22\]. Bacterial growth in the small intestine destroys enzymes on the intestinal cell surface, which prevents carbohydrate digestion and absorption. The last stage of carbohydrate digestion takes place at the minute projections called microvilli. Complex carbohydrates that have been broken down by the enzymes embedded in the microvilli can be absorbed properly and enter the blood stream. But when the microvilli are damaged, the last stage of digestion cannot take place. At this point only monosaccharides can be absorbed because of their single molecule structure. In the small intestine, the body should absorb the nutrients needed from what is eaten. But in the case of malabsorption, the undigested carbohydrates left in the small intestine cause the body to draw water into the intestinal tract. This pushes the undigested carbohydrates into the colon where the microbes can feast on it. This allows for even more proliferation of the unwanted microbes and continued increase in malabsorption problems. Some parents of children with attention-deficit/hyperactivity disorder believe their children are allergic or sensitive to the components found in these foods. Some seek allergy testing for confirmation. Yet, even when no allergy is confirmed, many parents of attention-deficit/hyperactivity disorder children still...
choose to offer the gluten-free/casein-free (GFCF) diet. Among the benefits they report are changes in speech and behavior. A gluten-free/casein-free (GFCF) diet is also known as the GFCF diet. It is one of several alternative treatments for children with attention-deficit/hyperactivity disorder. When following this strict elimination diet, all foods containing gluten and casein (found in milk and dairy products) are removed from the child’s daily food intake. The benefit of a gluten-free/casein-free diet is based on the theory that children with attention-deficit/hyperactivity disorder may have an allergy or high sensitivity to foods containing gluten or casein. Children with attention-deficit/hyperactivity disorder, according to the theory, process peptides and proteins in foods containing gluten and casein differently than other people do. Hypothetically, this difference in processing may exacerbate attention-deficit/hyperactivity disorder symptoms. Some believe that the brain treats these proteins like false opiate-like chemicals. The reaction to these chemicals, they say, leads a child to act in a certain way.

Conclusions

Results indicate greater prevalence of irritable bowel syndrome symptoms among children with ADHD. Identified studies involved high methodological variability and lack of comprehensive data prohibited analysis of GI pathophysiologies typically associated with organic etiologies, limiting conclusions about the underpinnings of the observed association. Future research must address critical questions about the causes and long-term impact of GI symptoms in ADHD.

Abstract

Diabetes mellitus is a metabolic disorder of multiple aetiology. Destruction of pancreatic beta cells, hyperglycaemia, and insulin deficiency cause type 1 diabetes mellitus. Diabetic nephropathy is the damage to kidneys because of diabetes. It is predominantly seen in patients with type 1 diabetes (insulin-dependent type) and type 2 diabetes (non-insulin-dependent type). An active peptide hormone, C-peptide has the likelihood of causing major physiological effects. C-peptide is the best indication of endogenous insulin secretion occurring in patients with diabetes. In this regard, the current study undertakes a comprehensive study of C-peptide and kidney (renal) failure in patients with diabetes mellitus type 1, in order to assess their association. The subjects for this study were (70) patients with type 1 DM and (65) patients with diabetic nephropathy in different age and both sex, Laboratory tests such as (serum creatinine, urea, glucose, albumin, total protein and fasting serum C-peptide, are conducted. Data was compare the values between different category patients.

Keywords: parameters, Estimation, diabetic nephropathy.

Introduction

Diabetes mellitus

is a metabolic disorder of multiple aetiology ¹ destruction of pancreatic beta cells, and insulin deficiency cause type 1, diabetes mellitus can cause long–term damage which includes dysfunction or failure of various organ.

Diabetic nephropathy (DN)

also know as (diabetic kidney disease) is the chronic loss of kidney function occurring in those with diabetes mellitus¹, protein loss in the urine due to damage to the glomeruli may become massive and cause a low serum with resulting generalized body swelling (edema) and result in the nephrotic syndrome (Medline Plus Medical Encyclopedia (2015) likewise, the estimated glomerular filtration rate (eGFR) may progressively fall from a normal of over 90 ml/min/1.73 m² to less than 15, at which point the patient have end stage kidney disease (ESKD) it usually is slowly progressive over year.

C-peptide as a marker for diabetic nephropathy

The connecting peptide, or c-peptide is a short (31- amino-acide polypeptide) that connects A- chain its B- C-chain in the proinsulin molecule, in the insulin synthesis pathway, first preproinsulin is translocated into the endoplasmic reticulum of beta cells of the pancreas with an A-chain, a C-peptide, a B-chain, and a signal sequence, the signal sequence is cleaved from the N-terminus of the peptide by a signal peptidase, leaving proinsulin after proinsulin is packaged into vesicles in the Golgi apparatus (beta-granules) the C-peptide is removed, leaving the A-chain and B-chain bound together by disulfide bonds that constitute the insulin molecule ²-⁴ an active peptide hormone, c-peptide has the likelihood of causing major physiological effects, C-peptide and insulin are produced in equal amounts, it has the capacity to weaken glomerular hyperfiltration and bring down urinary albumin excretion in experimental as well as human type 1 diabetes ⁵-⁷.

C-peptide is the best indication of endogenous insulin secretion occurring in patients with diabetes, the amount of C-peptide in the blood indicates the amount of insulin produced by the pancreas, blood sugar level in the body is not affected by C-peptide, the purpose of performing C-peptide test done after the initial diagnosis of DM, is to ascertain whether it is type 1 or type 2.
Indian Journal of Forensic Medicine & Toxicology, July-September 2020, Vol. 14, No. 3

Diabetes, in the individual whose pancreas does not produce insulin (type 1 diabetes) has a reduced level of insulin and C-peptide, determination of C-peptide levels is preferred to determination of insulin levels as insulin concentration in the portal veins is (2-10) times greater than in the peripheral circulation. About half the amount of insulin that reaches liver plasma, is observed by the liver, however, this varies with the nutritional state, in type 1 DM there is a reduced level of insulin production by the pancreas, and in this case, the patients will also have a reduced level of C-peptide, whereas in type 2 DM the C-peptide levels in patients are more than the normal levels.

**Materials and Methods**

This study was performed in (The Iraqi center of dialysis). The present study was carried out to evaluate some chemicals in sera collected of (54) Iraqi patients affected with renal failure and type-1 Diabetic Mellitus involved both sexes with age between (20—40) years. In addition to (54) case healthy control. Most of patients were of age group between (20—40) years. Laboratory tests were performed, using enzymatic methods for (Blood glucose, urea, creatinine and C-peptide).

**Results**

Comparison of baseline characteristics among different categories of patients C-peptide level

In the table (1) A & B showed distribution of C-peptide levels with (70) diabetics and (65) diabetic nephropathy with different age and both sex.

Discussions

The following tables and figures involved the results for many parameters: -

(1) C-peptide: the determination of serum C-peptide levels can be considered in diabetes clinical practice for patients under insulin treatment, C-peptide measurement is particularly useful when there is uncertainty about the treatment (Kitabchi AE (1977) With the discovery of the method of insulin biosynthesis, many initial studies focused on the possible physiological effects of C-peptide. Efforts to find insulin-like effects on blood glucose levels, glucose disposal after glucose loading were in vain.

(2) In the recent times, new data that have been presented confirms a specific binding of C-peptide cells to cell surfaces that indicate G-protein coupled membrane receptors. Therefore, it can be stated that C-peptide can induce certain intracellular processes and thereby influence nerve and renal function in C-peptide deficient type diabetes patients. With the increasingly common clinical context, C-peptide can be highly useful in disease classification and in providing appropriate treatment. The current (Jones AG, Hattersley AT (2013) in table (1) note that C-peptide levels was normal (category 1) in (55) patients among them (20) male (36.4%) and (35) female (63.6%), C-peptide was elevated (category 2) in 20 patients from female only, C-peptide below normal (category 3) 60 patients 30 male (50.0%) and 30 female (50.0%) and high levels of sugar (206.75 ± 7.18) was P value (0.827) and high levels for each (blood urea (62.25± 5.28), creatinine (3.47 ± 0.42), albumin (5.57 ± 0.18) and total protein 8.20 ± 0.26).

(3) In this study show the prevalence of diabetes was 63% higher among females than males. Differences in lifestyle, tradition and culture were presumed to be the possible reasons for higher prevalence of obesity and diabetes among female. Comparison of baseline characteristics among different categories note low C-peptide in patients with diabetes but high in diabetics nephropathy this result from hypersecretion of B-cells, a decreased degradation or secretion. (5) note hyperglycemia in patients with diabetic nephropathy (217.69± 3.55) more than patients with diabetes (129.93± 2.36) and high level for each blood urea (78.38± 1.68), creatinine (4.72 ± 0.15), albumin (6.22 ± 0.074) and total protein (8.91 ± 0.06).

(6) note the low of (c-peptide) in the diabetic of high type which is used to know the amount of insulin Secreted from the body where it is produced equally to produce normal insulin from the pancreas and it is not affected by any external insulin. Low (c.peptide)level relationship with low produce insulin hormone and can this happen when not produce enough from insulin by B.cell in case diabetic mellitus. In addition allows us to determine what is the pancreatic reserve a mount, ie how much insulin the pancreas is still able to secrete in diabetic. It helps to determine the type of diabetes that the patient is concerned with. When the peptide levels are low and the body does not produce insulin, the diagnosis is almost certain for type 1 diabetes and beta cells are almost destructive.

Each kidney is made up of hundreds of thousands of small units called Nevron, which units task to carry out blood filtering and remove harmful chemicals from the body control of fluid balance in the body and people with diabetes slowly changes the composition of the unit of nephrons, especially the thickening of its components and show small scars of fibrous tissue over time and then start nephrons in the leakage of albumin protein in the blood to get out with urine.

Conclusion

1- In early stages of renal failure, insulin secretion and resistance in peripheral tissues, primarily skeletal muscle, is reduced.

2- in advanced stages of renal failure, renal clearance is reduced.

3- These facts are clinically important in the treatment of diabetes,

Although insulin resistance increases the insulin requirement.

4- decreased insulin degradation reduces the need for administration of insulin in diabetic patients with advanced corticotrophin-releasing factor, which increases the risk of hypoglycemia.

5- Severe hyperglycemia in oliguric or anuric ESRD patients is not associated with features of osmotic diuresis, which is seen in patients without renal failure, but it can cause hyponatremia, hyperkalemia, and acute increase in the intravascular volume.
In several large studies on ESRD patients, there was no correlation between increased survival and tight blood glucose control of patients.

7- It is suggested that the incidence of hypoglycemia was significantly higher in patients receiving strict glycemic control.

8- It is recommended that blood sugar control be considered an important goal in the treatment of ESRD diabetic patients to prevent additional damage to other organs including the eyes, kidneys, and heart

**Recommendations**

1- adjust the blood sugar level and maintain its natural rates because the high level of sugar for a long time causes rough internal internal wall for arteries this causes platelet deposition, which can lead to a mild stroke. When these clots grow, they close the arteries and hinder blood from reaching the tissues leading to impaired kidney.

2- analyze every three months with the periodic follow-up with the specialist doctor to ensure that there are no complications.

3- adjust the blood pressure especially if they are accompanied by a diabetes.

4- the work of the urine analysis and kidney functions periodically.

5- physical exercise in the case of uncontrolled blood sugar level.

A Chronic Toxicity Study of Oral Administration of Collagen-α® Supplement using Pregnant Rabbits

Alia M. Kudayer1, Nawras A. Alwan2, Alaa A. Sawad1

1Department of Anatomy and histological, College of Veterinary Medicine, University of Basrah, 2Department of Physiology, Pharmacology and Biochemistry College of Veterinary Medicine, University of Basrah.

Abstract

Since collagen derived products are highly used in food supplements due to its bioactive properties by influencing cellular and tissue health, flexibility with high effect of repairing and adaptation. It is necessary to carry out safety requirement of an oral chronic toxicity assessment. This study investigated the adverse effect of long term oral administration of collagen-α® in pregnant rabbits. We have conducted a thirty days randomized controlled trial in pregnant rabbits. Rabbits were randomized into two groups; Group 1 (control group) were administrated with 1 ml of normal saline PO, SID while Group 2 (collagen-α group) were administered with 1 ml of collagen-α® PO, SID for one month. Bodyweight gain, viscera weight and histopathological evaluation of the individual rabbit were recorded. The results revealed that the body weight gain and visceral tissues weight in the collagen-α group were significantly lower than the control group. Moreover, various histopathological changes were recorded in heart, lungs, liver and kidneys of the collagen-α group when compared with the non-significant changes that noticed in the control group. Under the conditions of the current study, a high risk of chronic toxic effect was observed in pregnant rabbits inoculated with 1 ml of oral dose of collagen alpha supplement. This result suggests that the adverse effect of collagen derived supplements is overbalancing the benefits.

Key words: Collagen-α, Rabbits, Food Supplements, Weight Gain,

Introduction

Collagen is considered as the most plenteous structural protein of living organism including vertebrates and invertebrates that constituting approximately 30% of total animal’s proteins [1]. It’s a complex alloy of the extracellular matrix of variable members of diverse families of protein exhibiting various physiological functions and structural integrity. Fundamental cell biology such as proliferation, migration cytoskeletal organization, apoptosis and differentiation are essentially regulated by collagens [2]: Moreover, collagen is the major structural element of all the connective tissues, and presents in the interstitial tissue of parenchymal organs. Thus as a results of its fibrillar structure, collagen is contributing the extracellular scaffolding which subsequently safeground the stability of tissues and organs and maintain their structural integrity [3,4].

Around 28 types of collagen have been yet identified, which is composed of 46 distinct polypeptide chains [5]. The collagen has triple helix characteristic polypeptide chains. It probably formed by three identical homotrimer chains represented as collagens II, III, VII, VIII, X and others; or heterotrimer as in types of collagen I, IV, V, VI, IX, and XI [6,7]. Permanent processes of collagens exchange take place in the body during human life; replaced of the old fibrils by new one. In the young, production of the collagen and its degradation takes place in dynamic balance, while during tissues maturation, degradation is occurring more intensive [8,9,10]. Smoking cigarettes, stress, UV radiation and unhealthy diet lead to the degradation of natural structure of collagen and to earlier senility [11].

The sources of collagen mostly came from wild animals (mainly porcine and bovine) and birds [5]: Due to their functional and nutritional properties, the collagens and “collagen-derived” products are recently widely used as food supplements, in pharmaceutical, and cosmetic industries [1]. However, collagen supplements have clinically given their beneficial functions, especially maintaining and improving the connective tissues for instance of; joints, skin dermis, ligaments, tendons, and...
blood vessels\cite{3,5,12}.

The exploration of the functions of the different collagen types is contributes to a better understanding the progress of the diseases as well as the embryonic and fetal development processes \cite{3}. Little is knowledge’s about the role of collagen defect as a source of abanants diseases/conditions among both human and animals in Iraq that threatening its utilization in daily life food-supplement as well as the chronic toxicity effects of these products. Therefore, the current study was designed to evaluate the effects of collagen-α as a food supplement on clinical and cellular changes using pregnant rabbits as a useful group study model.

**Material & Method**

**Animals and Experimental Design**

This study was conducted as a thirty-day prospective blinded assessment trail on female laboratory rabbits during November 2018. Twelve pregnant rabbits weighting between 960-1100 grams were housed in controlled environmental conditions at Animal House, College of Veterinary Medicine, Basrah University, Iraq (temperature of 25-28 °C). The rabbits were divided randomly into two equal groups; Group 1 and 2. The group 1 (control group) were orally administrated with 1 ml of normal saline while group 2 (collagen-α group) were inoculated orally by 1 ml of collagen-α\textsuperscript{®} (CH-Alpha\textsuperscript{®}, GELITA Thailand) SID for 30 days. Our experiment was approved following the roles and the guidelines of the Scientific and Researches Committee of the College of Veterinary Medicine, University of Basra, Iraq.

The body weight (BW) of each rabbit was recorded separately at the onset and at the end of the experiment. Weight gain was calculated following the formula (BW gain=Final BW-initial BW).

At the end of the study, all rabbits of both groups were euthanized. Organs such as the heart, liver and kidneys were immediately severed and weighted and fixed in 10% formalin buffer at for 24 hrs. The Specimens were dehydrated through a graded series of ethanol and xylene prior to paraffin embedding and staining with hematoxylin and eosin (Harris H&E) finally mount with DPX \cite{13}.

Statistical analysis was performed using SPSS version 22.0 for Windows. Independent “T” test analysis of variance with Tukey test was used to evaluate the differences among the two groups with regard to the study variables. Measuring of body and visceral weight are expressed as mean ± standard deviation (SD). A value of P < 0.05 was considered statistically significant.

**Results**

The weight of the pregnant rabbits of the treated group (collagen-α group (was significantly lower than in control group. However, a significant (P < 0.05) decreases in the weight of the kidneys, heart, lungs and liver were recorded in the treated group as comparasion with the control group (Table 1).

The most predominant changes of the renal tissues of the treated group are closure renal tubules that could be due to degeneration hemorrhage, and the vacuolation of the renal tubules when compared with the control group (Figures 1, A and B). Moreover, the vacuolation of the cardiocyte, hyperatrophy and spaces hemocedrosis were observed at the heart treated group (Figures 2, A and B) in contrast of control group. Thickening of alveolar wall, dilated of bronchiole and serous exudates at the lumen are most common cellular changes in the lungs tissues of the treated group comparing to normal lungs of control group (Figures 3, A and B). Finally, investigation of the tissue sections of the liver of the treated group showed moderate to severe congestion in central vein and fibrosis and swelling of hepatocyte) in comparation with control group (Figures 4, A and B).

Discussion

With the numerous bioactive properties, collagen derived products have long been used in food supplements and also in pharmaceutical products for maintaining the connective tissues. One of its clinical applications is for treatment the disorders of cartilages and skin [14]. Moreover, collagen and gelatin supplements could influence cellular and tissue health, flexibility with high effect of repairing and adaptation [15]. Commercial collagen products have been generally recognized as “saved” and approved for human consumption by the US FDA (16). Despite the collagen supplements appear to be with low risk, little data are available; recovery from injury, functional benefits, and the negative effect in athletes are also not known [15]. However, little literature exists that demonstrates the adverse effect of collagen supplements on visceral organs. In the current study, we have reported that the long term oral supplementation of collagen (collagen-α®) reduces weight gain companied with occurrence of cytopathic changes in heart, liver, lungs and kidneys of pregnant rabbits. To the best of our knowledge, this is the first chronic-toxicity study of collagen supplements using pregnant rabbit in Iraq.

The results of our study have suggest that the using of collagen-α® as a supplement consequently led to decrease weight gain as a results of its “Anti-Obesity” effect through regulation the metabolism of lipids [17]. Additionally, post mortem examinations of liver, lungs, kidneys and heart were also correlated to the results of the body weight gain findings. In contrast, Schauss et al., have conducted an acute and subchronic toxicity studies in rats that orally administrated by type II collagen derived from hydrolyzed chicken sternal cartilage. Regarding to acute and subchronic toxicity, all the rats were exhibit normal body weight with no significant histopathological changes throughout the study [18]. Collagen with hyaluronic acid and elastin have key role in providing elasticity and integrity to the organ. Collagen represents a family of 28 different proteins [19] which account for 30% of the total protein mass in the human body and play a pivotal role in the structure of several tissues, such as skin and bones, providing rigidity and integrity [3].

Despite the fact that there are no previous reports available on the hepato-toxicity induced by oral inoculation of food-derived collagen [20], our records have demonstrated histopathological alterations in liver after 30 days of collagen feeding. Similarly, Woo et al., have been mentioned that the collagen-fed mice had a lower level of hepatic Triglyceride; which was consistent with liver histological results. The Triglyceride lowering effect of collagen suppressed adipose tissue differentiation leading to diminish the adipocytes of collagen-fed mice [17]. These findings were in accordance with those of a previous related study, in which the intake of collagen peptide has decreased fatty acid synthesis and increased β-oxidation in the liver of mice [21].
The most dominant histopathological changes in kidneys were found in closure of renal tubules of collagen-α®-group; degeneration hemorrhage and vacuolation were observed. This cyto-nephrotoxicity is closely associated with the chronic effect of high protein renal filtration [22, 23]. Nevertheless, rats cold exhibit a renal hypertrophy at a dose rate of hundred times of the recommended daily collagen intake [24]. Regarding to the renal toxicity impact of collagen peptide, renal hypertrophy could be induced in growing rats following administration of porcine skin derived collagen peptide [25].

In the present study, we report that the oral supplementation with specific alpha collagen has adverse effects if be taken unnecessarily, it caused the vacuolation of the cardiocyte, hypertrophy and spaces hemocedrosis in heart as a result of high concentration of collagen (high protein diet). However, cardiac arrhythmias [26], myocarditis and cardiac atrophy [27] have been observed in individuals who after prolong receiving a low calorie and high protein (collagen) diet as a treatment of obesity.

In the present study, histopathological evaluation of lungs in collagen-α®-group showing thickening of alveolar wall, dilated of bronchiole and serous exudates into the lumen that could be due to accumulation of fluids as a result of circulatory impairs or as a sequel of heart damage. Moreover, inflammatory cell foci and emphysema were the most dominant lesions in lunges of rate after a 24-month feeding with marine collagen peptides [20]. Thus, no marked deleterious effects of collagen from bovine skin have seen in various animal studies except for local irritation when parenteral administrations are applied [28].

**CONCLUSION**

We provide a clinical trial of the oral chronic toxicity of specific collagen (collagen-α®) on pregnant rabbits for the first time in Iraq. Our data demonstrates that the prolonged oral administration of the specific collagen supplements can induce harmful cellular effects in the target organs and reduce weight gain. Despite the study’s size and limitation, the results suggest that the high risk of adverse effect of collagen derived supplements is outweighing the benefits. Further investigations are needed to clarify the role of collagen-α® in other organs such as muscles, bones and cartilages as well as evaluate the related biochemical parameters. It will be interesting to compare different collagen sources regarding to their metabolic and adaptation effects.

Nurses’ Knowledge Concerning the Management of Bleeding in Patients with Leukemia

Safad R. Isam

Assistant Instructor, Adults Nursing Department, College of Nursing, University of Baghdad

Abstract

To achieve the objectives of the study, a non-probability (purposive) sample of (50) nurses were selected those were working at the oncology wards at the above listed hospitals. The data selected according to the criteria of the study sample. The validity of the questionnaire was determined through an expert panel consists of (11) specialist expert and its reliability was determined through a pilot study by test – retest which was estimated as averages (R=0.89). Data was collected by direct interview technique using the questionnaire formal and data was analyzed by application of descriptive & inferential statistical methods (frequency, percentage, mean of score and Chi-Square). The results of the study indicated that most of the study sample were male (60%), (78%) within age group (20-29 years), (70%) were nursing college graduates and (62 %) has 1-3 years of experience at oncology wards. The results of the study indicated that the majority of the study sample had a low significance in items concerning nurses’ knowledge about managements taken by nurse to avoid bleeding, and the majority of them had a moderate significant relationship between nurses’ knowledge and the years of experience and training sessions inside and outside Iraq.

Keywords: Nurse, Knowledge, Bleeding, Leukemia.

Introduction

The patient with leukemia is at risk for many problems, including fatigue, bleeding, infection, and other complications of the disease and its treatment.\textsuperscript{1}

In 2016, the estimated number of leukemia cases in the United States was about 16,430.\textsuperscript{2} while in Iraq the estimated cases for leukemia were about 22,568 for the year 2017.\textsuperscript{3}

The most dangerous complications of leukemia are bleeding and infection, those considered the major causes of death. The risk of bleeding correlates with the level of platelet deficiency (thrombocytopenia).\textsuperscript{4}

The major goals for the nurse may include absence of complications and pain, ability to provide self-care and to cope with the diagnosis and prognosis, and an understanding of the disease process and its treatment.\textsuperscript{5}

Nurses should follow a set of practices concerning the management of bleeding in patients with leukemia at all times and use critical thinking and problem solving in managing clinical situation.\textsuperscript{6}

The first precaution of intended bleeding is following a good personal protective equipment measures including ; hand washing, gloves, masks cover the mouth and nose, gown, face and eye protection.\textsuperscript{7}

For this reason the researcher do this study to assess the nurses’ knowledge about management of bleeding in patients with leukemia.

Material and Methods

A descriptive study carried out at three teaching hospitals at Medical City Complex (Baghdad teaching hospital, consultation clinic at Baghdad teaching hospital and oncology teaching hospital) starting from September 4\textsuperscript{th}, 2019 up to December 10\textsuperscript{th}, 2019.

A simple random sample of (50) nurses who were working at the oncology wards according to the following criteria (adult nurse age (20-49 years) with at least one year of experience).
The questionnaire that used to collect the data and measure the variables, it consisted of two parts; the first part concerned with the nurses’ demographic characteristics of (7) items (age, gender, residency, marital status, educational level, years of experience, and specialized courses taken inside and outside Iraq). The second part concerned with nurses’ knowledge concerning management of bleeding which consists of (2) domains which include (20) items. The first domain is for the measures taken by the nurses to prevent bleeding, the second domain involves the advices which provided by the nurse to prevent bleeding. These items are measured, scored and rated on a 3 level type Likert scale (3) for always, (2) for sometimes and (1) for never.

Content validity of the questionnaire is determined through a panel of (11) experts they are faculty members of nursing college, university of Baghdad. A pilot study was carried out on the 6th, September, to the 10th September, 2019. Determination of the reliability of the questionnaire was based upon the (test-retest) which has been (0.89) for (10) nurses. Data was collected from (13th, September to 25th October, 2019 by utilization of the study instrument and interviewing with the nurses.

**Data Analysis**

Data were analyzed through application of descriptive and inferential statistical data analysis approaches. This approach used for determining the following measurements:

1. Frequency (F).
2. Percentage ( % ).
3. Arithmetic Mean.

$$x = \frac{\sum x}{n}$$

$$\sum xi = \text{sum of the (3x always + 2x sometimes + 1x never) for items. n = number of the sample}$$

4. Mean of score (MS): A mean of score equal to (1.67- 2.33) was considered moderate MS, greater than (2.34) was considered high MS, less than (1.67) was considered low MS.

5. Pearson Correlation Coefficient

It was used to estimate the scale (test & retest ) reliability through the application of the following formula :

$$r = \frac{n \sum x y - (\sum x)(\sum y)}{\sqrt{n(\sum x^2) - (\sum x)^2} \sqrt{n(\sum y^2) - (\sum y)^2}}$$

6. Chi – square: it was applied for the confirmation of association between the nurse’s knowledge about infection control and his/ her demographic characteristics such as years of experience and specialized courses taken inside and outside Iraq. This was computed using this formula :

$$X^2 = \sum \frac{(O_i - E_i)^2}{E_i}$$

**Results**

The analysis of the data after being processed and tabulated. Such presentation is systematically oriented relative to nurses and their demographic characteristic.

<td>30</td>
</tr>
</tbody>
</table>

$\chi^2$ Obs. = 18.951 , df = 13 , P ≤ 0.05 , $\chi^2$ Crit. = 23.362

This table shows that there is a high significant relationship between nurse’s knowledge and courses taken inside Iraq, while there is a moderate significance in having courses outside Iraq.
Discussion

Regarding the management taken by the nurse to avoid bleeding (table 1) showed that the study sample reflect a moderate significance in items concerning with taking temperature through mouth and avoiding intramuscular injection. This result agrees with Weightman et al., (2009) who discussed the first line of preventing bleeding during injections and taking temperature through axilla rather than rectal and oral methods. But, this result is disagree with Jafari et al., (2008) and Shinde and Mohita, (2014) who listed that the nurses’ knowledge must be at highest as possible to achieve better prevention of bleeding.

The results of the present study (table 2) showed that the majority of study sample reflect a low significance in items concerned with advices given by nurse concerning management of bleeding. These results disagree with Mehtar and Marais, (2011) who studied the policy to practice education in dealing with bleeding prevention and infection control.

These results are similar to a study done by Kumbargere, (2015) who analyzed that shortage of nursing staff and the decrease in the specialized training courses was the main causes. In addition to the huge numbers of patients with leukemia admitted to the medical wards at Baghdad teaching hospitals.

Table (3) showed that there is a moderate significant positive relationship between years of experience and nurses’ knowledge about management of bleeding. These results supported by Saini et al., (2011) who had done a study on infection control among health care assistants and he found that there is a positive relationship between nurses’ knowledge and their years of experience. In addition, the commitment of standard precautions for all nursing staff in selected Egyptian cancer hospitals even those with less years of experience may improve the nurses’ skills in dealing with bleeding as discussed by Eskander et al., (2013).

Table (4) showed that there is a high significant positive relationship between nurses’ knowledge about management of bleeding and specialized training courses taken inside Iraq, while there is a moderate significance in having courses outside Iraq. These results supported by Joshi et al., (2014) in the study results that reflected a positive significant relationship between nurses and health care staffs’ knowledge and training. A similar study done by Farmer et al., (2010) confirmed the existence of that relationship.

Conclusions

The study indicated that the majority of the study sample had a low significance in items concerning nurses’ knowledge about managements taken by nurse to avoid bleeding with the presence of moderate significant relationship between years of experience and nurses’ knowledge. In addition, there is moderate to high significance in participating in training courses inside and outside Iraq.

The Histological Alteration of Proximal Part of Aorta Exposed to (MSG) and Protective Effect of α Lipoic Acid (ALA) in Male Rabbits

Eman.M.Heil 1, Wefak Al-Bazi 2, Muna .Hussain AL-Aameli3
1 M.Sc. Student, 2 Prof., 3 Assist. Prof., Faculty of Veterinary Medicine, University of Kerbala, Kerbala, Iraq

Abstract

Background. Monosodium Glutamate is one of the most world’s most widely used food additives. Its toxic effect have been shown in numerous animal studies, in which study MSG effects on cardiovascular system, therefore, This study was aimed to investigate the effect of alpha lipoic acid(ALA) on the damage in the large blood vessels induce by Mono sodium glutamate. Thirty two male rabbits was divided equally and randomly into four groups as following. Control group in which rabbits where fed with normal diet without supplementation, second group was gived MSG orally (8mg/kg.BW), While animals of third group were given ALA orally (60mg/kg.BW) while animal in fourth group were given orally (MSG 8mg/kg.bw and ALA 60mg/kg.bw), all treatment are extended to 8 weeks. The outcomes of research revealed a significant increased (p<0.05) in aortic medial layer thickness in animals administration of MSG in a comparesion with control and groups treated and distortion structure of laminar fibers, endothelial cells lost normal squamous. In addition, there is a significant decreased (p<0.05) in medial tunica thicken in animals used ALA combination with MSG, so we noted return the disarranged of architecture tissue near.

Keywords: aorta, MSG, protective effect, α lipoic acid

Introduction

Cardiovascular diseases (CVD) considered one of the main causes of death all the world and more developing countries, CVD, is the most common form of heart disease, CAD is a disease infecting the arterial blood vessel and is generally referred to as hardening or furring” of the arteries. It is caused by configuration of multiple plaques within the arteries 1, 2, 3, 4. Atherosclerosis derives from a Greek word, Atheros meaning gruel 4,Fatty streaks evolve to formation atherosclerotic plaques which is consisted of three components called of inflammatory cell, smooth muscle cell, a fibrous component of connective tissue, a Fat component of lipids 5. Monosodium glutamate (MSG) is the sodium salt of the non-essential amino acid glutamic acid. Glutamic acid is one of the most abundant amino acids presented in nature and found both as free glutamate and bound with more amino acids into protein.

Animal proteins may involve about 11 to 22% by weight of glutamic acid, with plant proteins including as much as 40% glutamate6. Glutamate is thus presented in a wide variety of foods, and in its free form, where it has been demonstrated to have a flavour enhancing effect, is also exist in relatively high concentrations in some foods such as tomatoes, mushrooms, peas and cheeses. ALA represent as a defensive agent versus hazard factors of cardiovascular disease. ALA may impact the CVD risk via the beneficial action on LDL oxidation, blood lipid profiles(LDL,VLDL,HDL) , plaque formation , hypertension7. ALA is a natural antioxidant created in the mitochondria of the liver and more tissues, so it has anti-inflammatory characteristics, ability to scavenge ROS, metal chelating, regenerate glutathione, vitamins (E, C) and diminished the atherosclerotic plaque by it can mending vascular function 8, 9. The dearth information about role protective to alpha lipoic acid on the distortions in large red artery induce by Mono Sodium Glutamate for this reason, the experimented was determent.

Materials and Method

Experimental design

In June–July month’s adult eight male rabbit’s per group, weight 1300-1500 g/kg which captured from the Karbala conserve were used in this study. First group gives diet without supplementation. Second group was administrated of MSG dissolved by water by orally at dose 8mg/kg B.W, for eight weeks. While rabbits included in third group were gives Alpha lipoic acid dissolved by DMSO orally at dose 60 mg/kg B.W for eight weeks. The experimental rabbits of euthanized by intra muscular administration of diazepam (1mg/1kg) combined with ketamine HCL (30Mg, 1Kg). After thoracic incision, the large artery (aorta) is obtaining and fixed in the 10% neutral buffer formalin. Cross sections was prepared histologically. Routine heamatoxylin and eosin stains were used to general structure study, in addition to other special stain (Massson’s trichrom stain) to give more histological details. The parameter that thickness medial tunic was measured.

Statistical Analysis

The collected data were represented by mean ± standard deviation. Comparisons were done between rabbits group. The mean of differences between data were estimated.

Results and Discussions

All histological stains were used in control group of our study appear the structure of elastic artery was consist of three layers, tunic intima which contain endothelium, basal lamina, and sub endothelial connective tissue, smooth muscle cells, internal elastic lamina that represent first layer but, the tunic media composed from greater fenestrated elastic laminae with lesser amount of smooth muscle with collagen fibers second layer thicker evaluated (588.4±52.8), fig.(1) table(1) while, the third layer connective tissue concentrate collagen with scatter of elastic fibers and vaso vasorum this structure named tunic adventitia fig.(2,A,B). These results superposes many authors’ who reported during your researches in differ model animals. The many studies were to evaluate the effect induced by monosodium glutamate(MSG) on systems body include cardiovascular system in a rodent, fowls and rats animals these have shown irregular structure of the laminae fibers, thinning and fragmentation of elastic laminae, proliferation of medial smooth muscle, thickened of the aortic artery greatly in tunica intimal these similar under line of the histomorphological study in our research of the aortic artery in supplementation rabbits group with MSG revealed the nuclei of endothelial cells in intimal surface were irregular and lost squamous cells specialty with foam cell existences and increased aortic medial thickness measured (1054.3±39.9),fig. (1)table(1) and deterioration architectural of elastic fibers in tunica media when compared with control rabbit groups figs.(2,C,D; 3, E,F) in addison greater of adipocytes penetrated connective tissue of adventitial layer fig.(4, A,B).

The diabetic and hypertension rats treated with ALA the endothelial cells of intimal layer having squamous property and appear smoother with fewer defect so the smooth muscles don’t reactively proliferation and organization of the lamina fibers of tunica media these results of author similar of our investigation research. In microscopic section examined of the MSG &ALA supplementation rabbits group that shows histomorphological architectural near from the control groups the endothelial cells of intimal layer squamous characteristic so that, when we image analysis observed, decreased aortic media layer thickness, was (660.12 ±81),fig.(1) table (1) compared with the treated MSG rabbits group and appear more regulars’, more organized structure of lamina fibers and reduced proliferate smooth muscles in tunica media figs. (2, E; 3, G, H).

Thioctic acid (ALA) was easily converts dihydrolipoic acid represented reduced form, so it was neutralizes free radicals in both the fatty and watery regions of cells,. Our outcomes of research, three layers of the aorta in ALA treated rabbit groups (intima, media and serosa) had of normal microscopical details structures and decreased thickened in aortic media evaluated was ( 615.8 ± 77.5) fig (1) table(1) when compere with MSG treated rabbits group these revealed micrograph (2,G,H;3,C,D) this described assembly who reported author.
Table (1): measured thickness tunica media of aortic control and treated rabbits group. Values represent means±SD. Different letters were means significantly (P<0.05) different.

Effect of Pioneer Aeromedical Evacuation Program on Flight Medics’ Practices toward Emergency Casualties at Army Aviation Bases in Iraq

Ammar Kadhum Gaeed¹, Huda Baker Hassan²

²Ph.D. Professor, Adult Nursing Department, College of Nursing, University of Baghdad, Iraq

Abstract

Objective(s): The study aims to determination the effect of aeromedical evacuation program on flight medics’ practices.

Method: A pre-experimental design is carried in army aviation bases in Iraq, for the period of February 1st 2019 to September 25th 2019. Non-probability “purposive” sample of (30) flight medics are selected from army aviation bases. Non-probability “purposive” sample of (30) flight medics are selected from army aviation bases. The questionnaire is composed of two main parts (demographic characteristics of the flight medics, and the second part involves five domains which as (67) items concerning flight medics’ practices regarding first aid of emergency casualties format, the researcher used SPSS version 20 to analyze the data. The reliability of the participant responses was estimated by alpha correlation (r) practice test was (r= 0.94), and content validity of the instrument was determined through a panel of (twenty-five) experts. Data was analyzed through the use of descriptive and inferential statistical analysis.

Results: The results of the pretest for flight medics revealed that flight medics’ practices about five domains of aeromedical evacuation program toward emergency casualties was moderate, while the posttest I and II results shows that flight medics’ practices was improved to high level because of the positive impact of the instruction program, and there were significant association between the effectiveness of present program on flight medics’ practices and there level of education at P≤0.05.

Conclusion: The study concluded that the present program was effective on flight medics’ practices.

Recommendation: The study recommended to increase the training courses for flight medics inside and outside Iraq, and included the present program on their plan of training.

Keywords: Pioneer, Aeromedical evacuation, flight medic, practices, Emergency Casualties.

Introduction

Aero- medical services are a comprehensive term covering the use of air transportation, airplane or helicopter, to transport patients to and from healthcare facilities and accident scenes. Air medical services have a particular advantage for major trauma injuries. The well-established theory of the golden hour suggests that major trauma patients should be transported as quickly as possible to a specialist trauma center.⁽¹⁾⁽²⁾ Helicopter emergency medical services has its origins in military evacuation by air transport during the war, its use in civilian situations was initiated in the 1960s in the United States, since then, it has played an important role in pre hospital emergency medical systems, rapid transport of major trauma patients to a definitive care center is a cornerstone of modern trauma systems, and delay in this element of care is a widely known cause of mortality.⁽³⁾ Key to success is evenly built medical support with strong, balanced system of medical evacuation.
The evacuation of sick and wounded during military operations is influenced by many factors as are operational environment, weather, length and quality of medical evacuation routes and number and type of suitable medical evacuation means in time of need. (4)

The highest percent of trauma deaths occurs in the prehospital setting of the traumatic incident. Mortality and morbidity can be reduced by effective identification, field triage, the intervention of ambulance caregivers to give pre-hospital trauma care and transport of severely trauma casualty to hospital. (5)

Pre-hospital trauma triage standards ordinarily acquire a blend combo of physiological, anatomical, and mechanisms of trauma constriction made to meet casualties’ trauma system needs. (6)

**Method**

A pre-experimental design is carried in army aviation bases in Iraq, the present study started from February 1\textsuperscript{st} 2019 to September 25\textsuperscript{th} 2019, which carried out in the Al Taji Air Base clinic; Al Habbaniyah Air Base clinic; Al Shuaiba Air Base clinic; Al Kout Air Base clinic; and Kirkuk Air Base clinic, Army aviation college. A non-probability (purposive) sample included was (35) flight medic, the researcher constructed a questionnaire format based on program in order to reach the objectives of the study, which consists of two parts; first part deals with of demographic characteristics of the flight medics which as age, gender, level of education, years of experiences in first aid, years of experiences in aeromedical evacuation, number of training courses in medical category, and Place of the courses. The second part refers to flight medics’ checklist items related to practices. the content validity of the present program and instruments was established through a panel of twenty-five (25) experts. The reliability of the participant responses was estimated by alpha correlation (r) practice test was (r= 0.94), The data of the present study are analyzed through the use of the Statistical Package of Social Sciences (SPSS) version 20. through descriptive statistics (frequency, percentage, mean, standard deviation, and graphical presentation) and statistical inferential (t-test, person correlation coefficient, and analysis of variance ANOVA).

Discussion

Aeromedical evacuation played a key role in the battles that occurred in Iraq after 2003 by rescuing the injured immediately from the battlefield by competent flight medics, as well as in the current study concerned with training air paramedics to aid the wounded through ambulances towards Emergency injuries. A purposive sample which included 30 flight medics distributed to various air bases, including Taji, Habbaniyah, Kut, Basra.

The discussion focuses on interpreting the results of the distribution of the study sample by their characteristics, responses of flight medic toward practices of aeromedical evacuation of emergency casualties (pretest and posttest I), responses of flight medic toward practices of present program of emergency casualties (pretest and posttest I), and association between the effectiveness of program and flight medic’s variables.

Data analysis had revealed that the implementation of the present program had a positive effect on flight medics’ practices through measurement of practice concerning adult pre-hospital trauma care as defined by Care according to seven domains.

Frank et al., (2014) concluded in their research to study PHTLS pre-hospital sessions in Germany and demonstrate the assumption that the level of training for pre-hospital health and care providers was deficient. Where the researchers confirmed that the majority of paramedics had received adequate training regarding pre-hospital care, and mentioned after the session’s confidence increased significantly and it reached higher rates than before the course. (7)

Kumar et al., (2008) revealed that mean performance score of participants regarding prehospital and emergency care was below average. (8)

Deakin et al, (2009) they added that pre-training medical assistants are not acceptable at using advanced airway skills to keep endotracheal intubation skills at a good level. they emphasized that the educational program presented to them has improved a lot of endotracheal intubation skills in inserting tracheal tubes, and more continuous training is obtained through clinical practice. (9)

Bayraktar (2009) It was mentioned that paramedics practicing first aid before training on the smart puppets were not ambitious. Later, they were given more scenarios of first aid, and most drivers became impeccable worse or approached an ideal point in assessing first aid. (10)

The American Heart Association (2015) It is mentioned that many of the results make us think about publishing first aid training courses for the entire ambulance team. (11)

The present study Agree with the study of Romundstad, Sundnes, Pillgram, et al, (2004) (2004) they explained that a large percentage of people who are exposed to natural disasters in remote places with multiple scenes, and limited access to them, remains the medical air evacuation is the best solution to save such emergency injuries. (12) Assa, Landau, Barenboim, et al, (2009) revealed that the airomedical evacuation played an important role in the event as reflected from the severity of injuries of the patients transported. of most casualties defined as urgent or severely wounded, life-threatening injuries are evacuated by air.

Conclusion

The study concluded that the present program was effective on flight medics’ practices.

Anatomical, Histological and Histochemical Investigation of Soft Palate in Cat (Felis Catus Domesticus.L)

Abbas Lafi Batah 1, Hussein Bashar Mahmood 2, Walaa F Obead3
1 Lecturer, Department of Anatomy and Histology\College of Medicine\Misan University, 2 Assist. Prof., Department of Anatomy and Histology\College of Veterinary Medicine\University of Kerbala, 3 Lecturer, Department of Anatomy and Histology\College of Veterinary Medicine\University of Kerbala

Abstract

Objectives: The aim of this study was to evaluate the normal structure and provide distribution for palatine glands in cranial and caudal part of soft palate. Also, afford information to be useful for both surgical interventions and pathological disease. Method: Sixth healthy cats were caught in Iraq farms. All experimental animals euthanized by intramuscular injection of ketamine (0.5 cc) and xylazine (0.5 cc). Sections were stained by H&E and combined AB+PAS stain 2.5 pH. Results: The soft palate was triangular in shape, the dimensions was (2.8, 2) cm in length and width respectively. Also, had two surface; nasopharyngeal surface lined by pseudostratified columnar epithelial ciliated and oropharyngeal surface lined by stratified squamous epithelia. The palatine glands appeared magenta in color during staining by AB+PAS combined stain due to neutral secretion. Conclusion: The palatine glands variance in distribution between dorsal and ventral surface of soft palate, most of these glands constricted in oropharyngeal surface.

Keyword: Histological, Soft palate, Cat.

Introduction

Usually, the normal of anatomical characteristic supports in diagnosis and successful treatment of many intricate cases. Apart from evaluation of clefs, diversity in radiographic appearance of soft palate has remained unrecognized. Enumerates of studies 1,2 have been done in past towards the dimensional analysis of the soft palate and its surrounding structures, but there are not many studies regarding normal variants of soft palate morphology and configuration3. The dimensional analysis of the soft palate and its surrounding structures, especially the velar length and width has been studied; on the other hand, the variety of velar morphology which is the most logical cause of different dimensions on the soft palate has been frequently overlooked 4. The soft palate is one from main structures in oral cavity, musculo-membranous part, separating the digestive tract and respiratory system. It extends caudally to the hard. The two system’s working is extremely important because it requires both swallowing and breathing. In fact, soft palate disorder is involved in the pathogenesis by well-recognized respiratory syndromes, including such obstructive sleep apnea disease in human patients and intermittent soft palate displacement in farm animals 5,6. The morphological incongruity of the soft palate plays a vital anatomic role in functional rehabilitation of speech, breathing, hearing, and managing patients with cleft lip-palate, obstructive sleep apnea, skeletal craniofacial malocclusion and oral submucosa fibrosis7. The aim of this study to provide date for normal structure of soft palate for supported other sciences as histopathology, surgical study and clinical examination.

Materials and Method

Specimens of soft palate taken from (6) adult cats. The average weight of the animals was (1.8) kg. Anaesthetized with an intramuscular injection of ketamine (0.5 cc) and xylazine (0.5 cc)8. The Anatomical study of the soft palate included shape, length, and width. These measurements were recorded in centimeter (mm) using a calibrated scale. The weight was recorded in gram (g) using the sensitive electronic balance. For histological dedications the samples were fixed in 10%
neutral buffered formaldehyde and sectioned serially at 5 µm. Sections were stained with H &E and combined AB+ PAS, 2.5 pH 19.

**Result & Discussion**

**Morphologically,** the soft palate in domestic cats was appeared as triangular- shape, base of this triangular located cranially but pointed part caudally toward epiglottis. There are two surface of soft palate; dorsal surface or (naso-pharyngeal part) and ventral surface (oro-pharyngeal part), the ventral surface was smoothly and don’t have any papillae, most of oral papillae located in hard palate (Fig, 1, 2). The dimensions of soft palate was (2.8) cm in length, width in base of palate was (2) cm (Fig, 3). This result disagreement with 9 who stated that the soft palate have well-developed papillae in oral pharyngeal part.

**Histologically:** the nasopharyngeal surface lined by psuedostratified columnar ciliated epithelia without goblet cells (Fig,5), rested on the thick layer of collagen fibers, with numerous of infiltrated lymphatic cells. Also, continuous between lamina propria and submucosa, lacking a lamina muscularis. The palatine salivary glands in nasopharyngeal side fewer in numbers, located close to basement membrane (Fig,6). These results akin partially with 10 who stated that the soft palate in dogs have two side; oral and nasopharyngeal, the later side lined by psuedostratified columnar ciliated epithelia but there are no glands underneath mucosa.

The oropharyngeal surface lined by thicker stratified squamous epithelial non-keratinized, wavy in shape, rested on the thick layer of collagen fibers. The submucosa was loose connective tissue, undistinguished line between lamina propria and submucosa. The palatine salivary glands in this part was crowded, intermingled as groups or aggregated in many lobes, each lobe had numerous of branch mucous glands, separated from others by collagen fibers. 11 Whoever describe the palatine salivary glands in the oropharyngeal surface as being heavy for mucosal coat lubrication is necessary to prevent injury during consumption of food. The caudal part of soft palate or muscular part consists of numerous of glands intermingled between longitudinal skeletal fibers, lacking to epithelial layer this part. This is the thickest layer of the soft palate. The mucous acini are of the usual pattern, separated by thin connective tissue septa. These results disagree with 12 who stated that the deep of soft palate of albino rat had a dense collagen layer, there is a lack of skeletal muscle other than at the caudal part. In addition these results disagreement with 13 who describe that the thick glandular layer gradually becomes thinner towards the posterior part of the soft palate.

The epithelial lining of the interlober glandular ducts duct lined by simple squamous epithelia while main duct located near to the basement membrane and lined by stratified cuboidal epithelia. These finding variance partially with 14 who stated that the glandular epithelial of main duct lined by stratified cuboidal while the interlober duct lined by simple cuboidal epithelia.

Histochemical study of soft palate in cats during staining with combined with (AB+PAS at pH 2.5) appeared strong reaction, the acini of glands was seemed magenta in color due to secreted neutral type (Fig, 9, 10). These results akin with 15 who stated that the histochemical affinity of the palatine glands was homogeneous, independent of their localization and positive reaction with combined with AB+PAS stain.

![Figure 1: Oral cavity showing, hard palate (green arrow) and soft palate (blue arrow).](image-url)
Figure 2: Soft palate in cat appeared as triangular in shape consist of cranial part (yellow arrow) and caudal part (green arrow).

Figure 3: Nasopharyngeal part of soft palate showing A- Mucosa and B- Submucosa had loose connective tissue. Salivary glands were little amounts and close with nasopharyngeal part (blue arrow). H&E stain.40X.

Figure 4: Soft palate in cat showing nasopharyngeal part lined by psuedostratified columnar ciliated. H&E stain.400X.
Figure 5: Soft palate of cat showing oropharyngeal part lined by stratified squamous epithelial non keratinized (A) rested on thick layer of submucosa (B) with heavy layer of salivary glands (Blue arrow). H&E stain. 100X.

Figure 6: Caudal part of soft palate showing the salivary gland separated by striated muscle fibers (blue arrow). H&E stain. 400X.

Abstract

\textit{Pseudomonas aeruginosa} is a gram negative rod shape bacterium belonging to the family Pseudomonadaceae. \textit{Pseudomonas aeruginosa} is a major uropathogen in a hospital. It can tolerate a wide kind of physical conditions and many antibiotics via several mechanisms resistance. The study included genetic study blaOXA50 gene utilizing technique PCR by specific forward and reverse primers to common bacteria that causes otitis media, 40 isolated from otitis media patients (ear swab). Primary identification was depended on Gram stain, biochemical tests and vitek 2 system was done. The results demonstrate 30 isolate of them were \textit{P.aerginosae}. The result appear \textit{P.aerginosae} contain on 25(19\%) blaOXA50 gene.

Keyword: \textit{P.aerginosae}, blaOXA50 gene, Resistance antibiotic

Introduction

Otitis media (OM) refers to a group of compound contagious and diseases in inflammatory effecting the ear middle. general the Otitis media is very rife, the study appear that about 82 \% of children need to experience at lower one episode via their birthday third. Otitis media have 2 kinds, chronic, acute. (A.O.M) is characterized via the fast onset of signs of infection, specially bulging and promising perforation of the tympanic membrane, fullness, erythema as well as symptoms associated with inflammation for example fever, irritability, otalgia. In spite of suitable therapy of the antibiotic, AOM may progress to (C.S.O.M) characterized via continual drainage from the ear middle related with perforated ear drum. \textit{Pseudomonas aeruginosa} is one of the most ecologically significant species among the genus Pseudomonas. \textit{P. aeruginosa} is of extreme importance because of the widespread distribution of its strains in nature, its high intrinsic anti-bacterial resistance and its virulence. Many antibiotic resistance mechanisms report in \textit{P. aeruginosa} counting: 1) Reduced expression or loss of Op rD porin causing reduced antibiotic permeability 2) Over-expression of Mex AB Op r M pump which increases antibiotic efflux 3) Production of \textit{β}-lactams and aminoglycosides inactivating enzymes 4) Mutations of gyrases and topoisomerases which causes resistance fluoroquenolone. The mechanisms in combination lead to multiple drug resistance. \textit{β}-lactamases are hydrolytic enzymes that are responsible for the resistance to \textit{β}-lactam antibiotics. \textit{β}-lactamases have many types containing (E.S.BLs), AmpC \textit{β}-lactamases, carbenicillin hydrolysing \textit{β}-lactamase, \textit{Pseudomonas} specific enzyme (PSE) and (M.\textit{β}.Ls). ESBLs are encoded by different genes in P. aeruginosa including VEB gene. M\textit{β}Ls are encoded by different genes involved V.I.M and I.M.P.

Bacterial pumps efflux greatly included in the intrinsic resistance of Gram-negative bacteria. When overexpressed, pumps efflux can accord raise resistance to already effective antibiotics. Many pumps efflux conveyance enormous range of unrelated drugs known as multidrug resistance (MDR) pumps efflux. Four antibiotic efflux method has been reported in P. aerugenosa. Mex AB-Op r M is the efflux method that is responsible of ejaculation of quinolones and \textit{β}-lactams. The evolution of isolates M.D.R.P.A through therapy report in 27\% to 72\% of patients by primarily susceptible P. aerugenosa isolates. Patients by MDRPA different infections have to treated thru therapy combination, involving of an antipsaudomonal...
β-lactam fluoroquinolone oraminoglycoside, to some extent fluoroquinolone and aminoglycoside group, tool up convenient therapy and get better patient outcomes.

Methodology

Samples collection

collected (40) clinical samples from patients suffering otitis media signs through the period from 2019 January to October, 2019) from patients present to AL-Hakem General Hospital and AL-Sadder Medical City. All the samples cultured onto MacConkey, Blood and Mannitol agar plates then protected at 37°C for 18 to 24 hr.

Results and discussion

Pseudomonas aeruginosa Isolation and Identification

Identification the primarily of specimens bacterial relied of some criteria which like biochemical tests, cultural, morphology. concurrence the last complete with the automated vitek-2 compact method utilizing GNID cards include 64 tests biochemical and 1 negative control. accentuation of aeruginos Pseudomonas showed utilized P.C.R method. deferent physiological, biochemical and morphological, tests was made to identify isolates bacterial.

Results appeared the Pseudomonas aeruginosa counted 30 isolates (30%), and another isolates bacterial was Proteus, Kleabiseslla pneumoneae, S.aureus and Enterobecter aerogenes. Bacterial isolates was specified give to the cultural, biochemical and microscopical physical appearance that approval. aeruginosa Pseudomonas was products pyocyenin and
granting positive strongly oxidase, grant indole (Indole test is utilized the capability of an organism to split tryptophan amino acid to form compound indole, methyl red (test reveal the product the acid sufficient through the form of glucose, the result concur 8.

Isolates Pseudomonas aeruginosa give tests biochemical; result positive oxidase, and capable toward used citrate by way of sole source of carbon, in Kliegler Fe agar give alkaline slant and not alteration the bottom, negative H2S without production gas payable to fact the aerobic strictly 9.

Detection of the blaOXA50 gene

All isolates was investigated to discover genes blaOXA50 utilizing technique PCR with specified forward and invert primers. results appear in fig. (1) present the study to blaOXA50 gene tested isolates represented 25(19%) in bacterial isolated, all the resistant carbepenem isolates P. aeruginosa was found to harbor the gene blaOXA50. Oxacilleinase is ambler kind D β-lactamases by hydrolytic action against the penicillins, spectrum extended cephalosporins, aztreonam and methicillin. determination β-lactamases of group B and group D, like OXA and genes IMP, at the same order, was found to harbor the gene blaOXA50.

The mechanisms catalytic, has been established two group; the group B enzymes are metaello-β-lactamases that demand Zn of the activity, the group A, C, and D β-lactamases include groups serine at active site. Oxacillinases are Ambler group D β-lactamases with against penicillins that active hydrolytic, spectrum extended methicillin, cephalosporins, aztreonam 10.

Effects of Alcoholic Extracts of *Cinnamomum zeylanicum* and *Origanum Majorana* on Expression of *Hly* Gene in *Escherichia coli*

Luma Saeed Mohammed¹, Enass Ghassan Sweedan¹, May Talib Flayyih²

¹Lecturer/Professor, ²Professor/Biology Department, College of Science, University of Baghdad/Iraq

Abstract

*Escherichia coli* isolates isolated from urinary tract infection identified by biochemical test and confirmed by Vitek 2 compact system. Minimum inhibitory concentrations of *Cinnamomum zeylanicum* and *Origanum majorana* alcoholic extracts determined by broth macrodilution assay, it range (12.5-25) mg/ml for *C. zeylanicum* and 100mg/ml for *O. majorana* leaves. The expression of *hly* gene studied in presence of 16sRNA as reference gene, four isolates of *E. coli* (A1 ,A2,A5 and A6) used to detect the expression of *hly* gene by using Quantitative reverse transcription-PCR (1-StepqRT-PCR) before and after treatment with plants extracts calibrated with 16sRNA. There was inhibition in *hly* gene expression with *O. majorana*, the fold changes were 1.23 and 2 in isolates A5 and A6 respectively while there were induction in *hly* gene expression with *C. zeylanicum*, the fold changes were 137 and 73.5 for isolates A1 and A2 respectively.

**Keywords:** *Escherichia coli*, hemolysin, urinary tract infection, gene expression

Introduction

Urinary tract infections (UTIs), the most common bacterial infections affecting high percent of people per year worldwide and more common in women than men.¹ *E. coli* is the most frequent bacteria followed by Klebsiella and Proteus species to cause UTI, and other predominant species include Enterococcus, Klebsiella, group B Streptococcus, group B Staphylococcus Citrobacter, Acinetobacter and Pseudomonas species.² High resistance to antimicrobial agents and the recent emergence of the resistant made UTI control high costly and difficult.³ Uropathogenic *E. coli* (UPEC) is the major cause of UTI.⁴ A study on UPEC showed 100% resistance percentage of bacteria against antibiotics like cefazidime ciprofloxacin, kanamycin and others.⁵ Virulence factors of recognized importance in the pathogenesis of UTI contain adhesions, hemolysin, capsule, and a cytotoxic pore forming toxin.⁶

*Origanum vulgare* contain essential oil with high percentages of phenolic compounds which gave the antimicrobial properties.⁷

*Origanum* has anti inflammatory effects, anti microbial action, decreasing cardiovascular disease, boosting cognitive function and reducing danger of colon cancer.⁸ *Cinnamomum zeylanicum* essential oil has antibacterial activity against bacteria and its main components against *Paenibacillus larvae*.⁹

Materials and Method

**Bacterial isolates:**

*Eight* *E. coli* isolates from patients suffering from UTIs were identified by biochemical test and confirmed by Vitek2 compact system.

**Plants extracts:**

Alcoholic bark extract *C. zeylanicum* and *O. Majorana* alcoholic leaves extract were prepared.¹¹

**Determination of Minimum Inhibitory Concentrations (MIC) of plants extracts:**

Broth macro dilution assay used to determined the MIC of Alcoholic extracts against *E. coli* according to "..."
**HLY expression in E.coli isolates in presence of alcoholic extracts of O. majorana and C. zeylanicum**

hly expression was studied in E.coli in presence of sub MIC concentrations of C. zeylanicum and for O. majorana

**RNA Extraction from bacteria:**

The RNA was extracted from the bacteria by using ZR Fungal/Bacterial RNA MiniPrep™ kit, according to the kit protocol as manufactured company

**Extermination of RNA Concentration:**

1. 200 µl from Tris EDTA (TE) was added to 3,800 from D. water the mix 4000 µl,pull 10 µl ignore it and add 10 µl from dye (RNA Dye).

2. 200 µl of the mix for each sample was Pulled.

3. The series of the following tubes are prepared as follows:

4. The mixture was shacked by vortex for second to mix and then leave on a rank at room temperature.

5. The value was extracted from the device immediately.

**Quantitative reverse transcription-PCR**

Step 1: Preparation of qPCR master mix

qPCR was prepared, the volume of components was calculated based on the following table 1 and kept on ice during use, and assembled reactions on ice to avoid premature cDNA synthesis. The specific primer of 16srRNA and hly genes showed in table 2.

Results and Discussion

Isolation:

Six E. coli isolates from urine samples were identified by biochemical test and confirmed by Vitek2 compact system.

MIC of alcoholic plants extracts:

The MIC of Alcoholic extracts against E. coli was determined by broth macro dilution assay. MIC value of bark extract of C. zeylanicum was (12.5-25) mg/ml for isolates. MIC value of O. majorana leaves extract was 100 mg/ml. The result of this study demonstrated that the plant extracts had inhibition activity on E. coli isolates and varied in their effect. Evaluate the antibacterial properties of medicinal plants like Ocimum sanctum (Tulsi), Origanum majorana (Ram Tulsi), Cinnamomum zeylanicum (Dalchini), and Xanthoxylum armatum (Timur), for potential antibacterial activity against bacterial strains. The antibacterial activity of ethanol extracts was determined by agar well diffusion method. The plant extracts were more active against Gram-positive bacteria than against Gram-negative bacteria. E.coli were the high resistant bacteria followed by Shigella dysenteriae, Klebsiella pneumoniae and Salmonella typhi. Antibacterial effects of O.majorana essential oil on E.coli may be related to thymol which has phenolic compound distinguish by GC/MS.

RNA Concentration (ng/ µl):

RNA was extracted from 6 isolates of E. coli to study the expression of hly gene, the results showed that the RNA concentrations for E.coli isolates were 71.1 ng/µl, 70.3 ng/µl, 6.5 ng/µl, 5 ng/µl, 87.4 ng/µl and 96.5 ng/µl for isolates A1 to A6 respectively.

Effect of C.zeylanicum and O.majorana alcoholic extracts in expression of hly gene in E.coli

The expression of gene was detected successfully by using new molecular technique which is Real time PCR (qRT-PCR) with used specific primer (house keeping gene of 16srRNA). The amplification accuracy of gene product was noticed by the value of cycle threshold (Ct) for the triplicate reactions as show figure 1 and 2.

Figure (1): Ct value of hly after treated with O.majorana in E.coli
Effect of *C.zeylanicum* and *O.majorana* alcoholic extracts in expression of hly gene in *E.coli*

The result showed that there were slightly induction of *hly* expression in *E.coli* isolates in presence of *O.majorana*in sub MIC concentration (50 mg/ml) according to fold change values which were 1.23 and 2 for *E.coli* isolates 5 and 6 respectively , while there were high expression of *hly* gene in presence of *C.zeylanicum* in sub MIC concentration (6mg/ml) , the fold change values were 137 and 73.5 for *E.coli* isolates 1 and 2 respectively (table 4) , this mean that *O.majorana* had an inhibitory effect on *hly* gene in *E.coli* isolates in contrast to *C.zeylanicum* which induced the expression of this gene in isolates.

Haemolysin is important virulence factor of *Salmonella*, *E.coli* and other enteric bacteria .Haemolytic activities of cell extracts of *S.typhi* and *E.coli* grown under stress conditions like oxygen or glucose starvation, either separately or together, were found to be considerably normal growth conditions .

The therapeutic plants, for example, cinnamon, timur, tulsi and origanum are being utilized normally in treatment of irritation and a few diseases. The antimicrobial action has been related to the presence of some important components . Studies refered to the antimicrobial activity of cinnamon was due to their main factors , cinnamaldehyde, which is a natural antioxidant and the animal studies indicate that an extract of cinnamon bark taken orally to diminish stomach ulcer, because Cinnamaldehyde inhibit strains of *Helicobacter pylori*. A significant property of plant extracts and their contituent is their hydrophobicity, which enable them to split membrane lipids and mitochondria of bacterial cell, disturbing the cell composition and increase the permeability.

The antimicrobial activity of many plant extracts can be as a result of different mechanisms, like destruction...
of membrane, increase its permeability and polarity, decrease pH of cytoplasm and ATP concentration.19

The activity of extracts of *Lippiagraveolens* and *Haematoxylonbrassiletto*, and carvacrol, brazilin tested by an microdilution method using citral and rifaximin as controls. All products showed bactericidal activity with minimal bactericidal concentrations ranging from 0.08 to 8.1 mg/ml. These extracts influence *E. coli* growth, motility swarming and expression of virulence gene, sub lethal concentrations had various effects on phenotypic and genotypic character, and expression of virulence gene.20

**Conclusions**

The use of natural compounds afford a good way to control the growth of microorganisms. Results obtained in the present study on the antimicrobial effect with *C. zeylanicum* and *O. majorana* denote a down regulation and up regulation of hly gene.

Assessment of Systemic Lupus Erythematosus in Term of Serum Anti-nucleosome and Interleukin 12 Markers in Relation to Epstein–Barr virus and Cytomegalovirus

Saif S. Ibrahem¹, Ahmed Sahib Abdulamir²

¹BSc Pathological Technology, AL-Nahrin University, College of Medicine/Iraq. ²Prof. Virology And Infectious Diseases, Al-Nahrin University, College Of Medicine/Iraq

Abstract

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease, more dominant in female, associated with high risk of life threatening complication and increase morbidity and mortality. the exact cause of SLE is not yet known with many suggestions about a possible role of viral infection in the development of the disease. Epstein –Barr virus is the most commonly studied virus in an attempt to prove its presumed association with development of SLE. The objectives of this study are the measurement of the effect of CMV and EBV seropositivity in the autoimmune status and severity of disease SLE measured by estimating the level of immunological markers anti-nucleosome and IL-12 with viral marker.

Materials and Method: Forty newly diagnosed female with SLE were randomly selected from patient attended rheumatology clinic at medical city in Baghdad during the period between December 2018 to May 2019. In addition, with 40 apparently healthy females, as, a control groups. Both group were investigated for IL12, anti-nucleosome, EA, VCA, EBNA and CMV by ELISA and the results were statistically evaluated.

Results: The studied viral markers in the current study which included EBV markers EA, VCA, EBNA, have shown significantly higher level compared to the control group. Similarly, anti-nucleosome and IL12 have shown significantly higher level compared to the control group.

Conclusions: The possible defect in controlling viral infection and increased number of latent infected cell in SLE may enhance production of auto-antibodies

Keywords: SLE, EBV, VCA, IL-12; Erythematosus

Introduction

SLE represents an autoimmune disease with chronic clinical course that is associated with a wide range of clinical features and variable types of autoantibodies including anti-double strand DNA (dsDNA) and antinuclear antibodies (ANA) involving multiple organs in the body such as joints, skin, respiratory system. As most of the body organs are affected by SLE, the clinical features sound extremely variable and involve the affected organs, of course, the most commonly encountered clinical features include photosensitivity, recurrent oral ulcers, malar rash, discoid lesions, arthritis, serositis, hemolytic anemia, neuropsychiatric and poor vascularization. Different infectious agents are implicated in SLE, and were shown by serology to be more prevalent in SLE patients(1).

Because SLE is a multisystem disease, there is no obviously validated or standardized “gold standard” biomarker that can cover the whole aspects and the variable phenotypes of the disease. The many traditional laboratory assays commonly used for diagnosis and monitoring of SLE, such as complement Factors in serum, anti-double-stranded DNA (Anti dsDNA) and anti-nuclear antibodies (ANA) have never been validated or standardized themselves (14).

Corresponding author:
Ahmed Sahib Abdulamir
E-mail: ben.saad9370@gmail.com
Despite that anti-dsDNA antibodies are significantly specific for SLE, the high majority of patients might be negative for anti-dsDNA for these antibodies during the disease course. These are present in 70% to 100% of SLE patients and have a very high specificity (around 97%) for the disease. Amongst SLE patients, the anti-nucleosome antibodies are significantly more prevalent in patients with lupus nephritis and can serve as an important biomarker for the diagnosis of patients with active lupus nephritis, at the same time it has a significant correlation with disease activity in general (2).

EBV is a lymph tropic double stranded DNA virus. It is one of a human herpes virus belongs to the gamma herpes family and infects more than 95% of the adult population worldwide.(3)

EBV infect B-cell, and persist in latent form in memory cell, and the virus used many mechanisms that lead to developed SLE like (molecular mimicry, epitope spreading, Infection and Immortalization of Autoreactive B-cells).(4) So when the virus infection occurs, EBV invade the B cells reprogramming them, and control of their functions. A limited number of studies have implicated another herpes virus, cytomegalovirus (CMV), in SLE, although the effects of CMV on SLE development and autoantibody production remain unclear (5).

Materials and Methods

The current study has included 40 young female patients with SLE on no specific treatment for SLE with at least four of the American College of Rheumatology (ACR) criteria for the diagnosis of SLE. Patients other chronic autoimmune diseases were excluded. Patients were recruited between December 2018 to May 2019 as they consulted at the Departments of rheumatology clinic of Baghdad Teaching Hospital at medical city. The control subjects were apparently healthy and age-, sex- matched volunteers; written informed consents were obtained from subjects.

Venus blood was drawn from patients and control to measurement EBV protein EA, VCA, EBNA, CMV IgG, IL12 and Antinucleosome by enzyme linked immunosorbent assay and the results were statistically evaluated using SPSS software version 23.

Results

The results of the current study have shown that the titer of IL-12, was increased in 40 (100%) of patients group while it was increased in only 13 (32.5%) of control group and the difference was statistically significant (p<0.001). The titer of anti-nucleosome, was increase in (62.5%) of patients group while it was increased in (2.5%) the control group, this difference was statistically significant (p<0.001).

In respect to EBV, the findings have shown that the titer of VCA was increased in ___ (92.5%) of patients group while it was increased in only (55.0%) of control group which was significant statistically (p<0.002). In addition, mean titer of EA was increased in (90.0%) of patients group while it was increased in (22.5%) of control group, a difference that was statistically significant (p<0.001). Regarding EBNA level, the current study has shown that the mean titer of EBNA was elevated in (75.0%) of patients group while it was elevated in (22.5%) of control group which was statistically significant as well (p<0.002).

Regarding CMV IgG, the current study has shown that the mean titer of CMV IgG, was increased in (97.5%) of patients group while it was increased in (27.5%) of control group (p<0.002).

Discussion

The role of immunological markers in the development of SLE has been thoroughly studied. The current study revealed that IL-12 was significantly higher in SLE patient compared to the control group and surprisingly, 100% of SLE patients revealed high IL-12 concentration indicating the role of dendritic cell in development of SLE as these cells represent the main source of IL-12 (6). These findings are consistent with results revealed by similar studies; CK Wong for instance has revealed a similar result to the current study in respect to IL12 during his study of various proinflammatory cytokines in SLE patients(7). Similarly, E. R. CAPPER in his study that discussed IL12 in both active and quiescent SLE has also revealed a significantly higher concentration of IL12 in patients with SLE compared to control group(8)including interleukin (IL. Many other studies have shown similar results despite being different from the current study in study design and aim(8)(9). The current study has shown a significantly higher serum anti-nucleosome antibody concentration in SLE patients compared to control group This increase in anti-nucleosome may reflect the extent of cell damage caused by SLE which explain its
flare up shown in the current study as well, these result consistent with that revealed in studies of Ahemd Ali Abid and P Cairns where anti-nucleosome concentration was significantly higher in SLE patients compared to the control group\(^{10}(11)\). In simon study, a similar result has been also obtained. Many studies have discussed the association between various infectious factors and the development of SLE at the top of which is EBV infection. In the current study, 92.5% of patients with SLE were positive for anti- EBV-VCA, while 45% of the control group were seropositive for the same antibody, a result clarifies the significant association between EBV and SLE. Chougule, for instance has revealed a similar result to the current study in respect to VCA during his study of EBV antibody profile in SLE patients\(^{12}\). Similarly, Alaa Y. Al-Hamadany, in his study that discussed EBV in Systemic Autoimmune Patients has also revealed a significantly higher concentration of VCA in patients with SLE compared to control group\(^{13}\). Many other studies have shown similar results despite being different from the current study in study design and aim\(^{14}(15)\).

At the same time, 90% of patient with SLE were anti- EBV-EA positive while only 22.5% of the control group were seropositive for the same antibody. In fact, the difference of EA seropositivity between SLE and control group was more significant than VCA; this might indicate the role of increased EBV reactivation in patients of SLE and this reactivation could be secondary to decreased cytotoxic T cell response to EBV with subsequent impaired control of replication of EBV in SLE patient\(^{16}\). This finding is consistent with the results revealed by many similar studies ; NS Rasmussen, for instance has revealed a similar result to the current study in respect to EA during his study of antibodies to early CMV, EBV, and HHV6 antigens in SLE patients\(^{17}\). Similarly, Evan S Vista, in his study discussed viral associations with SLE in Filipinos and this study also revealed a significantly higher concentration of EA in patients with SLE compared to control group\(^{18}\). Many other studies have shown similar results despite being different from the current study in study design and aim\(^{19}\). In addition, the current study has shown a significantly higher concentration of EBNA in patients with SLE compared to control group, a result that is consistent with the findings revealed by many similar studies. Chougule, for instance has revealed a similar result to the current study in respect to EBNA during his study of EBV antibody profile in SLE patients\(^{20}\). Similarly, Evan S Vista, in his study that discussed viral associations with SLE in Filipinos has also revealed a significantly higher concentration of EBNA in patients with SLE compared to control group\(^{18}\). Another study has shown similar results despite being different from the current study in study design and aim\(^{21}\).

Regarding CMV infection, it was noticed that 97.5% of SLE patients were seropositive for CMV IgG while only 27.5% of control group were seropositive for the same antibody; a result is statistically significant and was consistent with similar studies which revealed a similar association, BARZILAI, for instance revealed a similar result to the current study in respect to CMV during his study of EBV and CMV in autoimmune diseases \(^{1}\). Similarly, Muhsin, in his study, he discussed the association of various viral infections with the development, in his study, Muhsin revealed a significantly higher concentration of CMV in patients with SLE compared to control group\(^{14}\).

Taken together, this study revealed an essential association of all EBV serological markers studied, namely VCA, EA, and EBNA proteins, when compared to control group. And a threshold values were statistically assigned in order to differentiate between SLE and normal population which might help in diagnosis. This association revealed in this study was also confirmed by previous reports done elsewhere in the world. This indicates several things. First, the association between SLE and EBV can be expressed as a scientific fact. Second, it was found that EBV markers of reactivation, namely EA protein, and markers for latency, EBNA proteins, are remarkably increased in SLE when compared to control group; this highlights that EBV is highly reactivated in SLE patients as well as ssEBV latency is an active ongoing process where EBNA proteins are abundantly synthesized. A recent study found that EBNA 1 and 2 work as transcriptional activators for about half of high risk genes associated with SLE occurrence\(^{15}\). Therefore, EBV is related to SLE in different ways including both active ongoing latency and reactivation of latent infection.

Actually, this poses a question, is EBV a consequence or an etiology for SLE. The research to answer this question is underway; however, it is thought that the most probable nature of relationship between EBV and SLE is bidirectional in which EBV is reactivated in SLE patients due to deregulated immune system and this in turn can further promote and/or propagate SLE disease \(^{22}\). It is noteworthy to mention that SLE as such is not
considered an immune suppression condition; moreover, the SLE patients selected in the current study were those not receiving immunosuppressive drugs. Hence, it is believed that the significance of this study might issue from comparing a non-immunosuppressed patient of SLE with control group. Therefore, any significant association shown in the current study was not due to immune suppression. This accordingly, shed light on a probable role of EBV in promoting/propagating SLE disease in susceptible individuals. Nevertheless, this requires a far deeper research in terms of molecular and immunological levels.

Study of Immunological Parameters, Hematologic Outcomes And Epidemiology Features of Renal Dysfunction Frequently in Karbala Province, Iraq

Alyaa Aziz Gubi Al-Nasrallah
Lecturer. Dr. Ibn Hayyan University College, Ministry of Higher Education And Scientific Research, Karbala/Iraq

Abstract
Renal failure or dysfunction: A disease occurs by a severe weakness in one kidney or both, they lose ability to do their functions effectively, resulting in the body’s inability to remove waste and fluids, Leading to a significant changes in chemistry of blood and body fluid.

The study occurred in Karbala province where study samples were collected, which included (124). Samples divided in (64) patients and (60) control, patients had another division according to sex (44) male and (20) female. Immunologic parameters include (kidney injury molecules (KIM-1), pro-inflammatory TNF-α, IgG antibodies) Elabscience Kit, concentration in serum was massacred by (ELISA) Technique and hematologic test measured automatically by (Humlate plus-1 Device).

The results showed increase in kidney injury in age groups beyond the age of 40 years. A significantly higher incidence of disease among males more than females. Results show significant statically variations in serum levels:

1- kidney injury molecules (KIM-1) levels was increased in serum in patients significantly compare with control.
2- (TNF-α) levels was increased in patients than control.
3- IgG levels decreased in patients than control.

Another routine tests occurs to patients to know the effects of disease on blood variations, the test was included CBC count the results show CBC tests: (WBC, MHC, MCHC, RDWS, RDWC, PLT, PCT, PDWS, PDWC, P-LCC and P-LCR) have no significant differentials while CBC tests: (LYM., MON., GRA., RBC., HGB., HCT., MCV , MPV) which decrease in patient compare with control significantly.

Increase kidney injury and inflammatory in serum patients with disease, by measured some parameters levels in sera as indicators for disease progression and decrease in some antibodies such as IgG concentration of in sera, as well as the hematologic tests refer to disease may associated with anemia.

Keywords: Renal failure, (KIM-1), TNF-α cytokines. IgG antibodies, CBC test.

Introduction
Kidney failure is a syndrome occurs when the kidney loses its ability to filter blood from toxins, along with several other factors that interfere with kidney dysfunction such as exposure to toxic substances, environmental contaminants, chemical preservatives and many renal failure diseases. Kidney failure (Renal disease) sometimes lead to death by accumulation of toxins in the body (1). Etiology of renal insufficiency include loss of blood flow to the kidneys, resulting in heart failure, heart attacks, heart disease and liver cirrhosis, as well as dehydration, severe burns and infections, as well as the use of certain anti-inflammatory drugs. Some diseases and conditions lead to kidney failure such as exposure to blood clots, urinary hemolytic syndrome,
plasma cell carcinoma of the bone marrow, scleroderma, use of chemotherapy drugs, Priority (2). Kidney failure is due to insufficient blood delivery to the kidneys for a long time result decrease in kidneys size, kidneys begin to shrink and slowly work until stopping or caused by a sudden blockage that affects the flow of urine from the kidneys (3) Acute kidney injury is common disease (4). According to The National Institute for Health and Care Excellence refer that the epidemiology of renal failure is seen in approximately 13–18% in the world specially in elderly population (5). Symptoms of renal failure are swelling of the legs, ankles and feet, undue distress in breathing, drowsiness or fatigue, nausea, confusion, pain or chest compression and other coma sometimes (6). Kidney failure is diagnosed by urine analysis, by measuring the amount of urine, along with blood samples to measure the material that is filtered by the kidneys such as urea and creatinine (7). Kidney injury molecule 1 is a protein . Its precise function is unknown, but elevated serum and urinary KIM-1 levels are associated with human renal injury, KIM-1 levels increased associated with histopathological evidence of kidney damage, fibrosis, and inflammation (8), along with some imaging tests such as ultrasound, magnetic resonance imaging, And radiographic tomography (9). Treatment of renal failure is through what is known as dialysis as an alternative to what the kidneys do in normal conditions, and the other treatment lies in kidney transplantation (10). There are strong relationship between of kidney failure development and other risk factors can be minimized by age, sex, exposure for chemical toxicants, such as gases, tobacco, pesticides and other toxic products. Attention should be paid to the doctor’s recommendations, appropriate treatment under his supervision and proper diet (11).

Current study pointed out on kidney failure disease, which is one of the most common diseases at present, by Establishing Demographic study to the patient of renal failure to show frequently diseases in patients according to aging, gender. Determent of renal failure by measured kidney injury molecule-1 as an indicator by ELISA technique. Estimate serum immunologic parameters such as TNF-α, IgG. Tacking the routine tests (CBC tests) for all patients with renal failure.

The samples were collected from the renal dialysis unit at Al Hussein Educational Hospital in Karbala city during the period of time 1/12/2018-15/3/2019. groups included 64 patients composed of (44) males and (20) females and healthy control (60) was apparent with no disease symptoms, based on clinical diagnosis by the physician and their health history. Data collected for patients including age and gender, some cases was excluded such as patients with hepatitis, Because of the and the interaction between patients and the impact of this on immune standards.

2- Blood sampling collection

5 ml of venous blood was collected in gel tubes for immunological studies; The serum was separated by Centrifuge (3,000 cycles for 5 minutes). The serum was then collected in sterile clean plastic tubes and kept in the refrigerator at -10 ° C until use. The serum was used to investigate the level.

Statistically analysis: by ANOVA appropriate, \(X^2\) test, students’ independent T test, And \(p\) value (<0.05).

Results and Discussion

Demographic distribution of renal failure patients:

In current study which dealing with demographic, immunologic and hematologic parameters in Renal Failure patients in Karbala city. Distribution of Renal Failure patients according to study variables including (age, gender of renal failure) table (1). The number of current study (124) samples distribution according to age categories ranging from (>39-<51) year including (64) patients and 60 (control) and divided according to Gender (44) male and (20) female. The result show no significant in demographic data \(P\) value more (<0.05). The \(P\) value result recorded 0.33, according to the age and 0.15 according to the gender. According to the Age frequency disease is increase in male more than female.

Materials and Method

1- Patients: Study type was identified as a study of patients’ cases with renal failure compared to control.

The data of the study showed about the demographic distribution that age groups after 40 years is the most vulnerable to the disease and the kidney failure as the results of the study is widespread in males compared with female. That refer to important demographic data (Age, Gender) effects on disease development. Kidney exposure during ageing to changes can be divided two parts namely: structural and functional. Structural changes include: decreased kidney weight and volume; cortical atrophy, loss of renal parenchyma atrophy. Kidney loss of functional glomeruli include decreased glomerular filtration rate, decreased effective renal plasma flow, increased impaired water, electrolyte, and glucose handling and decreased vasodilator activity of prostacyclin mechanisms for ageing-associated with increase oxidative stress. Alterations in sexual responses and hormones can effected on kidney functions the cause may result from high levels of uremic toxins. Change in sex hormone such as decreases in testosterone levels and increases in prolactin levels, are common and cause erectile difficulties and decreased spermatocyte counts in male that can effect on kidney function.

**Immunologic study of renal failure patients:**

Immunologic parameters in current study as showed
in table (2) significant differences at (<0.05). The concentration of (KIM-1) molecules increase in serum of patients with Renal Failure (10.44±3.44 ng/ml) compare with control (0.78±1.25 ng/ml) at p. value (0.00) (Figure 1). Levels of pro-inflammatory TNF-α significantly higher in patients serum compared to control group where means have (151.81±81.69, 84.90±69.36 pg/ml) respectively (Figure 2). IgG registered decline (0.45±0.29 ng/ml) in patients than control (6.29±4.71 ng/ml) in sera (Figure 3).

**Figure 1: KIM-1 molecule levels in renal failure patients and control.**
During immunologic study which dealt with important parameters such as KIM-1 molecules, pro-inflammatory TNF-α, IgG antibodies show all parameters levels was increased in Renal failure patients serum except the level of antibodies that indicated the patients have immune response against disease lead to induced pro-inflammatory cytokines in the end stage of disease and decrease the level of antibodies which may increase in early stage of disease and return to decline. Immune detection of KIM-1 found high levels in serum and urine by the sandwich ELISA technique. All aspects of inflammation and immune function may be affected by the high levels of urea and metabolic wastes, including a decrease in humeral and cell-mediated immunity, and defective phagocyte function. Inflammatory response mediated by TNF-α response causes from persons who are
receiving dialysis, vascular access devices are common portals of entry for pathogens (17). Increase levels of TNF-α were more common and associated with decrease levels of kidney function (18). In experimental models, TNF-α causes direct kidney injury, TNF-α molecules may mediate glomerular injury by promoting an influx of immune cells such as macrophages and monocytes, induced proliferation of mesangial cells, and facilitating fibrosis in kidney (19). The results demonstrated a significant decrease in serum total protein and in patients with kidney failure compared to healthy individuals (20) research showed that antibodies such as IgG, production by plasma cells from patients with kidney failure was lower than those produced by B cells from normal individuals. This found demonstrated decrease humeral immune response in patients with renal failure (21).

Hematologic study of renal failure patients:

Current study dependent on hematological data collected by mean (CBC tests) which give picture to WBC, RBC, Platelets numbers in blood was score different in some blood variables this variations have significant statically at (<0.05) was appeared in (LYM., MON., GRA., RBC., HGB., HCT., MCV, MPV.) testing there are different between patients and control which recorded (1.06±0.42, 0.64±0.38, 3.62±1.04, 3.04±0.78, 8.33±1.84, 24.72±5.44, 85.06±8.29, 8.48±0.49) respectively compare with control (4.81±1.11, 0.40±0.18, 5.42±1.14, 4.02±0.46, 14.93±1.45, 33.64±3.58, 9.22±1.10) respectively at p. value (0.00) lower (<0.05). While remain tests have not significant statically between patients and control such as (WBC, MHC, MCHC, RDWS, RDWS, PLT, PCT, PDWS, PDWS, PLCC, PL-CR) tests.

As a routine tests can be using to all patients with renal failure to find out how the disease effect on another blood criteria, so that all patients take all blood films. During this study the results showed higher percent of patients have anemia by decline in RBC numbers and hemoglobin level. Patients with end-stage renal disease can suffer from anemia (22). Results reported that anemia can develop well before the onset of uremic symptoms due to renal failure, and red blood cells production (23). The deficit in red blood cell production is affected by several factors such as the inability of kidneys to secrete erythropoietin hormone. In addition, other factors associated with renal failure, such as the accumulation of uremic toxins which play a role in inhibition bone marrow function (24). In patients receiving dialysis blood loss resulting from loss of blood in the dialysis tubing and dialyzer after each hemodialysis treatment may also contribute to decrease Hb rate in blood (25). Laboratory results refer that patients with renal disease show a variety of changes in hematological parameters (26). The RBCs count, Hb and HCT levels in these patients, although often within the normal range, were significantly lower when compared to their levels in healthy controls the fall in white blood cells (WBC) that occur during hemodialysis may be attributed to the different dialysis membranes and sterilization methods employed (27). However, indicated that the decreased RBC production by the bone marrow can attributed to iron deficiency, (28).

Conclusion

Increase kidney injury and inflammatory in serum patients with disease, by measured some parameters levels in sera as indicators for disease progression and decrease in some antibodies such as IgG concentration of in sera, as well as the hematologic tests refer to disease may associated with anemia.

Study on Correlation between IL-33 serum level, IL-33 Gene Single Nucleotide Polymorphism and Rheumatoid Arthritis Susceptibility

Hind Fouaad alhammami¹, Mahdi H. AL-Ammar²
¹Department of Biology/ Faculty of Science / University of Kufa/Iraq

Abstract

Objective: To discuss the association between single nucleotide polymorphism (SNP) of rs1929992 in IL-33 gene and IL-33 serum level in rheumatoid arthritis (RA) susceptibility among Iraq population. Methods: A total of 50 samples were collected from 35 RA patients from November 2018 until end of January 2019 together with 15 healthy physical examines in the same period were chosen as the subjects. The serum IL-33 levels measured by commercial ELISA kits. Erythrocyte sedimentation rate, white blood cell were measured by standard laboratory techniques The RFLP-PCR reaction technique was used to detect the genotype distributions for rs1929992 in IL-33 gene was carried out by using restriction enzyme. The frequency of each allele and genotypes distribution was calculated so as to evaluate the association between genotype distribution and RA susceptibility. Results: Serum IL-33 concentration was significantly higher in patients with RA than in control groups. The homozygous genotype AA recorded higher frequency in RA patients (42.9%) than controls (6.7%) with a significant difference (P-value 0.001). Homozygote genotype GG frequency (45.7%) was a significant in patients compared to controls subject (33.3%) with a significant difference (P-value 0.016), and the genotype heterozygous GA frequency (11.4%) were non-significant in patients compared to controls (60.6%). The allele frequency for allele G was (51.4%) in patients compared with controls (63.3%) with a significant difference (P-value 0.022) while for the allele A was (48.6%) in patients compared with controls (36.7%) with a significant difference (P-value 0.001). Conclusions: significant correlation between RA patients susceptibility and genotype AA and alleles at rs1929992 in IL-33 gene is observed. From this study showed that the IL-33 levels were influenced by genetic variation at SNPs rs5743708 and rs1929992, respectively.

Keywords: rheumatoid factor, single nucleotide polymorphism, Rheumatoid arthritis.

Introduction

Rheumatoid arthritis (RA) is one of the most common inflammatory autoimmune diseases. It is characterized by persistent synovitis, systemic inflammation and production of autoantibodies. The molecular mechanisms of RA pathogenesis are not fully understood it is believed that approximately half of the risk factors for RA are attributed to genetic factors such as the human leukocyte antigen (HLA) alleles while the other half of the risks are environmental factors including infection and smoking. The human IL-33 gene and protein, structure of the human IL-33 gene. The gene spans >42 kb, contains 8 exons, and is located on chromosome 9 at 9p24.1 has also been described. IL-33, a member of the IL-1 family, is a ligand for the ST-2R receptor. When binds to IL-33, it enhances inflammatory cytokines via the activation of nuclear factor-κB (NF-κB) and MAP kinases. Although it was initially thought that IL-33 was crucial for Th2 cytokine-mediated immune responses, it is now known that, it can overcome to have a role in RA.

Methodology

A total of 50 samples were collected from 35 RA patients from November 2018 until end of January 2019 together with 15 healthy physical examines in the same period were chosen as the subjects, with age ranged between 30to 69 years old. The RA patients diagnosed by RF test. RFLP-PCR was used to detect the genotype distributions single nucleotide polymorphisms (SNP) in
the gene of IL-33. About 6 ml of blood samples were
drawn from each patients and control, 4ml were collected
in sterile test tube (plain tube) and allow to clot at room
temperature for minutes to 1 hr., the sera were separated
by centrifugation for 10 min. at 2500 r.p.m, (then serum
would be divided into two Eppendorf tube, one tube for
RF test, and other for IL-33 ELISA assay), the separated
sera were labeled and stored at -30°C until in-vitro tests
were performed. other 2 ml of blood were collected in
ethylinditetracic acid (EDTA)tube and stored at 4°C for
ESR,WBC count and for DNA extraction for detection
of IL-33 polymorphism gene by PCR-RFLP technique.

Peripheral blood DNA extraction

2 mL of fasting peripheral venous blood was taken
from all subjects and 0.2% of EDTA-Na2 was used for
anticoagulation. Modified salt fractionation was used for
DNA extraction (Genomic DNA Extraction Kit (Human
blood).Favorgen, USA) and the extraction was reserved
in refrigerator at -20 °C.

Primer design

Primer and probe were synthesized by Bio Labs,
England Company with forward primer being F:5-
GAAGTCTCATCATCAACTTGGGAACC-3, and reverse
primer being,R:5GGATTGGAATCCCATGGTC-3.

DNA amplification and purification

PCR reaction system was 20 L, containing 100 ng of
genomic DNA. The reaction conditions were as follows:
predenaturing at 95 °C for 10 min, followed by 35 cycles
denaturing at 95 °C for 30 s, annealing at 61 °C for
30 °C s, and extension at 72 °C for 30 s, with a final
extension at 72 °C for 7 min. Gel DNA Purification Kit
was used for the purification of amplified production.

Genotyping

RFLP-PCR mix was prepared by using SspI
restriction enzyme (New England Biolabs,UK); this mix
has been done independently according to company ,
After PCR cycles was finished, (1 µl) unit of enzyme
was added to(1µl) of IL-33 PCR product with (5µl)
of enzyme buffer, then incubated for 5-15 min in 37
° C.After cooling down, they were put into mixed liquor
of polyacry lamide and carbamide for electrophoresis
for 3 h at 70 V.

Immunological investigations:

The serum IL-33 levels measured by commercial
ELISA kits (USA, Elabsciencee) according to the
manufacturers guidelines. This study including RF
test, CRP, in this method all the reagents preparation
and assay procedures were carried out according to
manufacturer’s descriptions.

Statistical Methods

Sample collection of patients and genotype
frequencies of IL-33gene were estimated by direct counts
and expressed as percentage. The comparison between
patients and control was analyzed by Unpairedχ²-cal.
The statistical significance of the measured number
was assessed by a special χ² formula. p-value (<0.05)
was considered significant by using software packages
SPSS the figures constructed was by SPSS program of
Microsoft Office 2010. Significant association between
RA susceptibility and the genotype distribution were
assessed using Chi-squared test to estimate the Odd
Ratio (OR) and 95% of confidence interval (CI) for
genotype. IL-33 polymorphism was tested by using Chi-
squared test. all significance were determined as being
below the conventional level of P= 0.05.

Results

The clinical features of the35 RA patients and15
healthy controls were listed in Table1.Mean age of
disease was 51.80±1.55. years, mean age of healthy
control was 53.07±3.25. years. There were no statistical
differences between the RA patients and controls
regarding to age and , P> 0.05. The finding obtained
from this study were illustred in table 1 that shows
the gender distribution and reveal that the majority of
patients with RA were females ( 88.6%)with significant
difference at (p-value0.001)compared with control of
females were(66.7%) while in males were(11.4% )in
RA patients (females at more risk than males) compared
with control of males were(33.3%) with non-significant
at(p-value 0.73). As shown in table 1, the the mean of
ESR ,WBC and IL-33 were significantly higher in RA
group than control group.

Genetic polymorphism of IL-33 gene which was
observed with three genotypes (GG,GA, and AA)
as shown in table 2 which illustrated the distribution
of genotypes of IL-33 in RA patients and healthy
controls. The homozygous genotype AA recorded
higher frequency in RA patients (42.9%) than controls
(6.7%) with a significant difference (P-value 0.001).
Homozygote genotype GG frequency (45.7%) was a
significant in patients compared to controls subject
(33.3%) with a significant difference (P-value 0.016), and the genotype heterozygous GA frequency (11.4%) were non-significant in patients compared to controls (60.6%). The allele frequency for allele G was (51.4%) in patients compared with controls (63.3%) with a significant difference (P-value 0.022) while for the allele A was (48.6%) in patients compared with controls (36.7%) with a significant difference (P-value 0.001) as in table 3. The levels of IL-33 according to cytokine gene polymorphism in RA patients and the control groups have been demonstrated in Table 4. The mean serum level of IL-33 in patients with AA genotype (1.396) was higher than mean serum of GG (1.249), AG (1.362) genotype that in patients, but the differences were not statistically significant (p-value 0.687). Moreover, no significant differences were observed among RA patients with AA, GA or AA genotypes regarding the mean serum levels of IL-33. But the significant differences were observed between RA patients genotypes AA (p-value 0.006) and GG (0.001), AG (0.005) and healthy groups at rs1929992 with respect to the levels of IL-33 Table 4. The frequency of genotype AA recorded odd ratio (OR) 10.500 with a confidence intervals (CI) value between 1.240-88.920 under 95% it showed a significant difference (p-value = 0.012) according to Pearson chi-square, this genotype AA association with risk RA according to OR. The genotype AG recorded OR 0.086 with CI between 0.02-0.373 under 95% it showed a non-significant difference (p-value = 0.001) according to Pearson chi-square. The frequency of genotype GG recorded OR 1.684 with CI between 0.476-5.954 under 95% it showed a non-significant difference (p-value = 0.416) according to Pearson chi-square.

Discussion

Rheumatoid arthritis (RA) is a long-lasting autoimmune disorder that primarily affects joints. It typically results in warm, swollen, and painful joints. Pain and stiffness often worsen following rest. Most commonly, the wrist and hands are involved with the same joints typically involved on both sides of the body. The disease may also affect other parts of the body. This may result in a low red blood cell count, inflammation around the lungs, and inflammation around the heart. Fever and low energy may also be present. Often, symptoms come on gradually over weeks to months. This study showed this disease occur in all ages but the highest frequency of patient age infected with RA was in 50 - 59 years from other group. This study agree with the disease affects all ages, but the rate of infection increases with age and the severity of the disease with age between 60 to 40 years. This results which showed the female more than male in study groups with infected in RA were agreement with Gabriel et al., the cohort of RA patients were predominantly female, which is similar to findings from other parts of the world, including the USA. The dysregulation of the oestrogen level might explain why women are much more likely to develop RA than men, whereas androgens may play a suppressive role in the development of the disease. In this study show the level of IL-33 in serum of RA patients was significantly higher than that in the control group this agreement with also reported that in patients with RA, the serum level of IL-33 and ST2 was significantly higher than that of healthy controls. this study demonstrated that the patients with RA had detectable levels of IL-33 in serum, supporting the idea that IL-33 is implicated in the pathogenesis of RA, this result similar with study of which showed that IL-33 has been implicated in joint inflammation and destruction in animal models. This study show Genetic factors contribute to the development of RA that IL-33 gene plays an important role in the pathogenesis of RA and indicate that the IL33 genetic variants associated with RA, this result agree with they found The gene encoding IL-33 may serve as a genetic factor and be associated with the risk of RA. Human IL-33 gene is mapped on chromosome 9p and several SNPs have been reported in the cytokine gene. The association of the SNP rs1929992 with several non-malignant diseases such as ankylosing spondylitis and Behcet’s disease. SNPs within IL33 seem to be an asthma-susceptibility gene, IL33 encodes a cytokine belonging to the IL1 superfamily, and is the natural ligand for the IL1RL1 receptor which has been previously implicated in asthma, inflammation, and a number of immune disorders. Another study show that the implication of 6 genetic IL33-IL1RL1 variants in the susceptibility to several inflammatory diseases. Regarding genetic studies, polymorphisms located both in IL33 and IL1RL1 have been associated with autoimmunity, cytokine pathway genes, which have critical modulatory effects on innate and adaptive immunity, have been shown to represent an important component of the genetic network associated with immune-mediated processes. In conclusion, this study to discuss the association between IL-33 gene polymorphisms and the risk of RA. The present research suggested that the IL-33 gene rs1929992 was related to RA susceptibility in Najaf population. These data showed that the IL-33 levels were influenced by genetic variation at SNPs rs5743708 and rs1929992, respectively. These data signify that the IL-33 levels were influenced by genetic variation at SNP rs1929992, a significant differences in the frequencies of genotypes AA at SNP rs1929992 in IL-33 gene between RA patients and controls, the genotypes AA at SNP rs1929992 association to patients RA this result agree with they showed that rs 1929992 IL-33 gene polymorphisms may be associated with susceptibility to RA.

Association between IL12A Gene of G/A genotype Polymorphism and Pulmonary Tuberculosis Risk in Baghdad Population

Anwar Abed Nasser Dhabaan¹ and Mayes Abdul-Hadi Mahdi²

¹Assit prof Dr., Post graduate. AL-Iraqia University/ Collage of Education/department of biology, Baghdad, Iraq

Abstract

The study included eighty samples. This cases-controlled study was performed including fifty Pulmonary tuberculosis patients, their ages ranged from 12 to 77 year (27 female and 23 male) and thirty controls (healthy), their ages ranged from 19 to 58 year (15 female and 15 male). We confined the frequency of IL12A gene (G/A rs568408 genotype) polymorphism by Tetra-ARMS PCR (Tetra amplification refractory mutation system-polymerase chain reaction) technology. Also, we determined the association of IL12A Gene (G/A rs568408 genotype) polymorphism with Pulmonary tuberculosis patients in Baghdad. Statistical results showed significant difference in genotype frequency of IL12A Gene (G/A rs568408 genotype) polymorphism between Pulmonary tuberculosis patients and control (healthy). The G allele shows high frequency in Pulmonary tuberculosis patients comparison with control (healthy) and present related with etiological fraction risk of Pulmonary tuberculosis patients and its ratio 62% in patients and 51.67% in control (healthy), While A allele shows high frequency in control (healthy) comparison with Pulmonary tuberculosis patients and present related with protective fraction of Pulmonary tuberculosis patients and its ratio 48.33% in patients and 38% in Pulmonary tuberculosis patients. The genotypes of GG and AA homozygotes shows high frequency in Pulmonary tuberculosis patients comparison with control (healthy), and its ratio 42% and 18% respectively in Pulmonary tuberculosis patients, while its ratio 3.33% and 0% respectively in control (healthy), also GG and AA genotypes appear related with etiological fraction risk of Pulmonary tuberculosis patients, while the GA heterozygote show high frequency in control (healthy) and its ratio 96%, GA genotypes related with preventive fraction of Pulmonary tuberculosis patients. Our findings demonstrate that the IL12A Gene (G/A rs568408 genotype) polymorphism may represent a significant risk factor for pulmonary tuberculosis patients in Baghdad population.

Keywords: IL12A Gene, Pulmonary Tuberculosis, Polymorphisms, Tetra-ARMS PCR

Introduction

The Pulmonary tuberculosis (TB) is a major cause of morbidity and mortality throughout the world, especially in Asia. The statistical data showed 9.6 million new cases and 1.5 million deaths, based on the WHO (World health organization) of 2015 year (1). TB caused by Mycobacterium tuberculosis is an aerobic rode and intracellular pathogenic bacteria which have target the lungs and causative agent of tuberculosis (2). Cytokines are pivotal in activation of the cell mediated immunity required for controlling of intracellular growth and eliminating of pathogens (3). Interlukin-12 cytokine play an important role in immune response of Mycobacterium tuberculosis (4), and mainly produced by immune cells (macrophages and dendritic cells) (5). IL-12 induces T lymphocyte cells and Natural Killer cells to produce pro-inflammatory cytokines such as TNF-α and IFN-γ in the immune response of pulmonary tuberculosis (6). IL12A gene is located on chromosome 3 of short arm in region 12 (3p12) (7). There is an association of IL-12A gene polymorphism with the risk of pulmonary tuberculosis (8). The variability in the IL-12A gene circuit association studies probably confirm of the genetic heterogeneity underlying susceptibility to pulmonary tuberculosis (9).
The study presents an association between IL-12 gene and pulmonary tuberculosis risk, by using a panel of single nucleotide polymorphism providing comprehensive coverage of these genes (10). IL12A gene is hypothesized to be involved in the progression and development of Pulmonary Tuberculosis. Genetic polymorphisms of \textit{IL12A} gene, was found that genetic variants G/A rs568408 genotype associated with an increased risk of Pulmonary Tuberculosis. The results of this study demonstrate that genetic polymorphism of IL12 pathway may individually or jointly contribute to the sensibility to and prognosis of Pulmonary Tuberculosis TB (3). The study aimed to the finding association between IL12A gene polymorphism in position G/A rs568408 genotype and risk of pulmonary tuberculosis development in Baghdad population.

**Materials and Methods**

**Population samples Study**

The population samples Study consisted of 50 patients with pulmonary tuberculosis (27 female and 23 male), there ages range from 12 to 77 years, and 30 control healthy individuals, (15 female and 15 male), and there ages range from 19 to 58 years. All the samples of pulmonary tuberculosis patients were collected from The National Center for Chest and Respiratory Diseases/ Medical City in Baghdad. They had an established diagnosis of pulmonary tuberculosis by the clinical examination and laboratory test.

Genotyping of IL12A gene (G/A rs568408 genotype)

Genomic DNA was extracted by taking five ml of blood from each patient and healthy control by venipuncture, later, 2.5 ml was added in to EDTA tubes then DNA was extracted by DNA isolation kit (Promega, USA) and according to manufacture instructions manual. DNA purity was qualified by Nano drop and it was about 1.6 ±1.8. All samples were kept at 20 °C for further study. Polymorphism of IL12A gene (G/A rs568408 genotype) was examined by using Tetra-ARMS-PCR technology. The PCR reaction was carried out on a DNA template with a pair of specific primers (Alpha DNA, Canada) that designed according to (11). Table (1), 20 μl was the total volume of reaction mix (PioNeer, Korea), and the molecular marker size (Promega, USA) 100-2000 base pair. Tetra-ARMS-PCR programs were summarized in table (2). The genotypes were established by analyzing electrophoresed 2.5% agarose gel stained with diamond dye (Promega).

Statistics

Differences in the frequencies of of IL12A gene (G/A rs568408 genotype) for pulmonary tuberculosis patient in this study with control groups were analyzed with a value P<0.05 by Fisher’s exact test. Odds ratios (OR) and confidence intervals (CI) were calculated using Compare 2 Ver.3.04 software J. H. Abramson (2003-2013). Preventive Fraction (PF) and Etiologic Fraction (EF) results were compared with Hardy-Weinberg equilibrium and according to the software within the following website www.had2know.com.

Results

The genetic polymorphisms of IL12A gene (G/A rs568408) in fifty pulmonary tuberculosis patients with mean age 34.95±1.4 year, and thirty of healthy individuals as a control samples with mean age 26.7 ±1.9 year. Notably, the two alleles G/A are more present for IL12A gene (G/A rs568408) with GG, GA and AA genotypes in pulmonary tuberculosis group and control (figure 1), use of tetra-ARMS PCR technology in study. The allelic frequency and genotypes distribution for each tested polymorphisms for healthy control and pulmonary tuberculosis patient are presented in table (3). With respect to the IL12A gene (G/A rs568408) polymorphisms, there was a significance in pulmonary tuberculosis patient in compare with control group (P>0.05), and the G and A alleles were different in frequency, so allele G frequency was 62% for pulmonary tuberculosis patient while allele A frequency was 38%, as compared with G and A alleles in control group that it’s frequency was 51.7% and 48.3% (figure 2). The odds ratio (OR) for G allele was 1.53 with confidence intervals (CI) 0.80 to 2.90 at 95 % (Table 3), and it was 0.21 as an etiological fraction (EF), while for allele A there is no significance in pulmonary tuberculosis patient comparison with control and OR was 0.6 with CI 0.34 to 1.25 at 95%, and the value of allele A as preventive fraction (PF) was 0.17 (Table 3). The previous report on polymorphisms of IL12A gene (G/A rs568408) show that may G allele be an etiological fraction and also, it’s describe that the A allele may be a preventive fraction that correlated with the risk of pulmonary tuberculosis patients. The genotyping polymorphisms for IL12A gene (G/A rs568408) by tetra-ARMS PCR technology, there are a genotypes frequency significance in pulmonary tuberculosis patients, so GG and AA genotypes showed the high frequency in pulmonary tuberculosis patients as compared with control (health) group, and it was 42 % and 18 % respectively (Figure 3), also the OR for GG and AA genotypes was 21 and 14 respectively, with CI 2.74 to 161.1 and 0.82 to 238.1 respectively. The GG and AA genotypes presented of association with etiological fraction for risk pulmonary tuberculosis, while for GA genotype the frequency was 40% and 96% for pulmonary tuberculosis patients and control (health) group respectively (Figure3), also the OR was 0.02 and CI was 0.00 to 0.18 and the value for GA genotype as protective fraction was 0.94. Briefly, the result showed that GG and AA genotypes were correlated with the risk of pulmonary tuberculosis, while GA genotype was correlated with the protective fraction of pulmonary tuberculosis in Baghdad Population. The results are
consistent with (8, 10 and 12).

Figure (1): The genotypes of IL12A gene (G/A rs568408) polymorphisms for Pulmonary tuberculosis patient samples. Electrophoretic scheme (M is DNA marker, IL-12 gene 565bp, samples of 1 and 10 GG homozygous (352bp), 2, 4, 6, 8, 11 and 12 AA homozygous (271bp) and 3, 5, 7 and 9 heterozygous).

Discussion

Interleukine-12 is an immuno-regulatory cytokine, which linked innate and acquired immune responses to mycobacterium through induction of IFN-γ production (13). A series of recent reports in the cytokine pathway suggest that more subtle variants of relevant genes may contribute to susceptibility to tuberculosis at the general population level. To investigate whether polymorphism in the interleukin-12 (IL-12) gene predispose individuals to tuberculosis, we studied these genes by single-strand conformational polymorphism analysis and direct sequencing (6). The most potent enhancer of reactivated T-cells and interferon production which is necessary for killing intracellular bacteria like mycobacteria is interleukin-12 (IL-12), and confirms to be an effective and successful adjuvant to a standard anti-tuberculous medication in patients suffering from progressive pulmonary tuberculosis (TB) (14). IL-12, produced mainly by macrophages and dendritic cells, has an important role in the immune response to Mycobacterium tuberculosis, also, IL-12 induces T cells and NK cells to produce pro-inflammatory cytokines such as Interferon-γ and Tumor necrosis factor-α while also regulate the production of IL-17 in immunity response for Mycobacterium tuberculosis (6). The genetic polymorphisms of the IL-12 pathway may individually contribute to the susceptibility to and prognosis of pulmonary tuberculosis TB (12). We investigated the impact of IL12A rs568408 gene polymorphisms on risk pulmonary tuberculosis in a sample was living in southeast (13). The IL12A rs568408 variant was not a risk factor for susceptibility to pulmonary tuberculosis in codominant, dominant and recessive tested inheritance models (11), but another study showed association between IL12A rs568408 polymorphisms and risk of pulmonary tuberculosis in Chinese population and It was found that genetic variants AG/GG of rs2243115 (IL12A) were associated with a decreased risk of pulmonary tuberculosis (12).

Conclusion

The statistical data of current study proved the association between of IL12A gene (G/A rs568408) polymorphism and Pulmonary tuberculosis risk in Baghdad Population.

Evaluation of Oxidative Stress and Antioxidants in Iraqi Patients with Hydatid Disease

Ahmed A. Mohammed

Branch of Clinical Laboratory Sciences, College of Pharmacy, Mustansiriyah University, Baghdad-Iraq

Abstract

Antioxidants and oxidative stress status are clinically important in the detection of many diseases. In order to estimate the role of oxidative stress in hydatid disease pathogenesis, the antioxidant levels and oxidative stress status were examined in the patients of hydatid cysts. Thirty patients having active hydatid cyst of Echinococcus granulosus, previously diagnosed by X-ray, were adopted as patients’ group. Additionally, 25 healthy individuals who did not have hydatid infection or any other parasitic infection constituted the control group. Antioxidant status and oxidative stress levels were determined using biochemical tests including plasma Malondialdehyde (MDA) level, and erythrocyte Catalase (CAT), Glutathione Peroxidase (GSH-Px), Superoxide Dismutase (SOD), Glutathione-S-Transferase (GST) activity, in addition to erythrocyte Glutathione concentration GSH-conc. The statistical evaluation of plasma MDA levels showed significantly higher levels in hydatid patients than in healthy controls, while erythrocyte SOD, GSH-Px, CAT, GST and GSH levels were significantly declined in hydatid patients compared to the control which can be used as diagnostic markers in the laboratory diagnosis of the disease. To conclude, hydatid patients show elevated oxidative stress status, and therefore, the antioxidant therapy should be considered in addition to the routine medicines in this group of patients.

Keywords: Hydatid disease, Echinococcus granulosus, Antioxidant, Oxidative stress.

Introduction

Hydatid disease, or cystic echinococcosis (CE), is an endemic cosmopolitan zoonosis. It is developed from an infection with the larval stage of the tapeworm Echinococcus granulosus. The disease is transmitted to human by oral intake of parasite eggs expelled in the dogs’ feces, the main definitive host, which can result in single or multiple hydatid cysts (1-3). The liver and lungs are noticeably most affected organs; however, the brain, kidneys, spleen, heart as well as bones can also be infected via lymphatic and hematogenous routes (4,5). Indeed, earlier diagnosis leads to a highly successful rate of treatment, yet, it is difficult to be diagnosed clinically due to the variable signs and symptoms, which correlate with the infected organs. However, successful diagnosis requires a combination of different techniques including physical examination, imaging and serological investigations (2,6-8).

Free reactive oxygen radicals such as nitric oxide (NO), hydrogen peroxide H₂O₂ and hydroxyl as well as superoxide radicals are strongly reactive molecules which are produced during the normal metabolism or after exposition to ecological pro-oxidants. Overproduction of free radicals causes a serious chain reaction which can destroy the lipids, nucleic acid, proteins and other cellular compounds (9). The body fights the excessive free radicals via its antioxidant defence system, which comprised of antioxidant enzymes such as catalase (CAT), superoxide dismutase (SOD), glutathione peroxidase (GSH-Px) and by nutritional antioxidants for instant vitamins E and C and also ceruloplasmin (10). However, oxidants and antioxidants level in healthy individuals are at a good balance.

The oxidant and antioxidants balance will be disrupted in the prolonged exposure to E. granulosus antigens due to the continuous immune reactions of the parasite products with oxygen radicals during the parasitic infection, which increases the oxidant stress and ultimately leads to oxidative damage, which in turn has an impact in the complications of the disease as in various other diseases (11).

Cells containing antioxidant functions have a great
influence in the protection against reactive radicals by fighting the oxidative damage of the basic structural elements of cells such as lipids, proteins and nucleic acids (12), and ultimately, it leads to cell death via necrosis or apoptosis (13). However, it is noteworthy that the antioxidant system is composed of antioxidant enzymes including superoxide dismutase (SOD), catalase, glutathione peroxidase (GPx) and glucose 6-phosphate dehydrogenase (G6PD); metal binding proteins which are non-enzymatic substances such as transferrin, ceruloplasmin and albumin; vitamins such as alpha-tocopherol and beta-carotene, as well as trace elements including iron, copper and zinc (12).

The hydatid cyst causes phagocytic cell activation during the host immunosuppressive response, resulting in the release of reactive oxygen species (ROS) and reactive nitrogen products from the macrophages in response to the cyst pathogenicity (13). Although studies of oxidative stress have been reported in humans (14), camels, sheep and cattle (15), there is no study performed in the patients of cystic echinococcosis that studied together the plasma malondialdehyde (MDA) level and erythrocyte CAT, SOD, GST, GSH-Px activities and erythrocyte GSH-conc. Therefore, the goal of this study is to estimate whether oxidative stress has any role in the pathogenicity of hydatid infection by examining the levels of oxidative stress and antioxidant status in the patients of hydatid disease.

Method

Subjects

Plasma and erythrocyte samples were obtained from the Hospital of Specialized Surgeries in Baghdad-Iraq from the patients of hydatid cysts. Thirty patients and 25 controls were considered in the current study. The controls were free of any medication for at least one week before and during the study.

Biochemical tests

A- Plasma MDA assay: the plasma MDA was assayed according to Ohkawa et al. (1979) with the modification done by Hirayama et al. (2000). Every two acid-reactive molecules of Thiobarbituric acid (TBA) will react with one molecule of plasma MDA to produce a reddish chromogen which can be detected at 532 nm wave length.

B- SOD assay: SOD was investigated according to Kakkar et al. (1984). In this method, the resulted oxygen from the photo-reduction of riboflavin will inhibit the reduction of nitro blue tetrazolium (NBT). Fifty percent of inhibition known as one unites of SOD activity.

C- CAT assay: The activity of CAT was estimated according to Eaton et al. (1972) method. CAT catalyzes the H₂O₂ to H₂O₂ and O₂. The rate of H₂O₂ decomposition by the action of CAT is measured photometrically at 230nm. To increase the stability of the hemolysate, the ethanol should be added to prevent the breakdown of the catalase and H₂O₂. After applying 50µl of tris buffer, 900µl H₂O₂ and 30µl of H₂O, the system incubated at 37˚C for 10 minutes, and the hemolysate was applied following 10 minutes. The decrease of OD is measured versus a blank at 412 nm.

D- GSH-Px assay: GSH-Px has assayed according to Paglia and Valentine (1967) with some modifications from Hopkins and Tudhope et al. (1973) and Pleban et al. (1982). The recycling procedure of the estimation of the activity of GSH-Px relies on the oxidation of the glutathione to glutathione reductase by the GSH-Px in the presence of NADPH and exogenous GSSG which regenerates GSH for GSSG (16). The enzyme level was monitored by following the decline in the absorbance at 340nm as an indicator of NADPH exhaustion (10).

E- GST assay: GST was assayed by the procedure of Habig et al. (1974) with some modifications from Carmagnol et al. (1981). The enzyme concentration was investigated through monitoring the absorbance difference at 340nm. A complete assay mixture without glutathione was used as a reference.

F- GSH: Measuring the level of GSH in the erythrocyte was performed as prescribed by Virgil et al. (2000) and Beutler et al. (1963). Virtually, all the non-protein sulfhydryl groups of erythrocytes are found as a reduced GSH. In addition, 5, 5-Dithio bis 2-nitrobenzoic acid (DTNB) is a disulphide chromogen that is readily reduced by the sulphydryl compounds to an intensely yellow compound. The reduced chromogen absorbance is measured at 412nm.

Statistical Analysis

The results were analyzed by t-test. P value ≤ 0.05 was considered significant. Data analysis was performed using statistical software (IBM SPSS Statistics 20).
Results

The mean ± SD of plasma MDA level (µmol/L Hb) was significantly increased in the patients with hydatid disease compared with that in healthy subjects \((p < 0.005)\). Moreover, the mean ± SD of erythrocyte SOD activity was decreased in hydatid cyst patients compared with healthy control \((p \leq 0.001)\).

Additionally, the mean ± SD of erythrocyte CAT activity (U/mg Hb) in hydatid patients was lower than those in the healthy control \((p < 0.001)\).

Moreover, the mean ± SD of erythrocyte GSH-Px activity was significantly declined in group 2 of hydatid patients compared with healthy control \((p < 0.005)\). However, hydatid patients had a significantly lower mean ± SD of erythrocyte GST activity (U/g Hb) compared with healthy individuals \((p \leq 0.005)\).

Similarly, the mean ± SD of erythrocyte GSH-conc. (µmol/g Hb) of hydatid patients was also lower than that of the control \((p \leq 0.001)\).

Discussion

The current study has investigated the levels of plasma MDA, erythrocyte CAT, SOD, GST and GSH-Px activities as well as the erythrocyte GSH in cystic echinococcosis patients to find if they can be used as indicators to the oxidative stress and antioxidant status in the patients of hydatid disease. The statistical evaluation has reached significant differences in the level of plasma MDA, CAT, SOD, GST and GSH-Px activities as well as GSH concentration in the patients with hydatid cysts compared to healthy individuals.

To begin, it has been found that the SOD concentrations were enormously decreased in the patients having hydatid cysts compared to healthy individuals. In addition, it has demonstrated that MDA, a non-enzymatic antioxidant and a biomarker of lipid peroxidation, was extremely higher in hydatid cysts patients compared to normal control. Importantly, lipid peroxidation is a main deteriorating change in unsaturated fatty acids of the cell membranes induced by the excess free radicals \(^9\). Similarly, it was shown that MDA level has been adopted as a biomarker to the extent of free radicals’ production, oxidative stress and tissue damage and it was increased significantly in the hosts infected with hydatid cysts \(^{14,27}\). Undoubtedly, the over-generation of MDA is clearly confirming the accumulation of reactive oxygen radicals and the incidence of oxidative stress, especially in hepatic hydatid infection. Therefore, the estimation of MDA levels is a reliable approach to evaluate the percentage of peroxidative damage of cell membranes because it serves as the most abundant aldehyde.
produced as a secondary product (28). Moreover, lipid peroxidation resulted from excess free radicals leads to the disarrangement and, subsequently, disruption of cell membranes which leads to necrotic death (15). Deger et al. (2008) reported a positive correlation between the serum MDA and aspartate transaminase, an important predictor of hepatic damage, in the sheep with cystic echinococcosis. Thus, it has suggested that the oxidative damage could have an impact on the liver damage in the sheep with hydatid cysts.

Additionally, the current study revealed a significantly lower reserve of CAT, GSH-Px, GST activities and erythrocyte GSH in the hydatid patients, which is consistent with the previous reports indicated that the concentrations of antioxidant enzymes including the GSH, glutathione peroxidase and SOD were prominently declined in hydatid patients (14). Surely, glutathione transferases and enzymes in the cellular metabolic detoxification process are involved in the removal of genotoxic and cytotoxic compounds and in the protection against the oxidative damage as well (30). The cellular metabolic detoxification process depends primarily on the reduction and hydrolysis reactions due to the low cytochrome P450 efficiency. Consequently, the cytosolic GSTs became the major types of detoxifying enzymes in helminths (31).

The examination of oxidative stress level and antioxidant status in the patients of hydatid disease and their role in the pathogenesis of the hydatid cyst has not investigated before by determining the oxidative stress level and antioxidant status using biochemical tests included the levels of plasma MDA, CAT, SOD, GST, GSH-Px activities and the erythrocyte GSH-conc in hydatid cyst patients.

Conclusions

The current study showed that the oxidative stress increases in the patients infected with hydatid cysts, which suggest that it might lead to the increase in the tissue necrosis and inflammation, while the decrease in the antioxidants level can be associated with low stimulation of cell-mediated immune response. Therefore, the antioxidant therapy should be considered in addition to the routine medicines in this group of patients.

Abstract

Dexamethasone is one of the most widely used glucocorticoids which has a prominent glucocorticoid with slight mineralocorticoid property. This study was performed on twenty four adult Sprague Dawley rats to evaluate the proposed effects of dexamethasone offering as intraperitoneal injection. The animals were allocated randomly into three groups of eight rats to each. The protocol of experiment was: the control group; animals are injected intraperitoneally with 2ml of distilled water, the dexamethasone 1 group; animals are injected intraperitoneally with dexamethasone 2mg/kg, and the dexamethasone 2 group; animals are injected intraperitoneally with dexamethasone 4mg/kg. The injection period extended for one month. The results illustrate that dexamethasone cause significant declination in RBC, PCV, Hb, HDL, and neutrophils besides significant elevations in WBC, eosinophils, monocytes, LDL, TC, TG, VLDL, AST, ALT, and creatinine on a direct positive proportion with the increase in dexamethasone dose comparing with control group at (P≤0.05).

Key words: Dexamethasone, Rats, intraperitoneally.

Introduction

Dexamethasone is one of the most widely used artificial glucocorticoids which has many properties like anti-inflammatory, immune suppressant and others (1; 2). It is associated with vast range of diseases related to metabolism (3). Many studies have reported the effects of dexamethasone on different body functions and systems like dexamethasone effects on rat’s body weight (4), on the embryonic development of rat (5), the dexamethasone effects on bone related diseases (6), on the blood electrolytes of rats (7), the effect on musculoskeletal system (8). It’s effect on liver by causing steatosis (9), on the eye retinal neurons and optic nerve (3), and others. Extended use of dexamethasone has been associated with increasing its adverse effects so we focus in our study on the proposed effects of dexamethasone on blood lipids, electrolytes, red cells parameters, leukocytes parameters and liver enzymes of rats for one month.

Materials and Method

Animals of the experiment

Twenty four adult male Sprague - Dawley rats (Rattus norvegicus) of 175 - 180 grams weights were adopted. The animals were bought from the Iraqi Center for Genetics and Cancer Research in Baghdad. The animals were housed in standard opened cages made of plastic with a stainless steel roof. The temperature of the room was set on 24±1℃ and the lighting was fit on a pattern of 12 hours dark/light cycle. The animals lived two weeks of acclimatization prior to the experiment.

Diet of animals

Animals were fed a standard rat diet recommended by the subcommittee on laboratory animal nutrition (Nutrient requirements of laboratory Animals, 1995) along the experiment period which continued for three months. Rats were given free access to food and water ad libitum along the period of experiment.

Experimental protocol

The allocation of the animals into groups was on a random pattern as below:

Corresponding author:
Safa Azhar Razzaq
E-mail: safaazher@gmail.com
1- Control group, comprises 8 male rats. They were being dosed intraperitoneally with 2ml of normal saline NaCl 0.9% daily for one month.

2- Dexamethasone 1 group (DEXA1), comprises 8 male rats. The rats of this group were being dosed intraperitoneally with 2ml solution containing dexamethasone as 2mg/kg daily for one month.

3- Dexamethasone 2 group (DEXA2), comprises 8 male rats. The rats of the second treatment group were dosed intraperitoneally with 2ml solution containing dexamethasone as 4mg/kg daily for one month. The dose of dexamethasone was chosen according to (10; 11). Dexamethasone was given for 1 month according to (12). Dexamethasone was purchased from local veterinary bureau supplier (trademark of Merck, Germany).

Specimens’ collection

Blood samples were collected from the animals of all groups at the end of the one month period of the experiment. Syringes with needles of 25 gauge were used to collect 2.5 ml of blood from the saphenous (lateral tarsal) veins of rats. The collected 2.5 ml of blood were being divided as 1 ml to be poured into anticoagulant tubes to perform the hematological exam and 1.5 ml to be poured into a gel tube to obtain serum to perform the serological tests. The handling of the rats, intraperitoneal injection and the blood sampling technique were applied respecting the recommendations of (13).

Results

Blood Parameters Changes: The effects of dexamethasone were very clear from the results, where it causes significant declination in the number of red blood cells (RBC), hemoglobin (Hb) and packed cells volume (PCV) and the declination was more prominent in direct proportion with increase in dose of dexamethasone comparing with control group as it is seen in table (1). Dexamethasone also causes leukocytosis representing by increased total white cells count (WBC), eosinophilia, and monocytosis beside declination in number of neutrophils (neutropenia) significantly and positively directional with increase of dexamethasone dose as it is obvious in table (2).

Effects Of Dexamethasone On Lipid Profile: Considering the lipid profile results in table 3 which reveal that dexamethasone causes significant elevations in total serum cholesterol (TC), triglycerides (TG), low density lipoprotein (LDL), very low density lipoprotein (VLDL), beside significant declination in high density lipoprotein (HDL) with a positive proportion with the dose of dexamethasone comparing with control group at (P≤0.05).

Effects Of Dexamethasone On Hepato-Renal Functions: Regarding the hepato-renal function, table 4 reveal that dexamethasone causes significant elevations in aminotransferases enzymes (AST and ALT), and creatinine with a positive correlation with the dose of dexamethasone comparing with control group at (P≤0.05).

Discussion

The present study has been conducted to study the pharmacological effects of two doses of dexamethasone on hematological parameters, leukocytes, lipid profile and finally its effect on liver and kidney functions. The effect of dexamethasone on red blood cells, hemoglobin, and packed cell volume in our study comes in line with the study of (14) who explained that consuming a constant amount of dexamethasone may cause suppression of the bone marrow. Dexamethasone was reported in our study to cause elevation in total leukocyte account and this agrees with the studies of (15, 16). The hyperlipidemic effect of dexamethasone and its effects on hepatic-renal enzymes in our study agrees with the studies of (17, 9). The mechanisms by which dexamethasone exerts its effects like hyperlipidemia are not fully recognized (18). But, one is assured that the effects of dexamethasone are greatly depends on the dose of which, the period of treatment and the type of animal (19).

Association of soluble HLA-G and HLA-G 14bp ins /del Polymorphism in some Iraqi patients with Breast Cancer

Hanaa N. Abdullah¹, Alia Gh. Abdulwahid²

¹Professor, College of Health and Medical Technology-Baghdad, Middle Technical University, Iraq, ²Post Graduate, College of Health and Medical Technology-Baghdad, Middle Technical University, Iraq

Abstract

Human leukocyte antigen-G is known to be implicated in a tumor-driven immune escape mechanism in malignancies. The main objective of the study is to evaluate the HLA-G 14-bp polymorphism in the 3′-untranslated region of the HLA-G gene in that associated with the susceptibility to breast cancer patients. This study has been done on 60 BC patients & 30 Benign tumor and30 control groups. Estimation of sHLA-G markers was assayed by using ELISA technique. Thus, polymorphism of HLAG HLA-G 14-bp were detected by PCR methods. The plasma levels of HLA-G shows a significant elevation in BC patients compared to benign breast tumour and controls (32.79±0.9 vs. 13.84 ±0.30 and 12.72 ±0.45 ng/ml, P≤0.05). There was a significant difference between newly diagnosed breast cancer patients and healthy control groups in homozygous genotype HLA-G 14-bp del/del genotyping (66.7% vs. 36.7%; OR=3.45; P˂0.01). While, no significant differences in the homozygous genotypes Ins/ins frequency were observed between patients with breast cancer (6.6%) and the healthy control group (0.0%) (OR=3.45, P˃0.001). There was a significant increase frequency of heterozygous genotype Ins/del in controls compared to patients (63.3%vs.26.7%). No significant difference was found between the patients and control groups at HLA-G 14bp insertion and deletion allelic frequency.

Keywords: Human leucocyte antigen-G, Gene polymorphism, Breast cancer

Introduction

Breast cancer is most commonly found malignancy in women around the world, & almost 1.7 million new cases have been diagnosed in 2012, representing approx.. (12%) of the new cancer cases & (25%) of all women cancers¹. The increased CEA is correlated with metastatic disease in breast cancer. The pre-operative CEA measurements was shown to be related to pathological stages & it is stages dependent. The levels of circulating CEA in BC patients directly depends upon the sizes of metastatic & the primary tumor. CEA in BC patients is replaced by other markers with high specificity like CA- 15-3². The tumor marker is used to diagnose and monitor the clinical course of the breast cancer, and this marker can also be found in benign breast tumors³⁴⁵. The HLA-G gene can be an excellent candidate gene for the disease susceptibility, since, given its immunomodulatory function, can act as a protective molecule in inflammatory responses⁶. The human leukocyte antigen-G (HLA-G) belongs to class I non-classical HLA gene family & is located on chromosome 6p21⁷. HLA-G gene encodes 7 isoforms by alternative splicing of the primary transcript, including 4 membrane-bound (HLA-G1, -G2, -G3, & -G4) as well as 3 soluble isoforms (HLA-G5, -G6, & -G7)⁸. HLA-G plays an important role in suppression of the immune responses and participate in the long-term immune tolerance or escape. HLA-G expression may be induced in many diseases such as cancers⁹¹⁰. HLA-G alleles relatively restrict polymorphisms & low sequence variations in many populations¹¹¹². To HLA-G gene, 47 alleles were assigned, primarily in the exons 2, 3, & 4. The diversity of the promoter and the 3-untranslated region (UTR) of HLA-G gene controlled the HLAG protein expression¹³. HLA-G gene also has the absence or presence of a 14 bp at the 3′-UTR)¹⁴¹⁵. A 14 bp
ins/del polymorphism in exon 8 in the 3’UTR of HLA-G was found to be associated with the stability and splicing patterns of HLA-G mRNA isoforms. In addition, HLA-G polymorphisms were investigated in several cancers types and were regarded as predictive markers and risk factors for cancers\(^\text{[16]}\).

**Patient & Method**

This study has been performed on 60 untreated patients with breast cancers, who were diagnosed by oncologist consultant doctors at the oncology teaching hospital baghdad / Iraq and 30 healthy control groups with age range 40-60 years (Mean:50.73±1.60) from March to June 2019 for diagnosis and treatment. All of them had no malignancy other than BC, recurrent breast cancer cases and untreated with chemotherapy or radiotherapy or hormone therapy were also excluded. In addition, 30 Benign and 30 apparently healthy women were also included in this study; matched patients with mean (46.90±2.58; 48.93±3.00). Five ml venous blood was collected from each patients and controls. Blood samples were divided into two aliquots. The first aliquot was transferred into an EDTA tube and stored at -20 ºC until assayed for HLA-G 14bp ins/del polymorphisms. The second aliquot was to transfer to EDTA tube and then centrifuge samples for 10 min at 5000 rpm and then collect the plasma to assayed sHLA-G.

**Mesurment of sHLA-G in the sera of the studied groups**

The serum sHLA-G levels were estimated by sHLA-G Enzyme Linked Immunosorbent Assay (ELISA) kit (Elabscience, USA).

**The amplification of exon 8 of HLA-G 14bp in/del gene using PCR.**

DNA was extracted from EDTA blood samples of the BC patients & the healthy controls using the commercial Geneaid method kit (Geneaid Biotech. Ltd, Taiwan). The genotype of HLA-G 14bp ins/del was detected by PCR with specific primer(forword 5’-TCA CCC CTC ACT GTG ACT GAT A - 3’ and reverse 5’-GCA CAA AGA GGA GTC AGG GTT - 3’). Five μL of Master Mix was used in a 25 μL reactions mixture with 1 μL for each primer and 1.5 μL DNA, then complete volume by add 16.5 μL. The PCR Steps composed of of initial denaturation at 95°C for 3 minutes, followed by 40 cycles of denaturation at 95°C for 40 seconds, annealing at 50°C for 45 seconds, extension -1 at 72°C for 40 seconds and extension- 2 at 72°C for 7 minutes. The PCR product have been observed under the UV on a 2% agaroses gel (Promega Company, USA) stained by 3 μl red safe stains. The size targeted fragment size was compared with 5 μl of universal DNA ladder fragments (KAPA™, Universal LadderKK6302, USA).

**Statistical Analysis**

The IBM SPSS version 25 computer program was used to calculate the mean, standard error and the probability by using student t-test, ANOVA table and Duncan test. Also, For allele & genotyping frequencies, the online Hardy-Weinberg calculator was applied to calculate the variation significance. The differences were significant if \(P<0.05\).

**Results**

The serum HLA-G level was significantly elevated in BC patients in comparison to benign breast tumour and control groups (32.79±0.9 vs. 13.84 ±0.30 and 12.72 ±0.45 ng/ml, \(P\leq0.05\)). Thus no significant variation was pointed between benign tumor group & the healthy controls (13.84 ± 0.30 and 12.72 ±0.45 ng/ml, \(P>0.05\) (Table 1).

Genotyping of HLA-G 14bp in/del polymorphisms in exon 8 at the 3’UTR regions were performed by PCR methods. The HLA-G 14 bp alleles & genotypes frequency in breast cancer patient group & the healthy control are shown in the table (2). The allele & genotyping frequency of HLA-G 14bp polymorphisms have been examined as for Hardy-Weinberg equilibrium.
The current HLA-G Ins/del findings detected 2 alleles (Ins & del), which were corresponding to 3 genotypes (Ins/ins, Ins/del & del/del). No significant differences were shown between the expected and observed genotype frequency among SLE patients and the control group.

Comparing between controls & patients revealed a significant difference between the BC patients and healthy control groups in homozygous genotype HLA-G 14-bp del/del genotyping (66.7% vs. 36.7%; OR=3.45; P˂0.01). While, no significant differences in the homozygous genotypes Ins/ins frequency were observed between patients with breast cancer (6.6%) and the healthy control group(0.0%) (OR=3.45, P=0.279). In addition, there was a significant increase frequency of heterozygous genotype Ins/del in controls compared to patients (63.3%vs.26.75) (Table 2).

In contrast, del allele exhibited a non-significant increased frequency in the patient group in comparison with the control group (80% vs. 68%). Ins allele showed a non-significant elevation in healthy control groups compared to breast cancer patients (32% vs. 20%) (Table 2).

Discussion

serum levels of CEA and CA15-3 in patients with breast cancer are higher than the healthy control group.

Circulating levels of sHLA-G were significantly increased in BC patients in comparison with the controls, which is close to a formerly data reported by Khattab and Jeong et al. who stated that serum sHLA-G was significantly higher in BC group than that of the controls(17)(18). We found that serum sHLA-G levels were significantly increased in the breast cancer group, which was in agreement with results of Rebman et al(19) who showed a significant high serum sHLA-G level in patients who suffered from BC. This result strongly hypothesized that sHLA-G could be utilized as tumour markers in the sera of BC cancer patients for the detection or treatment monitoring. Despite the usefulness of sHLA-G might be proven to help identifying malignant vs benign clinical cases, there are lways many challenges ahead.
Several studies demonstrated that the HLA-G molecules are relatively highly expressed in different tumor types like hematologic malignancies (acute leukemia, lymphomas), primary solid (melanomas, neck & head, urogenital, gastrointestinal, lung and breast cancers) as well as metastases \(^{(20)(16)}\). This mechanism can be used by tumors to escape from immune surveillance\(^{(21)}\). Other studies showed that HLA-G expression is affected by 14-bp ins/del polymorphisms in the 3’ UTR\(^{(22)}\). In 3’ untranslated region (3’ UTR) of HLA-G gene, an insertion/deletion polymorphism of 14 bp was found to affect the stability of mRNA. The effect of this polymorphism in disease susceptibility is controversial. In Iraqi people, no report on HLA-G polymorphisms regarding BC has been found. In the present study, HLA-G Ins/Del polymorphism & risk of Iraqi women with breast cancer patients have been studied, there was a significant increased frequency of del/del genotype as well as of del allele in breast cancer patients compared to the controls, while Ins/del genotype as well as Ins allele showed a non-significantly decreased frequency in the controls when compared with the patients. The present results were in agreement with Al Omar and Mansour, (2019) who showed a high significant increase between the14-bp Del allele & occurrence of breast cancer. Females with homozygous genotype Del/Del were 2.5-fold more probably to develop breast cancer than the non homozygous\(^{(23)}\).

Our results affirm the important influence of HLA-G 14-bp Ins/Del polymorphism on BC occurrence in the Saudi Arabia population and agreed with those stated formerly by\(^{(23)}\) and agreed with the Tunisian results which confirmed the elevation of del allele frequencies among the patients in comparison with the control group and conferred a risk to BC development (52% Vs 45%). An Iranian study showed elevated Del allele & del/del genotype frequencies in BC women in comparison with the control group\(^{(24)}\). These results illustrated the potential role played by the 14-bp polymorphisms in BC history development owing to its role in HLA-G alternative splicing & in the stability of RNA\(^{(25)}\)\(^{(18)}\).

Our results did not agree with Ge et al. & Ramos \textit{et al.} when they stated that the HLA-G 14-bp Ins/Del polymorphisms were correlated with BC and all cancer risks among Asian people\(^{(26)}\) and Brazilian population\(^{(27)}\). In this state, several studies revealed that the 14-bp Ins/Del polymorphisms played a key role in development of different diseases such as various cancers types including the Non Hodgkin lymphomas\(^{(28)}\), hepatocellular carcinoma\(^{(29)}\) and esophageal carcinoma. These discrepancies in the results between studies may be associated with the genetic variations between various ethnic people investigated.

### Conclusions

These results showed an association between breast cancer susceptibility and HLA-G 14-bp Del/del as a potential genetic risk factor in the progression of the disease. While HLA-G 14-bp Ins/del was considered as a protective factor against breast cancer.

Detection of Acute Childhood Meningitis using PCR in a group of Children at Childs Central Teaching Hospital/Baghdad

Rana Fahmi Shitran,¹ Warqaa Y. Khudur ¹, Mohammed E. Atallah²

¹ Lecturer, Department of pediatrics, University of Anbar/ Iraq, ²Specialist, Alramadi Teaching Hospital for Maternity and Childhood/ Iraq

Abstract

Bacterial meningitis is an important cause of death in both developed and developing world.

The study was done on 116 patients admitted to child central teaching hospital in Baghdad, and diagnosed with meningitis depending on CSF findings and PCR results while determination of type of microorganism depend on PCR result. In this study we aimed to assess the patients regarding their numbers, clinical manifestations, complications and type of bacteria causing the disease. Regarding the results of PCR, streptococcus meningitis at the top of the list for the bacterial causes while no any reported cases with Hemophillus influenza and this could be referred to the program of vaccination applied in Iraq which included the vaccines against both types of bacteria. Results of 116 patient involved in this study, majority (44%) were below 1 year, with male predominance (57.8%), most of the patients symptoms between 1-3 days (56%). All patients presented with fever. The diagnosis depend on the PCR results (57.8%) were negative and (37.9%) showed streptococcal infection. All blood culture were surprisingly negative because majority of included patients received antibiotics in outpatient visits before admission and diagnosis.

Patients admitted and followed up to one year for development of complications. Sixteen cases developed complications, (3.4%) of them with subdural effusion and most of complication occur in streptococcal positive PCR results.

Keywords: PCR; Childs central teaching; childhood; Baghdad

Introduction

Meningitis in generic is defined as membranes of the inflammation that surround the spinal cord and brain. The causes Microbiological include, utilize the routine pneumococcal vaccine conjugate, meningitis bacterial affected about 6000 people all the year in the United States; the children at 18 years old or less happen the half case [1].

In infants and young children, Streptococcus pneumoniae, Neisseria meningitides, and Haemophilus influenzae type b are the commonest causes of bacterial meningitis worldwide. While among children older than 5 years of age and adolescents, S. pneumoniae and N. meningitidis are the main causes of bacterial meningitis [1,2].

The incidence of meningitis caused by Hib has decreased predominantly in areas of the world where Hib conjugate vaccines are used routinely [3].

In 1995, before global fortification versus Streptococcus pneumoniae, the happen of meningitis pneumococcal was most than 20 cases per 100,000 US population in younger children less two years old [1]. The seven more common types that cause meningitis in the United States are 4, 6B, 9V, 14, 19, 18C, and 23 [4]. These types are involved in the heptavalent pneumococcal conjugate vaccine. The incidence of disease invasive, containing meningitis bacterial, make happen via S. pneumoniae has been markedly reduced via near 90% after the introduction of this vaccine beginning in
in infancy.[5]

Typical result of CSF in meningitis bacterial contain pleocytosis commonly with a WBC count major, than 1000 cells/mm3 and dominance of polymorphonuclear leukocytes. the WBC count can be normal in some cases, especially when performed early in the course of the disease, [6], and there could be a lymphocyte predominance. It is common for the polymorphonuclear leukocyte count to increase after 48 hr. of diagnosis and then reduced gradually after that [7], usually concentration of Glucose is decreased with a CSF-to-serum ratio glucose at 0.6 or low in neonates and 0.4 or low in children less 2 months of age, while concentration of protein is increased [8].

Exception of meningitis happen via gram-negative bacilli enteric, the benefit of bacterial CSF cultures ordinarily decreases soon after antibiotic therapy started [9-10]. Polymerase testing chain reaction of CSF is most sensitive than CSF culture, especially in patients who previous received therapy antimicrobial [11].

Wide-range polymerase chain reaction have appear a sensitivity Of at 86% and specificity of 97% in detecting organisms multiple together compared with the results culture [12]. The reaction of polymerase chain techniques sensitive comparative with o clinical setting [13]. The focal neurologic signs, instability cardiovascular, makes the doubt of increased pressure intracranial most like. In that cases, imaging brain should be done prior to a lumbar puncture to possible avoid the herniation [14].

**Patient and Method**

A retrospective study was conducted on patients admitted to child’s Central teaching hospital in Baghdad from the first of January 2018 till first of July 2018. This hospital is a tertiary care center for pediatrics and receive many referred cases from periphery of Baghdad and other governorates.

Data were collected, according to preformed questionnaire designed by the researchers, the information regarding, Age, sex, clinical presentations, laboratory tests including CSF findings and PCR results, lines of treatment, and acute complications were recorded.

The studied sample include 116 patients admitted to infectious ward at child’s central teaching hospital. The inclusion criteria include clinical manifestations of meningitis including (fever, seizure, refuse to eat, vomiting, headache, bulging fontanel and positive meningeal signs)[15] plus either a culture positive from CSF or culture negative with a positive CSF antigen study or gram stain in conjunction with CSF leukocyte concentration of > 10/mm3, blood positive culture with CSF, WBC. >100/mm3; in ambiguity of isolates bacterial; CSF WBC > 4000/mm3.[16] CSF samples collected on admission were subjected to laboratory investigations including cells count and their differentiation, glucose and protein level, and CSF culture and CSF samples for PCR results also had been sent to Central public health laboratory. Because PCR of CSF is more sensitive than CSF culture in patients previously treated with antibiotics [11]; and as soon as most of the included patients were treated with antibiotics prior to admission, so we depend on PCR of CSF results while CSF culture results was non informative. All patients underwent full neurological examination on admission to assess any neurological deficit at time of diagnosis, during the period of treatment and up to 1 year follow up visits.

Management usually started with empirical antibiotics with intravenous dexamethasone and supportives then the antibiotics can be changed depending on CSF culture and PCR results then the patient was followed for response to treatment and for acute complications during the period of hospitalization.

Any recorded cases with missed information regarding clinical manifestations, CSF findings, PCR results and complications was omitted. Patients with chronic disease, congenital cranial or spinal cord malformations, prosthetic valve on CNS, cerebral palsy and previous episodes of bacterial meningitis were all excluded from the study.

All included patients were vaccinated according to Iraqi schedule of vaccination, those who were not complete their vaccination and immigrants who are missing many doses of vaccination were all excluded from the study.

All admitted patients were followed during the period of admission for development of acute neurological complications (subdural effusion, hydrocephalus, abscess, stroke, cortical atrophy, diminished consciousness, persistent seizure, spasticity, hypotonia). Those with acute neurological deficit at time of admission were also registered.
Brain imaging was done for patients with focal neurologic signs, cardiovascular instability, or papilledema prior to a lumbar puncture to avoid possible herniation\textsuperscript{14}. Imaging study also done for those with new onset neurological deficit and suspected complications.

**Results**

The mean age of patients was 2.58 ± 3.36 years; 57.8% were males and 42.2% were females and 90.5% were from Baghdad. Fever was presented in all patients followed by seizure which was found in 64.7% as shown in table and figure (1). Subdural effusion was found in 3.4% of cases as shown in table (2).

Regarding outcome, all study patients were discharged well.

**Discussion**

regardless of the advance in medicine, meningitis...
bacterial causes essential morbidity and death-rate in children in both developing and developed countries. loss of the hearing Sensorineural, hydrocephalus and mental retardation, seizures, motor disabilities, as well as most delicate outcomes such as academic and cognitive, and problems the behavioral are discover in post-meningitis children.\textsuperscript{[17]}

Bacterial meningitis is an important cause of morbidity and mortality worldwide so early diagnosis is an important step to decrease its complications and this must be start from high index of suspicion regarding any symptom that may present bacterial meningitis and at the top of the list the fever which was seen in all patients in our study and this differs from a study done by HFM farag\textsuperscript{[18]} who found that fever was the presenting feature in 92.1% of the patients and this may be explained by the time lag between the onset of symptoms and presentation at hospital as majority of patients in current study delayed in seeking medical attention and hospitalization. Regarding the age distribution of the patients, the infants in current study were more liable for bacterial meningitis than other age groups (44%) of the total cases and this result agree with Rehana Basri et al’s\textsuperscript{[19]} study where (54%) of the patients were below one year.

The male patients was the predominat in current study (57.8%) and this result agree with H Choudhury etal and Kirimi E etal\textsuperscript{[20]} where male patient accounting for 58.6%.

The most important point in our study is the type of microorganism that causing meningitis. we depend on PCR result rather than CSF culture although it’s more expensive than CSF culture and sensitivity but it’s more precise and it is not affected by prior use of antibiotics\textsuperscript{[11]} ,as soon as most of participated patients in our study were given oral antibotics before diagnosis of meningitis and prior to blood sampling so majority of the results of CSF culture involved in our study were negative.

In current study PCR results showed that streptococcal pneumonia is the most common causative organisms (37.9%) followed by Neisseria meningitis (4.3%) and this result agree with Erleena nur H etal who found that streptococcal pneumonia also the commonest organisms and account for (23%) and Neisseria meningitis (4%)\textsuperscript{[21]}

In current study there is no H. influenza microorganisms and this differs from Hussain IH et al who found that Homophiles influenza kind b (Hib) were the utmost common aetiological agent\textsuperscript{[22]} and this may be explained by the vaccination program in Iraq which include H.influenza vaccine since 2012 and all included patient in this study were vaccinated according to Iraqi schedule of vaccination.

As a part of our study we look for the development of complications and this depends on the early and late follow up of the patients during admission and after discharge from the hospital, and its relationship to causative agent. subdural effusion was at the top of the list (3.4%)of the total complications followed by spasticity(2.6%), then stroke, hypotonia, disturbed level of consciousness (1.7%) finally the hydrocephalus, persistent seizure and abscess(0.9%). These results compared with Sadie Namani (1) where subdural effusion founded in 28.6%, recurrent seizure 7.8% and hydrocephalus (2.6%)\textsuperscript{[17]} and this is explained as the insufficient drainage of CSF through the arachnoid villi which is more occurred in children which favor the development of subdural effusion.

**Conclusion**

Infectious meningitis is a big health problem. Though the introduction of vaccination program in Iraq had changed the frequency of the causative agents ;and eliminate H. Influenza from the list. Streptococcus pneumonia remains on the top; We hope in the next years with recent introduction of pneumococcal vaccine to Iraqi schedule of vaccination ,to reduce or minimize the number of infected patients and in turn reduce complications and suffering children..

Molecular Physical Properties of Cryoglobulin in Patients with Hepatitis B Virus in Al-Najaf Province

Ahmed Aleiwi Al Hassani¹, Adil Ibadi AL-Luhaiby², Mohammed Jasim Al-Shamarti¹

¹University of Kufa, Faculty of Science, ²Department of Laboratory Investigations, Najaf, Iraq

Summary

Cryoglobulins (CGs) are a cold precipitating abnormal immunoglobulins. The incidence of hepatitis B was discovered to be greater in age groups (46-55 years) relative to other age groups. CGs were detected in 50 (33.3%) out of 150 patients with Hepatitis B. Three types of CGs precipitation nature were identified. Gelatinous (76%), flocculate (20%), and crystallineous (4%). No relation was found between patient’s age and CGs molecular physical properties.

The cryocrit test of 50 serum samples revealed that CGs are characterized by their reversible precipitation at 4°C between 12 hours to five days and solubility time at 37°C ranged between half an hour and three hours.

Keywords: Hepatitis B virus, Cryoglobulins (CGs), Najaf province.

Introduction

Hepatitis B virus is a public health problem worldwide. It causes acute and chronic liver disease. Chronic hepatitis B can progress to cirrhosis, liver insufficiency or liver cancer¹. The world health organization has prepared a plan in 2016 to eliminate the public health threat of HBV infection globally by 2030².

Fulminant hepatic failure may occur due to acute liver injury caused by HBV infection and cute exacerbations of chronic HBV infection. The mortality rate in this case exceeds 75%³. The most effective method to prevent HBV infection is vaccination⁴.

CGs are immunoglobulins (IGs) characterized by precipitation ability at low temperature (below 37°C) and re-dissolving after warming⁵. CGs can cause damage to many organs such as liver, kidney, peripheral nerve, skin, and others⁶. CGs have different composition, which influences the clinical course and the type of underlying disease. Cryoglobulinemia is classified into two categories: type I, that is exclusively found in clonal hematologic diseases, type II and III, which is known as mixed cryoglobulinemia and is found in hepatitis C virus infection and systemic diseases such as connective tissue disorder and B-cell lineage hematologic malignancies⁷.

The best description of GCs pathogenicity is the one of Hepatitis C virus (HCV) associated cryoglobulinemia. Clonal B-cell expansion is induced due to HCV infection. B-cell secretes monoclonal IgM that binds anti-HCVIgG and form immune complexes. Endothelial cells bind to these immune complexes via C1q to C1q receptors receptor. This combination promotes the recruitment of inflammatory cells. Consequently, Vasculitis is produced⁷. The extrahepatic manifestation of cryoglobulinemia associated with HBV are rarely reported⁸.

The clinical presentation of cryoglobulinemia is broad and differs between types of diseases, it includes: purpura, arthralgia, glomerulonephritis, skin ulcers, and peripheral neuropathy. Life-threatening manifestations can develop in a small proportion of patients⁷.

The aim of this work was to detect the presence of CGs in the serum of patients with Hepatitis B and study their molecular physical properties.

Methods

Blood sample processing

Between July 2018 and March 2019, blood samples were collected from 150 patients (15-65 years) were clinically diagnosed with viral hepatitis type B attending public health laboratories in Al-Najaf province. 10ml of blood samples was drawn from each patient and immediately incubated at 37ºC to allow the blood to clot. The blood was centrifuged at 1500xg for 5 minutes at 37ºC. 2ml of serum samples were used for the detection of GCs.

ELISA detection of hepatitis B surface antigen (HBsAg).

This is a sandwich-type direct immunoenzymatic technique in which anti-HBs covered antibodies on microtiter plate reservoirs act as the peroxidase-marked antibody capture and goat antibodies act as conjugate antibodies. The sample to be analyzed is incubated in one of the antibody coated reservoirs during the test operation. If the sample includes HBsAg, the antigen will attach on the palate to the antibody. To eliminate any unbound material after washing. Goat anti-HBs conjugate is added to the well and permitted to respond with antigen-antibody complex created during the first incubation. An enzyme substratum containing chromogen is added after a second incubation and subsequent washing. If the sample is positive for HBsAg, the substratum will create a blue color. After blocking with sulphuric acid, the blue color shifts to yellow. The intensity of the color is proportional to the quantity of HBsAg in the test sample.

Cryoglobulin assay

The experiment was conducted according to Irish Committee of Cryoglobulinemia guidelines. 2ml of serum was loaded into Sahli tube. The Sahli tubes were incubated at 4ºC for 7 days. The tubes were checked for the appearance of precipitate each 12 hours for the first day. Then the tubes were checked daily.

After the appearance of GCs, the tubes was transported into a water bath at 37ºC to solubilize the GCs. The tubes were checked every hour for the disappearance of GCs precipitate.

Results

Age of patients

CGs were detected in the serum of 50 patients out of 150 patients infected with HBV. There was no relations between patient’s age and the CGs properties, as both the precipitation and solubility time varied within each age group. HBV patients were divided into seven age groups (Fig1).

Percentage of HBV infections in age groups

Figure (1). The percentage of HBV infections according to patient's age.
The highest incident of HBV infection was found in age group of 46-55 years, followed by age groups 26-35, 36-45, 16-25, 56-65, 5-15, and over 65 years. No relation was found between the GCs properties and patient’s age.

**Cryoglobulin molecular-physical properties**

**Nature of CGs precipitates**

CGs are temperature sensitive proteins, they form different types of precipitates depending on the type of CG, physical nature, and precipitation conditions (13. In this study, three precipitate types were noticed. 38 out of 50 were gelatinous, 10 were flocculent, and 2 were crystalline (Fig 2).

**Cryoglobulin precipitation time**

CGs differ in their precipitation time, type I CG may precipitate within 24 hours of incubation at 4°C. While type II and III (mixed) may precipitate within several days. In this study, the first CGs precipitate started to appear after 12 hours of incubation at 4°C in one of the serum samples, while the longest time of GCs precipitation was five days. Most of the cryoglobulins (36%) in the serum of patients with Hepatitis B appeared after one day of incubation (Fig 3).
Most of CGs (18 samples, 36%) in HBV patient’s serum have precipitated in one day of incubation at 4°C, followed by 28% (14 samples) in two days, 22% (11 samples) in three days, 8% (4 samples) in four days, and 4% (2 samples) in five days. 2% (only one patient’s serum) showed a CG precipitation in 12 hours.

**Cryoglobulines solubility time**

In this study, CGs solubility time was between half an hour and three hours at 37°C. Most of the cryoglobulins (19 samples, 38%) became soluble after one hour and half (Fig 4).

![Figure (4). Time of solubility cryoglobulin in 37°C](image)

Most of CGs (19 samples, 38%) in HBV patient’s serum was solubilized in one hour and half, followed by (15 samples, 30%) in two hours, (9 samples, 18%) in one hour, (3 samples, 6%) in two hours and half, (2 samples, 4%) in three hours. And another (2 samples, 4%) in half an hour.

**Discussion**

Chronic Hepatitis B induce a massive monoclonal expansion of B-cell and mixed cryoglobulinemia. About 20% of patients with chronic HBV infection develop mixed cryoglobulinemia\(^{14}\). In contrast, another report has demonstrated that HBV-associated cryoglobulinaemia is rarely reported\(^ {15}\). Our results showed that 33.33% of HBV patients have developed a cryoglobulinemia. This percentage is much higher than the other reported ones. It seems that the prevalence of CGs in patients with Hepatitis B varies in different populations. Another reason for the low percentage of cryoglobulinemia in HBV patients reported by Li et al is the improper management of blood samples. Specimens for CGs detection should be transported and centrifuged at 37°C\(^ {16}\).

Gelatinous precipitate is the dominant type of CGs precipitation, crystalline precipitation is rarely seen. The extra-hepatic clinical manifestation varies widely depending on the type and precipitation nature of cryoglobulins produced\(^ {13}\). Type I CGs (mostly IgM) are found in the serum of lymphoproliferative disease patients\(^ {17}\). Type I CGs cryoprecipitate can appear within 24 hours after incubation, while mixed cryoglobulins (type II and III) cryoprecipitate appears after several days\(^ {6}\). In this study, 36% of cryoglobulins precipitate appeared after one day of incubation, and 76% of the CGs precipitate have a gelatinous nature. Most likely they are type I cryoglobulins. This finding demonstrates that lymphoproliferative disease is most likely to be the extra-hepatic manifestation in patients with HBV.
We found that 38% of GCs precipitate can solubilize within one hour and half. All the CGs precipitated in this study were soluble at 37°C within the range of half an hour to three hours.

Hospital Door Knobs as a Source of Bacterial Contamination: A Study in Iraqi Hospitals

Zainab Salim Jaafar
Lecturer/ Biomedical Informatics College, University of Information Technology and Communications, Baghdad, Iraq

Abstract
In this study, 20 swabs were collected from three hospitals in the holy city of Karbala (Al Hussein General Hospital, Al Abbas Private Hospital and Maternity Hospital). Nutrient agar was grown on solid feed medium and incubated at 37 °C for 24-48 hours for isolation and diagnosis. Bacterial isolates obtained underwent biochemical and bacteriological tests for diagnosis. I prepared different doses of isolated bacteria according to the McFarland model. Then take 0.1 ml of 1/10000 IV dilution and add to Muller Hinton agar medium.

The results of the preliminary diagnosis of the isolated bacteria showed that the positive bacteria of Cram stain were higher than those of Cram negative bacteria. The largest number of \textit{S.aureus} bacteria was in the hospital environment from which swabs were taken and in all locations, especially bathrooms. By calculating the percentage of the total number of samples diagnosed for each hospital separately, the results showed that Hussein General Hospital had the highest contamination rate of 90%, while Al-Ahli Hospital had the lowest contamination rate of 40%. With regard to the effect of antiseptics, the concentration gave 75% Dettol the highest amount of inhibition of bacterial growth compared with other concentrations.

On the other hand, the synergistic effect of both antiseptics (Dettol and chlorine) 75% -25% had an effect on inhibition of bacterial growth and its total elimination in the medium compared to other concentrations.

Keywords: Door Knobs, Bacteria, Contamination, Antiseptic, Microorganism.

Introduction
With the application of the principle of prevention better than treatment and with the development and scientific progress and scientific achievements of many inventions and discoveries that are in the interest of humanity we had to know the impact of microorganisms in hospitals and health environments, according to the campaign of infection prevention in hospitals and provided by the United States Hospitals aggravated by routine work and failure to adopt hygiene standards applied to the physical environment of diseases of the same level of importance available in cleaning hands and people led to this large amount of pollution and can be avoided Reducing the rates of contamination in hospitals to 10% by establishing or adopting modern sterilization mechanisms and designing studies that focus on the basic rates of infection and the type of injury and trying to avoid them and identify the causes. Persons facilitate the transmission of germs throughout the building (1).

In recent times, many types of antibiotic-resistant bacteria have begun to emerge. The poor health culture of many nurses, they help spread it (2).

Door handles for toilets and taps in toilets are parts contaminated with microorganisms. Microbes carry human skin on two endemic and transient species (3) (4) (5) (6).

Human hands are usually the port of microorganisms as a normal flora of the body, as well as the transmission of microbes through the environment (5) (6) (7).

Corresponding author:

abbaszain2003@yahoo.com
Some of the most important species that may be found on the hand as transmitted species from external sources include *Escherichia coli*, *Salmonella spp.*, *Shigella spp.*, *Clostridium* \(^8\) at a high rate and have a significant impact on the third of public places.

Repeated use of the same surfaces, including door handles by people living on the hand, will be easily transmitted to other users of all ages and environments.

Substances used to eliminate microorganisms (disinfectants, detergents and disinfectants) are variously concentrated chemical compounds used in the medical field to prevent the spread of diseases causing hospital infections and are used for personal health and to prevent accidental contamination of nurses and staff \(^9\).

### Materials and Method

#### Sample Collection

In this research, samples were collected from Al-Husseini, Abbasi and Maternity Hospital in the holy city of Karbala, where swabs were taken from the hospital environment (door handles for bathrooms, emergency and operations) during the period 1/1/2016 to 25/1/2016 as shown in Table (1)

The number of swabs taken was 20 swabs per hospital. These swabs were transported to the laboratory by Transport media. They were transplanted to Nutrient agar solid medium and incubated at 37 ° C for 24-48 hours for isolation and diagnosis.

#### Diagnosis of samples

Bacterial isolates obtained from biochemical and bacteriological tests were subjected to diagnosis as well as the action of slices and dyed with Gram stain.

#### Isolation of bacteria

Wipes were planted on the following media: Nutrient agar, Blood Agar and MacconKy agar.

**Mannitol salt agar** (especially for the diagnosis of *S. aureus*).

The dishes were incubated aerobically for 24 hours at 37 ° C and the colonies were initially diagnosed by recognizing their morphological and agricultural characteristics in the general culture media (Nutrient agar) to determine the type and isolation of the isolated bacteria.

#### Confirmation tests:

After that, confirmatory tests were carried out:

**Confirmation examination on the center of Mannitol Salt Agar for the diagnosis of S.aureus**

The isolates were planted on the mannitol glue. The dishes were incubated for 24 hours at 37 ° C to study the agronomic characteristics of the form, color and size of the colonies and their ability to ferment lactose sugar.

**Blood Agar confirmation for Streptococcus Spp.**

The isolates were planted on the medium of B.A. Then the dishes were incubated for 24 hours at 37 ° C to study the agricultural characteristics of the shape, color and size of the colonies and the types of decomposition they produce (α, β, γ).
Test of the effectiveness of the enzyme cytochrome oxidase (Oxidase test)

The filter paper was moistened with drops of reagent and several colonies were transferred from the center of the glue feeding with wooden sticks and mixed well with the reagent and after (20 - 30) seconds after the colonization of the colonies violet positive result \(^{(11)}\).

Catalase test

Transfer part of the bacterial suspension to the surface of a clean glass slide and add a drop of reagent (5% hydrogen peroxide solution). The emergence of bubbles indicates that the result is positive. This detection is used to investigate the ability of the bacterium to produce the catalase enzyme that decomposes H\(_2\)O\(_2\) into oxygen and water \(^{(12)}\).

CO - Agulase test

Two drops of plasma were placed on the surface of a glass slide and then a rich colony of bacterial suspension was added. After 10-15 seconds, the coagulation or agglomeration was an indication of the positive result and the bacterium was \(S.aureus\).

Diagnostic tests were carried out which included the examination of all specimens in Gram stain where the dominance of \(Staphylococcus\ Spp\) was recorded. On other bacterial species. Confirmation tests were also conducted for all samples that included both growth on the center of Mannitol Salt Agar. Blood lysis, Oxidase, Catalase.

Exposure to disinfectants:

After isolation and diagnosis of bacteria for swabs taken from hospitals and then their development on the liquid nutrient broth (nutrient).

Different dilutions of the isolated bacteria were prepared according to the McFarland model. Then 0.1 ml of the fourth dilution was taken 1/10000 and added to the center of Muller hiton agar \(^{(13)}\).

Some disinfectants used in the hospitals were swabs, which included (Dettol and chlorine), which was in the concentration of chlorine (5% sodium hypochlorite) and dettol at a concentration of (10% xylenol) prepared four different dilutions for each disinfectant separately (100%, 75%, 50%, 25%). Where distilled water was adopted for dilution. Where the sample was taken without dilution 100%, 75% by adding 25 ml distilled water and 75 ml of disinfectant, 50% was 50 ml of disinfectant and 50 ml distilled water and 25% was 25 ml disinfectant with 75 ml of distilled water and so on for the second disinfectant. The same number of mitigations but both antiseptics attended together to study their synergistic effect together to inhibit bacterial growth.

Each dilution was taken 0.1 ml and added to the implantcenter (muller hiton agar) by two repeaters for each dilution after being pollinated with bacteria that were isolated and diagnosed from the door handles on the one hand and on the other hand the same amount of disinfectants were taken together and in the same way the circles were held in a temperature of 37 for 24 hours.

Results and Discussion

The results of the initial diagnosis of bacteria isolated from (door handles) for all hospitals adopted in the study showed that the bacteria positive to the pigment of karam were more compared to the bacteria negative for the pigment of the pigment and as shown in table 2 that shows the results of diagnostic tests and biochemical For isolated bacterium No. 5, this is consistent with the search results \(^{(10)}\). and table (2).

H: Heavy I: Intermediate W: Weak V.W.: Very Weak

The concentration gave 75% Dettol the highest amount to inhibit the growth of bacteria compared to other concentrations.

On the other hand, the results showed that the synergistic effect of disinfectants combined (ditto-chlorine 75%-25%) The highest inhibition rate of the bacterium in the middle compared to other concentrations and the basic sample without the addition of disinfectants.

We note through the results of the isolation and diagnosis of bacteria from the swabs of door handles to hospitals that the number of bacteria positive for the dye of the dignity more than the negative bacteria of the pigment of gram and this means that the negative bacteria of the dye of the gram can be transmitted through the handles of the doors but by a small percentage where the spread of the common ity of positive bacterium is the dominant, and this is consistent with what he has come up with(12).

As for disinfectants and sterilizers performed on a series of disinfectants which are (100%, 75%, 50%, 25%), it was found that the dilution rate of 75% Dettol gave a high rate of inhibition of bacteria for disinfectants each individually, and on the other hand the results showed that the synergistic effect of disinfectants together Dettol Chlorine with a dilution of 75% was enough to eliminate the bacteria in the middle compared to the other disinfectants, whether for disinfectants on the cheek or both disinfectants (binding 2). Exposure to biocides, disinfectants and sterilizers results in reducing the sensitivity of insulation to antibiotics and deadly biomaterials by means of natural or acquired resistance mechanisms in addition to the possession of adaptable microbiology when exposing to biomaterials. The killer by acquiring plasmids or jumping genes that make these micro-organisms resistant and that the same strategies that gain bacteria to resist biocides give them resistance to antibiotics(10).

Conclusions

1- In this study we reviewed the effects and microbiology that can be transmitted between infected people and when they use door handles in hospitals as well as medical staff when conducting tests or operations or neglecting the necessary preventive and health measures at the present time and few Attention to the beginning of prevention, especially in the health and medical services. The results discussed confirmed that the increased use of door handles on a continuous basis leads to increased amounts of microbes and that the majority were from the bacterium positive for the pigment of Karam.

2- Bathrooms are considered one of the most important sources of contamination with microbes as a result of human secretions of skin, saliva, administration, fecal matter and others.

3- Cleaning hands after using bathrooms in a routine way especially by people who do not have health awareness and do not use detergents in the right way before leaving and using door handles for bathrooms makes it a rich medium and ideal for various pathogenic microbiology especially Hospitals and public places.

4- From our findings, it is found that local hospitals had high levels of contamination of the handles and the presence of bacteria at high rates requires greater...
attention to hygiene and sterilization.

5- Disinfectants on the surfaces are very necessary to prevent injuries and the transmission of microbes, especially on the surfaces that are constantly touched by the hands in order to reduce and determine their presence and prevent their transmission from one person to another.

Estimation the Level of Metals (Lead, Cadmium, Copper and Zinc) In Multiple Sclerosis Patients in Basra\ Iraq

Ali Diam Nashmi 1, Ali Faris Hassan2, Mazin Mohamed Hammady3

1 Pharmacist post graduate. Department of Pharmacy/ Basra Directorate/Iraq, 2Lec. Dr. Departments of Pharmacology and Toxicology / College of Pharmacy / University of Baghdad/Iraq, 3Assist Prof Dr. College of Medicine/ University of Basra/Iraq

Abstract

Multiple sclerosis (MS) is a demyelinating inflammatory disease of the central nervous system white matter that displays a triad of pathogenic symptoms. The toxicity of heavy metals can disrupt or damage central nervous systems. Long-term exposure of human population to heavy metals has shown neurological impairments. The degenerative processes are similar to Alzheimer’s disease; Parkinson’s disease. This study compared the serum level of Lead, Cadmium, Copper and Zinc in MS patients with their levels in a control group.

Methods: prospective study of cohort includes fifty Iraqi people selected from the Southern area of Multiple Sclerosis Clinic Center divided into two groups, in which the first group contains twenty five patients with MS and twenty five people without MS. Serum level of Lead, Cadmium, Copper and Zinc have been measured.

Results: In the present study, there was a significant increase in the concentration of (copper - lead –cadmium) in patients with multiple sclerosis as compared with normal people ($p<0.05$). There is a significant decrease in the concentration of zinc in patients with multiple sclerosis as compared with normal people ($p<0.05$).

Conclusion: Lead, copper, cadmium and zinc could affect on the susceptibility of patients to induce MS attack.

Keywords: heavy metals, health; Patients; critical levels

Introduction

Multiple sclerosis (MS) is a chronic autoimmune, inflammatory neurological disease of the central nervous system (CNS)[1]. MS attacks the myelinated axons in the CNS, destroying the myelin and the axons to varying degrees [2]. In most patients, the disease is characterized initially by episodes of reversible neurological deficits, which is often followed by progressive neurological deterioration over time[3], and 50% of patients will need help walking within 15 years after the onset of the disease[4].

Twice as many women are affected as men, and persons of Northern European descent appear to be at highest risk for MS[5]. The disease is diagnosed on the basis of clinical findings and supporting evidence from ancillary tests, such as magnetic resonance imaging (MRI) of the brain and examination of the cerebrospinal fluid (CSF). MS typically presents in adults 20 to 45 years of age; occasionally, it presents in childhood or late middle age[6].

The cause is unknown, but it appears to involve a combination of genetic susceptibility and a non-genetic trigger, such as a virus, metabolism, or environmental factors, that together result in a self-sustaining autoimmune disorder that leads to recurrent immune attacks on the CNS[7].

The term “heavy metals” refers to any metallic element that has a relatively high density and is toxic or poisonous even at low concentration. Heavy metals is a general collective term, which applies to the group of metals and metalloids with atomic density greater than 4 g/cm3, or 5 times or more, greater than water[8].

Cadmium and lead are among the most abundant heavy metals and are particularly toxic. The excessive
content of these metals in food is associated with etiology of a number of diseases e such as chronic obstructive pulmonary disease, lung cancer, nephrotoxicity and mild anemia\(^9\).

Nonessential heavy metals and metalloids (e.g. arsenic [As], lead [Pb], mercury [Hg] and cadmium [Cd]) are xenobiotic and theoretically are capable of exerting toxic effects at any level of exposure\(^{10}\).

Some metals (e.g. copper [Cu], zinc [Zn], selenium [Se] and chromium [Cr]) serve as micronutrients and are essential to normal metabolic function as trace elements but are toxic at high levels of exposure\(^{11}\). A few metals are not known to be essential to human health but may have some beneficial effects at low levels of exposure. These include silicon, nickel, boron, and vanadium\(^{12}\).

Heavy metals usually enter the human body via different food chains, inhalation, and ingestion. In addition, heavy metals have been used for long time by humans for making metal alloys and pigments for paints, cement, paper, rubber, and other materials\(^{13}\). The toxicity of heavy metals can disrupt or damage central nervous systems\(^{14}\), change blood composition\(^{15}\), damage lungs \(^{16}\), kidneys \(^{17}\), livers. \(^{18}\) The long-term exposures of human population to heavy metals have been shown many degenerative diseases like Alzheimer’s disease\(^{19}\), Parkinson’s disease\(^{20}\).

### Subjects and Methods

A cross section study of 25 MS patients and 25 healthy participants without MS. They were selected from the Multiple sclerosis center in Basra Governorate.

**Exclusion Criteria**: The exclusion criteria include the Patients with renal failure, Patients with congenital condition, Patients live near high way, gas station and industrial factory, Patients taking food supplement containing zinc and other elements.

**Blood sampling:**

Blood sample (10 ml) taken from each participant studied groups , centrifuged to isolate the serum that be used for estimation of trace elements ,and the remaining of the sample put into Ethylene diaminetetraacetic acid (EDTA) tubes to keep whole blood for estimation of heavy metals\(^{21}\).

### Biochemical assay

Frozen serum was allowed to thaw at room temperature, assessment of inorganic elements (Zn, Cu) \(^{22}\). Refrigerated (Whole blood Pb) was performed by Flam Atomic Absorption Spectrophotometry (FAAS) \(^{23}\), while(Cd ) was performed by Graphite Furnace Atomic Absorption spectrophotometry (GFAAS)\(^{24}\).

### Statistical Analysis

Numerical data were expressed as mean± standard deviation (SD). The data were analyzed by utilizing computerized statistical package for the social sciences SPSS program. Unpaired student t-test was performed for each group pair includes comparison between two groups (\(P\)-values\(<0.05\)) were considered to be statistically significant. Chi-square test was used to assess the statistical significance in distribution between different discrete variable.

**Ethical Consideration:** All administrative approvals were taken from the Participants, the administrative team of the hospital. Also we take patients concern.

### Results

In table (1), there are no significant differences in age and weight when compared between the patients with multiple sclerosis and normal individuals \((p>0.05)\). In the table (1), there were no significant relationship in sex, marital status and residency when compared between the patients with multiple sclerosis and the people without multiple sclerosis meanwhile there was significant differences in job status between the patients with multiple sclerosis when compared to the people without multiple sclerosis.

**Discussion**

Multiple sclerosis (MS) is a demyelinating inflammatory disease of the CNS white matter that displays a triad of pathogenic symptoms: mononuclear cell infiltration, demyelination, and scarring (gliosis)[25].

Toxicity by heavy metals has been shown to be affected by individual susceptibility, genetic factor, nutritional and health[26].

Lead plays a crucial role in the redox-reactions which generate free radical species by participating in the transfer of electrons. The molecular mechanism of lead toxicity is multifactorial as it generates free radical species, decreases glutathione antioxidant sulphhydril pools; inhibits enzyme activity and blocks important trace element absorption[27]. Other report study has described a patient with MS treated for neurological symptoms which were thought to be a progression of his disease but which were subsequently found to be caused by lead poisoning; his clinical signs improved with oral chelation therapy[28].

In this ecological study, there are evidences that lead positively correlated with MS incidence. Thus, further investigation is suggested for the effects of lead poisoning on MS patients[29].

Zinc (Zn) has a key role in regulation of the immune system. For instance, Zn is involved in releasing tumor necrosis factor alpha (TNFα), which activates the immune system. It was shown that even a mild Zn deficiency can weaken the function of the immune system[30]. Copper (Cu) is used in the synthesis of myelin; thus, the deficiency may potentially cause myelinopath[31]. Furthermore, its influence on autoimmune diseases through the catalyze of prostaglandins (anti-inflammatory drugs) has been known. In addition, it is documented that there is an interaction between Zn and Cu. This means that a high level of Zn could be a reason for Cu deficiency and vice versa. Moreover, Cu and some other elements, such as cadmium, may compete with Zn[32].

Many studies have been focus on the role of heavy metals in the pathogenesis of MS. One study showed that an increase in Cu and a decrease in Zn might stimulate the immune system toward MS[33], other studies also highlighted the etiological role of zinc and Cu. This study suggested that impaired Cu and Zn homeostasis may be a cause of MS disease[34]. Cadmium is one of the most important toxic metals[35]. The precise molecular mechanisms of Cd toxicity are not known however, it has been suggested that Cd indirectly enhances the free radical generation and participates in oxidative
stress via Fenton reaction\textsuperscript{[35]}.

Cd induces neurological abnormalities, neonatal cerebral edema and cerebral hemorrhage in animal experimental studies\textsuperscript{[36]}.

As Cd has been increased the production of reactive radicals and interferes with antioxidant enzymes activity in adult rat brain. This effect in turn results in alteration of membrane-bound enzymes including Na+/K+ ATPase and structural lipids integrity\textsuperscript{[37]}.

In developing rat, it has been observed that initially Cd changes the vascular endothelium permeability resulting in focal edema, brain oxygen and nutrient uptake interference and finally the necrotic changes in neuronal components which are secondary to this effect\textsuperscript{[38]}.

A previous study has been found that, blood cadmium level was higher in multiple sclerosis patients in comparison with healthy individuals also the researchers suggested the possible relation between premature mortality and tobacco smoking in MS patients\textsuperscript{[39]}.

On the other hand, other study was shown that there is a significantly elevated cadmium level in patients’ blood sample. It could be inferred that various cadmium exposure might be affected susceptibility to multiple sclerosis and could increase its risk of development\textsuperscript{[40]}.

Conclusions

1- Patients with MS show high level of Lead, Cadmium, Copper, and low level of Zinc.

2- There could be a role of Lead, Cadmium, Copper, and Zinc in pathogenesis of MS.

3- There is increase in concentration of Lead, Cadmium, Copper in healthy participant without MS.

The Differences of Individual Characteristics and Working Environment That Influence Job Stress on Female and Male Workers at Pt. X Sidoarjo (Using Gender Perspective)

Adli Prasetyo¹, Tri Martiana², Rr. Soenarnatalina Melaniani², Firman Suryadi Rahman³

¹Student in Magister of Occupational Health, ²Lecturer in Department of Occupational Health and Safety, ³Student at Doctoral Program of Public Health, Airlangga University, Surabaya, Indonesia

Abstract

Job stress can be defined as a dangerous physical and emotional response that occurs when work requirements are not matched with our own ability, resources, or needs of the workers. Job stress needs special attention by the company because it relates a worker individual’s health and affects operational continuity of the company’s production. The risk factors as the cause of job stress on female and male workers in PT. X are related to the characteristics and the perceptions of a work environment. The purpose of this research is to examine the individual characteristics and perceptions of the working environment that affects the incidence of job stress on female and male workers.

This type of research is observational by designing cross-sectional research with the number of respondents as many as 50 people. The independent variables in this study included age, education, employment, marital status, noise, lighting as well as temperature. Dependent variable was job stress on female and male workers in PT. X.

Female workers at PT. X experienced 32% of job stress and 20% of male workers. The results of logistic regression analysis obtains a significant influence of working time with job stress (P=0.027) as well as noise with job stress (P=0.017) on female workers. Male workers are significant to the job stress namely age (P=0.011), working period (P=0.030) as well as lighting (P=0.005). Advice for job-stress workers to take a leave, using personal protective equipment to reduce the risk of working environment. The company provides leave permits for workers and periodically performs work rotation.

Keywords: job stress, female worker and male, individual characteristics, work environment.

Introduction

The use of technology in the industry demand workers to continue to evolve following the progress. Workers will face 3C (complexity, competition, changes), therefore workers must follow them in order not to be left behind. The condition resulted in workers who are unable to keep up with the development will result in anxiety with increasing stress as one of psychosocial risks. Job stress is a dangerous physical and emotional response that occurs when there is a discrepancy between capacity and the workload experienced by the worker.¹ Job stress can cause complaints on health and may even result in injuries or accidents. One is able to work optimally with the compatibility between task and working capacity, lowering the risk of psychosocial.²

The main cause of job stress is the interaction between the characteristics of the worker and working Conditions.¹ Based on the analysis of the main components of the ergonomic workplace revealed that human factors and significant environmental factors related to the job stress.³ Occupational stress is
influenced by individual factors and physical workloads, impactful individual factors including age, employment and the education level. Physical work of labor, affecting employee work stress, the better the condition of physical work environment based on lighting, air temperature, color, sound noise, hygiene, motion room, and occupational safety, the work stress felt by the The officers will decline.

Factors that affect job stress to the aluminum industry workers are the physical factors of the working environment including temperature, humidity, lighting and noise, as well as individual worker factors that include the age and working period. The stressful physical environment is characterized by noise, air pollution, temperature, vibration, heavy loads and works in an inappropriate or exhaustive position that is potentially a potential source of stress as well as an influence on employee health.

Data of BPS shows that in the last decade, the women’s employment indicator in Indonesia showed improvement. During the period 2014 – 2017, female labor force grew 2.09% per year over the male workforce which was only 1.43% per year. This suggests that more and more women are involved in the industrial world.

A national Survey of working conditions in Spain in 2012 that women had higher stress levels than in males when exposed to the demands of certain tasks. Women workers in the Australian construction industry have experienced more anxiety and symptoms of acute stress than the male workers.

PT. X is one of the companies in Sidoarjo Regency, Indonesia. The company is engaged in manufacturing industry which manufactures export grade plastic sacks and has long stood almost approximately 30 years. Preliminary studies conducted at PT. X known that the company employs female employees and men in the production section which are fairly balanced. The company gives the same treatment to women and men (gender equality) workers in work. Workers get the same treatment in working in hot, noisy, workload and uptime.

**Method**

This research aims to analyse differences in individual characteristics and perception of work environment influencing job stress on female and male workers in PT. X, Sidoarjo. The design of this research is cross-sectional by going through an observation approach or data collection at a time. The subject of this study amounted to 50 people, independent variable of the research were age, education, employment, marital status, noise, lighting and temperature. Dependent Variable binding was the job stress on women and men workers at PT. X. Data collection techniques was done using Questionnaire instrument to know the individual characteristics and environmental factors influencing workers job stress.

**Results**

**Age:** Based on the results of the study, we found that most female and male respondents were in a group of age 25 – 49 years, of which as many as 21 respondents (84%) and 14 respondents (56%).

**Education level:** Based on the results of the study, we found that most female respondents were educated in Middle School amounting to 16 respondents (64%) and 23 respondents (92%) High school-educated men.

**Working Period:** Based on the results of the study, we found that most female and male respondents have been working for 5-19 years many as 13 respondents (52%) and 14 respondents (56%).

**Marital Status:** Based on the results of the study, we found that most female and male respondents were married as many as 25 respondents (100%) and 16 respondents (64%).

**Noise:** Based on the results of the study, we found that most female and male respondents felt their working environment was noisy as many as 20 respondents (80%) and 22 respondents (88%).

**Lighting:** Based on the results of the study, we found that most female and male respondents felt their working environment was well lit, as many as 16 respondents (64%) and 19 respondents (76%).

**Temperature:** Based on the results of the study, we found that most female and male respondents felt their working environment was hot as many as 18 respondents (72%) and 16 respondents (64%).

The result of analysis on Gender difference to job stress in PT. X
The Mann-Whitney and cross tabulation test results in table 1 indicate that there is a difference in gender to job stress (p-value = 0.04). We found that female respondents and men with job stress were 8 respondents (32%) and 5 respondents (20%).

**Results of analysis on factors that influence job stress on female workers with male workers in PT. X**

The results of logistic and cross tabulation regression in table 2 indicate that an independent variable that influences the dependent variable (job stress) based on a logistic regression test (P-value of < 0.05) on a female respondent was working time variable (P-value= 0.027) and noise (P-value= 0.017). On male respondent, the influential factor was the age variable (P-value= 0.011), the working period (p-value= 0.030) and the lighting (p-value= 0.005).

### Discussion

Based on the statistical results, the factors that influence job stress on female workers are working days and noise. The work period that influences the job stress on women is worth a negative value, meaning that the length of the respondent’s work will reduce the incidence of job stress. A person working with a long working period will have lighter job stress because the person is experienced and fast response in facing various problems of the work. The female respondent at PT. X with a little working experience is a new employee, so they are still learning about the problem of work. Female respondents with a new experience are still adjusting to the job and the working environment, resulting in greater risk of job stress. Other research suggests that fewer working days tend to suffer from the job stress.

Another factor that influenced female respondents was the noise, the effect of noise on job stress was positive value. This means more and more female respondents are feeling noisy, the bigger the female respondents will experience working stress. Workers who are in a working environment with high noise intensity and long periods are more prone to stress and boredom in routine work that tends to be monotonous. The threshold value of physical factors and chemical factors at work mentions that the work in the area with a noise exposure of 85 dB maximum 8 hours per day. The noise existed in the working environment of PT. X is 88.2 dB for 8 hours per day, this has exceeded the specified threshold value. Women in work are more sensitive about the company’s environmental concerns compared to the men.
Women’s sensitivity to environmental noise encourages negative effects of a noisy workspace condition. Most female respondents assumed that while carrying out production activities at a high noise level, the employees were quick to feel tired, giddy and less comfortable in work, thereby triggering the onset of job stress.

The factors that influence job stress on male workers are age, employment and lighting. The influence of age of male respondents to job stress was a negative value which means workers aged older men tend to have lower working stress. Another study expressed the level of occupational stress experienced by older workers usually tends to be low. This is because in elderly workers, they are more mature thus they have the ability to process stress better compared to young workers. Most of the male respondents in PT. X are under 25 years of age, this is one of the factors of significant relationship between age and job stress. Male respondents with younger age have no experience and a lot of understanding in working, thus in certain types of occupations, age becomes a trigger for stress.

The work period that influences the job stress on male respondents is positive, which means that workers with longer working days have a greater chance of experiencing work stress. Work life-related stress is related in the cause of boredom in work. Workers who have worked more than five years usually have a higher working boredom rate compared to new workers. This boredom can then affect workplace stress. The capacity of male respondents is considered to be active, strong, intelligent, and independent when compared to women. Male respondents who do easy job when it is compared to their capacity and repetitive work routines, there will be a risk of boredom that can trigger the onset of stress. Respondents who stated that they are tired have a greater chance of experiencing heavy job stress compared to respondents who do not get bored.

The next factors that influence the job stress of male respondent was the lighting. An influential explanation had a negative value, which means that more and more male respondents declared that the lighting was less likely to experience job stress. The data on the explanation of the information of lighting by PT. X is an average of 757 lux. The influence of lighting on job stress on male respondents who considered too strong lighting could have a psychological impact on workers as most male respondents complained of tired and giddy. This condition can even lead to a working accident due to lighting in the workspace. High glare levels and minimum lighting can cause eye strain and cause stress in the workplace.

**Conclusion**

Female workers at PT. X experienced 32% of job stress and 20% of male workers. The results of logistic regression analysis obtains a significant influence of working time with job stress (P=0.027) as well as noise with job stress (P=0.017) on female workers. Male workers are significant to the job stress namely age (P=0.011), working period (P=0.030) as well as lighting (P=0.005).

Estimation of Pitch and Fundamental Frequency Variation Between Normal Males, Females and Intersex Population

Akashlina Basu¹, Pooja Ahuja¹, M. S. Dahiya³

¹Student, MSc Forensic Science, ²Assistant Professor, ³Director, Institute of Forensic Science, Gujarat Forensic Sciences University, Gandhinagar, Gujarat

Abstract

Human beings have certain uniqueness in their voices that helps determine their individuality. The most important characteristic of voice is the Pitch. The average vocal range for masculine voice ranges from 90-150 Hz and for feminine voice, it ranges from 190-240 Hz. This pitch is decided by the development of the vocal tract during puberty by the effect of testosterone hormone i.e. Longer the tract, lower the pitch and vice versa. However, for people belonging to the intersex community, the low production of testosterone causes the vocal tract to develop differently than males and females. Because of this reason, their pitch has its own individual range and hoarseness of quality. This study was aimed to evaluate the difference in intersex population voice characteristics as compared to normal adult males and females. It was found that intersex voice has a distinctive Pitch range of 150-190 Hz with the mean frequency being 167 Hz. It was also discovered that due the peculiar dialect practiced by the intersex community, especially in the western part of the Indian subcontinent, there is a noticeable difference in the time duration for pronouncing various vowels from the time duration taken by males and females to pronounce the same vowels.

Keywords: intersex; pitch; fundamental frequency; forensic

Introduction

The sound produced in a person’s larynx and uttered through the mouth, as speech or song is known as the ‘voice’ of that person, as defined by the Oxford Dictionary. Voice has many different measurable characteristics like loudness, pitch and quality. The human sound system consists of 3 systems- Respiratory system generate the air pressure that produces sound through the vocal cords. Phonatory system causes the closure and opening of the vocal cords. Sub-glottic air pressure is chiefly responsible for producing sounds by vibrations of the vocal cords. The frequency of vibration of the vocal cords is called fundamental frequency, also known as the Pitch. As the sounds moves through vocal tract, it gets modified into different formant frequencies, based on language, size, illness etc. Articulatory system is responsible for converting sound into speech.

Intersex is a condition due to which a person is born with sexual organs that do not classify completely under the definitions of male or female physiology. The adrenal glands are responsible for production of endocrine hormones like testosterone. During puberty this hormone causes the development of secondary sexual characters like facial hairs, pubic hairs and deepening voice. At birth, the vocal tract of males and females are of same length. But due to action of testosterone during growth years, the vocal folds of males increase in length twice the rate of females. However, in intersex people, there is abnormalities in the levels of testosterone produced due to several reasons causing the quality of voice to differ from males and females. These conditions may not be seen at birth but may develop at the onset of puberty due to virility caused by low or none production of sex hormones. The various conditions that cause intersex in a person, as given by Intersex Society of North America are:

- Androgen Insensitivity Syndrome (AIS)

This is seen in a genetically male human, due to a genetic anomaly passes from the mother. Due to this
anomaly, the body does not respond to the androgen hormones like a normal male. Hence, they do not develop male reproductive organs. Their physiology is like that of the external female reproductive system.

- **Aphallia**
  
  This condition exists when a person is born without a penis and the testicles do not descend. They are otherwise biological male, without being able to function as one.

- **Clitoromegaly**
  
  This condition is seen due to introduction of unsafe steroids in a pregnant woman causing the female foetus to develop a large clitoris. As they reach adolescence the biological women tend to acquire male characteristics.

- **Congenital Adrenal Hyperplasia**
  
  This is a type of genetic disorder that affects the adrenal glands. It affects the production of androgens, that regulate the development of primary and secondary sexual characters in a human being. This results in development of ambiguous genitalia in female fetuses. The other symptoms seen are absence of menses, excessive facial and body hairs, and a deepened voice. Excessive production of testosterone affects the overall development of a genetic female.

- **Klinefelter Syndrome**
  
  This syndrome is seen when a biological male child is born with an extra X chromosome. It causes lower production of testosterone at adulthood. They have lesser facial hairs and enlarged breast tissue. They are mostly sterile.¹

The effects of these syndromes produce varying results in different individuals. But the underlying insufficiency of testosterone affects the overall development of voice, which is the main focus of this study. While performing any automated speech analysis to determine the culprit, algorithms used generally classify the voices according to pitch and formant frequencies. So, it is of utmost importance that there be an objective range of pitch for all the three genders existing in the society today.

For **literature review**, the researches that were considered showed that mostly subjective tests like questionnaires, rating scales and interviews were used to judge how the subjects themselves, speech therapists and neutral audience perceived the voice they heard. This raises a lot many questions, regarding the perceived masculinity or feminity of one’s voice, irrespective of their physical features or the way they perceive themselves. The subjects underwent a number of procedures such as testosterone treatment, Pitch-raising surgery and Glottoplasty to change the range of Fundamental Frequency of their voice. Although all the researches showed a huge correlation between Pitch and Gender Perception, an objective value of the pitch range of Intersex community was not established.

**Materials and Methodology**

**Sample Collection:**

In this study, we collected total 300 samples from the Gujarati population. 100 of these samples were from the intersex population, 100 were from the male and 100 from the female population. Consent forms were prepared for collecting information about the subjects with fields about the subjects’ mother tongue, place of origin, any habits of oral conditions that might affect the speech sample and finally, a declaration that the samples will not be used for any other purpose other than for the research intended. Since most of the subjects were illiterate and knew little or no English, a standard text could not be used. Instead they were made to give their introduction for a period of 2 minutes. The recording was done in indoor environment making sure that only one speaker was being recorded. All the recordings were done in a standard instrument, namely, Digital Voice Recorder VN-711PC.

**Sample Preparation:**

For the purpose of sample preparation, Goldwave software was used. Using this software, the formats were changed from .wma to .wav as Praat software accepts only .wav or .mp3 format for analysis. The samples were then saved as a PCM signed 24 bit mono channel at 11025 Hz sampling rate. If there was noise in any of the samples, it was reduced using this software.

Further 5 samples of each vowel chosen for analysis, was segregated by cutting and pasting into a sub-file of mono channel and 11025 Hz sampling rate from the entire sample. This was used for the final analysis done in Praat software.

**Analysis**

- The sample of interest is fed into the software
from the Open→ Open long sound file option in the main window of Praat (13,15).

- The sub-window of Praat showing the waveform of speech is opened. It has 2 windows. The top one shows the frequency time graph. The bottom one shows the energy graph and pitch markings.

- The entire sample is heard and the mean pitch of the whole sample is noted (Figure 1). The words with the chosen vowels are selected and ‘sel’ option is clicked at the bottom of the screen.

- This magnifies the selected portion of the sample. From this the vowel is selected and time duration notes. The average pitch for that segment is taken as an observation.

- This process is repeated 3 times in the same sample for the same vowel. The chosen vowels are /a/, /e/ and /u/.

- The analysis is done on all the 30 samples of speech. The observations are noted down in Excel worksheets.
Findings

Observations based on Pitch Frequency among the three groups

Graph 1: Bar graph representing the mean pitches of the three groups according to vowels.

Using the graph above, we can see that there is a clear demarcation of pitch range between males, females and intersex. The intersex pitch range exists between the male and female pitch range, i.e. from 150-190 Hz if seen in a broad sense. This information can be used to further individualize the voice function for the intersex community. Individualisation of pitch values while working with voice samples is a very important tool when it comes to forensic voice analysis as it can help in narrowing down the suspect pool and characterize the voice as male, female or intersex.

Observation based observations of time duration for chosen vowels among the three groups

<table>
<thead>
<tr>
<th>Gender/ Time duration (Seconds)</th>
<th>Vowel /a/</th>
<th>Vowel /i/</th>
<th>Vowel /u/</th>
</tr>
</thead>
<tbody>
<tr>
<td>Intersex</td>
<td>0.083</td>
<td>0.073</td>
<td>0.074</td>
</tr>
<tr>
<td>Males</td>
<td>0.075</td>
<td>0.064</td>
<td>0.084</td>
</tr>
<tr>
<td>Females</td>
<td>0.075</td>
<td>0.064</td>
<td>0.086</td>
</tr>
</tbody>
</table>
From the above bar graph, we can clearly see that the time duration needed to enunciate the chosen vowels shows more similarities between males and females, than with intersex subjects. This is due to the fact that the intersex community, especially in the western part of India have developed their own unique pattern of intonation of speech. Some words that would otherwise not be dragged as much while speaking in normal dialect by male and female subjects, are pronounced in a distinctive prolonged fashion by the intersex subjects. This is another individualizing characteristic that could be found through this study.

**Conclusion**

From this study undertaken using 100 subjects each from the male, female and intersex genders, it was found that the Pitch, also called Fundamental Frequency is unique for each of the genders. The pitch for males and females were known to us due to different studied previously done. The purpose of this study was to find an objective range of Pitch values for the intersex voice. From the results obtained it was seen that intersex voice lie in the range of 150-190 Hz, whereas male and female voice lies in ranges of 116-133 Hz and 217-255 Hz respectively. This gives us a very individualized characteristic of intersex voice, which can be a topic for further research.

**Conflicts of Interest:** There are no conflicts of interests to be declared

**Source of Funding:** This was a self-funded project for partial completion of MSc Forensic Science degree in GFSU, Gandhinagar.

**Ethical Clearance:** The samples were collected from volunteering participants and a record of their signed consent had been maintained using consent forms.

Dating of Long Bone Fracture Healing among Egyptian Pediatrics by Radiography (X-Ray)

Amal Salama Mahmoud1, Amany Mohamed Fahmy1, Alaa Mohamed Mahmoud1, Amani Abdelfattah Bayomi1, Ahmed Yosri El-Amir2

1Department of Forensic Medicine and Clinical Toxicology, Faculty of Medicine, Cairo University, Cairo, Egypt.
2Department of Diagnostic Radiology, Faculty of Medicine, Cairo University, Kasr Alainy Street, Cairo 11562, Egypt.

Abstract

Background: Estimating the timing of skeletal injury accurately is of great importance in forensic cases and has a significant bearing on the judicial process (related to abused children). This work aimed to assess dating of long bone healing in fractures occurring to children aged from 1 to 18 years through using plain radiography (X-Ray) which can determine 6 features of fracture healing process that are especially important in alleged cases of child abuse. The most commonly affected ages were “1-6” years presenting 68%. Males were the majority of cases (56%). The illustrated data of each feature of healing (6 features of fracture healing) form a prototype timetable of fracture healing. These data suggest that fractures with soft-tissue swelling alone are acute fracture (< 1 week old). Fractures with periosteal reaction alone are likely to be recent fracture (between 8 days and 3 weeks old). Once Remodelling, bridging & hard callus fractures detected then old fracture is expected (more than 6 weeks old).

Key words: dating, long bone, fracture healing, X-ray.

Background

One of the biggest challenging areas of pediatric medicine is what relating to child abuse. Child abuse includes wide variations of injuries and assaults which includes social, emotional and sexual in addition to physical matters. Therefore, the diagnosis of a child as being suffer from an event of abuse has important social, civil and criminal implications. Child mortality and morbidity are a significantly outcome from exposure of those children to maltreatment and abuse.

To investigate children who have suffered potential abuse, the investigation must be multi-disciplinary and involve healthcare and social professionals, physicians with appropriate medical subspecialties and paediatricians. Radiology supplies a relatively small but important role to the investigation of visceral and skeletal injuries.

Methodology

The study represents collaborative research between Forensic Medicine and Clinical Toxicology Department and Diagnostic & Interventional Radiology Department, Faculty of Medicine, Cairo University, Egypt.

Study design and setting

This study is a prospective, cross-sectional study that was conducted on injured paediatrics, of known injury timing in the period between January 2017 to January 2018.

Study population

For this study one hundred patients of both sex aged 1-18 years were selected during the study period and subdivided into 3 main groups, group 1: 68 children (1 to 6 years), group 2: 22 young (<6 to >12 years) and group 3: 10 young from (<12 to 18 years). Potential participants who had Unknown time of fracture, Fractures need to be treated with internal fixation, Patients with co-existent

 Corresponding author:
Amal Salama Mahmoud Mahmoud
E-mail: amalsalamabadawy@yahoo.com
head injury and who had metaphysial fracture were excluded from the study.

The study was conducted according to the declaration of Helsinki and the protocol was approved by Ethics Research Board of both departments. All participants provided written informed consents by their legal guardians before being enrolled in the study.

**Methodology in Detail**

Cases were analysed according to Demographic data of the patients: age, sex, time of imaging (measured in days since injury), date 1, 2, 3, 4, 5, 6 and 7 up to 50 days or more from time of fracture.

**Radiography**

Radiographs were presented to the pediatric radiologist in a random order where the identity, age of the child, time and cause of injury were unknown for him. They were supplied in batches of 6–12 to minimize memory bias and fatigue and he assessed each radiograph with irregular time interval.

**Interpretation of radiographs:**

The presence or absence of each of the following six radiographic features of fracture healing was scored for all radiographs.

1. **soft-tissue swelling**, which was defined as disruption of the soft-tissue planes or the presence of an effusion in a supracondylar fracture.

2. **periosteal reaction**, which was defined as linear elevation and calcification of the periosteum along the shaft of the bone around or adjacent to the fracture site.

3. **soft callus**, which was defined as the fluffy appearance of early new bone around the fracture site which gradually ossifies and calcifies.

4. **hard callus**, which was defined as well-demarcated new bone with a dense edge that is nearly as dense as the cortex as more mature callus develops.

5. **bridging**, which was defined as the loss of fracture line definition with complete bridging of the fracture gap by a soft or hard callus.

6. **remodeling**, which was defined as the complete healing with the shape at the fracture site returning to that of the original bone.

Radiologist of the study scored films with an initial 5-point scale plus an additional score, P, for undetermined.

Radiographs time was grouped into bands based on the known age of the fracture. The time bands were selected according to the data (with at least 20 radiographs in each time frame) and to reflect the age estimation process in practice. Narrow time bands were possible for the first week, with increasing width thereafter. The time bands were: 1–2, 3–7, 8–14, 15–21, 22–35, and 36 days up to 50 days. They were classified as follows:

- Date 1: 1-2 days / Date 2: 3-7 days / Date 3: 8-14 days / Date 4: 15-21 days / Date 5: 22-35 days / Date 6: 36-50 days / Date 7: < 50 days.

**Statistical Analysis**

Data were coded and entered using the statistical package SPSS (Statistical Package for the Social Sciences) version 25. Data were summarized using frequency (count) and relative frequency (percentage) for categorical data. For comparing categorical data, Chi square ($\chi^2$) test was performed. Exact test was used instead when the expected frequency is less than 5.

P-values less than 0.05 were considered as statistically significant.

**Findings**

302 radiographs were done as follows: (97 cases had radiographs at date 1), (48 cases had radiographs at date 2), (52 cases had radiographs at date 3), (44 cases had radiographs at date 4), (43 cases had radiographs at date 5), (14 cases had radiographs at date 6), (4 cases had radiographs at date 7).

Results show that 68 % of cases were from 1-< 6 years old, 22 % of cases from 6 - <12 years and 10% of cases 12- 18 years old, according to sex; 56% of cases were males & 44% of cases were females.

Figure(5) shows tissue swelling only detected during date 1 by 33.8% of cases. Periosteal reaction started to be detected during date 1 by 10.8% of cases, it was detected during date 2 in 3.4% of cases, during date 3 in 69.4% of cases, in 81.2% of cases during date 4, in 88.5% of cases during date 5. During date 6; it was detected by 50% and in 100% of cases during date 7. Soft callus detected only during date 6 in 25 % of cases. Hard callus started to be detected during date 1 by 10.8% of cases, it was
detected during date 2 in 10.3% of cases, during date 3 in 58.3% of cases, in 75% of cases during date 4, in 80.8% of cases during date 5. During date 6; it was detected by 50% and in 100% of cases during date 7. **Bridging** started to be detected during date 1 by 3.1% of cases, it was not detected during date 2, during date 3 in 27.8% of cases, in 21.9% of cases during date 4, in 57.7% of cases during date 5. During date 6; it was detected by 50% and in 100% of cases during date 7. **Bone remodelling** started to be detected during date 4 by 3.1% of cases, it was detected during date 5 in 19.2% of cases & lastly detected in 50% of cases during date 6.

Figure (5): Collective graph for 6 signs of healing during the seven dates for age group (1-6 years).

Figure (6) shows **tissue swelling** started to be detected during date 1 by 19% of cases, it was detected during date 4 in 20% of cases and lastly detected during date 5 in 36.4% of cases. **Periosteal reaction** started to be detected during date 1 by 9.5% of cases, it was detected during date 2 in 38.5% of cases, during date 3 in 20% of cases, in 60% of cases during date 4, in 72.7% of cases during date 5. During date 6; it was detected by 75% and in 100% of cases during date 7. **Soft callus** was only detected during date 5 by 18.2%. **Hard callus** started to be detected during date 1 by 19% of cases, it was detected during date 2 in 61.5% of cases, during date 3 in 30% of cases, in 40% of cases during date 4, in 81.8% of cases during date 5. During date 6; it was detected by 75% and in 100% of cases during date 7. **Bone remodelling** started to be detected during date 2 by 9.5% of cases, it was detected during date 2 in 15.4% of cases, during date 3 in 10% of cases, in 81.8% of cases during date 5, during date 6; it was detected by 75% and in 100% of cases during date 7. **Bone remodelling** started to be detected during date 2 by 15.4% of cases & lastly detected during date 7 in 100% of cases.

Figure (6): Collective graph for 6 signs of healing during the seven dates for age group (6-12 years).
Discussion

In forensic cases, it is highly important to estimate the timing of skeletal injury appropriately as it has a significant bearing on the judicial process\(^9\).

The study showed that the most commonly affected ages “1-6” years followed by < 6- > 12 years and the least ages affected were <12-18 years. These results are in agreement with the results obtained by Prosser\(^7\,9\) who showed that broken bones are very common in childhood who have more physically active lifestyles and their fractures are generally less complicated than fractures in adults. As age increase, bones become more brittle and more likely to suffer fractures from falls that would not occur in young age. This in contrary to study done by Islam\(^5\) who showed that most of cases were adolescence (8-17) years.

In this study, males represented the majority of cases (56%) in comparison to females (44%), these results are coincident with the results obtained by Islam\(^5\), where boys 67% of cases. The other studies did not mention gender as point of study as most of studies was done on young ages less than 6 or even 1 year.

Soft tissue swelling most detected during 1\(^{st}\) period of healing “1-2 days” from fracture. Then its detection regressed during the later periods of healing.

This come in agreement with study\(^11\) which recorded that early soft-tissue resolution occurs between 2 and 5 days, peaking between 4 and 10 days, which concurs with the peak presence of soft-tissue swelling in our dataset at 1–2 days. Islam\(^5\) detect it within the first week also, Prosser\(^7\) detected soft tissue swelling in 59% of radiographs around the same time.

Regarding periosteal reaction it was highly significant detected <50 days from fracture while its detection was significantly increasing from day 1 to 35 days from fracture from 9.4% to 86% respectively. This come in agreement with study\(^12\) which showed that periosteal reaction had a time frame similar to subperiosteal new bone formation suggested by studies\(^6,11\) whom detected also that periosteal reaction persisted longer as in our study, Prosser\(^7\) showed that highest detected periosteal reaction between 15-35 days, warner\(^9\) showed it was early identified and seen at day 7 and in increasing pattern. In contrary Islam\(^5\) showed that periosteal reaction not detected before 2 weeks.

Soft callus was detected between 8 to 50 days since fracture. This come in agreement with Islam\(^5,6\) who detected soft callus up to the day 35 then it started to decline, also with Prosser\(^7\). This in contrary to\(^11\) in their study soft callus was identified earlier in time while Halliday\(^10\) found that no any callus detected before 20 days.

Hard callus highly significant detected <50 days since fracture while its detection was significant increasing during the periods of healing.

This come in agreement with\(^5,7,11\) that detected hard callus increase in prevalence with time. In contrary to Halliday\(^10\) who didn’t identify any callus before 20 days.

Bone bridging highly significant detected <50 days from fracture, on the other hand its detection was significant increasing during the periods of healing.

This come in agreement with\(^5,7,11\) whom detected that bone bridging was increasing in prevalence with time while Warner\(^9\) showed that bridging was first identified at day 15 & majority of cases between 15-67 days.

Bone remodelling highly significant detected< 50 days from fracture, on the other hand its detection was increasing during the periods of healing. This come in agreement with\(^5,7,11\) who detected bone remodelling increase in prevalence with time. In contrary, Warner\(^9\) showed that remodelling was first seen from days 51-247; the study was performed among infants less than 1 year.

To discuss each age group separately we can find some differences between groups, the group (1-6 years), showed that remodeling last seen was from 35-50 days. The group (6-12), periosteal reaction was detected with high percentage of cases 38.5% during the first week & soft tissue swelling was still detected in some cases during the 3\(^{rd}\) week of fracture. The group (12-18 years), showed that periosteal reaction last detected during the period from 22-35 days & remodeling last detected during the 3\(^{rd}\) week but it may be explained by small sample size at this age.

In other study of Prosser\(^7\), soft tissue swelling alone is acute (<1 week old). Fractures with periosteal reaction alone are likely to be between 5 days and 2 weeks old. When periosteal reaction and soft callus are present, these findings are consistent with a fracture of
2–3 weeks old. Once hard callus or bridging appears, the fracture is 3 weeks old or older. Remodelling intimates that a fracture is more than 6 weeks old.

**Conclusion**

The presence of the different radiologic features of fracture healing can indicate fracture ages. Each line represents the prevalence of each feature in the radiographs assessed. less than 1 week, soft-tissue swelling was the predominant feature. (8–35 days) fractures showed a combination of soft callus and periosteal reaction, with increasing prevalence of hard callus and bridging. (≥36 days) fractures showed a combination of periosteal reaction, hard callus, bridging, and remodelling.

So that appearance of each feature forms a prototype timetable of fracture healing. These data suggest that fractures with soft-tissue swelling alone are acute fracture (<1 week old). Fractures with periosteal reaction alone are likely to be recent fracture (between 8 days and 3 weeks old). Once remodelling, bridging & hard callus fractures detected then old fracture is expected (more than 6 weeks old).

For each age group separately, some differences were noticed between groups, the group (1 - >6 years), showed that remodeling last seen was from 35 -50 days. The group (6 - >12), periosteal reaction was detected at high percentage of cases 38.5% during the first week & soft tissue swelling was still detected in some cases during the 3rd week of fracture. The group (12 -18 years), showed that periosteal reaction last detected during the period from 22-35 days & remodeling last detected during the 3rd week but it may be explained by small sample size at this age.

Risk of Nutritional Status and Blood Sugar on Type 2 Diabetes Mellitus with Pulmonary Tuberculosis in Sawahan Subdistrict, Surabaya, Indonesia

Ana Mala Fitri1, Muhammad Atoillah Isfandiari1

1Departement of Epidemiology, Faculty of Public Health, Airlangga University, 60115, Surabaya, East Java, Indonesia;

Abstract

The diabetics have risk of pulmonary tuberculosis. It caused by lacking of immune system and malnutrition, eventhough the diabetics’ nutritional status commonly is normal or overweight. This research aimed to analyze risk of nutritional status and blood sugar to patients of diabetes mellitus with pulmonary tuberculosis. The study was observational analytic with case control design. There were 20 samples in each case and control located in Sawahan Sub-district, Surabaya. The data collection used questionnaire and medical record of participants from the community health care. The data was analysed using Pearson test correlation and odd ratio. The result showed no correlation between body mass index and blood sugar of both random (p=0.138) and fasting (p=0.166). The obesweight diabetics are much more likely to get pulmonary tuberculosis 1.3 times compared to normal diabetics (95% CI= 0.313<OR<5.393), while the odd ratio of pulmonary tuberculosis in underweight diabetics is estimated to be 1.2 times compared to diabetics who are normal (95% CI= 0.121<OR<11.865). The diabetics who have random blood sugar level of ≥200 mg/dL are 0.46 times to have pulmonary tuberculosis compared to blood sugar level of <200 mg/dL (95% CI=0.111<OR<1.94). The diabetics who have fasting blood sugar level of ≥126 mg/dL showed effect 2.43 times to be likely get pulmonary tuberculosis either they have <126 mg/dL 95% CI= 0.51<OR<11.51). There was no relationship between blood sugar level, nutritional status, and pulmonary tuberculosis on patients with type 2 diabetes mellitus.

Keyword: Nutritional Status, Blood Sugar, Type 2 Diabetes Mellitus with Pulmonary Tuberculosis

Introduction

Non-communicable diseases are a public health discussion globally due to the recent cases that have occurred this. In 2016, non-communicable diseases have caused 41 million deaths (71%). The problem of non-communicable diseases is more prevalent in developing countries. Metabolic factors such as high blood sugar and obesity require attention from public health experts. This is due to the prevalence of excessive blood sugar levels in 2014 estimated at 9% in the world according to WHO in 2018. The number of people with diabetes has nearly a quarter of the world’s population since 1980 and it is estimated that there are 650 million obese people above the age of 18 in 2016(1).

Diabetes mellitus includes non-communicable diseases and is a metabolic disorder with characteristics of hyperglycemia caused by the pancreas not producing enough insulin or the body cannot use insects that are produced effectively so that there is an increase in glucose concentration in the blood2. Diabetes include a serious threat to public health because of one of the diseases that contribute to high mortality, morbidity and health costs across the country(2). Indonesia as one of the developing countries is estimated to have total deaths from non-communicable diseases in 2016 of 73% of total deaths(1).

Diabetes is positively associated with the risk of tuberculosis (TB)(3). East Java Province has a diabetes prevalence of 2.02% while the prevalence of diabetes mellitus in the city of Surabaya alone reaches almost 3.5% (4). Sawahan Subdistrict in Surabaya City is one of the regions with a third population density of Mostof 29.75%(5). Variable occupancy density and contact
between households include risk factors for transmission of pulmonary TB\(^6\).

The incidence of pulmonary TB in diabetics is related to nutritional status and blood sugar levels\(^7\). Patients with type 2 diabetes mellitus are in fact more often found with normal or nutritional status overweight so that the risk of nutritional status of the two categories needs to be studied against cases of pulmonary TB in patients. Based on these problems, the study will analyze the risk and correlation of nutritional status and blood sugar levels of patients with type 2 diabetes mellitus with and without pulmonary TB. This study aims to analyze the risk of blood sugar levels and nutritional status on the incidence of pulmonary TB in patients with type 2 diabetes mellitus. This study is expected to be useful for improving the quality of health services in disease prevention and adding new information about the incidence of type 2 diabetes mellitus with TB lung.

**Material and Method**

This study used design case control with observational analytic types. The research locations were in the Sawah Puloh and Sawahan Health Center, Surabaya City. The study took place from September 2017 to December 2017. The population of the case was all patients diagnosed with type 2 diabetes mellitus with pulmonary TB in Sawahan District, Surabaya City while the control population was all patients with type 2 diabetes mellitus in the same location. Retrieval of data using probability sampling techniques with method simple random sampling. Sample calculation using the formula case control uses the value of \(Z_{α} = 95\%\) and \(Z_{β} = 90\%\) \(^8\). The proportion of population effect cases \(P_1 = 0.82\) and control population \(P_2 = 0.49\) \(^9\). The results of the sample calculation with the ratio of the number of cases compared to the number of controls of 1:1, there were 20 samples in each case and control. Sampling of cases and controls were randomized (random).

Characteristic variables studied in the respondents included case group and control, sex, body mass index, random blood sugar, and fasting blood sugar of type 2 diabetes mellitus. The dependent variable is pulmonary TB while the independent variable is blood sugar levels and nutritional status.

Data retrieval is done by interviewing questionnaires and documentation from the respondent’s medical record from the health center where the respondent is treated. Data taken from medical records is a diagnosis of pulmonary TB and type 2 diabetes mellitus.

**RESULTS**

The results of the study on the characteristics of the respondents (Table 1) showed that the majority were women (22%). The nutritional status of the respondents was mostly in the category overweight (62.5%) and the lowest was the group underweight (10%). The majority of respondents had random blood sugar 80-180 mg / dL (80%) and fasting blood sugar ≥100 mg / dL (85%).

The results of the Pearson test correlation with \(α = (0.05)\) showed no correlation between body mass index and random blood sugar levels \((p = 0.14 > 0.05)\) and fasting blood sugar \((p = 0.17 > 0.05)\) Pearson correlation coefficient showed a weak correlation in both correlations, namely the correlation of body mass index with random blood sugar levels (Pearson correlation = 0.24) and body mass index correlation with fasting blood sugar levels (Pearson Correlation = 0.22) (Table 2).

</tbody>
</table>

Values odds ratio in table 3 show the meaning that the risk of type 2 diabetes mellitus with pulmonary tuberculosis in respondents who have a random blood glucose levels ≥200 mg / dL was 0.46 times than that flies random blood sugar levels <200 mg / dL. The result of the odd ratio in fasting blood sugar levels showed the risk of type 2 diabetes mellitus with pulmonary TB in respondents who had fasting blood sugar levels 6126 mg / dL was 2.43 times greater than respondents with fasting blood sugar levels <126 mg / dL. The two odd ratio values do not show the relationship between blood sugar levels and the incidence of pulmonary TB in patients with type 2 diabetes mellitus, which is viewed from the confidence interval values (Table 3).

The results odds ratio of the risk pulmonary TB in patients with type 2 diabetes mellitus with nutritional status underweight 1.2 times greater than respondents with normal nutritional status. In respondents with nutritional status they overweight have a risk 1.3 times more likely to be exposed to pulmonary TB than respondents who are of normal nutritional status.

Discussion

The majority of respondents who suffer from type 2 diabetes mellitus have nutritional status overweight. Similar studies also state that the majority of the nutritional status of diabetics is overweight (10). The results of research in Indonesia also stated that based on the 2014 TB-DM Registry, comorbidities of TB and DM were more commonly found in patients who had a relatively heavier body weight than TB without DM(11). Similar to the results of a study which states that someone with nutritional status obesity and overweight is associated with TB infection in diabetics (12). This is
because obesity is a risk factor for diabetes\textsuperscript{(13)}. The risk of developing diabetes is four times greater in obese people than those who have a normal BMI \textsuperscript{(14)}. Other causes can be related to reduced exposure to rifampicin (antibiotics for pulmonary TB) in patients treated\textsuperscript{(15)}. In contrast to the research of Chiang \textit{et al} in 2019 the majority of patients with type 2 diabetes mellitus with pulmonary TB experienced weight loss. Decreasing weight occurs as a result of decreased appetite due to TB disease which is also experienced\textsuperscript{(15)}.

The risk of pulmonary TB for diabetics can occur in both patients with nutritional status \textit{underweight} and \textit{overweight} \textsuperscript{(16)}. Findings in this study found a different matter, namely there was no correlation between nutritional status of BMI of type 2 diabetes mellitus patients with the incidence of pulmonary TB. These results are also similar to the study by Lin \textit{et al} in 2018 which is a non-significant risk between obesity, diabetes and tuberculosis. Possible causes of these results are confounding variables that affect like socio-economic status. If confounding variables can be controlled or regulated while the research is taking place, there may be an association between the two variables that can occur such as dividing the average number of people with obesity who are obese and not obese with their socio-economic status. The variable diabetes mellitus itself is an intermediate variable between the causal relationship between BMI and pulmonary TB but cannot be connected entirely because the BMI has two traits. The two characteristics of BMI associated with pulmonary TB are protective and risk. The biological mechanism in the body about this matter has also not been found clearly. Several possible mechanisms of origin originate from the role of fat tissue in the body against the bacteria \textit{Mycobacterium tuberculosis} \textsuperscript{(17)}.

The risk of high blood sugar levels from normal limits in diabetics has been designated as a causal factor for type 2 diabetes mellitus with pulmonary TB \textsuperscript{(18)}. It is different from the findings of this study which shows that there is no relationship between blood sugar levels and incidence of pulmonary TB in patients with type 2 diabetes mellitus. There are studies that also support these results, no relationship to the diagnosis of diabetes mellitus with a history of 37,862 respondents\textsuperscript{(4)}.

The results of the study by Lin \textit{et al} in 2017 explain that 90\% of TB patients who initially have fasting blood sugar levels \textless{}6.1 mmol / L can maintain \textless{}6.1 mmol / L while undergoing treatment for tuberculosis and show absolutely no symptoms of diabetes mellitus. This proves that TB patients who do not have a history of diabetes mellitus are proven by normal fasting blood sugar, there will not be comorbid diabetes mellitus \textsuperscript{(19)}.

This study shows no association between blood sugar levels and nutritional status with the incidence of pulmonary TB in type 2 diabetes mellitus, but the risk of nutritional status and blood sugar levels in diabetics needs to be considered together to avoid complications and comorbidities such as pulmonary TB. Lifestyle changes and physical activities to maintain normal nutritional status and routine blood sugar checks are preventative steps that can be taken for diabetics. Health services also need to improve diabetes care so that it can reduce comorbidities in patients and prevent diabetes with pulmonary TB \textsuperscript{(18)}. For diabetics with TB, health services should have diabetes screening at the beginning of TB treatment, appropriate treatment, and monitoring treatment to reduce the failure of TB treatment in patients with diabetes mellitus \textsuperscript{(20)}.

\section*{Conclusion}

There is no relationship between BMI and random blood sugar levels in people with diabetes mellitus with the incidence of pulmonary TB but there is a risk of BMI \textit{underweight} and \textit{overweight} and abnormal random blood sugar levels in diabetics for co-occurring pulmonary TB. The important thing to recommend for diabetics is to keep controlling blood sugar regularly, changing healthy lifestyles, and increasing physical activity in order to prevent comorbidities that arise.

Risk Factors of Green Tobacco Sickness on Tobacco Farmers in Jember Indonesia

Anita Dewi Prahastuti Sujoso¹², Tri Martiana³, Santi Martini⁴

¹Doctoral Program of Public Health Faculty of Public Health, Universitas Airlangga, ²Faculty of Public Health Jember University, ³Occupational Safety and Health Department Faculty of Public Health, Universitas Airlangga, ⁴Epidemiology Department Faculty of Public Health Universitas Airlangga

Abstract

Introduction. Green Tobacco Sickness (GTS) is a disease in the working population that is still not widely disclosed. GTS characterized by the main symptoms of nausea, vomiting, dizziness, excessive sweating, and occurs when in contact with wet tobacco. This research purpose is to assess the factors associated with the incidence of GTS in tobacco farmers in Jember, Indonesia. Methods. The research design is case control. Research variables are occupational factors and individual factors. Data analysis using binary logistic regression. Result and Discussion. The results stated that the variable influencing the case of GTS in tobacco farmers was the work period OR = 2.944, (CI 1.127-7.693) smoking status OR = 18.083 (CI 6.815-47.984) dermatosis complaints OR = 3.876 (CI = 1.238-12.138) and nutritional status was assessed with a BMI, OR = 2.643 (CI = 1.038-6.733). Farmers with a working period of working 18 years have a risk of 2.944 times GTS compared to farmers with a work period of <18 years. Farmers with smoking status have a risk of 18.083 times GTS compared to non-smoking farmers. Farmers who have dermatoses have a risk of 3.876 times GTS compared to farmers who do not have complaints of dermatosis. Farmers with an abnormal (overweight) BMI have a risk of 2.643 times GTS compared to farmers with a normal BMI. Conclusion. Factors that influence the GTS are age, sex, smoking status, complaints of dermatosis, nutritional status, and years of service. The findings of this study suggest that integrated promotive and preventive measures from both agricultural owners and first-rate health care providers need in the form of providing self-help to reduce direct contact with wet tobacco, healthy living behavior without smoking and maintaining nutritional status.

Keywords: work-related diseases, green tobacco sickness, tobacco farmers.

Introduction

Green Tobacco Sickness (GTS) is an acute nicotine poisoning that occurs through absorption through the skin(1). GTS occurs in the population of workers or tobacco farmers, especially when planting and harvesting tobacco(2)(3). Some previous studies have suggested that GTS characterize by the main symptoms of dizziness, nausea, vomiting headaches, and excessive salivary secretion sometimes accompanied by decreased consciousness. The risk of nicotine poisoning increases when mixed with wet conditions due to rain, dew, or sweat(4).

GTS describes as occurring in several tobacco-producing countries throughout the world, in Brazil, Korea, Thailand, and several other countries (5)(6)(7). In Brazilia, the prevalence of GTS in men is 6.6%, and in women, 11.9% occurs during the harvest season and results in workers having to take leave (5). The incidence of GTS in Korea is 15 people among 40 people (37,5). Based on gender, the incidence of GTS in women (55%) was higher than in men (20%), and this difference was significant. However, if it is distinguished by age, there is no difference in the age group towards the occurrence of GTS. The incidence of GTS was high in the nonsmokers (57.5%) compared to the smokers’ group (0%), and this difference was significant (p <0,01) (6). A study in Malaysia states that farmers who use personal protection experience GTS complaints more often than those who do not use personal protection. GTS complaints are more common than complaints of pesticide poisoning (8). Tobacco farmers are groups of working populations that are vulnerable to work-related diseases. In Indonesia, research on GTS as work-related disease or occupational
illness has not been widely revealed. This study aims to identify what factors influence the occurrence of GTS in tobacco farmers. From the results of this research, it is expected that prevention programs work-related diseases can run effectively and efficiently.

**Material and Method**

**Research design.**

The study observed the variables, then carried out an analysis of risk factors or causal factors for the events to be studied. The research design used was Case Control.

**Location and time of research.**

The study was conducted on farmers in Jember Regency. The first consideration is that some health risks to tobacco farmers show that tobacco farmers in Jember Regency have a history that leads to work-related diseases. The second consideration is that initial research has been conducted on the health risks of tobacco farmers. The study was conducted for six months starting in May 2018-October 2018.

**Population and Samples.**

The study population was all tobacco farmers who met the inclusion criteria and exclusion criteria. Inclusion criteria are having age between 18-55 years, working at least five years as a tobacco farmer, being involved in the process in tobacco farming for at least the last three months, and willing to engage in research by signing informed consent. Exclusion criteria for respondents who were pregnant or sick had a history of pulmonary disease and skin disease.

Sample size. The sample size is taken using the following formula (9)

\[
\begin{align*}
P2 &= 0.31, \text{ Proportion of Exposure to the group that is not sick} \quad (10) \\
P1 &= \text{Exposure proportion in the sick group} \\
\text{Odds Ratio} &= 2.31, \text{Odds ratio in previous studies} \quad (11) \\
Z1-\alpha / 2 &= \text{value in the standard normal distribution which is equal to the significance level } \alpha = 0.05, \text{ so the value of } Z = 1.96 \\
Z1-\beta &= \text{value in the standard normal distribution equal to power by 90%, value 1.28.}
\end{align*}
\]

From the formula for calculating the sample above, the sample size is 129 (=130). Sample of 25 people was added, so the number of samples became 155 people.

**Research variable**

The variables examined in this study were individual variables in the form of age, sex, education, smoking status, passive smoking, nutritional status, individual hygiene, personal protective use, dermatosis complaints. While the work variables studied are the main work, workload during work, length of work, and length of rest.

**Instrument**

In this study, respondents with GTS, cases were defined as people who tested positive for urine cotinine and experienced some significant clinical symptoms, namely dizziness, headache, nausea, vomiting, decreased consciousness. Urine Cotinine is measured using the COT Rapid Test Cotinine Cassette Right sign which is capable of detecting cotinine up to 200 ng/ml and can detect cotinine 2-3 days after exposure. Other data was taken through interviews with questionnaires.

**Data analysis**

The collected data were analyzed using the back wald binary logistic regression test. The level of significance was determined from the value of \( p <0.05 \). Interval Confidence (CI) values are classified into two groups if CI> 1 is a risk factor, and if CI <1 is a protective factor. Whereas if CI passes number 1, it means that the variable is not meaningful.

**Finding**

**Result and Discussion**

In general, the work process in the tobacco processing industry is divided into two, namely upstream industry and downstream industry. In this study, it is limited to the upstream industry. Each stage of tobacco processing contains health risks.

The first stage is processing land, including irrigation, eradicating pests, planting seeds, and providing fertilizer. Risks that arise are exposure to solar heat, contact with chemicals and unnatural work postures. The next stage is harvest. At this harvest stage the biggest risk is direct contact with nicotine tobacco. At this stage many workers experience complaints of dizziness, nausea, headaches and itching. After harvest,
the next stage is sorting and drying tobacco leaves. The health risks that appear at this stage are itching of the palms and feet, coughing and complaints of joints.

The binary logistic regression analysis of individual factors and GTS obtained results of individual variables related to GTS were gender, smoking status, passive smoking, and nutritional status. In detail, they are presented in Table 1.

</table>
From the results of the logistic regression test showed that tobacco farmers with age <45 years had a risk of 0.42 times being affected by GTS compared to age ≥45 years. Young age is a protective factor of GTS. Similar to a study conducted by Saleoon (7), Unlike Fassa et al. (5), the prevalence of GTS at a younger age is more than that of old age. Based on gender, tobacco workers are dominated by female sex. The condition is because the characteristics of work in tobacco farming require patience. From the results of the above research, it is seen that the risk of the female sex is 5,308 times as significantly as GTS compared to men. This condition is consistent with the GTS study in Korea that the incidence of GTS in women was higher (55%) compared to men (20%) (6). The prevalence of GTS is also higher in women compared to men. GTS occurs more in the female population compared to men (12).

Tobacco farmers who have low education have a risk of 1,068 times experiencing GTS compared to low education. Education about occupational health is essential for farmers and owners to be able to reduce the risk of GTS. The education in question covers the symptoms and prevention of GTS (13).

Tobacco farmers who have a smoking habit have a risk of 18,083 times experiencing GTS compared to tobacco farmers who do not smoke. Smoking causes a decrease in body defense immunity, making it easy to experience pain. In field observations, it was found that farmers who smoke often experience GTS complaints less. The condition might occur because of the mechanism of nicotine intolerance. However, McBride et al. Stated that smoking is not a protection factor for GTS (14). The status of tobacco farmers as passive smokers have a risk of 0.773 for GTS compared to farmers who are passive smokers. Non-smoking status is a protection factor for GTS.

Based on nutritional status, farmers who have poor nutritional status have a risk of 2,643 times experiencing GTS compared to farmers with proper or healthy nutrition. This risk is statistically significant. Farmers with functional nutritional status will have active self-defense against physical work activities, not quickly tired, not easily sick, so high work productivity.

Farmers with poor individual hygiene are at risk of developing GTS 2,289 times compared to farmers with good individual hygiene. The habit of using bad personal protective risks is 1,142 times the occurrence of GTS compared to those who regularly use personal protection. The use of personal protection for tobacco farmers in addition to preventing the risk of GTS also protects from contact with pesticides (15).

Farmers who complain of dermatosis have a risk of 3,876 times the occurrence of GTS compared to farmers who do not complain of dermatosis. The same thing happened to tobacco farmers in North Carolina. Farmers who reported subjective rash complaints were more at risk of having GTS with OR 3.3 (95% CI 2.17-5.02) (11). Nicotine in tobacco leaves more easily enters through the skin. In the skin that has a rash, wounds, nicotine will be more easily absorbed.

Based on the analysis of occupational factor, and the incidence of GTS, the results of the working period variables were significantly associated with GTS and in detail, presented in Table 2.

</table>
Farmers are at risk of experiencing GTS by 1,171 times compared to landowners and farmers. Farm workers do almost all stages of the upstream tobacco industry, so contact with tobacco is higher than the landowner.

High workloads are at risk of experiencing GTS of 1.439 times compared to low workloads. High workloads indicate the type of activity carried out varies and with varying frequency. Hoang Van Minh expressed a similar thing that farmers who cultivated tobacco 3.5 times had health problems compared to those who did not cultivate tobacco (16).

Long working period means greater exposure to hazard exposures. Tobacco farmers with a working period of ≥ 15 years risk 2,944 times experiencing GTS compared to farmers with a working period of <15 years and statistically significant. The working period is related to the length of exposure to the hazard received. Long-term exposure can affect the somatosensory sensory system and the central process of sensory information (17).

Working time <8 hours is a protection factor for farmers with long working hours <8 hours will protect from GTS. Long rest more than 1 hour is a protection factor. Farmers with longer breaks of more than 1 hour will protect from GTS.

### Conclusion

The findings of this study indicate that female sex, farmers with smoking status and passive smoking, poor nutritional status, having a subjective complaint of dermatoses, and a work period of more than 18 years are risking factors for GTS.

Identification of the Direction and Strength of Relationship between Complaints of Musculoskeletal Disorders (MSDs) to Smoking Habits and Repetitive Movements of Informal Workers in Surabaya, Indonesia Using Spearman Correlation Test Methods

Annisa Dwinda Shafira¹, Genduk Lintang Rusmawarda²

¹Department of Biostatistic and Population, ²Department of Occupational Safety and Health, Faculty of Public Health, Airlangga University, 60155 Surabaya, East Java, Indonesia

Abstract

The right statistical test to find out the relationship between variables that have ordinal data scale is a spearman correlation test. Spearman correlation shows how strong the relationship and the direction of the relationship between variables. The increasing muscle complaints have a close relationship with smoking habits. The longer and the higher the frequency of people smoke, the smaller the lung capacity. It then results in a decrease in the lung ability to consume oxygen. It also causes one more easily tired when carrying out tasks that require exertion. In addition, complaints due to repetitive movements occur because the muscles continuously receive workload pressure without a chance for relaxation. This condition triggers the occurrence of nerve swelling which will cause pain in the musculoskeletal area. This is an observational study with a cross sectional design. The study used a total sampling population of 12 workers. Spearman correlation is used to examine the strength and direction of the relationship between the dependent variable, MSDs complaints, an ordinal data scale, with independent variables, smoking habits and repetitive movements. This study found that smoking habits and the level of complaints of MSDs in the shelf frame bending workers have fairly strong, positive and unidirectional relationship with correlation coefficient value of 0.357. It also found that repetitive movements and complaint levels MSDs have a positive and perfect relationship with the correlation coefficient value of 1.000.

Keywords: smoking habits, repetitive movements, complaints of musculoskeletal disorders, spearman correlation

Introduction

Spearman test is a statistical tool used to test the relationship between variables with ordinal scale data. Spearman correlation method is a method used for ordinal or ranking scale and free of distribution (non-parametric). The Spearman correlation value is between -1 and 1. The coefficient value of 0 indicates that there is no correlation or relationship between independent and dependent variables. The spearman value of 1 indicates that there is a positive relationship between independent and dependent variables and if the value is -1, it indicates that there is a negative relationship between the variables¹.

After the industrial revolution, the development of the industrial sector in Indonesia grew rapidly. This was marked by the development of informal industries. This development occurs because this sector has strong resistance to economic crisis and high absorption capacity of labor. The informal sector is an unorganized and irregular sector, yet many of them were unregistered.
Complaints often felt by workers are usually in parts of tendons, ligaments and joints. According to the European Agency for Safety and Health at Work, MSDs are one of the occupational related diseases. The Institution of Occupational Safety and Health estimates 553,000 workers in 2014-2015 suffered from musculoskeletal disorders caused by their current or past work. About 223,000 of these workers suffer from back pain. 233,000 of them had problems related to the upper limb and neck and around 97,000 had lower limb problems. As a result of the incident, it was estimated that 9.5 million workdays were lost due to illness in the musculoskeletal area caused by or worsened by work.

In his book, Tarwaka suggested that there are several factors that cause complaints of musculoskeletal disorders, such as excessive muscle stretching, repetitive movements, unnatural working attitudes, secondary causes, and combination causative factors. Some experts also argued that individual factors, such as smoking habits, and occupational factors, such as repetitive movements, can also cause musculoskeletal complaints.

The increasing muscle complaints have close relationship with the length and level of smoking habits. The longer and higher the frequency of smoking a worker has, the higher the level of muscle complaints they make. Smoking habits can reduce lung capacity which then makes lungs ability to absorb oxygen decreases. As a result, the body’s freshness also decreases. This then makes workers to be easily tired, especially when they carry out tasks that require exertion. The tiredness is because oxygen in the blood is low, burning carbohydrates is inhibited, and lactic acid accumulates, which then leads to the rise of muscle soreness.

Repetitive movements are the second main factor causing MSDs complaints. Repetitive motion is a movement that repeats itself at certain intervals. The time interval of the movement may be the same or not the same. Complaints due to repetitive movements occur as the result of continuous workload pressure received by the muscles without the opportunity for relaxation. Repeated movements that are carried out without sufficient relaxation time have the potential to cause nerve damage or swelling, which will cause pain in the musculoskeletal area.

Previous research on chronic musculoskeletal pain and smoking habits in Canada stated that, even though the relationship between the two variables is not very strong, chronic back pain is more common in smoking individuals, who smoke every day. Another study conducted on electricians stated that ergonomic factors such as awkward postures, static and repetitive movements were closely associated with the occurrence of musculoskeletal disorders.

This study aimed to examine the direction and strength of the relationship between complaints of musculoskeletal disorders with smoking habits and repetitive movements of informal workers using the Spearman correlation test.

**Material and Method**

This study was an observational study as the data was obtained by interviews and observations without any treatment to the object of research. This study used a cross sectional design as the variables were observed at the same time. Data was analyzed using descriptive statistics, which describes the process by analyzing the direction and strength of relationships between variables.

The population of this study was all workers in the welding section of the informal industry in Surabaya Indonesia, totaling 12 people. The sample in this study used the total sampling method, so the sample was 12 workers. The variables in this study were smoking habits, repetitive movements and musculoskeletal disorders. Only primary data was collected in this study. The data was obtained through interviews, for the variables of smoking habits and complaints of perceived MSDs (Nordic Body Map method), and observations, for the variable of repetitive motion.

The dependent variable in this study was MSDs complaints, which is an ordinal data, while the independent variables were smoking habits and repetitive movements, which were nominal and ordinal data. For the data type of those variables, the right statistical test to use to analyze data is the Spearman correlation test.

**Findings**

To obtain data on workers regarding smoking habits, repetitive movements and complaints of MSDs, two methods were used. Interviews were used to collect data on smoking habits and complaints of worker MSDs, while observations were used to collect data about repetitive movements.
MSDs complaint assessment can be done using the Nordic Body Map (NBM) method. The NBM method is a method used to assess the severity of musculoskeletal system disorder (MSDs) occurrence. Some argued that this method is a very subjective assessment method, which means that the successful application of this method depends on the situation and conditions experienced by workers. However, this method has often been used by ergonomists to assess the severity of disorders of the musculoskeletal system and has proven to have fairly good validity and reliability.

This method was proven to be able to assess the level of complaints felt by workers on 28 body parts. It asked the workers to range the degree of pain they felt, ranging from no pain to very pain. The result of body map analysis of workers’ complaints was used to determine the level of MSDs complaints.

</table>
On the table above, TS means not hurt, AS means a little hurt, S means hurt, and SS means very hurt. The table illustrates complaints of the informal workers based on the level of pain from the 28 body parts. The table shows that the pain complaints by informal workers were mostly on the body parts of the left and right shoulder, back, right upper arm, right knee right thigh, right leg, and right ankle. This can be seen from the largest percentage in the complaints category of very pain from 28 body parts.

Table 2. Frequency of MSDs Complaints Levels of Informal Workers Using the NBM Method

<td>58</td>
</tr>
<tr>
<td>Total</td>
<td>12</td>
<td>100</td>
</tr>
</tbody>
</table>

The MSDs complaint level category was divided into several categories, namely low, medium, high and very high. However, the results show that there were no workers whose complaints of MSDs in the level of either low or very high. Therefore, based on Table 1, it is known that the majority of 58% of workers have high levels of MSDs complaints and 42% of workers have moderate levels.

The results on the direction and strength of the relationship between smoking habits and repetitive movements with MSDs complaints can be found in the tables below:

Table 3. Relationship between Smoking Habits and MSDs Complaints Levels of Informal Workers

<table>

<td>12 100</td>
</tr>
</tbody>
</table>

The table above shows that the majority of workers who have a smoking habit (64%) are at a high level of complaints of MSDs. Meanwhile, all workers who did not have the smoking habit were at the complaints level of medium category. Data analysis found that smoking habits and MSDs complaint rates in shelf frame bending workers had a strong, positive and unidirectional relationship. This can be seen from the Spearman coefficient of 0.357.

This finding is in line with the research conducted on rock breaker industrial lift-up workers in Karangnongko Sub-district, Klaten which found a positive relationship between smoking habits and musculoskeletal complaints. This is due to the fact that smoking can cause loss of bone mineral content. The pathogenesis is complex, due to direct toxic effects on the activity of osteoblast or nicotine osteoclasts, and indirect effects on sex and adrenocortical hormones, vitamin D, and calcium absorption in the intestines, vessels and oxygen.
smoking can trigger or even worsen the development of rheumatoid arthritis and back pain\textsuperscript{9}.

</tbody>
</table>

Repetitive movements were divided into two categories, namely low (cycle time $>30$ seconds) and high (cycle time $<30$ seconds). However, the results show that there were no respondent with low level of repetitive movements. Table 4 shows that most respondents (58\%) with high repetitive movements have high rates of complaints of MSDs. Data analysis found that repetitive movements and complaint levels of MSDs in informal workers in Surabaya had a perfect relationship and positive direction. It is shown by the correlation coefficient of 1.000. This result is in line with research conducted on Ulos weaving workers in South Siantar Sub-district, Pematang Siantar City which found that there was a relationship between repetitive movements and musculoskeletal disorders\textsuperscript{10}.

**Conclusion**

There is a fairly strong correlation between smoking habits and MSDs complaints in informal workers in Surabaya, Indonesia. In addition, there is a perfect relationship with a positive direction between repetitive movements with the level of MSDs complaints of informal workers in Surabaya, Indonesia. Workers are recommended to stretch between jobs to reduce pain complaints in some of their body parts and reduce smoking, both in terms of quantity (number of cigarettes) and intensity.

Influence of Vitafort and Lactobifadol Probiotics on Excremental Microbiocenoses of Turkey Poults

Ayrat Khabirov1, Fail Khaziakhmetov1, Yaroslav Rebezov2,4, Olga Gorelik2, Marina Derkho3, Valeriy Kozlov4, Anna Vasyukova4

1Bashkir State Agrarian University, Ufa, Russia, 2Ural State Agrarian University, Yekaterinburg, Russia, 3South-Ural State Agrarian University, Troitsk, Russia, 4K.G. Razumovsky Moscow State University of technologies and management (the First Cossack University), Moscow, Russia

Abstract

The article presents the results of research on the use of probiotics “Vitafort” at a dose of 0.5 ml (107 CFU / g) and “Laktobifadol” at a dose of 0.2 g per 1 kg of live weight in the turkey poults breeding, which ensured the development of beneficial intestinal microflora, increased preservation turkey poults, an increase in the digestibility of raw protein and nitrogen-free extractive substances, nitrogen absorption, improvement of hematological and biochemical blood parameters and, ultimately, an increase in live weight and intensity of turkey poults by 9.2 and 12.5%.

Key words: turkey poults; Vitafort and Laktobifadol probiotics; intestinal and excremental microbiocenosis; live weight, growth rate; blood

Introduction

In modern conditions of livestock and poultry development, complex biologically active substances, prebiotics and probiotics are widely used mainly to stimulate the growth and development of young farm animals and poultry1-3. Specifically, probiotics, being cultures of microbes that are symbiotic with respect to the normal microflora of the gastrointestinal tract 4, suppress the vital activity of pathogenic and conditionally pathogenic bacteria of the intestine, increase the resistance of the animal’s organism, improve digestibility and assimilation of nutrients of food, activate metabolic processes 5,6, produce an antiallergic action in a number of cases 7-10. The new probiotic “Vitafort” investigated by us on the basis of the antagonistic bacteria Basillussubtilis of strain 11B is produced by OOO Research and Production Enterprise “Biofort” (Ufa)4, 11. Preliminary doses and safety of probiotic “Vitafort” are established on the basis of experimental data obtained on experimental laboratory animals (white mongrel mice), in which 109 colony-forming units (CFU) were the optimal dose for an organism per animal. Probiotic Lactobifadol contains live microorganisms of the L. acidophilus lactobacterium (not less than 1 million/g) and B. adolescentis bifidobacteria (not less than 80 million/g). Lactobifadol is a probiotic preparation for veterinary use12-14. Its use improves metabolism, feed conversion, increases daily average gains, reduces the time of growing and fattening.

The aim of the research is to study the effect of probiotics “Vitafort” and “Lactobifadol” on the quantitative composition of microorganisms: lactobacteria, bifidobacteria, E. coli, Staphylococcus aureus, enterococci and clostridia contained in feces of poults.

Material and Method

The study of the influence of probiotics “Vitafort” and “Laktobifadolo” on the formation of intestinal microbiocenosis conducted studies of excrements of turkey poultry in the framework of the experiment carried out according to the scheme presented in Table 1. The scientific and economic experience was conducted in the conditions of the “Bashkir poultry breeding complex M. Gafuri” Meleuz district of the Republic of Bashkortostan on broad breasted white turkey poults during 42 days (6 weeks). For the experiment, 3 groups of pairs-analogues
of turkey poulters were formed at a day old without division by sex. The poulters of all groups were kept on deep litter in accordance with the technology adopted at the complex, and the technological parameters corresponded to the recommended ones. The poulters were fed with feeds produced at the feed mill complex with a content of 100 g of feed 285 kcal of exchange energy and 27.5% of crude protein in the period from 1 to 21 days old, 295 kcal of exchange energy and 27.5% of raw protein in the period from 21 to 42 days of age (Table 2). Probiotic intake was daily throughout the study period. Probiotic “Vitafort” was given to turkey poulters with boiled chilled drinking water, “Lactobifadol” was distributed manually after the step of pre-mixing with compound feed. Bacteriological examination of feces was carried out according to the methodological guidelines “Isolation and identification of bacteria in the gastrointestinal tract of animals”, approved by the Veterinary Department of the Ministry of Agriculture of the Russian Federation No. 13-5-02 / 1043 from May 11, 2004. Weights of feces weighing 1 g were homogenized in 9 ml of sterile buffer solution (content of inoculum 10⁻¹ g / ml). From the main dilution, by transferring 1 ml of the suspension, a series of ten-fold serial dilutions was made in a sterile buffer solution containing native seed material from 10⁻² to 10⁻¹⁰ g / ml. For the indication of pathogenic enterobacteria, a sowing from the main breeding was carried out on Levin and Ploskirev medium. In order to study the cultural and biochemical properties of Escherichia coli, nutrient media were used: Endo, meat infusion agar-agar, meat infusion broth, beef-extract gelatin, Simmons agar, Giss medium; indole formation and production of hydrogen sulfide was studied. On 5% blood agar, morphologically different colonies with hemolytic properties were counted, counting their percentage of the total number of specified microorganisms of this family. Isolation of Staphylococcus aureus was performed on yolk-salt agar in Petri dishes with subsequent microscopy of the grown colonies. Bacteria of a round shape with a characteristic grape-like arrangement were attributed to the genus Staphylococcus. After a day of incubation, colonies with golden pigment were taken into account, the ability to ferment mannitol (+) was determined from the isolated microorganisms, tested in the plasma-coagulation reaction (+), and the lecithinase activity (+) was determined. To isolate anaerobic spore-forming bacteria, Wilson-Blair medium was used. The presence of clostridia was judged by the detection of black colonies in the depth of the medium at the bottom of the tube. Gram-positive rods with slightly rounded edges were detected by microscopic examination – Gram stain. The population level of each group of microorganisms was expressed in decimal logarithms. For this, the number of colonies was transferred to the decimal logarithms and, taking into account the appropriate dilution, the population level was calculated in lg CFU / g of feces.

**Table 1. Scheme of scientific and economic experience in growing turkey poulters using probiotics “Vitafort” and “Lactobifadol” (n = 50)**

Statistical data processing was performed by generally accepted methods of variation statistics using the statistical analysis package for Microsoft Excel. An assessment of the significance of differences in arithmetic averages was performed using Student’s t-test, the differences were considered statistically significant at P <0.05.

Results and Discussion

The results of microbiological studies of turkey poultry feces are presented in Table 3. Research has established that the use of probiotics Vitafort and Laktobifadol in diets of turkeys poults of all ages led to an increase in lacto- and bifidobacteria, i.e. there occurred an increase in the acidity of the intestinal contents due to lactic acid bacteria, which naturally prevented the development and further reproduction of pathogenic microorganisms. At 14 days of age, the number of lactobacilli in experimental groups 1 and 2 was 6.68 and 7.44 lg KOE / g, which is 1.7 and 1.9 times more, and the number of bifidobacteria was about 2 times higher (6.32 and 6.42 lg KOE / g and the number of E. coli significantly decreased by 42.6 and 41.2% (P <0.05) correspondingly compared with the control group. The number of Staphylococcus aureus, enterococci and clostridia in the experimental groups showed a tendency to decrease without significant differences. At the 28-
day age, the same tendency was observed as in the 14-day age. By the 42-day age, along with an increase in the proportion of lacto-and bifidobacteria and a decrease in E. coli, a significant decrease in Staphylococcus aureus and enterococci was found in the experimental groups, except for clostridia. Thus, throughout the entire period of scientific and economic experience in the experimental groups, more useful and less pathogenic microflora were observed, which naturally affected the safety and growth rate of the poults. During the 42-day cultivation period, the safety of the population of turkey poults in the control group was 92.0%, which is 6.0% less than in the experimental group 1, and 7.0% less than in the second. The increase in live weight and growth rate of turkey poults was higher by 9.2% and 12.5%, respectively (P <0.01 and P <0.001). Consumption of feed also decreased by 7.9–11.0% per 1 kg gain in live mass in the experimental groups compared to the control group.

A study of the digestibility of nutrients in the diet of poults at 42 days of age showed that the use of probiotics Vitafort and Laktobifadol contributed to an increase in the digestibility of crude protein by 3.6–4.3 abs. % and nitrogen-free extractive substances - by 4.2–5.0 abs. % (P <0.05). We found that turkey poults of the first and second experimental groups actively digested and actively transformed the nitrogen of feed into the protein of the muscle tissue; accordingly, the nitrogen utilization ratio was higher by 8.8–9.2 abs. % than in control. According to the balance of calcium and phosphorus, we established a tendency for their better assimilation in the body of the poults of the first and second experimental groups compared to the control group, however, no significant differences were found.

</tbody>
</table>
Positive changes also occurred in the blood composition, an increase in the number of erythrocytes by 12.8–15.8% was noted; 7.0–8.7% and hemoglobin by 7.1–8.8% at 28 and 42 days of turkey poult life compared with the control group (P <0.05). It is quite logical that only in the first 14 days of use of probiotics “Vitafort” and “Laktobifadol” there was a significant increase in the content of leukocytes by 13.7 and 14.7% (P <0.05) as compared with the turkey poult's of the control group.

It is well known that an increased level of leukocytes in the blood can be in cases where the body takes probiotics for foreign organisms. Within the physiological norm, as the poult's of all groups grew and developed, an increase in the concentration of total protein was observed in the serum, especially in turkey poult's who received the probiotics Vitafort and Laktobifadol, respectively, 9.67% and 9.89% compared to the control group. With an increase in the content of total protein in the serum of turkey poult's, especially at 42 days of age, a redistribution of serum protein fractions was observed towards the reduction of the amount of albumin (by 11.4–11.8%) and towards the increase of the amount of globulins mainly due to β- (by 7.1–8.1%) and γ-globulins (by 5.0–5.7%) as compared with the control, which is usually characteristic of intensively growing animals and birds.

**Conclusion**

The use of probiotics “Vitafort” in a dose of 0.5 ml (107 CFU / g) and “Laktobifadol” in a dose of 0.2 g per 1 kg of live weight when growing turkey poult's ensured the development of beneficial intestinal microflora, increase of the safety of turkey poult's, increase of digestibility of crude protein and nitrogen-free extractive substances, nitrogen digestibility, improvement of hematological and biochemical blood parameters and ultimately an increase in live weight and growth rate of turkey poult's from 1 to 6 weeks by 9.2 and 12.5%.

Analysis Of Work Climate And The Increase Of Blood Pressure Of Construction Workers In Pamekasan Regency

Dzul Fahmi Afriyanto¹, Noeroel Widajati¹

¹Department of Occupational Safety and Health, Faculty of Public Health, Universitas Airlangga, Surabaya, 60115 East Java, Indonesia

Abstract

The excessive exposure of work climate can cause health problems to workers. One of the problems is a change in physiological response in the form of increased blood pressure. The purpose of this study is to determine the relationship between the work climate and the increase of blood pressure in construction workers in Pamekasan Regency. This study is a descriptive observational study with a cross sectional design. The contingency coefficient correlation test was used to analyze and determine the relationship of the variables. The subjects were 19 construction workers in Pamekasan Regency, East Java, Indonesia drawn from the population according to the specified criteria. To collect the data, several different instruments were used. Questtemp 36 was used to measure the workclimate, direct observation with the standard of SNI 7269-2009 was carried out to assess the physical workload and sphygmomanometer was used to measure the blood pressure. The blood pressure measurement was carried out the someone with the medical competence. The result of work climate exposure showed that most of workers (84.3%) were exposed to beyond-threshold-value work climate. The results of blood pressure measurement showed that (36.8%) workers showed abnormal blood pressure. The statistical analysis for the correlation of work climate and the increase in blood pressure showed a moderate correlation with the contingency coefficient value of 0.314. It is recommended for companies in this construction project to add blower fan to the working areas where the work climate exceeds the threshold limit value (TLV) as well as at workers’ resting places. In addition, companies are suggested to hold periodic health checks, especially routine blood pressure checks.

Keywords: work climate, workload, blood pressure

Introduction

Hot work climate is a physical factor, a micrometeorology of the work environment, which is related to air temperature, humidity, air movement speed, and radiation heat. The comfortable temperature for Indonesians to work is in the range of 24-26°C with 35%-60% humidity. More than that range, workers will likely feel uncomfortable as the working environment being too hot. The continuous hot and humid working environment will reduce work productivity and bring a negative impact on the safety and health of workers¹².

Workers who are in a hot working environment can experience excessive exposure to a hot work climate by means of heat that arises from the production process that spreads throughout the work environment. The heat increases the air temperature in the work environment. Hot work climate in the work environment can be emitted from the body to the surrounding environment by conduction, convection and sweat evaporation. The heat can also be transferred from the environment to the body through radiation and convection⁹. Responding the heat, the thermoregulatory system in the hypothalamus will respond by performing controls such as conduction, convection, radiation and evaporation. This is to regulate body temperature and maintain the body heat to 36–37°C. However, the hot exposure that continuously ignored can cause the control system to stop working⁷.

A hot work climate increases the workload and has a negative impact on the physiological response of
workers. Therefore, workers need to have good health condition and acclimatization to work in the workplace. The physiological reaction to the exposure to heat pressure can also be an indicator to identify the danger of physical factors, especially the presence of heat stress in the workplace environment\(^9\). One of physiological responses that caused by hot work climate is increases in blood pressure\(^2\).

Based a study in Machine Division at PT. PLN (Persero) and found increase in blood pressure after exposure to a hot work climate. The measurement of blood pressure showed that the average of systolic and diastolic before exposure to heat was 116.33 mmHg and 79.00 mmHg and after the exposure to be 123.29 mmHg and 80.89 mmHg. These results showed an increase of 6.96 mmHg in systolic blood pressure and of 1.89 mmHg in diastolic blood pressure\(^6\).

Based a research on the Confined Space Heater division in PT. Nippon Shokubai Indonesia. Her result showed that there was an increase in the average pulse and blood pressure with Wet Bulb Globe Temperature Index value of 34.9\(^\circ\)C. The results of physiological responses examination showed an increase before and after work. Blood pressure measurement showed that the average systolic and diastolic pressure before work was 124.85 mmHg and 72.05 mmHg, while the average systolic and diastolic after work was 126.05 mmHg and 72.45 mmHg. It then can be concluded that the pulse and blood pressure of workers increase as they work in high temperatures workplace\(^14\).

Furthermore, if heat exposure continuous and the physiological impact is not immediately addressed, health risk will increase due to the hot workplace. There are several occupational illnesses caused by hot exposure in the workplace, such as Heat Edema, Heat Cramps, Heat Exhaustion, Heat Syncope, Heat Stroke\(^3\). Data from the CDC (Center for Disease Control and Prevention) also reported 20 cases of heat-related illnesses, 13 of them died and 7 of them suffered non-fatal losses but their suffering affected other workers. From 2001 to 2010, there were more than 28,000 hospitalizations in 20 countries participating in the tracking program from the CDC\(^10\).

This kind of cases makes the companies suffer a loss as the productivity decreases due to workers take work leave for the health issues. Workers are also disadvantaged by large financial expenditures due to the cost of their medical treatment for their illness which is caused by the hot work climate. The purpose of this study is to identify the relationship between the work climate and the increase in blood pressure in construction workers in Pamekasan Regency.

**Material and Method**

Based on the method of retrieval of data, this is a quantitative study, a descriptive observational study with a cross sectional design. The subjects were construction workers. The study used total population sampling. The sample was drawn from the population according to the specified criteria. The criteria were to have no history of hypertension and cardiovascular diseases and willing to be the subject of this research. Based on the criteria, 19 construction workers in Pamekasan Regency, East Java, Indonesia were selected as the subject of this research.

Data used in this research were primary data as it was collected and measured directly in the workplace. There were three variables collected namely work climate, physical workload, and blood pressure. Those variables were measured using different methods. The work climate was measured with the Wet Bulb Globe Temperature (WTGB) using Questtemp\(^36\) Thermal Environment Monitor was used (wet-bulb temperature, dry-bulb temperature, globe temperature, relative humidity (RH), and absolute humidity). The workload of each worker was calculated using the assessment table for workload based on caloric requirements according to SNI 7269:2009\(^8\). The measurement of blood pressure was performed by someone with medical competence using sphygmomanometer. The secondary data was the profile of working area and list of the workers. Data was analyzed using chi-square which presented in a cross tabulation. The correlation level between variables can be seen from the \(r\) value on the output result from the contingency coefficient correlation. Data collection was carried out in March 2019 for one week.

**Findings**

**Work Climate**

The work climate was measured with the Wet Bulb Globe Temperature (WTGB) using Questtemp 36. The results of measurements obtained include Wet Temperatures (WT), Dry Temperature (DT), Radiation Temperature (RT), and Wet Bulb Globe Temperature (WGBT). The result for work climate measurement is shown in table 1.
Table 1 shows that the highest WBGT is in the Room 1 which is 28.8 °C and the lowest is in the Room 6 with the temperature of 28.2 °C. The average wet temperature is 26.5 °C. The average dry temperature is 30.2 °C. The average radiation temperature is 33.7 °C. Given that temperatures data, the WBGT was calculated and came with the average WBGT of 28.8 °C. To determine the working climate whether appropriate or not with a threshold limit value (TLV) on workers was determined by comparing the measured indoor WBGT index, the workload based on the energy level expenditure and caloric needs according to SNI 7269:2009, and patterns of work with established standards. The standard used was the Regulation of the Minister of Manpower and Transmigration No. 5 of 2018. A light workload is categorized as ≤ 200 kcal/h, a medium workload is 200 kcal/hr < workload ≤ 350 kcal/h, and a heavy workload is 350 kcal/hr < workload ≤ 550 kcal/h. Therefore, the working climate is divided into 2 two categories (> TLV and ≤ TLV).

The result shows that 3 workers (15.7%) were exposed to safe work climate in accordance with the threshold limit value (TLV) and the rest samples (84.3% or 16 workers) were exposed to unsafe work climate, beyond the threshold limit value. The hot work climate they received in the work environment will be an extra heat load in addition to the heat load generated by the their body. This can bring a negative result that influences their health and can lead to health problems, one of which is the increase in blood pressure.

Hot work climate, especially one that exceeds the threshold value, can cause health problems to workers, both physical and psychological problems. A high-temperature work environment needs to be carefully supervised as it can cause bigger problems than the low-temperature one. This is due to the fact that human will generally be easier to protect themselves from the effects of low temperatures than high temperatures.

Workers who exposed to the hot work climate, will more likely to show signs or symptoms of discomfort such as increasing blood pressure, increasing body temperature, headaches, nausea, and other symptoms of excessive exposure to heat. To be continuously exposed to excessive heat makes workers to acclimatize as a sign of environment adaptation. Among body adaptation mechanism are sweating efficiency, stable circulation, relatively low pulse and low body temperature. Therefore, the caused symptoms are less seen than of those who do not acclimatize.

A comfortable temperature for Indonesians, who are accustomed to the tropical climate, to do activities is the temperature ranging from 24-26°C, by acclimatizing with temperatures around 28-32°C with 85% - 95% humidity. Hot temperatures can reduce the ability to think and even worse when it reach the temperature above 32°C. In addition, hot temperatures also result in a lack of agility, long reaction time, and slow decision making. Therefore, hot temperature can decrease work efficiency and productivity.
**Blood Pressure**

Increased blood pressure is one of the causes of occupational diseases and productivity decreases. Blood pressure was measured using a *sphygmomanometer*. The increase of blood pressure was divided into two categories, normal and abnormal. The normal increase showed the systolic of < 140 mmHg, while the abnormal was the systolic of > 140 mmHg¹.

The result shows that the lowest blood pressure before working is 100/70 mmHg, the highest is 130/100 mmHg, and the average is 117.8/80/5 mmHg. The measurement result of blood pressure after working shows that the lowest is 110/80, the highest 160/100 and the average is 127.4/89.4 mmHg. Based on the results of blood pressure measurements before and after work, it is known that all respondents experienced an increase in blood pressure. As the increase blood pressure increases, 12 workers (63.2%) showed an increase but were still in the normal category and 7 workers (36.8%) showed an increase and were in the category of abnormal blood pressure.

An increase in blood pressure is classified to be above the threshold if it passes the limit of hypertension. The limit is systolic blood pressure (SBP) of ≥ 140 mmHg and/or diastolic blood pressure (DBP) of ≥ 90 mmHg in two different measurements¹. Every individual who experiences changes in blood pressure has a mechanism to distribute blood in varying amounts to various parts of the body, depending on what someone is doing and the current condition of the person. The main reason why blood pressure changes up and down is to keep the capillary blood pressure at the same condition and remain constant. It is also to change the spiral muscles that surround the smallest arteries (arterioles) that cause changes in blood pressure⁴. Someone who does a job that expose them to heat will experience an increase in blood pressure as the work environment temperature increases. In addition, physiological changes in blood pressure will also occur when someone does excessive and continuous physical work¹¹.

**Work Climate and the Increase of Blood Pressure**

<table>
<thead>

<td>9</td>
<td>56.3</td>
</tr>
<tr>
<td>Total</td>
<td>12</td>
<td>63.1</td>
</tr>
</tbody>
</table>

Table 2 shows that respondents who work in the working environment with the unsafe work climate (exceed the threshold value) experience the increase in their blood pressure. Seven of them experienced abnormal blood pressure, while 9 of them experience an increase but still below or on the threshold limit value. Respondents who work in the safe work climate experience normal increase of blood pressure. None of them showed abnormal blood pressure. Statistical analysis showed that there is a correlation between work climate and the increase in blood pressure of construction workers in Pamekasan Regency. It is shown by the Contingency Coefficient value of 0.341, which means that there is a moderate correlation between the two variables.

Workers work under the influence of a hot environment, the brain still controls body temperature by monitoring blood temperature. However, when the blood temperature rises, the body begins to take control of the heat mechanism. Comprehensive control of the mechanism resulted in increasing body heat. This can also cause the heat regulating system to rise, which then encourages the increase of blood pressure. The increasing blood pressure makes the heart pump more
One effort to prevent workers from experiencing work-related illnesses as a result of a hot work climate is to consume mineral water at least 1 glass (150-200 cc) every 15 - 20 minutes\textsuperscript{13}. The body needs to replace fluids and electrolytes lost due to exposure to heat by drinking water. Therefore, there is a need for media promotion, periodic health checks and training for workers about health hazards due to exposure to heat\textsuperscript{10}.

**Conclusion**

The measurement result of WBGT showed that the highest is Room 1 with temperature of 28.8 °C and the lowest is in the Room 6 with the temperature of 28.2 °C. It also showed that (84.3\%) workers were exposed to beyond work climate in accordance with the threshold limit value (TLV). The measurement of blood pressure showed that 12 workers (63.2\%) showed normal blood pressure. There were 7 workers (36.8\%) who showed abnormal blood pressure. There was also a moderate correlation of work climate and the increase in blood pressure with contingency coefficient value of 0.314.

It is recommended for companies in this construction project to add blower fan to the working areas where the work climate exceeds the threshold limit value (TLV) as well as at workers’ resting places. In addition, companies are suggested to hold periodic health checks, especially routine blood pressure checks.

Relationship between Temperature and Behavior with Pulmonary TB Incidence in Women in the Banyu Urip Health Center Surabaya, Indonesia

Fenti Nur Aini Amallia1, Retno Adriyani1
1Department of Environmental Health, Public Health Faculty, Airlangga, University, 60115, Surabaya, East Java, Indonesia

Abstract

Tuberculosis was a one of infectious disease caused by Mycobacterium tuberculosis. The transmission of this disease was influenced by environmental factors and poor behaviour. Based on observation result, the working area of Banyu Urip Health Center was a densely populated area. The purpose of this research was to analyze the house physical quality and behaviour with pulmonary TB incidence in women at the working area of Banyu urip health center.

This research was observational analytic research with case control study design. The data analysis was using chi square test. The sample was taken by simple random sampling of 30 houses with pulmonary TB patients and 30 house with no pulmonary TB patients. The data collection was using questionnaire, house physical quality measurement was using observation sheets. The result of the study indicate that temperature and behavior have a significant relationship with the existence of Mycobacterium tuberculosis in house air (p<0,05).

The conclusion based on chi square test was bedroom temperature and behavior have a relationship with pulmonary TB incidence in women at the working area of Banyu urip health center 2018. The communities were expected to maintain their house physical quality by maintaining the cleanliness of the house and increasing ventilation to facilitate air circulation in the house.

Keyword: Temperaure, behavior, pulmonary TB

Introduction

Tuberculosis (TB) is an infectious disease caused by the bacterium Mycobacterium tuberculosis which more often infects the lung organs than other organs. This disease can spread through droplets of people who have been infected with TB bacilli(1). Worldwide, TB is one of the 10 causes of death and the main cause of a single infectious agent. Every year millions of people fall ill due to tuberculosis(2).

Patients and deaths from TB in most countries in the world, more common in men than women. But TB is a cause of death from infectious diseases in women. Every year, around 700,000 women die from TB, and more than three million get TB. The impact of TB on women is primarily economic and reproductive, and affects children and other family members(3).

The second highest number of TB cases in Indonesia in the last 3 years (2015 - 2017) are in East Java Province. The discovery of new TB cases in 2017 reached 22,585, in 2016 it reached 23,390, in 2015 it reached 23,487(1,4). The health profile of East Java Province shows that the city of Surabaya is the region with the highest number of TB patients in 2016 with 5,428 cases and increasing in 2017 with 6,338 case(1).
Various factors are thought to be related to the incidence of pulmonary TB in women, namely marital status, pregnancy, parity, history of DM involvement, physical activity, education level, knowledge, contact history, kitchen smoke pollution, occupancy density, and ventilation area. Various problems will arise if women suffer from TB, given the role of women, especially those who are married, pregnant, and have children. His role as a housewife who has to carry out the physical and mental care tasks of children while taking care of her husband will be disrupted\(^{(4)}\).

**Material and Method**

Research on the relationship between temperature and behavior with the incidence of pulmonary TB in women in the work area of Banyu Urip Health Center in Surabaya City was an observational analytic study that aimed to obtain an explanation of the risk of a disease cause. This study is a case-control study that is by identifying groups with certain diseases or effects (cases) and groups without effects (controls), this study uses a retrospective approach (looking back) that aims to determine the causes of disease by tracking risk factors in the incidence of tuberculosis Lung in women.

Analysis of the relationship between the incidence of pulmonary TB in women with behavior and temperature is using the chi-square test with \( \alpha \) 5%. If \( p < 0.05 \), it can be said that there is a significant relationship between the two variables so that \( H1 \) is accepted, \( p > 0.05 \), meaning that there is no meaningful relationship between the two variables, \( H1 \) is rejected.

**Findings**

Measurement of temperature variables is carried out using a thermohygrometer. Based on the results of research in the Banyu Urip Health Center Work Area, the environmental characteristics based on temperature can be seen in Table 1 below:

**Table 1. Temperature distribution in the Banyu urip Health Center Work Area in 2018**

<table>

Temperature categorization based on PMK No. 1077 of 2011 which categorizes room temperature 18 °C - 30 °C is the room temperature that meets the requirements. In Table 1, it can be seen that most of the respondents environmental characteristics are based on temperature in the case group, there are 16 (53.3%) respondents having a temperature <18 °C and >30 °C. Whereas in the control group there were 24 (80%) respondents who had a temperature of 18 °C - 30 °C which means that most control groups in the Banyu urip Health Center Work Area had temperatures that met the requirements of PMK Number 1077 of 2011\(^{(5)}\).

Behavior variables in this study were in the form of knowledge, attitudes, and actions of the case group respondents and the control group related to prevention and control efforts regarding pulmonary TB. In this study several questions were asked with a questionnaire.

Based on the research results of the respondents knowledge with 10 questions in the questionnaire in the Banyu Urip Health Center Working Area, the results in Table 2 can be seen:
Table 2 Distribution of knowledge levels of respondents in the Banyu Urip Health Center work area in 2018

<table>
<thead>
<tr>
<th>Knowledge</th>
<th>Case</th>
<th>Control</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>n</td>
<td>%</td>
</tr>
<tr>
<td>Less</td>

</tr>
<tr>
<td>Well</td>
<td>23</td>
<td>76,7</td>
</tr>
<tr>
<td>Total</td>
<td>30</td>
<td>100,0</td>
</tr>
</tbody>
</table>

Based on Table 2, it can be seen that the assessment of the level of knowledge in the case group respondents obtained less categories as much as 7 (23.3%) people and as many as 23 (76.7%) people. In addition, knowledge in the control group found that there were less categories (1, 3.3%) and 29 (96.7%) good categories. Knowledge of respondents who were still lacking was caused by respondents who did not know the causes of pulmonary tuberculosis and also many respondents who did not know how to prevent transmission of pulmonary tuberculosis.

Based on the results of the research on the attitude of the respondents with 7 questions in the questionnaire in the Banyu Urip Health Center Working Area, the results in Table 3 can be seen:

Table 3 Distribution of the attitude level of respondents in the Banyu Urip Health Center work area in 2018

<table>
<thead>
<tr>
<th>Attitude</th>
<th>Case</th>
<th>Control</th>

<td>7</td>
<td>23,3</td>
</tr>
<tr>
<td>Well</td>
<td>23</td>
<td>76,7</td>
</tr>
<tr>
<td>Total</td>
<td>30</td>
<td>100,0</td>
</tr>
</tbody>
</table>

Based on Table 3, it can be seen that the assessment of attitudinal level in the case group was obtained in the less category as many as 7 people (23.3%) and the good category was 23 (76.7%) people. In the control group, there were less categories of 1 (3.3%) people and 29 (96.7%) good categories of people. The attitude of respondents is still lacking because there are still many respondents who do not agree with how to prevent transmission of pulmonary tuberculosis.

Based on the results of the research of the respondent’s actions by being given 7 questions on the questionnaire in the Banyu Urip Health Center Working Area, the results in Table 4 can be seen:

Table 4 Distribution of respondent’s practice in the Banyu Urip Health Center work area in 2018

<table>
<thead>
<tr>
<th>Practice</th>
<th>Case</th>
<th>Control</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>n</td>
<td>%</td>
</tr>
<tr>
<td>Less</td>
<td>22</td>
<td>73,3</td>
</tr>
<tr>
<td>Well</td>
<td>8</td>
<td>26,7</td>
</tr>
<tr>
<td>Total</td>
<td>30</td>
<td>100,0</td>
</tr>
</tbody>
</table>
Based on Table 4, it can be seen that the assessment of the level of action in the case group obtained less categories as many as 22 (73.3%) people and good categories as many as 8 (26.7%) people. In the control group, there were 2 (6.7%) less categories and 28 (93.3%) good categories. The respondent’s actions that were still poor were caused by respondents being lazy and busy working especially in terms of cleaning the house such as mopping with disinfectants and cleaning spiderwebs on the walls and ceiling.

Temperature variables with the incidence of pulmonary TB in women were tested by Chi Square test. The test results can be seen in the following table:

Table 5 Chi Square Test on temperature variable with the incidence of pulmonary TB in women

<table>
<thead>
<tr>
<th>Variable</th>
<th>p-value</th>
<th>Explanation</th>
<th>OR</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Temperature</td>
<td>0.016</td>
<td>There is a relationship</td>
<td>0.219</td>
<td>protective risk factors</td>
</tr>
</tbody>
</table>

Based on Table 5 shows that the temperature variable has a relationship with the incidence of pulmonary TB in women because it has a significant p value (p <0.05). If seen from the OR value it can be said that the temperature variable that does not meet the requirements is 0.219 times more risky with the incidence of pulmonary TB in women in their homes.

Behavioral variables consisting of knowledge, attitudes and actions of respondents related to prevention and prevention efforts about pulmonary TB with Chi Square test. The test results can be seen in the following table:

Table 6 Chi Square Test on Behavior Variables with the incidence of Pulmonary TB in women

<table>
<thead>
<tr>
<th>Behavior Variables</th>
<th>p-value</th>
<th>Explanation</th>
<th>OR</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Knowledge</td>
<td>0.052</td>
<td>There is no relationship</td>
<td>0.113</td>
<td>protective risk factors</td>
</tr>
<tr>
<td>Attitude</td>
<td>0.052</td>
<td>There is no relationship</td>
<td>0.113</td>
<td>protective risk factors</td>
</tr>
<tr>
<td>Practice</td>
<td>0.015</td>
<td>There is a relationship</td>
<td>0.080</td>
<td>protective risk factors</td>
</tr>
</tbody>
</table>

Based on Table 5 shows that the knowledge and attitude variables do not have a relationship with the incidence of pulmonary TB in women because they have a p value that is not significant (p > 0.05). While the action variable has a relationship with the incidence of pulmonary TB in women because it has a significant p value (p <0.05) If seen from the OR value it can be concluded that the respondent’s actions were 0.080 times more risky with the incidence of pulmonary TB in women in his home.

**Discussion**

Temperature is the average air temperature in the house measured using a thermohygrometer. Based on the results of the study it can be seen that the temperature is related to the incidence of pulmonary TB in the Banyu Urip Health Center Work Area in 2018 (p <0.016 <0.05).

Respondents who have a temperature <18 ° C and> 30 ° C 0.219 times more at risk of pulmonary TB incidence than respondents who have a temperature 18 ° C - 30 ° C. According to Gould and Brooker, there is a temperature range that is favored by the bacteria Mycobacterium tuberculosis, in that temperature range there is an optimum temperature that allows the bacteria to grow rapidly. Mycobacterium tuberculosis is a
mesophilic bacteria that thrives in the range of 25 ° C - 40 ° C, but at 31 ° C - 37 ° C it will grow optimally(6).

Knowledge is the result of human sensing or the result of knowing someone about something through their senses. Knowledge plays an important role in forming one’s actions. Behavior based on knowledge will be longer than that which is not based on knowledge(7). Knowledge in this study is knowledge about pulmonary tuberculosis (TB).

The results of the study of 60 respondents indicated that the level of knowledge of patients and non-tuberculosis (TB) patients was good. The Chi Square test results showed that knowledge with the incidence of pulmonary TB in women did not have a significant relationship.

The research obtained results (p = 0.019 and OR = 0.107) which means that there is a relationship between knowledge and the presence of Mycobacterium tuberculosis in the air in his house. The results of this study indicate that there is no relationship between knowledge and incidence of pulmonary TB in women, but knowledge still plays a role in the transmission of pulmonary tuberculosis (TB). This happens because knowledge influences one’s actions in clean and healthy lifestyle as an effort to prevent transmission of pulmonary tuberculosis (TB)(8).

Attitude is a reaction or response of someone who is still closed to a stimulus or object. Attitude is not yet an action or activity, but it is a tendency to accept or refuse to take an action in a behavior(7).

The results of the study of 60 respondents showed that patients and non-tuberculosis (TB) sufferers had a positive or good attitude in an effort to prevent transmission and treatment of pulmonary tuberculosis (TB). While the Chi Square test results show that the action and presence of Mycobacterium tuberculosis in the air has a significant relationship, besides that the Odds Ratio (OR) value is 0.080, which means that the respondents who have a bad action 0.080 times the risk of Mycobacterium tuberculosis in the air in the environment his house.

Attitudes are very important in an effort to prevent pulmonary tuberculosis (TB), a good attitude will allow someone to have good actions. Attitude is the second stage after knowledge. The attitude is shown by someone’s interest to be willing to take an action(7).

Attitudes are not taken from birth but are learned and formed from experience and practice throughout one’s development. The formation of a person’s attitude is influenced by several factors, including personal experience, culture, other people who are considered important, mass media, educational institutions or institutions and religious institutions, and emotional factors in individuals(9).

The practice is the manifestation of attitude into a real action or activity that requires supporting factors in the form of facilities and support from various parties so that the practice can be realized. This is because an attitude does not automatically manifest in an action (overt behavior)(9).

The results of the study of 60 respondents, most of them showed good action. These results indicate that pulmonary tuberculosis (TB) sufferers are still not paying attention to clean and healthy living practices that can prevent the occurrence of Mycobacterium tuberculosis in the air which is the cause of pulmonary tuberculosis (TB). While the Chi Square test results show that the action and presence of Mycobacterium tuberculosis in the air has a significant relationship, besides that the Odds Ratio (OR) value is 0.080, which means that the respondents who have a bad action 0.080 times the risk of Mycobacterium tuberculosis in the air in the environment his house.

Actions (practices) related to disease include practices in preventing and curing diseases. The results of this study indicate that the majority of respondents both the case group and the control group had actions that tended to be bad even though they had shown a positive or good attitude in an effort to prevent transmission and treatment of pulmonary tuberculosis (TB)(10). The respondent’s practice that were still poor were caused by respondents being lazy and busy working especially in terms of cleaning the house such as mopping with disinfectants and cleaning spiderwebs on the walls and ceiling. There were still many respondents who did not cover their mouths when they sneezed or coughed and did not use masks during their daily activities on the grounds of being hot and uncomfortable. Just as respondents in the case group, which made the actions of the control group respondents still poor. In addition, they also do not limit contact with pulmonary tuberculosis (TB) patients.

**Conclusion**

From the results of the study it can be concluded that:
1. Based on the results of the analysis of the chi square test, the results showed that the behaviors that included knowledge, attitudes and actions related to the incidence of pulmonary TB in women in the Banyu Urip Health Center Working Area in 2018 were practice.

2. Based on the results of the chi square test analysis that the temperature is related to the incidence of pulmonary TB in women in the Banyu Urip Health Center Working Area in 2018.

Correlation of Standing Work Position and Musculoskeletal Disorders (MSDs) Complaints on Rack Frame Bending Section Workers in Informal Industry of Rack Making in Surabaya, Indonesia

Genduk Lintang Rusmawarda1, Endang Dwiyanti1
1Department of Occupational Safety and Health, Faculty of Public Health, Airlangga University, 60155 Surabaya, East Java, Indonesia

Abstract

This research was conducted to analyze the correlation between standing work position and complaints of musculoskeletal disorders on rack frame bending workers in the informal industry of rack making in Surabaya, Indonesia. When doing rack bending, standing work position was affected by work position. The jobs forced workers to work with non-ergonomic standing work position. This caused workers to experience complaints on the skeletal system (MSDs) faster. This research was an observational research with cross sectional design. The sample used a total population of 5 workers. Data obtained by interview, measurement of height and weight and observation of work position. The data analysis method used was descriptive statistics. It was known that due to non-ergonomic standing work position, 40% of rack frame bending workers had a moderate and high MSDs risk category while 20% of other workers were in the low category. In addition, it was known that 40% of workers had low and moderate MSDs complaints category and 20% of other workers had high MSDs complaints category. Based on the results, the standing work position on the rack frame bending workers had a strong and positive correlation with a correlation coefficient of 0.655. In addition to the work position, there was a strong correlation between age, working period, and BMI with MSDs complaints of rack frame bending workers. It was recommended that the employer adjust the frame size on each bending machine and provide seat for workers to rest.

Keywords: standing work position, musculoskeletal disorders complaints, REBA, NBM

Introduction

Musculoskeletal complaints are complaints of skeletal muscle parts that are felt by a person starting from a complaint of bearable to unbearable pain. Complaints to this disorder are usually termed musculoskeletal disorders3. According to Peter Vi, there were several factors that can cause musculoskeletal disorders (MSDs) such as excessive muscle stretching, repetitive movements, unnatural working attitudes, secondary causes, and combination factors4.

According to the European Survey on Working Condition in 2005, around 24.7% of European workers complained back pain, 22.8% complained muscle pain, and about 45.5% of workers reported working with fatigue while 35% were assigned to handle heavy loads in their work5. In Europe, this occupational disease affected millions of workers and can spend billions of euros to fund treatment for workers. Whereas in chronic cases, MSDs can even caused disability which can caused workers to stop working6.

Workers in the rack frame bending section in the informal rack making industry in Surabaya, Indonesia, worked with standing work position. This section
required workers to work with changing work position while standing, that was stooping and twisting their waist to press and lift the lever so that the rack frame can be bent. The working process of the rack frame bending section was carried out for 7 working hours/day or >50% work shift. Based on observations, it was known that the frequency of repetitive motion in rack frame bending section every 30 seconds was 6 times, and there were workers who’s complaining pain in some of their limbs.

According to previous research on welders with standing work position, showed that there was a correlation between standing work position and MSDs complaints especially on the neck, back, and shoulders, also the risk of MSDs was included in the moderate category. In addition, based on the results of research conducted on weaving workers at PT. Delta Merlin Textile, Kebakramat, Karanganyar, known that there was a very strong correlation between standing work position and musculoskeletal complaints and a positive direction of correlation.

Thus, the purpose of this research was to learn the direction and strength of the correlation between working position and musculoskeletal disorders complaints in rack frame bending section workers in the informal industry of rack making in Surabaya, Indonesia.

**Material and Method**

Based on the data collection method, this research was observational, data obtained by observing without giving any treatment to the objects of research during the research. Based on the analysis, this research was descriptive statistics, which described the process by analyzing the strength and direction of correlation between variables.

The population of this research were all workers in the rack frame bending section in the informal industry of rack making in Surabaya Indonesia, with total of 5 people. Sampling of this research used the total sampling method, namely the sample used in this research were all members of the population. Variables in this research were age, working period, Body Mass Index (BMI), work position and musculoskeletal disorders complaints. The data collected in this research were only primary data obtained by interviews, measurements of height and weight and observation of work position.

**Findings**

The research results of workers data collection about the workers age, working period, Body Mass Index (BMI), work position and musculoskeletal disorders complaints were obtained by different methods. Age and working period obtained by interview method, while BMI obtained by calculating using formulas related to measurement of height and weight.

Assessment of work position were done using the Rapid Entire Body Assessment (REBA) method. The application of REBA method is intended to prevent the risk of injury to the musculoskeletal system muscle.

<table>
<thead>
<tr>
<th>MSDs Risk Category</th>
<th>Frequency (n)</th>

<td>2</td>
<td>40%</td>
</tr>
<tr>
<td>Total</td>
<td>5</td>
<td>100%</td>
</tr>
</tbody>
</table>

The risk level of MSDs is divided into several categories, namely very low, low, moderate, high and very high risk but in this research there were no workers with very low and very high MSDs risk categories. Therefore, based on Table 1, it was known that the majority of 40% of workers had moderate and high MSDs risk category and 20% of other workers had low MSDs risk category.

For example, the risk level of MSDs on one of the rack frame bending section workers was known in the high category because it got a final score of 10 (high category final score = 8-10). The final score was obtained from the position score of the position of the neck, body, legs, upper arm, forearm, wrist, type of coupling, type of muscle activity (repetitive movements, significant changes in body posture, and unstable body posture during work) and load or workers force which were of course also significant (the position is becoming flexion-extension or getting more non ergonomic). The risk level of high MSDs category certainly required action.
to improve work posture as soon as possible to minimize and prevent the occurrence of higher musculoskeletal complaints in workers.

The assessment of musculoskeletal complaints in this research used the Nordic Body Map (NBM) method. Nordic Body Map is a method used to assess the severity of the disruption of the musculoskeletal system. This method can be used to know the level of complaints felt by workers on 28 limbs ranging from feeling bearable to unbearable pain. Determining the level of MSDs complaints can be done by seeing the result of the workers’ body map analysis.

Table 2. Frequency Distribution of MSDs Complaint Levels on Rack Frame Bending Section Workers Using NBM Method

<table>
<thead>
<tr>
<th>MSDs Complaints Level</th>
<th>Frequency (n)</th>
<th>Percentage (%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Low</td>
<td>2</td>

</tr>
<tr>
<td>High</td>
<td>1</td>
<td>20%</td>
</tr>
<tr>
<td>Total</td>
<td>5</td>
<td>100%</td>
</tr>
</tbody>
</table>

The level of MSDs complaints was divided into 4 categories, namely low, moderate, high and very high, but in this research there were no workers with very high MSDs complaints. Based on Table 2, the majority of 40% workers had low and moderate MSDs complaints, while 20% of other workers have a higher level of MSDs complaints.

Table 3. Correlation between MSDs Risk Category and Complaints Level on Rack Frame Bending Section Workers

<table>

</tbody>
</table>

The correlation between standing work position and MSDs complaints can be seen in Table 3. Based on the results of data analysis that produced the table above, it was known that all workers who had a low MSDs risk category had a moderate MSDs complaints. In addition, it was known that the association coefficient value was 0.655 which means that there was a strong and positive direction of correlation that means the higher the risk of musculoskeletal disorders complaints on rack frame bending section workers will also becomes higher. This was in line with research carried out on plywood making that there was a correlation between standing work position and musculoskeletal complaints on plywood makin in Ketapang, Kendal (p=0.001)

Research result about workers age, working period and Body Mass Index (BMI) with MSDs complaints can be found in the tables below.
Table 4. Correlation between Age and MSDs Complaints Level on Rack Frame Bending Section

</tbody>
</table>

Based on the table above, the results showed that all workers (100%) aged 20-24 years were at a high level of MSDs complaints. In that age group was dominant productive age to work, because workers in this age group will try to work for a long time to get bigger salary. According to Oborne (1995) stated that age is the main cause of complaints on muscle, because as we get older or age increases than the muscle strength decreases\textsuperscript{11}. Supported by a research stated that MSDs are the most common and symptomatic health problems in middle and old age. The results of the research revealed that the age group with the highest rate of back pain and muscle fatigue was aged 20-24 years for men\textsuperscript{12}

According to the data analysis that has been done, the age and MSDs complaints level on rack frame bending workers had a strong correlation and a positive or same direction of correlation that seen from the association coefficient of two variables by 0.756.

Table 5. Correlation between Working period and MSDs Complaints Level on Rack Frame Bending Section

<table>

<td>2 40%</td>
<td>1 20%</td>
<td>5 100%</td>
<td></td>
</tr>
</tbody>
</table>

Based on the table above it was known that workers whose 6-10 working period were mostly 67% of workers with moderate levels of MSDs complaints. According to the data analysis that has been done, working period and the level of MSDs complaints on rack frame bending workers had a strong correlation and a positive or same direction of correlation that seen from the association coefficient of the two variables by 0.607.

This was not in line with the theory which states that when a muscle receives excessive workload that is carried out repeatedly for a long time, complaints will
arise due to damage in joints, ligaments and tendons. So based on this theory, the working period was directly correlated to MSDs complaints. However, based on the results of the data analysis, it was known that the working period of the worker had a strong and positive direction of correlation or in line with the level of MSDs complaints. In accordance with research conducted on informal workers, that there was a relation between working period and MSDs complaints. Based on the results of the research, it was known that workers who experience high MSDs complaints were workers with <5 years working period not workers with a working period of >5 years.

Table 6. Relation Between Body Mass Index (BMI) and MSDs Complaints Level on Rack Frame Bending Section Workers

<table>
<thead>
<tr>
<th>BMI</th>

<td>0 0%</td>
</tr>
<tr>
<td>Total</td>
<td>2 40%</td>
<td>2 40%</td>
<td>1 20%</td>
</tr>
</tbody>
</table>

Based on the table above, it was known that workers included in the thin BMI category had complaints of low and high MSDs around 50% each, whereas in the normal BMI category, the majority of workers around 67% had moderate MSDs and the remaining 33% have low MSDs. According to a research, it was said that height, strength, and body mass were also considered could increase the risk of MSDs but the evidence is far from convincing. But based on the results of other studies conducted at maintenance workers PT. Antam Tbk 2014 UBPE, Pongkor, stated that there was a significant relation between BMI and MSDs complaints.

According to the data analysis that has been done, BMI and MSDs complaints level of workers in rack frame bending section have strong and a positive direction of correlation that can be seen from the association coefficient of both second variables by 0.607.

Conclusion

The existence of a strong degree of correlation between working position with MSDs complaints on rack frame bending section workers. In addition, the strong and same direction of the correlation (positive) between the characteristics of workers which are age, tenure, and body mass index (BMI) with MSDs complaint level. The advice given to the company is the company should be evaluating the work station that is usually occupied by rack frame bending section workers. If reshaping the work station to minimize the risk of MSDs requires a large amount of money, the employer can adjust the size of the bending machine lever to the size of the rack that is about to be bend by workers (specialization of frame size on each bending machine) to reduce workers to work with hunchback positions that are too low. In addition to reduce MSDs complaints on workers in standing work position, the employer can provide seats for rack frame bending section workers around the bending machine area so that workers can rest to relax tired limbs after work in a standing work position.

Conflict of Interest: All authors have no conflicts of interest to declare.

Genetic variation analysis and kinship relationship between Dayak Ngaju tribe and Dayak Bukit tribe through examination of core DNA of Bukit CODIS STR Locus (combine DNA index system) 13 for the purpose of Forensic Identification

Iwan Aflanie¹, Wening Prastowo², Roselina Panghiyangani³, Ahmad Yudianto⁴, Toetik Koesbardiati⁵

¹Doctoral Student in Medical Science, Medical Faculty of Airlangga University, Indonesia, ²Department of Forensic and Medicolegal Medicine, Medical Faculty of Brawijaya University, ³Department of Biomedics, Medical Faculty of Lambung Mangkurat University, Indonesia, ⁴Department of Forensic and Medicolegal Medicine, Medical Faculty of Airlangga University, Indonesia, ⁵Department of Anthropology, Faculty of Social and Political Science, Airlangga University, Indonesia

Abstract

Dayak Ngaju tribe lived scattered along the Kapuas and Kahayan river. Meanwhile, the Dayak Bukit tribe lived scattered the mountain and valley area. Kinship between Dayak Bukit and Dayak Ngaju tribe is still under debate. DNA examination is one of the most reliable methods in determining personal identity, community, and kinship relationship. FBI has recommended DNA analysis using 13 short tandem repeat loci, known as CODIS 13 for DNA test. We used the system to identify the difference between Dayak Ngaju and Dayak Bukit tribe and analyze the kinship between these two tribes. There are loci and alleles that always owned by each individual of Dayak Ngaju tribe. The Dayak Ngaju characteristic which cannot be discovered in Dayak Bukit tribe are TPOX allele 6 locus, FGA allele 25.2 locus, CSF allele 8, 10.3, 11 locus, VWA allele 13, 15.1 locus, D18S51 allele 9, 13, 18, 20 locus, D21S11 allele 34 locus, D7S870 allele 12.1 locus. Dayak Bukit tribe has locus and allele that owned by each individual of Dayak Bukit tribe. The Dayak Bukit tribe characteristic which cannot be discovered in Dayak Ngaju tribe are FGA alleles 18.3, 19.3, 21.2, 23, 23.1 locus, CSF allele 28.2 locus, D7S870 allele 7.3 and allele 8 locus. The similarity of Dayak Ngaju tribe and Dayak Bukit tribe lied on 5 dominant loci named THO1 allele 9.3 locus, D5S818 allele 11, VWA allele 16, D3S1358 allele 16, D13S317 allele 8, but these loci are also found in Banjar Hulu tribe. The similarity that only discovered in Dayak Ngaju and Dayak Bukit tribe are located in TPOX allele 7 locus, FGA allele 20.2, 20.3, and D3S1358 allele 15.2. According to the research results above, it can conclude that Dayak Ngaju tribe doesn’t have a close kinship to the Dayak Bukit tribe.

Keywords: Dayak Ngaju tribe, Dayak Bukit tribe, Identification, Kinship, CODIS 13

Introduction

Dayak tribe are considered as the original inhabitants of Borneo Island. Dayak tribe is divided into approximately 405 sub-tribes.¹ The Dayak tribe existence’s spread throughout the Borneo Island, they lived scattered on the headwaters, highlands, valleys, and foothills. There have been some difference of opinion about the Dayak Bukit (Dayak Meratus) tribe population’s origin. According to Tjilik Riwut, The Dayak Bukit tribe population is part of Dayak Ngaju tribe but it is still in doubt because there are differences in language and beliefs aspect.² Whereas Idwar Saleh argues that the Dayak Bukit tribe is the South of Borneo Island original inhabitants who used to inhabit the coastal area and outskirts of Tabalong river, but due to the arrival of Melayu immigrants in 400-500 A.D. They were excluded to the mountain area.³

The absence of acurate data about different characteristics of these tribes may cause difficulties in further identification. In the aspect of forensic medicine, DNA profile plays a role in identifying the perpetrators and murder victims, sexual violence, mutilation victims,
mass disaster victim, and can be used to determine paternity.\textsuperscript{4}

Examination of Short Tandem Repeats (STR) in the core of Deoxyribonucleic Acid (DNA) is often used in the determination of genetic variation and forensic identification. The STR is generally an area that does not encode proteins but has a simple repetition of nucleotide motifs. Alleles at the STR locus are vary greatly depending on the number of its motif units, so that it can be used to study population sub-structure and short-term evolution and also to measure the phylogenetic relationships of its each populations. STR can also used as a marker in observing population proximity from ethnic, linguistic, cultural, and historical population aspects. In 1990, Federal Bureau of Investigation (FBI) began a DNA mapping project using Combine DNA Index System (CODIS). The FBI has recomended DNA analysis using the STR CODIS locuses in the identification process.\textsuperscript{5}

By conducting DNA analysis through the STR CODIS locuses, it is expected to be able to find and explain the genetic variation of Dayak Bukit and Dayak Ngaju tribe so that data can be used for the benefit of forensic identification and law enforcement, beside that it can be also be known the kinship between these two tribes.

\textbf{Materials and Method}

This type of research is descriptive observational, which is one type of research that aims to provide an explanation and real facts in the field that depending on the situation about the genetic variation of the Dayak Ngaju tribe and Dayak Bukit tribe, and the kinship between these two tribes, with a cross sectional design. The sample consisted of 35 volunteers (18 people from the Dayak Ngaju tribe and 17 people from the Bukit Dayak tribe) aged over 21 years who agreed to donate their blood for genetic studies. All volunteers were asked and confirmed that they were from the Dayak Ngaju tribe or Dayak Bukit tribe along 3 generations. Blood is taken from the arm vein based to the standard protocol for DNA isolation. The laboratory analysis did in Genetic Laboratory of Tropical Disease Center, Faculty of Medicine, Airlangga University. All performed procedure had got the ethical approval from the Ethical Committee of Medical Research, Faculty of Medicine, Lambung Mangkurat University.

DNA is isolated from the blood using the Nucleospin Blood Quick Pure device. Amplification of 13 STR loci was carried out using PCR (Takara) application, with a total volume of 10 μl per tube consisting of 6 μl ddH2O, 10 μl PCR master mix kit (10x buffer Taq polymerase, dNTP, MgCl2, primer, Taq DNA Polymerase, ddH 2O), 1 μl primary forward, 1 primary reverse and 2 μl blood genomic DNA with 94° C PCR 1 minute cycle for pre-denaturation, followed by 35 cycles of 94 ° C 1 minute denaturation, 60 ° C 1 minute for strengthening process, and 72 ° C 1 minute for extension, and one cycle 72 ° C for final incubation.

In the PCR result DNA that have been amplified using the primary STR CODIS are carried out electrophoresis using polycrilamide composite gel to determine the success of these DNA amplification and continued by analysis of each electrophoresis result.

The alleles frequency for each CODIS 13 locus was analyzed to determine the genetic variation and kinship relationship between the Dayak Ngaju tribe and Dayak Bukit tribe.

\textbf{Results and Discussion}

Based on this study results, Dayak Ngaju tribe has loci and alleles that owned by each individual of Dayak Ngaju tribe which are D8S1179 allele 12 locus and D16S539 allele 12 locus. Alleles on these locuses are distinctive markers for Dayak Ngaju tribe. Therefore in order to determine an individual as a member of the Dayak Ngaju tribe population, the alleles at these loci must be present. On the other hand, the Dayak Bukit tribe has their characteristic locus and allele which owned by each individual of Dayak Bukit tribe which are TPOX allele 9 locus, D13S317 alelle 8 locus and D8S1179 allele 12 locus. Alleles at these loci are distinctive markers for the Dayak Bukit tribe. Therefore, in order to determine an individual as a member of the Dayak Bukit tribe population, the alleles at these loci must be present.

The distinctive features of the Dayak Ngaju Tribe which cannot be discovered in the Dayak Bukit tribe are the presence of TPOX allele 6 locus, FGA allele 25.2 locus, CSF allele 8, 10.3, 11 locus, VWA allele 13, 15.1 locus, D18S51 allele 9, 13, 18, 20 locus, D21S11 allele 34 locus, D7S870 allele 12.1 locus. The presence of alleles at these loci is very valuable, in order to distinguish the Dayak Ngaju tribe from the Dayak Bukit tribe. While the distinctive characteristics of the Dayak Bukit tribe that cannot be discovered in the Dayak Ngaju
tribe are the presence of the FGA alleles 18.3, 19.3, 21.2, 23, 23.1 locus, CSF allele 28.2 locus, D7S870 allele 7.3, 8 locus. Therefore, the presence of alleles at these loci can distinguish the Dayak Bukit tribe and the Dayak Ngaju tribe.

<td></td>
</tr>
<tr>
<td>• D21S11 allele 34 locus</td>
<td>• D7S870 allele 12.1 locus</td>
<td></td>
</tr>
</tbody>
</table>

In this study, it was known that the Dayak Ngaju tribe had 215 heterozygous alleles and 45 homozygous alleles, indicating that the Dayak Ngaju tribe had heterogamous patterns of marriage. Dayak Ngaju population has exogamous pattern of marriage. While the Dayak Bukit tribe had 214 heterozygous alleles and 42 homozygous alleles, indicating that the Dayak Bukit tribe has a heterogamous pattern of marriage. Dayak Bukit population has exogamous marriage patterns.

The Dayak Ngaju and Dayak Bukit tribes respectively have specific loci with the same allele which are TPOX allele 7 locus, FGA allele 20.2, 23.3 locus and D3S1358 allele 15.2 locus. Meanwhile, these two tribes also has similarities at the THO1 allele 9.3 locus, D5S818 allele 11 locus, VWA allele 16 locus, D3S1358 allele 16 locus, D13S317 allele 8 locus, D8S1179 allele 12 locus, but the presence of these loci based on research are also found in the Banjar Hulu tribe.

From the this study results, we know that the Dayak Ngaju tribe does not have a close relationship with the Bukit tribe. The reason that might be the cause of their low level of kinship is geographically separated, where the Dayak Bukit tribe inhabits the highlands of the Bukit Mountains while the Dayak Ngaju Tribe inhabits the watersheds that far from the Bukit Mountains. The Dayak Ngaju tribe lived scattered the Kapuas River and Kahayan Rivers with extensive distribution, mainly in Palangka Raya, Pulang Pisau, Gunung Mas, Kapuas, Katingan, East Waringin City and Seruyan. The Dayak Ngaju villages are scattered along the river with the far distance between villages and scattered, as well as their lamin or betang (Dayak Ngaju houses). On the other
hand, the Dayak Bukit tribe occupied the forest area of Bukit Mountains. They lived scattered the mountain and valley area between the river stream. The main villages are villages that have never been abandoned, while the location of their underling village is far apart. Between one underling village and the other are separated by mountains, forests and rivers, with springs as a natural barrier.

Their low level of kinship is in accordance to the previous research which states that the population inhabiting the Bukit mountains is not a Dayak, but coastal Malay residents who migrated into the forest of Bukit Mountain.6,7

Conclusion

Dayak Ngaju tribe has loci and alleles that only owned by each individual in the population, namely D8S1179 allele 12 locus and D16S539 allele 12 locus. Dayak Bukit tribe has the locus and allele that only owned by each individual in the population, namely TPOX allele 9 locus, D13S317 allele 8 locus, D8S1179 allele 12 locus. The presence of these loci and alleles is a distinctive marker for these two tribes. The Dayak Ngaju tribe doesn’t have a close kinship with the Dayak Bukit tribe.

Occurrence of Emerging Pollutants in Skudai River in Johor Bahru Region of Malaysia

Juhaizah Talib1,2, Azmi Aris1,2, Jafariah Jaafar3, Zaiton Abd Majid3, Ainul Syarmimi1

1School of Civil Engineering, Faculty of Engineering, Universiti Teknologi, Malaysia, 81310 Skudai, Johor Baru, Malaysia, 2Centre for Environmental Sustainability and Water Security (IPASA), Universiti Teknologi Malaysia, 81310 Skudai, Johor Baru, Malaysia, 3Department of Chemistry, Faculty of Science, Universiti Teknologi, Malaysia, 81310 Skudai, Johor Baru, Malaysia.

Abstract

Increase in landuse development and human activities have significant influence on the occurrence of emerging pollutants (EPs) in water bodies such as rivers. As rivers are the main source of water supply in Malaysia, a study was conducted to determine the occurrence of EPs in one of the drinking water sources, namely Skudai River. Samples were collected five times at eight sampling points from the upstream up to the water intake of the river. Sample pre-treatment was performed by solid-phase extraction (SPE), whereas the analyses of the EPs were performed by Liquid Chromatography-Mass Spectrometry (LCMS-MS QTOF). Results showed that about 50 compounds were detected and fall into categorise as pharmaceuticals, Personal Care Products (PCPs), and Endocrine Disrupting Chemical (EDC). The most prevalent (75-100%) compounds detected were of these categories, whereas the least (less than 40%) were mainly pharmaceuticals. The concentration of styrene, a health-hazards EPs ranged from 45.11 to 203.48 µg/L with increasing trend towards downstream of the river. Based on the landuse data of Skudai River Basin, the study concluded that human activity, landuse, and environmental factors could possibly contribute to the presence of the EPs in the river.

Keywords: pharmaceutical, personal care products, styrene, endocrine disrupting chemical, Skudai River

Introduction

Emerging pollutants (EPs) are defined as synthetic or naturally occurring compounds that are not often monitored but have the potential to enter the environment causing known or suspected adverse ecological and human health effects (1–3). They are categorized into more than 20 classes based on their origin. The most important classes are pharmaceuticals, personal care products (PCPs), pesticides, by-products of disinfection, wood preservative and industrial based chemicals (3,4).

Emerging pollutants have been detected in surface water, groundwater, treated water and in effluent of wastewater treatment plants (WWTPs) (5). Several countries including UK, US, and Japan had reported the presence of PPCPs in concentrations ranging from ng/L to µg/L in WWTPs (6). In addition, EPs are also released from diffuse sources through atmospheric deposition or from crop and animal production (3,7,8).

One of the main concerns with regards to EPs is their ability to alter the normal function of endocrine systems and give adverse effect in animals and human. These EPs, known as Endocrine Disrupting Chemicals (EDCs), act by blocking, mimicking, development disorders and alter function systems of hormones in animals and human body (9–11).

Skudai River is an important river in the district of Johor Bahru as it is one of the sources of water supply in the area. The river originates from oil palm plantation and flows through several townships and industrial areas before it reaches the water intake point. As the river is exposed through various landuse and human activities, the river is anticipated to receive different types of pollutant including EPs. Being the source of water supply, it is of our interest to investigate the impact of the landuse and human activities on the occurrence of the EPs in the Skudai River. This paper reports the findings of the study on EPs conducted over a one-year period.
of 2016-2017 and quantifying the presence of styrene in Skudai River.

Methodology

The Study Area

The Skudai river is 46 km length with basin coverage area of 325 km². Skudai River is located in the southern part of Johor. The river starts from Sedenak area and flows down to the Straits of Johor. The average monthly rainfalls in the Skudai River basin is 169.5 mm with the highest rainfall occurring in October to November (12). The upstream of the river is mainly covered by oil palm plantation while the central and downstream of the river are mainly urbanized.

Sampling

The water samples were taken at eight sampling points. The surrounding landuse of the sampling points is shown in Table 1. Five sampling exercises were conducted during the study. Grab samples were taken at about 0.5 m depth from the water surface. Samples were kept in clean amber glass bottles at temperature below 4°C prior to analysis. The collected samples were analysed within 48 hours of sampling.

Chemicals

Methanol and acetonitrile were of gradient grade for liquid chromatography and purchased from Merck, Germany. Styrene standard solution was obtained from Sigma Aldrich, USA. Ultra-pure water was produced using Sartorius H₂O PRO-UV-T Arium.

Analytical Method

Sample extraction procedure

Chromabond C18 (500 mg, MachereyNagel, Germany) was used for the SPE process. SPE cartridges were used on a 10-fold vacuum extraction box (Vacmaster10, MachereyNagel, Germany). The cartridge was first conditioned with 5.0 mL of methanol, followed by 5.0 mL acetonitrile, and finally, 5.0 mL of ultrapure water. Water sample of 500 mL was eluted at 10 mL/min. After the sample passed through the cartridge, 5.0 mL of ultrapure water was eluted from the cartridge followed by drying under vacuum conditions for about 30 min.

The analyte in the cartridge was eluted with 2.5 mL acetonitrile, followed by 2.5 mL methanol. The eluted part was collected in soda glass tubes (Samco, England) and air-dried until dryness. The residue was dissolved in 2.0 mL of the same solvent and capped with a poly stopper. The extract was transferred to a 2.0 mL glass vial (Agilent Technologies USA) with flexible stopper and injected into LCMS-MS QTOF.

Liquid Chromatography-Tandem Mass Spectrometry of Quadrupole Time of Flight

After pre-treatment, the samples were analysed using Liquid Chromatography-Tandem Mass Spectrometry of Quadrupole Time of Flight (LC-MS-MS QTOF) (Agilent 6560 IM-QTOF). The capillary column used was Zorbax Extend-C18(2.1X50 mm/1.8 micron), equipped with a splitless injector. Purified helium (99.99%) was used at a flow rate of 1.6 mL/min as the carrier gas. The oven ramp was set to an initial temperature of 70°C, (and held for 2.0 min), followed by an increase to 100 °C at a rate of 5 °C per min (held for 2.0 min), to 200°C at 5°C/min (held for 2.0 min) to 250°C at 5 °C/min (held for 2.0 min) and increased stepwise up to 250°C with a total run time of 32 minutes.

Results and Discussion

Characterisation of EPs

The occurrences of EPs along with its percentage of detection during the sampling exercise are shown in Figures 1 to 3. About 50 compounds of different types were detected and they are categorized into three, namely pharmaceutical, PCPs and EDCs. The
The pharmaceutical group comprises of medicines, antibiotics, supplements, and steroids, while the PCPs comprised of soaps, surfactants, perfumes, lotions, toiletries and cosmetics. The EDCs are those related to manufacturing industries such as plasticizers, resin and polymers.

Figure 1: Frequency of detection of pharmaceutical compounds

Figure 2: Frequency of detection of personal care product compounds
Of the pharmaceutical compounds detected, majority of them are detected at a frequency of more than 50%. Eighteen compounds were detected at 75% and more, while only four compounds were detected less than 50%. Seven of these pharmaceutical compounds were detected at all samplings. As for the PCPs, only one of the eight compounds was detected less than 50% frequency, while five were detected at 75% and above, including two were detected at all samplings. All the EDCs were detected at 50% frequency and more with four of them detected at all samplings.

The findings of the study indicate that the water of Skudai River comprised of mixtures of EPs as it received effluent discharges from sewage treatment plants and industries which are located in Kulai and Senai areas. Additionally, sullage from the housing areas and shop houses, and urban runoff during rainy season contribute to the river pollution. The presence of the EPs in the river water suggest their poor biodegradability or resistance that results in their leaching into the environment. In the long run, these compounds, particularly EDCs, can exert adverse health effects to human and the environment due to accumulation even under exposure at low concentrations (13). As Skudai River is used for the source of water supply, further study is therefore needed to determine the ability of the conventional water treatment process in removing these EPs.

**Styrene**

Styrene is a semi-volatile organic compound found in daily use and the industrial production of numerous chemicals and industrial products (14). It is considered a carcinogenic compound with significant risk of cancer, as well as toxic and mutagenic effects on humans. Styrene is regarded as a potent toxin with potential adverse effects on the renal, respiratory, nervous, and gastro-intestine systems of humans (15,16). As styrene was detected in Skudai River at a very high detection frequency (ie. 90%), and due to its health hazards, further study was carried out to determine the concentration of styrene in the water samples. Table 2 presents the concentration of styrene based on the five sampling exercises at the different sampling points. The concentration of styrene was determined using LC-MS-MS based on the calibration curve made using styrene standard solutions of 200, 250, 500, and 1000 µg/L.

\(^{+}\)ND – Not detected

Based on the average values of each sampling points, the concentration of styrene increased along the path of Skudai River from 45.11 to 203.48 µg/L. The highest and lowest concentrations were observed at P1 and P5, respectively, although P8 also recorded a relatively high concentration of styrene at 181.95 µg/L. The results reported for P1 can be ascribed to its location in a less densely populated but predominantly agricultural area compared to P5 which is located in the heart of the industrial belt. Styrene is an important raw material for the large-scale production of plasticisers, beverages, and PCPs \(^{(14)}\). Therefore, the high concentration observed at P5 is expected since numerous factories in the vicinity utilize styrene as their raw material. The presence of styrene in the water samples examined in this study suggests that the wastewater treatment in these areas requires further attention.

**Conclusions**

The study presented preliminary findings on the occurrence and detection of EPs in Skudai River in Johor Bahru region of Malaysia. The detection technique employed was LC/MS-QTOF. The selected method was based on the preliminary assessment of EPs in selected river water samples, which was found to be sensitive and selective for the characterisation of some pollutants. The results showed that the detected compounds could be broadly categorised as pharmaceuticals, PCPs and EDCs. Some of the compounds in these categories were detected at 100% frequency. Some of the pharmaceutical compounds, however, were detected, the least prevalent (Less than 40%). Furthermore, the concentration of styrene was examined and found to be present in the range 45.11 to 203.48 µg/L. The results highlight the urgency to examine the discharge of EPs such as styrene in Skudai River. It is envisaged that such measures will help to forestall future risks to human health, safety, and the environment.

Relationship of Individual Factors, and Social Factors with Mother’s Intention to Continue Early Marriage Tradition in Indonesia

Nurma Fuji Astutik¹, Ira Nurmala¹

¹Department of Health Promotion and Behavioral Sciences, Faculty of Public Health, Universitas Airlangga, 60115, Surabaya, East Java, Indonesia;

Abstract

Early marriage is a marriage conducted by teenagers under the age of 20 who are not ready to carry out a marriage. Indonesia ranks 37th in the world and 2nd in ASEAN as a country with high rates of young marriage. Marriage at a young age affects physical, psychological and social health. The tradition of getting married at a young age is still high in Sumenep Regency. Sumenep Regency occupies the first position on the island of Madura with 2692 married women <20 years old. This happens because the tradition of young marriage still continues as a result of low individual understanding and supported by social factors. The purpose of this study was to analyze the relationship of individual factors and social factors to the mother’s intention to continue early marriage tradition in Sumenep Regency.

This is a descriptive study using a qualitative approach. The method of data collection was performed qualitatively using in-depth interview and observation methods. The research instruments in this study were observation sheets and interview guidelines with a total of 32 main and key informants. Data analysis was performed using qualitative analysis including content analysis, analytical procedure, and translations.

This study shows that in Sumenep, mothers with history of experiencing young age marriage had the intention to continue the tradition of early marriage. The mothers’ intention to continue the early marriage tradition is formed due to the existence of individual factors of past behavior and social factors including education, employment, culture, first marriage and religion.

The conclusion of this study is that early marriage will continue. Therefore, cross-sector collaboration between central and regional governments, community leaders and related agencies (KUA and Health center) to reduce and prevent the occurrence of marriage of young children is required.

Keywords: early marriage, tradition, child marriage

Introduction

Early marriage is conducted by teenagers under the age of 20 who are not ready to carry out a marriage. It has an impact on physical, psychological and social health. According to Abdurradjak, et al (2016) marriages under the age of 20 years lead to pregnancies under the age of 20 years which result in complications. There were 764 cases of complications consisting of pregnancy complications, complications of labor and complications of the baby’s delivery(1). The psychological impact arises in 5 out of 6 married women of young age who are not ready to play a role in the household. The social impact arises in 2 out of 6 married women at a young age in the form of a bad relationship with the community(2).

Early marriage is related to maternal death and infant mortality. The World Health Organization (2012) stated that 90% of the 16 million young women who give birth every year are married and 50 thousand of them died. The risk of maternal mortality and mortality of newborns is 50% higher born to mothers of <20 years than mothers of ≥20 years\(^3\).

Sumenep is one of the districts with highest number of early marriage with brides younger than 20 years in Madura. Based on the results of data collection from BKKBN East Java province in 2017, the number of women who were married for the first time at the age of <20 years was 2692 people\(^4\). Factors that influence the occurrence of early marriage in Sumenep Regency is the existence of early marriage tradition formed by customary law combined with religious understanding about Islam and the social environment.

Tradition is a hereditary habit. Every tradition carried out by the community usually has the meaning and benefits perceived the perpetrators of the community. This tradition also encourages people to increasingly do and obey certain social orders\(^5\).

The elaborated description shows that individual and social factors lead to early marriage. The researchers were interested in conducting research on the relationship of individual factors and social factors with the mother’s intention to continue the tradition of child marriage in Sumenep Regency.

The purpose of this study was to analyze the relationship between individual factors and social factors with the intention of mothers to continue the tradition of early marriage in Sumenep Regency.

Material and Method

This is a descriptive study with a qualitative approach. The informants in this included main and key informants. The main informant in this study was the first-married woman <20 years old. Key informants include husbands, parents, community leaders and health workers. A total of 32 informants were included in this study.

Determination of 32 informants was carried out based on two principles of qualitative sampling including suitability and adequacy. Data collection was performed qualitatively using in-depth interview and observation methods. The research instruments in this study were observation sheets and interview guidelines. Data validity was checked using source triangulation.

Data analysis in this study used qualitative analysis. The data analysis stages were content analysis, analytical procedure, translations.

a. Content analysis

The activity carried out is to determine the informant in accordance with predetermined criteria. Data from in-depth interviews were converted into transcripts and read repeatedly for understanding.

b. Analytical procedure

The activity carried out is to make a collection of interview data to be analyzed. The next step is giving category terms to people/groups with the same potential. These categories are arranged in a coding book in the excel application. Coding books are also compiled to facilitate further analysis.

c. Translations

Interviews were conducted in Madurese Language. Madurese was used to adjust the language used by informants to make it easier to extract information from informants.

Findings

The main informants in this study included 10 informants with the first age of marriage <20 years. The key informants included 22 informants including husbands, parents, community leaders, health workers.

Based on research, individual factors appeared in ten informants with history of early marriage. The tradition of matchmaking in Sumenep Regency is high. The reasons for the matchmaking among the 5 informants was of family relations, 2 informants were physical growth, and 2 informants were the elderly people in the family.

Based on the research, social factors were related to the marriage of young children including education, employment, culture, age at first marriage, and religion. Of the ten informants, 8 informants had elementary school level and 2 informants had junior high school education. In terms of work, the informants’ jobs are as follows: Housewives (5 informants), Farmers (3 informants), Shop employees (1 informant), Laborers (1 informant).
The first age of the informant’s marriage varies. The lowest age is 13 years and the highest age is 19 years. The culture of young marriage in Sumenep Regency was revealed by ten informants with a marriage age range of 15-17 years for girls. The marriage tradition of young age is inseparable from religion. The ten informants adhered to Islam. Religious reasons are one of the factors in the tradition of young marriage in society.

The interview results showed that 6 out of 10 informants had the intention to continue the marriage of children at a young age. A total of 4 informants did not have the intention to continue the marriage of children at a young age.

Discussion

Individual factors are actions or activities carried out by informants in the past related to the occurrence of his first marriage at a young age. The results of the study showed that informants carried out young marriages because of arranged marriages by their parents in the past. In line with the research conducted by Munawarah, et al. (2015) the occurrence of young marriage in Madurese society was due to child marriage conducted by parents (6).

The reasons for matchmaking include family relationships, physical growth, and elderly people in the family. First, matchmaking on the grounds of family relations still occurs because parents want to re-strengthen the relationship between families and to bring families closer. Matchmaking was carried out since the informants was still toddler with his own family to bring the family relationship closer together. The union of families is carried out to continue family tree. Matching a child with someone who is still in a family relationship is a separate control for parents. Parents will find it easier to help solve a problem if there is a child domestic conflict.

Second, matchmaking takes place on the grounds of physical growth. Physical growth is a benchmark for people to marry off their children. Girls have fast physical growth, are easily seen and discussed by the community. Fast physical growth is characterized by a high and full body size. When children have attracted attention, parents experience promiscuity. Parents will immediately receive a male application without having to listen to the child’s opinion.

Third, matchmaking with the reasons of elderly people in the family that elderly people can see their grandchildren and grandchildren get married before he dies. The elderly person is the oldest person in the family, grandfather, grandmother, great-grandfather, and great-grandmother. Elderly people feel happy if they can still see their grandchildren getting married.

The tradition of matchmaking has become a separate law in the community. This makes the marriage behavior of young children difficult to prevent. This behavior will continue to be applied and become an individual factor to encourage mothers to continue the marriage of young children.

In addition to individual factors, there are also social factors that encourage mothers to continue the marriage of young children. Ajzen (2005) adds social aspects in background factors including education, work, culture, age of first marriage, and religion because it has something to do with one’s intention to do a certain behavior (7). The results of the study show that most of the informants had a low level of education, namely elementary school graduates. Low education affects the mother’s intention to marry her child at a young age. This is supported by research conducted by Anisa (2015) that the higher the parental education, the more positive the parents’ attitudes toward young age marriage (8). Education is one of the factors that influence a person’s perception. Education makes it easier for people to accept or choose a better change. The level of education illustrates the level of maturity of a person’s personality in responding to an environment that can influence thinking insight or respond to knowledge around him (9). Informants with a low level of education have insufficient knowledge and understanding of the impact that will occur when marrying young children. Informants tend to assume that marriage at a young age is a normal thing to do and does not feel a very visible impact.

The results showed that the majority (5 informants) worked as housewives (IRT). The community has a view that women do not have to work, enough to be a housewife by taking care and looking after the house. Similar to the research conducted by Munawarah, et al. (2015) women do not have freedom in the workplace (6). This view influences the informant’s intention to immediately marry off his child so that he can help him in terms of housewife’s work and looking after the house. After the child is married, the girl will live with her parents. It is a tradition of the community that most
married girls will live in their parents’ homes.

Early marriages and marriages have become a tradition in Sumenep community, even becoming customary law. The results of the study revealed that most girls have been married at the age of 15-17 years. According to Musfiroh (2016) the cultural and religious values that developed in the community were the driving factors for the occurrence of early marriage[10]. Culture has become the most influential factor in marriage behavior aged <20 years. The community has made marriage a young age as a local customary law that is obeyed by the community so that its implementation is considered normal.

Informants in this study revealed that they followed a culture or tradition that is the habits that exist in society. All behaviors that they will do must be in accordance with local behavior. Like early marriage, if marrying a child at a young age has become a culture of society, then any prevention will not be able to inhibit the implementation of marriage.

The other social factor is age. The age in this study focused on the age of women during the first marriage. The results showed that the lowest age of married women was 13 years and the highest age was 19 years. Ten informants in this study married for the first time under the age of 20 years. Girls in Sumenep Regency will be rushed to marry to prevent deviations from religion. Informants in this study revealed their fear of child relationships because nowadays it is easy to prioritize relationships before marriage (courtship). Khaparistia & Edward (2015) in their research revealed that girls had known dating since the age of 15 years[11]. As a result, informants anticipate this by marrying off children at a young age so as not to prioritize lust. Various methods are used to be able to marry off children at <2 years of age including age manipulation. According to Munawarah, et al. (2015) age manipulation is considered legitimate, because the aim is only to get a marriage book. Manipulation of age and married sirih has become a common thing for the people of Sumenep because the most important thing for the community is marriage and marriage witnesses. In addition, there is no other thing that can hinder the occurrence of marriage[6].

The results showed that there were 6 informants who had the intention to continue the marriage tradition of young children. This intention arises because of individual factors and social factors that encourage informants to marry off children at a young age. The informant in this study revealed that the intention was to marry off a child at a young age because he saw his past who was married at a young age. According to the informant, getting married at a young age does not have a loss. This shows that there is a relationship between individual factors with the mother’s intention to marry off a child at a young age.

Furthermore, there are also social factors that are also related to the emergence of the intention of the mother to marry off the child at a young age. The social factors are education, work, culture, first age of marriage, and religion. Social factors have a greater influence than individual factors. This is because informants are more obedient to culture and religion. Sumenep community cannot be separated from culture and religion. Culture and religion have merged into one in the order of life of society. The emergence of the prevailing Tradition in the community regarding the marriage of young age provides a positive perception for informants. According to Anisa, et al. (2015) people will follow traditions while according to the community this is good to do and not against religion[8].

**Conclusion**

Based on the explanation above, it can be concluded that of the 10 main informants in Sumenep Regency:

1. Ten informants had past experience of arranged marriages.
2. Most of the informants (8) only had primary education.
3. Most informants (5) work as housewives.
4. Early marriage culture still exists for girls of 15-17 years.
5. Ten informants had the first marriage at the age <20 years.
6. Ten informants adhered to Islam.
7. Married mothers of young age in Sumenep Regency had the intention to continue the marriage tradition of children aged <20 years.
8. There is a relationship between individual factors and social factors with the mother’s intention...
to continue the child marriage tradition in Sumenep Regency.

**Recommendation**

1. Mothers need to include children in any issues related to children, including marriage problems.
2. Parents need to fulfill children’s educational rights to reduce the risk of marriage of young children.
3. Health workers need to improve interventions in school youth evenly to increase their knowledge and understanding of the impact of young marriage.
4. Community leaders need to develop an atmosphere about marriage and the importance of mental readiness to deal with domestic life with parents and the community.
5. The Education Agency needs to provide intervention to the community regarding the fulfillment of children’s education rights with a minimum fulfillment of children’s education to high school (High School)

Knowledge, Attitude and Practice of Menstrual Hygiene among Primary School Adolescents in Surabaya, Indonesia

Pinesa Rachma Andani
Faculty of Public Health, Airlangga University, Surabaya, Indonesia

Abstract

Background: Menstruation is a normal physiological process of an adolescent female. Adolescence is a very important transition period that requires special attention to ensure progress for all girls. Some studies found that menstruation is taboo to be discussed and many girls just known about menstruation when they have menarche. The genitourinary becomes more sensitive and susceptible to infection during the menstruation period. So the appropriate menstrual hygiene practice is very important to maintain the health of reproductive organs. This study objective is to assess the current knowledge, attitude, and practice of primary school adolescents on menstrual hygiene management in Surabaya, Indonesia.

Method: This is a descriptive cross-sectional study that was carried out from May to June 2019 in a primary school in Surabaya. This study was done among 78 students selected through total population sampling from a primary school in the urban area of Surabaya.

Results: The findings showed that 66.7% of participants have good knowledge, 60.3% have a good attitude and 79.5% have good practice regarding menstrual hygiene.

Conclusions: The majority of the participants have good knowledge, attitude and practice regarding menstrual hygiene. Nevertheless, the knowledge, attitude, and practice of all the participants still need to improve. The school along with the parents and health provider are expected to reinforce the health education program about menstrual hygiene management.

Keywords: Knowledge, attitude, practice, menstrual hygiene

Introduction

Menstruation is the release of blood from the uterus which is a natural process experienced by women because of the decay of the uterine wall when the egg is not fertilized by sperm cells. Menstruation lasts 2 to 7 days which occurs every 28 days.[1] Menstruation is a natural physiological process in adolescent females who usually experience it for the first time at the age of 9-12 years.[2]

Menstrual hygiene is the act of maintaining cleanliness during menstruation. This act such as cleaning the genitals properly and changing pads every 3-4 hours. Poor personal hygiene during menstruation can increase the potential for reproductive tract infections. To be able to practice menstrual hygiene properly, good knowledge about menstruation and menstrual hygiene management are needed.[3]

Health effects found based on the Menstrual Hygiene Management Research, one in four women reported problems with itching or pain in the pubic area and 9% stated pain during urination during menstruation. This is because they use sanitary pads too long because they cannot replace it at school. While the impact on education is decreasing participation and learning ability in schools due to illness, low concentration, and fear of being translucent or leaky.[4]
Many girls don’t have the understanding that menstruation is a normal biological process. They just find out when menarche or when they have menstruation for the first time.[5] Only 1 in 44 (2%) of elementary school students and 8 of 31 (26%) of junior high school students have an understanding that menstruation is a biological aspect, their knowledge is very limited. Their knowledge of menstrual hygiene is mostly not appropriate according to the recommended standards. In general, female primary school students also don’t understand what reproductive organs are and how they relate to menstrual hygiene.[1]

The main purpose of this study is to assess the knowledge, attitude, and practice of menstrual hygiene among primary school students in Surabaya.

**Material and Method**

This is a descriptive cross-sectional study. This study was carried out from May to June 2019 in a primary school in Surabaya. This study was done among 78 students selected through total population sampling from a primary school in the urban area of Surabaya.

Measuring instruments in this study using a questionnaire made by the researcher based on theoretical concepts and have been tested its validation and reliability. The level of knowledge, attitude, and practice were measured by using a set of five knowledge related questions, six attitude related statements, and eight practice-related questions. Each correct answer of knowledge and practice items were given score one and zero for an incorrect answer. The attitude item was measured four points Likert scale. All scores were summed and classified into two categories, good (the one with a score higher or similar to median) and poor (the one with a score less than the median).

**Findings**

The respondents involved in this study were 10-13 years old. The frequency distribution of the respondents was at most 12 years old with a percentage of 43.6%. As many as 23.1% of respondents were 13 years old and only 3.8% were 10 years old.

The majority of the respondents (46.2%) experienced menarche at the age of 11 years. As many as 28.2% experienced menarche at 12 years of age, 23.1% at the age of 10 years, and only 2.6% at age 13 years.

Most respondents have early menarche so they are vulnerable to early menarche impact which could affect their lives both socially and biologically. The younger age of menarche causes an unwanted pregnancy that causes premarital sexual activity. How it will increase the prevalence of illegal abortion and sexually transmitted diseases in adolescents.[6]

Respondents stated that information about menstruation and personal hygiene menstruation is very important to know. So they try to get this information from various sources. Some sources of information mentioned by respondents included family members (85.9%), teachers (32.1%), internet (26.9%), friends (15.4%) and books (11.5%).

On the other hand, the school or teachers only delivered a minimum menstrual-related study material because it was considered a sensitive topic. Meanwhile, parents as the main source of information for students usually only provide information after the child has menstruated.

Comprehensive information about menstruation and menstrual hygiene is needed by adolescent girls, especially before they menstruate. This is evidenced by the statement of all respondents or 100% stating the need for information about menstruation and menstrual personal hygiene. So that respondents will not have difficulty in accessing information and are sure of the truth of the information.

As many as 94.9% of respondents knew that menstruation is the release of blood from the vagina caused by normal biological processes. Respondents who knew that the purpose of maintaining the cleanliness of genital organs during menstruation is to maintain cleanliness and health as much as 93.6%. The majority of respondents or as many as 83.3% already know if moist genitals will facilitate the growth of bacteria and fungi. As many as 92.3% of respondents knew that if they do not frequently change pads during menstruation, the bacteria will develop more easily into the vagina and cause infection. There are still quite a number of respondents or as many as 39.7% who do not know that the correct timeframe for changing sanitary napkins is every 4-6 hours.

Based on the analysis, found that the majority of the participants are 12 years old. Also most of them have menarche in the age under 12 years. The participants have good knowledge of menstrual hygiene because they have early menarche and have received the information regarding menstruation and menstrual hygiene. Moreover they have experience so automatically it will make them gain more knowledge about menstrual hygiene.[7]

All respondents agreed to wash their hands before cleaning the genital area. As many as 93% of respondents did not agree to replace underwear only once a day. 85% of respondents agreed to replace sanitary pads every 4-6 hours. There are still quite a number of respondents who agree that there is no need to replace sanitary pads after urinating and defecating. Almost all or 96.1% of respondents agreed to wrap used sanitary pads with paper or plastic before disposing of it. 85.9% of respondents did not agree that it’s no need to change sanitary pads while at school.

Although most of participants’ attitude of menstrual hygiene are good. At some points there still some or quite a few participants stated that no need to replace sanitary pads after urinating and defecating.

</table>

Respondents’ practice of menstrual hygiene was assessed by analyzing the habit of hand washing, habit of
replacing sanitary pads, and habit of removing sanitary pads waste.

The habit of respondents’ hands washing is generally good, because as many as 59% of respondents wash their hands with soap every time before and after changing sanitary pads. And only 9% or 7 people do not wash their hands before and after changing the pads.

Respondents’ habits in replacing sanitary pads are shown by as much as 75.6% of respondents keep replacing pads every 4-6 hours a day even though menstrual blood has decreased. 41% of respondents did not replace sanitary pads after urinating or defecating. And as many as 23 female students or 29.5% female students claimed not to change pads while in school.

Respondents’ habits in disposing of pads waste are known as many as 71.8% of respondents stated that they always wash used sanitary pads before throw it away. Most of the respondents or 96.2% stated that they always wrap sanitary pads with paper or plastic before dumping it in the trash, only 3 people did not do so. As well as known only 2 or 2.6% female students who claimed ever thrown sanitary trash into the toilet, 76 people remaining or 97.4% claimed to have never done so.

Generally most of participants have good practice of menstrual hygiene. But if we take a look a little closer, it seen that quite a few participants (41%) don’t replace sanitary pads after urinating and defecating also 29.5% of participants don’t replace the pads when they at school. They choose to hold it until they come home from school even the pads already full of menstrual blood.

Respondents’ habits in disposing of pads waste are generally good, because as many as 59% of respondents wash their hands with soap every time before and after changing sanitary pads. And only 9% or 7 people do not wash their hands before and after changing the pads.

Respondents’ habits in disposing of pads waste are known as many as 71.8% of respondents stated that they always wash used sanitary pads before throw it away. Most of the respondents or 96.2% stated that they always wrap sanitary pads with paper or plastic before dumping it in the trash, only 3 people did not do so. As well as known only 2 or 2.6% female students who claimed ever thrown sanitary trash into the toilet, 76 people remaining or 97.4% claimed to have never done so.

Generally most of participants have good practice of menstrual hygiene. But if we take a look a little closer, it seen that quite a few participants (41%) don’t replace sanitary pads after urinating and defecating also 29.5% of participants don’t replace the pads when they at school. They choose to hold it until they come home from school even the pads already full of menstrual blood.

Figure 1. Summary Index of Knowledge, Attitude, and Practice Regarding Menstrual Hygiene

This study found the knowledge, attitude, and practice of menstrual hygiene among a primary school adolescents in Surabaya generally are good. As shown on the figure 1, as many as 66.7% participants have good knowledge, 60.3% participants have good attitude, and 79.5% participants have good practice.

Based on this study known that there still quite a lot or as many as 39.7% of participants who don’t know when they should replace sanitary pads. Then from the attitude and practice assessment, known some participants state that they don’t replace pads after urinating and defecating and they agree with that. Besides that quite a lot of participants who don’t replace their pads in school and choose to hold it until they come home from school.

Besides because of lack of information or knowledge there is another reason that makes students feel lazy to replace sanitary pads at school is that the condition of the bathroom is poorly maintained, the number of toilets is small and the availability of water is inadequate. The poorly maintained condition of the toilet creates an uncomfortable impression for the users, especially for students who will replace the pads. Also, the quantity or proportion of bathrooms in schools is not comparable to the number of students. So that it can result in students urinating carelessly and students are reluctant to replace sanitary pads at school.[7]

Conclusions

The results indicate that the majority of the participants have good knowledge, attitude, and practice regarding menstrual hygiene. However, it was unsatisfactory, because there are still quite a lot of participants who haven’t understand about the right time when they have to replace the sanitary pads yet. Hence, health education program should be conducted in those communities to persuade behavior change. Also, menstrual hygiene management friendly water, sanitation, and hygiene infrastructure and facilities should be developed in school.

The Effect of Chromium Exposure on Creatinine and BUN Level of Tanners in Leather Industry in Magetan

Siti Asiah, Abdul Rohim Tualeka, Y. Denny Ardyanto W

Department of Occupational Health and Safety, Public Health Faculty, Airlangga University, Surabaya

Abstract

Chromium in the leather tanning industry can have an impact on workers’ health. Kidney disease is often referred to as a side effect from exposure to chromium. Measurement of creatinine and BUN level is a method of examining kidney function.

The purpose of this study was to analyze the effect of chromium exposure on creatinine and BUN level in leather tanning workers in small leather industry in Magetan. This type of research is observational with cross sectional design. The sample of the study was 13 exposed worker groups namely chromium operators and 13 unexposed groups namely administrative workers.

The results showed that there were differences in the average levels of urine chromium in chromium operators and administrative workers (p-value = 0.000), there were differences in the average creatinine levels in chromium operators and administrative workers (p-value = 0.031), and there were no difference in the average level of BUN in chromium operators and administrative workers (p-value = 0.644). There were no influence of chromium levels in urine on the increase in creatinine levels (p-value = 0.189) and BUN (p-value = 0.854) in tanning workers, with a significance value of p-value> 0.05.

The conclusion of this study had that chromium was no effect on creatinine and BUN levels. High levels of urine chromium in tanning workers indicate a health risk that requires control effort. Suggestion given is that the tanners need periodic health examination, keep personal hygiene before and after working as well as using Personal Protective Equipment (PPE).

Keywords : chromium, creatinin, BUN, leather tanning

Introduction

Chemical material used in tanning process in chromium (Cr), in which 85% of the world’s leather is tanned by using chromium. In tanning industry, chromium can affect the tanners’ health. Chromium enters the body can be through direct contact of chromium with the skin, inhaled or swallowed by the body.

Kidney illness is often called as the side effect of chromium exposure. Chromium which is piled in the kidney will go through oxidation and reduction process where electrons are released. Electrons released have the characteristic of reactive or Reactive Oxygen Species (ROS). The increase of ROS in the body causes oxidative stress so that leads to damage of renal glomerulus cell. According to Pearce (2006), disorder of kidney function marked by the decrease of glomerulus filtration rate, so that the remaining metabolism substances including creatinine, urea, or BUN or creatinine which should be disposed causes the level decreases in urine, and increases in the blood instead.

The result of research conducted by Rasoul et al (2017) obtained that the exposure of chromium on the tanners in Egypt causes the significant mean of BUN and creatinine level on the tanners group who were exposed.
to chromium (18.01±5.2 and 0.61±0.26 mg/dl) higher than the group controlled (15.5±4.8 and 0.49±0.19 mg/dl). The increase of BUN and creatinine level in blood is one of the indicators of kidney function disorder.

Result of the work environment measurement on the preliminary survey in January 2019 using PDS (Personal Dust Sampler) obtained that from 3 points for 2 work hours, it was known that the chromium level in the air <0.0014 mg/cm³ which means that the chromium level in the air was still below the normal limit determined by the Regulation of the Ministry of Manpower of the Republic of Indonesia no. 5 of 2018 regarding the occupational safety and health of the work environment7 which is 0.5 mg/m³. However, based on the interview result on the indication of health complain conducted in the preliminary survey in 10 tanning industrial location in 10 chromium operators obtained data of health complain related to its workers which is itchy skin (60%), dizzy (40%), breathless (40%), tired (30%), dehydration (30%), low back pain (20%) and urinary disorder (10%) during working. This is also supported by the previous research conducted by Wibowo (2018)8. Based on the research, it was known that the mean of chromium level in the tanners’ blood was 36.1 µg/L which was more than the standard of health complain experience by the tanners.

Complain of low back pain and urinary disorder are ones of the indications of kidney function disorder symptoms9. According to Pusdatin (2017)10, the indication of chronic kidney disorder is the decrease of glomerulus filtration along with complain of being weak, nausea, decreased appetite, and decreased of body weight. The health complain occurred is possibly caused by the exposure of chromium. Based on the explanation above, it is considered that the analysis of the effect of chromium exposure on creatinine and BUN level on tanners in small leather industrial environment in Magetan is needed.

Method

The research design was observational through cross-sectional. This research was conducted in tanning industrial in Magetan in April-Mei, 2019. The research sample was 13 chromium operators who were exposed to chromium and 13 administrators who were not exposed to chromium. The data collection was performed through interview as well as urine and blood sampling. The examination of chromium level in urine used Atomic Absorption Spectrometry (AAS), while the creatinine and Blood Ureum Nitrogen (BUN) level were measure using Bartholot method. The data analysis was carried out using Mann-Whitney, anova and linear regression test.

Results

A. Characteristics of Worker

The individual characteristics in this research included were the education level, knowledge, personal hygiene, and the use of Personal Protective Equipment (PPE) including mask, glove, and boot. The illustration of workers characteristic frequency distribution was shown in Table 1.

| Table 1. Distribution of characteristics frequency on tanners in Magetan |

Based on Table 1, in terms of the education level, 6 chromium operators, 6 (46.2%) were Secondary schools, while 7 (53.85%) workers of the administrators were high school. The knowledge was determined based on their understanding on the chromium risk effect known by the workers. The chromium operators who had poor knowledge were 4 workers (30.77%), while the administrators who had good knowledge were 6 workers (46.15%).

Chromium operators who did poor personal hygiene were 7 (53.85%) workers, while the administrators who did well personal hygiene were 6 (46.15%) workers. The use of PPE was seen based on the equipment used by the workers including mask, glove and boot. Most of the chromium operators did not use mask as many as 7 (53.85%) workers, while the administrators who did not use mask were as many as 8 (61.54%) workers. In terms of the use of glove as PPE, most of the chromium operators did not use glove for as many as 7 (53.85%) workers, while the administrators who did not use glove were as many as 11 workers. In terms of the use of boot as PPE, 7 (53.85%) chromium did not use boot, while the administrators who did not use boot were as many as 8 (61.54%) workers.

B. The effect of workers’ characteristic on chromium level in urine

This research was conducted in order to know whether there was an effect of characteristics on the chromium level in urine on the chromium operators and administrator which was presented on table 2.

</tbody>
</table>

Based on Table 3, the characteristics of education, knowledge, personal hygiene, the use of PPE of mask, glove and boot affect the urine chromium level at the chromium operators. The characteristics of education, knowledge and personal hygiene affected the urine chromium level at the administrators.

C. The difference of Urine Chromium, Creatinine Level and BUN Level
The mean difference between chromium operators and administrators can be seen in Table 3.

**Table 3. The mean difference of urine chromium, creatinine level and BUN level on the tanners in Magetan**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Chromium operators</th>

<td>0,031</td>
</tr>
<tr>
<td>BUN (mg/dL)</td>
<td>18,93±2,75</td>
<td>19,29±2,22</td>
<td>0,644</td>
</tr>
</tbody>
</table>

Based on Table 3, the mean of urine chromium level for the chromium operators was 34,40 μg/L, while the mean of chromium level in urine for the administrators was 5,46 μg/L. The urine chromium level of the chromium operators was higher than the administrators.

The mean of creatinine level for the chromium operators was as much as 1,0462 mg/dL, while the administrators’ was as much as 0,8615 mg/dL. This means that the creatinine level at the chromium operators was higher than the administrators.

The mean of BUN level on the chromium operators was 18,93 mg/dL, while on the administrators was 19,29 mg/dL. This means that there was no difference on the BUN level between the chromium operators and administrators.

D. The effect of urine chromium exposure on creatinine and BUN level

This was carried out to know whether there was an effect of chromium level in urine on the creatinine and BUN level on the tanners using linear regression test. The research result can be seen in table 4.

**Table 4. The effect of chromium exposure to creatinine and BUN level on the tanners on Magetan**

<table>
<thead>
<tr>

</thead>
<tbody>
<tr>
<td></td>
<td>p-value</td>
<td></td>
</tr>
<tr>
<td>Urine Chromium</td>
<td>0,003</td>
<td>0,189</td>
</tr>
</tbody>
</table>

Based on Table 4. The effect of urine chromium level on creatinine and BUN level on the tanners had significance value or p-value > 0,05, which means that the urine chromium did not affect the creatinine and BUN level on the tanners in Magetan.

**Discussion**

Based on this research note that the level of education affect chromium urine on workers operator chromium and administration. High education level encouraged the increase of health status since the knowledge of the danger of substances used in tanning process was known. One of the supporting factors of someone behavior is the education level. So, the education level of someone determines the level of someone in behaving and acting.

Personal hygiene on tanners was known to be poor. This caused the entrance of chromium into body and increased in urine during excretion. This was due to the workers who seem to wear clothes when they had their meal. According to Were et al., (2014) on the research of tanners in Kenya, it obtained that poor personal hygiene caused the entrance of chromium into the body.
The result of the characteristic effect of the use of PPE including mask, glove and boot only affected the chromium operators and did not affect the administrators. The chromium operators did not use PPE such as mask, glove and boot during the tanning process. The custom of using PPE is one of the ways to decrease the workers’ risk of chemical exposures during the production, considering the chromium exposure route is respiration, absorption on the skin, and digestion route

The urine chromium level of the chromium operators was higher than the administrators’. According to Rosul et al., (2017) on the tanners in Mesir, it was known that the urine chromium level on the workers who were exposed to the chromium was higher than the workers who were not exposed. According to ACGIH (2005) BEIs (Biological Exposure Indices) of chromium in urine is as much as 25 µg/L.

The high level of chromium in the urine of chromium operators can be caused by the intensity of working period, the length period of working with chromium as well as the entrance path of chromium into the body. According to Rosul et al., (2017), the working duration of tanners in Mesir who worked for more than 8 hours caused the tanners to be exposed to the chromium concentration in the air in the tanning working environment.

Creatinine level of the chromium operators and administrators was caused by their working activity, where the chromium operators were exposed to chromium every day. In addition, the chromium operators also need more energy because of their heavy work. This is different from the administrators whose working pattern was in the room so that they were not exposed to chromium and their activity was light so that they did not need more energy. The creatinine level does not only depend on muscle mass, but also the muscle activity, diet and health status. The reference value of creatinine level in blood at adult male of 0.6 – 1.1 mg/dL, while for the female was 0.5 – 0.8 mg/dL.

There was no difference of BUN level between the chromium operators and administrators since both groups had BUN level above normal. The reference value of BUN level in blood as much as 6 – 20 mg/dL.

Based on the results of the impact that the level of known chromium urine will not effect the creatinin and bun on tanning leather workers in magetan. This research concluded that the effect chromium did not lead to the kidney function disorder yet, although the urine chromium mean value was above normal.

This could be possibly caused by other factors including eating pattern, diet, protein consumption, working period, and exposure frequency on the workers. According to Wang et al., (2010), the determination of high chromium level in urine which can significantly increase the serum urea level, creatinine level and the excretion of urine micro albumin showed the existence of damage in kidney tubules.

**Conclusion**

This research showed that the chromium exposure did not affect the creatinine and BUN level. The high chromium level in urine on the tanners showed that there was health risk so that effort of control was needed. Suggestion given is that the tanners need periodic health examination, keep personal hygiene before and after working as well as using Personal Protective Equipment (PPE).

The Relationship Between Husband Support and Health Workers Support with Exclusive Breastfeeding Behavior in Sidotopo Village, Surabaya, Indonesia

Yurike Dian Pangesti¹, Shrimarti Rukmini Devy¹

¹Health Promotion and Behavioral Sciences, Public Health Faculty, Airlangga University, 60115, Surabaya, East Java, Indonesia

Abstract

Exclusive breastfeeding is breast milk given to babies from birth to 6 months without added food or drinks except drugs for medical indications. Many factors can affect mothers in giving exclusive breastfeeding. The purpose of this study was to analyze the relationship between husband’s support and the support of health workers with exclusive breastfeeding. The research used observational analytic method with cross sectional research design. The sample in this study were 65 mothers who have baby aged 7-12 months in Sidotopo Surabaya. The research used simple random sampling technique with Chi-square test with 95% confidence level. The results showed there was no correlation between husband support (p = 0.426) and health workers support (p = 0.166) with the behavior of mothers in exclusive breastfeeding. The conclusion of the study is that there is no significant correlation between husband support and health workers support with the behavior of mothers in exclusive breastfeeding. So it is necessary to increase counseling about the importance of exclusive breastfeeding, family planning counseling and lactation management.

Keyword: Exclusive breastfeeding, husband support, health workers support

Introduction

Exclusive breastfeeding is breast milk given to babies from birth to 6 months without added food or drink except drugs for medical indications. The benefits of exclusive breastfeeding are that it can support the growth and development of the baby. Whereas, the nutrients contained in breastmilk are like fat, protein, carbohydrates, vitamins and contain protective or immune substances(¹).

WHO and UNICEF recommend the importance of exclusive breastfeeding in infants because it can reduce infant mortality and can speed up the recovery of babies when they are sick. Exclusive breastfeeding given to babies can protect against common diseases suffered by babies such as diarrhea, pneumonia and have long-term benefits such as reducing the risk of being overweight and obesity in childhood and adolescence.

Based on other studies breast milk can reduce infant morbidity by 10 to 20 times and can reduce infant mortality 1 to 7 times, especially in infants who have a age of 4-6 months(²). One developing country that still has the problem of giving exclusive breastfeeding is Indonesia. The number of Indonesian women who provide ASI is 96%, but only 42% of babies under the age of 6 months are still exclusively breastfed. Based on Indonesian health profile data for 2017, the percentage of infants who get exclusive breastfeeding until the age of 6 months is only 35.73%. This is far from the national target set at 80%.

East Java Province is one of the provinces that have not met the National target in the scope of exclusive breastfeeding which is equal to 74% in 2016. As in one city in East Java, Surabaya is the advanced and largest city in Indonesia that exclusive breastfeeding coverage is still below the national target of 65.1% in 2017.
The Indonesian government has made various efforts to increase the coverage of exclusive breastfeeding. One of the efforts made was to make a policy on exclusive breastfeeding as in UU No. 36 of 2009 pasal 128 concerning health and PP (Government Regulation) No. 33 of 2012 concerning Provision of Exclusive ASI. The Surabaya City Government also made efforts in the Surabaya City Regional Regulation number 2017 on Health Efforts, one of which is to provide facilities for workers namely breastfeeding mothers through the provision of facilities for breastfeeding companies and agencies, providing opportunities for working mothers to provide breast milk Exclusive or pump breast milk during work time at work, and making internal workplace regulations that support the success of the Exclusive Breastfeeding program.

Many factors can affect mothers in giving exclusive breastfeeding. As is the case with research in the Cilacap Tengah I Public Health Center, Cilacap District, things that can affect exclusive breastfeeding are maternal age, maternal knowledge, and family support factors. Husbands support and health workers support have an important role in the success of exclusive breastfeeding.

The coverage of exclusive breastfeeding in Sidotopo Community Health Center in 2014 was 60.44% and decreased in 2015 which was 59.39%. In 2016 the coverage of exclusive breastfeeding in the work area of Sidotopo Community Health Center did not increase or decrease or stagnate at 59.39%.

The purpose of this study was to analyze the relationship between husband support and health workers support with exclusive breastfeeding behaviour.

Material and Method

The method in this study is analytic observational using a cross sectional research design. The population in this study is mothers who have babies aged 7-12 months in Sidotopo Village, Surabaya City. It is known that mothers who have babies aged 7-12 months number 148 people. Then the sample obtained in this study were as many as 65 mothers who had babies aged 7-12 months and were taken randomly using a simple random sampling method. This study was conducted in May to June of 2019.

In this study, the variables studied were husband’s support and health staff support as independent variables. Meanwhile, the dependent variable is the behavior of mothers in exclusive breastfeeding. Data collection in this study used a questionnaire sheet and analyzed using the chi square test with α less than 0.05.

Findings

Description and Research Location

Sidotopo Village is one of the villages in Semampir District, Surabaya. The total area of Sidotopo Village is 40 Ha with a population in 2018, namely a total of 16839 people and a total of 18552 people, with a total family of 10598 households.

Sidotopo Village also has several health facilities such as 1 unit Maternity Hospital, 1 pharmacy unit, and 1 unit of health center in the area. Sidotopo Village consists of 12 RW with 96 RT and 15 posyandu.

In addition, the Surabaya City Health Office also has a program in an effort to increase exclusive breastfeeding. The program is like Breastfeeding Village, Breastfeeding Motivator Cadre, Smart Mother Class, Pregnant Women Companion and others. Sidotopo Health Center has also implemented the program in its working area as in Sidotopo Village.

Description of Exclusive Breastfeeding Behavior

The following are the results of research on the description of exclusive breastfeeding behavior.

<table>
<thead>
<tr>
<th>Exclusive breastfeeding behavior</th>
<th>n</th>
<th>%</th>
</tr>
</thead>
<tbody>
<tr>
<td>Breastfeeding</td>
<td>19</td>
<td>29.2</td>
</tr>
<tr>
<td>Not exclusive breastfeeding</td>
<td>46</td>
<td>70.8</td>
</tr>
<tr>
<td>Total</td>
<td>65</td>
<td>100</td>
</tr>
</tbody>
</table>

Based on Table 1, above show that more than half of mothers do not give exclusive breastfeeding to their babies as much as 70.8% of 65 respondents. While the behavior of mothers who give exclusive breastfeeding is only 29.2%. This means that there are very few mothers who have the awareness to give exclusive breastfeeding to their babies.
Description of Husband Support and Health Workers Support

The following are the results of research on the description of husband support and health workers support.

Tabel 2. Distribution of husband support and health workers support Kesehatan di Kelurahan Sidotopo Surabaya

</tbody>
</table>

Based on Table 2, above show that more than half of mothers get husband support that is equal to 69.2% of 65 respondents. While mothers who have support from health workers are 70.8% of 65 respondents. This means that mothers who have support from their husbands and support from good health workers for exclusive breastfeeding behavior.

Relationship between Husband Support and Health Workers Support with Exclusive Breastfeeding Behavior

</table>
Based on Table 3, above show that the exclusivity in Sidotopo Surabaya is still relatively low. This is because of some reasons mothers do not give exclusive breastfeeding. These reasons are like the milk can not flows well, so that the mother no longer gives breast milk to her baby. The fact is that if the mother increases her breastfeeding frequency, it will increase milk production.

Breast milk can not flows well caused by a lack of care for the breast during pregnancy or before giving birth. In addition, there were some mothers who claimed that their breast milk not smooth because they participated in a family planning program. The condition is in accordance with the results study that inappropriate use of family planning indeed affects mother’s milk production(4).

Another reason for the mother not giving exclusive breastfeeding is because of the mother’s assumption that her baby is fussy and cries constantly because she is hungry, so the mother decides to provide additional food and drinks before the baby’s age is 6 months. The food provided is in the form of bananas, team rice and porridge, while the drink is formula milk. This action actually affects the health of babies who have not reached the age of 6 months. The impact on the health of the baby is in the form of respiratory tract disorders and the digestive tract of the baby.

Factors of social support consist of husband’s support and support from health workers for exclusive breastfeeding. Based on the results of the study showed that there was no significant relationship between husband’s support and exclusive breastfeeding behavior. is in accordance with study in Kademangan Sub-district, Blitar Regency. It was found that there was no significant relationship between husband’s support and the behavior of mothers in exclusive breastfeeding(5).

Husband support is one of the factors that can affect the success of mothers in giving exclusive breastfeeding. The form of husband’s support is given starting from information support, emotional support, instrumental support and award support. The form of husband’s support is like the husband informs the mother that the baby can only be given breast milk until 6 months, helps the mother’s daily activities in managing the household and hears complaints when the mother is tired.

The results of this study also show that there is no significant relationship between the support of health workers with exclusive breastfeeding behavior. This is in accordance with research in the RI Ministry of Health that there is no significant relationship between the support of health workers and the behavior of mothers in exclusive breastfeeding(6).

However, this study is not accordance with research in the Wundulako Health Center in Kolaka Regency that there is a significant relationship between the support of health workers and exclusive breastfeeding behavior(7). Support from health workers is very important especially during pregnancy and postpartum. This is because the information obtained from health workers will be a provision for mothers to prepare to breastfeed their babies. In accordance with the theory that health worker support influences a person’s behavior, so that someone will be able to determine his own healthy behavior(8).

The presence of mothers who have support from health workers but do not provide exclusive breastfeeding is due to the influence of giving formula milk because there is an assumption that this is the case more practical. In addition, according to the mother, health workers cannot monitor directly to the mother to continue giving her milk until the age of the baby is 6 months.

Conclusion

The conclusions in this research are as follows: there is no significant relationship between husband’s support and behavior in exclusive breastfeeding. There is no significant relationship between the support of health workers and the behavior of exclusive breastfeeding

Recommendation

1. Increasing counseling activities to mothers and husbands about the importance of exclusive breastfeeding and the impact on the health of the baby when given additional food and drinks before the age of 6 months.

2. Inviting mothers to participate in family planning counseling, so that mothers can choose a suitable family planning program and not inhibit exclusive breastfeeding.

3. Optimizing training activities for health workers such as doctors and midwives about management of lactation or breast care for pregnant women during counseling, so that mothers prepare to breastfeed their babies from birth to 6 months of age.

Human Rights Based Law Protection Model for the Mental, Spiritual and the Healing Victims of Child Trafficking In Indonesia

Sulistya Eviningrum, Hartiwiningsih Hartiwiningsih, Mohamad Jamin

Doctoral Student, Universitas Sebelas Maret, Surakarta, Professor, Universitas Sebelas Maret, Surakarta, Associate Professor, Universitas Sebelas Maret, Surakarta.

Abstract

Abstract: The protection needed by children to face the reality of being the victims of child trafficking is not only physical protection, but mental, spiritual, and social healing as well. The punishment system still focuses on criminals instead of the victims. The law protection model for the victims of child trafficking in Indonesia is not comprehensive, so there is little chance that the victims get their rights. Although Act Number 21 Year 2007 has guaranteed the victims’ rights, the chance to get their rights is relatively minimal.

Keywords: law protection, children, trafficking and human rights

Introduction

Indonesia is still considered weak in handling trafficking in person cases. Indonesia Tier-2 has arranged minimum policies as a deterrent to human trafficking. The law enforcement needs to be in accordance with the applicable law, Pancasila and the the 1945 Constitution of the Republic of Indonesia, and human rights. There are regulations related to the victims of child trafficking, for example Article 2 of Act Number 21 Year 2007 on the Eradication of the Criminal Act of Trafficking in Persons that states, an act of recruitment, transportation, storage, shipping, transfer or acceptance of somebody with the threat of violence, the use of violence, confinement, falsification, fraud, abuse of power, or vulnerable position, debt bondage, or giving payment or benefits, so that the perpetrator gets permission from the person who have control of somebody else, whether it is done domestically or internationally, in order to exploit or make somebody to be exploited. The birth of the Protocol to Prevent, Suppress and Punish Trafficking in Persons, Especially Women and Children as one of the protocols created from the United Nations Convention Against Transnational Organized Crime in Palermo, 12th – 15th December 2000, as stated by Bank Data KPAI is a very useful international instrument to prevent and fight trafficking in persons, and especially child trafficking.

According to the background above, the writer conducted two main problems that will be discussed is Why is the law protection on the victims of child trafficking? And How is the ideal human-rights-based law protection model for the victims of child trafficking?

Research Method

Normative research method is used in this paper, which is a research done with library studies. The discussion is based on the theories, legislations, documents, law journals, paper, and references which are relevant to the research topic, as stated by Marzuki.

Result and Discussion

1. The Law Protection for The Victims of Child Trafficking

Children are the most vulnerable group to the criminal act of human trafficking. As stated by Norris, “Child Trafficking, whilst not a phenomenon, remains a heinous activity as children are the most vulnerable members of society, yet it is exactly this vulnerability
that makes trafficking possible in the first instance. Official statistic by the Home Office and the United Nations highlight a continuing increase in this “industry” and whilst most of society holds the notion that children are not a commodity to be bought and sold, there remain a small but determined proportion of the population who are willing to exploit children for profit.”

In 2014 (January-April), there are 600 cases and 876 victims, 137 of which are child perpetrators, as stated in the UAJY Library.(5) In 2016, there are 99 prostitution victims. Today, according to the data of KPAI (The Indonesian Commission on Child Protection) during 2016, the trend of child sexual crimes tends to increase. In that year, there are 1,593 cases of children sexual crimes. According to Mia(6), 25 cases among them are online sexual crimes. Article 1 paragraph (2) of Act Number 35 Year 2014 Amendment of Act Number 23 Year 2002 on Children Protection defines Children Protection as any activities to guarantee and protect children and their rights to live, grow, thrive, and participate optimally according to their human dignity and get protection from violence and poverty. The victims of child trafficking are usually used in prostitution and exploitation. The protection for the victims of child trafficking is regulated in Act Number 1 Year 2007 on The Eradication of The Criminal Act of Trafficking in Persons. Chapter V paragraph 43 stated that the protection for the witness and victim is conducted based on Act Number 13 Year 2007 on the protection of witness and victim. The protection model based on Act Number 1 Year 2007 on The Eradication of The Criminal Act of Trafficking in Persons does not differentiate between children and adults, article 44 stated that the victims are given the right of confidential identity for the victims, witnesses, and their family until the second degree. Article 47 gives the police the duty to provide protection before, during, and after the process of case review.

2. The Ideal Law Protection Model for The Victims of Child Trafficking

Trafficking victims do not only have the right to get law protection, but to get rehabilitation as well because they suffer economically, physically, and psychologically. Rehabilitation can be attempted by conducting mentoring by the non-governmental organizations or the child-protection-related organizations. The rehabilitation is expected to return and heal victims’ condition both physically and psychologically. The mentoring conducted by the NGOs in attempting the rehabilitation for the victims of child trafficking has the same purpose, but there are differences in terms of the technique of socialization based on the needs of child trafficking victims. The act on human trafficking has been enacted, but the local legal protection in city / regency level is highly expected since the local regulations will be very helpful in stimulating the effectiveness of the central legislation implementation. The implementation of the local regulations have 5 (five) purposes: 1) Prevent all forms of violence and trafficking in persons against women and children; 2) Protect women and children victims of violence and human trafficking; 3) Punish the perpetrators of violence and trafficking of women and children; 4) Provide security for women and children victims of violence and trafficking in persons; 5) Heal the physical, psychological and economic conditions of women and children victims of violence and trafficking, as stated by Absor.(7) Act Number 23 Year 2014 on Local Government supports that child protection becomes regional obligatory affairs, as quoted from Sindonews.(8) Although the legal instruments have been owned, on its progress, the Act Number 23 Year 2002 on Child Protection as amended by the Act Number 35 Year 2014 still cannot work effectively since there are some overlaps between sectoral legislations regarding to the definition of child. The amendment of Act Number 23 Year 2002 on Child Protection also confirms the need for punishment and fines for the perpetrator of criminal action against children, in order to give a deterrent effect, and stimulate concrete actions to heal the physical, psychological, and social condition of the victims of child trafficking and/or the children of the criminals. Integrative efforts are the responsibility of the society and state to realize the better survival of the victims of child trafficking, in which these efforts involve all components of the society and family. This step makes the victims of child trafficking feel that chances exist in their society and family. The importance of child trafficking victim’s protection, in order to observe the victim – offender relationship for the sake of judicial process, both to seek for the perpetrators’ responsibility, and to determine the form / amount of restitution and/or compensation for the victims. The state takes over the responsibility of the security of all its citizens because when a crime happens to a victim, it is as if the crime destroys the system of trust, so the function of law is to return the trust to the victim. The reformation of policy formulations is expected to overcome the social problems so that a prosperous society can be realized. Legislation emerges regarding to the protection of witnesses and victims to cover the lacks
of KUHAP (Criminal Code Procedure), for example Act of The Republic of Indonesia Number 31 Year 2014 on Witness and Victim Protection, and Act of The Republic of Indonesia Number 11 Year 2012 on Child Criminal Justice System. The legal aid attempts to give solution in developing the legal protection for the victims of child trafficking by accommodating the children’s experience of being victims of child trafficking, especially those who experience sexual exploitation. In which it shows the correlation process between the authorities that handle law protection for the victims of child trafficking and the easy-and-effective service techniques for the process of law protection for the victims of sexual exploitation in child trafficking.

The law protection is realized in various ways such as those existing in the concept of integrated law protection on the victims of child trafficking, for example by: a) Coordinating and working on the mechanism between the authorized agencies in providing legal protection for children of human trafficking victims (child trafficking) and understanding the needs of victims; b) Renewing, developing of ideas and thoughts of revising policy formulations relating to the issues of legal protection for children of human trafficking victims (child trafficking); c) Estimating the budget for dealing with legal protection for child victims of human trafficking (child trafficking), which starts from the process of mentoring, investigating, examining and restoring good names for victims. d) Communities are sensitive and responsive to their environment in monitoring cases of human trafficking (child trafficking); e) Providing human resources assistance, such as psychologists for human trafficking victims (child trafficking) in order to solve the problem of human trafficking crime (child trafficking); f) Providing a special room to conduct examinations, especially in sub-districts, in order to handle human trafficking crimes.

The development of human rights protection principles through children law protection has always been the focus in the International Documents of the United Nations on Human Rights, for example Universal Declaration of Human Rights (UDHR); International Covenant on Civil and Political Rights (ICCPR); International Covenant on Economic, Social and Cultural Rights (ICESCR), The Convention on the Rights of the Child (CRC); Convention Against Torture And Other Cruel, Inhuman or Degrading Treatment or Punishment. The approach used in the judicial system to help the victims of trafficking (child trafficking), such as: the role taken by the law enforcements such as police, prosecutors, court, and correctional institution; through normative approach by implementing the applicable laws; through administrative approach by means of a management organization that has a working mechanism, with vertical relationships based on the prevailing organizational structure; through social approach where an inseparable part of the social system so that the whole community is partially responsible for the success or failure of the law enforcement agencies. The multi-pressure that happens to the victims of child trafficking and the perception of human trafficking (child trafficking) in the society shall result in the enforcement of policy formulations of child trafficking, the perpetrators of child trafficking will be given severe punishment such as death sentence or castration for those who commit sexual crime. Synergy of regulation is needed to protect the victims of child trafficking. In its implementation, the national legislation regulations do not give deterrent effects to the perpetrators of human trafficking (child trafficking). Local regulations are initiated by mapping the problems of child trafficking through stakeholder workshops from the government, NGOs, labor union, college, etc. The forum involves all stakeholders such as from social authorities, police, labor offices, family planning office, education authorities, regional development agency, public health agency, labor and migrant union, NGO, society, mass organization, college, and public education center. Those forums are useful in overcoming children trafficking because those forums act as a place to solve various problems and coordinate for the action to overcome trafficking, as stated by Absor. Some forms of children protection such as placing them in social homes are funded by Jamkesmas (public health insurance) which sources are the State Budget, Budget Implementation List, Local Government Social Work Unit, Local Government Work Unit on Transmigration and Labor, NGO which coordinates with the Local Government Social Work Unit, by attaching a certificate as resident of a hall, halfway house, foundation, or social homes, where the victims can get treatment (Act Number 11 Year 2009 on Social Welfare). If the social rehabilitation is done by the NGO, then the funding can be obtained from the State Budget which coordinates with the Ministry of Social Affairs or the Local Government Budget which coordinates with the Local Government Social Work Unit. It needs capability and capacity to make local regulation, especially regarding to the prevention
and protection of the victims of child trafficking. When making the regulations, the local government needs to refer to the Act Number 21 Year 2007 on the Eradication of the Criminal Act of Trafficking in Persons and Government Regulation Number 9 Year 2008 on National Action Plan for the reference for their activity. The positive expectation for the eradication of trafficking emerges when utilizing the established conditions that leads to the removal of trafficking that is supported by 1) Government’s commitment, as shown by the ministry of woman empowerment; 2) The growth of community-based services that can be utilized to eliminate women and children trafficking; 3) Availability of community service facilities in terms of education, social and health; 4) Regional autonomy will be more efficient and effective in eliminating trafficking; 5) The existence of community organizations or non-governmental organizations that care about women and children; 6) The development of human rights enforcement; 7) Openness; 8) Democratization; 9) International commitment; 10) The existence of international institutions that support the eradication of trafficking; 11) Involvement of international NGOs observing women and children; 12) The information technology that supports the eradication of women and children trafficking, as quoted from Abdussalam. To get optimum results in conducting those duties, some actions need to be taken, for example creating strategic alliance with the related sectors and stakeholders to build collective commitment as the framework of policy-making in all sectors; harmonizing international law instruments into the national law that strengthen the efforts to eradicate children trafficking; make an agreement with the legislature so that each Laws and Regional Regulations drafting considers the importance of children protection from trafficking; strengthening the coordination with local government in preventing and eradicating children trafficking; expanding the source of funds to support the eradication of trafficking; building strong cooperation with all components of the society so that trafficking eradication can become a collective program.

Conclusion

1. The law and human rights protection to the victims of child trafficking is regulated in the national legislation system. The implementation of law protection to the victims of child trafficking is not appropriate yet, such as the appropriateness to the principles and regulations of children protection against child trafficking, the principles and regulations of children in the perspective of restitution, compensation and rehabilitation and non-legal policies, and the principles and arrangements for child protection in the perspective of regional autonomy.

2. The law protection model is integrated with the formulation of women and children trafficking eradication policies, and by providing special regulations regarding to law protection for the victims of children trafficking. The revisions for future policies do not totally use applicable law, but they are more adjusted to the needs of the child. Strict sanctions need to be given to make deterrent effects, without setting aside the needs of the child.

Abstract

Results of the Public Research Anti Corruption Clearing House The Corruption Eradication Commission submitted on December 2, 2016 that until mid-2015 there was a potential of 175,774 hospital claims of fraud that had been detected with a value of Rp. 440 M. In 2016 found an indication of 1 million fictitious claims from the hospital with a value of Rp. 2 trillion. The potential for fraud in hospitals in the era of National Health Insurance (NHI) in Indonesia will have an impact on health financing inefficiencies and at the same time a threat to the sustainability of the NHI program which is expected to reach Universal Health Coverage in 2019. This phenomenological study aims to explore understanding and meaning of the concept of fraud for parties who has had the potential to commit fraud at the hospital. The research method used qualitative research with a Descriptive Phenomenology Research approach. The informants were officers who served patients in administrative and medical matters and the hospital management was selected by purposive sampling. The focus of the study was the experience felt by informants in running the NHI program and how knowledge and attitudes of informants towards the phenomenon of fraud in hospitals. The results achieved in this phenomenological research were in the form of a reflection of the implementation of NHI in hospitals, especially relating to the phenomenon of potential fraud reflected in the knowledge and attitudes of the hospital about fraud and a description of the occurrence of fraud in the hospital. This is the basis for researchers to formulate indicators of potential fraud that still needs to be tested in a larger population.

Keywords: fraud, hospital, health insurance.

Introduction

Healthcare fraud is intentional deception or misrepresentation that an individual knows, or should know, to be false, or does not believe to be true, and makes, knowing the deception could result in some unauthorized benefit to himself or some other person(s).

(1) Reforming health care financing is an unavoidable consequence. Gradually the community will switch from out of pocket payments to premium payments paid monthly. Likewise for health service providers must start leaving the old payment mechanism (fee for services) to be claims based on Indonesia Case Based Group (INA-CBG). (2) The Social Security Organizing Body (BPJS) Health as the organizer of National Health Insurance (NHI) has a payment mechanism to health care providers namely capitation for primary outpatient health facilities and claims based on INA-CBG for Advanced Referral Health Facilities both inpatient and outpatient. (3) The change in the payment system will potentially lead to fraud or fraud, where the diagnosis is regulated to obtain the largest CBG amount called upcoding.
(increasing the code with a larger payment). Acts like this are actually acts of corruption that are against the law. The Government of Indonesia has been concerned with the prevention of fraud in the implementation of the Health Insurance Program in the National Social Security System. The Government of Indonesia has given attention and anticipation of fraud in the implementation of NHI.

Definition of fraud (Fraud) in the Implementation of the NHI Program according to the regulation is the action taken intentionally by participants, BPJS Health officers, health service providers, as well as providers of drugs and medical devices to obtain financial benefits from the health insurance program in the National Social Security System through cheat that is not in accordance with the provisions.

The problem of fraud in Indonesia that is of concern today is illustrated by an article posted by the Public Research Anti Corruption Clearing House of the Corruption Eradication Commission (KPK) on December 2, 2016 which stated that up to mid-2015 there were 175,774 claims of fraud, or FKRTL with a value of Rp. 440 M. In 2016 found an indication of 1 million fictitious claims from the hospital with a value of Rp. 2 trillion. This fraud potential is only from a group of health service providers, not from other actors such as BPJS Health staff, patients, and suppliers of medical devices and drugs. The biggest form of fraud potential is done by upcoding which reaches 50%, then another 25% is done by unbundling, and then the third is by reading with a value reaching 6%. Also stated in the article that INA CBG rates that are considered low by clinicians and the high workload make them think of unnatural efforts to defend themselves (coping strategy) so as not to lose money.

The potential for fraud is also a concern of the one district in east java which was stated directly by the Regent to fight it. This Regency has 3 regional hospitals, 1 provincial-owned hospital, 2 state-owned hospitals, and 6 private hospitals. Based on the results of interviews with the Head of Health BPJS Branch on November 13, 2017, information was obtained about the potential fraud reported in the form of potential claim fraud from hospitals detected through intelligence business in the form of applications developed to assist in the claim audit process. The menus provided include DeFraida (data fraud detection). Through this application display, a warning system in the form of red flag is provided for claim transactions that are indicated as potentially fraud. This red flag is the basis for BPJS verifier officers to clarify and trace data to ascertain whether there is an element of error and intentions in filing claims that are indicated by fraud. This is what underlies the selection of the Jember Regency as a place of research.

Phenomenology study according to Packer is a reflective study of the essence (core) of the awareness experienced from the perspective of the first person, namely the perspective of people who experience an event or event directly. The event referred to in this study is the potential for fraud in the implementation of the NHI program which has changed the health care and financing system in Indonesia. Phenomenological studies are widely used for policy implementation research so that it can describe the experience of implementing policies that determine the success or failure of a policy.

**Method**

The research method used qualitative research with a Descriptive Phenomenology Research approach because what is the object of research is the experience of informants in running the NHI program as an event or transition event of health care and financing policies. The informants were officers who served patients in administrative and medical matters and the hospital management who were willing to fill out informed consent and were selected by purposive sampling. The confidentiality of informants and institutions where research was conducted was the responsibility of the researcher.

The focus of the study was the experience felt by informants in carrying out the NHI program and how the knowledge and attitudes of informants towards the phenomenon of fraud in hospitals. Research transcripts are the basis for processing and analysis using the Descriptive Phenomenological Analysis (DPA) approach. According to Kahija that DPA moves from all the informants’ words in the transcript to the core meaning of all the informants’ words.

**Results**

The informants were chosen based on their involvement in the implementation of JKN policies and the phenomenon of potential fraud in hospitals. After conducting interviews with research informants, the results of the interviews are presented in the transcript. Research transcripts form the basis for processing and analyzing with the Descriptive Phenomenological Analysis (DPA) approach. The results will be divided
Knowledge of Fraud

This study of knowledge aims to understand the most fundamental aspects of the phenomenon of fraud in hospitals. Knowledge about fraud will provide an overview of the extent to which this potential fraud is understood by hospital practitioners. Descriptions of knowledge are needed considering that the implementation of national health insurance in Indonesia has only begun in 2014. The potential for fraud as one of the problems that arise in the implementation of fraud is the concern of the government and health practitioners today.

The results showed that the informants have had enough knowledge about fraud that might occur in the hospital. This is indicated by the participation of informants in the dissemination of regulations on fraud in the NHI era held by hospitals, BPJS, as well as from professional organizations. The results of the interview indicated an expression of disagreement, especially from the clinician informants on the concept of fraud as outlined in government regulations. The informant mentioned “…the term “fraud version of BPJS” as a form of rejecting the concept of fraud as what informants understood and felt while providing services…” (Informant TR06, lines 8-9). Informants try to provide a rationalization of the potential for hospital fraud. Rationalization is an act that seeks justification by people who feel themselves trapped in a bad situation.

Situation Awareness

Implementation of national health insurance will have an impact on the situation in the hospital. The hospital is required to make changes and adjustments in order to carry out its functions in the new regulations. The potential for fraud as one of the negative consequences of implementing national health insurance must be fully realized by the hospital. Fraud actions, in addition to being contrary to moral values, also have the potential to act against the law. Hospitals need to identify points that have the potential to cause fraud so that planning, monitoring and evaluation activities can be carried out to prevent potential fraud.

The results of the interview indicated that there was an awareness of the informants about the risk of fraud, namely in the form of criminal sanctions. Therefore, informants are uncomfortable when their activities are often associated with potential hospital fraud. This discussion of fraud must be discussed in depth so that when the regulation on fraud sanctions is applied, it does not harm the parties who actually greatly contribute to the implementation of the NHI program.

Perception of Fraud

One of the themes that emerged in all informants was an increase in workload during the NHI era. This is a logical consequence of increasing public access to hospitals which is characterized by high visits, both outpatient and inpatient care. Along with the increase in workload, the main issue that should be considered by hospitals is the provision of fair rewards. Remuneration as an instrument for the distribution of rewards must be arranged as well as possible to avoid job dissatisfaction due to negative perceptions of the reward received. The emergence of attempts to commit fraud is possible because of the influence of dissatisfaction with NHI actors on the rewards received.

Potential fraud in health services during the NHI era has been aware by informants (risk awareness). But there was informant who argue “… maximizing claims is not fraud, but efforts to rationalize costs to meet medical needs …” (Informant SPG01, lines 12-13). The theme of the potential for fraud in these hospitals deserves attention in an effort to succeed in NHI implementation. The potential for fraud in hospitals is the subject of the KPK’s publication. So that matters relating to the causal factors, the mechanism of prevention and control, and the mechanism of action are the themes that arise from informants, especially from DPJP.

Discussion

The Government of the Republic of Indonesia seeks to fulfill the constitutional mandate for the implementation of National Health Insurance (NHI) which started on 1 January 2014 and established the achievement of Universal Health Coverage (UHC) in 2019. This means that all communities must obtain guarantees for their health needs (preventive, promotive, curative, and rehabilitative) with a health insurance mechanism.

One of the fundamental policies in the NHI program is the change in hospital payments from fee for services to claim INA CBGs as Minister of Health Regulation concerning the Indonesian Case Based Groups (INA-CBG’s) guidelines NHI. This has put pressure on the
policy implementers at the hospital level. Not to mention the problem with the difference between hospital rates and the value of INA CBGs given. This is considered to trigger the potential for fraud in hospitals as FKRTL.

Fraud in health services usually refers to false statements or false claims, complicated schemes, cover-up strategies, misrepresentations of value, misrepresentations of service.\(^{(1)}\)\(^{(13)}\) The subjective experience of individual implementing policies plays a very large role for the success of policy implementation.\(^{(14)}\) There are three elements of implementing responses that can affect their abilities and desires to implement policies, namely: cognition (comprehension, understanding) about policies, kinds of responses to policies (acceptance, neutrality, rejection), and the intensity of those responses.\(^{(15)}\)

Based on the conceptual framework of the policy implementation process, the attitude of acceptance or rejection of the implementing agent (disposition of implementers) will greatly affect the success or failure of the performance of public policy implementation.\(^{(16)}\)\(^{(17)}\) Disposition or attitude of the implementer will cause real obstacles to policy implementation if the existing personnel do not implement the policies desired by the policy holders.

Based on the phenomenological studies that have been carried out, the three elements triggering the occurrence of fraud appear in the experience of the informants. The pressure appears from the information conveyed by the informant in the form of dissatisfaction with the reward received compared to the perceived workload. Rationalization appears in an informational statement stating that maximizing a claim is not fraud. The third element, opportunity, is reflected in the experience of informants who stated that the hospital’s antifraud team was not yet effective.\(^{(9)}\)\(^{(10)}\)\(^{(11)}\)

Fraud prevention needs to be done both from the internal aspects of the hospital and external hospitals on health services covered by NHI, so that there is no dispute with BPJS and does not invite civil or criminal prosecution from legal apparatus. Thus, the substance of the policy and guidelines for preventing NHI fraud is an arrangement that wants to be applied along with the implementation procedures. These include the standards of behavior and discipline, monitoring and evaluation that ensure compliance with implementation, and the implementation of sanctions against violations.\(^{(18)}\)

**Conclusion**

An increase in workload is an experience that arises in each informant’s theme. Job dissatisfaction marked the implementation of NHI program at the hospital. The informant acknowledged that the potential for fraud was present, but not to be labeled with one particular profession or organization. Some concepts that are considered to be the triggers of fraud that need to be tested in a wider population, such as: increased workload, job satisfaction, acceptance or rejection of health service financing policies in NHI era (disposition of implementers), risk awareness of fraud behavior, and effectiveness of internal and external monitoring.

**Acknowledgment:** Our gratitude goes to all those who have supported the implementation of the research, in particular: The team of dissertation promoters, hospital directors, respondents, enumerators, and the Education Fund Management Institution (LPDP) of the Republic of Indonesia who have provided financial support for successful research.

**Conflict of Interest:** There is no conflict of interest with any party related to the process or research results.

**Ethical Clearance:** The ethical test for this research was conducted at the Health Research Ethics Commission (KEPK) at the Faculty of Dentistry, University of Jember in the form of the Ethic Committee Approval No. 348/UN.25.8/KEPK/DL/2019 issued on 6 February 2019.

Breast Feeding Practice Prevention for Nutritional Stunting of Children In Buginese Ethnicity

Agustian Ipa1,4, Rudy Hartono 1,4, Sirajuddin 1,2,4, Aswita Amir1,4, Sharifah Intan Zainun Sharif Ishak3
1Associate Professor in Nutrition and Dietetic Department of Health Polytechnic of Makassar, Indonesia. 2Student Doctor al Public Health Hasanuddin University, Indonesia. 3Lecturer in Nutrition Department of Management Sciences University, Malaysia. 4Center of Excellence Science and Technology in Urban Health of Health Polytechnic of Makassar, Indonesia

Abstract

Background. The practice of breastfeeding is very important to determine the quality of nutrient intake in children under two years. In ethnic Bugis. The purpose of this study was to determine the effect of breastfeeding on stunting prevention in ethnic Bugis.

There is a cross-sectional study in this study. The sample size in this research is 300 mothers and children. The enumerators in this study were applied to undergraduate students of nutrition & dietetic programs in the Makassar Department of Nutrition Health Polytechnic, Indonesia. Research ethics was obtained at the Makassar Health Polytechnic Ethics Commission. Stunting risk factor data analysis with logistic regression test.

The results showed that 32% of children were breastfed, with a frequency of 5-8 times / 24 hours breastfeeding. The reason for not breastfeeding a child is over 2 years old, the child refuses to breastfeed (10%), has 17.3% formula milk. Statistical analysis showed that breastfeeding (frequency of breastfeeding), p = 0.013, or 1.99 (1,148-3,173) was significant as stunting prevention. The conclusion is breastfeeding habits in ethnic Bugis can prevent stunting.

Key words: Breast Feeding, Nutritional, Stunting, Bugis.

Introduction

Two variables that are always related to improving the nutritional status of children are breastfeeding and supplementary feeding of breast milk. Stunting is a condition of failure to thrive characterized by short, recurrent infections and low psychosocial stimulation. The 2017 Indonesia stunting prevalence is 36.4% and the determinant factor stunting is multifactors 1,2,3,4. Stunting in Makassar City as a red zone area (prevalence> 40%) at the same time Makassar City is the largest Metropolitan city in Eastern Indonesia and the development center of eastern Indonesia 5.

A systematic review determinant factor stunting in Indonesia is caused by various factors factor Households and Families, insufficient food addition to breastfeeding, infection and and factors of social6,7,8.

The practice of breastfeeding is also a variable that is studied in this research because. The population of Makassar City is 50% Buginese. This means that the prevalence of stunting in Makassar City is also related to Buginese. And having uniq character in the economic field and the ability to survive anywhere. The study required to find breastfeeding ethnic Buginese and its effect on the prevention of stunting.

Method

The subjects of this study were obtained from Bugis Ethnic who live in Makassar City. The study sites were three Puskesmas working areas in the North of Makassar City. Tamalanrea Health Center, Health Center, Paccerakkang, and Sudiang Raya Health Center. The reason for choosing the northern area of the city is because the Bugis ethnic population inhabits the north of the city more than any other location, due to
geographical proximity to the Bone, Soppeng, and Wajo (Bosowa) Regencies as the Bugis ethnic base in South Sulawesi.

The population is all mothers who have children aged 6-59 months in Makassar City. Criteria for inclusion of Buginese ethnic samples in Makassar City

1. The mother is from the ethnic Bugis and the husband is also from the ethnic Bugis
2. Having children aged 6-59 Months in September 2019
3. Have lived for at least the past 6 months in Makassar City
4. Willing to participate in this research

The sample size in this study is 300 people, based on the estimated prevalence of stunting in Makassar City as a Bugis ethnic center that is 35.7%, using 80% power test with 95% confidence, design effects 1 and 5 with the addition of 10% additional data estimated not to participated in this research because they refused or were not present at the time of screening

Data collection in this study uses a list of questions that have been tested with good reliability. The questionnaire was tested using structured questions using official data on children aged 0-59 months (data mom and household data) Data collected included age, gender, weight and height/length; mother level, education level and participation in household decisions; breastfeeding practices, supplementation, and washing hands; children’s access to health and nutrition services (growth monitoring, micronutrient supplementation, and immunization); maternal access to health services (antenatal care, assistance during labor and place of delivery); household water, sanitation and hygiene; and social economy

My child’s weight is measured using electronic SECA scale with an accuracy of 0.1 kg and a length of the child (for children aged 0-23 months) or height (for children aged 24-59 months) was measured using high board / long local made with an accuracy of 0, 1 cm. SECA scales are calibrated every morning, before data collection, using a standard weight of 5 kg. Duplicate anthropometric measurements were carried out for 10% of the sample; the coefficient of variation in subjects from duplicate measurements in children and women is less than 5%. All enumerators receive training at least two days before data collection, and those responsible for taking anthropometric measurements receive one additional training day. Supervisors are tasked with supervising the work of enumerators and facilitating good relations with community members. Stunting is defined as Z-score for height <<2. In the 2006 WHO Anthropometry standard.

Results and Discussion

Demographic Characteristics

Based on the results of this research it is known that the main occupation of mothers is as housewives as many as 243 people (83.3%), and private employees as many as 26 people (8.7%). Father’s occupation is as a private employee and laborer, 153 people (51.1%) and 85 people (28.6%).

Distribution of Stunting Children on Ethnic Bugis

*) variable code, you can see the attached question list.

***) based on logistic regression analysis, with stunting as the dependent variable.

Based on the results of risk factor analysis various variables that influence stunting are breastfeeding factors (frequency of breastfeeding), p = 0.013, OR 1.99 (1.148-3.173). Factors breastfeeding by reference are 1-4 times, above 4 times a day be a protective factor against stunting.

Determinant analysis of factors against all variables that are strongly suspected is a stunting risk factor. Variable groups consisted of household factors, child factors and MP-ASI, breastfeeding factors, hygiene and sanitation, infectious diseases, child care, feeding style, and caring practices.

Discussion

The prevalence of ethnic Buginese stunting is 22.7%, where this percentage is still above the threshold set by WHO as a threshold for health problems with a prevalence of <20%9. Based on these parameters, it can be proven that the ethnic Buginese made a significant contribution to the percentage of stunting in South Sulawesi in 2018. The province of South Sulawesi ranks the fourth highest percentage of stunting in Indonesia. Various factors were analyzed in this study in accordance with the conceptual framework published by Unicef in 200610.
In this research, it is known that breastfeeding habit is a positive factor that is able to provide prevention to children not to stunting. The most critical period is 0-24 months. In this period if the child is breastfed completely and supported by quality additional food after the age of 6 months to 24 months, then the child’s nutritional status is good. If the child is not perfectly breastfed then the risk, stunting becomes greater11,12,13,14,15,16.

Buginese ethnic habit is the same as other ethnic groups, where the marketing of formula milk which is quite large in the community causes the practice of breastfeeding to decrease. Indonesia’s experience in regulating the marketing of formula milk is not good. There is no strict supervision of formula milk sellers at small kiosks throughout the region not only in cities but also in villages. Buginese are ethnic peddlers and busy working outside the home. This causes the position of the child can be left out while working outside the home. Parenting practices entrusted to neighbors are not common except for close relatives 17,18.

The breastfeeding factor theoretically determines the quality of macro and micro nutrient intake, especially in the period of 1000 HPK19. If the support of maximum breastfeeding, the child’s height will be normal and vice versa. This is due to many biological and psychological beneficial factors obtained by breastfed children compared to children who are not breastfed. This study examines the variables of lack of frequency breastfeeding is risk factors for stunting. The reference used is breastfeeding > 12 times in 24 hours and frequencies lower than that are at risk for stunting. This proves that in the period of breastfeeding which is the age of 0-24 months, it is important to breastfeed properly with the right frequency20.

**Conclusion**

The practice of breastfeeding children aged 0-24 months in ethnic Buginese is able to prevent stunting. It is recommended that social marketing of breastfeeding practices be carried out at all levels, so as to strengthen the community that breast milk is the best food for children aged <6 months and continued until the child is 24 months old.

**Conflict-of-Interest Statement**

Between researchers and investigated there was no conflict of interest in the conduct of this study.

**Source of Funding:** The funding in this study came from the overseas collaboration research scheme through the Makassar Health Polytechnic based on the operational costs of state universities in 2019.

**Ethical Clearance:** The Makassar Health Polytechnic Health Research Ethics Committee has issued research ethics under number 1123 / KEPK-PTKMKs / X / 2019.

Assessment of Undergraduate Critical Care Nursing Students’ Knowledge and Attitudes toward Caring of Dying Patients In Colleges of Nursing at Baghdad University

Ahmed F. Hassan1, Haider M. Majeed1, Aqeel H. Jasim2

1Assistant Instructor, 2Instructor, Fundamentals of Nursing Department, College of Nursing-University of Baghdad,

Abstract

Nurses have played various roles in the development of palliative care, offering leadership, support and focus for the movement. Experiences of death on a clinical placement by nursing students were a major cause of anxiety and sadness.

Objectives: To assess of students’ knowledge toward care of dying patient and to find out the relationship between students’ knowledge and their demographical characteristic such as age, gender, post level of education.

Methodology: A descriptive study was conducted in the period of December 10th 2018 up to the end of 5th May 2019. A non-probability (purposive) sample of (100) student at college of nursing from different post educational levels, both sexes (males and females), were selected. The data collected was analyzed using SPSS version 17.0.

Results: the majority of the study were male who accounted for (58%) of the total participants while female constituted (42%). Most of the study participants (98%) were ages (21-30) years old. (90%) of the student were secondary school graduate. Nanty three percent of the student were married and sixty nine percent were sufficient.

Conclusions: The undergraduate critical cares nursing students were adequately prepared to care for terminally ill and dying patients as they had deficiency in some knowledge about palliative care but their knowledge towards palliative care was good.

Keywords: Assessment, Undergraduate Critical Care Nursing Students Knowledge, Attitudes, Dying Patients

Introduction

Palliative care is considered, and will remain, a vital part of the duties of nursing. Nurses are members of the most respected computer team who are involved in physical, functional, social and spiritual care areas. Usually, when working in the field of health care, it is the face of the death of the patient, and specifically, most of the patients in critical care units die. Therefore, critical care nurses play (CCNs) a key role in palliative care and end of life, and they are responsible for knowing how to take care of patients who die properly (1). Although there is an indication of the value of PC support, and a number of workers in the field of health care available to provide PC are insufficient to meet the needs of patients and their families through a lifetime, adjust the course of the disease and health care. One important factor affecting the success of the delivery of your computer is to know the attitudes of nurses and provide care for patients who are dying (2). As part of the American Basics Association of Colleges of Nursing (AACN) for the education of baccalaureate and peaceful death document, it has been identified specific objectives and guidelines to ensure

Corresponding author:
Assist. Instructor Ahmed F. Hassan.
E-mail: haider_m2008@yahoo.com
efficiency in the computer before graduation. There is no doubt that the value of personal computers in CCN networks that provide the majority of care for patients with diseases do not end, studies have been conducted in the past to study the attitudes of nurses towards the care of death, but only a little is not made of research focused specifically on CCNs. Moreover, a number of authors discussed the lack of research in the attitudes of nurses towards students with disabilities. Therefore, there is a need to support education and nursing students in critical care (UCCNS) to provide high-quality computers.

Methodology

A cross-sectional descriptive and analytical study: Assessment of Undergraduate Critical Care Nursing Students’ Attitudes toward Caring of Dying Patients In colleges of Nursing at Baghdad University. This study was conducted at college of nursing between December 8th 2018 up to the end of 10th May 2019. A tool of knowledge questionnaire was developed and distributed to the participants in this study. The sample consisted of (100) student at four stage college of nursing. A questionnaire-interview format was designed and developed by the researcher for the purpose of the study; such development was employed through the available literature, clinical background and interview with student. All the items were measured on scale of (2) indicates that the know 1, don’t know 0. The questionnaire consisted of (3) parts. Part I: Demographic Information Sheet. Part II: Undergraduate Critical Care Nursing Students’ knowledge Sheet. Part III: Undergraduate Critical Care Nursing Students’ Attitudes Sheet. Rating scale was used to rate the frequency and extension of the problems. The content validity of the instrument was established through a panel of (10) experts. The data were collected by using the questionnaire structured format through interview and inspection technique for nursing student Attitudes toward Caring of Dying Patients. Each student was interviewed personally by the researcher. Throughout each interview explanation of the study was held up with student in order to accept participation. The determination was conducted during the period from January 29th to the 9th April 2019. The data were analyzed through descriptive data analysis and inferential data analysis the data were analyzed through the use of Statistical Package of Social Sciences (SPSS) version (17).

This table shows that there is no significant difference between (Gender, Age, and Past Level of Education) and student knowledge domain.

Discussion

Through the course of the data analysis of the present study the finding showed that the majority (58%) of the study were female while the remaining was male. The highest percentage of age group in present study (98%) were (21-30) years old and lowest percentage (2%) were (31- 40) years old .Concerning Marital status and past level of education, (93%) from the sample were single, most of them are (90%) secondary school graduate. monthly income for study sample were (69%) barely sufficient income.

This finding supported by Paolo and Lorys, (2014). who shows that the 82 participant students, 22 (26.8%) were males and 60 (73.2%) were females. The mean age was 21.46 (SD = 1.13) (5).

The result of accurate study that show of dying patient domain in table (2) for student nurses knowledge are poor in items(The fluid imbalance in the body reduces the patient’s need for sedatives and Palliative care philosophy is compatible with the philosophy of aggressive therapy).The mean of score is good at all dying patient domains.

This finding is disagrees by Chari, et al, (2016), which that that 48.48% of students had average knowledge prior to the workshop while 6.06% had good knowledge, whereas, 45.45% had poor knowledge. After the intervention, none of the students were with poor or average knowledge (6).

The result of accurate study that show Table (2) the total nursing student’ attitude toward caring of patient dying, which indicated that nursing student’ had positive attitude , with respect to the total mean of score (MS) which was (.667).

The findings of the study disagree with result obtained from other study who reported that Findings from the present study suggest a need for end-of-life care nursing education in Italy. The preliminary results concerning the psychometrics of the scale suggest that the Italian version of the FATCOD-B could be in need of revision. The implications for practice are discussed. (7).
Age, gender and Level of education in comparison of the respondents total Student Nurses knowledge domain in table (3), there was non-significant between Age (c² obs=.519, df=2, p ≤ 0.05), gender (c² obs=.519, df=2, p ≤ 0.05), past Level of Education (c²-obs=5.886 df=2, p ≤ 0.05) with Student nurses knowledge domains.

This finding is supported by Paolo and Lorry’s, (2014), who reported that no significant differences (p = .857) were found between male (114.93 ± 7.78) and female (115.28 ± 7.97) students (12).

Another study agreement by suad, (2017). Show that no significant differences were found between the studied UCCNSs’ age and sex and their total knowledge score (P = 0.422 and 0.70 respectively) (8).

Conclusions

This study demonstrates that, despite good nurse’s student knowledge and positive attitudes regarding caring of dying patient. Based on the results and conclusions of the present study; the researcher recommends To integrate palliative care education within critical care nursing course to better prepare novel graduates for the inevitable care prepare the best graduates of the novel to take care of the inevitability of a patient of a terminally ill patient.

Abstract

Objective: This study was done to evaluate the potential toxic effect of aspartame (APS) artificial sweetener after chronic oral administration in rat pups as a model for children that consumption high quantities of different types of sweets and juices from the peddler, regularly and daily.

Methods: Twenty-four rat pups were divided equally into three groups. Therapeutic dose group (T1) and double dose group(T2) received 0.08, 0.16 g/kg. body weight(BW), respectively, while control group (C) received distilled water orally for 90 (d)ays.

Results: The result of present study revealed that there was an increased consumption of food, water and arising nervous signs(aggressive) in T1 and T2 groups comparing with control. The cytogenetic study includes the mitotic index and blast index showing a substantial decline relative to the control one in both treated groups. While the blast index showed a significant reduction(P<0.05) in T2 relative to T1 and the control group. No chromosomal aberration observed in all groups exposed to aspartame. Different histopathological lesions were recorded in the liver of T1 group represented by inflammatory cell (neutrophil & mononuclear cell) aggregation around the blood vessels. While noted in a double dose group (0.16g/ kg.bw), a granulomatous lesion with mild change in fat is shown.

Conclusion: Used daily for lengthy periods ASP has cytogenetic and pathological risks.

Keywords: Aspartame, chronic toxicity, pups, cytogenetics.

Introduction

The passion of human beings of sweet foods is inborn, the studies proved a preference for sweet-tasting nutrition in newborns, human beings draw near to caves, even ancient cave paintings show a Neolithic man taking honey from a bee’s nest(1). It’s a dipeptide artificial sweetener that is widely used in all ages as a non-nutritive sweetener in foods and drinks, a high intensity sweetener most commonly found in low calorie beverages, chewable multi-vitamin, breakfast cereals, dessert mixes, diet Soda, tabletop sweeteners added to tea or coffee and food products, and pharmaceuticals which has been approved as a sweetener for liquid carbonated beverages(2). ASP has fair acid stability but poor heat stability(3) After ingestion, aspartame is immediately absorbed from the intestinal lumen and metabolized to phenylalanine, like aspartic acid, and methanol(4). ASP is metabolized by digestive esterase and peptidases in the intestinal lumen to methanol and its constituent amino acids phenylalanine and aspartic acid or absorbed by intestinal mucosal cells were hydrolyzed to its components(5).Followed by absorption into the systemic circulation, phenylalanine enters the plasma free amino acid pool from the portal blood after
partial conversion to tyrosine by hepatic phenylalanine hydroxylase(6). Methanol has previously been shown to result in the generation of ROS(7).

**Materials and methods:** Twenty-four (24) pups of the albino rat, aged 30-40 d with weight range (100-150g), supplied from the animal house of the College of veterinary medicine of Al-qasim green university, according to the ethical standard of working on laboratory animals. They were housed and maintained in a conventional animal facility, with controlled conditions of temperature (20 ± 5ºC). The animals were fed on special formula feed pellets and given water *ad libitum*, throughout the experiment, each group of rats was housed in a plastic cage containing hard-wood chip as bedding.

**Chemicals:** Aspartame obtained from NutraSweet–Monsanto company _ America.

**Preparation of concentration for chronic toxicity study:** Dose of Aspartame measured according to(8). When approved it as a sweetener.

**Therapeutic dose (T1):** (0.08g/ kg.BW): to obtain 80mg/kg.bw of Aspartame dissolve 8g in 100ml distilled water, and dosing 1 ml for each 100g (rat) daily for 90 d.

**Double dose (T2):** In the same way in therapeutic dose but in double dose give 2 ml for each 100g (rat) daily for 90 d to obtain 0.16g/kg.bw of ASP.

**The control group(C):** Was given 1ml of distilled water for each 100g (rat) orally daily.

**Histopathological examination:** The samples prepared according to(9).

**Cytogenetic analysis:** According to(10).

Mitotic index(MI) = \[ \frac{\text{Cells in metaphase}}{1000} \times 100 \]

Blast index (BI) = \[ \frac{\text{Number of lymphoblast}}{1000} \times 100 \]

**Statistical analysis:** Statistical analysis was applied by one-way ANOVA and the mean difference is significant at the 0.05 level in using statistical package for social sciences (SPSS), Version 10.

**Results**

**Chronic toxicity:** After 90 days of oral administration the animals of T1 and T2 groups showed some physiological and neurological signs listed in table (1).

**Blast index and Mitotic index:** The results revealed a significant decrease ($P<0.05$) of mitotic index (number of cells in mitosis/1000 in cells of the bone marrow) of exposed groups (T1 and T2) comparing with the control group and in a dose-dependent manner. While the blast index (number of lymphoblasts/1000 in cells of the bone marrow) showed a significant decrease in T2 group comparing with T1 and C groups.

**Histopathological finding:**

The histological examining of the liver section in the control group of rat pups showed normal tissue. Furthermore, in sections of the liver of animal received 0.08g / kg.bw of ASP for 90 d there was inflammatory cell (neutrophile & mononuclear cell) aggregation around the blood vessels. While in double dose group (0.16g/kg.bw) observed shows granulomatous lesion with moderate fatty change.

**Fig(2): Histopathological finding of the liver of rat pups after chronic exposure to ASP.**

**Discussion**

The results showed that ASP increases the consumption of food and water, the appetite increase through ASP metabolites by different mechanisms one of these mechanisms is that an increased phenylalanine concentration releases cholecystokinin(12).Which is an endogenous anorectic agent(11). As a precursor of catecholamine neurotransmitters(13). Phenylalanine may facilitate intake via the hypothalamic adreno-receptors implicated in the central appetite control mechanisms, stimulating appetite(14). Increased fluid intake can be associated with the intensive sweet taste of ASP and its hedonic impact. ASP is about 200 times sweeter than sucrose(6). On the other hand, the result showed there was an increase in weight gain of animals exposed to as this is the natural result when you have increase in food consumption and that’s who recorded (16).When reported increased body weight and fluid intake in a group treated with ASP. There are opposing opinions about the effect of ASP on body weight changes. Some studies reported increased body weight caused by ASP(15,2). While others showed that ASP is efficient in body weight loss(16,17).We observed predicted increased appetite and high weight gain in ASP-treated rats. From the foregoing it is clear that the methanol, which is a by-product of aspartame, may be responsible for the alteration observed in the free-radical-scavenging system. Since methanol is freely permeable through membranes and lipids, it also gets distributed in the brain tissues and may cause damage. Increased production of free radicals and increased oxidative damage to proteins in distinct brain regions, retina and optic nerve after methanol administration(18,19).

Also, we agree with(20), who was reported that the aspartame intake has been reported to be responsible for neurological and behavioral disturbances in sensitive individuals. Oxidative stress is an imbalance between the elevated level of ROS and the impaired function of the antioxidant. Overproduction of ROS can induce the death of immature cultured cortical neurons(21). And DNA damage(22). Marko D, et al have reported that increased ROS can trigger cell damage. The increase in ROS level may be due to methanol that is released during aspartame metabolism in the GI tract, as the pathway leads to formaldehyde and format production by the catalase enzyme. Cell death could occur in response to high oxidative stress(23,24). The result of the cytogenetic study revealed there are significant decreases ($P<0.05$) in MI of animals exposed to a therapeutic and double dose of ASP comparing with control which received DW. In contrast, the result of BI showed significant decrease ($P<0.05$) in the T2 group comparing with T1 and C groups. Aspartame is hydrolyzed to several products including methanol, which can be further metabolized to formaldehyde, which is a DNA cross-linking agent, known to induce chromosome damage in mammalian cells(25).We thought that metabolites (methanol, formaldehyde, formic acid, and acetic acid) that respectively released when ingestion of Aspartame play a vital role in inhibition of MI and BI, and that agrees with Rencuzogullari, et al 2004(2). when they reported that aspartame showed cytotoxic effect by decreasing the mitotic index at all concentration and treatment periods. Furthermore, the present study showed no chromosomal aberration in stem cells of exposed pups, on the opposite to AISuhaibani who observed that aspartame induced a significant increase of chromosome aberration frequencies in mice compared to control(26).

Rencuzogullari et al(2), studied the genotoxic effects of aspartame on human lymphocytes in vitro using chromosomal aberration test, SCE test, and micronucleus test. They found that aspartame induced a significant increase in chromosomal aberrations(27). Other authors evaluated the effect of blends of aspartame and acesulfame-k on induction of chromosomal aberration in bone marrow cells of male mice. The authors observed an increase in the percentage of cells with chromosomal
aberrations with increasing doses of the two sweeteners(28). Also, our results are supported by(29), who tested the possibility of micromolar formaldehyde, a metabolite of methanol derived from aspartame exerts cytotoxicity. Strachan and Read explained the occurrence of numerical aberrations through two main mechanisms after aspartame exposure(30). The result of histological sections of the liver of rat pups received 0.08 g/kg.bw of ASP for 90 d showed there was inflammatory cell (neutrophile & mononuclear cell) aggregation around the blood vessels. While in double dose group (0.16g/kg.bw) observed shows granulomatous lesion with moderate fatty change . that’s maybe due to increase the ROS in the tissue of liver and other vital organs due to long term exposure to aspartame. Hydroxyl radicals oxidize polyunsaturated fatty acids in an increased in biological membranes to induce the formation of lipid peroxides(31). The results indicated that exposure to ASP increased lipid peroxidation in the liver and other organs, this idea supported by Mourad IM and Noor NA 2011 When recorded that ROS increase in long-term ASP treatment in brain, liver and kidney tissues. The high level of ROS may be due to methanol formation during ASP metabolism and formaldehyde release as part of methanol metabolism(32). This has been well confirmed by Parthasarathy, et al who observed an increase in the LPO level in the lymphoid organs after methanol administration(33).The present study with an agreement with Abdel-Salam, et al who reported that increase aspartame concentrations than Acceptable daily intake (0.04g) the effects begin to appear on many vital organs like liver, brain and kidney(34).

Conclusion

According to our results, we can conclude that aspartame has a genotoxic risk. Therefore, it is necessary to be careful when using it in food and beverages as a sweetener.

Examining The Forensic Toxicity of Ricin Using Lc/Ms Techniques

Bandr Siraj Fakiha

Department of Medical Health services, Faculty of Health Sciences, Umm Al-Qura University K.S.A.

Abstract

As one the naturally occurring toxins, Ricin is classified among the deadliest poisons available. Ricin and Ricinus communis agglutinin (RCA120) are derived from the castor bean plant. Ricin and its related activities can be detected using either mass spectrometric (MS) assay or Liquid Chromatography (LC). Further, the two methods can be to differentiate ricin from RCA120 because it is less toxic of the two. The sequence of Amino acid is identified by monitoring the active ricin using mass spectrometric. This study discusses how LC and MS methods can be applied to quantify, detect, and differentiate ricin from RCA120 in test samples. On the overall, the two methods were applied to tell aside ricin samples from RCA120. The study concluded that mass spectrometry is the most efficient approach in identifying ricin from RCA120.

Keywords: Ricin; Chromatography; Peptide; Castor Bean; Protein; Toxin Peptide; Liquid Chromatography; RCA120; Mass Spectrometric.

Introduction

As one of the most toxic substances, ricin is primarily obtained from the castor bean plant (Ricinus communis). Castor bean plant grows naturally in subtropical and tropical regions. Since the plant is easily available, ricin is easy to prepare, therefore, it can be argued that the substance can be used as a biological weapon by malicious people [1]. This makes it the only protein classified as Schedule 1 chemicals [2]. Since ricin is a protein, it is made up of both A and B chain subunits [3]. The primary responsibility of chain B lectin is binding lectors with galactose on the surface of the eukaryotic cells. By so doing, they trigger endocytosis of ricin. Chain B lectin is responsible for initiating all the deadenylase activities that are responsible for initiating an irreversible depurination reaction of 28S rRNA which terminates protein synthesis in the cell. Therefore, the fact that ricin is readily available should be a major concern because it could be either knowingly or unknowingly to contaminate global and domestic food supplies [4]. For prevention purposes, there need is develop an effective approach that can be applied to detect ricin in foods and avoid possible deaths from the same.

Ricin can get into the body through inhalation or ingestion of materials that contain the same. However, the substance can also be directly injected into the bloodstream [4]. An injection is an unlikely method because the victim must be present for the chemical to be injected into their bloodstream. In a situation where a person is attacked using the chemical, it important for the toxin to be detected as soon as possible. Detection of this chemical includes sampling of materials such as foodstuffs and soil where a case of food poisoning is suspected [5]. In regards to the nature of risk in ricin, a lot has been invested in research to help identify the most accurate and effective method that can be used to detect ricin that might be in a range of substrates. The main aim of this article, therefore, is to examine the forensic toxicity of ricin using the methods attempted and the extent of their achievement.

Materials and Method

Safety

As one of the most poisonous known substances, all the experiments and extraction processes involving ricin should be conducted in a biosafety cabinet [6]. However, the samples coming from the digestion process are not considered toxic. Therefore, when dealing with ricin, safety measures should be considered.

Preparation of Antibody-Coated Beads

Biotinylated Anti-Ricinus Communis Agglutinin
(RCA) antibodies were purchased by the researcher from Somatco in Jeddah. The antibodies were employed as intermediates to localize lectin receptors [7]. 5 mg lyophilized aliquots were bought and later restored using distilled water with a density of water of 1 mg/mL. To add to that, the researcher also bought MyOne T1 streptavidin-coated beads from ThermoFisher. The instruction of the manufacturer was used when preparing the beads. Ideally, principle of using magnetic beads is that they have an immobilized affinity to the isolated structure of ricin as the target compound [7].

**Extracting Ricin and RCA120**

5 mg/mL purified solutions of ricin and RCA120 agglutinin were purchased by the researcher from Somatco. The matrix sample with agglutin and toxin was incubated for 30 min and then a magnetic capture was used to recover the components. The capture beads were removed from the mixture after an hour and washed using distilled water, 0.5 mL of PBS, 1 mL of 0.05% PBST, and 1 mL of 0.01% PBST [8].

**Extraction of Castor Bean**

The researcher purchased castor beans with approximately the same weight from M.A.B.M. Trading Est. To facilitate the process of extraction, the beans were crushed using pestle and mortar a then put in the sample matrix. The mixture was then left to incubate for 18 hours and later centrifuged to settle the particles. The beads coated with antibody were used to extract 0.5 mL aliquot of the supernatant. The analysis was then carried out using relevant methods [9].

**Digestion of Protein**

To facilitate the process of protein digestion during the study, the researcher purchased Rapigest SF from Somatco. Rapigest SF acted as enzymes to speed up the reactions within the solution. The enzymes were purchased in 1 mg lyophilized aliquots. These quantities were then converted in 0.1% solution using 100 mM ammonium bicarbonate. Further, the process of protein digestion was carried out using buffer exchanging magnetic beads which contained ricin in the Rapigest SF solution [8].

**Preparation of Peptide**

Ricin quantification peptides that combined both A and B chains were chosen by the researcher. This also helped to distinguish ricin form RCA120. However, the researcher was very keen to avoid all the peptides that contained tryptophan, methionine, and cysteine. Further, all the glycosylated peptides were omitted. Finally, the peptides that passed all the criteria were selected for synthesis [7].

**Liquid Chromatography**

The process is very critical in separating a sample matrix into sub-components. Ideally, the separation process is initiated by various interaction of the matrix while in both mobile and stationary phases. Further, a 1200 capillary pump was used in the chromatographic separation. All the solvents were developed by Jackson and Burdick [8].

**Mass Spectrometric Quantification**

The method was very effective both in sensitively and selectively detecting and assigning a signal to a particular chemical even when it was in low concentrations. LTQ module was used by the researcher to actively perform mass spectrometric quantification. The sample was later put to LTQ through electrospray for ionization purpose. The process recovered all the productions that were within the mass and not exceeding a certain low mass cutoff during the Collision-induced dissociation (CID) [8].

**Activity Assay**

Various methods can be employed to detect ricin protein, however, the majority of these approaches in practice cannot differentiate between active and inactive ricin. The primary objective of this study was to come up with a selective and sensitive method that can be used to completely analyze ricin by taking into considerations both the structural components and biological activities of the chemical. Both MS and LC-based methods use three layers to detect ricin activities that might be present in a mixture. Therefore, the process involved various activities which include separation of ricin from the lab samples by use of antibody-coated beads. Ricin was then digested and the analyzed using MS and LS methods to identify the toxin.

**Results**

Ricin substrate was detected in the sample matrix spiked with 15 pmol ricin in the activity assay. However, the same did not happen in similar pure samples. Both MS and LC-based methods were effective in detecting ricin peptides and further helped to distinguish them
from RCA which has a less toxic homolog. Even though both methods were effective in detecting ricin substrates in the matrix, the main challenge was to differentiate toxic and less toxic forms. The researcher found that including four more peptides as confirmation ions did not increase ambiguity. The four additional peptides were very critical in confirming the presence of both A and B chain as well as distinguishing ricin from RCA120. The process of quantifying took into account four tryptic peptides with T7 peptide which empirically yielded charge ion and resulted in the best sensitivity. T18, T10, and T11 peptides were also unique in the experiment and they produced quantitative results similar to those from T7. Use of T7 as while quantifying the peptides lead to low limit of detection for the protein.

Differentiating Ricin form RCA120

Both substances share more than 85% sequence homology [9]. In addition to that, there are no known antibodies with a potential of binding to ricin over RCA120 [10]. Mass spectrometry method effectively and selectively differentiated the two type of toxics based on the natural sequence of proteins. Quantitative measures that employ MS/LC technique are limited because they can only be use on few tryptic peptides. Further, T7 peptide obtained from ricin can be used to tell apart ricin from a sequence of amino acids [11]. In this context, the amount of ricin produced using LC/MS experiments was constant throughout the process regardless of the amount of RCA120 employed. This was a clear indication that only ricin was being quantified and the quantity of RCA120 did not play any role in the perceived protein.

Contamination of Castor Bean

During the experiment, four sample matrixes with already crushed castor beans were evaluated for ricin after they incubated in LC and MC methods. Since a castor bean is off 1.5% toxic of weight, the researcher estimated the maximum amount of ricin in a castor bean to be about 10 mg. Further, this was because the limit of ricin recovery for LC and MS method is approximated to be about 10 mg. However, to ensure that the collected ricin was within the established range, the tryptic samples were split to form several aliquots and then LC and MS analysis were carried out. After the dilution process, the matrixes were passed through an immune purification process and LC/MS analysis processes. The amount of ricin present in the sample was then evaluated using ricin T18, T 7, T10, and T11 peptides. Despite all the sample containing some significant amount of ricin, the amount varied from one sample to another. As the same sample of extracted ricin was used in all the matrices, pH level and complexity of the matrix did not have a significant impact on the recovery of ricin [13].

Discussion

Most methods used in forensic toxicology of ricin can be classified into three categories [14]. To begin with, the first category of the methods utilizes immunogenic interactions when detecting the presence of ricin. For example, the enzyme-linked immune-sorbent assay is one of the methods that fall under this category. Secondly, the second group makes use of the enzymatic activity of ricin. The final category of methods used to detect castor bean DNA is based on the assumption that they would contain ricin toxic as well. For instance, the polymerase reaction falls under this category. Further, these methods are very fast but have a low limit of detecting ricin [15]. In addition to that, these methods also require cheap instruments to set them up. However, despite being effective, none of the three methods represents a comprehensive assay. Further, despite polymerase chain reaction being quantitative and sensitive, the presence of toxic ricin is indirectly carried out. In addition to that, enzymatic activities in the mixture can be inefficient in scenarios when the sample contains other toxic proteins.

Almost all the biotechnology and bioscience separate, isolate and purify both peptides and proteins and other molecules in the cell. Therefore, the use of technology and separation process is very critical; this calls a further investment in the biotechnology field [16]. Hence, there is need for the stakeholders to develop a more accurate and advanced technique of separating the two toxic substances. Further, the new technique should have the capability of treating dilute solutions containing a minimum amount of the target proteins mixed in other compounds. This research was advantageous over other methods used in the separation of ricin and RCA120 because it made the use of peptides corresponding to both proteins. Therefore, LC/MS methods enable analysts to quantify ricin independently from RCA120 depending on the quantification peptide used.

Importance of Ricin Activity Measurement

Given the toxic level of ricin, it is critical for public health investigators to effectively react to any contamination cases involving ricin. Currently, various analytical methods are available to facilitate the analysis
of proteins [17]. Since the mass spectrometric techniques have been found to offer direct evidence on the structure of molecules by measuring the mass of the molecules, identifying possible modifications, and determining the sequence of amino acids, it is useful in determining whether the protein toxins is a risk factor to a certain disease [18].

**Conclusion**

The study analyzes the ability of MS/LC methods to detect the presence of ricin in laboratory samples. Further, the research explores selectivity and specificity of such methods in examining and quantifying the amount of ricin in a substrate. Analysis carried out using chromatography and mass spectrometry is advantageous over other methods in different ways. To begin with, they offer a direct approach to the measurement of ricin. Secondly, the approach is not easily influenced by other proteins in the sample. Further, LC/MS can successfully be used in quantifying ricin and RCA peptides. Even though LTQ approach can be used to tell apart ricin from other proteins, immune purification approach was used in the experiment because it enables the analyst to maintain a low detection limit. Further, it also ensures that a second layer is available. Finally, the choice of tryptic peptides for forensic toxicity of ricin makes it possible for the analysts to accurately and independently quantify ricin from RCA120.

**Acknowledgment:** I would like to acknowledge my university department for being supportive when conducting the research. Further, I am grateful to the University for providing their database and resources for use in the research.

**Ethical Clearance:** There were no ethical issues involved as the study was analytical and did not include any human participants or animals.

Nurses knowledge about Management Extravasation Intravenous Cytotoxic Medication At Amal National Hospital in Baghdad City

Batool Kadham Hussin¹, Wrood Abdul Razaq Ahmed²

¹Assistant Instructor, Nursing Department, Institute Medical Technology, Baghdad, Middle Technology University,  
²Trained Technician, Commnunity Health Department, Institute Medical Technology, Baghdad, Middle Technology University

Abstract

Background: Extravasation, the unintentional leak of an anticancer agent from a vessel into the close tissues, is an uninvited and difficult problem that can lead to permanent local harms and severe disability.

Objectives: To assess nurse’s knowledge about management extravasation vesicant intravenous cytotoxic medication.

Methodology: Descriptive design using a self-administered questionnaire was employed. At al-Amal national hospital for tumor treatment in Baghdad city from 2nd December 2018 to 10th February 2019. Random sampling method. The sample size was 45 nurses completed a questionnaire about management extravasation vesicant intravenous chemotherapy. Instruments: developed by the researcher consist of three sections the first section to assess the demographic data. And the second section questionnaire consists of 20 items divided into two parts to measure the information of team nurses on vesicant drug and management extravasation Vesicant intravenous chemotherapy. Data analysis by using the Statistical Package for Social Sciences version (SPSS) 23.0 included. (Frequency, percentage, Kruskal Wallis H test, Chi-square test, and Mann-Whitney U test). The level of significance was the threshold at p<0.05.

Results: shows that the high percentage (42.2%) of oncology nurses ages (30-39 years old). Most of them (57.8 %) were female. The education level represents (42.2%) of nurses were from nursing institute graduates, the high percentage (46.7%) of them their experience in oncology unite were (5-9) years. Mostly no training session. Inferential there are statistically significant between education levels groups the nursing college showed a higher mean knowledge score than other levels. also, a higher significantly difference was observed between mean knowledge and participate with Training courses by mean (36.40) The researcher decide that nurse’s knowledge is the poor component about vesicant cytotoxic and management extravasation according to of assessment result

Conclusion: there is a need for structuring a permanent education program due to the poor scientific of nurse’s knowledge about the vesicant and management of extravasation by chemotherapeutic drugs. Therefore, the issue of training courses should be highlighted for it is an effective role in improving the performance of nurses.

Keywords: Nurses, knowledge Vesicant, Cytotoxic, Management Extravasation

Introduction

Broad chemotherapy works an essential part in curative therapy for patients with hematological
neoplasms and numerous categories of advanced fixed tumors. Most anticancer agents are managed intravenously. Extravasation, the unintentional leak of an anticancer agent from a vessel into the close tissues, is an unwelcomed and difficult problem that can lead to permanent local harms and severe disability (1, 2). Extravasation follows when a vesicant chemotherapeutic agent that has a possibility to cause burning leaks external the vein into the around tissues. This leakage could lead to management delays Finish of chemotherapy, tissue necrosis, a loss of Extremity deep tissue toxicities, and maybe a loss (3). The rate of extravasation in adults is approximate to be in the range from 0.1 to 6% (4). Then few findings report the prevalence on the origin of fixed data with an overall number of patients who received chemotherapy (5). Extravasation can reason a diversity of non-specific symptoms, the severity of which can vary broadly. Any delays in discovering and treating extravasation may raise the chance of developing tissue harm and necrosis (6,7). The extravasation as indicated by Erythema, swelling or hardening, the absence of blood return, increased resistance when managing a bolus, a decline in the infusion rate and Ulceration Vesicants can cause pain, edema, and erythema and potentially lead to blister and tissue necrosis when injected outside the vein or into the tissue. (7,8,9) Classification of Anti-cancer drugs is grouped into three classifications according to their capability to cause tissue harm after being extravasated vesicants, irritants, and non-irritants (10).

Material and Method

A descriptive design study was conducted to measure staff nurse’s information about management extravasation vesicant intravenous cytotoxic medications. At. Al-Amal National Hospital for tumors treatment in Baghdad city from 2nd December 2018 to 10th February 2019. Purposive sampling technique will be used in this study. Consist, 45 nurses, Moral issues: An agreement for research procedure was achieved from the Al-Amal National Hospital for the treatment of tumors, Health Department of the Medical City. Before data collection. The privacy of participants’ information was confident, and the access to the information taken from the participants was controlled and not revealed outside the research panel. A questionnaire was established. To evaluate the information of team nurses concerning management extravasation vesicant intravenous cytotoxic medication, by using the broad publication of the literature. A scientific source was directed by using the search of the scholar, “PubMed and the Cochrane library database” for published clinical articles in professional and academic journals, including literature reviews, Systematic Reviews inclusively. Only literature published in English was considered from The period covered was from 20 September to (1st November 2018). The instrument used in the current study involves three sections. The primary section is socio-demographic variables involving nurse’s gender, age, level of learning, Number of years working in oncology units and participated in a training course related to chemotherapy. And the second section is related to knowledge consists tow axis each axis consist of 10 items which covering knowledge about. Vesicant cytotoxic medication and management extravasation. The participants are requested to select one the following answer (correct, incorrect, or I don’t know ) and recoding answer, the true answer in the information axis taken (2) point while incorrect was (0) and don’t know carried (1) mark. This gave a total score range of 0 - 40 for information questioners. The Validity was an evaluation by a panel of (10) Experts they are (5 faculty members from the College of Nursing University of Baghdad, (4) experts from Al- Amal National Hospital, and (1) expert from College of Medicine University of Baghdad. The reliability was (.819) assure through the pilot study by Cronbach’s alpha test. For analysis of data, Statistical Package for Social Sciences software, version 23.0 (SPSS) was used. Initially, all information gathered via questionnaire was Coded into variables and answers coded were incorrect (0) don know (1) correct (2). The normality of data was tested using the Kolmogorov-Smirnov test. Descriptive used Frequency, mean, Sander deviation and percentage. And inferential statistics involving Chi-square test, Mann-Whitney U test, Kruskal Wallis H test.

Results

The outcomes descriptive statistics for each demographic data were shows that the high percentage (42.2%) of oncology nurses ages (30-39 years old). Most of them (57.8%) were female. The education level represents (42.2%) of nurses were from nursing institute graduates, the high percentage (46.7%) of them their experience in oncology unite were (5-9) years. The table also shows most of the nurses had no training session by (77.8%).

Dissection

The total outcome of the study indicated that the participants have poor information; this paper is the initiative to evaluate the information concerning vesicant cytotoxic drugs extravasation between nurses. But there is one search for the general cytotoxic extravasation the current study differs from previously conducted studies in certain respects. First, knowledge specific for vesicant cytotoxic drugs. Secondly, a scoring system was developed and scores of participants for each domain were analyzed and correlated with various demographic factors. This finding is risk for quality nursing care to patients cancer because if oncology nurses did not have logical knowledge and not capable in their skills will be reflected as unsafe nursing care to patients with cancer and chances for practical errors can be high as various studies in past already highlighted these points. Nurses’ awareness and information about the management vesicant of cytotoxic drugs remains a concern linked to improvement in safety standards. On the other hand, the result of the study indicated the ineffective function of continuing education in the hospital and the lack of interest in updates with scientific developments.

From result of present study, the characteristics of the demographic variables described that the participants were, mostly participation female (57.8%), and male (42.2%) it disagree with study was all participation female (1) with high percentage level 30-39 (42.2%). The level of education included in the present study was (42.2%) of study group graduated from nursing institute included in their study which was conducted on 16 nursing team professionals who work in a hospital in the interior of the state of, Brazil hospital conduct to measure information of the nursing team about the prevention and management of extravasation of chemotherapy. it study different by classified sample according to Professional category. There are Nursing assistants (6.25%), Nursing Technician (31.2%) and Nurse (62.5%). The present study has the Years of working in the oncology unit high present(46.7%) which is of (5-9) years due to the new appointment in the nursing career of nurses who participated in the study sample. (1) in this study, the majority of the study sample have (0-10) years of experience Time of work in oncology. While another study was (71.7%) 20–25 years of age group (2). Concerning participation in training courses in the field of chemotherapy treatment, showed Low percentage of the group study which selected from Al-Amal center who participated in training courses is (22.2%). This result agrees with point of view who presented that (56.2%) of nurses had no participation in training courses with chemotherapeutic agents. This may be indicated lacking the role of continuing education units in center and some of the nurses do not interest to participate in training courses in their center (1). Regarding Association of The Nurses Information and their Demographic Data, The outcome showed that there was no statistical significant associated between Nurses’ Knowledge and their demographic data (age-gender Number of years working in oncology wards) at p-value > 0.05, thus Demographic variables have no influence on the level of knowledge of the staff nurses on management of extravasation this result is supported by (2) who assess the existing knowledge and practice of staff nurses on prevention and management of extravasation among Infant receiving I.V. Therapy, at hospital in India He found that there was no statistical significant associated between nurses Information and their demographic data (age gender and years’ working in oncology wards) at p-value 0.05.

About demographic variables (level education and training courses) there are high statistical significant education level and training courses and nurses knowledge about management extravasation intravenous. it because of attending continuous nursing education courses and training have the advantages of preservation nurses up-to-date and refining their knowledge in oncology wards.

The total result of the current study shown that the participants have deficient knowledge, this result supported by (1). Point of view that lack of technical and scientific knowledge about the prevention, identification, and treatment of extravasation by cytotoxic drugs. And study (3) conduct of the nursing staff in Barisal hospital. The review results show an information insufficiency, on the other hand, disagree with study (2) the study conducted in India to assess staff nurses of information and Practice on avoidance and treat of extravasation among Infant receiving I.V.

Conclusion

The present study indirect that the majority of the nurses need essential information about extravasations of non-cytotoxic drugs. This study prescribes that nurse’s attendants need to take an interest in the additional inside and out instructive projects, given that learning lessons that can assist nurses to completely comprehend
distinguish the danger, avoid in addition manage the extravasations of no cytotoxic drugs.

Correlation between BMI and Thyroid Hormones in Infertile Groups

Etab Abdul-Ameer Al-ogla1, Manar Saad Hussain2, Suad Torki Abd-AL abbas3

1 Lecturer, pharmacy college / Ahlulbait University, 2 Lecturer, Medical Laboratory Technique / Al Safwa University College, 3 Lecturer, pharmacy college / Ahlulbait University

Abstract

Infertility is the failure to become pregnant after 12 months of copulation without contraception. Thyroid defeat in function can caused to the: menstrual disorder, an ovulatory phase and lower fertility. This search formed to assess the importance of thyroid syndromes in infertility women and importance the autoimmunity by assessing value of TSH, T3, T4, & anti Thyroid peroxidase antibody in infertile woman comparison the consequences with women controls. The direction in this search started from March 2015 to September 2015 at Karbala Maternity Hospital, infertility unit, and some private clinics. Showed significant relation between TPO and BMI in controls and patients p-value (<0.002, <0.0001) respectively, and significant relation between BMI and T4 in patients and controls p-value (<0.0001), and shows significant relation between, the relation between BMI and sex hormones shows no significant relation with LH in patients but significant in controls p-value (<0.0001) and relation with FSH was not significant in patients and controls, and relation with E2 shows significant relation in patients p-value (<0.01) but no significant in controls. This search directed to estimation the relationship between thyroid function and sex hormones with BMI. Where the height of BMI affects the body to increase TPO and T4 and affect estradiol, we recommend that women maintain the body weight within normal

Keywords: BMI, T3, T4, TSH, TPO, E2, infertility, thyroid syndromes

Introduction

Infertility (clinical definition) is currently defined as 1 year of unwanted non-conception with unprotected intercourse in the fertile phase of the menstrual cycles. Infertility (clinical definition) is defined as 1 year of unwanted non-conception with unprotected intercourse in the fertile phase of the menstrual cycles

Hormonal disturbance of women reproductive system are involve of a numeral of troubles generating from disorder of hypo-thalamic-pituitary ovarian axis. These comparatively communal disorders often caused infertility[1]. Infertility (clinical definition) is defined as 1 year of undesirable non-conception with unprotected copulation in the fertilization phase of the menstrual cycles [2]

It is classified into: Primary infertility: in female whose gestation suddenly miscarry, or whose gestation produced in a still born child, without always having had a live birth. Second infertility: in women that frequently involuntary miscarriage or the pregnancy come in a still birth next the preceding pregnancy or a previous portability to a pregnancy to a live birth[3]. Thyroid disorder are the major common endocrine disease in women at generative age. Due to above mentioned features of thyroid hormones, estimation of thyroid functions during both pregnancy and treatment of infertility and treating related pathologies become important. In primary stage of pregnancy thyroid hormones are actively involved in the step of placentation; because it was detect that T3 and epidermal growth factor have synergistic effect inthe culture media [4]. Pituitary hormones such as TSH, prolactin or growth hormone may doing Supporting with FSH and

LH to improve the pass of non-growing follicles into the growth phase[5]. The correlation between fatness and procreative function has been famous for a lot of years and it is still being research. Obesity may weaken or damage generative system by Impacting both the ovaries and endometrium, this harmful effects of fatness on generative consequence are well known [6]. But, it is not easy to refer to the exactly how action of the fatness affects to the generative system due to it is complicated. Increased the fat in female heightens polycystic ovarian syndrome (PCOS), and anovulation and may cause hypothalamic hypogonadism[7,8].

Infertility (clinical definition) is currently defined as 1 year of unwanted non-conception with unprotected intercourse in the fertile phase of the menstrual cycles.

Infertility (clinical definition) is currently defined as 1 year of unwanted non-conception with unprotected intercourse in the fertile phase of the menstrual cycles.

Material & Method

Study design: The study is case-control, based study designed to determine thyroid disorders in infertile female. We directed through the time from March 2015 to September 2015 at Karbala Maternity Hospital, infertility unit, and some private clinics. The search consisted of a whole number of 143 females at procreative stage, the age range was among (15-43) years. The patients were 92 infertile women and 51 fertile women. Control samples were collected from the community and some of the staff in the hospital and the university. Diagnosis of infertility and patient selection were done by gynecologist present in infertility unit at Karbala Maternity Hospital. Blood samples were collected from all participants; sera were separated and frozen for measurement of T3, T4, TSH, & Anti-TPO using ELISA device in Imam Hussein Teaching Hospital.

Result

Statistical analysis in table(1) of BMI in relation with thyroid hormones test shows significant relation between BMI and TPO in patients and controls p-value (<0.0001, <0.002) respectively, and no significant relation between BMI and T3 in patients but significant in controls p-value (<0.01), and significant relation between BMI and T4 in patients and controls p-value (<0.0001), and shows significant relation between BMI and TSH in patients p-value (<0.0001) but no significant in controls, the relation between BMI and sex hormones shows no significant relation with LH in patients but significant in controls p-value (<0.0001) and relation with FSH was not significant in patients and controls, and relation with E2 shows significant relation in patients p-value (<0.01) but no significant in controls.

Table (1): relation between BMI with thyroid hormone test and hormonal female in patients and controls.

Discussion

Infertility is a medical, publicly and physically problems in Iraqi society[10]. Most of patients in this study were with primary infertility; this agrees with previous studies[9,11]. Most newly married couples seek pregnancy and attend health services more frequently than those who already have a child. Moreover; Iraqi families take primary infertility much more seriously than secondary infertility.

Twenty percent increased or decreased from typical body mass can have impact on ovulation. Correlation between increased lipid and ovulatory disorders show for early-onset fatness[12]. Abnormal Thyroid functions is related to the increased in body mass, clinical hypothyroidism are commonly related with : mass increase, low temperature , and metabolism speed[13]. Results of the present study BMI in relation with thyroid hormones test shows significant relation between BMI and TPO in patients and controls p –value (<0.0001,<0.002) respectively this result, Results of the present study BMI in relation with thyroid hormones test shows significant relation between BMI and TPO in patients and controls p –value (<0.0001,<0.002) respectively, and no significant relation between BMI and T3 in patients but significant in controls p-value(<0.01) , insignificant relationship between BMI with T4 in patients but significant in controls p-value (<0.0001) , this consequence are compatible with earlier search made by [15] and not compatible with a earlier search done by [14], The reason for the difference with the researcher may be that he compared men and women while in our research the comparison between the patient and control, when relation between T3 and BMI the result shows no significant in patients but significant in controls p-value(<0.01) , and shows significant relation between BMI and TSH in patients p-value (<0.0001) but no significant in controls our results are consistent with a precedent searches done by [14,16] and not compatible with a precedent search done by [15].Results of the present study the relation between BMI and sex hormones shows no significant relation with LH in patients but significant in controls p-value (<0.0001) and relation with FSH was not significant in patients and controls ,our results are consistent with a previous study done by [17,18] and relation with E2 shows significant relation in patients p-value (<0.01)our results are consistent with a precedent search done by [18] , but no significant in controls. our results not correspond to a precedent search done by [18].

Conclusion

At our search was conducted to research the relationship or correlation between thyroid function as well as sex hormones with BMI women . Where the height of BMI affects the body to increase TPO and T4 and affect estradiol , we recommend that women maintain the body weight within normal.

Effectiveness of an Educational Program on Primary School Teachers’ Knowledge about Attention -Deficit/Hyperactivity Disorders

Hassam M. Al-Amarei¹, Saja H. Mohamed²

¹P.H.D.Student. Psychiatric and Mental Health Nursing, College of Nursing, University of Kufa, Iraq, ²Prof., Psychiatric Nursing, College of Nursing, University of Babylon, Iraq

Abstract

The child is one of the most important assets of the nation, the future of mankind, the source of its true power, the promotion and enhancement of the child’s life and welfare is also anchored on the moral supervision and support given by his parents or guardians in order for a child to succeed, parents exert a lot of influence on their child’s cognitive development in the early years, the investigator made an insight into the aim of the study as follows: To determine the effectiveness of the teaching program on teachers knowledge. The study was conducted on at governmental primary schools in Al-Najaf City/ Iraq. A total of the (10) governmental primary schools selected randomly from total (253) governmental primary schools in Al-Najaf City. A purposive (non- probability) sample of (70) primary school teachers’ were selected from the candidate schools were included in the present study. During the period of 1st September 2018 to 20th February 2020. The data was collected by questionnaire which consisted of two main parts, first part consists socio demographic sheet. Second part is about knowledge which consist of (31) items scale of teachers’ knowledge about children with ADHD . Findings revealed confirmed that the teachers who not attended for program about ADHD have poor level of knowledge pupils with attention -deficit/hyperactivity disorder among elementary school teachers. While the teachers who attended for program about ADHD have improve and increase knowledge about ADHD in phase two, and three. Thus, it is recommended for responsible parties to notes the need for greater efforts to teachers should trained to recognize students with behaviors problems / disorders in their classes to provide them with proper and timely education as well as necessary referral for their assessment.

Keyword: Attention deficit/ hyperactivity disorder ,Teachers, knowledge , perception; Elementary school.

Introduction

ADHD is a chronic neurodevelopment condition which is often associated with disturbed classroom behavior that can result in a range of functional difficulties for the childhood and social problems , learning disorders, externalizing behavior problems, psychological difficulties, problems with peer relations, reduced self-esteem. AD/HD can occurs without a clear cause. Some theorists suggest the possibility of neurological dysfunctions as the main cause, whereas others point to family stress as the main reason for its development. Given the uncertainty about its origins, most researchers are now of the opinion that it has multiple and interactive causes. AD/HD is characterized by inattentiveness, over activity, and impulsiveness. ADHD is a common disorder, especially in boys, and probably accounts for more child mental health referrals than any other single disorder. Symptoms include difficulty with sustained attention, being unable to complete tasks, and inability to complete chores and school. The onset of the disorders is hard to diagnosis in kids younger than four-year-old because their characteristic behavior is much more variable than that older children. Teacher can be monitoring and knows child behaviors in the classrooms and other school contexts, so the teacher with parents can pay attention to the child behavior , practitioners rely on teachers to provide information to assist in establishing to observe of ADHD ,more than half of the pediatricians- on information from school reports to diagnose ADHD. Because children with ADHD put great demands on family life, they may
be at higher risk for punitive responses from parents and teachers, which can increase their distress. The presence of ADHD puts the child at risk for a lifetime of maladaptive behaviors and impaired social relationships, so early identification and treatment will be important. Every day, five days a week, children spend the majority of time in schools and interact with teachers, teachers play a vital role in the assessment of student behavior and their academic performance; therefore, they need to possess an adequate level of knowledge and understanding of the various disorders that may occur during childhood. School is the unique setting for the early detection and effective management of ADHD children to function successfully within the classroom setting, appropriate and efficient intervention strategies are required, teachers need a broad knowledge about this condition in order to understand the needs of the children and to plan effective behavior modification strategies, studies show that interventional programs promise an increase in knowledge of teachers regarding, improved awareness and understanding by the teachers allow for a better performance of these children in the classroom, the success of these children largely resides in the hands of their teachers. This study was conducted with an aim to determine the effectiveness of the teaching program on knowledge toward ADHD to help in the early detection and effective management of children with ADHD.

**Material and Method**

"quasi-Experimental study “ was carried throughout the application of test-retest approach of pre-test, post-test I, and post-test II; for the both groups from the period (1 September 2018 to 20th February 2020) through implementation the educational program on primary school teachers’ knowledge towards primary school pupils with ADHD in Al-Najaf Al-Ashraf city. A purposive (non- probability) sample of (70) primary school teachers’. The selected teachers were distributed equally into study and control groups. The study group were selected from 7 schools and the control group selected from the remaining three schools and this selection because: All the selected schools and teachers are from the same geographical area so there is no diversity in their characteristics in a degree which affect the study results. The questionnaire has been constructed and developed as a tool for data collection. Such development was employed through an extensive review of literature, related studies, related books, on the study program. The final copy of the study instrument consists of the following parts: Part I : Covering letters to obtain the subjects’ agreements. Part II: Demographic information. Part III: Knowledge of Attention Deficit Disorder Scale. The third part is the consists of 31 items distributed into three domains of knowledge (general information domain(15 items), signs and symptoms / diagnosis (8 items), and the treatment (8 items).). The researcher adopted and developed the scales based on previous studies such as . Some modifications are needed to complete the study instrument as the experts suggestions. After review and evaluation by the experts, reveal that the instrument has adequate content and major changes have been done such as number of alternative become multiple selection questions to all items according to their suggestions. The most important part in this study is the program and how it meets the needs of primary school teachers. The construction of the education program is based on the results of assessment of teachers’ needs and extensive review of related literatures, the program was constructed to achieve the objectives of the study from the period of 1st December 2018 throughout 1st January 2019. Data collection carried out from 21st /April to 24th /April 2019. The self-report measurement are used as a data collection measurement. The pre-test instrument is distributed for both the study and control groups participants. Second .Implementation phase: this phase conducted to implement the program for the study group participants only. Educational program is implemented throughout six sessions, all sessions are presented in AL-Masoudi primary school in Al-Najaf City. Two lectures every week on Sunday and Thursday. Third . Evaluation phase: this phase is conducted through applying post-test1 and post-test 2. The post-test 1 conducted after application of the program for both study and control groups. While the post-test2 is conducted after three months from the post-test1 for both study and control groups. Before that the researcher distribute a booklet for the study group participants. The post-test1 is conducted in 30/May/2019. While the post-test 2 conducted in 29/ August/2019.

This table shows the level of knowledge between study and control groups over three trials. The level of knowledge about ADHD at pre-test is 40% of teachers have poor level in control group and (41%) of teachers have poor level from study group. Concerning post-test I the table shows that 42% of study group have good level of knowledge while (25%) of control group have fair level of knowledge. Finally, the post-test II indicates that the teacher’s knowledge about ADHD between study and control group were similarly at post-trial I.

The results of table 3 show that: 1- The within subjects test indicates that the interaction of time and group is significant (F= 48.328, p= 0.00). 2- The main effect of time is significant (F= 40.336, p= 0.00). 3- The between groups test indicates that there the variable group is significant F= 41.655, p= 0.00). The significant interaction indicates that the control group and study group are changing over time.

Discussion

Shows the level of knowledge between study and control groups over three test. It’s clear that the level of knowledge about ADHD at pre-test was poor in study and control groups. Concerning post-test I the table (1) reveals that most of the study group (42%) .They have good level of knowledge in comparison with control group (25%), they have fair level of knowledge. in comparison with control group which, are having a fair level of knowledge. While post-test II indicates that the teacher’s knowledge about ADHD between study and control group after three months from education program were similarly at post-trial (study group were 40% compare with control group 22%) . This finding were consistent with 1, under the tattle ‘Effect of AD/HD training program on the knowledge and attitudes of primary school teachers”, who found that the intervention group had significantly higher post-intervention scores on knowledge of ADHD, compared with the control group. As our expectation the result of present study shows not significant differences between study group and control group at (pre-test) for knowledge (t= (-0.255) and t= (1.303), P. value was more than 0.05), because both of them do not attend the educational program about ADHD. The result of the present study indicate highly significant differences between study group and control group at (post-test I and post test-II) for knowledge ( t= 6.244) and t=(10.166), both P. values were less than 0.05). our result enhanced the implementation of education program about ADHD. The result of the present study indicate highly significant differences between study group and control group at (post-test I and post test-II) for knowledge ( t= (-0.255) and t= (1.303), P. value was more than 0.05), because both of them do not attend the educational program about ADHD. The result of the present study indicate highly significant differences between study group and control group at (post-test I and post test-II) for knowledge ( t= (6.244) and t=(10.166), both P. values were less than 0.05). our result enhanced the implementation of education program about ADHD among school age (table2). So, their responses have been improved directly post the complication of the education program in the classroom. The results of the present study are supported by the study of 16, who found significant differences between the pre-test and post-test knowledge of ADHD among teachers who attended education programs on ADHD, also the study of the17, found before and after the training program, and 35 of them filled it out at the 6-month interval. Mean scores of these tests were compared using an a paired t-test. The authors found the difference of mean score of 1.48 ± 2.95, and this was statistically significant (p < .005),authors conclude that the workshop improved the knowledge of the school teachers regarding ADHD symptomatology, and it remained significant even after 6 months of training. (Table 3). With regard to the repeated measures of ANOVA, the study results indicate that there is a significant difference in teachers’ knowledge regarding ADHD between the three levels of measurements (pre-test, post-test I, and post-test II) among the study group (F=48.328, p.value =0.001) which indicate that the study group participants exhibit a good knowledge at the post-test I and post-test II compared with pre-test. This may be because the teachers’ length of exposure to educational programs and presentations on behavioral disorders of pupils with ADHD, however, the booklet was given to each teacher for the study group to help with reviewing and support teaching at home, was more effective in improving knowledge of behavior management of students with ADHD ,it had a positive impact and a strong relationship with accepted useful teacher knowledge. These results agree with 18. The studied the Hispanic teachers’ perception toward child with ADHD, their results indicate that there is a statistically difference through using the repeated measure of ANOVA between the study and control groups. i.e. the study group present a good knowledge at the post-test compared with the control group participants. Conclusion:. Findings revealed confirmed that the teachers who not attended for program about ADHD have poor level of knowledge to pupils ADHD among elementary school teachers. While the teachers who attended for program about ADHD have improve and increase their knowledge about ADHD in phase two, and three. Thus, it is recommended for responsible parties to notes the need for greater efforts to teachers should trained to recognize students with behaviors problems / disorders in their classes to provide them with proper and timely education as well as necessary referral for their assessment. The nurse and the family of children as well as their teachers should be cooperate to detect what exact problems are facing child with ADHD and give proper intervention and relying more on observational methods than on subjective reports by the parents. Arrange an orientation programme for teachers to on various behavioral problems among primary school children is needed.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.
Ethical Clearance: “After the administrative arrangements are completed, acceptance of teachers participants was sought for after explaining to them the aim of the study and inform them that all the information taken will be treated confidentially and it is for research purposes only, then taken the consent from them to participate in this study. Also, an ethical approval was obtained from ethical committee of research in Faculty of Nursing University of Babylon regarding confidentiality and anonymity of participants”.

Anatomical and Immunohistochemical Variations Regarding the Epidermal Stem Cell among Different Traumatic Fingers of Hands in Iraqi Male Workers

Hatem A Hatem¹, Ahmed S. Mazyon², Hala Mohammed Majeed³

¹Lecturer, Department of Anatomy, College of Medicine/Ibn sina University of Medical And Pharmaceutical Sciences, Baghdad, Iraq, ²Lecturer, Department Surgery, College of Medicine/Ibn sina University of Medical and Pharmaceutical Sciences, Baghdad, Iraq, ³Assistant Professor, Department of Microbiology, College of Medicine/Ibn Sina University of Medical and Pharmaceutical Sciences, Baghdad, Iraq

Abstract

Background: The role of stem cell during the whole life of human constricted into two stages. First stage occurred during prenatal life when stem cell take part in formation of organ in process called embryogenesis. Second stage occurred in postnatal life when these cells contribute in regeneration of damaged or old tissue as repairing or substituting cell in adults.

Patient and Method: 150 male volunteers who work in different industries with traumatic finger of the right or left hand (33 right thumb, 25 right middle finger, 22 right little finger, 28 left thumb, 26 left middle fingers, 16 left little finger) were taken on from the Department of surgery, Baghdad Hospital, Baghdad; Iraq from February 2019 to October 2019.

Results: Anatomical results showing that The grip was affected only in case of traumatic thumb. Vimentin rich-stem cells were highly positive in the proximal epidermal areas of traumatic fingers more than the stem cells in the distal areas of the same fingers.

Conclusion: there is a little hope in the near future that the injured or even amputated finger or any part of the body could be replaced by new one made by culturing stem cells in laboratories.

Keyword: - Anatomical immunohistochemical, epidermal stem cell, traumatic.

Introduction

The hands of the human and some apes had significant manual functions in nearly most of human daily manual works. Hand injury without doubt will affect the life style of manual workers as well as affect the social life too. So study of anatomy and histology of the hand will gave the scientists the clue to solve many problems that occurred during hand injury. Any part of the hand which include bone or muscle or nerve will cause tremendous hand dysfunction, therefore the main goal of hand treatment was restoring the main hand functions depend on the knowledge of hand anatomy which represented by griping function (¹).

In present day, plastic surgeons repair and reconstruct many tissue damage and defect. Technological improvements in plastic surgery department increase the rate of success in repair fingers injuries. Despite the availability of many high centers of hand surgery, permanent hand dysfunction could occurred till now (²).

Tissue transplantation being the second choice for limb injures but this part of management need immunosuppressive therapy because there was a chance of tissue rejection (³, ⁴).

Another solution for compensate tissue loss was the Cosmetic prostheses in this case, patient couldn’t use all

of his skills in daily manual wok (5). Therefore, to solve this dilemma, researchers suggest regenerative methods by aid of tissue engineering (6,7,8).

Tissue engineering now consider as a hopeful field that in future can generate and construct limbs, fingers in the clinical laboratories (9).

Salamanders as a good example of urodeles had wondrous ability to substitute any injured or even amputated part in their bodies. Human as example of mammals had no this ability except in prenatal life (10).

In postnatal life, this ability will be limited for some organs like liver or skin (11,12,13).

Ability of substitution of body parts depend on regeneration of stem cells. This kind of cell had major function in keep the biological balance in human body in addition to developing of the body during life (14,15).

The role of stem cell during the whole life of human constricted into two stages. First stage occurred during prenatal life when stem cell take part in formation of organ in process called embryogenesis. Second stage occurred in postnatal life when these cells contribute in regeneration of damaged or old tissue as repairing or substituting cell in adults (16).

**Patients and Methods**

150 male volunteers who work in different industries with traumatic finger of the right or left hand (33 right thumb, 25 right middle finger, 22 right little finger, 28 left thumb, 26 left middle fingers, 16 left little finger) were taken on from the Department of surgery, Baghdad Hospital, Baghdad; Iraq from February 2019 to October 2019. Their age and jobs were recorded. Age of the male volunteers rounded between 20 to 38.

They didn’t complain from any dermatological or systemic diseases. Skin specimens was obtained under local anesthesia by making superficial surgical excision of an epidermal graft from distal and proximal areas (proximal area which was near the traumatic area of finger and the distal which was far from traumatic area of the finger), fixed in 40% formalin and as soon as possible embedded in paraffin section. Histochemical staining were performed in the laboratory of department of anatomy in the medical college of Baghdad university on skin samples.

After immersion of all samples throughout the night in a fixative with 3.5% paraformaldehyde in saline solution. Samples dehydrated in ethanol toward xylene successions then embedding was made as a paraffin wax.

Staining by aid of a streptavidin -biotin technique. Sections with thickness about 2 to 5 mm sliced and putted on positive charged - slides. At last all of the sections were stained for vimentin and putted in autoclave for 13 min.

Treatment of sections with 6% H2O2 mixed with methanol for 12 minutes. Again incubation was done all over the night at degree of about 50 C with diluted anti-vimentin antibody (Bio Connect, USA).

The positive cell mean that vimentin protein was appear in the cell as brown color and , the negative cell means that the stem cell had no vimentin which appear blue in color. The vimentin protein found in cytoskeleton of stem cell cytoplasm, so the cytoplasm appear as brown (17)

Estimation with light microscope at X10,X20,X40 and X100 was done in optimal conditions. Recording of percentage scores were based on the amount of positive signals tacked by the protein. Counting of cell depend score categories: Score(1)=1-25% , Score(2)=26-50% , Score(3)>50% (18).

**Result**

Anatomical results showing that The grip was affected only in case of traumatic thumb which represent the highest percentage among cases while other fingers not showing any affect even if they were injured all regardless which type of finger was injured .

Histochemical results showing that vimentin, the cytoskeleton marker of skin stem cells was detected in this study in order to recognized the stem cell which contained this protein . As appeared during the laboratory work ,vimentin staining was clear in the basal layer as showed in table (1) and figures (1,2and 3). Vimentin rich-stem cells were highly positive in the proximal epidermal areas of traumatic fingers more than the stem cells in the distal areas of the same fingers .Proximal and distal was decided according to the site of injury. Vimentin-histochemical stain clearly showing cytoskeleton staining. No differences were appeared regarding the side of limb(right or left) , age and the type of fingers between the samples of volunteers.

Discussion

In the hand of the human, thumb is considered as the most significant part. Significances of thumb came from its important role in a grip.

First anatomist called Napier in 1956 was interested in understanding the mechanism of grips. Napier was tried to understand the biomechanical anatomy of the hand in order to increase his knowledge more about compensation of hand injuries. This anatomist divided the grips into two types, precision and power grip. Power grip done by using the fingers, thumb as well as the palm together like grip the hammer. The precision grip done by using only the distal parts of thumb and fingers like writing with a pen (19).

Clearly, there was no doubt that the thumb had the major role in control the function of griping in both types. Therefore, any kind of trauma to the thumb which may complicated or not or sometimes leading to amputation of thumb will lead to dysfunction of this vital and significant part of the hand (20,21).

Traumatic injuries to the hand increased with increasing the age with frequency ranged from 2nd to fifth decade. Controversially, some epidemiologists conveyed that most of the trauma occurred during the early decades of life (2nd to 4th decades) who works manually in factories (22).

Other epidemiologists believed that the higher risk was founded in the late decades (6th to 8th decades) (23).

All of these decades from 2nd to 8th were workers while, in non-worker people also observed high risk of hand trauma among children and aging people (24).

In worker group, 60% of them worked in industries or farms (25). Boyle et al, Onuba and and Stanbury et al agree with this percentage (26,27,28).

In non-worker group most of causes of trauma were by car or motor vehicle accident (24%) (29, 24).

Many trials in the last decades try to minimize or even terminate the dysfunction or paralysis of fingers especially the thumb that result from trauma to the hand or any part of the body. This was done by made many public programs all over the world for education of the people who works in farms or factories by making them aware about the most precautions that help them to be save during the time of work (25).

The usual period of epidermal turnover was nearly (311 hour more or less) depend on optimal conditions. Mitosis of cells usually happened by stem cells located in the most basal part of epithelial layer of skin. Usually in most of cases the stem cells had a growth rate which might consider as slow rate, in addition to their capacity to made different type of cells (differentiation processes) (30,31,32).

The aim of existing such type of stem cell was to make balance between the lost and newly formed cells as a compensatory mechanisms to maintain the layers of skin within usual manner in case of injury to tissues. So, it’s very important for the scientists to look for the good conditions and optimal mechanisms that may help in developing or even accelerate the proliferation and differentiation of his kind of cells after creating a simple and good manner to isolate these cells in laboratories (33).

Franssen et al, suggested different type of markers that may be useful in detecting the stem cell in their tissues one of these markers was the vimentin (34).

In spite of the huge and tremendous development in different branches that have to do with detection and isolation of stem cells, working in such branches carry many and unexpected difficulties (35).

Unfortunately, regeneration in case of amputated finger was restricted only in distal part rather than proximal and some experiment done on mice showing that complete regeneration not happen if the percentage of remaining proximal tissue was less than 60% after amputation (36).

Many studies demonstrate that regeneration came after period of healing injury by aid of epidermal stem cells (37).

The motivation of fibroblastic and neural cells in remaining parts also had significant role in regeneration of smooth muscle, blood vessel and nerves (38).

Abstract

Background: The protein tyrosine phosphatase non-receptor type 22 (PTPN22) gene has been involved in the immune response to tuberculosis infection by affecting the inflammatory response and subsequent antimicrobial immunity. This study aims to determine the PTPN22 expression and differences in the levels of PTPN22 in pulmonary TB patients (PTB) with household contacts and healthy control.

Methods: We analyzed PTPN22 expression and the level of plasma PTPN22 from pulmonary tuberculosis patients (PTB), household contacts and healthy control using real time PCR and ELISA method.

Results: Thirty PTB, 30 household contacts and 30 control were involved in this study. Analysis of the association of PTPN22 gene expression against TB showed that PTPN22 gene expression was 7.3 times upregulated compared to household contact and 12.1 times upregulated compared to healthy controls. Levels of plasma PTPN22 in PTB: 10.0620 ng/ml, in Household contact: 6.7923 ng/ml and in control: 4.4293 ng/ml. These values did not differ significantly between the patients, household contact and control.

Conclusion: Our study results found that PTPN22 gene expression is significantly increased in PTB than household contact and control. Levels of plasma PTPN22 in PTB patients did not differ significantly than in household contact and control.

Keywords: PTPN22, Pulmonary tuberculosis, Gene expression, Real time PCR, ELISA, Level of plasma.

Introduction

Pulmonary tuberculosis (TB), an infectious disease caused by Mycobacterium tuberculosis (Mt). TB remains a major cause of morbidity and mortality in humans worldwide. One-third of the population worldwide is infected by Mt. About 5-10% of them manifest clinically to be active TB1,5,10,15. World Health Organization in Global Tuberculosis Report 2019 revealed that there were an estimated 10 million new TB cases worldwide in 2018. TB is the top infectious killer in the world. There were 1.5 million people died from TB2,3,11,12,18. TB is the leading killer of people with HIV and a major cause of deaths related to antimicrobial resistance. Indonesia is one of the countries with the highest TB burden in the world. There were 845 thousands TB incidence (316 per 100 thousands population) and 98.3 thousands (37 per 100 thousands population)4,6,7,8,21.

Studies in United States revealed that 20-30% of the household contacts occurred latent infection and about 10% became active TB9,10,13,14,28. A person susceptibility to TB infection and developing active TB is influenced by several factors including host
genetics, host immunity, mycobacterium virulence and environment. The prevalence rate of TB was significant different among several ethnic minorities, therefore, the differences in susceptibility to TB may be related to a genetic predisposition. Genetic predisposition as one of the host factors influencing risk factors for the development of TB\textsuperscript{15,16}.

Studies revealed the pivotal function played by cellular immunity in Mycobacterium tuberculosis (Mtb) infection. The immune responses are implicated to control the infection through cytokine production and specific surface molecules interactions. T-cell activation is a crucial step in the immune response against Mtb. Several genes are reported to have been associated with TB pathogenesis, one of them is protein tyrosine phosphatase nonreceptor type 22 (PTPN22)\textsuperscript{17,18,23}. The PTPN22 gene were involved in maintaining the T cells in the resting stage. PTPN22 were also responsible for bringing back the activated T cells to the resting phenotype in the absence and presence of antigen. Phosphotyrosine phosphatases are involved in reversion of T lymphoblastic proliferation Tyrosine phosphorylation in T cells is regulated by phosphatase activity.

Several transmembrane molecules, like PD-1 (programmed death 1) and CTLA-4 (cytotoxic T-lymphocyte antigen 4), play an important role in downregulating signalling through the T-cell receptor (TCR). The PTPN22 is a cytosolic inhibitor of TCR signalling. The PTPN22 gene is located on chromosome 1p13.3-p13.1. This gene product is the intracellular protein tyrosine phosphatase known as Lyp and expressed in cells of the immune system, including dendritic, T and B cells. Lyp is expressed in cells of haematopoietic origin and has a variety of substrates, including Lck, Zap70, Valosine containing protein (VCP), Vav and TCRzeta, all of them are important players in T-cell signalling. The dephosphorylation of these substrates by LYP negatively modulates T-cell activation. Lyp forms a protein complex with the intracellular tyrosine kinase (protein tyrosine kinase) Csk. The Csk protein tyrosine kinase is a potent suppressor of T cell activation due to its ability to phosphorylate tyrosine residue at Src family kinases, thereby antagonizing the action of CD45, that mediates dephosphorylation of the inhibitory C-terminal SH2 domain of Lck.\textsuperscript{19,1,4}

Numerous studies from several countries result, suggest that the PTPN22 gene affect susceptibility to TB. However, no research has been conducted in Indonesia about PTPN22 and TB.\textsuperscript{4,7,12} The purpose of this study was to compare gene expression and levels of plasma PTPN22 in pulmonary tuberculosis patients and their household contacts in Makassar, Indonesia. The results of this study are expected to provide a better understanding of the relationship gene expression and levels of plasma PTPN22 with susceptibility TB.

**Materials and Method**

**Research design and study subjects**

We analyzed gene expression and the levels of plasma PTPN22 from pulmonary tuberculosis patients (PTB), household contact and control samples using real time PCR and ELISA method. QuantiFERON-TB Gold Plus (IGRA) was used to screening latent TB infection among household contacts. A total of 90 samples were collected in this study, consisting 30 pulmonary tuberculosis patients, 30 household contacts and 30 control. Pulmonary TB patients who were participants in this study were recruited from the Community Center for Lung Health Makassar, Indonesia, which is one of the referral health facilities for tuberculosis.

All TB patients were diagnosed based on clinical manifestations, chest radiograph, microscopic smear which was further confirmed through TB culture with MGIT medium. Inclusion criteria for TB patients in this study included new TB cases (no history of anti-tuberculosis drugs treatment), ages 18 years and over, willing to participate in this study by giving written consent and having positive smear results. The exclusion criterion was HIV-positive (SD Bioline). The inclusion criteria for household contact are those aged 18 years and over, have no clinical symptoms of TB, have no history of TB or anti-tuberculosis drugs, and stay at home with TB patients for at least 6 months and are willing to participate by giving written consent. We collected blood and sputum samples from 30 TB patients, blood samples from only 30 household contacts that met the criteria and 30 blood samples from healthy control. Positive sputum samples were decontaminated and continued with the culture process at the Tuberculosis Unit of the HUM-RC Laboratory (Hasanuddin University Medical-Research Center), Makassar, Indonesia. Blood samples were centrifuged at 4,400 rpm for 10 minutes at 250°C to separate plasma samples. Plasma samples were stored at -200°C before ELISA. Specifically from the contact sample, we examined IGRA with the QuantiFERON Gold Plus TB Test (Qiagen, Germany) according to the
Measurement levels of plasma PTPN22

Concentration PTPN22 was determined by the ELISA method using an ELISA Human PTPN22 kit (Diagnostics Biochem Canada Inc., Ontario, Canada) according to manufacturer’s instructions. Linear curves are used to determine the concentration of PTPN22 samples from a calibration curve. Measurement gene expression of PTPN22 by real timePCR

Amplified comementary DNA (cDNA) from RNA extracted blood sample by Reverse Transcriptase-PCR based on the method of Invitrogen. Using SuperScript First-Strand Synthesis System for RT-PCR. This cDNA strand stored in -20°C until used for real time PCR. Measurement gene expression (up regulation or down regulation)PTPN22 bySYBR Green Dye using the real time PCR (qPCR) method according to manufacturer’s instructions. Before amplified, a master mix was prepared by mixed 12.5 ml SYBR green dye, 0.5 ml cDNA and 0.5 ml forward primer (5’-ACAACTGTCGCTGAAGCCCA-3’), 0.5 ml reverse primer (5’-GTAGCTGGAATCCTCATCAGG-3’)(each primer 5 pmol/ml) and 11.3 ml H2O. The same procedure was carried out for the GAPDH gene as a control but using a different primer sequence. GAPDH forward primer (5’-CCTGCACCACCAACTGCTTA-3’) and GAPDH reverse primer (5’-GGCCATCCACAGTCTCTGAG-3’). The qPCR cycle with a condition of 50°C for 2 minutes, 95°C for 1 minute each1 cycle, denaturation 95°C for 15 seconds then followed by aneling 60°C for 30 second and extension 72°C for 30 seconds was repeated 40 times (cycles). The last cycle was the final extension at 72°C for 10 minutes.

Statistical analysis

All experimental data were analyzed using SPSS software (version 21.0, Chicago, IL, USA). P values <0.05 were considered statistically significant. Data obtained from ELISA results were analyzed and assessed for differences between the three groups (pulmonary TB patients, household contacts and control). The Chi-square test is used for the comparative analysis of nominal variables.Data (parametric) will be presented as mean ± SD (median) and will use statistical analysis to distinguish values between the three groups. Data were analyzed using the One-way ANOVA test which compared levels of plasma PTPN22 in the three groups.

Results

We analyzed a total of 30 TB patients, 30 household contacts and 30 healthy control for the PTPN22 gene expression and levels of plasma.

* Chi-square test.
Table 1 shows the gender and age of study participants. There was a gender difference between groups (p=0.009). There were more male subjects (56.7%) than female (43.3%) in the TB patients group. However, more female subjects (80%) than male (20%) in household contacts group. It can be seen that there was no age difference between the three groups (p=0.475).

PTPN22 levels were measured using ELISA. The lines on the boxplot indicate the median and the points show extreme values. PTPN22 levels in TB patients group: mean 10.06 ng/ml with standard deviation 15.98 ng/ml. PTPN22 levels in household contacts group: mean 6.79 ng/ml with standard deviation 10.24 ng/ml. PTPN22 levels in control group: mean 4.43 ng/ml with standard deviation 6.68 ng/ml. Data were analyzed using the One-way ANOVA test which compared PTPN22 levels in the three groups.

The mean value PTPN22 levels in TB patients compared to household contacts and control, did not differ significantly (p = 0.175).

Gene expression of PTPN22 in TB patients group: 12.11629, household contacts group: 1.65801 and control 1.00000. Analysis of the association of PTPN22 gene expression against TB showed that PTPN22 gene expression was 7.3 times upregulated compared to household contact and 12.1 times upregulated compared to healthy controls.

Discussion

In this study, from 90 participant, there were more male subjects in TB patients group. This was in accordance with the theory. We found that PTPN22
gene expression is significantly increased in PTB than household contact and control. Several studies analyzing the role of PTPN22 in TB show an association between PTPN22 and susceptibility to active TB disease. Some of the earlier studies reported a significant association between PTPN22 and TB. These studies results suggest that PTPN22 gene may affect susceptibility to TB like in Colombian population, Moroccan population, Brazilian Amazon population and Chinese Uygur population.

The mean of levels plasma PTPN22 gene on TB patients group was higher than mean of levels plasma PTPN22 gene on household contacts and healthy control. But these values did not differ significantly levels plasma of the PTPN22 gene between the three groups. Several studies results also found that PTPN22 gene is not associated with the susceptibility to TB, such as in Iranian population and Indian population.

There were differences in terms of genetic predisposition and serum levels in TB and non-TB subjects. It was likely due to geographical location, genetic differences and the presence of other disease conditions. A person susceptibility to TB infection and developing active TB is influenced by several factors including host genetics, host immunity, mycobacterium virulence and environment. Several factors were increased susceptibility TB, such as malnutrition, Diabetes mellitus and age by suppressed the immune system.

Conclusion

The PTPN22 gene expression is significantly increased in pulmonary TB patients than household contact and control. Patients with active TB have higher levels of plasma PTPN22, but did not differ significantly compared to household contacts and control.

Acknowledgments: The authors would like to thank the patients, household contacts and healthy subjects who willingly participated in the study, and all the partners and staffs who help us in the process of this study.

Quantitative and Histological Study of the Effect of Cadmium Oxide on Both Body and Kidney of Mice

Khalid H. Gathwan¹, Ahmed Anwar Albir¹

¹Department of Basic Sciences/ College of Dentistry/ University of Baghdad, Baghdad, Iraq

Abstract

The present study was conducted using 24 normal male of Swiss white mice weighing (36-40 gm), 70 days old. The mice were divided into four groups of six mice each. The mice of control group were fed pellet and given tap water during the entire period of the experiment (30 days). The other three groups of mice were given cadmium oxide orally at doses of (7.0 mg / kg body wt., 14.1 mg / kg body wt., and 22.3 mg / kg body wt.) consecutively every day for 30 days and weight in gm was taken once a week. With standard histological techniques, samples were obtained from kidney of the mice. The body weights along with kidney weights were decreased with increase of doses. Also it has been concluded that cadmium oxide caused damages in renal corpuscle (Bowman’s capsule and glomerulus) and renal cortical tubules as well as decrease in body weight and kidney weight (wt.).

Key words: cadmium, body weight, histological alteration, kidney, mice.

Introduction

The mammalian kidney both anatomically and functionally is extremely complex organ and it plays an important role in the control and regulation of homeostasis. Heavy metals occur naturally in the environment and are found in varying levels in the ground. Cadmium is ubiquitous environmental pollutant, toxic element; enter the human body via food (¹, ²). Cadmium is absorbed rapidly, toxic to several tissues and accumulated in the liver and kidney (³, ⁴), which resulted in the reduced availability of cadmium to such organs as the kidney (⁵).

Therefore, the present study was designed to examine the effect of cadmium oxide on male mice body weight along with kidney weight quantitatively and to determine whether or not cadmium oxide can cause histological alterations which may affect kidney functions.

Materials and Method

Twenty four normal male of Swiss white mice were used in this experiment. They were 70 days old, weighing (36-40gm), and divided into four groups of six mice each. The mice of control group were fed pellet and given tap water during the entire period of the experiment (30 days). The other three groups of mice were given cadmium oxide orally at doses of (7.0 mg / kg body wt., 14.1 mg / kg body wt., and 22.3 mg / kg body wt.) consecutively every day for 30 days and weights in gram of the mice body were taken once a week. After the end of the experiment (30 day), the initial and final weights of mice in each group were taken, and, then, the mice were sacrificed and the kidney was removed and perfused with normal saline and the weights of kidney of treated groups along with control were also taken. Kidney was excised, fixed in 10% formalin. After fixation, the kidney was processed; wax block and slides were prepared then stained in Hematoxylin / Eosin for histological studies (⁶).

Results and Discussion

The mice kidney of the second group which was given a dose of 7.0 mg / kg body wt. of cadmium oxide, showed histological alterations but there was no significant (p > 0.05) change in body weight and kidney weight while there was a significant (p < 0.05) loss in body weight and kidney weight treated with (14.1 mg / kg body wt. and 22.3 mg / kg body wt.) as shown in Tables (1 and 2). The intake of fed and water by treated group reduced as compared to control and the decrease was dose dependent.

Histological observations of kidney after different doses of cadmium oxide treatment showed degenerative alterations. The kidney of control group of mice showed normal architecture (Figure 1). With a dose of 7.0 mg / kg body wt., the observations of the kidney of the second group of mice showed congested glomerulus and blocked lumen of renal cortical tubules due to some necrosis (Figure 2) as compared to control. With a dose of 14.1 mg / kg body wt., the observations of the kidney of the third group of mice showed damaged glomerulus and dark appearance of renal cortical tubules (Figure 3), whereas with a dose of 22.3 mg/kg body wt., the observations of the kidney of the fourth group of mice showed disappearance of the kidney glomerulus due to destruction and the lumen of renal cortical tubules was widened, besides, the cells of renal cortical tubules were damaged that they were hardly distinguishable due to negative effects of cadmium oxide (Figure 4).

Metal can enter proximal tubular cells by endocytosis following binding of metal itself or a metalloid protein complex to the brush border membrane (7). Once inside the cell, the metal can be released from the protein metal complex by lysosome degradation. The intracellular distribution of the metal then depend on the presence of various high – affinity binding sites or sinks within the cell (8). The binding of metal glomerular basement membrane has been reported by (9). Ionic blocking of these site leads to the loss of selectivity infiltration of albumin (10). The cytosolic protein might be a fragment of the renal basement membrane and the determination of acute toxicity is usually an initial screening step in the assessment and evaluation of toxic characteristics of all compounds (11). Lastly, we have presented evidences that necrotic is an important and predictable event of effect of cadmium. In conclusion, it seems reasonable to consider that the present study provided evidences
regarding degenerative changes in the architecture of the mice kidney due to harmful effects of cadmium oxide.

**Abstract**

**Background:** Malassezia furfur and Aspergillus sp are fungi associated with infection in humans. One of the plants that can use as anti fungi is clove (Syzygium aromaticum).

**Aim:** The purpose of this study was to determine the growth barriers of Malassezia furfur and Aspergillus sp on media with the addition of Clove Powder (Syzygium aromaticum).

**Material and Method:** The equipment used by cloves (Syzygium aromaticum) is a part of the reddish-green flower. The samples used in this study were Malassezia furfur and Aspergillus sp. Specimens planted on Saboraud Dextrose Agar media with the addition of clove powder (Syzygium aromaticum) in various concentrations.

**Results:** Malassezia furfur in media with clove powder concentration of 0%; 0.05%; 0.1% shows the number of colonies 1330; 1135; 765. Aspergillus niger, Aspergillus flavus, Aspergillus fumigatus on media with clove powder concentration of 0%; 0.05%; 0.2% indicates colony diameter of 6.8 cm; 5 cm; 3.7 cm (Aspergillus niger), 6.7 cm; 5 cm; 4.3 cm (Aspergillus flavus), 7 cm; 5 cm; 2.3 cm (Aspergillus fumigatus).

**Conclusion:** Media with Addition of Clove Powder (Syzygium aromaticum) can inhibit the growth of Malassezia furfur and Aspergillus sp.

**Keywords:** Malassezia furfur; Aspergillus sp; Clove (Syzygium aromaticum).

**Introduction**

The development of fungal infections in Indonesia strongly supported by a tropical climate with high humidity, sanitation, and an unhealthy lifestyle. Indonesia has a problem with bacterial and fungal infections. Bacterial infections such as tuberculosis¹,²,³ and Staphylococcus aureus⁴,⁵ are significant obstacles. There are also environmental contaminant bacteria and fungal⁶ such as Salmonella², E Coli⁸, Staphylococcus aureus⁹,¹⁰ and Bacillus¹¹,¹². Fungal infections such as Malassezia furfur which cause Pityriasis Versicolor often found in the community of children and adults.

Fungi can cause disease not only by infecting the body but also creating mycotoxin contaminated food. Foods contaminated by fungi have a potential danger to human health. Aspergillus flavus, Aspergillus fumigatus, and Aspergillus niger produce aflatoxin which is harmful to health.

Handling fungal infections and contamination in food can use natural ingredients. Indonesia is a country rich in herbal plants such as Anredera cordifolia¹³, Cananga odorata (Lamk). Hook¹⁴, lime¹⁵, Syzygium polyanthum¹⁶, Carica papaya Linn¹⁷, Jatropha curcas¹⁸, Kaempferia galanga L.¹⁹, Cinnamomum burmannii²⁰, Eleutherine palmifolia (L) Merr²¹, Hibiscus sabdariffa L.²² Since ancient times herbal plants have been widely used as antimicrobials²³. These herbaceous plants contain essential oils with antibacterial and antifungal activity²⁴. Some essential oils show important antifungal activity, namely yeast, dermatophytes fungi, and Aspergillus strains. This therapy is mainly used in mucosal, skin, and respiratory tract diseases²⁵.

Syzygium aromaticum is a plant that widely cultivated in Indonesia. Clove and eugenol oils from
Syzygium aromaticum have antiseptic, analgesic and anesthetic effects\textsuperscript{26}. And have been tested in experimental animals as an antifungal\textsuperscript{27,28}. Clove oil and Eugenol also have activities against filamentous fungus of food\textsuperscript{29} and pathogenic fungi in humans\textsuperscript{30}. Pinto et al. (2009) proved that clove oil and Eugenol had considerable antifungal activity against Candida, Aspergillus, and Dermatophytes fungi. Clove oil and Eugenol from clove flowers (Syzygium aromaticum) have been shown to inhibit the growth of Malassezia furfur and Aspergillus. But clove flowers (Syzygium aromaticum) which processed into powder have not been shown to inhibit the growth of these fungi. The clove powder material is expected to contain still essential oils which function as antifungals. Although this essential oil is not removed directly from the powder, it is possible to diffuse it on the media and thus inhibit the growth of Malassezia furfur and Aspergillus fungi. This study aims to describe the growth of Malassezia furfur and Aspergillus fungi on media with the addition of clove powder (Syzygium aromaticum) and determine the concentration to prevent the growth of fungi effectively\textsuperscript{31}.

Subjects and Methods

The population in this study was Clove flowers obtained at Jalan Meratus Kemuning Village, Banjarbaru Selatan District, South Kalimantan, Indonesia. The sample used is a fresh clove flower, which is reddish-green.

The independent variable of the study was SDA media with the addition of clove powder with a concentration variation of 0%, 0.05%, 0.1%, 0.2%, 0.5%, 1%, 2%. The dependent variable of the study was the growth of Malassezia furfur and Aspergillus sp as measured by colony diameter/number of colonies.

The cloves used are part of the fresh reddish flower. The flowers are washed first and dried in oven Hock at 45 °C for 6 hours until the cloves are dry. Cloves are blended to powder and sieved on 40 mesh sieves. Making each concentration in 100 ml of Sabouraud Dextrose Agar (SDA) so that the concentration is 0.05%: 0.05gr, 0.1%: 0.1gr, 0.2%: 0.2gr, 0.5%: 0.5gr, 1%: 1gr, 2%: 2gr.

Planting Malassezia furfur used a suspension that conformed to the MacFarland Standard 0.1. Spread to Sabouraud Dextrose Agar as much as 10µl then count the number of colonies on the 7th day after incubating room temperature.

Planting Aspergillus sp at Sabouraud Dextrose To use the ose at one point with a diameter of 1 cm, the width of the colony measured at the 7th-day room temperature incubation.

Results

The results of the description of the growth of Malassezia furfur on media by adding clove powder to each concentration can see in table 1.

Discussion

Based on the results in table 1, Malassezia furfur can inhibit by growth in media containing clove powder. This result is by Alharisy’s research (2018), which proves that 1% clove extract (Syzygium aromaticum) can inhibit the growth of Malassezia furfur.22

The results in table 2 show that there are differences in the diameter of the colonies of Aspergillus niger, Aspergillus flavus, Aspergillus fumigatus, each concentration of clove powder (Syzygium aromaticum). This study proves that clove powder can inhibit the growth of fungi. The same thing was confirmed by Utami’s research (2010) that clove powder (Syzygium aromaticum) could hinder the growth of microbes and fungi at concentrations of 0.2% and 0.6% on pineapple jam.33 According to Pinto et al. Research, clove oil can also inhibit the growth of Aspergillus sp.31

Clove oil tends to cause interference with bacterial cell membranes and fungi.24 This activity occurs in the lipid bilayer of cell membranes resulting in changes in permeability and leakage of cell contents.34 Recent antimicrobial studies from several essential oils have shown disruption to bacterial membranes and fungi.35

The effectiveness of inhibition of fungi by clove powder is also likely due to the eugenol compound found in clove plants. Eugenol is one of the main elements of clove oil (Syzygium aromaticum). Eugenol also shows excellent antimicrobial activity against fungi and Gram-positive. And Gram-negative bacteria.36

According to Park et al. (2007), the mechanism of growth inhibition of fungi caused by compounds of Eugenol, which can damage misellia. Which have smooth cell walls with a long section of hyphae, Eugenol will damage the inner mitochondrial membrane of cells and damage cell walls. Mitochondria functions to produce energy and food because mitochondrial cells destroyed, so the energy and food sources in fungi cells are blocked so that the fungi will die. In Conclusion Media with Addition of Clove Powder (Syzygium aromaticum) can inhibit the growth of Malassezia furfur and Aspergillus sp.37

Conclusion

Media with Addition of Clove Powder (Syzygium aromaticum) can inhibit the growth of Malassezia furfur and Aspergillus sp.

Assessment of Aggression among High Schools Students

Mansour Abdullah Falah Al-Zorfi¹, Hussein Jassim Muhammad Al-Ibrahimi.²

¹University of Kufa, ²University of Babylon, College of Nursing - Family and Community Health Nursing

Abstract

Background: Aggression is a behavioral characteristic that refers to forceful actions or procedures (such a deliberate attack) with intentions to dominate or master. It tends to be hostile, injurious, or destructive, and is often motivated by frustration for an individual, aggressive behavior is considered understandable and normal under appropriate circumstances, but when it is frequent, intense, lasting, and pervasive, it is more likely to be a symptom of a mental disorder. Likewise, aggression between groups, can be in the form of healthy competition, but can become harmful when unfair or unjust disadvantage or frustration is perceived, leading to hostility. Objectives: assessment aggression among high school students. Methodology: A descriptive cross-sectional study was carried out in order to achieve the stated objectives. The study has begun from 1st September 2018. Settings of the Study: The settings of the study include (41) High secondary schools which are distributed in (3) Districts of Al-Najaf Governorate, urban (23) schools and rural (18) schools, these schools are systematic randomly selected. Results: most majority was moderate aggressive. Conclusions: this study show which included an overall assessment of Aggressive, where the study showed that the most majority was moderate aggressive. Recommendations: Supporting educational methods by the Educational Committee that limits aggressive behavior of adolescents in schools, such as (moving away from scenes of an aggressive nature, beating, violence, fighting, quarrels, and blood scenes). And The teacher devotes part of the lesson time to clarifying issues and harms of aggression, and to show the benefits of tolerance and contentment. and The school administration cooperated with the teenager’s family to identify the causes of his aggression. Finally, The Ministry of Education is working to create posters that reject aggression and suspend it throughout the school.

Key word: Assessment. Aggression. High Schools Students

Introduction

Aggressive behavior is an associated symptom of many psychiatric disorders and can manifest throughout the life span, from attention-deficit hyperactivity disorder (ADHD) in children and adolescents, to domestic violence in adults, to dementia in older adults. While much of the aggression literature has focused on adolescents and adults, less attention has been given to understanding the etiology of aggressive behaviors across the entire developmental spectrum. The purpose of this paper is to provide an overview of the manifestation and causes of aggressive behavior across the life span as well as provide suggestions for the roles that nurses, who frequently interact with patients from all age groups, can play in preventing and intervening in aggressive behavior. Potential consequences to both the victims and aggressors are also outlined. Aggression is a highly studied area in the psychosocial literature, particularly adolescent aggression and developmental theories, adult aggression and violence, aggression and criminal behavior, and psychopathology. These discussions have been detailed elsewhere¹.

Methodology

Design of the Study:

A descriptive cross-sectional study was carried out in order to achieve the stated objectives. The study has begun from 1st September 2018.

Settings of the Study:

The settings of the study include (41) High secondary schools which are distributed in (3) Districts of Al-Najaf Governorate, urban (23) schools and rural (18) schools,

This table show which included an overall assessment of Aggressive, where the study showed that the most majority was moderate aggressive by 52.7%

Discussion of the Results

Table 1, which includes the sub-domain of Aggressive, which comprises four axes, where most of the axis (Anger) was compared to the other axes.

Pullen, and et.al., 2015, in United Kingdom, the Anger is a common factor in two causes of death in adolescence: homicide and suicide.2

In Colorado, a number of researchers conducted a study on aggression among adolescents in secondary schools, where the results of the study showed that the sub-field anger was the highest response and then verbal aggression came. 3

In the same topic in Nepal, a study was conducted on the sub-domains of aggression for adolescent students at the secondary level, where the results of the research found that the predominant sub-domain is physical aggression and anger comes after it. 4

Table 2, which included an overall assessment of Aggressive, where the study showed that the most majority was moderate aggressive.

In United States A research report on the origin of antisocial behavior was conducted for adolescents and found that they have moderate aggression 5

In the state of Oklahoma, and the same context, a survey study was conducted on the aggressive behavior of adolescents, and the study aimed to know the level of aggression they had, and the results of which they reached were that they had moderate aggression. 6

Gaza also conducted a study on a group at a similar teen in high school where he used a special aggression questionnaire, showed research that they have a high aggression results, and attributed the reason to the Zionist occupation of their country is going through conditions. 7

Returning to the aforementioned about violence where the results showed a low level of violence, unlike what appeared in the results of the aggression where the results showed a moderate aggression, and the sub-response (anger) was the dominant and then verbal aggression comes, and this indicates that people or adolescents in particular, in Conflict and quarreling, do not leave the matter worse until it reaches the stage of excessive violence, but rather remains at the level of verbal aggression, anger, and hatred, and they are aware
that in the event that the matter develops into physical violence or using injurious tools such as (a knife or a firearm) it may have the matter Dangerous consequences for the person, but awareness and commitment to the principles Religious, moral and tribal prevent this matter, and to resort to peaceful solutions satisfy the parties to the conflict.

**Conclusion**

The sub-domain in anger in aggression was predominant and Most of the study sample had moderate aggression.

**Recommendations:**

1. Supporting educational methods by the Educational Committee that limits aggressive behavior of adolescents in schools, such as (moving away from scenes of an aggressive nature, beating, violence, fighting, quarrels, and blood scenes).

2. The teacher devotes part of the lesson time to clarifying issues and harms of aggression, and to show the benefits of tolerance and contentment.

3. The school administration cooperated with the teenager’s family to identify the causes of his aggression.

4. The Ministry of Education is working to create posters that reject aggression and suspend it throughout the school.

**Financial Disclosure:** There is no financial disclosure.

**Conflict of Interest:** None to declare.

**Ethical Clearance:** All experimental protocols were approved under the College of Nursing, University of Kufa, Iraq and all experiments were carried out in accordance with approved guidelines.

Correlation of Anthropometry Characteristics and Six-Minute Walking Test Distance In Children Aged 7-8

Martha Kurnia Kusumawardani1, Ratna Darjanti Haryadi1, Andriati1

1Department of Physical Medicine and Rehabilitation, Dr. Soetomo Teaching Hospital, Faculty of Medicine, Universitas Airlangga, Surabaya 60285, Indonesia

Abstract

Background: The six-minute walk test (6MWT) is a useful test for measuring functional capacity and predicting morbidity and mortality. The 6MWT is not widely used in children because the exact reference data are often not known, and the test requires concentration and co-operation from the participants, which is harder to manage in children. The anthropometry characteristic influences the 6MWT distance.

Objective: This study aimed to investigate the correlation between anthropometry characteristic and 6MWT distance in children aged 7-9 years old.

Methods: This research was an observational analytic study using cross-sectional design that was conducted on August 2013. Weight, height and body mass index were measured according to the Decree of Ministry of Health Republic of Indonesia. The 6MWT was performed according to American Thoracic Society (ATS) in a 15m indoor walkway. The data were analyzed using several tests, including Kolmogorov-Smirnov test for data normality test and Pearson’s correlation test.

Results: The average 6 MWT distance in all subjects was 390.45±50.05 meters, with the average 6 MWT distance in subjects aged 7 and 8 were 370.15±45.64 and 410.75±46.47 meters, respectively. Pearson’s correlation test showed a positive correlation between height and 6 MWT in all subjects, but there was no correlation between height, weight and body mass index with 6 MWT distance in each age group.

Conclusion: The anthropometry characteristic was not correlated with the 6MWT distance in children aged 7 and 8 years old.

Keywords: anthropometry characteristic, children, six-minute walking test

Introduction

Decreased children’s physical activities have become a growing health problem in recent years. Outdoor physical activity has been replaced with many indoor activities. Children’s participation in sports begins to decline as they prefer watching television and playing video games. Epidemiological studies suggest that sedentary lifestyle is associated with early onset and progressivity of cardiovascular disease and doubling the risk of premature death 1,2.

Functional training capacity assessment is necessary to determine human body’s physical fitness, particularly cardiovascular, respiratory, metabolic and musculoskeletal systems 3. The gold standard for determining objective functional capacity is by testing incomplete cardiopulmonary training using either a treadmill or an ergometer bike. The implementation of maximum training test requires facilities, tools and trained people. This makes health centers with minimal facilities difficult to conduct such trainings 4. The use of a six-minute walking test (6MWT) as a submaximal test has been proved to be an alternative to the functional capacity assessment in adults 5.

The reliability of 6MWT in children aged 5-14 has been demonstrated by studies in China and Belgium...
by investigating bilateral, knee dominant, knee joint alignment (tibio-femoral angle and Q angle), body mass index, pain and quadriceps muscle activity on the incidence of body swing disorders dynamically in patients with knee osteoarthritic. Some studies also found that 6MWT was easy, safe and cheap, and it could reflect daily activities compared to other types of walking tests.

The 6MWT is useful in clinical use, but has not been widely used in pediatric practice due to lack of data reference in healthy children. In addition, this test requires concentration and co-operation of the participants, which is harder to manage in children. Some studies investigated a standard value reference of 6MWT in children as well as the correlation of anthropometric characteristics, including age, sex, weight, height, body mass index (BMI) and heart rate, with 6MWT distance. The 6MWT study in 1,455 healthy children aged 7-16 in China suggested the first standard value reference in international literature. Some studies aiming to obtain standard value references of 6MWT have been conducted in various countries, including Austria, United Kingdom, Brazil, Tunisia and Thailand. A study aiming to obtain 6 MWT average distance was also conducted in Indonesia in 2010. The study conducted in Jakarta was only investigating 6 MWT average distance in healthy children aged 9-10. To date, there has been no data available in Indonesia that examine 6 MWT distance in healthy children outside that age group. Anthropometry characteristics affect 6 MWT results. Therefore, demographic, anthropometric and nutritional differences in different ethnic groups should be taken into account in 6 MWT results. Shorter individual and woman have shorter stride length that subsequently shortens travel distance. Bulgarian children, who are taller and heavier, have a superior cardiopulmonary function compared to Romanian children.

Different anthropometric characteristics also appear in ethnic differences. It was found in a study conducted in Malaysia as the results found anthropometric differences in ethnic Malays, Indian and Chinese. Therefore, we were interested in investigating correlation of anthropometric characteristics and 6MWT distance in children aged 7-8.

**Methods**

This observational analytic study using cross sectional design was carried out from August 2013 at Department of Physical Medicine and Rehabilitation, Dr. Soetomo Teaching Hospital, Surabaya, Indonesia. The subjects were Muhammadiyah 4 elementary school students aged 7-8 who met the inclusion criteria. They were taken using cluster sampling method. One cluster that met the minimum sample size was taken from each stratum.

Subjects must meet the following inclusion criteria:
1) Muhammadiyah 4 elementary school students aged 7-8 who had no contraindication to undergo 6MWT; 2) Having wide joint motion and level 5 muscle strength on manual muscle testing (MMT) examination. We excluded subjects with following criteria: 1) Having cardiorespiratory, neuromuscular and other diseases affecting gross motor skills and walking capabilities as evidenced by anamnesis and clinical examination; 2) Having been ill in the last two weeks and taking medications that may affect walking ability. On the other hand, the drop criteria was subject who could not complete 6 MWT for any cause.

This research began with subjects declaring their willingness to participate in this study by signing the informed consent and filling in the questionnaire. The subjects were determined in accordance to the inclusion and exclusion criteria as evidenced by the results of anamnesis and physical examination. We used One Med digital weighing device, One Med height meter, Riester tensimeter, Littman stethoscope, Oxyone pulse oximeter, stopwatch, calculator, cone, markers, bright-colored tape, gauge, chair, rating sheet, informed consent and emergency kit. Furthermore, we prepared a 15-meter walkway. The walkway was marked with a cone placed on the starting line and at the end of the track (15 meters) as a turning point. The line was marked with a bright-colored tape as a marker for the subjects to walk straight alongside the mark. Black-colored tape was placed at a distance of 5, 10 and 15 meters.

We asked the subjects to have enough rest before the test. The test was carried out for at least 2 hours after breakfast. The subjects must use sportwear and training shoes, and they were not allowed to perform any exercise prior to the test. The subjects waited for their turn by sitting in a chair near the track. The subject’s primary data were collected before the test. The data included subject’s name, age, sex, weight, height, body mass index, vital signs (pulse, blood pressure and oxygen saturation). The researcher/assistant prepared the equipment and walkway. The subjects were given instructions and examples of how to perform the
6MWT. We marked the distance obtained by the subject with markers. Afterwards, we immediately measured the subject’s vital signs.

All data were statistically processed using SPSS (SPSS., Inc., Chicago IL). The data were analyzed using several tests, including Kolmogorov-Smirnov test for data normality test and Pearson’s correlation test.

Results

Subjects’ Characteristics

Table 1 showed subjects’ basic characteristics. The subjects’ average weight was 29.49±9.10 kilograms. The subject’s average weight in age group 7 and 8 were 26.88±7.58 kilograms and 32.10±9.85 kilograms, respectively. The subject’s average height was 129.11±7.49 centimeters. The subject’s average height in age group 7 and 8 were 125.68±6.70 centimeters and 132.55±6.69 centimeters, respectively. The subjects’ average BMI was 17.42±4.06. The subjects’ average BMI in age group 7 and 8 were 16.81±3.59 and 18.03±4.45, respectively (Table 1).

Results of Six-Minute Walking Test

We measured 6MWT distance after obtaining anthropometry characteristics. Of 60 subjects who participated in the 6MWT, no one dropped out. The subjects’ average 6MWT distance was 390.45±50.05 meters. The subjects’ average 6MWT distance in 7-year age group was 370±45.64 meters, with the shortest and longest distance were 300 meters and 462.8 meters, respectively (Table 4).

The average 6MWT distance achieved in the 8-year age group was 410.75 ± 46.47 meters, with the shortest and longest distance were 333.5 meters and 514.6 meters, respectively.

Correlation between Anthropometry Characteristics and Six-Minute Walking Test Distance

Kolmogorov-Smirnov test found normal distribution of all data in both groups. Pearson’s correlation test showed a significant correlation between height and 6MWT distance, with r = 0.256 and p = 0.049 (p <0.05). On the other hand, there was no significant correlation between weight (p = 0.585) and BMI (p = 0.829) with 6MWT distance (p >0.005; Table 5).

Discussion

The anthropometric characteristics observed in this study were height, weight and BMI. The basic anthropometric measurements in this study were in accordance with the standards used by the Ministry of Health of the Republic of Indonesia based on World Health Organization (WHO) regulation in 2005. The anthropometric data of children reflect the general health status, nutritional adequacy, growth and development.

Based on the growth table of children aged 2-20 from the Center for Disease Control (CDC) in 2000, indicates that the subjects’ average body weight, height and BMI are normal. The 6MWT distance illustrates the walking ability and individual abilities in daily activities, as the energy used in daily activities matches the submaximal level.

The 6MWT is one of submaximal exercises used to assess training capacity in patients with chronic disease. This practice test has been widely used in adult and child population, including for estimating the physical fitness of children with severe illness. The 6MWT in this study used a 15-meter indoor walkway. The procedure was in accordance with American Thoracic Society (ATS) standards. Subjects were instructed to walk as far as possible within 6 minutes without running.

Subjects were asked to rest for 10 minutes before undergoing the test. The subjects spent more time resting to keep doing the activity without control (rolling, jumping, running and so on). Vital sign monitoring, including blood pressure, pulse rate and oxygen saturation, was performed before and after the test. In this study, the average 6MWT distance was 390.45±50.05 meters, with the average distance in the age group of 7 and 8 were 370.15±45.64 meters and 410.75±46.47 meters, respectively. We found an increase in the average 6MWT distance as much as 40.6 meters between the age groups. Lammers et al. found an increase in 6MWT distance based on age. They found that distance increased by 37 meters at the age of 4-5, 43 meters at the age of 5-6 and 25 meters at the age of 6-7, while they not investigated increase in the age group 7-8.

The average distance in this study was lower than two studies conducted by Goemans and Ulrich in the same age group. Goemans’ studies were conducted in Caucasian boys aged 5-12 years. They divided the subjects’ age into 4 groups. The 7-8-year group achieved average distance of 547 ± 68.9 meters.

Li argued that anthropometric character that mostly influences distance is height. Li’s study found that subjects with a height of 120 centimeters had average distance of 550 meters and 595 meters for female and male, respectively. This indicated the comparison between average distance and height in this study was below the 25 percentiles in accordance with Li’s standard. Lower average distance obtained in this study might be caused by various reasons, including motivation factor and child’s cognitive level. According to Enright, walkway distance, motivation and cognitive levels are factors influencing child’s 6MWT distance.

Age, height, weight and gender factors affect the average 6MWT distance in healthy children. These factors should be taken into consideration when interpreting the results of 6MWT conducted in one time. We found a significant positive correlation between height and 6MWT distance in all subjects. It indicated that the higher the child, the further the distance achieved.

Nevertheless, we found no significant correlation between height and distance in each age group. We also found a negative correlation between weight and BMI with 6MWT distance in all subjects. These findings were consistent with a study of 6MWT distance based on gender in the age group of 9-10 conducted by Munadia in Jakarta. Munadia found no correlation between height, weight and BMI in boys aged 9-10. There was a correlation between distance and height in girls aged 9-10.

Conclusion

We found a positive correlation between height and 6MWT distance in children aged 7-8. There was no correlation between weight and BMI with 6MWT distance in both groups. In this study, the average 6MWT distance in children aged group 7-8 years was lower than the studies conducted in other countries.

Ethical Clearance: The study protocol was approved by the Ethical Commission to conduct basic science/clinical research in Dr. Soetomo General Hospital Surabaya, Indonesia. This study implemented the basic principle ethics of respect, beneficence, non-maleficence, and justice.
Conflict of Interest: The authors report no conflict of interest of this work.

Source of Funding: This study is done with individual funding.

Ultrasound Characterization of Abdominal Wall Endometriosis

Mohammed Bader Hassan, Omar Muayad Sultan, Adnan Mohammed Brayyich

1Assistant professor in radio diagnosis – AL-Iraqia University – College of Medicine – Iraq, 2Lecturer of radio diagnosis - Tikrit University – college of Medicine – Iraq, 3Head of general surgery department in Altarmya general hospital -Baghdad

Abstract

Background: Aim: Our aim in this study is to define the ultrasound finding in the patients have abdominal wall mass proven by postoperative histopathology as abdominal wall endometriosis.

Patients & Methods: A cross sectional study was done from first of August 2016- first of September 2019 in Baghdad governorate. The study included 32 patients. Diagnosis done by superficial ultrasound examination.

Results: 32 female have done at least 1 Cesarean section the commonest presenting symptom was pain in 90% of patients , all the lesions were hypoechoic in texture , with heterogeneity and small foci of echogenisity in 75% of our population , the consistency of the lesions was purely solid in 93.8% of lesions ,on color Doppler only 18.7% was avascular, the resistive index of the arterial flow was below 0.70 in 31 % of patients ,on elastography 78.5% of lesions was hard , the accuracy of assessment of muscle infiltration was 71% ,the ultrasound was the only imaging required preoperatively in 85% of our patients , the ultrasound was able to discriminate between endometrioma and collection or hernias in all patients and was the in the differential diagnosis list in about 90% of our population

Conclusion: the ultrasound characteristics of abdominal wall endometriosis if combined with clinical features and symptoms of the patients is excellent preoperative imaging modality to reach the diagnosis and exclude other lesions and accurately assessing muscle invasion in most of cases for proper surgical planning

Key words: cesarean section, abdominal wall, endometriosis, ultrasound, elastography.

Introduction

Endometriosis is a term describing any abnormal presences of endometrial stromal tissue outside the normal outlines of endometrial cavity\(^1\), endometriosis considered one of the common gynecological problem its incidence reaching to about 15% of women at productive age \(^2\) the most common site of this entity is the pelvic region \(^3\), it is rarely found in extra pelvic region. the abdominal wall endometriosis (AWE) considered one of the rare sites of endometriosis its incidence is about 0.3-3.5 % of population \(^4\).Although its predisposing factor is previous surgery mostly CS or other gynecological surgical interventions but it may include other abdominal wall endometriosis without any previous surgery \(^5\).Many theories are sets to describe the cause of this condition but the most accepted one is the implantation of endometrial tissue during surgery , which subsequently proliferate under hormonal effect \(^6,7\). the clinical symptoms of abdominal wall endometriosis include, periodic abdominal wall pain mainly during menses and palpable lump \(^8\). This entity of disease is misdiagnosed as granuloma or abdominal wall hernia, or malignant soft tissue tumors \(^1,3,9\). That’s why AWE is underestimated as its clinical and radiological signs are non specific \(^1,3\).
Aim

Our aim in this study is to define the ultrasound characteristics of the abdominal wall endometriosis as rare entity and to emphasis the importance of ultrasound in its diagnosis.

Patients and Method

*Ethical consideration:* The researchers consider taking the permission from patients before data collection and explaining the aim of the study for them. The study included patients who agree to participate, and assure of them about the confidentiality and privacy of their information.

*Study design:* The current study is prospective study performed from first of August 2016- first of September 2019 in Baghdad governorate.

*Sampling:* There were 32 patients included in current study. The patients were referred to ultrasound privet clinic to perform abdominal ultrasound examination complaining form pain along the scar of previous cesarean section scar. All cases are undergo surgical resection and all lesions are proved by histopathological study as abdominal wall endometriosis. All of the patients included in this study have been examined by ultrasound prior to surgery by expert radiologist. The ultrasound examination including gray scale, Doppler scans and elastography.

*Machine & Scan protocol:* The abdominal ultrasound examination was done using E-CUBE 11 ultrasound machine of high-density single crystal linear transducer (3-12MHz) (SC3-12H).

Result

The age of the patients included in this study ranging from 17-41 year old the mean is about 30.4 year with standard deviation (SD) of 2.1 years, all patients have previous SC, 78% are multiparous women with average CS is (2.7). The commonest presenting symptoms are pain at menses and lump. About 90% of our population are presented with abdominal pain, from those about 82% the pain is related to menstrual period, and about 18% have non specific or continues pain, while the 65% of patients presented with a lump at lower abdominal region.

*Sonographic Characteristics of AWE:*

**B mode** all the lesions was hypoechoic although about 75% of lesions was heterogeneous with small echogenic foci, the lesions borders was irregular in about 87% of our population, and ill defined in about 65.6%, the consistency of the lesion is solid in 93.5% of our patients and cystic changes seen in 6.5% only. The length of the lesions was ranging from 11.7 -41 mm with average 20.8 mm mean round index was 1.7.

**Doppler US:** the lesions show internal vascularity in about 71.8%, peripheral vascularity seen in about 9.37%, while avascular lesions were seen in 18.75.

The use of power Doppler didn’t change this ratio of internal vascularity detection in regard to our study.

The Resistive index of the lesion ranging from 0.54-1 and it measured above 0.70 in 50% of patients and its below 0.70 in 31.25% of patients, the other lesions was avascular on color Doppler.

Fig (1) color and spectral Doppler ultrasound in a 33 year old female, an ill defined border heterogeneous hypoechoic oval shape mass measured 18 x 9 mm invading the muscle with internal vascularity.
Elastography

The lesions show significant increase of tissue strain in comparison to surrounding tissue, the lesions were hard in 87.5% of our population, the elast/o B ratio is more than 1 in 41% while lesions were similar in size or the hard tissue is smaller than the lesion in 59% of the lesions. The radiological findings of AWE are listed at Table (1).

Assessment of Depth and Wall Invasion

The detection of muscular and fascial involvement is mandatory for proper operative planning, the assessment of muscle involvement is assessed by B mode the muscle involvement proved by surgery in about 53% of patients while, the accuracy of muscle involvement was 71.8%, the negative predictive value was 60% as seen in Table (2).

Diagnosis of the Lesion

The radiological findings of endometriosis was not specific but the endometriosis was one of the differential diagnosis in 90.6% of the patients in our study. The other differential diagnosis was granuloma, soft tissue sarcoma and desmoid tumors.

Ultrasound was very sensitive exclude all the patients that was clinically suspected to be hernias or collections. The CT scan and MRI was used to confirm US findings and to exclude malignancy and muscle extension in some patients only. CT sac used in about 6% and MRI used in about 9% of our patients.

Fig (2) : longitudinal section view shows 11.7 x 8 mm subcutaneous endometrioma in a multiparous 27 year old woman. The nodule is irregular margins hypoechoic in texture dose not infiltrating the muscle fascia, the lesion is hard on elastography.

Discussion

The most common presenting symptom is pain in about 90% mainly related to menstrual cycle in about 75% while felling of lower abdominal mass was described in about 65% of our population. The cyclical pain is the presenting symptom in most of studies [3,5,6,10], this finding was compatible with this study the cyclical pain was presenting symptom in 75% while [3], found that the pain the commonest presenting symptom in about 80% but the cyclical pain was seen in 44% only [11], in other study the first presenting symptom was mass and lump feeling in 98.5% and cyclical pain was less frequent in about 86.9% according to [12].

Cesarean section was the predisposing factor for development of AWE in our population, this was agreed by [1,3,12], that all the patients in their studies doing CS or
other gynaecological surgery [6] spontaneous abdominal wall endometriosis was emphasis in many studies [11], 2 of 72 patient have no previous surgery, [13] reported 9% of his patients was not associated with previous surgery , and the comments site of this lesions was the umbilicus, this was compatible with [10], who found 17% of niliparous , female with no previous surgery developed abdominal wall endometriosis , all are located at umbilical region 14 and in some series spontaneous endometriosis was high reaching to 20%.

the ultrasound the first choice of imaging exam in evaluation of abdominal wall endometriosis [7,3,15], the ultrasound was able to identify all the lesions in our patients this was clos to the finding the sonography was able to show the endomtrioma in 92% of his patients [1].

although the ultrasound findings of AWE is not specific but it can exclude some of the lesions that may mimic endometriosis such as hernia ,abscess collection or hematoma [1,16].

all the patients in our study do at least one ultrasound examination ,some patient with high suspicion of malignancy or difficult examination such as in obese patients

the sonographic findings in B mode in most of the lesions was an ill defined irregular heterogeneous hypoechoic solid mass with multiple small echogenic focuses inside the lesions these findings are similar to many studies [1,3,5,7,15,16], although some of our patients shows some atypical finding as cystic component was seen in 6% of our population ,the cystic changes in endometriosis is rare findings and it reported in many literature [1,3,5,15, 16], our result was compatible to L. SAVELLI et al who found small cystic changes in 2% of patients [5].

on color Doppler 81.2 % of our population shows peripheral or central vascularity this was relatively comparable to result of other studies [3], which found internal and peripheral vascularity in about 83% and avascular in only 2 patients. while other studies [1], found all the lesions was vascular on color Doppler.

no vascularity can be seen in about 18.8% . the avascular lesions was small in size < 2 cm in widest diameter and located within SC the explanation of this could be due to small vessels which can not be detected by Doppler US or due to its growth within hypovascular SC tissue .16) in one of the studies the internal vascularity can not be seen in all lesions smaller than 15 mm [17].

, the Resistive index was high in about 62.5% of vascular lesion and the with average of RI is about 0.71 the high impedance this was compatible to many literatures [5,19,17,18].

Elastography : to our knowledge few literatures write about the characteristics of abdominal wall endometriosis , we found that elastography was hard in 87.5% of patients , the elast/o/B ratio in assessment of size was more than 1 in about 59% of patients with average 1.1 which can be interpreted by the histopathological findings of inflammatory cells infiltration in the subcutaneous tissue which alter the normal elastograpic characteristics of the surrounding fatty tissue [5].

In one study the use of elastography to assess fascia and muscle involvement shows improvement from 33% to 87.9% by elastography .20 ,the accuracy of ultrasound in detection of muscle involvement was 71% with negative predictive value about 60%.

Conclusion

The Presence of an ill defined oval shape hypoechoic mass near the cesarean section scar with internal or peripheral vascularity on Doppler ultrasound which significantly increase tissue strain on elastography if combined with repeated cyclical aggravated pain are strong evidences of suggesting endometriosis. the ultrasound is excellent preoperative imaging modality to reach the diagnosis and exclude other abdominal lesions and it accurately assessing the muscle and fascia involvement in most of the patients

Gene Polymorphism Vitamin D receptor BsmI in Thalassemia Children in Al-Muthanna Province

Mohammed Qasim Waheeb1, Yasar Adil Jabbar Alabdali2, Hanaa Ali Azez2
1Assistant Professor, 2Lecturer Department of Biology, College of Science, Al Muthanna University, AL-Muthanna, Iraq

Abstract

Introduction: Vitamin D is crucial for calcium, phosphate homeostasis and mineralization of the skeleton, particularly through growth time developments. Vitamin D deficiency lead to rickets in children and osteoporosis in adult. The activity of vitamin D receptors (VDR) are responsible for the vitamin D so that the single nucleotide polymorphism was detected using BsmI. Material and methods: In this study, the vitamin D3 level were measured using enzyme-linked sorbent assay (ELISA) technique, followed by detection of the polymorphism VDR- BsmI gene using PCR and BsmI restriction enzyme assay (PCR-RFLP). Results: Vitamin D, alkaline phosphate and others biochemical were performed in 50 patients beta-thalassemia were divided into 25 males and same number females. The biochemical results demonstrated no significant difference p<0.05 between males and females according gender, whereas showed high significant serum calcium p value 0.048 according body mass index. We using RFLP-PCR technique to amplify VDR gene BsmI, DNA ladder molecular weight was 1000-2500 base pair and BsmI digestion showing predicted product in 823 to 175 pb in all lane. Conclusions: BsmI digestion was showing heterozygous mutant (Bb) and homozygous (BB). These result gene polymorphism VDR BsmI effected on vitamin D levels and related with bone diseases and process metabolism.

Key words: BsmI, VDR, thalassemia, gene, vitamin D, polymorphism.

Introduction

Beta thalassemia syndrome are one of the most popular autosomal recessive hereditary defects diffuse global, with high dominance in the populations of the Mediterranean, Middle East, Central Asia, Indian subcontinent and Far East1. Thalassemia bone disease has increased as the major morbidity rate associated with thalassemia transfusion-dependent. Bone disease including of low bone mineral density (BMD), bone pain and fractures are private features of thalassemia2. The vitamin D receptor (VDR) gene is by far of the most widely investigated osteoporosis marker. The chosen polymorphism was a BsmI and FokI3. Few studies have described an associated between the BsmI polymorphism of VDR and thalassemia children4, and with skeletal and non-skeletal parameters in thalassemia major5. The receptors of both VDR and calcitonin genes polymorphisms are linked with osteoporosis5. The VDR polymorphism and decrease BMD has been linked also amongst patients with the BB VDR genotype7.

In this contextual relationship, the fundamental interaction of the active form of vitamin D (1,25-dihydroxyvitamin D3) and its nuclear receptor VDR has been known as an important mediator of the innate immune response. The mechanism of action of VDR is by promoting the expression of multi antimicrobial peptides, consist of cathelicin and by the activation of autophagy of the infected cell, consequently limiting the intracellular growth of Mycobacterium tuberculosis in macrophage8,9.

The human VDR gene four common SNPs that have been conducted an investigation extensively: ApaI (rs7975232), BsmI G>A (rs 1544410), Taq T>C(rs 731236) and FokI T>C(rs2228570). The polymorphism BsmI and ApaI are both situated in intron 8 and TaqI is a wordless SNP in exon 9, and all are associated with in regulating the stability of the VDR mRNA10,11. The VDR FokI gene polymorphism causes a constitutional amendment. This SNP is a T/C transition at the translation initiation site of exon 2 at the 5’coding region of the gene. The change makes a new start codon (ATG to ACG), which
leads to the expression of a shorter VDR protein 424 amino acids, which has higher transcriptional action as compared to the full length VDR protein of 427 amino acids.

The aim of the current study conducts an investigation into the rate of occurrence of VDR gene polymorphism BsmI (rs1544410) in a group of Iraqi populations. In thalassemia children patients inspect the relationship between VDR and the conservation bone health and metabolism.

Materials and Methods

Subject

The participants to the case study were enlisted with a future effect between September 2018 and September 2019 in the Samawa City (SC). A total of 50 patients. All entrant signed acquainted documentary approval previous to providing a blood sample and data privacy was protected according to the protocol Helsinki Declaration.

Parameters measurement

Five milliliters of blood outgoing under optimal status by venous blood from every child, 3ml on EDTA and 2ml on DNA extraction, thereafter VDR gene polymorphism whereas the other portion was centrifuged and sera were gotten and stocked under -20°C for measure of serum 25 hydroxy vitamin D3 with Enzyme Linked Immunosorbent Assay (ELISA). Serum vitamin level was assayed based on the manufacturer’s directives. Currently accepted standards for diagnosed vitamin D values in thalassemia children are:

1- VD deficiency < 10 ng/ml
2- VD insufficiency 10-30 ng/ml
3- VD sufficiency 30-100 ng/ml

Other laboratory criteria by utilizing Fujifilm clinical biochemistry (FUJIDRI-CHEM 4000i) inspections including: Alkaline phosphate(U/L), potassium(mmol/L), total protein(g/dL) and calcium(mmol/L), in addition computation body mass index(BMI) for all genders.

Genotyping

Genomic DNA was isolated by utilizing the phenol chloroform extraction method. Genotypes were uncovered by using PCR, followed by the BsmI restriction

fragment length polymorphism (rs 1544410) and carried out (PCR-RFLP). The BsmI upstream primer is 5’AAGACTACAAGTACCGCGTCAGTG-3’ and reverse downstream primer is 5’ AACCAGCGGGAAGAGGTCAAGGG-3’. The primers are in figure 1 A.823 pb fragment BsmI in the start codon of the VDR. DNA was extract by utilizing an axis column kit (Qiagen kit) polymerase chain reaction (PCR) amplification and enzymatic digestion with BsmI.

The BsmI genotypes were revealed by utilizing electrophoresis of the DNA samples 1.5% agarose gels and were named as followers: BB (not present restriction site); bb (not present restriction site); Bb (heterozygous of the restriction site). The PCR products for the BsmI polymorphism was 823pb and the restriction fragments were 175pb.

Statistical analysis

The data were analyzed by using SPSS version 22 for windows (SPSS, Chicago, IL, USA). The mean of data was predestined by one- way ANOVA and t-test. Moreover, frequency results were analyzed by pearson chi-square and Fisher exact test. The variations were indicated significant at p>0.05.

Results

This study was executed on 50 patients infected with thalassemia, 25 males (50%) and 25 females (50%) their ages extending between 1 to 12 years old. An allocation of the studied vitamin D3 according to the genders both were 15.6±3.9 in female and 15.5±4.2 in male that was less in females in table 1. P. value was 0.976, as well biochemical criteria were less in females except alkaline phosphate was higher registered 76±27.9 and 72.5±27 in males p-value was 0.650.

Discussion

Until now, there are four restriction fragment length polymorphism (Taq1, ApaI, FokI and BsmI) of VDR which have been studied related with thalassemia disease. Over the years, the interaction between VDR polymorphism and genetic diseases sensibility is still unclear. Several factors are responsible for the conflicting results, like racial variation, different genotyping methods, sample sizes, lifestyle features of people. The human VDR gene be composed of 11 exons that jointly with related introns. Exon1A,1B, and 1C make up the 5' noncoding region, and eight supplemental exons (2-9) encode VDR structural component14. BsmI situated in intron VIII. All of them were observed at the 3’ end of the VDR in the during 1990s. In spite of, none of the effect the action of the VDR protein expression15. Our study demonstrated that a deficiency of hydroxylase vitamin D (25 OH D) is common in thalassemia children. Vitamin D mean level were no significantly at $P \leq 0.05$. Studies of serum vitamin D have shown harmonious with our results16. Prevalence of the vitamin D deficiency was found in children thalassemia patients. Level of serum vitamin D were low to normal, according with previous studied17,18. The 25-OH-vitamin D to be had in these patients should be sufficient for a normal 1- hydroxylation in the kidney to make 1,25-OH-vitamin D. Serum 25-OH vitamin D concentrations are a lot of time higher (ng/ml) than those of the product of the
kidney enzyme, 1,25-OH-vitamin D (pg/ml).

In figure 2-C gene polymorphism BsmI in relation to thalassemia patients showed homozygous (BB) while in fig 1 showed heterozygous (Bb) and absent allele (bb) in this study that was conflicting with19. Actually it is not clear whether the BsmI polymorphism has an impact on the expression level or actin of the translated VDR protein20, but it is in strong related imbalance with the poly(A) microsatellite located in the 3 untranslated region21 of the VDR gene, that evidence to effect VDR messenger RNA constancy and VDR translation activity22, demonstrated23 observed a decrease VDR expression while, at the mRNA level24 found an up-regulation. Likewise, to detect a clinical pertinent phenotype is prospect needful to contain in the analysis other genes implicated in the vitamin D metabolism as the linking the binding protein (GC) and the anabolism and catabolism enzymes25,26. Vitamin D has a significant role in multiple myeloma (MM) patients because of the mutual relations with calcium homeostasis bone metabolism27 closely connected to calcium and phosphorus homeostasis.

**Conclusion**

Vitamin D is a steroid hormone which plays an important role in calcium homeostasis and skeletal metabolism. The vitamin D receptor (VDR) mediates the action of its linked and results in normal bone mineralization and reconstructing. Subsequently, the gene that encodes for the VDR is taken into consideration a nominee gene for osteoporosis. This study revealed that the (BB) of the BsmI polymorphism was related with increased bone loss, whereas in (Bb) had decreased rates of bone loss.

Role of Interleukin-36 in Response to *Pseudomonas Aeruginosa* Infection

Muslim Idan Mohsin¹, Mohammed Jasim Al-Shamarti¹, Rusul Idan Mohsin³, Sarmad Al-Sahaf²

¹Department of Laboratory Investigations, Faculty of Science, University of Kufa, Najaf, Iraq. ²Baghdad College of Dentistry, University of Baghdad. ³Department pathological analysis, collage of Al-Tossi University, Najaf, Iraq.

**Abstract**

**Background:** One of the causative agents of the lower respiratory tract (LRT) is *Pseudomonas aeruginosa* which can lead to severe infection associated with a lung infection. Many cytokines are secreted in response to bacterial infection, in particular, interleukin IL-36 cytokine in response to *P. aeruginosa* infection. IL36 promotes primary immune response via binding to the IL-36 receptor (IL-36R). Indeed, an over activity of IL-36 might be an initiating factor for many immunopathologic sceneries in pneumonia.

**The aims of Study:** the involvement of IL-36 in the *P. aeruginosa* infection could be a clue to find a specific way for treatments of different inflammatory and degenerative lung diseases.

**Methodology and Results:** we used manual and VITEK2 system to isolate and purify all the species, also using qPCR real-time to demonstrate that the involvement of IL-36 cytokine in response *P. aeruginosa* infection which is isolated from (LRT). We found that one of the most common pathogens is *P. aeruginosa* after *Klebsiella pneumonia*, and more resistance bacterium against antibiotics is *P. aeruginosa* (P4). Furthermore, we found that IL-36 cytokine increased in response to *P. aeruginosa* infection.

**Conclusion:** *P. aeruginosa* is one of the main causative agents in LRT in many hospitals in Iraq, and the contamination and antibiotics resistance for these nosocomial pathogens is increased. Also, IL-36 expression significantly upregulated in human lung epithelial (A549 cells) after infected by *P. aeruginosa* at the mRNA level.

**Key words:** IL36, *Pseudomonas aeruginosa*, LRT infection and A549 cells

**Introduction**

One of Gram-negative bacterium is *Pseudomonas aeruginosa*, which is the main causative agent of LRT infection. It can lead to nosocomial infection and chronic infection in immunocompromised patients. The most serious cases are sepsis and pneumonia (¹). Due to virulence factors of *P. aeruginosa* lead to increase the proportion of multidrug resistance (MDR) in *P. aeruginosa* (², ³).

In recent publication, IL-36 is classified as one of members of IL-1 family (⁴). IL-36 binds with IL36 receptor complex and IL-1 receptor accessory protein (IL-1RAcP). Receptor of IL-36 could bind to the IL-33 and the IL-1 receptor (⁵). The IL-36 induces primary immune response and contributes to neutrophil accumulation or/ and dendritic cell activation (⁴-⁶). During early stage of *P. aeruginosa* infection, many immune cells are activated (⁷, ⁸). Interestingly, it has been reported that IL-36 mRNA is unregulated during *P. aeruginosa* infection in human bronchial cells (⁹).

Taken together, these clarifications suggest that IL-36 are involved in host defense against *P. aeruginosa*. This involvement could be because inflammatory cells recruitment and/or activation. The involvement of IL-36 in response to *P. aeruginosa* infection is still unclear. We hypothesized that IL-36 is involved in acute *P. aeruginosa* lung infection. In this study, we also demonstrate that IL-36 produced by A549 cells during *P. aeruginosa* infection which is isolated from LRT.
Methodology

Bacterial strains:

*P. aeruginosa* (P4) was chosen based on the antibiotics resistance and virulence factors. *P. aeruginosa* (P4) was used for all experiments, and grown in lysogeny broth medium or agar. *P. aeruginosa* were grown an overnight culture and were cultured at 37 °C to reach OD_{600} 0.4. It was equal 1x10^8. *P. aeruginosa* was 2x washed and diluted by DMEM medium with 10% heat-inactivated foetal calf serum to achieve an appropriate MOI.

Culturing of human lung cell line

The incubation conditions for A549 cells was 37ºC and 5% CO₂. Trypsinisation was used to harvest A549 cells. Briefly, A549 cells were washed with 5ml HBSS without Ca++ and Mg++. Then 2.5ml of 1x trypsin (Lonza) was added and keep the flask in incubator for 8min. 10ml of DMEM medium was added to pellet. The pellet was spent down at 300xg for 5min and then re-suspended with 5ml DMEM. An appropriate number of A549 cells were counted for seeding to next experiments.

Antibiotics sensitivity test

The Kirby-Bauer standardized single disk method was performed according to Kirby method (10). Briefly, Mueller Hinton medium plates were prepared. Using an L-shape sterile spreader, *P. aeruginosa* is evenly seeded throughout the plates. The bacterial cells density was approximately 1×10⁸ cell/mL. This density was compared with OD_{600} about 0.4. The antibiotic disks were used with standard concentration. The antibiotics disks are evenly dispensed and placed onto the medium and then incubated at 37 °C 24h in an incubator. Using a ruler, inhibition zone was measured to the nearest millimeter (mm) Therefore, the susceptibility of bacteria to an antimicrobial agent was detected as compared to the zones of inhibition determined by formerly NCCLs (2014) (11).

Statistical Analyses

GraphPadd prism.8 was used to make all graphs and analyse the data statistically. The significant differences between samples were determined using one and two-way ANOVA for multiple comparisons. Results are shown as mean ± SEM.

Results

Isolation of bacteria

The aim was to examine which species are the most virulent pathogen in lower respiratory tract infection. We collected 50 specimens from different hospitals in alnajaf province. We diagnosed form all samples depending on phenotyping, biochemical tests, morphology shape and selective media. Findings showed that only 21 specimens have bacteria but other samples have no bacteria. The highest number is *Klebsiella pneumonia* 9 (42.86%). The lower number is *Staphylococcus aureus* 3 (14.28%). However, our interest pathogen *P. aeruginosa* 5 (23.81).
% and other bacteria were about (19.05), as demonstrated in Fig 1. It seems that the main our interested bacterium from the main pathogen in lower respiratory tract infection.

![Percentage of different types of bacteria isolated from lower respiratory tract infection (LRT). Data shows number and percentage of isolates from 50 sample of LRT infection from different hospitals in Alnajaf province (Alsadar Medical city and Alforat hospital). Pure colonies were isolated and placed in VITEK2 microbial identification. To more validation, manual diagnostic methods have been performed included biochemical and culturing tests.

Antibiotics sensitivity test

As shown in Fig 1, the percentage of P. aeruginosa seemed more correlate to be the main causative agent of LRT infection. These strains were selected to closely study to determine which strain has the highest antibiotics resistance. This section aimed to select the highest species to antibiotics resistance. All isolates were screened for antibiotics sensitivity. The finding shows that there is a variation of antibiotics resistance for isolates. P. aeruginosa (S-4) has highest antibiotics resistance than other samples, as demonstrated in Fig 2.

![Antibiotic profiles of P. aeruginosa used in this study. P. aeruginosa of bacteria are purified and plated on Muller Hinton agar using sterile swap, different types of antibiotics disk were placed on the plates, and bacteria were incubated for 24hr to measure the inhibition zone. The findings are mean of 3 independent experiments with duplicates.

Infection efficiency of P. aeruginosa in A549 cells

This section was to test a different multiplicity of infection to determine which MOI can attach to A549 cells. This cell line was infected with P. aeruginosa to measure the total bacterial infection after 2hr, and to detect the best MOI to the further experiments. The CFU equation was used to count how many bacteria per host cells at 2hr. The MOI was used 10, 50, and 100 bacteria per each mammalian cell. The finding shows that the number of bacterial per host cells was increased related with MOIs (Fig 3). The MOI 100 was statistically significantly different than other MOI. It was suggest that this MOI can use to further experiments.
IL-36 induced in A549 cells during *P. aeruginosa* infection

The aim of this section was to test whether IL-36 is changed in the A549 cells infected *P. aeruginosa* clinical strain. In brief, we tested a mRNA expression during 3 time points during bacterial infection. To do this, mRNA from A549 cells is extracted before and after infected by *P. aeruginosa*. Complementary DNA (cDNA) were made for all samples during 3-time points. The PCR products were quantified by using the SYBR green pigment. The $C_\text{t}$ was used to quantify the findings. Also, $\Delta \Delta C_\text{t}$ method to calculated the fold change using the $2^{-\Delta \Delta C_\text{t}}$ equation. IL-36α mRNA level was significantly up regulated in response to *P. aeruginosa* infected A549 cells during all the time points included: 4, 6 and 24hrs post infection (Fig 2).

Figure 3 *P. aeruginosa* infection in A549 cells at different MOI of infection. A549 cells were infected at MOI 10, 50, 100. The total number of *P. aeruginosa* was counted after 2hr using CFU methods. Using one-way ANOVA to test the significant differences, where ** $p<0.01$ meant significant. The findings are the means of 3 experiments performed in 3 replicates ($\pm$ S.E.M).

Figure 4 IL36 expression during *P. aeruginosa* infection in A549 cells over-time.
Both infected and non-infected A549 cells were harvested at 2, 6 and 24hr post-infection. Using qPCR to determine the mRNA level post infection. The significance of differences were analysed using two-way ANOVA, where ** p<0.01; **** p<0.0001 significant compared to non-infected A549 cells. The results are the means (± S.E.M) of 3 experiments in 2 replicates.

**Discussion**

The aims were to select the highest bacterial antibiotics resistance and to determine that IL-36 plays a role in *P. aeruginosa* infection. We found that *K. pneumonia* and *P. aeruginosa* are the main causative agents in LRT infection (Fig 1). This finding is in agreements with the previous findings of (12, 13). Zhou et al. have found that *P. aeruginosa* percentage was about 25.2% and *K. pneumonia* was 31% (14). Ramana et al. also found that *K. pneumonia* is the most common pathogens in LRT infection (12). This does not support our findings that revealed *P. aeruginosa* has a sensitivity to Ampicillin. Another study supported our result, which demonstrated *P. aeruginosa* to have resistance to erythromycin and sensitive to gentamicin (Fig 2) (15). Taken together, it seems that *P. aeruginosa* is one of main the causative agents of LRT infection, and it must be taken seriously. It is probably that the mechanism of antibiotics resistant is upgraded and that are not likely updated in Iraq, in particular, alnajaf hospitals. The reason for that could be the clinician staff have a lack of awareness to avoid contamination. We strongly suggested that using antibiotic randomly must be avoided; otherwise, the problem will be increased. In the (Figs 3 and 4), we demonstrated that the bacterial efficiency in A549 cells and the role of IL-36 in *P. aeruginosa* infection. Interestingly, we showed that IL-36 mRNA level appeared to increase in A549 cells. Significant induction of IL-36 mRNA level was observed between 2 and 6h (p ≤ 0.001) in A549 cells, while IL-36 mRNA was highly increased at 24h (p ≤ 0.0001) relative to uninfected controls, as demonstrated in Fig 4. Some studies report that IL-36 plays a positive role in bacterial infection. In particular, it has a positive role in *P. aeruginosa* infection (12). This observation was in agreement with our data that shows IL-36 increased during *P. aeruginosa* infection. Interestingly, Vos et al have reported that IL-36 mRNA is unregulated in human bronchial cells during *P. aeruginosa* infection (Vos, van Sterkenburg *et al.* 2005). Ultimately, this explanation suggests IL-36 induces as primary immune response of host defense against *P. aeruginosa*.

**Conclusions:** IL-36 could contribute in early stage of immune response to *P. aeruginosa* infection. It is likely that the bacterium induced the inflammatory cell recruitment, and induced the cells to activate during infection. Our observation could approve our understanding for the mechanisms of bacterial pathogenesis in the epithelial cells, and also could identify a new therapeutic target in lung diseases using antibodies, or block material to this cytokine.

Abstract

Platelets are one of the most important cells in human blood, and help control bleeding. Mean platelet volume (MPV) play a vital role to indicate the activation of platelets. any significant changes of mean platelet volume will effect on platelet activity. Vibration-stimulates changes in the platelets activity as a type of stress upon MPV. This study aimed to investigate the impact of ultrasound waves on MPV of healthy and hypertension subjects in vitro model study. Venous blood samples obtained from healthy subjects (n=43) and hypertensive patients (n=61) have been exposed to ultrasound waves for two periods (5-10) minutes. The MPV was measured using the Coulter electronic count (Complete blood Count). The results have been shown that ultrasound waves caused a significant changes MPV in healthy subjects and hypertensive patients. The changes in the MPV are dependently related to the exposure time. In healthy subjects, the MPVs have been significantly increased by 12.6% for 10-min exposure while in hypertensive are significantly decreased by 9.1% for 10-min. It concludes that ultrasound induced an increase of the MPV, and this effect is tended to be less in patients with hypertension indicated that the responses of platelets are reduced in chronic diseases. It is clearly indication that the cellular response of MPVs in hypertension patients were very weak may because of hypertension. Whereas, MPVs response of healthy subject remained normal and effective.

Keywords: Vibration, Platelets, Hypertension, Mean platelet volume (MPV), Ultrasonic waves.

Introduction

Platelets are the most important vital cells in human blood. which are small nucleate cells play a critical role by helping the body form clots to stop bleeding. If one of the blood vessels is damaged, the body sends signals that are captured from the blood platelets to stop the bleeding by adhesion process, because when the platelets reach the site of infection, they grow sticky claws that help to adhere, and they send chemical signals to attract more Platelets to accumulate on the thrombus. Human body consist of 1×1011 of plateletswhich formed every day as the result of complex processes of differentiation, maturation and fragmentation of megakaryocytes [1]. Platelets are different in volume, density and reactivity individually [2]. The range of normal platelet counts is 150–400×109/L. Naturally, platelets spread in blood stream for 8–10 days while upon vascular injury, platelets instantly adhere to the exposed extracellular matrix resulting in platelet activation to form hemostatic plug. If the platelet number is low, the risk of bleeding is high [3].

Mean platelet volume (MPV) is a signal for platelet activity. Furthermore, altitude of MPV values is important, To be considered as a vital indicator for detect chest pain that is due to myocardial infarction, from that of non-cardiac one [4]. In addition, MPV is predictor marker for ventricular dysfunction and clinical outcome of acute myocardial infarction [5].

In case of hypertension, studies found that MPV being an independent factor which related with morning blood pressure rise also high sensitivity C-reactive protein and therefore, which may serve as a predictor atherothrombotic cardiovascular event [6]. Numerous studies noted that the workers who exposed to local vibration have a significant low of lipid profile involving triglycerides, serum cholesterol and high density lipoprotein at the same time the viscosity of blood will increase [7]. Studies related with animals which exposed to vibration exercise for short period in-vivo have been noted that there is no significant changes in hematological indices [8].
One types of mechanical energy form is Ultrasound waves which is a mechanical vibration, longitudinal waves composed of compression and rarefaction areas. Particles of a material which exposed to a ultrasound wave will fluctuated around a fixed point rather than move with the wave itself. When the energy within the sound wave is transfered to the material, it will lead to oscillation of the particles of that material. Clearly any increasing in the molecular vibration in the tissue can result in heat generation, furthermore, ultrasound can used to produce thermal changes in the tissues, although current usage in therapy does not focus on this phenomenon [9],[10].

Of general principles that the temperature expands biological material [11]. Based on this rule our study has been conducted to investigate in mean platelet volume response when exposed to ultrasound waves for healthy as a control and hypertension patients in-vitro model because the ultrasound waves may cause altering in MPV when exposed to the physical injury like vibration sound.

Materials and Method

This study was done in University of Diyala/college of medicine from october 2019 to january 2020. An agreement form has been obtained from each patient before starting our study. This study has been conducted according the ethical guidelines constructed by the Scientific Committee of the Institute. The patients were recruited from the hospital. A total number of 102 patients were enrolled in the study; 61 patients with essential hypertension and 43 healthy patients. 3ml of peripheral venous blood have been drawn and putted into EDTA-tubes then each tube was exposure to ultrasound vibration (sonoscope s50 )for 5 minutes and for 10 minutes. The blood was used directly after its withdrawal. Initially the blood was examined before it was exposed to ultrasound, then the blood model was exposed to ultrasound in a precise way where the probe covered all the area of blood which exist in EDTA tube. The platelet number (per cubic millimeter) and the mean platelet volume (fl) were measured for each sample before and after exposure to the vibration using Coulter (diagon Ltd, D-Cell 60) AUTO HEMATOLOGY ANALYZER apparatus.

Statistical Analysis

Data of current study were analyzed by using Chi-square ($X^2$) test to compared between percentages. Also, measured sensitivity and specificity of mean platelets volume (MPV). Numeric data were described by (Mean ± SD). T test used to compare between two numeric variables, while F test (ANOVA) used to compared between three numeric variables or more. A level of significance of $\alpha=0.05$ was applied to test. (SPSS v.22 and Excel 2013) programs used to analyze current data.

Results

104 volunteers was participated in our study grouped into two groups ( 43 subjects were healthy as a control and 61 subjects was hypertension). The mean age of study volunteers was significantly 34.30±11.34 year for control individuals and 53.59±15.31 with range of 1-80 years. Mean and standard deviation values of the BMI for control individuals 26.90±4.78 and 27.33±4.59. According to residence 77% of hypertention individuals were urban and 61% of healthy individuals were urban as show in (Table1).

Befor starting with our investigation, MPV have been checked for controls and hypertension cases as shown in (Table 2), MPV values in heathy subjects and Hypertension cases nearly the same and no difference appear in statistics. after that, the blood have been exposed to ultrasound for 5min and MPV checked again. We found that mean platelets volume started to significantly increasing in controls and decrease in patients with (hypertensive) groups (T=4.717 Df=93 P=0.001). then, the blood exposed again to ultrasound for 10min, surprisingly, MPV response for healthy subject showed significantly increasing comparing with hypertension values(T=8.235 Df= 93 P=0.001). Moreover, the MPV of hypertension patients have been noted a significantly decreasing.

Interestingly, MPV response in hypertension patients was different during the time periods Where the response was inversive compared to a MPV response in healthy subjects, there was a significantly decreasing when increasing time periods of exposure to ultrasound waves. as shown in (Figure 1).
Discussion

The results of our study showed that ultrasound has severe adverse impacts on mean platelet volume (MPV) regardless of weight and age, particularly on hypertension patients.

There are many researches undertaken in the past indicating the bioeffects of ultrasound waves and its benefits in can promote satellite cell proliferation, achieve collagen supra-molecular myoregeneration phase, increase the differentiation of muscle lineage, reduce oxidative stress and treatment of idiopathic thrombocytopenic purpura [12-15].

On the other hand, many studies indicating the hematological changes due to exposure to ultrasound [16, 17] and this in agreement with the results of the present study that show the MPV of hypertensive patients affected by ultrasonic waves rather than healthy individuals as the platelets decrease in size and this goes with other studies who demonstrated that hypertensive patients exposed to ultrasound at work have an increase in platelets aggregation with increased generation and activity of von Willbrand factor.

Study undertaken on discoid platelets suspension when exposed to ultrasound waves, changes in platelets orientation and damage to platelets occurs after 5 minutes of exposure and damage to the cells is directly proportional to the intensity and duration of time exposure [18-20] and this also in agreement with our study results as the MPV of hypertensive patients decreases when exposed to US waves for 5 and 10 minutes.

Conclusions

It concluded that there is a lack response within hypertension patients which is lead to poor activation of the platelet when exposed to ultrasound, furthermore ultrasound considered as a kind of stressor may has a negative effect on platelets by increasing of mean platelet volume (MPV) which is make to be highly in healthy cases Unlike the response of hypertension patients.

Objective: The study aims to: 1. Identification and isolation of candida spp in Patients with renal dialysis. 2. To identify the relationship between some important parameters (age, gender, other disease) associated with chronic kidney disease and oral candidiasis. 3. Study of antifungal susceptibility profile for *C. albicans* in oral candidiasis. This study was performed in AL-Zahraa Teaching Hospital (Kidney Center) Wasit Governorate during the period from the first of December 2018 to the end of July 2019. The samples were collected from oral swabs, then cultured on sabouraud dextrose agar (SDA), examined under microscope to show hypha and pseudohypha of Candida spp and cultured on chrom agar for identifying the *Candida* spp. The molecular methods that used in this study were vitek 2 system and Polymerase chain reaction (PCR). The results showed that from 50 oral sample from Patients with renal dialysis 24 (48%) infected with Candidiasis 20 (83.3%) was *C.albicans* and 4 (16.7%) other *Candida* spp (*C. Famata*, *C. Prosabilosis* and *C. Tropicalis*), while 26 (52%) non infected. There is not relationship between the age, gender and other disease in chronic kidney disease and the infections with oral candidiasis.

Keywords: Oral candidiasis, Chronic Kidney diseases, Candida albicans

Introduction

Patients with chronic kidney failure have disturbances of immune function involving both innate and adaptive systems. These result in both immunodepression which increases susceptibility to infection and immunoactivation leading to a chronic inflammatory state. Dialysis treatment may further aggravate aspects of this, especially the induction of inflammation. In addition, there is a growing number of patients who have returned to dialysis programmes following transplant failure. Many of these will have been intensively immunosuppressed, often over years or decades. These patients are at particular risk [1]. The colonization can cause oral candidiasis, which can progress to its more invasive form, esophageal candidiasis. Moreover, if the immunosuppression continues or becomes stronger, it will continue to be a risk factor for systemic candidiasis [2]. Renal failure can cause defects in cellular and humoral immunity by affecting T-lymphocyte subsets. Uremia causes a decrease inphagocytic activity of macrophages, [3].

Immunocompromised are a condition where the mechanism of host defenses are impaired (weakened or absent) by primary (congenital) or secondary (acquired) causes [4] and these Immunocompromised hosts include diabetes, neutropenia, burns, persons with intravascular catheters, patients undergoing hemodialysis, abdominal surgery, persons with parenteral nutrition, immunocompromised individuals can frequently suffer from recalcitrant infections of the oral cavity. These oral infections with Candida species are termed “oral candidiasis” (OC). Such infections are predominantly caused by *C.albicans* and can affect the oropharynx and/or the esophagus of persons with dysfunctions of the adaptive immune system [5]. Diagnosis of Candida in the laboratory is done by simple microscopy, culture or antigen detection assays. The wet mount microscopy detects budding yeasts cells and hyphal or pseudo hyphal forms. They also grow well on routine culture medium and on gram-stain, appear gram positive and oval in shape. The culture media that used is sabouraud
dextrose agar with chloramphenicol (antibiotic) are used. Creamy colored colonies are seen on the agar; making the slide from these colonies and examine, the yeast cell and pseudohyphae under the microscopes seen [6]. Then use several techniques for confirmation like the The Vitek 2 system, first introduced a fluorometric and then a colorimetric card for the rapid identification of yeast species. The performance of both cards has been evaluated in several studies [7-11]. In contrast, during routine diagnostics, yeasts are also commonly isolated on other media, including CHROMagar Candida [12]. PCR is a crucial tool in the diagnosis of human pathogens. This molecular method is based on nucleic acid amplification, and hybridization has been rapidly adapted to reliably detect a broad range of infectious agents. The use of PCR to diagnose medical mycoses has been challenging, however, because fungi have cell walls that impede the efficient lysis of organisms and liberation of DNA (which can lead to false-negative PCR results) and because some human pathogens are also ubiquitous in the environment (leading to false-positive results [13]).

**Material and Method**

**Study design:**

This prospective study was performed in AL-Zahraa Teaching Hospital (Kidney Center) Wasit Governorate during the period from the first of December 2018 to the end of July 2019. 50 patient of CKD (male and female, age ranged from 17-80 years, have been randomly selected from dialysis center in AL-Zahraa teaching hospital According to following inclusion criteria.

- (Blood uria > 50 mg/ dc, creatinin >1.2 mg /dc, duration of illness ranged from few months to 7 years).

- Exclusion criteria: negative medical history with normal blood uria and serum creatinin.

- physician diagnosis.

**Procedure of samples collection:**

Mouth swabs were collected by using a sterile disposable cotton swabs and rubbed over the tongue palate and buccal mucosa as outlined in appendix (1) Figure (1). Cotton swabs were aseptically dipped in sterile culture tubes containing transport medium and were transported as soon as possible to the laboratory and incubated at 37 °C for 24 hours [14].

Isolation and identification of Candida species:

After taking swaps from the suspected patients, the swap samples were cultured immediately on SDA with chloramphenicol and incubated aerobically at 35-37°C for 24-48 hours, the agar plates were examined for visible growth after the incubation period [15]. Identification of Candida was done based on the colony morphology of the isolates, and then staining with gram stain and examined under the microscope to show the morphology of Candida spp. Then use several techniques for confirmation like the The Vitek 2 system, first introduced a fluorometric and then a colorimetric card for the rapid identification of yeast species (BioMérieux, France), CHROMagar Candida medium and the molecular method Polymerase chain reaction technique (PCR) technique was performed for detection Candida albicans based on 18SrRNA.

**Statistical Analysis**

All results obtained from the present study were entered and analyzed statistically by the statistical package for social science (SPSS) version 21 for Windows Software and Microsoft Excel 2007. Chi-square test and one way Analysis of variance (ANOVA) with least significant were used for the assessment of association between the variables studied. A value of P < 0.05 was considered statistically significant.

Discussion

The present study states that the age of renal dialysis patients infected with candidiasis showed that there was no significant differences (P value > 0.05) between the 3 age groups, and the high percent were in moderate age patients (31-50 years) as shown in Table 1, this result agreed with Godoy et al., (2013) [16] when he mentioned that the more significant infected patients were over 45 years. But still no correlation due to various population samples and races. Uremia is associated with a state of immune dysfunction characterized by immunodepression that likely contributes to the high prevalence of infections among these patients as well as by immunoactivation resulting in inflammation (Kato et al., 2008)[11]. According to gender of infected patients,17 (70.8%) of them were males and 7 (29.2%) were females, as clarified in Table 2, this result disagreed with Godoy et al., (2013) [16] when he mentioned that 53% of samples were females and 47% were males, this might be counting on other factors like the number of dialysis sessions and immune states. The most common underlying diseases in renal failure patients infected with oral candidiasis were hypertension and diabetes mellitus as Godoy et al., (2013) [16] stated. but in current study there was no clear relationship between underlying diseases and *Candida* infection as clarified in Table 3. Diabetes and hypertension diseases that strongly predispose people to renal failure (Bakris et al., 2000)[17] but not necessary associated with oral Candidiasis as showed in current study. *Candida albicans* is the most dominant *Candida* spp. In Patients with renal dialysis, as clarified in Table 4, this result agreed with Kerawala et al., (2010)[18] when he mentioned that 60% of *Candida* isolate is *Candida albicans*. *C. albicans* is the most common fungal species isolated from biofilms either formed on implanted medical devices or on human tissue (Kumamoto, 2002)[19]. A mortality rate of 40% has been reported for patients with systemic candidiasis due to *C. albicans* [20].

Conclusion

*Candida albicans* is the most dominant *Candida* spp. In Patients with renal dialysis. There is not relationship between the age, gender and other disease in chronic kidney disease and the infections with oral candidiasis.

The Effect of Boiling Time on the Concentration of Nitrite in Sausages

Nurlailah¹, Dinna Rakhmina¹, Badar Ruddin², Anny Thuraidah¹
¹Lecturer, Medical Laboratory Technology Poltekkes Kemenkes Banjarmasin, Indonesia, ²Tutor, Medical Laboratory Technology Poltekkes Kemenkes Banjarmasin, Indonesia

Abstract

Background : Nitrite is often used as a preservative as well as curing to brighten foods made from raw meat such as sausages. Excessive use of nitrite can cause symptomatic methemoglobin, tumors to cancer in humans. One method that can be used to reduce nitrate levels in sausages is by boiling.

Aim : The study aimed to determine the effect of boiling time on the nitrite content of sausages.

Material and Method : This type of research is an experiment with a one group pretest-posttest design. The research material is sausages obtained from distributors, Banjarbaru. The research material treatment was carried out by boiling sausages with distilled water for 5, 10, 15, 20, and 25 minutes at 80-90°C.

Results : There was a decrease in the level of nitrite in sausage after boiling, which is consecutive at 1.44 ppm (5 min); 1.17 ppm (10 minutes); 0.98 ppm (15 minutes); 0.83 ppm (20 minutes) and 0.7 ppm (25 min). The linear regression test found that R square was 0.574 or 57.4%.

Conclusion : Meat sausage boiling process can lower nitrite levels in sausages, the longer the boiling process is increasing the amount of nitrite being eliminated from the sausage with the highest number of boiling for 25 minutes there is a decrease of 70%.

Keywords: Sausage, nitrite level, boiling time

Introduction

Meat is one source of animal protein that is needed by humans protein functions for cell growth, replacement of damaged cells, and as fuel in the human body. In addition to protein, meat has other components such as minerals, carbohydrates, and fats that cause meat easily damaged, especially by microorganisms such as fungi and bacteria. To maintain the freshness of meat-based foods such as sausages, nitrite preservatives often added by producers. The nitrite preservation mechanism is using nitrite binding to the sulphhydryl group to form salts which are challenging to metabolize by microbes in anaerobic conditions¹,².

Nitrite is one of the preservatives that is allowed to use based on Republic of Indonesia Minister of Health Regulation No. 1168/Menkes/Per/X/1999 concerning Food Additives, with a limitation of the maximum use of nitrite preservatives in processed meat products of 125 mg/Kg. Nitrite is widely used in meat because in addition to preventing microbial growth it can also function as curing or improving the color of meat. But the risk of nitrite use limits its use. Nitrite in the beef will react with oxygen to form nitroxide which will then respond with pigments in the flesh to build nitrosomyoglobin, which gives a bright color to the flesh. Furthermore, in the body of the nitrite can also bind to amino or amide in the body to form derivatives of nitrosamines, which are toxic and carcinogens³.

As the food and beverage industry develops, more food products from meat are produced, sold and consumed in forms that are more durable, attractive and more practical than fresh products such as bread, meatballs, nuggets, sausages and corned beef. There are still many food products currently circulating that do not
meet the hygiene requirements and food safety quality standards. In terms of microbiological safety, some food products are still found to be fungal contamination, Salmonella, Staphylococcus, Bacillus. In terms of chemical safety of many foods and beverages in circulation that still use food additives that not permitted for food and the use of doses that exceed the required threshold for permitted food additives such as the use of nitrite.

The case of nitrite poisoning in sausages had occurred in 2008 at Sukosewu 1 Gandusari Blitar elementary school. The students poisoned after eating sausages sold at the school. Nur’s HH reported that five sausage brands examined all positively contained nitrites and there was one brand of sausage with nitrite levels of 208.19 mg/Kg which exceeded the quality standard according to Permenkes No.1168/Menkes/Per/1999 which is equal to 125 mg/Kg.

The use of nitrite compounds in processed meat products such as sausages seems to have become a necessity of the community because nitrite compounds in meat besides acting as preservatives also provide a distinctive color of fresh red meat. However, the use of nitrites in food must remain vigilant because if consumed excessively and repeatedly it can adversely affect health either directly or indirectly, among others, can result in methemoglobinemia, teratogenic, tumors to cancer through a reaction between secondary or smear amines contained in the body.

One way that can be done to minimize nitrite content in doses is by boiling before consumption — this theory supported by the results of research conducted by Li. The results of Li’s research proved to be able to reduce nitrite levels in sausages by 19.47% after boiling for 60 minutes at 80°C. Study of the effect of boiling time on nitrite levels in sausages by spectrophotometry using the Griess method.

Methods and Materials

This type and design of the study were experiments with the study design one group pretest-posttest. The research material is unbranded sausage from processed beef, which is known to have positive nitrite content after a preliminary qualitative test was carried out using the Griess method. The research instruments consisted of UV-Vis spectrophotometer. The reagent used was Natrium nitrite, Sulfanilic acid, Naphthylenediamine, 30% Acetic acid, Glacial acetic acid, quads.

Sausages treated with five sausages each cooked with 500 ml of water with variations time of 5 minutes, 10 minutes, 15 minutes, 20 minutes, and 25 minutes at a temperature of 80-90°C. After that, the sausages are taken to check each nitrite level with four repetitions. Analysis of nitrite examination carried out qualitatively and quantitatively. A qualitative study using Griess reagent based on the formation of the color of azo substances. Quantitative analysis using spectrophotometric methods.

The sausage weighed and then it is heated as much as 5 grams in a 50 ml glass beaker, add 50 ml of hot distilled water, stirring and strain. The filtrate was taken as much as 25.0 ml and put in a 50 ml volumetric flask, diluted with distilled water until the boundary mark. Add 4.0 ml of Griess reagent. Leave it for 15 minutes, put it in the cuvette, and read the absorbance on the spectrophotometer with a wavelength of 548 nm. Nitrite levels at doses are calculated based on the line equation $Y = bX + a$. It repeated for variations time of sausage 10, 15, 20, and 25 minutes.

The making of the standard sodium nitrite curve solution is each with a concentration of 0.2; 0.6; 1.0; 1.4; 1.8 and 2.2 ug/ml into 50.0 ml volumetric flasks then advert with distilled water. Then 10.0 ml of each solution was taken, and then 2.0 ml of Gress reagent was added to each 50 ml volumetric flask and the boundary mark. The answer was left operating time for 30 minutes then read the absorbance value using a UV-Vis spectrophotometer at a maximum wavelength of 548 nm. The absorbance result data is made a standard curve so that the line equation $Y = bX + a$ obtained. This line equation is used to determine sodium nitrite levels in sausages. 2). Determination of nitrite levels in doses, namely as much as 5 grams of mashed sample put into a glass beaker plus 50 ml of distillate water temperature 80oC, strain. The 25.0 ml filtrate was put into a 50.0 ml volumetric flask and then diluted with distilled water to the boundary mark, plus 4.0 ml Griess reagent, homogenized, the solution left for 30 minutes and measured the absorbance by a spectrophotometer at a wavelength of 548 nm.

Result and Discussion

Data on the results of the examination of nitrite levels in sausages that have boiled for 5, 10, 15, 20, and 25 minutes with four repetitions can be seen in table 1 and figure 1.

Based on Figure 1, it is known that the longer the sausage boiled, the less the amount or level of nitrate in sausages. This result is somewhat different from the research conducted by Li6 on sausages, namely the reduction of nitrite in sausages only by 19.47% after boiling for 60 minutes at 80°C.

The difference in nitrite levels in each treatment in this study caused by the difference in the length of sausage boiling. The longer the boiling time, the more nitrite is eliminated from the sausage. The highest percentage of nitrite reduction in sausages occurred at 25 minutes of boiling time, which is 70% and the lowest in sausages with a boiling time of 5 minutes, which is equal to 40%.

This study using the Griess method spectrophotometer. The principle is the Griess method based on the diazotization reaction, which is between the nitrite ion in the sample and sulfanyl acid in an acidic atmosphere to form benzene diazonium ions. Furthermore, benzene diazonium ions coupled with N-1-Naphthylen-diammonium dihydrochloride (NEDA) which will create a purple-red azo compound which can be measured absorbance at the maximum wavelength obtained in this study is 548 nm\textsuperscript{13,14}.

![Figure 1. Nitrit level reduction in sausages after boiling with different temperature variations](image-url)
the use of excess nitrite is carcinogenic and mutagenic because nitrite in the body can bind to secondary and tertiary amines to form derivatives of nitrosamines, especially at low pH and salt levels. Carcinogenic and mutagenic properties of nitrosamines are thought to be the cause of necrosis, which is the death of some cell tissues of living creatures as an early stage of cancer attack. One of the advantages of nitrosamines is its capacity to cause tumors in several organs, including liver, kidney, stomach, bladder, esophagus, and SSP[10]. Other than that, nitrite can also bind to Fe (II) contained in blood hemoglobin, which then forms methemoglobin which cannot carry oxygen, which can cause the body to experience oxygen deficiency. If this is allowed to continue, it can have fatal consequences primarily if it occurs in infants and pregnant women with symptoms of pallor, cyanosis, vomiting, shortness of breath to shock.

Taking into account the negative effects of nitrites in processed meat foods such as sausages, several ways can be done to reduce nitrite content before consumption, one of which is to boil sausages using water for a certain amount of time before consumption. In this study, boiling sausages for 5-25 minutes with a temperature of 80-90OC was shown to show different variations in nitrite reduction according to the length of boiling (see table 1). In another journal, it also reported that the use of nitrite in sausages eliminate by adding various combinations of ingredients such as celery, carrots, broccoli and ingredients that contain vitamins C and E during boiling sausages. In addition to boiling methods, the use of several types of natural dyes can also be an alternative as a red coloring in meat without causing health problems, such as angkak, bits (Beta vulgaris), the skin of red dragon fruit. Cochineal 0.015% can also be used as a substitute for nitrite in meat because it can develop the color of meat and is quite stable to light and pH. Some spice plant extracts such as cloves, lemons, licoric are also known to have antibotulinin activity in processed meat. Celery powder with a concentration of 10% can protect sausages from deterioration during storage as a substitute for nitrite. With several alternatives that can be used to replace nitrite as curing as a preservative in sausage meat it is hoped that food producers who still use nitrite could replace it with natural, safer and friendlier materials for the body.

Measurement of sample levels in this study using the calibration curve method, namely the standard curve of the standard solution of sodium nitrite. The purpose of making this standard curve is to get more accurate results because it uses more than one concentration of different standard solutions, which commonly referred to as standard series solutions. In this study using 6 standard series solutions each 0.2; 0.5; 1.0; 1.4; 1.8; and 2.2 ug / mL or (ppm). Based on the results of measurements of the absorbance of standard solutions obtained by absorbance in a row 0.125; 0.186; 0.217; 0.312; 0.384 and 0.481. From the results of the calibration curve, the linear regression equation \( y = 0.1763x + 0.0725 \) with \( R^2 \) is 0.9788. Furthermore, this line equation is used to determine the nitrite level in the sausage sample by entering the absorbance of the measured sample. The results of the calculation of nitrite levels in sausages that have undergone boiling with various variations of boiling time can see in table 1.

To find out whether there is an influence of the old boiling variable (independent variable) on nitrite levels (dependent variable) on sausages and how much influence the regression test linear. Previously, a regression test conducted before the normality test was carried out on the data to find out whether the data were normally distributed or not. From the test results, it knew that the significant value is higher than \( \alpha \) (0.05) so that the data usually distributed. Furthermore, the ANOVA test was carried out to find out the differences between the data groups and obtained a significant value of 0,000 which means that it was higher than \( \alpha \) (0.05) so that there were significant differences between the data groups. Based on the linear regression test, the R Square value is 0.574 or 57.4% so that it can say that the length of sausage boiling has an effect of 57.4% on nitrite levels in doses.

**Conclusion**

Based on the results of the study it can be concluded that the boiling process of meat sausages can reduce nitrite levels in sausages, the longer the boiling process increases the amount of nitrite eliminated from sausages with the highest number of boiling for 25 minutes a decrease of 70%.

Platelet Counts Analysis of Platelet-Poor Plasma (PPP) Produced by Several Centrifugation Techniques

Pande Putu Rangga Raditya¹, Yetti Hernaningsih²
¹Student, ²Lecturer, Department of Clinical Pathology, Faculty of Medicine-Universitas Airlangga, Dr. Soetomo Hospital General Academic Hospital, Surabaya, Indonesia

Abstract
Platelet-poor plasma (PPP) can be obtained by various centrifugation techniques. This study aims to analyze platelet count in PPP produced by three different centrifugation techniques. Samples came from a healthy adult who underwent medical check-up and had been given informed consent. A total of 2.7 mL of blood samples were collected using three citrated tubes. Samples were centrifuged by three different techniques to obtain PPP: 1,500 g for 15 minutes twice, 3,000 g for 15 minutes, and 3,260 g for 10 minutes. The platelet count of each PPP was examined using a hematology analyzer. All three centrifugation techniques produced <10,000/µL platelets in all PPP from 31 samples. The twice centrifugation of 1,500 g for 15 minutes produced a median number of platelets which was $1 \times 10^3$/µL (0-3). The 3,000 g centrifugation for 15 minutes produced a median number of platelets which was $1 \times 10^3$/µL (0-5). The 3,260 g centrifugation for 10 minutes produced a median number of platelets which was $2 \times 10^3$/µL (0-5). A comparison of platelet count showed a significant difference ($p<0.05$) among the three centrifugation techniques. The three centrifugation techniques in this study were able to produce PPP. The centrifugation technique of 1,500 g for 15 minutes twice produced the lowest number of platelets.

Keywords: centrifugation, platelet-poor plasma, platelet count

Introduction
Clinical laboratory testing plays an essential part in the detection, diagnosis, and treatment of diseases. Laboratory results contribute around 60-70% in determining the decision for patients to undergo hospitalization and receive treatments[1]. Effective and efficient laboratory services are characterized by three factors: precision, accuracy, and timeliness which is assessed by turnaround time (TAT)[2,3]. TAT is often used by clinicians as a performance guide or key performance indicator in laboratory services. It was reported that the preanalytic phase contributes around 75% of the total TAT[2].

In addition, one of the pre-analytical processes commonly done is the centrifugation process. Centrifugation is the separation process of solid particles and their solvents. This process is often used in laboratories to separate blood cells from their plasmas to produce PPP. PPP is a plasma with a platelet count of less than 10,000/µL used for coagulation study[4,5].

The preparation of PPP recommended by the Clinical and Laboratory Standart Institute (CLSI) is to use a tube with sodium citrate anticoagulant and centrifugation processes at a speed of 1,500 g for at least 15 minutes[5]. Different results were obtained in a study conducted by Kristoffersen which stated that the number of platelets after a single 1,500 g centrifugation results in a platelet count <22,000/µL[6]. Magnette et al. recommend a repeat of centrifugation to ensure platelet residue is less than 10,000/µL. The remaining platelet in plasma has been known to affect phospholipid-dependent coagulation tests such as those on Lupus Anticoagulant (LA)[7]. This repeating centrifugation process must be prepared for all coagulation parameters if there is a possibility that the measurement is not carried out immediately after centrifugation, or if the sample will be frozen[6-10].
A study conducted by Sicard showed that the amount of platelet residue in PPP produced at a speed of 3,260 g in 10 minutes was \(<10,000/\mu L^{[1]}\). PPP preparation in Dr. Soetomo Hospital used 3,000 g centrifugation for 15 minutes. There has been no prior research that confirmed this technique will produce less than 10,000/\mu L platelet residues. This centrifugation technique requires a long time in the preanalytic stage. An updated technique is needed to speed up this process without reducing the quality of the coagulation\[^{[4]}\].

This study aimed to examine the differences in the number of platelets in PPP produced in the 1,500 g centrifugation technique for 15 minutes twice, 3,000 g for 15 minutes, and 3,260 g for 10 minutes. The results that are accurate, fast, and precise are hopeful to help improve the laboratory services quality in Dr. Soetomo Hospital.

**Materials and Method**

The study was an analytic study with a cross-sectional design. The sample was obtained by conducting consecutive sampling during April-May 2019. The inclusion criteria in this study were healthy adult patients aged >21 years who underwent a medical check-up, were in good health and were willing to take part in the study. The exclusion criteria in this study were the history of drug consumption in the last 10 days that interfere with platelet function.

Becton-Dickinson Vacutainer tubes (Rutherford, New Jersey, United States of America) with sodium citrate anticoagulant were used in this study. The concentration of sodium citrate used was 0.109 M (3.2%). Venous blood samples were taken and put in 3 tubes of 2.7 cc each with a ratio of 9:1. Slow inversion 3-6 times was done to make blood and anticoagulants homogeneous. Then, the samples were centrifuged with Sorvall ST 8R (Thermo Scientific small benchtop centrifuges) at 24 °C that was calibrated with a tachometer twice a year. Three samples were centrifuged with three different speeds and times: 1,500 g for 15 minutes twice (Technique 1), 3,000 g for 15 minutes (Technique 2), and 3,260 g for 10 minutes (Technique 3). After the initial centrifugation, plasma in technique 1 was carefully transferred to an inactive plastic centrifugation tube using an automatic pipette, and then centrifuged again for about 15 minutes. Centrifugation in technique 2 and technique 3 was only done once. The plasma was carefully transferred to the aliquot with a pipette, leaving 1 cm to remain above the buffy coat. This was done to avoid the removal of the remaining platelet in the area around the buffy coat. The plasma of each sample was assessed by platelet count using a Sysmex XN 1000 hematology analyzer.

Statistical analysis was done using SPSS version 17.0. The collected data was carried out by cleaning, coding, tabulating, and entry into the computer. The median was also calculated. A paired T-test was done for data with a normal distribution. For data that were not normally distributed, a Wilcoxon test was performed. \(p\)-value \(<0.05\) was considered statistically significant.

**Results**

Participants who were willing to take part in this study were 31 people who came from Medical Check-Up (MCU). Samples consisted of 12 men and 19 women. All the 31 samples from the three centrifugation techniques have platelet count below 10,000/\mu L. The centrifugation technique of 1,500 g for 15 minutes twice produced a median number of PC which was \(1\times10^3/\mu L\ (0-3)\). The centrifugation technique of 3,000 g for 15 minutes obtained a median number of PC which was \(1\times10^3/\mu L\ (0-5)\). The centrifugation technique of 3,260 g for 10 minutes resulted in a median number of PC which was \(2\times10^3/\mu L\ (0-5)\) (Table 1).

Comparison analysis of the platelet count between groups of centrifugation techniques showed a significant difference between Technique 1 and Technique 2 (\(p = 0.004\)). Comparison analysis of platelet count from Technique 1 and Technique 3 showed a significant difference (\(p = 0.0005\)). Comparison analysis of platelet count from Technique 2 and Technique 3 also showed a significant difference (\(p = 0.004\)) (Table 2).

Discussion

The centrifugation parameters for removing platelets depend on the duration, speed, and radius of the centrifuge arm. The speed and radius of the centrifuge arm determine the “g” value. Each centrifuge produces different values of g and varies the time of centrifugation to obtain the desired PPP[10,12,13].

However, CLSI recommends that tubes with anticoagulants should be centrifuged at a speed of 1,500 g no less than 15 minutes to obtain PPP[5]. A study conducted by Favaloro et al. suggested that using a centrifugal force relatively greater than 1,500 g was not recommended because it could cause platelet activation, hemolysis, or other undesirable effects[14]. Higher speed (greater than 1,500 g) and shorter time (less than 10 minutes) in an emergency could be used to prepare PPP for coagulation examination[4,7]. Several studies that evaluated the impact of higher speed centrifugation on platelet count concluded that fast centrifugation did not change results and contributions by reducing preanalytic duration[4,11,15].

This study compared the platelet count in the 1,500 g centrifugation technique for 15 minutes twice, 3,000 g for 15 minutes, and 3,260 g for 10 minutes to obtain PPP. The Sorvall ST 8R centrifuge uses a swinging bucket rotor for high-speed horizontal processing. This centrifuge accommodates a maximum speed of up to 3,260 g (4,500 rpm)[12]. A study conducted by Magnette et al. demonstrated that a centrifuge with a swinging bucket rotor is easier to separate plasma from cellular components and minimize re-mixing of plasma with red blood cells[7].

Samples with hemolysis cannot be processed because clotting factor activation can occur and interfere with the clot detection by optical devices that use the principle of changing plasma turbidity[16-18]. Those samples will also cause spectral interference in devices using photometric methods. It can affect the examination of the coagulation study[19]. Fortunately, there were no samples with hemolysis in this study. Plasma from each sample was taken to assess the platelet count with a Sysmex XN 1000 hematology analyzer.

The lowest platelet count (<3×10³/µL) was obtained from the 1,500 g centrifugation technique for 15 minutes twice. This result was similar to a previous study conducted by Kristoffersen and Sicard which showed that the number of platelets of PPP produced by doing 1,500 g of centrifugation for 15 minutes twice and 3,260 g of centrifugation in 10 minutes was <10,000/µL[6,11]. This study was the first study to examine the centrifugation of 3,000 g for 15 minutes.

A comparison of platelet count among centrifugation techniques showed significant differences (p<0.05). These results differ from a study conducted by Sultan in 2010 which showed no significant differences between the PPP platelet count produced at 2,000 g centrifugation for 20 minutes and 3,000 g centrifugation for 5 minutes. This difference result is possibly due to the differences in the tools used and research procedures. Research conducted by Sultan used a Centurion-K40 centrifuge model with a fixed angle rotor[15].

In addition, Sultan showed no significant difference in the PT and APTT examination between PPP produced by 2,000 g centrifugation for 20 minutes and 3,000 g
centrifugation for 5 minutes\textsuperscript{15}. The limitation of this study was no evaluation of the high acceleration impact of centrifugation conditions on routine coagulation study (including PT, APTT, and fibrinogen) in each PPP resulted from each centrifugation techniques.

**Conclusion**

In sum, the three centrifuge techniques in this study were able to produce PPP because platelet count obtained was less than 10,000/μL. The resulting PPP was compliant with the CLSI standard despite the statistically significant differences in platelet count among the three different centrifugation techniques. The twice 1,500 g centrifugation for 15 minutes each was the technique that produced the lowest number of platelets. The difference in results obtained from this study was due to the different types and techniques of the tools used.

Abstract

Background. The study of Feeding Style of children in ethnic Buginese was focused on caregiver styles to feeding practices that influences nutritional stunting. The purpose of this study was to determine feeding style of Bugis ethnicity. Method. The cross sectional study and the sample size is 300 subjects, selected by random sampling. Located in in Makassar City, South Sulawesi Province Indonesia (starting January-December 2019). Enumerators in this study were students of the Applied Nutrition & Dietetic in Nutrition Department of the Health Polytechnic Makassar. Research ethics was obtained at the Makassar Health Polytechnic Ethics Commission. The results showed that stunting prevalence for children in Bugineses ethnicity was 22.7% and Feeding Style consists of four groups namely caring (indulgent), compromise (authoritative), free (uninvolved) and completely regulating (authoritarian). The conclusion is that the style of Bugis ethnic child feeding style consists of four groups namely indulgent, authoritative, uninvolved, and authoritarian.

Key words: Buginese, Feeding Style, Children.

Introduction

Stunting prevalence data collected by the World Health Organization (WHO), Indonesia is included in the third country with the highest prevalence in the Southeast Asia/South-East Asia Regional (SEAR) region. The average prevalence of stunting toddlers in Indonesia in 2005-2017 was 36.4%. The determinant factor of nutritional problems is multidimensional¹². The five factors are based on the conceptual framework of the causes of household and family factors include the low quality of nutritional intake during pre-conception, pregnancy and the breastfeeding phase. Besides, the nutritional status of the mother during pregnancy determines the height status of the child being born³⁴⁵.

Inadequate complementary feeding and breastfeeding are real phenomenon in urban communities in Makassar. Factors are the lack of knowledge about complementary feeding, and the occupation status of mothers outside the home so that they lack of attention to giving feeding their children⁶⁷. Feeding style lead to quality and quantity of micro and macronutrient intake for children. Feeding style depends on the family resources and type care givers by the gate keepers⁸. Ethnic Buginese is a very strong ethnic character in the economic field and the ability to survive anywhere, but others thins remains to height stunting prevalence across region their lives⁹¹⁰¹¹¹². Objectives of these studi to investigate nutritional stunting and feeding style for children in Bugineses ethnicity.

Research Method

The subjects of this study were obtained from Bugis Ethnic who live in Makassar Indonesia. The population is all mothers who have children aged 6-59 months in Makassar City. Criteria for inclusion of Buginese ethnic samples in Makassar City. (1) The mother is from the ethnic Bugis and the husband is also from the ethnic Bugis (2) Having children aged 6-59 Months in September 2019 ; Have lived for at least the past 6 months in Makassar City, willing to participate in this
research, mother comes from ethnic Bugis descent and husband is also Bugis descent. The sample size in this study is based on the estimated prevalence of stunting in Makassar City as a Bugis ethnic center that is 35.7%, using 80% power test with 95% confidence, design effects 1 and 5 with the addition of 10% additional data estimated not to participate in research this is because they refuse or are not present at the time of screening.

The questionnaire was tested using structured questions using official data on children aged 0-59 (age, gender, weight and height/length; parental occupation, education level and feeding style). Child’s weight is measured using electronic SECA scale with an accuracy of 0.1 kg and a length of the child (for children aged 0-23 months) or height (for children aged 24-59 months) was measured using high board/long local made with an accuracy of 0, 1 cm. SECA scales are calibrated every morning, before data collection, using a standard weight of 5 kg. Duplicate anthropometric measurements were carried out for 10% of the sample; the coefficient of variation in subjects from duplicate measurements in children and women is less than 5%. All enumerators receive training at least two days before data collection, and those responsible for taking anthropometric measurements receive one additional training day. Supervisors are tasked with supervising the work of enumerators and facilitating good relations with community members. Stunting is defined as Z-score for height Z-scores for age <−2 SD.

Statistical analyses used to exploratory factor of feeding style instrument by Kaiser Meyer-Olkin (KMO) Measures of Sampling Adequacy and Bartletts’s Test of Spericity.

Based on the results of this study it is known that the percentage of stunted children in the Bugis ethnic group in Makassar City is 22.7%.

Style of Child Feeding Ethnic Bugis

The style of child feeding of ethnic Bugis in this study was originally designed in 18 question items. Based on all of these items later, a confirmation analysis of the indicators was carried out and the results left 16 realiable question items. The factor analysis is carried out to group the parenting style variables into the parenting style groups according to the Buginese ethical practice. Based on the results of the factor analysis, then four groups of parenting styles on child feeding of Bugineses ethnicity. In accordance with the terms in the previous study of parenting style, there are four types, namely (1) indulge (2) Authoritative (3) Uninvolved and ( 4 ) Authoritarian. Variable style parenting based on the four types above are as follows:

Parenting style indulgence has the characteristic features as follows (1) giving opportunities for children to choose which foods he will eat (2) Not specify how many snacks should be eaten children (3) giving opportunities for children to try foods that have not been he has ever felt (4) Letting the child do anything in his food when he eats (5) If the child, is bored with certain foods, offers other foods (6) the child’s food is the same type of side dish as family food and (7) The family has eating habits, mealtime. Authoritative parenting style has several main characteristics namely ; (1) Encourage the child to eat food (2) If the child has wrong eating habits, then forbid it (3) Encourage the child to enjoy his food.

Uninvolved parenting style has characteristics (1) Providing interesting food for children, (2) If the child is sad, he entertains with food (3) Provides something to the child, if he has good eating habits. The authoritarian parenting style is characterized by feeding the child after the father eats.

Discussion

The prevalence of stunting children in Buginese ethnicity is 22.7%, where this percentage is still above the threshold set by WHO as a threshold for health problems with a prevalence of <20%. Based on these parameters, it can be proven that the ethnic Bugis made a significant contribution to the percentage of stunting in South Sulawesi in 2018. South Sulawesi Province ranks fourth in the highest percentage of stunting in Indonesia. Various factors were analyzed in this study by the conceptual framework published by Unicef in 2006.13,14 Based on the concept map of the occurrence of stunting compiled by Unicef 2006 consists of several factors that affect stunting, namely household and family factors, child factors and complementary foods for breastfeeding, breastfeeding factors, hygiene sanitation factors, infectious disease factors, health-seeking behavior, parenting feeding style or style of care for child feeding, and caring practices or stimulation of child development. All of these variables are included in the scheme of the conceptual framework of determinants of global stunting factors15,16 In this study, an analysis of risk factors is by the empirical evidence in the city of Makassar, especially in the ethnic Bugis.

Household and family factors in this study were tested with child stunting status and it is known that the mother’s age, father’s age, mother’s education, and father’s education did not have a significant effect on stunting of children under five. The number of family members and the number of children under five in one household as an economic burden variable also does not consistently affect stunting. In this study, several variables cannot be proven except for the work status of parents. Permanent employment with wages that can meet food and clothing needs is a protective factor while other jobs are a risk factor. This proves that the father’s work status has a very strong influence on the incidence of child stunting.

Factors child and complementary feeding breast milk in this study were tested against the risk of stunting and discovered some facts that status pre-lacteal feeding...
did not affect stunting, as well as several other variables; child food forms, frequency of eating, who makes food for children, who feeds children. All of these variables do not differentiate a child’s height status. The only variable that is very influential today is the child’s appetite as a protective factor.

Feeding Style is one of the variables that have a risk of stunting. This study has grouped ethnic Bugis childcare styles into four categories. This category is based on the same study in Turkey on Feeding Style by Sibel Oztruk, 2018\(^ {17}\). The study in Turkey took the location of the Turkic ethnic group with 19 items that had been tested for validity and reliability. The condition of Indonesia, especially the buginese ethnicity, is culturally different from Turkey, so this study carried out modifications and adjustments to the context of Indonesian culture in general and specifically the Bugis culture. Parenting style indulgence has the characteristic features as follows: (1) giving opportunities for children to choose which foods he will eat (2) Not specify how many snacks should be eaten children (3) giving opportunities for children to try foods that have not been he has ever felt (4) Letting the child do anything in his food when he eats (5) If the child, is bored with certain foods, offers other foods (6) the child’s food is the same type of side dish as family food and (7) The family has eating habits, mealtime\(^ {18,19}\).

**Authoritative** parenting style has several main characteristics namely ; (1) Encourage the child to eat food (2) If the child has wrong eating habits, then forbid it (3) Encourage the child to enjoy his food (4) avoid himself or process his child’s food Parenting style uninvolved own traits - traits (1) M giving eat interesting for children, (2) If the child was sad, he entertained with food (3) giving something to the child if he has good eating habits. The **authoritarian** parenting style is characterized by feeding the child after the father eats\(^ {20,21}\).

Caring practice or social psycho stimulation in this study, shows the maximum parameters ranging from play opportunities, time together with children, play equipment, gross motor exercises, and fine motor skills. This fact proves that the exposure to social psycho stimulation in children is homogeneous in all subjects so that its effects on population stunting cannot be known. This study found no strong evidence that caring practice is a risk factor for stunting\(^ {22,23,24,25}\).

**Conclusion**

The percentage of stunted children with ethnic Bugis as much as 22.7%. The way of feeding Buginese ethnic children is consisting of four groups namely caring (indulgent), compromise (authoritative), free (uninvolved) and completely regulating (authoritarian).

**Conflict-of-Interest Statement:** Between subjects and researchers there is no conflict of interest.

Abstract

This study was aimed to investigate the ability of gamma-mangostin to reduce plasma blood urea nitrogen (BUN) and creatinine and ameliorates the impaired renal proximal tubular cells in diabetic mice. Antioxidant assay was conducted by using male BALB/c mice. Mice were divided into two groups, they were normal control (KN) and streptozotocin-induced diabetic mice. Streptozotocin (STZ) induction was performed using multiple low-dose of 30 mg/kg body weight injected for five consecutive days. Diabetic mice have divided into three subgroups; diabetic control (KD), diabetic mice treated with acarbose (KA), and diabetic mice treated with gamma-mangostin. The gamma-mangostin treatment group was categorized based on the dose given; P1 (1 mg/kg BW), P2 (2 mg/kg BW), and P3 (4 mg/kg BW). Interestingly, gamma-mangostin administration was found to be able to lower plasma BUN and creatinine and ameliorate the impaired renal proximal tubular cells in diabetic mice significantly. Therefore, gamma-mangostin has demonstrated high antioxidant activity. The proof suggests that gamma-mangostin is a lead compound candidate for clinical management or prevent diabetes mellitus.

Keywords: antioxidant activity, diabetes mellitus, gamma-mangostin.

Introduction

Diabetes mellitus (DM) is a multifactorial disease characterized by a chronic hyperglycemia syndrome and an impaired metabolism of carbohydrates, fats, and proteins caused by insulin secretion insufficiency and endogenous insulin activity. Insulin insufficiency can occur due to a body’s cells irresponsiveness to insulin caused by the impaired insulin production in Langerhans beta cells of the pancreatic gland[¹,²]. Indonesia is currently the sixth biggest DM patients in the world, which is 5.8% of its population or around 10 million people. The number of DM patients at the national and international levels from year to year continues to increase[³]. Type-2 DM is the most common type of DM in Indonesia. Type-2 DM is caused by a decrease in the insulin sensitivity or an increase in the insulin resistance[², ⁴].

Hyperglycemia is a condition of the increasing blood glucose levels above normal due to insulin deficiency, damage of beta cells, and the presence of insulin resistance in the liver and muscles. Chronic hyperglycemia in DM has an important role in various organs damages including the heart, eyes, bones, kidneys, liver, nerves, and vascular system, which can cause complications in the body system. Complications
of DM are associated with non-enzymatic glycation reactions in the hyperglycemia called glycosylation. Glycosylation is a reaction that occurs between protein and glucose at high concentrations, this reaction is also called the Maillard reaction. Maillard reactions form an advanced glycation end products (AGEs) and advanced oxidation protein products (AOPP) which show an oxidative stress that disrupts the balance of oxidants and antioxidants in the body resulting in an increase in free radicals\[5,6,7\].

Antioxidants are substances that inhibit the negative effects of free radicals by giving the electrons so that the damage of lipids, cell membranes, blood vessels, DNA, and others caused by the reactive compounds such as ROS could be prevented\[8\]. To reduce the adverse effects of these free radicals, exogenous antioxidants are needed, such as vitamin E, vitamin C, and other antioxidants obtained from consuming various types of fruits and vegetables that contain high antioxidants. One of them is gamma-mangostin\[1\]. The gamma-mangostin compound is a pigment from \textit{Garcinia mangostana} which is able to donate hydrogen atoms and stabilize free radicals in resonance. In addition to neutralizing free radicals, these antioxidants are expected to reduce the oxidative stress, especially in various affected cells due to the prolonged hyperglycemic conditions, such as hepatocytes and renal proximal tubular cells\[4,6,7,8\]. Thus, this study was designed to answer the problem of whether the administration of gamma-mangostin can reduce BUN levels and blood plasma creatinine as well as repair the renal proximal tubular cells damage in diabetic mice.

**Materials and Method**

This experimental study was conducted at the Animal Laboratory and Animal Histology Laboratory, Faculty of Science and Technology, Universitas Airlangga and also at the Institute of Tropical Diseases (ITD), Universitas Airlangga. The used sample was adult male mice, strain BALB/C, 3-4 months old, weight ranged from 25-40 g. The study materials consisted of gamma-mangostin (purchased from Sigma). Other materials consisted of streptozotocin (purchased from Sigma), buffer citrate solution pH 4.5, and phosphate-buffered saline (PBS), solvent extract of carboxymethylcellulose (CMC), standard antidiabetic drug (Acarbose, 100 mg/kg body weight), ketamine hydrochloride/xyazine hydrochloride (purchased from Sigma), and D-glucose (purchased from Sigma)\[7\].

The study samples consisted of 24 male mice, distributed to the normal control group (KN) and the diabetic group which was induced by STZ. The grouping of experimental animals was performed as follows; non-diabetic mice were used as normal control group (KN), diabetic mice which were induced by STZ were divided into two control groups; they were diabetic control group (KD), diabetic control group which were given Acarbose of dose 100 mg/kg body weight (KA), and, the last one was gamma-mangostin treatment group. Furthermore, the gamma-mangostin treatment group was divided into 3 subgroups in which the treatment group 1 (P1) was given 1 mg/kg body weight gamma-mangostin, group 2 (P2) was given 2 mg/kg body weight gamma-mangostin, and group 3 (P3) given was 4 mg/kg body weight gamma-mangostin. Each group consisted of 4 mice and those treatments were administered for 14 days\[7\].

Blood glucose of diabetic mice was measured on 1st, 7th, and 14th day after gamma-mangostin treatment to make sure the mice were successfully in the hyperglycemic condition. On the 15th day, blood was taken from the intracardial and the measurement of BUN and blood plasma creatinine were done using Pentra C200 (Horiba Medical) in 510 nm wavelength. The damage on the kidney structure was determined from the histological sections stained with hematoxylin-eosin (HE). Furthermore, data with normal distribution and homogenous variation was analyzed using one-way variance analysis continued by Duncan test. Data with normal distribution and non-homogenous variation was analyzed using Brown Forsythe test continued with a t-test. All statistical test was conducted at $\alpha = 0.05$.

**Results**

The mean of mice’s blood glucose level before and after the STZ induction are presented in Figure 1. The data of BUN and creatinine level is presented in Figure 2. The mean data of swollen cells and necrotic cells in renal proximal tubules is shown in Figure 3. Photomicrographs of renal proximal tubular cells are presented in Figure 4.
Figure 1. Fasting blood glucose (mg/dL) before and after STZ induction. The different letter indicated a significant difference.

Figure 2. BUN and creatinine level changes in each mice group after treatments. The different letters indicated a significant difference.

Figure 3. The renal proximal tubular cells damage of each mice groups after treatments. The different
letters indicated a significant difference.

Figure 4. Histological structure of renal proximal tubular cells of mice after gamma-mangostin treatment.

N = normal cell, CS = swollen cell, Ne = necrotic cell. Bar: 100 µm.

Discussion

A condition of hyperglycemia in patients with DM causes a glucose autoxidation, resulting in the activation of protein kinase C, protein glycation, and the activation of the polyol metabolic pathway which further accelerates the formation of ROS or the oxidative stress conditions. The presence of ROS causes free radicals in the body to increase. Free radicals can damage the structure and function of various body tissues, one of them is the kidney tissue[9,10]. In patients with DM, the condition of hyperglycemia causes an increase in the production of ROS and RNS due to the increased oxidation of NADPH on endothelial tissue. ROS and RNS are highly reactive molecules that can directly oxidize and damage DNA, proteins, lipids, and cause an oxidative stress. An oxidative stress occurs when there is an imbalance between the number of highly reactive molecules (ROS and RNS) and the existing antioxidants[4, 6].

STZ is a free radical that can increase ROS and RNS, very reactive, especially for hepatocytes and renal tubule cells. In the group of mice induced by STZ, it showed an increase in BUN levels and plasma creatinine in the diabetic control group (KD). KD was significantly different from the normal control group (KN), KM, P1, P2 or P3. This is because the diabetic condition triggers the formation of ROS through the glucose autoxidation pathway, the formation of advanced glycation end products (AGEs), and the polyol pathway mechanism. ROS can trigger lipid peroxidation in the cell membranes and cause damage to these cells. Free radicals can cause lipid peroxidation, which can damage the structure of cell membranes, and damage to the structure and function of renal proximal tubular cells which is characterized by the increased BUN and plasma creatinine levels in the diabetic control group compared to the KN, KM, P1, P2, and P3. The data analysis on BUN and creatinine levels showed that the average BUN in the diabetic group was significantly different compared to KN, KM, P1, P2, and P3. This indicated that the injection of multiple low-dose STZ was able to significantly increase the plasma BUN levels and creatinine plasma levels. The plasma creatinine levels of diabetic group also showed the significant differences compared to KN, KM, P1, P2, and P3.

The kidneys are organs that play a role in regulating the body’s balance, maintaining body fluids, and regulating the disposal of metabolic waste and toxic substances such as urea, uric acid, ammonia, creatinine, inorganic salts, as well as the drugs that are not needed by the body[8]. BUN and creatinine are urea protein and creatine metabolites which are excreted through glomerular filtration and are actively secreted by the proximal renal tubules[11]. A damage to the kidney’s proximal tubular cells of the kidney is an indicator of disease progression. BUN and creatinine excretion
are the results of two physiological processes, namely glomerular filtration and proximal renal tubular secretion. If there is a disruption in BUN and creatinine secretion by the proximal renal tubules, then BUN and plasma creatinine levels will increase[12].

Creatinine excretion in the kidneys is relatively constant and is not affected by outside factors. Creatinine is an effective indicator of kidney damage because creatinine levels in the blood are more stable[8]. The increased creatinine levels in the blood can be caused by kidney damage mainly due to glomerular filtration disorders, acute tubular necrosis, glomerulonephritis or the damage to glomeruli and tubular apoptosis[13,14]. Normal plasma creatinine levels in mice (Mus musculus) are 0.2 to 0.9 mg/dL[8]. The results of research conducted by Husen et al.[15] showed that diabetic mice that had been injected with STZ experiencing an increase in the serum creatinine levels compared to the normal group. This is due to the result of kidney’s histology structural damage that occurs in the diabetic mice which causes the kidney’s work in eliminating creatinine is disrupted.

STZ is capable of generating a reactive oxygen which has an important role in cell damage[16,17]. ROS and RNS can interfere the physiological function of a tissue and then cause a kidney damage[6,8]. Lee et al.[18] stated that an increase in ROS and proinflammatory cytokines play an important role in the damage of glomeruli, tubules and blood vessels. The results of research from Zafar et al.[19] stated that diabetic Rattus norvegicus mice were injected with single dose STZ at a dose of 45 mg/kg of body weight can cause tubular necrosis, glomerulosclerosis, tubular atrophy, and thickening of the glomerular membrane. Other studies conducted by Hou et al.[20] found that an increase in BUN and creatinine levels in the diabetic group indicates the damage to kidneys. The biochemical parameters correlate with the renal histology studies. STZ causes a significant damage of kidney histological structure, including glomerulus and tubules. Thus, STZ injection is able to interfere in the structure and function of renal tubular epithelial cells.

The kidneys are not dependent on insulin for glucose absorption, so an increase in blood glucose levels in a diabetic condition will produce a high glucose at the intracellular level and could cause a severe and sustained hyperglycemia. Increasing the amount of glucose filtered by the glomeruli under hyperglycemia conditions will increase the workload of renal proximal tubular cells. In addition, the proximal tubular cells cannot reduce the glucose transport levels to prevent excess intracellular glucose in hyperglycemia. Excessive glucose uptake to the proximal tubule can inhibit the reabsorption and secretion in proximal tubular, thus, the creatinine levels increase[21]. Mohora et al.[5] states that hyperglycemia conditions can cause glucose metabolism disorders, as well as the direct reactions to other molecules in the cell which lead to the high formation of body’s oxidants. This condition heads to an oxidative stress, which is a condition where there is an increase in the production of oxidants in the body, while the endogenous antioxidants which play a role in neutralizing the oxidant’s performance are disrupted. This is supported by Winiarska et al.[22] which states that hyperglycemia is associated with the increased ROS production and oxidative stress condition which perform a key role in the pathogenesis of this disorder. In addition, study conducted by Li et al.[23] stated that PKC activation can induce the renal tubular epithelial cell damage.

Conclusion

Interestingly, gamma-mangostin administration was found to be able to lower plasma BUN and creatinine and ameliorate the impaired renal proximal tubular cells in diabetic mice significantly. Therefore, gamma-mangostin has demonstrated high antioxidant activity. The proof suggests that gamma-mangostin is a lead compound candidate for clinical management or prevent DM.

Abstract

Background. Breast milk and complementary foods are very influential variables in the nutritional status of children. The purpose of this study was to determine the risk factors for stunting in the Bugis ethnic group in Makassar based on breastfeeding factors, complementary foods for breast milk

Method. There is a cross-sectional study in this study. The sample size in this research was 300 subjects in Makassar City. Enumerators in this study were students of the Applied Nutrition & Dietetic Bachelor Program in the Nutrition Department of the Health Polytechnic Makassar, Indonesia, and the Nutrition Department Students at Science University Management. Research ethics was obtained at the Makassar Health Polytechnic Ethics Commission. Stunting risk factor data analysis with logistic regression test. Reliability and validity analysis of Bugis ethnic feeding style care with explanatory factor analysis, and Content Validity. Confirmatory factor analysis with Bartlett’s and The KMO Coefficient.

The results of the study note that the risk factor for stunting is a child factor that is good appetite being a protective variable with a significance value of \( p = 0.000 \), OR 0.289 (0.185-0.480). Factors for breastfeeding (frequency of breastfeeding), \( p = 0.013 \), OR 1.99 (1.148-3.173). The conclusion is that the risk factor for stunting is breastfeeding. The suggestion is that education about good breastfeeding practices among ethnic Bugis caregivers needs to be done at the family level.

Key Words: Feeding Practices, Stunting, Buginese.

Introduction

Stunting prevalence data collected by the World Health Organization (WHO), Indonesia is included in the third country with the highest prevalence in the Southeast Asia / South-East Asia Regional (SEAR) region. The average prevalence of stunting toddlers in Indonesia in 2005-2017 was 36.4%. The determinant factor of nutritional problems is multidimensional1,2,3,4.

Stunting, is a public health problem at all levels (National, Province, City), including Makassar City as a red zone area (prevalence> 40%) at the same time Makassar City is the largest Metropolitan city in Eastern Indonesia and the development center of eastern Indonesia5. Based on the results of the descriptive analysis above, nationally stunting is a very serious nutritional and health problem, because the trend has increased since the last five years 25.7% to 30.8% between 2013 and 2018. There has been an improvement for South Sulawesi and Makassar City by which is very slow with down from 40.9 to 35.7%5.
Inadequate complementary food for breast milk is a real phenomenon in urban communities in Makassar. The contributing factors are the lack of knowledge about complementary foods, and the work status of mothers outside the home so that they do not pay enough attention to eating children\(^{10,11,12}\).

Breastfeeding practice is also an interesting variable examined in this research because Indonesia’s experience in improving breastfeeding practices still needs to be improved. The challenge is marketing formula milk. Although there are regional regulations regarding the method for marketing formula milk, the results have not improved significantly\(^{13,14}\). The purpose of this study was to investigate the factors of breast milk and complementary foods for the stunting of children aged 0-59 months.

**Research Method**

The subjects of this study were obtained from Bugis Ethnic who live in Makassar City. The study sites were three Puskesmas working areas in the North of Makassar City. Tamalanrea Health Center, Health Center, Paccerakkang, and Sudiang Raya Health Center. The reason for choosing the northern area of the city is because the Bugis ethnic population inhabits the north of the city more than any other location. Criteria for inclusion of Buginese ethnic samples in Makassar City

1. The mother is from the ethnic Bugis and the husband is also from the ethnic Bugis
2. Having children aged 6-59 Months in September 2019
3. Have lived for at least the past 6 months in Makassar City
4. Willing to participate in this research

The sample size in this study is based on the estimated prevalence of stunting in Makassar City as a Bugis ethnic center that is 35.7%, using 80% power test with 95% confidence, design effects 1 and 5 with the addition of 10% additional data estimated not to participate in research. This is because they refuse or are not present at the time of screening. Based on the calculation results above, the sample size of 300 is determined. Data Collection

Data collection in this study uses a list of questions that have been tested with good reliability. The questionnaire uses structured questions which are tested using official data on children aged 0-59 months (mother’s data and household data). Data collected includes the child’s age, sex, weight and height/length; mother level, education level and participation in household decisions; breastfeeding practices, supplementary feeding. Child weight was measured using an electronic SECA scale with an accuracy of 0.1 kg and the length of the child (for children aged 0-23 months) or height (for children aged 24-59 months) was measured using a locally made height/length board with an accuracy of 0, 1 cm. SECA scales are calibrated every morning, before data collection, using a standard weight of 5 kg. All enumerators receive training at least two days before data collection, and those responsible for taking anthropometric measurements receive one additional training day. Supervisors are tasked with supervising the work of enumerators and facilitating good relations with community members. Stunting is defined as Z-score for height \(<<2\). The HAZ -core matches 2006 WHO growth standards.

*) based on logistic regression analysis, with stunting as the dependent variable;

Based on the results of the risk factor analysis of various variables that influence stunting is that the child factor is good appetite being a protective variable with a significance value of $p = 0.000$, $OR=0.289$ (0.185-0.480). In reference to the standard appetite, then a good appetite becomes protective against stunting. This means that children whose appetite improves can avoid stunting, while normal appetite or no appetite will cause children to risk stunting.

Discussions

Based on these parameters, it can be proven that ethnic Bugis contributed significantly to the percentage of stunting in South Sulawesi in 2018. South Sulawesi Province ranks fourth in the highest percentage of stunting in Indonesia. Various factors were analyzed in this study in accordance with the conceptual framework published by Unicef in 2006.

Based on the concept map of the occurrence of stunting compiled by Unicef 2006 consists of several factors that affect stunting, namely household and family factors, child factors and complementary foods for breastfeeding, breastfeeding factors, hygiene sanitation factors, infectious disease factors, health-seeking behavior, parenting feeding style or style of care for child feeding, and caring practices or stimulation of child development. All of these variables are included in the scheme of the conceptual framework of determinants of global stunting factors 7,15, 16, 17, 25, 26, 31.

Household factors and toddlers’ families are the closest factors to children where exposure to these
factors will greatly determine the nutritional status of children including height status. Theoretically, the concept can be easily understood as a very logical causal relationship. Household and family factors in this study were tested with child stunting status and it is known that the mother’s age, father’s age, mother’s education, and father’s education had no significant effect on the stunting of children under five. The number of family members and the number of children under five in one household as an economic burden variable also does not consistently affect stunting. In this study, several variables cannot be proven except for the occupational status of parents. Permanent employment with wages that are able to meet food and clothing needs is a protective factor while other jobs are a risk factor. This proves that the father’s work status has a very strong influence on the incidence of child stunting\textsuperscript{18,31}.

Child and breast milk supplementary factors in this study tested the risk of stunting and found several facts, namely the status of prelactal feeding does not affect stunting, as well as several other variables; child food forms, frequency of eating, who makes food for children, who feeds children. All of these variables do not clearly differentiate a child’s height status. The only variable that is very influential today is the child’s appetite as a protective factor\textsuperscript{20,31}.

The poor appetite of children at risk of stunting and vice versa good appetite, causing children to avoid stunting. Based on these results it can clearly be used as a recommendation that efforts to provide foods that children like or provide ways to improve children’s appetite are key points. Many factors affect a child’s appetite. Mealtime, type of food, and calorie content of food give different dynamics in each child to the quality and quantity of macro and micronutrient intake

The breastfeeding factor theoretically determines the quality of macro and micronutrient intake, especially in the period of 1000 HPK. If the support of maximum breastfeeding, the child’s height will be normal and vice versa. This is due to many biological and psychological beneficial factors obtained by breastfed children compared to children who are not breastfed. This study examined the variable breastfeeding factors and found that the frequency of breastfeeding became a risk factor for stunting. The reference used is breastfeeding $>12$ times in 24 hours and frequencies lower than that are at risk for stunting. This proves that in the period of breastfeeding which is the age of 0-24 months, it is important to breastfeed properly with the right frequency\textsuperscript{31}.

**Conclusion**

Complementary feeding factors for buginese ethnic is that the child’s appetite is an important factor. The better the child’s appetite, the more avoiding stunting. Strengthening of mothers’ groups to improve the quality of breastfeeding practices and children’s food culinary education. Provision of employment opportunities for fathers through related sectors.

Effect of Purified prodigiosin from *Serratia Marcescens* on the Inhibition of Breast Cancer (MCF-7 and CAL-51 Cell Line)

Taif H. Hassan¹, Sawsan H. Authaman¹, Khawlah J. Khalaf¹

¹Department of Biology, College of Science, Mustansiriyah University, Baghdad-Iraq.

Abstract

The prodigiosin pigment was extracted from *Serratia marcescens* bacteria by using different methods such as by using ethyl acetate and acetone and purified by using column chromatography, Detection and characterization of the pigment was done by using Thin layer chromatography and λ max, The purified Prodigiosin was dissolved in DMSO solvent and prepared in four concentration (1000, 500, 250, 125) µg/ml at exposure time 24 hrs so it was used in treating MCF-7 and CAL-51 cell line, the result showed that the inhibition ratio against MCF-7 was significant (p < 0.001) and maximum ratio of inhibition was 83% at conc. of 1000 µg/ml, 78% at 500 µg/ml, 73% at 250 µg/ml and 72% at 125 µg/ml while inhibition ratio against CAL-51 was also significant (p < 0.001) and 78% inhibition ratio was seen at conc. of 1000 µg/ml, 61% at 500 µg/ml, 27% at 250 µg/ml and 14% at 125 µg/ml, effect of the solvent DMSO on tumor cells also was studied and compared to the effect of prodigiosin and result showed that there was no effect or slightly effect of the solvent DMSO on MCF-7 tumor cells. (Inhibition was 6%, 13%, 16%, 22% for conc. 125, 250, 500, 1000 µg/ml respectively) also there was no effect or slightly effect of the solvent DMSO on tumor CAL-51 cells. (Inhibition was 2%, 8%, 21%, 26% for conc. 125, 250, 500, 1000 µg/ml respectively).

Keywords: Prodigiosin, MCF-7, CAL-51, DMSO, λ max

Introduction

* Serratia marcescens are pigmented and produce the red pigment, so the organism has been regarded in medical laboratory experiments as nonpathogenic bacteria (¹), Prodigiosin, is a group of natural red pigments, the scientist who first gave the name Prodigiosin to the red pigment produced by *Serratia spp.* was Kraft in 1902, after his successes in extraction of pigment from this bacteria (²), This pigment is a promising drug therapy due to its reported characteristic of having ant metastatic (³), anti-proliferative and immunosuppressive activit (⁴), Prodigiosin pigment induces apoptosis in hematopoietic cancer cells with no marked toxicity in benign cells (⁵), and has cytotoxicity effects on cancer cell and induces apoptosis in HT-29 and T47D cancer cell lines (⁶), it also induces cell death and morphological changes which is a clear signal of apoptosis in gastric cancer cell line HGT-1 (⁷), which increase the possibility of its therapeutic application as an antineoplastic drug. Prodigiosin appear its content of anticancer compounds (⁸), Prodigiosin pigment was regarded as anticancer agent (⁹), the effect of this pigment was studied on many tumor cell line, the main aspect of this pigment is that its inhibitor effect appears on tumor cells only while not effected normal cells, by its effect on cell cycle arrest and induce programmed cell death that’s the cause behind its use as treatment for tumor cells (¹⁰).

This study aimed to investigate the cytotoxicity effect of prodigiosin pigment on two breast cancer cell line MCF-7 and CAL-51.

Materials and Method

The selected isolate of *S. marcescens*, which isolated and identified in college of science-Mustansiriyah University was inoculated into 250ml flasks containing 50ml of peptone glycerol broth, (pH=8). The culture was incubated at 30 °C for 72 hrs with shaking (160 rpm), and then centrifuged at 10000 rpm for 15 minutes. The
resulting supernatant was taken and ethyl acetate was added in equal volume of the supernatant. The resulting pellet was re suspended in 1 ml of acetone in percentage 1:1 (W/V) and mixed gently. Then it was transferred into small tube to mix with the previously supernatant and concentrated in incubator at 40 °C for 24 hrs. The extract was sterilized using membrane filter (0.22 µm) and stored at 4 °C until purification step (11).

Purification of Prodigiosin by column chromatography

After extraction of prodigiosin by ethyl acetate and acetone from S. marcescens (SKT14) isolate the pigment purified by using column chromatography. The crude extract was dissolved in ethyl acetate and subjected to silica gel (20gm, Merck) column chromatography (2.5×17 cm). The colored fractions were eluted with ethyl acetate, and the individual fractions were evaporated to dryness. Because of the light sensitivity of the pigments, all further purification steps were carried out in the dark. The fraction 7ml were collected and assayed for absorbance at 535nm. The purified pigment was stored at -20 °C. The Prodigiosin peak fraction was pooled and dried at 40 °C to assay pigment concentration (12).

Pigment detection by using thin layer chromatography (TLC)

The TLC plates of silica gel (20×20cm) were used, the developing solvent which contains ethyl acetate. Chloroform and acetone (65:30:5) was standardized and poured into the chromatography tank, that was saturated with a mobile phase. The sample was spotted about 1 cm from the margin of silica sheet then the strip was kept in oven for 5 minutes for drying. then allowed to run up to 3/4th of the gel about 16 cm. After that, the strip was observed under U.V. light for spot observation. The Rf value of chromatography was observed in the TLC plates. The isolated prodigiosin was estimated using the following equation:

\[ R_f = \frac{\text{Distance of sample}}{\text{Distance of mobile phase}} \]

Pigment spot was scraped and dissolved in 5ml of methanol and centrifuged (6000 rpm for 15 minutes) to get rid of silica gel residue. Then measured the optical density at wave length range 200-700 nm and methanol was used as blank.

The purified pigment was stored in clean sterile glass tube and covered with aluminum paper away from direct light exposure at 4 °C (13).

**Determination of λ_max of prodigiosin at different optical density**

The pigment was analyzed for maximum UV–vis absorbance at pH values of 2 and 9 between 200 and 700 nm, using ethyl acetate as blank. The absorbance of pigment at different wavelength and λ max was calculated (14).

**Cell line preparation**

Two type of cell line were using included MCF7 cell line, this line was used from 170 passage, Primary tumor (invasive breast ductal carcinoma that originate from pleural effusion (11). Estrogen receptors present (12), and taken from Iraqi center for medical genetics and cancer research. This line was outgrown in RPMI-1640 supplemented with 10% Fetal calf serum, When single monolayer was formed these cells was treated with Trypsin/Versin solution to divide it into another secondary cell culture. other cell line was CAL- 51 cell line , this line was used from 210 passage, is a new mammary adenocarcinoma cell line derived from the malignant pleural effusion of a patient women with metastatic breast cancer. and taken from Iraqi center for medical genetics and cancer research.

**Cancer cell line**

**Development and growth of cancer cells**

The effect of prodigiosin pigment on cancer cells was done by using two cell lines. In special culture medium in tissue culture falcon 25 cm² at temp. 37 °C, when the confluent monolayer was get Subculture was done by disposal from old culture medium and washing the cells by 2-3 ml of Trypsin/versene solution (Sterilizer and warm) So that it covers the surface of the cells when falcon was put in horizontal mode with shaking gently for 10-15 min. and disposal from it and replace it by another 2 ml from the same solution and falcon was incubated at 37°C for 3-5 min. Then new culture medium was added in quantity about 10-15 ml with homogenization of the cells by mixing with the new medium then cells suspension was distributed in two falcons of the tissue culture falcons in 25 cm size and 5-7 ml in each falcon (15).
Seeding (Cell culture)

Micro titer plates with 96 well were used for cancer cells culture which was obtained after formation of cancer cells monolayer and remove them from falcon surfaces and dismantled by T/V solution, after that completely nutrient culture medium supported by serum (20ml) and incubated at 37°C was added and cells was well mixed with medium, then 0.2 ml was transferred from cells suspension by pipette from each well, every well contain not less than 1x10^5 cell, plate surface was covered with sterilized transparent adhesive paper, then micro titer plate was moved gently stirred and incubated at 37°C over night to allow cells attachment and its growth.

Treatment of cancer cell line by prodigiosin

Serial of half dilutions was prepared to get concentration (125, 250, 500, 1000) μg/ml dissolved in DMSO, culture medium was poured out from the well of falcons after removing of transparent adhesive paper, then 0.2 ml/well from each conc. was added about 3 well per each conc. and one column of wells regarded as negative control by adding 0.2 ml of RPMI free of serum. All plates were incubated at 37°C, Exposure time was 24 hrs only except for plate of Rat Embryo Fibroblast (REF) Exposure time was 72 hrs, after that all plate wells content was poured out and 0.1 ml of crystal violet solutions was added to all wells of the plates, then all plates was incubated at 37°C for 30 minutes. Crystal violet was then poured out then washed by distilled water and turned over and allowed to dryness at room temp. Then O.D was recorded at 492 nm by using ELISA micro plate spectrophotometer and inhibition rate (IR) percentage was calculated as the following equation:

\[
\% \text{Inhibition rate} = \frac{O.D \text{ control} - O.D \text{ test}}{O.D \text{ control}}
\]

Results and Discussion

1. Detection of prodigiosin pigment by Thin layer chromatography (TLC)

Thin layer chromatography method regard the earliest procedure used for detection and also for purification of prodigiosin, it regard as general method for purify of secondary metabolites products.

During Purification of pigment from S. marcescens SKT14, R_f was calculated and the result was about 0.67 as shown in (Figure 1) this result was agree with the result of some researcher which pointed out that the distance between the movement of spot sample to the distance of spot solvent movement was 0.65, while other studies pointed out the R_f was ranged from 0.9-0.95.

Figure 1: Separation and detection of prodigiosin pigment (Purified) from S. marcescens SKT14 isolate using thin layer chromatography (TLC).

2. Determine the λ max (U.V Absorption of prodigiosin at different optical density)

The maximum absorption of prodigiosin at different wave length ranged from (200-700)nm, Figure 2 and Table 1 showed two peak of absorbance (535,539nm), maximum absorbance was at the wave length 539nm at pH values 2 and the color was red, while drop in absorbance was found at pH 9 at 400nm and color was yellow. (p < 0.001).

3. Effect of prodigiosin on MCF7 cell line

Prodigiosin pigment in four concentrations at exposure time 24 hrs was used in treating MCF7 cell line. As shown in (table 2) inhibition ratio was significant (p value <0.001) and maximum ratio of inhibition was 83% at conc. of 1000 µg/ml, 78% at 500 µg/ml, 73% at 250 µg/ml and 72% at 125 µg/ml. also the table showed that there was no effect or slightly effect of the solvent DMSO on tumor cells. (Inhibition was 6% ,13%, 16% , 22% for conc. 125 ,250 ,500 ,1000 µg/ml respectively).

As showed by some researchers, staphyloxanthin pigment caused inhibition of MCF-7 cell line and the cell viability was 35% when 400 µg/ml of pigment was used (20), The apoptosis and inhibition of cancer cell is dose dependent and that is agree with the result of other researchers which showed that the apoptosis demonstrated a dose-dependent relationship in the early apoptotic cells (21).

Effect of prodigiosin on CAL-51 cell line

Prodigiosin pigment in four concentrations was used in treating CAL-51 cell line tumor. As shown in (table 3) inhibition ratio was significant (p < 0.001) and 78% inhibition ratio was seen at conc. of 1000 Mg/ml, 61% at 500 Mg/ml, 27% at 250 Mg/ml and 14% at 125 Mg/ml. also the table showed that there was no effect or slightly effect of the solvent DMSO on tumor cells. (Inhibition was 2%, 8%, 21%, 26% for conc. 125,250,500,1000 µg/ml respectively). The studies showed that some natural product that extracted from plant exhibited considerable cytotoxicity against Cal-51 triple negative breast cancer cell with even lower IC50 values (11).

Abstract

Background: The HCV the objectives of this study were to estimate the incidence of HCV infection (anti-HCV antibodies) in Iraq. Methodology: The criteria for diagnosis of HCV infection included new seroconversion manifested by the presence of positive HCV antibodies by screening tests and ascertained this result by confirmatory assays in the year 2018. The patients with HCV positive seroconversion recorded before 2018 are excluded from HCV incidence in 2018. The primarily positive cases were tested by anti-HCV antibodies confirmatory test prior to recording as new HCV infected cases. A sample size of 97,290 persons from the all 18 Iraqi governorates was enrolled in this study. Results: Among 97,290 persons screened for HCV antibodies, 576 new HCV infections were recorded as newly infected with incidence rate of 5.9:1000 among all Iraqi governorates in 2018. The highest incidence was reported in Baghdad-Resafa, Diwaniya, and Sulaymaniyah, and they were 15.2:1000, 13.7:1000, and 13.2:1000 respectively; the lowest incidence rates were registered in Erbil, Diyala, and Najaf and the results were zero, 0.32, and 0.53 respectively. In all Iraqi governorates, the highest incidence of HCV infection was at the age group 15–45 years and the lowest was in age group 1-4 years. For the total 576 new HCV recorded infections, 296 were males and 280 were females, with male to female ratio of 1:1.1.

Conclusion: The incidence rate of HCV infection is high among people screened for anti-HCV Abs in Iraq in the year 2018 especially in Baghdad-Resafa, nearly both genders are equally affected and HCV infection is mostly recorded in age group 15-45 years. The HCV screening program should be achieved in all regions of Iraq and for all the required population groups, and it should be a compulsory measure.

Keywords: Hepatitis C Virus, Infections, incidence, Iraq

Introduction

Hepatitis C virus (HCV) is a common cause of chronic hepatitis worldwide and it is an important cause of liver cirrhosis and hepatocellular carcinoma (1). Because HCV is a blood borne disease, it is more common among people exposed to contaminated blood or contaminated blood products (2). Epidemiological measures like the prevalence and incidence of HCV infections are important in understanding the existence of HCV infection and its endimicity among population for future planning to control this infection (3).

Globally, the incidence of HCV infections has been reported in some countries, and it is mostly determined by measuring the seroconversion in a person who is previously negative for anti-HCV antibodies, however, it is difficult to appraise if this is acute or chronic infection (4, 5). Epidemiologically, the prevalence of HCV infections is measured more frequently than incidence because the available laboratory tests cannot distinguished between acute infections, chronic infections, or even the cured infections as these tests are measuring the anti-HCV antibodies rather than HCV antigens (6). The incidence is a fundamental epidemiological measure; it represents

the number of new cases over a particular time in a given population. The incidence of HCV infection is important in study the susceptibility of people in different periods by comparing the new registered cases; moreover, it can study the risk of HCV infections among different people subgroups (7).

The Incidence of HCV infections in Iraq has not been estimated before, in this study we aimed to measure this valuable epidemiological marker and comparing the susceptibility of different subcategories to HCV infections. The aim of this study is to estimate the incidence of the infections with hepatitis C virus in Iraq in the year 2018.

**Methodology**

In this cross sectional study, we collected data from the files of peoples screened for HCV infections in Iraq in 2018. The governmental health care facilities in the all 18 Iraqi governorates screened 97,290 persons in the year 2018 for HCV antibodies, their screening was for a diverse reasons like preoperative screening, pre-employment health examination, screening before dental procedures, screening of pregnant women before labor, patients with hemodialysis, patients with thalassemia, patients with possible liver diseases, and healthy persons who seek annual screening. The criteria for diagnosis of HCV infection included new seroconversion manifested by the presence of positive HCV antibodies by screening tests and ascertained this result by confirmatory assays. The patients with HCV positive seroconversion recorded before 2018 were excluded from registration as new cases in HCV incidence in 2018. Two parameters, gender and ages are included as risk factors for HCV infections. The capital of Iraq, Baghdad, was divided into two regions, Karkh and Resafa; thus, HCV screening was done in 19 Iraqi regions.

**Results**

The highest record of new HCV infections was registered in Baghdad-Rusafa (n=151), while the lowest was in Erbil governorate (n=zero), the total number of new cases among 97,290 persons screened for anti-HCV antibodies in Iraq in 2018 was 576 (tables 1, 2). The top three regions that recorded the highest incidence rates of HCV infections were Baghdad-Resafa, Diwaniya, and Sulaymaniya, and they were 15.2:1000, 13.7:1000, and 13.2:1000 respectively; the lowest incidence rates were registered in Erbil, Diyala, and Najaf and the results were zero, 0.32, and 0.53 respectively. The overall incidence rate among screened individuals in Iraq was 5.9:1000. Most of HCV infections were recorded in March, July, and November as illustrated in table 1.

Discussion

Two major challenges in HCV infections is that it is mostly asymptomatic disease and the absence of vaccine till now, therefore, it can be transmitted from one person to another without being noticed, thus screening of HCV Abs among people consulting health care facilities is a major tool in controlling the disease transmission. The screening for anti-HCV Abs in Iraq is usually part for screening for three viruses: hepatitis B virus (HBV), HCV, Human immunodeficiency virus (HIV), and it is done before any surgical operation, dental procedure, or labor, in addition patients with some chronic diseases and in need for blood or plasma transfusion like thalassemia patients, or patients on hemodialysis are also screened for HCV Abs. However, this screening for HCV Abs is not universal in all health care facilities of all Iraqi governorates, moreover, the private health care facilities like private hospitals and the private dermatological centers, which are in growing more and more in all Iraqi governorates, are not entirely inspected for this screening and we are not sure if anti-HCV Abs are screened in every patient who is consulting these care facilities or not. Thus, we should apply a policy to ensure that anti-HCV Abs are screened in the necessary patients or persons consulting any health care facility as inpatient or outpatient, this will be an important tool for controlling HCV transmission.

In this study, we estimated the incidence rate among people attending hospitals and other health care centers in all Iraqi governorates, this large-scale estimation has not been done previously in Iraq, however, previous local studies described the prevalence of anti-HCV Abs in special groups of people and in limited regions in Iraq, like for example, Turky M. Ataallah, et al, detected the prevalence of hepatitis B and C among blood donors in Baghdad (8), Abdulameer K. Leelo, et al, detect the anti-HCV Abs in hemodialysis patients in Al-Diwaniyah city (9), and Muayad A. Merza and his coworkers detected the anti-HCV Abs among tuberculosis patients in Kurdistan region of Iraq (10).

In the current study, the incidence of HCV infection was 5.9:1000 which is higher than that reported by some abroad studies, for example, the incidence in thalassemia patients in Iran was 4.2/1000 (11). In rural northern Italy, the adult incidence of HCV is approximately 0.5/1000 inhabitants/year in 1996 (12), while in France, an incidence of 0.05% new HCV infections/year was determined in patients undergoing chronic haemodialysis (13). In the current study, The presence of healthy people in addition to risk group in the screening program, and the asymptomatic nature of HCV infection, make it clear that opposite to the total new 576 HCV infections
recorded in 2018 there are more number of cases not recorded in Iraqi governorates.

It is not surprising that Baghdad-Resafa has the highest incidence among Iraqi region due to high population density of this half of the capital Baghdad. In this aspect the high incidence of HCV in that region may be due to unKnowledge of infection status that associated with decreases in high-risk of infection such behaviors of individuals like sharing of injection drug equipment with individuals who have HCV infection status. The current study revealed that 60% of new HCV infections are aged 15-45 and there is an overall increase in HCV infections in adults than in children. The blood product seropositive had not been previously screened for HCV due to not available screening procedure at that time or may be due to longer exposure to risk factors for HCV at older age, this result is in accordance to that of Niu Z et al (14). In the current study, the HCV detection rate in males and females was nearly similar as the differences was statistically not significant with male to female ratio of 1:1.1, unfortunately it is difficult to compare this ration with the incidence in previous years as HCV infection among the gender was not recorded prior to this study.

The HCV screening program should be done before any interventional procedures, premarital, for risk groups like hemodialysis and thalassemia patients, pre-employment, and periodic for medical personnel and others in with continuous contacts with populations; this screening program should be monitored and evaluated continuously.

**Conclusion**

The incidence rate of HCV infection is high among people screened for anti-HCV Abs in Iraq in the year 2018 especially in Baghdad-Resafa, nearly both genders are equally affected and HCV infection is mostly recorded in age group 15-45 years. The HCV screening program should be achieved in all regions of Iraq and for all the required population groups, and it should be a compulsory measure.

Study of Gastroesophageal Reflex Disease in adult Type II Diabetes Mellitus Patients with Upper Gastrointestinal Symptoms

Maysam Riyadh Mohammed Hussein¹, Sadiq Jabar Almohana², Hayder Nadhum Muhsen³

¹Internal Medicine, Lectural/Medical College Kufa University/Iraq, ²Internal Medicine Professor/ Medical College Kufa University/Iraq, ³Internal Medicine / Alsader Teaching Hospital /Iraq

Abstract

Gastrointestinal symptoms are relatively common in clinical practice in patients with type II diabetes mellitus. type II DM has been described as possible risk factor for the development of gastroesophageal reflux disease, in this study we aim to detect the prevalence of GRED in symptomatic patients with type II DM , also to see the accuracy of reflex disease questionnaire (RDQ) in the diagnosis of GERD in patients with type II DM in relation to the esophagogastroduodenoscopy finding and to study the relation of autonomic neuropathy to the prevalence and stages of GERD in diabetic patients .

Method: A ninety patients with upper gastrointestinal symptoms was divided in to tow groups according to whether had type II DM or not and then each group involved in a two stage process (a) – a RDQ , (b) – OGD .

And patients in the DM group underwent another step to detect diabetic neuropathy by a bed side clinical test .

Results: The prevalence of esophagitis in this study was higher in the DM group .

RDQ had a statistical significance in detecting esophagitis in the DM group .

There is no relation of autonomic neuropathy to the prevalence of GERD in diabetic patients .

Conclusion: The prevalence of GERD was high in patients with type II DM , RDQ is a sensitive tool for the diagnosis of GERD in diabetic patients , Autonomic neuropathy did not increase prevalence of esophagitis in diabetic patients .

Keywords: diabetes mellitus , gastro esophageal reflex disease , RDQ, Esophagogastroduodenoscopy, Esophagitis.

Introduction

The current concept of GERD is “symptoms or complications associated with regurgitation from the stomach and or the duodenum to the esophagus”, It is estimated that 15%-30% of the general population are affected by GERD(1,2).

GERD develops when the esophageal mucosa exposed to gastroduodenal contents for prolonged periods of time, resulting in symptoms and, in a proportion of case , esophagitis(2).

Note that some degree of gastroesophageal reflux is normal, physiologically connected with the mechanism of belching (transient LES relaxation), but esophagitis results from excessive reflux, often accompanied by impaired clearance of the refluxed gastric juice. Restricting reflux to that which is physiologically intended depends on the anatomic and physiologic integrity of the oesphagogastric junction, a complex sphincter comprised of both the LES and the surrounding crural diaphragm. Three dominant mechanisms of esophagogastric junction incompetence are recognized: (a) transient LES relaxations (a vagovagal reflex in which LES relaxation is elicited by gastric distention),

(b) LES pressure decease, or (c) anatomic distortion of the esophagogastric junction inclusive of hiatus hernia$^{(1,2)}$.

Transient LES relaxations account for at least 90% of reflux in normal subjects or GERD patients without hiatus hernia, in many studies the first two mechanisms and other factors such as abdominal obesity, delayed gastric emptying, disruption of esophageal peristalsis, autonomic neuropathy, metabolic syndrome were thought to be a possible risk factors for the high prevalence of the typical GERD symptoms in patient with DM, but up to present, the pathogenesis of GERD in type II DM patients has not been fully clarified$^{(3,4,5)}$.

Peripheral and autonomic neuropathy especially has become a research hotspot in recent years, however, the impact of the above factors on the presence of GERD symptoms in type II DM patients is still under debate$^{(3,6)}$.

Patients with GERD may present with heartburn and regurgitation which are the major symptoms of GERD, somewhat less common are dysphagia and chest pain and a variety of other features has been described, and depending on this a clinical system of symptom-based diagnosis of GERD was made the so called reflex disease questionnaire RDQ$^{(7)}$.

RDQ comprises 6 questions assessing the frequency of heartburn, substernal chest pain, acid regurgitation, nausea, need for the medication, and trouble getting a good night sleep because of heartburn or regurgitation, per week, as shown in table 1.

### Table 1: GerdQ Questionnaire

Note: Add the point values for each corresponding answer. Total score of 0 to 2 points = 0 percent likelihood of GERD; 3 to 7 points = 50 percent likelihood; 8 to 10 points = 79 percent likelihood; 11 to 18 points = 89 percent likelihood.

Several investigation used to evaluate patients with suspected having GERD of which endoscopy is the initial investigation of choice, it used for the diagnosis and grading of GERD and to exclude other upper gastrointestential disease that can mimic GERD and to identify complications.
Aim of the Study

To study the prevalence of GERD in symptomatic patients with type II DM in relation to non DM, also to see the accuracy of RDQ in the diagnosis of GERD in patients with type II DM in relation to the OGD finding and to study the relation of autonomic neuropathy to the prevalence of GERD in diabetic patients present with upper gastrointestinal symptoms.

Patients and Method

This study was conducted in Alsader medical city, in Alnajaf center for gastrointestinal and hepatic diseases in which 122 adult patients referred for upper endoscopy because of upper gastrointestinal symptoms suggestive of GERD between March 2014 and March 2015 participate in this study.

Exclusion criteria were type I DM, esophageal motility disorder other than ineffective esophageal motility, patient with hiatus hernia and patient with a RDQ less than 8.

After performing the exclusion criteria a 90 patients were considered eligible for this study. 31 of them were females and 59 were males.

The recruitment patients were divided into two groups according to whether had a type II DM or not, the diagnosis of type II DM based on WHO definition (Defined as fasting blood glucose $\geq$ 7 mmol/l or on glucose medication for raised blood glucose or with a history of diagnosis of diabetes.)

The then every group involved in a two stage process

(a)- Reflux disease questionnaire (RDQ) and patients with at least a minimal score of 8 had been chosen as the (RDQ) likelihood of GERD were as fellow:

1- A total score 0 to 2 = 0 percent likelihood
2- A total score 3 to 7 = 50 percent
3- A total score 8 to 11 = 79 percent
4- A total score 12 to 18 = 89 percent.

(b)- OGD by the use of Olympus or pentax ED-3490 TK 4.2 HOYA corporation endoscopy system, which used in the diagnosis and staging of esophagitis according to Savery-Miller classification in these patients.

(c)- the patients with DM group underwent another step during interview by being underwent a simple clinical test to detect the diabetic autonomic neuropathy (a bedside test for the absence respiration-associated sinus arrhythmia by monitoring the pulse rate by a pulse oximeter while the patient instructed to breathe slowly and deeply at a rate of 6 breaths per minute, heart rate normally increase with inspiration and decrease with expiration, and at a respiratory rate of 6 per minute the difference between fastest and slowest heart rate is usually more than 15 per minute, a difference of 10 beats per minute or less are observed in autonomic dysfunction).

Statistical Analysis:

Statistical analysis were performed using spss 16 program correlation analysis was also performed.

A P value $<$0.05 was considered significant.

Results

Ninety patients were included in this study and divided into two groups: a thirty patients in DM group and sixty patients in the non DM group.

In the non DM group 22 of them were females (36.66%) and 38 were males (63.33%) with a mean age of (46.7 years $\pm$ 8.2).

In the DM group 9 were females (30%) and 21 were males (70%) with a mean age of (51.2 years $\pm$ 9.3). As shown in table 2.

<tr>
<td>Number of patients in non DM group with esophagitis</td>
<td>48 of 60=80%</td>
<td>32 of 60=53.3%</td>
</tr>
</tbody>
</table>

Table 4 comparing QRS and OGD in detecting esophagitis in both study groups.

In the DM group the clinical bedside test for autonomic neuropathy revile an autonomic dysfunction in 16 patients of 30 (53.33%) and 14 patients show not (46.6%).

13 (81.2%) of the 16 patients with DM and autonomic dysfunction were diagnosed with esophagitis by OGD and 3 patients show no sign of esophagitis by OGD (18.7%), while in patients with DM and without autonomic dysfunction there were 10 patients of 14 (71.4%) diagnosed with esophagitis by OGD and 4 patients (28.5%) are not, so there were no statistical significance P value=0.5287 as shown in table 5.

**Discussion**

Diabetes is a major health problem, as it is an important contributor to various other disease and its incidence still continues to rise. Gastrointestinal symptoms are relatively common in clinical practice in patients with type II DM. Type II DM has been described as possible risk factor for the development of GERD. Several studies reported that the prevalence of GERD symptoms in the type II DM was approximately 25%-40% in different populations, in these studies...
several methods used in the diagnosis of GERD includes; RDQ which had a sensitivity of 79% in the diagnosis of GERD at 8-11 score level in non DM patients, Endoscopic examination which had high specificity but low sensitivity for the diagnosis of GERD with a sensitivity about 55% for detecting esophagitis and other complications\cite{14,15} and ambulatory PH monitoring which is indicated if diagnosis is unclear or surgical intervention is under consideration, although the test yields accurate and reliable information it is inconvenient for the patient and many clinicians do not have access to the appropriate instrumentation and are unable to perform this test\cite{16}.

In this study a combination of RDQ and OGD is used to study the prevalence of GERD in patients with type II DM as a previous study by Lemeneh Tefera, B.A., Martin Fein.\cite{16} shows that this combination had a high proof value 98% and high specificity 97% for the diagnosis of GERD in non DM patients, in this study we found that the prevalence of GERD in adult symptomatic patient with type II DM as diagnosed by OGD were high 76.7% comparing to non DM patients 53.3% with a P value =0.03236.

We also found that the RDQ at level score >8 had a good prediction rate for esophagitis which about 80% in symptomatic patient with type II DM as the OGD result showed esophagitis in 76.66% in patients with type II DM comparing to non DM patients in regard to the sensitivity of RDQ with a P value=0.00244, and this was constant with a study by Yu Bai, Yiqi Du, Duowu Zou, Zhendong Jin and others , that suggest that the RDQ may be used for the diagnosis of GERD\cite{17}.

In previous studies neuropathy were thought of as possible risk factor for the prevalence of the typical GERD symptoms in DM patients \cite{13,20}, for example, in 2008, Wang et al.\cite{13} reported that the prevalence of GERD symptoms was higher in patients with neuropathy than in patients without neuropathy , in this study there were no significant difference in the prevalence of esophagitis in DM patients with or without neuropathy with a P value=0.05287 , this results are similar to the studies of Clouse and Lustman \cite{21} and Lee et al.\cite{19}. In 1989, Clouse and Lustman, through analyzing 114 diabetic subjects with gastrointestinal motor dysfunction symptoms, reported that gastrointestinal symptoms occurring in diabetic patients were poorly related to neuropathic complications. In 2011, Lee et al.\cite{19} studied 119 patients with type II DM and found that there was no significant difference in the proportions of patients experiencing typical GERD symptoms between the two groups of type II DM with and without neuropathy.

**Conclusion**

The prevalence of GERD were high in patients with type II DM, RDQ is a sensitive tool for the diagnosis of GERD in those patients, Autonomic neuropathy did not increase prevalence of esophagitis in diabetic patients.

Abstract

Sarcocystis diseases caused a serious illness in sheep flock which inducing decrease of growth conversion rates and complete or partial loss of carcasses at the abattoirs, This article which described an prevalence of parasites Sarcocystis gigantea in sheep slaughtered in a farm in kerbala governorate, Iraq, and performed a phylogenetic analysis by using the Euclidean distances calculation from the Sarcosystis gigntea nucleotide frequencies around the world sarcosystis genomes. Fifty sheep showed multiple nodules in the esophagus that were microscopically characterized as encapsulated cysts filled with elongated, nucleated structures morphologically consistent with S. gigantea bradyzoites. The prevalence and species of Sarcocystis gigantia were revealed as 10% (5 out f 50) for the macroscopic sarcosystis, the shape of these cysts were resembled to oval and pear shape, the sensitivity of Polymerase chain reaction was 75% with 95% of confidence intervals 19.41% to 99.37% and the specificity was 95.65% with 95% confidence intervals 85.16% to 99.47%. Our results suggest that oligonucleotide sequences were useful for estimation of Sarcocystis gigntea phylogenetic relationships for closely related species.

Key words: Sarcocystis gigntea, Phylogenetic analysis, PCR, sensitivity and specificity.

Introduction

Sarcocyst is intracellular cells parasites infect a wide range of domestic animal, some genus of Sarcocystes are pathogenic for animal like cattle and sheep that cause huge economic losses 1, cyst forming coccidiosis parasites with a mandatory two host life cycle which involved Herbivorous as intermediate hosts and carnivores as definitive hosts, an intermediate and final host may harbor more than one species of sarcocysts 2, Sheep are infected by swallowing sporulated cysts in food or water 3. They are numerous Studies in different city of the world suggested that the spread of parasites infestation in slaughtered cattle, sheep were recorded between 60 % to 90% 4-6. They are four species of Sarcocystis that have infected sheep which include Sarcocystis arieticanis, Sarcocystis tenella, S. medosiformis and S. gigantean, S. gigantea are responsible for the formation of cysts generally, in the muscles of the tongue and esophagus, or in the bowels of carcasses of slaughterhouses 7. In the official health control of slaughterhouses, the bodies of infected cysts are macroscopic examination and sometime this cysts are trimmed or removed by veterinarians and doesn’t depended on microscopic examination, these cysts are pathogenic in sheep if we leave without clinical and diagnostic tests, in this sense our study decided to conduct molecular identify macroscopic cysts of Sarcocytis parasites in sheep and study of the evolutionary relatedness among some closed related species around the world.

Materials and Methods

Sample collection:

The study was conducted by collection samples from sheep aged in different slaughterhouse regions of Karbala province, multiple nodules covered with intact mucosa were present and showed in the esophagus of sheep slaughter, the microscopic characterize as multiple cysts have encapsulated and filled with elongated fingers of small, basophilic, nucleated structures which morphologically consistent with S. gigantea bradyzoites.
Macrosopic sacs which visible in the esophagus organ and skeletal muscles were collected by sterile scapel from carcasses, and the samples were keep in sterile petri dish, and sent to the lab as soon as possible. The course of this study was beginning from February 2018 to January 2019, the age of this animals were estimated depending on permanent incisor of their teeth and the gender of each animal was documented. The cysts were excised in the same time the macrocysts samples were detached from the tissues and organs.

**Macrocysts DNA extraction procedure:**

Genomic pellet DNA was extracted from macrocysts samples by using (Geneaid™ DNA Isolation Kit (Tissue). The DNA extraction of macrocysts cells was done according to manufacture company, generally, the extracted DNA was calculated by Nanodrop-spectrophotometer device, and then the extracts were store in -30C at freezing for PCR analysis.

**Polymerase chain reaction assays:**

PCR assays has done for diagnosis sarcosystis spp. Depended on small subunit ribosomal RNA gene by using specific dual primers that used in this study (Bahari et al., 2014). These primers were prepared and made by (Bioneercom.Korea) as following table (1).

**Table(1): The primer used in this study with amplicon product size**

<table>
<thead>
<tr>
<th>Primer</th>

<td>580bp</td>
</tr>
<tr>
<td></td>
<td>5-CACCACCCATAGAATCAAG-3</td>
<td></td>
</tr>
</tbody>
</table>

The PCR solution mix was prepared by the company called (Bioneer). The PCR solution kept at small tube containing freeze-dried pellet of DNA and the PCR premix mixture products was done according to manufacture instructions then filled to the top by the PCR premix tube by deionized water into 20µl and used vortex centrifuge for good mixing. The reaction was done in a Thermal cycler system (Mygene Bioneer) by orders we can sit it on the control panel the following thermocycler conditions; The products were examined by electrophoresis on a 1% agarose gel under ultraviolet light.

**DNA sequencing method:**

Genetic sequencing of subunit ribosomal RNA gene by using analysis of phylogenetic relationship and study level of alignment by mega multiple sequence software alignment programs. a product was purified from the gel by using (QIAquick Gel Extraction/ Qiagen). The purified PCR product was sent to korea for high quality DNA Sequencing service by Macrogen providing techniques (https://dna.macrogen.com/eng/support/ces/guide/ces_sample_submission.jsp).

**Data Analysis**

The nucleotides’ Sequences were truncated and aligned at both ends using ApE software (A plasmid editor Version 2.0.51); therefore the sequences majority were started and ended at the homologous nucleotide positions. The sequences target was submitted to BLAST (http://www.blast.ncbi.nlm.nih.gov). the nucleotides with diversity index as well as the Euclidean distances calculated were uploaded to the UPGMA (clustering) tree and the Maximum Pairsony phylogenetic tree by using the software MEGA 6 (Molecular Evolutionary Genetics Analysis Version 6.0). Specificity and sensitivity were used in this study to compare between PCR assay with macroscopic examination according to (Altman et al., 2013).
Results and Discussion:

The prevalence and species of *Sarcocystis gigantia* were revealed as 10% (5 out of 50) for the macroscopic sarcocystis, the shape of these cysts were resembled to oval and pear shape as large rice grain ranged between 9 to 11 mm in length (Pereira & Bermejo 1988) this cysts were consist of white capsule with gelatinous translucent substances.

![Figure (1): macroscopic cysts observation of *Sarcocystis spp.*](image)

Our current study was limited to macroscopic examination and sequences analysis of *Sarcocystis gigantea*, otherwise, there are many methods should be consider to confirm this strain by epidemiologic, microscopic findings. The certain risk factors and clinical indicators for infection were the final host connection as well as supply raw meat from sheep to cats, all of them which contribute significantly to the spread of *S. gigantea*, as well as others types of sarcoecysts. Our finding is in agreement with previous studies reporting an epidemiological association with adults sheep; nevertheless Bertero et al. (1980) did not find macrocysts in their epidemiological study in lambs because *S. gigantean* macrocysts are found mainly in adult sheep.

PCR used to determine species of sarcosystosis is (4) out from (50) as (8%) strain isolates, the sensitivity of Polymerase chain reaction was 75% with 95% of confidence intervals 19.41% to 99.37% and the specificity was 95.65% with 95% of confidence intervals 85.16% to 99.47% table 1.

<table>

Table (2): Sensitivity and specificity of polymerase chain reaction with Macroscopic examination.
The specificity and yielding can be readily determined by running a gel electrophoresis that separated DNA molecules (Fig 1), so this specificity would generate one product of the correct size through using specific double primers (Ghazaei, 2018).

Many studies revealed that Sheep are vector and harbor of parasite to reach definitive host for four Sarcocystis species which include: *S. gigantea*, *S. tenella*, *S. medusiformis* and *S. arieticanis*, both species. *S. tenella* and *S. gigantea* have worldwide distribution phylogenic of *Sarcocystis spp.* has been making Homology sequence identity by use rRNA gene according to NCBI-BLAST site show table (2) highly sensitivity to accuracy of molecular detection.

### Table (4): NCBI-Blast Homology sequence identity for rRNA gene in Trichophyton sp. isolate-1 with NCBI-BLAST Trichophyton spp.:

University of Sulaimani, Sulimani, Iraq, 5 Lecturer, Periodontics Department, College of Dentistry, University of Sulimani, Sulimani, Iraq

Abstract

Purpose: Porphyromonas gingivalis is a keystone among perio-pathogengenic bacteria to initiate periodontitis and treatment is better when the periodontal pathogens including Porphyromonas gingivalis are totally eliminated. The essential oil of Thymus vulgaris has many bioactive constituents having antimicrobial activity against many bacteria. This study investigates the antibacterial effect of this extracts against Porphyromonas gingivalis. Methods: Sub gingival plaque samples were collected from individuals having periodontitis with the probing pocket depth of at least 6mm; Conventional microbiological tests and molecular technique used for confirmation of Porphyromonas gingivalis, hydrodistillation method was used for extraction of essential oil. Antibacterial activity of the extract against Porphyromonas gingivalis has been determined by using two fold serial dilution method to determine minimum inhibitory concentration (MIC) and minimum bactericidal concentration (MBC). Result: the essential oil extracted from Thymus vulgaris demonstrated antimicrobial effect against Porphyromonas gingivalis growth. Conclusion:The extract was able to demonstrate inhibitory and bactericidal activity against Porphyromonas gingivalis. Further studies should focus on the use of Thymus vulgaris essential oil in the treatment of periodontitis.

Keywords: Porphyromonas gingivalis, Thymus vulgaris, minimum inhibitory concentration, periodontitis.

Introduction

Thymus vulgaris is herb with an evergreen status and it is native to the Mediterranean and southern Europe area 1. The family Lamiaceae consists of approximately 150 plant genera with roughly 2800 species throughout the world, among which Thymus vulgaris, known as common thyme popularly 2. This plant has been used traditionally as a culinary component, to give flavor to cheeses 3,4 and liqueurs and meats 5,6. Now a day is a common ingredient of bouquet garni 7. In addition to its usefulness in foods, this plant is a well-known as a medicinal herb that has been used many years ago in treatment of alopecia, dental plaque, dermatophyte infections, bronchitis, cough, inflammatory skin disorders, and gastrointestinal distress 8. The major constituents of T. vulgaris essential oil are thymol (23%–60%), γ-terpinene (18%–50%), p-cymene (8%–44%), carvacrol (2%–8%), and linalool (3%–4%) 9. T. vulgaris essential oil has antibacterial, antifungal, and anti-inflammatory effects, accounting for the medicinal uses of T. vulgaris 8. The terpenoids and some hydrocarbons that are present in essential oils are responsible for their anti-microbial effect 10. For these purposes, researchers are searching for new antimicrobial agents, through the use of natural plant oils.

Porphyromonus gingivalis is major periodontal pathogens and one of the main etiological factors in the inflammatory episode in initiation and progression of periodontal disease 11. The therapeutic roles of Plant-derived essential oil products have been widely used in
the treatment of periodontitis. The data concerning the efficacy of this extracted oil against periopathogens is limited in Iraq. The objective of this work is to determine the antibacterial activity of the extracted essential oil from T. vulgaris against the growth of clinical isolates of porphyromonous gingivalis.

Materials and Methods

Setting: This study was approved by Ethics Committee Sulimani technical institute, Sulimani polytechnic University, Kursitan, Iraq.

Plant row material and extraction of essential oil

The T. vulgaris was collected in June-July, 2019 from the Piramagron Mountain, 50 km far from Sulimani city in north of Iraq. The plant was identified in College of Agriculture, University of Sulimani. The essential oil was extracted from the herb by hydrodistillation method; 100g of thyme soaked in 350 ml of distilled water in a conical flask and left for 5 hours using a Clevenger apparatus according to 13. The essential oil was collected after decantation and drying of the oils over anhydrous sodium sulfate, the oil stored under refrigeration (−4 °C) until its use.

Tested bacteria

Tested Microorganism was obtained from the Department of Biology, College of Science, University of Sulimani. Clinical strain was previously isolated from plaque of sub gingival deep pockets from patients having periodontitis according to 14.

MIC and MB determination

The antimicrobial effect of essential oil of thyme by detecting MIC was evaluated against a common oral pathogens in initiation of periodontitis by two fold serial dilution method, in which the stock solution of the tested material was prepared (800μL/1 ml) by dissolving the essential oil in (tween-80). For MIC, twelve dilutions of the essential oil were prepared by using Muller Hinton broth medium - two-fold serial dilution method. The procedure done by 1 ml from the stock solution was added into the first tube which contained 1 ml of broth. Then 1 ml of broth from the first tube was transferred into the second tube. The serial dilution was repeated for the tested agent till reach 0.2 μL /ml, thus the concentrations of serial dilution was—400, 200, 100, 50, 25, 12.5, 6.25, 3.12, 1.6, 0.8, 0.4, 0.2 μL /ml respectively.

To each of the above 12 prepared MIC tubes with different concentrations, 100μL of the earlier prepared suspension of bacterial (5*10 CFU/ml) was added to the tubes. Tubes were sealed with cotton and incubated for ≥48 h at 37°C in an anaerobic jar by using AnaeroGen® system Oxoid gas pack and observed for turbidity. The minimum concentration of the essential oil in the tube determined by which does not show any turbidity [Figure 1].

![Figure 1 different concentration of essential oil of thyme](image)
The determination of minimum bactericidal concentration (MBC) of thyme oil was done by choosing the concentrations that showed no bacterial growth during the evaluation of the MIC. Then a sample by micropipette was taken from the chosen tubes and spread on a blood agar plate using a spreader and incubated anaerobically. After 48 h at 37ºC, the plates that showed no growth of bacteria were identified as minimum bactericidal concentration [figure 2].

Results

Essential oil of thyme showed a significant inhibitory effect with mean MIC of 6.25 μL /ml. While, Mean MBC for the extract was 12.5 μL /ml as shown in (Table 1).

Discussion

Thymos is the name Greek that means small because of the fragrance of the plant, which belongs to over 300 species herbs and shrubs that are native to Europe and Mediterranean. It is one of the Hippocrates 400 simple remedies. Essential oil of Thymus Spp, vulgaris-Labiatae/ Lamiaceae) is got from the leaves and flowering tops of the herb. Its main constituents include 20-40% thymol and carvacrol with bornol, cineol, linalool, menthone, B-cymene, pinene and triterpenic acid. Thyme oil is a tonic stimulant used in stomachic and digestive system diseases such as gastritis, enterocolitis and mouth thrush. It was used in treatment of respiratory infections like asthma and bronchitis. It was useful in treatment of gout and rheumatic arthritis, for joint pains, backache and sciatica. Thyme oil is also used in urinary and genital
infections such as endometritis, prostrates and vaginitis\textsuperscript{1,2,15}. Thyme oil exhibits antibacterial activity and has been useful in dental practice\textsuperscript{16}. One of the components of thyme, which is thymol, has inhibitory effect on growth of oral bacteria that aid in decreasing dental caries\textsuperscript{17,18}. Study by Sköld-Larsson et al., demonstrated that use of a dental varnish containing thymol aid in reducing the amount of Streptococcus mutans in supragingival plaque near brackets\textsuperscript{19}. Thymol is used in mouthwashes because of its antibacterial activity such as Listerine mouth wash\textsuperscript{20}. Thyme oil also has antimicrobial effect against S. aureus, E. coli and C. albicans\textsuperscript{21-23}. Porphyromonas gingivalis is an anaerobic gram negative rod that is most prevalent etiological bacteria in periodontitis. Data on the inhibitory activity of Thymus vulgaris oil on this periodontopathic bacterium (p. gingivalis) is limited. A study by fani et al., exhibited antibacterial effect of thyme oil against p. gingivalis at (32 mg/mL)\textsuperscript{24}, while another studies showed higher concentration (62.5 mg/mL)\textsuperscript{25}. This study represents the first reported study in determination the antibacterial activity of essential oil of Thymus vulgaris in Kurdistan-Iraq against clinically isolated periopathogenic bacteria (P. gingivalis). In our study the minimum inhibitory concentration was 6.25 μL /ml. This difference with other studies may be due to harvesting time, climatic conditions, geographical origin, and sex of cultivars that affect the chemical compositions of essential oil which are responsible for their medicinal effects or their biological activity which varies from one region to another\textsuperscript{26}. MBC of the extract was 12.5 μL /ml against the P. gingivalis, indicated a bactericidal effect of the essential oil. The difference between bactericidal or bacteriostatic effect is clinically important in that bactericidal agents may be more effective in the treatment of diseases\textsuperscript{27}.

**Conclusion**

In this study, we report for the first time, the antibacterial activity of essential oil of Thymus vulgaris in Kurdistan region –Iraq against periopathogen p.gingivalis which was clinically isolated previously in vitro models. The extract of showed a significant antibacterial activity, therefore, it can be used as a natural adjuvant antimicrobial agent in treatment of periodontitis.

Salivary and Serum Aspartate Aminotransferase and Alanine Aminotransferase in An Uncontrolled Diabetic Patients

Dunya malhan henweet¹, Amina Ryhan Diajal²
¹Dentist in Department Of Oral Diagnosis, College of Dentistry / University of Kufa, Iraq, ²Assisitant professor in department of oral diagnosis, College of Dentistry / University of Baghdad, Iraq

Abstract

Background: Diabetes mellitus (DM) is a metabolic disorder, characterized by a higher level of blood glucose resulted from either abnormality in insulin production (type1 DM) or resistance to insulin action (type 2 DM) or both. Long lasting elevated blood glucose is responsible for chronic damage, defect in function and impairment of various organs including salivary glands. Aspartate aminotransferase (AST) and alanine aminotransferase (ALT) are cellular enzymes found in all animal tissues.

Aims of the Study: to estimate and compare the levels of salivary and serum AST and ALT between un controlled diabetic patients and normal control people.

Subjects, Materials and Method: The study comprised 90 adults of both gender. The patients were divided into 3 groups: 30 patients with type 1 diabetics (D1), 30 patients with type 2 diabetics (D2) and 30 healthy persons as a control group (C). Serum and un stimulated salivary samples were taking for the AST, ALT evaluating using standard spectrophotometer kits. The level of glycosylated hemoglobin (HbA1c) was measured using NycoCard kit to exclude the controlled diabetic patients. Data were analyzed using statistical analysis SPSS version 24.

Results: The results showed a significant increase of salivary enzymes in D1 and D2 compared to salivary enzymes of control group, while there was no significant difference in serum enzymes value among all studied groups.

Conclusions: An elevation in salivary AST and ALT in both types of diabetes compared to healthy group, with higher salivary level of AST and ALT in D1 compared to D2 and to healthy control group. This may suggest that autoimmunological activity in D1 responsible for more salivary gland injury in D1 group.

Key words: alanine aminotransferase, aspartate aminotransferase, diabetes mellitus.

Introduction

Diabetes mellitus is a group of metabolic diseases that are different clinically and genetically but with a common phenotype, defined by prolonged and abnormally high level of blood glucose with abnormal metabolism of carbohydrate, lipid and protein ¹.

The most important feature of DM is a long standing hyperglycemia, as a result of failure of the pancreas to produce insulin or cellular resistance to the insulin action or both. According to American Diabetic Association, diabetes mellitus is divided into 4 types: type1 which is due to damage of B-cells of the pancreas resulting in insulin reduction, type 2 is due to resistance of target organ to insulin cellular metabolic impact and the third type is the gestational DM that occur during pregnancy and another special type of DM due to other reasons ². Prolonged hyperglycemia in DM patients may lead to the formation of advanced glycation end products (AGEs) whose collection in blood and tissues is linked with DM complications ³. Uncontrolled DM increases the danger of complications, with HbA1c is an important plasma marker used to estimate the level of glucose amount in the plasma during the previous 2-3 months ⁴⁶. Cytological enzymes such as AST and ALT
may be considered as potential markers of salivary gland in the patho-mechanism of DM. Aminotransferases or transaminases are set of enzymes that stimulate the conversion of amino acid and oxalo acid by transmitting of amino groups to alpha-keto acid, so they are included in metabolism of protein. These enzymes are found in many body organs such as skeletal muscle, kidney, brain, pancreas, lungs, blood cells with more frequently found in the liver and heart, so any injury to these organs result in output of these enzymes into the extra cellular fluid.

### Subjects, Materials and Methods

This cross-sectional study composed of 90 subjects. The study group consists of 60 diabetic patients who were un controlled depending on the level of HbA1c test which should be above 8 %. All participants were carefully informed about the aim and objective of the study. Patients or their parents were sign a consent form after their agreement.

Patients were recruited from the Endocrinology and Diabetic Centre of AL-Sadder Teaching Hospital in AL Najaf city in Iraq, from December -2018 to March -2019).

The study group was divided into 2 groups; the 1st was 30 Type1DM patients and the 2nd was 30 Type 2DM patients. Control group consist of 30 healthy subjects without any history of systemic diseases, with an age and gender matched with the study group.

#### Inclusion criteria:

1. Patient with type1 and type 2 DM who were diagnosed at least 6 months before the study.
2. Patient without any systemic diseases.
3. Patient who was not taking any medications at least 3 months prior the study.
4. Non-smoker individual.
5. HbA1c test should be >8 %.

#### Exclusion criteria

1 Patients were excluded if they were on medications other than taking for type1 diabetes or type 2.
2. Those with any other systemic disease apart from diabetic mellitus.
3. Patient who will not sign his consent form.
4. Smoking patient.
5. If HbA1c test is below 8%.

### Saliva collection

The collection procedure of the saliva is by spitting method, with the subject was asked to set comfortably. Before collection of the saliva, patients were asked to rinse the mouth with distilled water.

Salivary sample were collected, for all subjects between 8 -11 a.m. to decrease the diurnal differences. Patient was asked not eat 1 hour before the sample collection, then saliva was collected for 10 minute and after that, saliva was placed in the ice box and send for laboratory for centrifuge (3000 rpm for 15 min) and then transferred for biochemical analysis.

### Blood collection

Two milliliters of venous blood was collected from antecubital vein, separated into 2 parts, one part in plan test tube for serum AST and ALT estimation, after centrifuging for 2 minutes, and in another test tube containing anticoagulant for HbA1c estimation. If the level of HbA1c was above 8%, then the collected samples in the plain tube (serum tube) were distributed in the appendrove tubes which then transferred for biochemical analysis.

### Method for AST, ALT determination

Estimation of serum and salivary AST, ALT were done by standard spectrophotometer method (340 nm) with the aid of kinetic spectrophotometer kits from AGGAPE Diagnostic (Switzerland) according to international federation of clinical chemistry (IFCC).

### Statistical Analysis

Descriptive statistic, mean, ANOVA test for variance analysis, post hoc (Dunnett T3) test, student T test and Pearson coefficient tests were used.

### Results

Salivary and serum Aspartate aminotransferase
Using ANOVA test, a highly significant difference was found in salivary AST value among type 1, type 2 and control groups (p=0.000), table (1-1).

Regarding the duration of DM, patients were divided into 2 groups: more than 5 years duration and less than 5 years duration.

There was a statistically significant increase in the level of salivary enzymes in group less than 5 years compared to those of more than 5 years in type 1 DM. Considering the level of enzymes in the serum, no significant difference was found in relation to disease duration.

**Discussion**

In the present study, there was statistically significant difference in the salivary AST and ALT levels in type1 and type2 DM as compared to salivary level of the control group. This is in agreement with other studies which found salivary AST and ALT levels was higher in type1 compared with type 2 DM and to healthy control group (3,7,9) as they were found three fold and four fold elevation in salivary level of AST and ALT of type1 DM group as compared to control group, respectively, similar to the result of present study.

Comparing type 1DM to type 2 DM, there was increasing in the salivary mean AST and ALT levels in type1 as compared to type2 DM was seen in the current study as there was twofold increasing in ALT and AST in type1 DM as compared to type2 DM group. This finding is consistent with what was reported in a study of Malicka et al. (2016) who reported twofold elevation in salivary AST and ALT levels as compared to type 2 diabetic group, also in agree with studies of (10,11,12) who found AST and ALT value were higher in type1DM as compared to type 2 DM. So the results of present and past studies support the hypothesis that an auto immunological process in type 1 DM will lead to salivary glands damage and increased level of these enzymes (3,10).

There was no significant difference was seen in serum levels of AST and ALT among study groups although there was slight rising in the value of AST and ALT in diabetic groups which is in parallel with a study that done by Vinod et al. (2018) who reported normal serum value of ALT and AST in diabetic and control groups but no statistically significant. Although the result of a study done by Vinod (2006) found normal value of serum AST and ALT levels in type 1 DM patients, but he was found significant difference regarding serum enzymatic value between type1 DM patients and control group.

Lactate dehydrogenase, aspartate aminotransferase and alanine aminotransferase are widely present in the body tissues and whole cells (cytological enzymes) especially in the cytoplasm of the cells in addition to that, AST is also located in the mitochondria. When there is damaging to the tissue, serum levels of these enzymes will be elevated as a result of their infiltration from the tissues that were damaged. In turn, elevated salivary level of AST and ALT may be attributed to damage to cells of the salivary gland by different way (3,10,13).

Also the study that done by Cinquini et al. (2002) on type1 DM children reported damage in the salivary gland demonstrated by histopathological presentation of lymphocytic cells in the damaged glands cells. So, it was reported that there was an immunological activity in the salivary gland and causing cells damage similar to the action of antibodies to pancreatic B cells as there was particular antibodies against antigens of the salivary gland (10). This demonstrated why level of salivary AST and ALT were higher in type1 DM when compared to type2 DM and to control group.

It was found that inflammatory process of periodontal tissues in the same time of presence of DM causing elevation in the salivary value of AST and ALT (14). The present study reported different periodontal disease in two diabetic groups so this lead to a suggestion that autoimmunological activity plus periodontal inflammation will result in significantly elevated salivary level of AST and ALT in type1 DM as compared to type 2 and healthy groups; also in type 2 when compared to healthy control group.

In addition to that, this study reported a statistically significant difference in salivary levels of AST and ALT in type1 DM regarding different disease durations as their values were higher in 1-5 years duration than in more than 5 years duration of DM. This result consistent with the findings that were reported by (7,10, 11) who found higher levels of AST and ALT in patients discovered with diabetes since 4 years and 5 years clinical duration, respectively.

Although Vinod (2006) and Vinod et al. (2018) found high levels of salivary AST and ALT in 0-5
year clinical duration of diabetes than in more 5 years duration, but was found no significant difference in serum and salivary AST and ALT values in different disease duration, but this study found statistically significant difference in salivary values of AST and ALT regarding different disease durations may be due to size of the sample and patient condition.

On the other hand, it was found no significant difference in serum and salivary enzymes level in different type2 DM duration. This finding is consistent with the study done by Al-Rubaee et al. (2010) (15) who reported no significant difference between salivary enzymes activities and various disease durations.

Effectiveness of an Educational Program Regarding Postpartum Care on Women’s Practices in Primary Health Care Centers at Amara City /Iraq

Rasha Leteef Neamah¹, Ezedeen F. Bahaaldeen², Iqbal Majeed Abbas³

¹Academic nursing Specialist, High Institute of Health Vocational, Ministry of Health. PhD student, ²Ph.D. Prof. and Academic Supervisor, Department of Maternal and Neonatal Nursing, College of Nursing; ³Ph.D. Emeritus Professor and Academic Supervisor, Baghdad college of Medical Sciences/ Department of Maternal and Neonatal Nursing

Abstract

Objective: determined the effectiveness of educational program on women’s practices for Mothers’ Care in Postpartum Period in Primary Health Care Centers at Amara City.

Methodology: Quasi-experimental design is accomplish on non-probability (Purposive sample) used to collect the data from 172 multigravida women, (86) study group and(86) control group who were selected from the eight primary health care centers (AL-Uroba Primary Health Care Center, AL Zahraa Primary Health Care Center, AL Hasen AL-Asker Primary Health Care Center, AL-Qudis primary health care center, AL-Ameer primary health care center, AL-Jawideen primary health care center, AL- Amam AL-Husaaan. Primary health care center and Ali AL-Ridha Primary Health Care Center.) These centers are choose randomly from 16 primary health care centers in the first sector. The study was conducted from (1st December, 2018 to 1st December, 2019.).

Results: The findings of the study indicated that (48%), (45%) respectively were in the age group (24-31) years for both study and control groups, a quarter of the both study and control group were primary school graduates, more than three quarter were housewives for both study and control groups, The majority of the women were living in urban area specifically for the study and control group, the majority of women in the study and control group were live equally of nuclear and extended families. Regarding to the reproductive characteristics more than a fifth women had five-six pregnancies for study group and quarter of the control group were had three pregnancies, and around a quarter of the study group were have three deliveries and more than fifth for control group were had two deliveries, as well as, three quarter of women in the both study and control group reported that they do not have abortion 64(74.4%), 62 (72.1%) respectively.

Key words: Education, Effectiveness, Postpartum Period, Practices, Women

Introduction

Postpartum period marks the establishment of a new phase of family life for women and their partners and the beginning of the lifelong health record for newborn babies¹, These have highlighted widespread and persistent health problems experienced by women after childbirth, many of which are unreported by women and not identified by healthcare professionals, common health problems include physical morbidity such as backache, breastfeeding problems, perineal pain, stress incontinence, and mental health problems², such as postnatal depression³. Mothers and their newborn babies are at highest risk of dying during the early neonatal period, especially in the first 24 hours following birth and over the first seven days after delivery it estimate about 45% maternal mortality, (50%) newborns who die do so in the first 24 hours after birth, and 65% Maternal mortality, and (75%) neonatal deaths occur within one week of birth (²) Postpartum period, or puerperium, starts about an hour after the delivery of the placenta and includes the following six
weeks. Postpartum care should include the prevention and early detection and treatment of complications and disease, and the provision of advice and services on breastfeeding, birth spacing, immunization and maternal nutrition (3).

Traditional practices are usually derived from the relations with the environment and the attitude of early humans toward nature. These practices usually develop over time and by trial and error in most cases (4).

Mothers in purperium period may be suffering from illness, heaviness, inability to speak, crying, loss of appetite, high fever, bruises, delusions and somniloquy. The example for the practices of mothers use to guard against puerperal fever including not leaving the household for 40 days, not being alongside another mother, not being left alone with the infant for 40 days and 40 nights, keeping a talisman and the Quran at hand, putting scissors or a knife under their pillow and hanging onions or garlic near their bed (5).

Every society and country has its own traditional belief and practice related to postpartum care, most of the practices like rituals and belief, some of the practices are beneficial to the mother and children (6).

Methodology

Quasi-experimental design is accomplish on non-probability (Purposive sample) used to collect the data from 172 multigravida women, (86) study group and (86) control group who were selected from the eight primary health care centers (AL-Uroba Primary Health Care Center, AL Zahraa Primary Health Care Center, AL Hasen AL-Askerry Primary Health Care Center, AL-Qudis primary health care center, AL-Ameer primary health care center, AL-Jawideen primary health care center, AL- Amam AL-Husaan. Primary health care center and AL-AL-Ridha Primary Health Care Center.) These centers were chosen randomly from 16 primary health care centers in the first sector. The study was conducted from (1st December, 2018 to 1st Decebet, 2019.). The questionnaire was consisted of three main parts, including: part 1 socio-demographic characteristics, part 2/ Reproductive Characteristics and part three women’s practices toward postpartum period this part consisted of (23) items these part consists of (three) domain, first domain: women’s practice toward nutritional behaviors in postpartum period, this domain consists of (nine) items. Second domain: women’s practice about breast feeding: this domain was consisted of (seven) items. Third domain: women’s practice related to personal hygiene, this domain was consisted of (seven) items. The content validity of questionnaires are determined through 12 panels of experts from different fields.

Ass. = Assessment, C.S. = Comparative Significance, Corr. = Correct, f = Frequency, H = High R.S less than 66.6% (Low), 77.77% - 88.88% (Moderate), 88.89%-100% (High), MS = Mean Score, n = Number of sample, R.S = Relative Sufficiency, % = Percentage, t = t-test, S = Significant at P-value ≤ 0.05.
Table (1) shows that more than a fifth had 5-6 pregnancies (19; 22.1%) for study group while more than a quarter have the same pregnancies (23; 26.8%) for control group, and Regarding parity around a quarter have three deliveries (n = 22; 25.6%). for study group and for control group less than a third have two deliveries (n = 26; 30.2%), These finding indicated that most of the study sample were “grandmulti gravida & para”. The study concluded that the study sample may had no awareness for using family planning ,or the desire and attitude of the couples to have big family related to the social norms and culture perspectives of the area in Governorate of Mysan. Begum (2003) who reported that the lack of health education ,religious taboos ,against the use of family planning methods and vogue of having large families (especially in a rural areas ) accounts for the increased complications associated with high gravidity(15). Shahid and Moshtaq (2009) who reported in their study that maternal complications increased with the increased of parity ,so the grandmultipara still as high risk pregnancy .In addition the risk of having suboptimal pregnancy outcomes increase in women who are experiencing their sixth or higher birth(16).

Alameda (2006). In a cross-sectional analysis of over 500,000 women delivered between 1992 to 1997 in New South Wales ,Australia ,the incidence of obstetric complications found to be increased significantly from parity 4 onwards.

Number of Live Children

Regarding the number of live children, more than a quarter reported that they have three live children (24; 27.9%), for study group , and for control group, less than a third reported that they have three live children (28; 32.6%). This result agree with Masoud and Saber(2016) who was conducted on (100) primiparous and multiparous, at the BeniSuef general hospital in Egyptian. They showed that shows that; nearly more than quarter of the sample of pregnant women had three live children (26%) (17).

Gestational Age

Regarding the gestational the result indicated that more than a half of study and control group weeks(46; 53.5%),(46; 53.5%) respectively were their gestational age between 35-38 weeks. This result agree with Salhi e et al., (2019) they conducted at Maternity & Children’s Hospital at the city of Najran,Saudi Arabia, between May and August 2018, on 502 women , who showed that( 49.6%) were 37–40 weeks of pregnancy. The results of present study indicated that major study sample were in third trimester, and Commitment visits within this trimester (22).

Conclusions

The study was concluded there was a statistically significant difference in women’s overall practices related to puerperium between the pretest and posttest for study group while for the control group, there is no statistically significant difference in women’s overall practices during puerperium between the pretest and posttest times.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

The changes in Blood Pressure in Patients Undergoing Spinal Anesthesia According to the Size of Spinal Needle (G22 versus G24): Case Reference Study

Ahmed Matrood Kadhim1, Salman Abbas Badi 1, Watheq Maeh Naji1

1Anesthesia and Intensive Care Specialist / Al-Diwaniyah Teaching Hospital / Department of Anesthesia / Al-Diwania / Iraq

Abstract

Background: Previous studies of patients with spinal anesthesia prior to sympathectomy revealed that vasodilatation and hypotension, with subsequent reduction in arterial pressure, were the most common side effects (observed in more than 30% of patients). Hypotension in epidural anesthesia was stated to be more gradual and less extreme than in spinal anesthesia when a comparable amount of anesthesia was given.

Aim of the study: In the current study, we are aiming to evaluate the effect of different size of spinal needle on development of possible blood pressure changes throughout the spinal anesthesia procedure.

Patients and Methods: The current observational case reference study was carried out at Al-Diwaniyah Teaching Hospital in Al-Diwaniyah Province, Iraq. The beginning of the study is dated back to the 3rd of April 2018 and the study continued till September the 15th 2019. It included 60 patients undergoing spinal anesthesia for various surgical operations. In 30 patients a spinal needle of 22 gauge was used whereas in the second group (n = 30), a spinal needle of gauge 24 was used. All patients were instructed to be nil by mouth overnight.

Results: In group 1 (22G), mean systolic blood pressure showed gradual reduction, 139.00 ±8.35 mmHg, 120.67 ±11.43 mmHg, 106.00 ±11.02 mmHG and 97.33 ±10.15 mmHg; similarly, in group 2 (24G) mean systolic blood pressure showed gradual reduction, 144.00 ±10.37 mmHg, 138.00 ± 7.61 mmHg, 131.33 ±9.00 mmHG and 131.67 ±11.40 mmHg; however, the rate of reduction in group 2 (G24) was less than that seen in case of group 1 (G22). In group 1 (22G), mean diastolic blood pressure showed gradual reduction, 84.00 ±7.24 mmHG, 72.00 ±6.64 mmHg, 61.33 ±9.73 mmHG and 54.00 ±8.94 mmHg; similarly, in group 2 (24G) mean diastolic blood pressure showed gradual reduction, 87.33 ±7.85 mmHg, 81.33 ±7.30 mmHg, 77.33 ±10.15 mmHG and 78.00 ±5.51 mmHg; however, the rate of reduction in group 2 (G24) was less than that seen in case of group 1 (G22).

Conclusion: It appears that the use of narrower spinal needle is recommended as it is associated with significantly less drop in both systolic and diastolic blood pressure, thus less hemodynamic disturbances in patients undergoing spinal anesthesia for various indications

Key words: blood pressure, spinal anesthesia according, spinal needle (G22 versus G24)

Introduction

The introduction of regional anesthesia accompanied the isolation of local anesthetic agents, cocaine being the first one, and the first regional technique can be traced back in time to 1898 when the German doctor August Bier did the an operation using spinal anesthesia 1. The spinal anesthesia is included within the umbrella of neuraxial type of anesthesia in which the local anesthetic agent is introduced directly into the subarachnoid space (intrathecal space) 2,3. The form of anesthesia procedure used depends on different factors, such as the desires of the anesthesiologist and patient, in addition to the age of the patient, the type of operation, underlying disorders,
the location of the body intraoperatively, the length of the surgery and the methods of pain management. Regional anesthesia (spinal and epidural) is often used for surgery involving the lower abdomen or limbs to produce the sensory levels required while having minimal effects on the sympathetic nervous system. Spinal and epidural anesthesia contraindications include patient resistance, sepsis, site infection, increased intracranial pressure, local anesthetic allergies and inability to maintain the required body position. A range of advantages have been identified in conjunction with spinal anesthesia, such as negligible failure rate, anesthesia onset is very rapid, pain relief is satisfactory due to dense neuronal blockage and patient morbidity avoidance after major surgery; however, solid opinion about these benefits is lacking. This form of anesthesia is actually preferred for the procedure of the cesarean section due to the rapid start of action. The results of some meta-analyses and randomized controlled clinical trials are uncertain about the outcome and benefits of spinal anesthesia.

A number of drawbacks have been identified in connection with spinal anesthesia, such as short-term pain relief, increased incidence of hypotension and post-spinal puncture headache. Previous studies of patients with spinal anesthesia prior to sympathectomy revealed that vasodilatation and hypotension, with subsequent reduction in arterial pressure, were the most common side effects (observed in more than 30% of patients). Hypotension in epidural anesthesia was stated to be more gradual and less extreme than in spinal anesthesia when a comparable amount of anesthesia was given.

In the current study, we are aiming to evaluate the effect of different size of spinal needle on development of possible blood pressure changes throughout the spinal anesthesia procedure.

Patients and Methods

The current observational case reference study was carried out at Al-Diwaniyah Teaching Hospital in Al-Diwaniyah Province, Iraq. The beginning of the study is dated back to the 3rd of April 2018 and the study continued till September the 15th 2019. It included 60 patients undergoing spinal anesthesia for various surgical operations. In 30 patients a spinal needle of 22 gauge was used whereas in the second group (n = 30), a spinal needle of gauge 24 was used. All patients were instructed to be nil by mouth overnight.

They were given the following premedications: ranitidine 50 mg and metoclopramide 10 mg. An intravenous line was established using the antecubital vein by an 18 gauge cannula on arrival to operative room. Monitoring included: pulse oximeter, blood pressure, pulse rate and ECG. An intravenous fluid in the form of ringer lactate was given in a dose of 10mg/kg for 10 minutes before starting subarachnoid block. A midline approach was used with the patient in sitting position at L3-L4 or L4-L5 level with a Quincke spinal needle (22G or 24G). Keeping the needle bevel parallel to dural fiber was assured. Injection of heavy bupivacaine 9-12.5 mg (1.8-2.5ml) was performed once clear CSF fluid was obtained.

The approval of this study was made by the institutional ethical approval committee and a verbal consent was made by every participant. Variables included in the current study were gender, age, type of operation and successive measurements of blood pressure. The obtained data were transformed into an SPSS (IBM, Chicago, USA, version 23) spread sheet for purpose of statistical description and analysis. Chi-square test was used to study association between categorical variables whereas, independent samples t-test was used to study mean difference of quantitative variables between the two study groups. The level of significance was set at P ≤ 0.05.

Results

The present study included 60 patients undergoing spinal anesthesia for various types of operations who were randomly allocated into two groups according to spinal needle caliber size (gauge 22 versus gauge 24). The age range and mean age in addition to frequency distribution of patients according to gender are shown in table 1. There was no significant difference in mean age and frequency distribution according to gender between both study groups (P > 0.05), table 1. Table 2 shows the frequency distribution of patients according to type of surgical operation.
Table 3 showed the mean systolic blood pressure readings at baseline, 10 minutes, 20 minutes and 30 minutes. In group 1 (22G), mean systolic blood pressure showed gradual reduction, 139.00 ±8.35 mmHG, 120.67 ±11.43 mmHg, 106.00 ±11.02 mmHG and 97.33 ±10.15 mmHg; similarly, in group 2 (24G) mean systolic blood pressure showed gradual reduction, 144.00 ±10.37 mmHG, 138.00 ± 7.61 mmHg, 131.33 ±9.00 mmHG and 131.67 ±11.40 mmHg; however, the rate of reduction in group 2 (G24) was less than that seen in case of group 1 (G22), table 3 and figure 1.

Table 4 showed the mean diastolic blood pressure readings at baseline, 10 minutes, 20 minutes and 30 minutes. In group 1 (22G), mean diastolic blood pressure showed gradual reduction, 84.00 ±7.24 mmHG, 72.00 ±6.64 mmHG, 61.33 ±9.73 mmHG and 54.00 ±8.94 mmHg; similarly, in group 2 (24G) mean diastolic blood pressure showed gradual reduction, 87.33 ±7.85 mmHG, 81.33 ±7.30 mmHG, 77.33 ±10.15 mmHG and 78.00 ±5.51 mmHg; however, the rate of reduction in group 2 (G24) was less than that seen in case of group 1 (G22), table 3 and figure 1.

The difference in mean blood pressure, whether systolic or diastolic, at similar occasions (10, 20 and 30 minutes) was highly significant between group 1 and group 2 (P < 0.001), tables 3 and 4.

Discussion

Despite being widely accepted by both patients and doctors, spinal anesthesia has some disadvantages that limit its use as a universal technique of anesthesia replacing the need for general anesthesia in daily surgical practice. Based on our clinical experience in Al-Diwaniyah teaching hospital, probably the most feared complication seen in association with spinal anesthesia is the development of hypotension. In the current study we demonstrated that blood pressure gets reduced with advancing time during spinal anesthesia; however, the magnitude of pressure reduction was clearly and significantly affected by needle size, being less with smaller caliber spinal needle of G24 in comparison with wider caliber spinal needle of G22.

Hypotension is a typical spinal anesthesia side effect and occurs in 16–33% of cases (Carpenter et al., 1992). This response is amplified in the elderly where a negative effect on a relatively higher sympathetic resting tone and reduced baroreceptor activity can explain the increased incidence of hypotension in response to spinal anesthesia (Salinas et al., 2003; Hartmann et al., 2002). Either a drop in systemic vascular resistance (SVR) or cardiac output (CO) or both are thought to cause hypotension after the onset of spinal anesthesia (Hofhuiizen et al., 2019). A decrease in SVR has been identified by several previous studies as the main determinant of hypotension. In these previous studies patients were given fluid loading just after or before the onset of spinal anesthesia (Lairez et al., 2015; Nakasuji et al., 2012). The loading of the fluid will greatly increase the intravascular volume and therefore the venous return (Hofhuiizen et al., 2019).

Probably this study is the first study that raised the issue that smaller size spinal needle is associated with significantly less drop in blood pressure during spinal anesthesia technique. Indeed, more research work is needed, experimental and clinical, in order to know exactly the mechanism explaining the lower reduction in blood pressure in association with smaller size spinal needle; however, for the present time it appears that the use of narrower spinal needle is recommended as it is associated with significantly less drop in both systolic and diastolic blood pressure, thus less hemodynamic disturbances in patients undergoing spinal anesthesia for various indications.

Nurses’ Knowledge based on Evidence Based Practice toward Eye Care for Intensive Care Units Patients

Sabah Abdullah Jaafr1, Mohammed Baqer Al-Jubouri2, Dergham Majeed Alfatlawee3

1Assistant Instructor, Adult of Nursing Department, College of Nursing -University of Al Muthanna, Samawah, Iraq, 2 Ph.D., Adult of Nursing Department, College of Nursing - University of Baghdad, Iraq, 3 Prof., Adult of Nursing Department, College of Nursing -University of Al Muthanna, Samawah, Iraq

Abstract

Background: Eye care in intensive care units is crucial to avoid eye problems associated with infections, use of medications, effect of mechanical ventilators, and patient position. Indeed, there is no specific guideline or protocols use in eye care in Iraqi intensive care units, so the study focused on nurses to assess their knowledge regarding evidence-based practice toward eye care.

Objectives: The objective of this study was to assess nurses’ knowledge regarding evidence-based practice toward eye care in intensive care units, and to find out relationships between their demographics and total knowledge.

Method: A descriptive study using a purposive sample (non-probability) was used to survey 30 nurses who met the sampling criteria in two teaching hospitals in the south of Iraq to assess their knowledge regarding eye care. A valid and reliable tool was used after getting the permission from the copyright holder.

Results: More than one-third of study sample were (22-26) years old they account (40%). Majority of them were male (56.7%), and (53.3%) of the study sample had bachelor’s degree in nursing. Regarding years of experience half of the study sample had more than five years of experience in intensive care units. Majority of the study sample (63.3%) has no participation in training courses about eye care and (83.3%) was day shift of work. The total mean of score of nurses’ knowledge was poor (0.33).

Conclusion: There is a need to conduct training courses for nurses who work in intensive care units about eye care based on standard as the results in this study indicated that there is a significance association between, nurses’ knowledge and participation in training course, about eye care.

Keywords: Eye Care, Nurse, Evidence Base, ICU Patients.

Introduction

The application of nurses’ knowledge in the critical care units promotes the professional identity of nursing practice. In intensive care units (ICU), the kingdom of nursing, nurse can play role, not only delivery of eye care and treatment, but rather assessment and diagnosis of eye disorders related to infection and can prevent complications if well trained and utilize right knowledge [1,2]. Unfortunately, nurses’ backgrounds regarding knowledge, even practice, toward eye care remains to be performed based on individual beliefs and tradition and documentation oftentimes unsatisfactory and poor [3,4]. The Royal college of Ophthalmologist (2017), designed guidance for non-ophthalmic staff in ICU includes, most common eye problems, identify disease and treatment when deliver to the eye when it is prescribed also, addressed factors such as, long length stay of mechanical ventilation, use of sedative drugs, and positive pressure ventilation as factors that can increase
risks of eye problems for patients with unconscious state [5]. Also, eye closure control, loss ability of blinking and tearing among ICU patients who are mostly comatose, sedated, paralyzed and under mechanical ventilation, because the altered level of consciousness (LOC), can cause ocular surface disease [6]. Eye closure is important to protect ocular surface (OS) via prevent not only the dryness but also bacterial growth. On the other hand, long-term eye closure decreases tear secretion and distribution, causes hypoxia and hypercapnia [3]. Blinking is important for distributing tears and sustaining eye health. Guler Eser & Fashafsheh in their international comparison study reported, that the impact of mechanical ventilation, intubation and tight securing taping for the artificial airways increase the intra-ocular pressure and aggravate cause chemosis (ventilator eye) [1]. Many literatures confirmed, not only pressure and infection related mechanical ventilation has effects on the eye, also patient positioning [3,7]. The prospective study investigates the effect of body position on intraocular pressure (IOP), confirmed the prone position record highest pressure among both, investigated and healthy groups [7]. Although, there are many studies in the world focused on eye care in intensive care units, in Iraq the information on this subject is inadequate [1,2,8,9,12,14]. In Iraq also, literatures published about eye screening and care in many types of eye disease in public, there is no study yet, assess nurses’ knowledge based on evidence-based practice toward eye care in ICUs [10]. The main goal of this study was to fill the gap and assess nurses’ knowledge based on evidence-based practice toward eye care for ICU patients in Iraq. The author hypothesized that most of nurses’ who works in ICUs in Iraqi hospitals have no enough knowledge toward eye care based on evidence-based practice.

Material and Method

Design: This is a descriptive study that was conducted to describe Iraqi nurses’ knowledge toward eye care using a questionnaire that contains questions based on evidence.

Ethical Approval: This study approved and permitted by Center of Staff Development and Scientific Research in the health directorate. The IRB was obtained from University of Al Muthanna. The purpose of the study was explained to the nurses who work in the ICUs in the selected hospitals. The informed consent was reviewed and permitted by the Center of Staff Development and Scientific Research. Every participant had the right to withdraw from the study at any time without any penalties.

Study sample: A non-probability (purposive) sample technique was used to collect the data. The populations are nurses who work in ICUs in Iraqi hospitals. The target population that provided the sample data was a group of nurses who met the sampling criteria. All male and female nurses with different educational levels who work in ICUs were included in this study. Also, nurses who work in day and night shifts were included in this study.

The total sample size was 42 who agreed to participate in this study. 12 participants did not wish to continue in the study or their responses were not complete, so they were excluded from the study sample. The total of 30 completed surveys was included in the statistical analysis.

Instrument: A valid and reliable tool that was developed by Fasafsheh et al. 2013, was used to collect the data in this study. The reliability of this tool shows, Cronbach’s alpha was 0.854, he permission to use this tool was obtained via email [11]. This tool consists 30 questions regarding eye care for ICU patients that are based on evidence. The total score for the tool measured based on the mean of the answers (<0.53= poor knowledge, 0.53- 0.79 =fair knowledge and > 0.79= good knowledge).

Also, the questionnaire included nurses’ demographics: age, gender, level of education, years of experience in the ICU, years of experience as a nurse, shift of work, and participation in training courses about eye care.

Data Analysis: The statistics done by the Statistical Package for the Social Sciences (SPSS) version 24 software was used to perform the statistical analysis that included descriptive statistics (frequency, percentage, cumulative percent and mean of score) and inferential statistics(standard deviation and Chi- square).

Findings

From the total 42 participants, 30 nurses completed
the survey and included in the statistical analysis. 40% of the nurses were between (22-26) years old with the mean of age (29.63) and standard deviation is (6.77). 60% of the study sample were married. Regarding to the gender distribution, male nurses were more than half of study subject (57.7%). Most of the nurses (83.3%) worked in day shift. Regarding their educational level, more than half of the nurses have bachelor’s degree in nursing (53.3%). The years of experience in ICU were half (50%) less than five years of the study sample, and 56.7% of them had more than five years of experience as a nurse in hospitals. Regarding the participation in training courses in eye care, 63.3% of study subject did not participate in any training courses about eye care for ICU patients. Table (1) Significance association between total mean of scores of nurses’ knowledge and their demographic characteristics (Age groups, gender, marital status, educational level, years of experience in ICUs, years of experience in nursing, and shift of work). The results showed that there are no significance differences between nurses’ knowledge toward eye care and their demographics. The total nurses Knowledge poor the mean of score (0.33). However, the results highlighted that participation in training courses regarding eye care has a significance association with nurses’ knowledge ($X^2$=10.622, p value=0.004)

**Discussion**

This study assessed nurses’ knowledge who work in ICUs in Iraqi hospitals. Even eye care are not top priority in nursing care, but it is basic for every nurse work in ICUs even, non ophthalmic nurses. The results in this study revealed that nurses’ knowledge toward eye care is not significantly differ regarding demographics such as age, gender, marital status, educational level, years of experience in ICUs, years of experience as a nurse, and the work shift. It was not expected for researchers to see these results because logically high level of education and long years of experience in ICU or hospitals could increase nurse’s knowledge toward evidence-based practice. However, this can be explained as nurses in Iraqi hospitals, especially in ICUs, do not practice based on evidence, and the results of this study clearly found that most of the nurses had poor knowledge regarding eye care based on standard care. Therefore, further
studies can be conducted to assess Iraqi nurses’ practice regarding eye care based on evidence-based practice.

The results in this study showed that most of the study sample was highly educated and had bachelor's degree in nursing; this result agrees with Khalil et al. 2019 [12]. However, there was no significant difference between nurses’ educational level and their level of knowledge regarding eye care for ICU patients. This indicates that evidence-based practice is not a focused topic in nursing education. The researchers in this study recommend that evidence-based practice must be more engrossed in nursing curriculum in undergraduate programs. Although most of the study sample in this study reported that they have not participated in any training courses regarding eye care, the results highlighted that there was a significant difference between nurses’ knowledge and participating in training courses regarding eye care. Alghamdi et al. 2018, assessed ICU nurses’ knowledge and perception about eye care were the most of their study sample not participated in training course about eye care and no significance with their knowledge [13]. These results were expected by the researchers, and the current study recommends conducting training courses regarding eye care based on standard care for nurses in Iraqi hospitals within continuous education to increase their knowledge, which can lead to patient safety and enhance quality of care.

**Conclusion**

The results in this study showed that little of nurses’ who work in ICUs have enough have knowledge regarding eye care for ICU patients that should be done based on evidence-based practice. The study is suggesting conducting training courses for nurses within continuous education in hospital is crucial to increase nurses’ knowledge toward standard practices. Also, teaching based on evidence-based practice in undergraduate nursing programs can play an important role to increase students’ knowledge who will be those nurses that would work in ICUs. All these steps can enhance the quality of care, provide patient safety, reduce costs, and decrease work burnout.

Prevalence of Musculoskeletal Pain among Iraqi Dentists

Alia Tabour Thijeel
Assist. Lecturer, Prevention department, Technical Medical Institute, Middle Technical University/Iraq

Abstract

Introduction: Prevalence of musculoskeletal disorders (MSD) very high among dentists world wide. Among these MSDs, neck pain & Low back pain are most common. Objective: After extensive search on prevalence of MSDs pain among dentists in different countries, we planned a study to examine prevalence among Iraqi dentists. Methodology: this study was cross sectional survey study conducted at Medical institute of Baghdad, Al-Falah dental center and Prosthetic and orthodontic dental center. Dentists were selected using simple randomized methods and using certain exclusion and inclusion criteria. Results: All participants filled the questionnaire forum. 44.4% were male, 66.6% female. Prevalence of back pain was 18.9%, Neck pain was 13.3%, 2.2% had hand pain, 30% had no pain. Conclusion: High prevalence of MSDs in general reach to about 70% and the most affected area were as fellow: Neck & shoulder, back and hand. Male and young age were more prone to different MSDs.

Keywords: Musculoskeletal pain, Prevalence, Iraqi, Dentists

Introduction

Job-related musculoskeletal disorders (MSDs) are common disorders among dentists especially neck and low back pain. There are many contributing factors for these disorders among dentists like long working hours, Awkward working postures, use of heavy instrument and limited work area with a limited scope of movement leads to overexertion of cervical spine and lumbar spine. Low back pain (LBP) is the most frequent complaint, and nearly all dentists worldwide have experienced this pain at some point during their careers. Prevalence for both low back pain and neck pain were high for both gender with some differences. Female dentists showed a higher frequency of cervical, lumbar, dorsal, and wrist pain. On the other hand, another study reported a higher frequency of back pain among male dentists while female dentists were at higher risk of tendonitis. It is also possible that dental students can experience musculoskeletal problems even during their clinical training period. As the prevention of MSDs could be better than cure, Various preventive measures could be taken such as stretching before work, taking a break in the middle of working hours, avoid awkward postures, and reduce repetitive motion. However, still there are many other factors that causes MSDs. After extensive search on prevalence of MSDs pain among dentists in different countries, we planned a study to examine the prevalence of MSDs among Iraqi dentists and differences in gender and different age groups.

Material and Method

This study is a cross sectional design using printed questionnaire forum. We take a sample of 180 dentists, who were selected using simple random sampling method with the provisions of a maximum 60 years old and have been active for at least one year of private practice. Participants were excluded if they had any past history of spinal deformities, spinal malignancies, musculoskeletal & neurological disease that may be vulnerable factor for neck & back pain, trauma to spine. A signed written inform consent was taken from dentist consisting of information about the details of the study. 100 of them were females and 80 were males. The study was conducted on 21 December 2018 and 21 February 2019. The questionnaire used for the study printed in Arabic and consisted of 15 questions about the general information(age, sex, weight, height, smoking) and woks history (subspecialty, presence of assistant, working hours per day, working years) and history about MSDs pain(onset, site) and some questions about preventive measure (knowledge, take into account or not
while working and if they were referred to a doctor and if they were taking medication for their symptoms. The dentists were selected from the following places:

1. Medical institute of Baghdad.
2. Al-Falah dental center.
3. Prosthetic and orthodontic dental center.

### Results

44.4% of dentists were male whereas 66.6% were females, 70% had pain in hand, neck & shoulder or back. Highest single pain experienced was back pain making 18.9% whereas neck pain experienced by 13.3%, 2.2% had hand pain, 30% had no pain, as shown in Table-2.

Discussion

The Purpose of our study was to see the prevalence of back, hand, neck & shoulder pain among Iraqi dentists as single entity and combined. The overall prevalence of MSDs in dentistry differs from 63% to 93% worldwide.

Wide, in our study, it was 70%. Prevalence of hand pain was 2.2% and back pain was 18.8% and neck & shoulder pain was (we consider them in our research as a single entity) 22.2% alone not combined while other studies showed prevalence of neck pain 30% and back pain was also 30% that may or may not associated with other pain area. Male dentists were more likely to have MSDs this is supported by recent research done by Kaur J et al., (2018) but different to older syudy done by Unruh AM. In contrast to other studies, our study showed higher prevalence of different musculoskeletal pain among the youngest age group (24-34) this may be due to not caring about proper posture, longer working hours and not taking breaks in between.

Proper exercise management can reduce the effects of overused repetitive micro trauma and relaxation of shortened muscles. This holistic technique might be a challenge to dental professionals, but the result benefits in reducing MSD symptoms.

Conclusion

High prevalence of MSDs in general reach to about 70% and the most affected area were as fellow: Neck & shoulder, back and hand. Male and young age were more prone to different MSDs.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

The Evaluation of Ochratoxin A in Patients Suffer from Renal Failure

Haider Abbas Hadi Al-Mhanaa¹, Ateer B. Al-Obaidi ²

¹Student, University of Kufa College of Science, ²Assistant Professor, University of Kufa College of Science

Abstract

The study is conducted on 94 patients (54 male and 40 female) and 15 healthy people (10 male and 5 female) as the control group. All these cases were suffers from renal failure, when attended to AL-Sader hospital in AL-Najaf province from February till May 2019. we make qualitative diagnosis by using TLC (thin layer chromatography) 29 cases have an ochratoxin A in serum and 65 cases without ochratoxin A and quantitative diagnosis by using HPLC (high-performance liquid chromatography) for 25 cases from positive results (15 male and 10 female) and detects of WBCs count for 29 cases with ochratoxin A and 15 with out ochratoxin A.

Keywords: ochratoxin, renal failure, TLC, HPLC, Iraq.

Introduction

Cutaneous failure is a medical condition in which the renals no longer work. Cutaneous failure can also be classified into two types of acute renal failure and chronic renal failure. Ochratoxin A (OTA) is a secondary metabolism mycotoxin produced by a number of filamentous species of the Aspergillus and Penicillium genera. It is a nephrotoxic mycotoxin that has been regarded as a part of the etiology of Balkan nephropathy (BEN). The blood OTA is higher than that of healthy people in patients with chronic renal insufficiency diagnosed with dialysis; and OTA is not less with this treatment. The risk of OTA for human renal disease because it is widely distributed around the world and the rarity of reported cases that show its role in chronic renal disease is paradoxical.

Aim: In this study, Ochratoxin A patients are recognized as having a relationship with renal failure.

Material and methods

Study design and patients

Serum collection

In healthy and infected patients, five ml of blood were collected. In sterile, plain tubes blood samples were drawn and left for 30 minutes at room temperature. Five minutes of centrifugation (Memmert, Germany) at 3000 rpm were performed. Serum was collected and kept under deep freeze at -20 in sterile tubes until use.

Thin-layer chromatography (TLC):

TLC is a simple and reliable method that is reasonably expensive to implement in a research laboratory. Most laboratories have considerable experience and expertise in developing countries.

Detection of ochratoxin A in serum blood by TLC

In patients suffering from kidney failure (94) person. The ochratoxin A was recognized after the examinations of the serum samples by using the TLC plate, twenty nine out of 29 (31%) , while renal failure patients without ochratoxin A was 65 (69%) .

This result is agree with study in Karbala government of Iraq (16) revealed that the main cause of infection agent acute kidney disease that caused renal failure in patients was ochratoxin A. high ratio of renal failure with OTA was (14.4%).

This result illustrated the present ochratoxin A in the blood serum in renal failure patients may be due to higher toxicity of OTA and its ability to kidney damage (direct effect) and the occurrence chronic kidney disease.

Detection of OTA with renal failure patients according to gender:

In patients suffering from kidney failure with OTA (29). OTA was recognized by TLC method to 17 male (59%) and female were 12 (41%) the incidence of males’ injury increases because the males are more susceptible to contact with the cause through continuous exit from their homes for the purpose of working and eating from shops and streets that lack cleanliness or play sports. This results disagreement with study of (16) in Karbala government revealed that renal failure with OTA in both female and male were (54.5%) and (45.5%) respectively.

In the study group, men had a higher proportion (59%) than women (41%) of renal failure due to weak immunity and chronic chronic kidney disease. More than women in OTA renal failure are caused by the regular action of males compared with female due to the causes of male injury. 17.

Detection of OTA with renal failure according to age:

This study showed that the highest prevalence of patients aged 17% (62%) and 21% (15-34) and (35-54) were diagnosed with RDA at age 55-74, as opposed to other patient age groups.

In age > 55, the high incidence of OTA renal failure can be due to low immunity and extremely toxicity of significant kidney damage than other classes. OTA 18.

This results agree with study of 16 that showed higher ratio with renal failure patients with OTA was 60% in (51-70) years old in Karbala government.

Statistical Analysis

In this analysis T-test was used to compare samples using the 10 program graph pad prism. 11.

Results and Discussion

The results of the study revealed a significant increase (P<0.05) to (1.298 ng/ml) and (0.543 ng/ml) respectively in the concentrations of (OTA) in the total number patients suffering from renal failure with OTA and the control group. Also they revealed that the concentration of (OTA) in male and female patients suffering from kidney failure were significantly increased to (1.136 ng/ml) and (1.231 ng/ml) respectively compared with the control group (0.573 ng/ml) and (0.48 ng/ml), respectively. It also revealed variation depending on ages (15-34), (35-54) and (55-74) years old was the concentration of OTA (1.613 ng/ml), (1.097 ng/ml) and (1.309 ng/ml) respectively compared with the control group (0.444 ng/ml), (0.618 ng/ml) and (0.7 ng/ml), as seen in Fig (1), (2) and (3).

In the current study used the thin layer chromatography (TLC) to detect the presence of OTA in serum of patients suffer from kidney failaur and used HPLC to measure the concentration of it in the province Al-Najaf. Ochratoxin is a group of mycotoxins produced by some Aspergillus species and some Penicillium species 3. Kidney damage is the most vulnerable and prominent effect but toxin can affect the development of the fetus and the immune system. This association in humans is unclear, contrary to the clear proof of kidney and kidney toxicity due to exposure of ochratoxin A in the animals 16. To order to prevent infectious diseases to commercially valuable animals, maintenance of a competent immune system is necessary. Mycotoxin OTA induces immunosufficiency, and prolonged low dose exposure to OTA is more significant than acute high-dosage exposure 4. The findings of this trials showed no significant improvements in the frequency of male and female infection. In the kidney OTA results in high nephrotoxicity, with a higher incidence of upper urinary tract malignancy 15. The study shows that this rise in OTA is significantly increased due to low dose exposure to OTA; OTA induces specific changes in the function and physiology of renal cells at nanomolar concentration. 5. Therefore, Very low OTA levels administered for a prolonged duration (up to 14 days), in the human tubular proximal, affect the cell destiny, and in addition they do not only function in the target organ, e.g., the kidney, but also in previously unsuspecting cells, e.g. fibroblasts. 6,7. In all ages of kidney-insufficient patients, OTA concentrations increased compared with control groups particularly at age 15-35 because of a size decrease in vital immune species, including thymus, spleen and lymphatic kernels, antibody response depression, number and functional alters. The study revealed an increase in OTA concentration in every age group 4. 9 It was shown that immunosuppressive mycotoxin, such as OTA inhibits humoral and cell immunity and lymphoid organ works at various levels of the immune system.

Figure 1: Comparison between Concentration of OTA (ng/ml) in total patients suffering from renal failure and total control. This different letter refers to significant differences at p>0.05 according to T test.
**Conclusion**

OTA has a role in changing the human immune response. OTA has an effect on some immunological biomarkers.

Estimation of Radiation Exposure to Some Iraqi Patients with Hyperthyroidism treated with Radioactive Iodine-131 as an Outpatient Basis

Nafal NazarBahjat¹, Zahraa Neamah Abbas²

¹Lecturer, ²Assistant Lecturer, Department of Medical Analysis, College of Health and Medical Technologies, Middle Technical University, Baghdad-Iraq

Abstract

A broadly established therapy is radioactive iodine-131 for patients with hyperthyroidism (1). The radioactive iodine-131 dose is given to the patient as a single dose, which leads to a high radiation exposure surrounding the patient’s location for several days, depending on the amount of the received radiation dose, patient’s isolation in a special room is necessary for a period of time until the amount of radiation exposure decreases to an acceptable limits according to the National regulations. This study aimed to obtain a measurable estimation to the amount of radiation exposure resulting from patients treated with iodine-131 and assessment of compliance of patients and their family members to radiation safety instructions (RSI).

In this study, (35) Iraqi patients with hyperthyroidism (15 male and 20 female) divided in to three groups according to $^{131}$I doses received that ranging from 3.7 to 7.4 GBq (100-200 mCi), the radiation dose rate was measured at different levels of the patient’s body as well as at different periods after receiving the I-131 treatment dose.

Results shows that the external dose rates decrease rapidly and as a result, the greater amount of radioactive iodine is disposed of in the urine in the first two days after therapy. Also there is no observed differences appears in the average radiation dose rate (µSv/hr) resulting from patients after giving the dose of iodine-131 between males and females within the same group, while a significant difference was observed in the average dose rate between the divided groups, especially after an hour of giving the dose.

Conclusion this study provide an estimation to the amount of radiation exposure resulting from patients for three days post $^{131}$I therapy on outpatient basis, also these results enables us to obtain a database that can be used in determining the amount of radiation reflected from patient to family members and contacts. Oral and written radiation safety instructions (RSI) are given in an appropriate way to patients and family members before patient’s discharge.

Keywords: Radiation Exposure, Iraqi Patients, Hyperthyroidism

Introduction

Hyperthyroidism is the increasing in the amount of thyroid hormones secretion in the blood while the amount of TSH is minimized, and the thyroglobulin creation is amplified ¹. The thyroid is used up of iodine because of the hormones that are quickly secreted from the thyroid gland. The general reason for hyperthyroidism are diffuse toxic goiter, also called Graves’ disease, toxic multi nodular goiter and toxic adenoma ². Radioactive Iodine-131 has been used widely for hyperthyroidism since the 1940s ³. A move towards radioactive $^{131}$I therapy hyperthyroidism treatment in western countries was listed as a result of well-known safety profile of I-131 therapy ⁴. Benefits to patients treated with radioiodine–131 must be balanced against radiation

exposure to contacts, family members and occupational workers. Each Medical center present these detailed self-protective recommendations that should be useful to minimize the exposure to radiation levels to the whole community. The ICRP and IAEA set a detailed strategy for all radiation employees to follow in dealing with radiation. The annual limit of occupational dose to an individual adult is 20 mSv and 15 mSv for adults older than 60 years according to national regulations. Whereas the U.S.NRC recommended dose base of 5 mSv per episode in all age. Many studies in western countries confirmed that radioactive I-131 treatment on outpatient basis is an efficient and secure therapeutic method with low exposure to radiation levels to family and contacts of patients treated with I-131, and also for relatives of patients who obtained high doses of I-131. While, there is a few in formations regarding exposure to radiation to family members and contacts of outpatients treated with I-131 in the Arab communities. A previous Saudi study noted that I-131 is very efficient in treatment of hyperthyroidism with little side effects, this mutually with its safety and minimum cost have made it a best treatment of many patients with hyperthyroidism. To our Knowledge, this study is the first to conduct on Iraqi patients for the purpose of obtaining a quantitative estimation to the amount of radiation exposure resulting from patients treated with radioactive iodine-131 on outpatient basis and evaluation of compliance of patients and their family members to radiation safety instructions (RSI).

Material and Method

Dose Rate Measuring System Graetz X5C plus was used directly and combined with Telescopic Probe DE for measurements from a (1 m) distance to obtain a quantitative estimation of the radiation exposure rate resulting from patients treated with radiiodine-131. Therapeutic doses using radioactive iodine-131 were all taken from the Jordan Nuclear Medicine Center (Jordan).

Thirty-five self-dependent hyperthyroidism Iraqi patients all were used I-131 for treatment on an outpatient basis. They were divided into three groups according to the amount of radiation dose received for each group.

Patients were administered into isolated rooms and doses were given orally in liquid form; iodine is fast and totally absorbed in the upper intestine, it is spread first in the body’s extra vascular fluid within the first one hour and the radiation dose rate was measured and recorded after 1, 24 and 48 hours at a distance of (1m) from the patient’s body at the level of the abdomen (bladder), thyroid and knees.

Oral and written radiation safety instructions were given to patients and family members before leaving the Nuclear Medicine Center.

Results and Discussion

The current study included (35) Iraqi patients with hyperthyroidism (15 male and 20 female) aged between (27 and 63) years old, all were treated for their hyperthyroidism with I-131 doses ranging from 3.7 to 7.4 GBq (100-200 mCi) as shown in Table (1). The female patients were more influenced with thyroid diseases than male patients for all groups around (57.14% female and 42.85% male). This is in accord with a previous study by Morganti et al. 2005 which reported that thyroid diseases are more common in females.

**Figure (1): The average dose rate (µSv/hr) of male patients after receiving radioactive iodine-131 doses.**
Figure (2): The average dose rate (µSv/hr) of female patients after receiving radioactive iodine-131 doses.

Figures (1) and (2) together with Table (3) shows that the external dose rates decrease rapidly and as a result, the greater amount of radioactive iodine is disposed of in the urine in the first two days after treatment, and the results do not indicate that there are a significant differences in the average radiation dose rate (µSv/hr) resulting from patients after giving the dose of iodine-131 between males and females within the same group, while a significant difference was observed in the average dose rate between the three groups, especially after an hour of giving the dose and the reason behind may relay on a personal basis that all I-131 incur patients do not importantly have the same iodine kinetics. A previous study by Mountford and O’Doherty, reported that keeping a patient in hospital needs an extra financial income, and the rules when discharging the hospital may reason a real disturbance of their family and daily life. Therefore, the time spend in hospital and the regulations to pursue after discharge could be depend on a proper radio protective evaluation and may not be so preventive. The residence factors should be relay on the patient’s daily life and the patient’s livelihood, also on their capability to accept a set of social restrictions for many days. Taking in to account the previous constraints and according to our results from Table (3) partners are advised to sleep apart for 3 days (1850 MBq in follow-up of patient) to 23 days in the case of 7400 MBq dose.

Conclusion

The results of this study indicate that the external dose rates decreases and to be within the ICPR limit of 1 mSv/year only after two days from receiving I-131treatment dose thus hyperthyroid patients can continue to be treated with radioiodine on an outpatient basis, if given appropriate radiation protection advice such as a preventive isolation of the patient with sleeping separately up to 23 days in order to strictly abide by ICPR limit of 1 mSv/year. For patients with hyperthyroidism, I³¹I is considered as a widely accepted therapy but the decisions of treatment is optional due to
the patient preference with taking in to consideration the balance of risks with advantages of each available treatment for hyperthyroidism as well as patient’s lifestyle and health status. We believe the results of this study provide a quantitative estimation to the amount of radiation exposure resulting from patients treated with radioactive iodine-131 on outpatient basis and it could be considered as a base for further future studies.

Evaluation of Some Minerals Content of Drinking and River Water in Iraq by AAS Method

Mustafa A. Kadhim1, Abd-alussain Sh. Naji1, Luay S. Khaleefah1, Hayder N. Salman1

1(M.Sc. Food Sc. & tech.); Lecturer in Dept. of Food Sc. & Tech. College of Food Science/ Al-Qasim Green University

Abstract

The experiment was conducted during 2018 to evaluate the presence of certain elements (Lead, Copper, Chromium, Zinc, Nickel, Cadmium, Arsine and mercury) in Tab and Bottled water in addition to riverbed and cliff water. The obtained data were compared with the corresponding international and national guideline values. The concentration of Tap and Bottled water samples for Cr and As were higher than the permitted concentration established by FAO/WHO scoring (0.0623, 0.3120) and (0.0680, 0.448) respectively. Whilst Zn, Ni, Pb, Hg, Cd, and Cu were lower than the permitted concentration established by FAO/WHO for both samples Tab and Bottled water which scored (0.0608, 0.0550, 0.0075, 0.00589, 0.0013 and nil) and (0.0420, 0.0152, 0.0105, 0.00581, 0.0003 and nil) respectively. Thus, the concentrations of As in both River bed and cliff water samples were higher than the permitted concentration established by the Iraqi (C.O.S.Q.C) Central Organization for Standardization and Quality Control which scored (0.754 and 0.245) respectively. Regarding the rest of the element which seem to be lower than the permitted concentration established by Central Organization for Standardization and Quality Control in Iraq for Riverbed and cliff.

Keywords: AAS, heavy metals, trace minerals

Introduction

Water can be defined as a substance composed of hydrogen and oxygen. Water can be exist in three states gaseous, liquid and solid. depends upon temperature, tasteless and odourless. It has the important ability to dissolve many other substances such as salts and gases. Water covers greater than two-thirds of the earth’s surface. however most of it salty and undrinkable. Only 2.7% fresh water from the sum of the whole water on planet earth is fresh, but 1% of the fresh water can be used and accessible presented in lakes, rivers and groundwater. The inaccessible freshwater portion presented in deep aquifers and frozen in the polar ice. In our life Water considered to be an essential component. Water is an important source of elements more over pollutants which affect humans health. Therefore, water quality and quantity is of major importance for the human health. There is no clear and uniform definition for SDW “safe drinking water.” Safe drinking water can be defined as the water that does not represent any significant risk to health (chemical and microbial) during consumption over a long period of time.Trace elements are carried in water as either dissolved. Majority of the harmful effects potentially comes from dissolved materials in the rivers or streams. Therefore, they may settles at the bottom of the riverbed sludge or penetrate into the underground water thereby it considered to be a source of ground water contaminations. Trace elements at a low concentration considered to be essential nutrients, but may became toxic at a high concentration, also because of its formula. Yet, in the aquatic ecosystem elements (macro and micro) are considered to be one of the most substantial and main pollutants. Toxic intakes and optimal intakes levels may vary from elements to other. Elements can be classified based on their biological activity in to essential trace elements which the human body needs it in very small amounts, and play a major role in good wellbeing. The second group are not considered as essential elements because of their toxicity and human nutrition. WHO (2004). Lead is a chemical element with the symbol Pb, it is a heavy metal that is considered to be widespread and environmental toxicant.
Lead is exist in the environments in three forms: Metallic lead, lead salts, and organic lead containing carbon. Lead is a normally and naturally exist in the forms of toxic metal found in the Earth’s crust, also Lead used widespread in may industry around the global has led to extensive environmental contamination. (WHO 2019). Lead is considered to be major harmful elements, can be accumulate in the environment thus causing pollutation that affect all biological systems through exposure to air, water, and food sources. Lead inside the human body is distributed in different organs such as brain, liver, kidney and bones. Also its stored in the teeth and bones. The main sources of environmental contamination include mining, smelting, manufacturing, recycling activities, leaded paint, leaded gasoline, and leaded aviation fuel. (WHO 2019). Copper is a chemical element with the symbol Cu. It is a reddish elements that occurs normally and naturally in rocks, soils, water, earth sediment, and air at relatively low level. Copper can also occurs in the crusts of the earth, plants and animals. It is considered to be an essential element for many living organisms including humans and other animals at relatively low levels. At much higher levels of Copper toxic effects can occur. Cu can enter to our body when we drink water or eating food, soil, or other substances that contain Copper. Chromium is a chemical element with the symbol Cr. It is a steelygrey, specular, hard and brittle transition metal. Cr is a part in lipid and protein metabolism inside human body. at low concentrations. For the normal human function very small amounts of Cr are needed. Chromium also exist at a relatively higher concentrations in industrial processes that can release potential pollutants to air and drinking water. Zinc is a chemical element with the symbol Zn. Inside the human body Zinc considered to be the most important trace elements. It’s important to life due to fundamental role in gene expression, cell development and replication. Zinc major role is in the stabilization of the protein structure. Nickel is a chemical element with the symbol Ni. Nickel is a silver-white elements found in several oxidation forms. Ni II is the most widespread in biological systems. Nickel easily forms nickel containing alloys, which have found an ever increasing use in modern technologies for over a hundred years now. Arsenic is a chemical element with the symbol As. Arsenic normally and naturally existed at relatively high levels in the groundwater of some countries. Arsenic is highly toxic in its inorganic formula. Polluted water which used used for drinking and some time in food preparation also in irrigation of food crops poses the greatest threat to public health. Arsenic is a natural component of the earth’s crust and is widely distributed throughout the environment in the air, water and land. (WHO 2018). Arsenic is highly toxic in its inorganic formula. Polluted water which used used for drinking and some time in food preparation also in irrigation of food crops poses the greatest threat to public health. Arsenic is a natural component of the earth’s crust and is widely distributed throughout the environment in the air, water and land. (WHO 2018). Mercury is a chemical element with the symbol Hg. Mercury is nonessential and toxic to the human body. Mercury is widely used in industry, agriculture, and medicine, and circulates in ecosystems, but is never destroyed. Mercury may have toxic effects on the nervous, digestive and immune systems, and on lungs, kidneys, skin and eyes. The main objective of the present study was to evaluate the presence of certain elements in tab water, bottled water, riverbed water and Rivercliff water to compare the obtained levels of the studied with the corresponding international and national guideline values. Selected trace elements was measured (Pb, Cu, Cr, ZN, Ni, Cd, As and Hg).

Materials and Method

The experiment was conducted during 2018, to evaluate the concentration of selected metals in tab water, bottled water, riverbed water and Rivercliff water to compare the obtained levels of the studied with the corresponding international and national guideline values. The selected metals of the study were (Pb, Cu, Cr, ZN, Ni, Cd, As and Hg).

Materials and equipment used

2. Glass tube and volumetric flask.
3. H2SO4, HNO3 and distilled deionized water.

Sample Collection
A total of 36 water samples were obtained from Djilas river and the tab and bottled water present in Baghdad city. The water samples were obtained from local markets located in Baghdad. The samples were stored until the chemical analysis.

Chemical Analyses
The analysis was done in a chemical laboratory belongs to the ministry of Industry and minerals – republic of Iraq. Atomic Absorption Spectroscopy (AAS) used to analyze the samples.

Results and Discussion
Mean concentration of Lead (Pb), Copper (Cu), Chromium (Cr), Zinc (Zn), Nickel (Ni), Cadmium (Cd), Arsenic (As) and Mercury (Hg) obtained from the water samples were measured using Atomic Absorption Spectroscopy (AAS) method.

Our results indicated the following findings:

Tab water
The data in table 1, shows that the highest concentration for tab water samples were in As (0.3120) followed by Cr, Zn, Ni, Cd, Hg, Pb, and Cu which were (0.0623, 0.0608, 0.0550, 0.0075, 0.00589, 0.0013 and nil) respectively. The concentrations of Cr(0.0623) and As(0.3120) in tab water samples were higher than the permitted concentration established by FAO/WHO which were (0.05 and 0.01) respectively. On the other hands the concentrations of Zn, Ni, Pb, Hg, Cd, and Cu which were (0.0608, 0.0550, 0.0075, 0.00589, 0.0013 and nil) respectively seemingly lower than the permitted concentration established by FAO/WHO.

Bottled water
The data in table 2, shows that the highest concentration for bottled water samples were in As (0.4480) followed by Cr, Ni, Pb, Zn, Hg, Cd and Cu which were (0.0680, 0.0420, 0.0152, 0.0105, 0.00581, 0.0003 and nil) respectively. The concentrations of Cr(0.0680) and As(0.448) in Bottled water samples were
higher than the permitted concentration established by FAO/WHO which were (0.05 and 0.01) respectively. On the other hands the concentrations of Ni, Pb, Zn, Hg, Cd, and Cu which were (0.0420, 0.0152, 0.0105, 0.00581, 0.0003 and nil) respectively Seem to be lower than the permitted concentration established by FAO/WHO.

Impact of Social Media upon Juvenile Delinquency in Basra Central Prison and AL-Maqal Police Station

Haider Falih Jabbar¹, Ali Kareem Al-Juboari²

¹ M.Sc. Haider Falih Jabbar / Academic Nursing Specialist, High Institute of Health Vocational, Ministry of Health. PHD student, ² PhD. Prof., Department of Psychiatric and Mental Health Nursing, College of Nursing, University of Kerbela

Abstract

Objective: This study aimed to determine the impact of social media domains. And find out the know which among social media sites were mostly used by the juveniles.

Methodology: Quantitative design (a descriptive study) of one hundred juveniles were selected. All the juveniles for both sexes as delinquent who were temporarily detained in police station convicted of felony, crime or misdemeanor who is awaiting trial; and delinquent convicted of crime or felonies for rehabilitation or punishment convicted of misdemeanors and major offenses in central prison; juveniles who were at 14-17 years, for the period from 3rd February 2019 until 4th April 2019 in AL-Maqal Police Station and 14th April 2019 until 14th May 2019 in Basra Central Prison. The collection of data is performed out of the utilization of developed questionnaire and by means of structured interview technique with the subjects who were individually interviewed by the using of Arabic version of the questionnaire in Basra Central Prison and AL-Maqal Police Station.

Results: The results of the study indicate more than half 59% of age 16-17 year; more than three-quarters 82% were male; also more than three-quarters 77% living in urban and in slum area 51%. The results revealed that the samples of social media were (100%) watch movies; (96.5%) used chat; (86%) play game; while (100%) use the you tube; (97.7%) use face book; while (98.8%) browse the violence program. The more types of offenses and misdemeanor committed by the Juveniles were (18%) theft; and (16%) drug abuse.

Keyword: Impact; Social Media; Juvenile Delinquency; Prison; Police Station.

Introduction

Mass media is a channel, device, utility, or instrument used as a means of mass communication process and as variety channel of information for knowledge and entertainment. Mass media are an inseparable part of lives. In the recent times, with reach technology to every segment of population across the world in a very short amount of time, this advancement in the accessibility more information that associated with various social alterations which have profound influences the individuals and community through influences on the social links intimate or personal interaction and system of communication between individuals and families. The media, whether visual or audio, it has become a family member. Juvenile can learn, imitate behavior and behave in the same way as media content is seen in daily life. So, the quantitative content received by juveniles with the increase in the number of hours spent in watching media materials that contain on news of killings, bombings, wars, and assassinations, as well as the detective, pornographic, crime, fictional, and violence films and exposing to scenes of violence, hatred aggression, and extremism and takes the feelings of compassion and mercy from their hearts lead to increased probability of a juvenile falling in delinquency. Social media is a group of web based applications and foundations of technological which includes Twitter, Facebook and Instagram has positive or negative effect
that acts to create new opportunities of connect with transfer and amplify the messages or information among people, it has a massive impact on the behavior and minds the juveniles through encourage and instigate to participate into criminal activities. Social media plays a role in shaping individual perceptions and spread, instill, influence and stimulate on the thoughts, value, actions, attitudes and behaviors of individuals and community that embrace all aspects of human life, media become the more profound to attraction the juveniles through tempting content. Media content create temptations of juveniles that are outcome of the interaction a juvenile’s desires of needs and wants with juvenile’s commitments and opportunities in pursuing an ambition or a goal with devote and convert much of time, resources, energy and motivated in engaging in delinquent behavior. Therefore, the power effect of media content on juvenile lead to acquiring, altering, triggering, and reinforcing the juvenile’s behavior according approaches the media and exposure to media overdoses due to media influence on an individual’s mental processes or the product of those processes that involves the acquisition of information, absorb this information then process of memorization and storage of information in human mind, transform information into knowledge to create new meanings with generalize to generate principles about real life. The ability of media to attract individual’s attention and influence them, it uses information manipulation through omits some facts and provides deliberately incomplete information and persuasion of the distorted information, with displays things that are not in line with local culture and values, this effect either occurs in the short term and occurs immediately and fade more quickly or in the long term and occurs slowly based on the content that contains. The effect whether positive or negative involved many aspects of affective, cognitive and psychomotor through read, listen, conversation and see of social media. Exposure to media content might lead juveniles to copy what they see, hear and read according the situations in which they might be able to copy it as knowledge, attitudes, skills and behaviors with make this copy is basic in deal with others. Media plays huge rolls an important role in juvenile’s cognition and comprehension as a motivating factor in effect on aspects of behavior through advocating freedom of expression and thought, and rejecting many of the conservative standards and values of society, promoting promiscuity, violence, alcohol and drug use, rape, vandalism, prostitution, with give the impression that aggression and violence is permissible in many deviant activities and disrespect of values and norms.

Juveniles are committing crime when disagree with rule of conduct stated in law or breaks a rule from rules of conduct through lack of ability to exercise self-control. A delinquency as a harmful act against the public and community, upon conviction, is punishable with a fine, imprisonment, and death. Juvenile delinquency takes various forms according frequency, degree, duration and seriousness like obscenity, pilfering, murder, burglary, fraud, loitering, gambling, drug abuse, begging, and disrespect of values and norms in society.

Wrongdoing, misdemeanor, felony, crime is a product of learning the values, norms and behaviors due to response to personal propensities or a specific motivation or environmental inducements that law is prohibited, associated with unwanted activity. Any violation in Iraq is punishable under the Criminal Code or known as the Code of Criminal Procedure, which regulates all Iraqis under the umbrella of the law.

Results

The results revealed that the majority of the samples (59%) at age 16-17 year; were male (82%); were living in urban area (77%) have interrupted at school (64%); and education level (37.98%) at 5-6 class, while lowest percentage (1.26%) at 11-12.

2.

Table (4) The results revealed that the samples of types of offenses and misdemeanor committed by the Juveniles that indicate to (18%) theft; (16%) drug abuse; (15%) murder; (10%) rape and threat; while were (9%) others offenses and misdemeanor committed. While (45%), (19%) friend and brother as high percentage which helped juvenile to commit the misdemeanor.

**Discussion**

The results revealed that the more than half of the samples were (59%) at age 16-17 year, while 14-15 year were less than half (41%); juvenile’s male more than four fifths (82%) and the rest of the sample were females; living in urban area were more than three-
quarters (77%), while were little more than ten (15%) continuous at school and third (21%) the juveniles were did not enter at school; while were more than three fifths (64%) samples have interrupted at school; with more than one-third (37.98%) of juveniles have fifth and sixth class; while eleventh and twelfth grade were less percentage (1.26%) of sample.

Concerning the results of the ways used the internet of social media table (2) that indicates to use internet more than four fifths (86%) of sample by mobile more than nine tenths (96.5%) for entertainment (100%); find a friendship (94.2%), this finding agrees and supported with results obtained from study done by 13 a study (Impacts of Media on Society, India) reports indicate that more than nine tenths (93%); and used internet by mobile were (75%); also this finding agrees and supported with results obtained from study done by 10; a study (The Uses of Middle Teenage Students for Networks Social Communication in the Schools of Nablus in Palestine) mentions that the more sites that juvenile’s used are face book (43.85%); while you tube is (9.65%), while this finding disagrees with results obtained from study done by 12; a study (The Features of the Internet Culture Among Adolescents in Algeria) reports indicate that juveniles use internet for browse the violence program were (40.6%).

Table (5) Show distribution of samples according to offenses committed by the juveniles; it indicates that high five percentages more than third were theft (18%), drug abuse (16%) and murder (15%), threat and rape were (10%); the friends (45%), Brotherhood (19%) and parents (16%) were more persons who help the juvenile commit the misdemeanor or crime, this finding agrees and support with results obtained from study done by (Hameed, 2011); a study (Personality of the Juvenile delinquency, Algeria) reports indicate that offenses committed by the juveniles are theft (38.13%), drug abuse (17.79%), also this finding agree with results obtained from study (Chowdhury et al, 2012); a study (Causes and Consequences of Juvenile Delinquency in Bangladesh) that indicates to theft (47.37%) and murder (36.84%), with help friends (54%).

Concerning the results of the social media sites the findings shown in table (4), that indicates to used internet were full percentage (100%) for watching movies and more than nine tenths (96.5%) for used chat with others; (86%) play game and the commonly sites that juvenile’s used were you tube (100%); face book (97.7%) and (98.8%) browse the violence program, these findings agree and support with results obtained from study done by 13; a study (Impacts of Media on Society, India) reports indicate that juveniles use internet in watching movies (84%), for used chat (89%) and for play game (81%), and also this finding agrees and supported with results obtained from study done by 10; a study (The Uses of Middle Teenage Students for Networks Social Communication in the Schools of Nablus in Palestine) mentions that the more sites that juvenile’s used are face book (43.85%); while you tube is (9.65%), while this finding disagrees with results obtained from study done by 12; a study (The Features of the Internet Culture Among Adolescents in Algeria) reports indicate that juveniles use internet for browse the violence program were (40.6%).

Conclusions

The findings of the present study conclude that the mostly social media used by the juveniles are you tube and face book by mobile of entertainment for more than four hours that lead the juveniles to broken the law and then delinquency.

Abstract

Aim: The aim of the study is to assess the referral system quality from clients’ perspectives at outpatient consultancy clinics in al-Hilla city hospitals.

Subjects and Methods: A descriptive analytic study design was carried out at outpatient consultancy clinics of Al- Hilla city hospital (Al-Hilla and Al-Imam Al-Sadiq general teaching hospital) from March 14th to December 12th 2019. Non – probability (purposive) sample of 200 clients who were coming to the Outpatient Consultancy Clinics were selected. Data is collected through used of an assessment tools and interview technique with (19) items of questionnaire. Reliability of instrument was determined through the use of Alpha Cronbach approach and the instrument validity was determined through a panel of experts. The analysis of the data was used descriptive statistics frequencies, percentages, mean, mean of score, cut off point, Chi square. In order to assess the referral system quality from clients’ perspectives.

Results: The findings of the present study reveal that overall assessment of the referral system quality is poor, grand mean of referral system services from clients’ perspectives are fair, majority reason for referring is lack of specialty(51%), and finally; medical diseases unit is most referred clients to it(24%).

Conclusion: The study concluded that poor referral system quality for clients at outpatient consultancy clinics in Al-Hilla city hospitals.

Keyword: Assessment; referral system; quality; clients; Outpatient Consultancy Clinics.

Introduction

The referral system is one of the cornerstones of basic healthcare systems. It is a complete and sustainable system with two directions to connect the primary healthcare units/centers and hospitals. It is one of the basic healthcare systems. It leads to continuous improvement of comprehensive health care for all patients by assigning priorities to those who need it (1). A referral can be defined as a process in which a health worker at a one level of the health system, having insufficient resources (drugs, equipment, skills) to manage a clinical condition, seeks the assistance of a better or differently resourced facility at the same or higher level to assist in, or take over the management of, the client’s case (2).

Most countries in the Eastern Mediterranean Region (EMR) are committed to strengthening family practice, however, implementation is uneven and inconsistent. An assessment of the status of family practice revealed significant gaps in terms of political commitment, client registration, packages of essential health care, essential medicines lists, referral systems and staff. Another big challenge is the insufficiency of trained care provider and the inability of current training programs to meet the enormous needs (3). The referral system given to primary care providers is based on clear guidelines detailing the referral process. This includes the use of a pre-designed standardized referral form with important relevant clinical and social information (4). The health care in Iraq are provided through a network of public Primary...
Indian Journal of Forensic Medicine & Toxicology, July-September 2020, Vol. 14, No. 3

Health Care (PHC) centers and hospitals where care are provided at very low charges. However, the Iraqi health system faces enormous problems that have mainly resulted from wars and economic sanctions during the last few decades(5). The Ministry of Health (MOH) in Iraq adopted a referral system in late 2008 to ensure a close relationship among all levels of the health system, to ensure people receive the best possible care closest to home, and to make cost effective use of hospitals and primary health care. Most PHC clinics (85%) had a referral system record, however (69%) did not have an electronic archive or family inventory and (64%) said they do not have any follow up mechanisms for the clients who are in need of continuous care(6). Although the Iraq referral system is between primary and secondary care, in practice, there is minimal coordination between the primary health care (PHC) level and the district hospitals apart from communicable disease surveillance(7). An effective referral system ensures a close relationship between all levels of the health system and helps to ensure people receive the best possible care. It also benefits in making cost-effective use of hospitals and primary health care. Support to health centers and outreach care by experienced staff from the hospital or district health office helps build capacity and enhance access to better quality of health care within a community(8). The important of the referral system can be brief as the following points: for the clients (prompt diagnosis and management, save time, low cost and effort, and better quality of health care), for primary care providers (learning and training, gaining self confidence, increase communication between the health care staff), and finally for consultant (improve the quality of client’s management, and increase communication between the primary health care staff by feedback reports)(9). Recently, The studies increase the interest in quality of referral system, with increasing focus for assessing and measuring the referral quality, evaluation of referral services which based on clients’ perspective are becoming very important. clients have a special perspective for evaluating the non technical aspects of health care. There are different definitions of referral system quality(10).

Materials and Method

A descriptive analytic study design was carried out at outpatient consultancy clinics of Al- Hilla city hospital (Al-Hilla and Al-Imam Al-Sadiq general teaching hospital) from March 14th to December 12th 2019. Non – probability (purposive) sample of 200 clients who were coming to the Outpatient Consultancy Clinics. These clients were selected according to the following criteria: clients who had referral from PHCCs to outpatient consultancy clinics of general hospitals in Al-Hilla city; both gender of clients (male and female); clients who had three referral times and above to outpatient consultancy clinics.. For the purpose of the present study a questionnaire was designed and developed by the researchers which consists of three parts: The first part of the questionnaire concerned with determination of the socio-demographic characteristics of the sample, and the second part was consist referral information and third part was assessment of referral system quality from clients’ perspectives. Reliability of instrument was determined through the use of Alpha Cronbach approach (r = 0.881), and the instrument validity was determined through a panel of (20) experts. In order to achieve the early stated objectives, the data of the study were analyzed through the use of Statistical Package of social sciences (SPSS) version 20 through statistical procedures that includes: frequency, percentage, mean, mean of score, cut off point, and Chi square.

Results out of this table present that most of the Primary Health has poor for referral system quality from clients’ perspectives (60.15%).

Discussion

The present study indicates that the majority (90.5%) of clients who were coming to the outpatient consultancy clinics of general teaching hospitals in AL-Hilla city were living in urban areas, and the remaining (9.5%) were living in rural areas(Table 1). This result is similar to the study in Jordan(11), who found that the majority of the study sample (89%) were living in capital (Amman), and 11% were living in city parties. Regarding to the clients’ age, the finding of the study indicates that the highest percentage of the study sample (33.5%) of clients who were coming to the outpatient consultancy clinics were at age group less than 30 years, while the lowest
percentage (4%) of them were at age group 50 years and above. These results agree with the study in Iraq\textsuperscript{(12)}, who found that the majority of the study subjects at age (20-30) years. The findings of the present study show that the majority of the study samples were male (71%) and the remaining (29%) are females. This result similar to study done in Iraq\textsuperscript{(15)}, show that most of referred client were male (80%) and (20%) were female. Concerning the educational levels, the findings of the present study indicate that (27.5%) who were coming to the outpatient consultancy clinics have bachelor and above, (20.5%) have primary school, (20%) have read and write, (18%) have illiterate(can't read and write), whereas only (14%)of them were secondary school degree. This result was supported by the study in Uganda\textsuperscript{(13)}, who found that the most of the study subject (50%) have bachelor degree, (34%) have primary school, whereas (8%) of them can’t read and write. With respect to the occupation, the findings of the present study show that (34%)of the clients have government employee; (23%) have retired , (18.5) unemployed, (14%) housewife , (10.5%)private employee. This result agree with The study which is conducted in Nigeria\textsuperscript{(14)}, which reported that the majority occupation of referred clients were 38% government employee and lowest percentage of clients’ occupation was private employee(7.4%).

According to indications for referral reasons were maximum percentage ( 51%) lack of specialty, followed (18%) unavailability to x-ray and ultrasound, (17.5%) lack of lab. tests, (7.5%)need for further management, and (6%) diagnosis difficulty(Table 2). This results similar to study done in Iraq\textsuperscript{(12)}, which illustrated that reasons for indicated referrals were (43.4%) lack of specialty, (42%) unavailability to x-ray and ultrasound, (7.7%) lack of lab. tests, (3.9%) need for further management, and finally; (3%) diagnosis difficulty. The departments and units selected for clients referral were highest percentage unit to medical diseases (24%), and lowest percentage unit to pediatric diseases. This results disagree with study done in Iraq\textsuperscript{(15)}, which presented that most the referred clients to pediatric unit (31.5%), and least referred clients were send to oncology department (1.2%). The disagreement between both studies is attributed to there are two specific hospitals (AL-Noor hospital, and Babil hospital for obstetrical and child) in AL-Hilla city which treatment the children and the most health care providers in PHCCs referred the children to this hospitals, therefore; the percentage of pediatric unit at general hospital in AL-Hilla city was lowest level.

Regarding the assessment of referral system from clients’ perspective in outpatient consultancy clinics(Table 3), the present results was fair in grand mean (2.73). Mean of score show that significant items were 1,2,3,4,5,6,and 7 while the non significant items were 6,9,10. Non significant items included referral system contribute to low of cost, provide health education by medical and nursing staff, the reason of this result can be attributed to insufficiency of indicated referral from PHCCs to hospitals, there are unnecessary requests for referral, self- requested referral, and most letters of referral that send from private clinics that leads to increase number of clients in hospital or outpatient consultancy clinics without clear dissemination guidelines for referral that is may be leads to increase of health care services and increase of cost and waiting time. Regarding lack of provide health education by medical and nursing staff may because of shortage of health care providers in PHCCs, lack of health care providers’ knowledge concerning administrative tasks and activities for referral system unit and the greater number of them does not participate in training sessions for referral system and unawareness of them toward benefits of health education for clients regard to referral system.

The overall assessment for the referral system quality from clients’ perspectives in present study is poor (60.15%) (Table 4). This result provides evidence that these centers are unable to provide acceptable and effective referral services. So, the quality of referral system was poor and lacking important and relevant items in majority of referral needs to be improved. This result agrees with study obtained in Iraq\textsuperscript{(16)}, which indicates that the overall evaluation of referral system quality for letters and feedback was poor and inadequate 69.5% and 78.5% respectively. Also this study similar to other study in Nigeria\textsuperscript{(17)}, the overall of referral system and quality of health care were insufficiency and at the low levels(56.3%).

**Conclusions**

The findings of the present study conclude that the overall assessment of the referral system quality from clients’ perspectives at poor services level in the present...
study, and the clients’ perspectives for referral system services are fair.

The Effect of Adding Different Concentration of Vitamin E to Frying Oil on the Peroxide Value

Abd-alussain Sh. Naji1, Luay S. Khaleefah1, Hayder N. Salman1
1M.Sc. Food Sc. & tech), Lecturer in Dept. of food Sc. & tech), College of Food Science/Al-Qasim Green University

Abstract
The aim of this research is to reduce the number of peroxide in two frying oil samples (Aldura and altusan) by using one of the natural antioxidants which is vitamin E. one of the chemical specifications that assess the oil is the peroxide number, which is the amount of free radicals formed in the oil and the number of peroxides increases during exposure to heat, moisture, oxygen, bad storage conditions, light or other conditions. These peroxides have a harmful effect on the consumer health (initiation cancer). The vitamin E had a clear impact on the peroxide value, as when conducting the experiment and using oil to fry potato slices, the number of peroxide was high before adding vitamin E which score (Peroxide number is 5.6 for 15 minutes, 9.8 for 30 minutes, and 11.6 for 45 minutes). After using vitamin E in amount of 10 microgram per 100 ml of oil, the effect was clear of vitamin E on the number of peroxide as it decreased significantly. Which scored (5 for 15 minutes, 8.1 for 30 minutes, 8.9 for 45 minutes). When vitamin E added by 20 microgram the result was (4.8 for 15 minutes, 5.5 for 30 minutes, 6.5 for 45 minutes). 50 microgram per 100 oil shown to have no significant effect on the peroxide value. it was found that the best concentration is 20 microgram for a sample of 100 ml of oil.

Keywords: frying oil, peroxide value, vitamin E

Introduction
Frying is one of the daily habits of most consumers around the world 1. When frying at the commercial or institutional level, it is usually done continuously and at high temperatures, and often an amount of old oil is added repeatedly and the frying process continues. also it is constantly exposed to oxygen, in addition to the presence of water in food, this may leads to a series of chemical changes due to the deteriorating characteristics of frying oil and for. Thus, it form non-volatile compounds and free radicals that negatively affect the properties of oil, and on the other hand, they negatively affect food and constitute a danger to the consumer health 1-6. Due to these changes that occur in foods during frying, the demand for more stable oils when frying increased, and it was found that Vitamin E has a positive effect to reduce these changes. Vitamin E have a unique colour which is pale yellow oil, acid and heat resistant, in-soluble with water 2. Extremely slow in oxidation. which gives it an important role as an antioxidant agents. Vitamin E is a soluble in fat but not water that consists of eight formulas alpha, beta, gamma, delta tocopherol and alpha, beta, gamma, delta tocotrienol, obtaining it means preventing oxidation of fatty acids and preventing oxidation of low-density Lipoproteins, which also reduces the possibility of human infection with atherosclerosis. This vitamin is concentrated in red and retinal blood cells and respiratory membranes 7,8. When a person increases the intake of unsaturated fatty acids, he should increase his intake of vitamin E, however, many of them ignore the importance of this vitamin and the reason for this because they follow a routine diet that lacks vitamin E as in the case of obtaining an appropriate amount of this vitamin by eating foods rich in it is considered an important factor in maintaining immunity and preventing a group of diseases and obtaining healthy and beautiful skin. 9 Vitamin E also has been found to be important in preventing colon cancer, prostate and breast cancers. Also some cardiovascular diseases some time poor eye lens, arthritis and some neurological disorders. Vitamin E, which is found in some vegetable oils such
as corn oil and soybean oil, is able to fight cancer and inhibit cell growth. Cancer vitamins in our diets are found in various forms, and Vitamin E is one of these vitamins. Researcher Zhong Yang stated in 1995 that vitamin E in the form of Tocopherols Gama is found in many natural diets and Tocopherols Delta is found in vegetable oils are useful in the treatment of types of cancer and chronic diseases and various infections and reduce the risk of infection by either Tocopherols Alfa is the most commonly used formula in vitamin E, which some take as a dietary supplement from pharmacies. Vitamin E is also considered to be one of the most important antioxidants agents that fight free radicals, the main cause of toxins accumulation and the spread of incurable diseases in the body. And as we mentioned, the thermal treatment of the oil leads to the rancidity of oils, forming peroxides, as oxidation occurs in light, oxygen, or traces of heavy metals and storage. The peroxide value is used to determine the degree of oxidation in fats and oils as oxygen interacts with the lipid molecule and creates free radicals in the form of peroxides. The objective of the current study is to evaluate the effect of adding different concentration of vitamin e to frying oil on the peroxide value.

**Materials and Method**

Oils and food

Two samples were used, the first is Iraqi origin oil type Aldar and the second is Tunisa which is Turkish made. The oil was obtained from local markets and vitamin E with a concentration of 98% from a specialized office for the supply of chemicals shop.

**Peroxide value**

All tests for the value of peroxide are based on a measurement of the amount of liberated iodine when potassium iodide interacts with rancid fat. In the Lea method, one gram of fat and one gram of potassium iodide are used with a solvent consisting of acetic acid and chloroform in a ratio of 2:1. After this heating is made to estimate the iodine produced by correction with a standard solution of sodium thiosulfate (0.03%). According to the following equation.

\[
\text{Peroxide number} = \frac{\text{volume (ml) } 10 \times 0.1 \times \text{Na}_2\text{SO}_3}{\text{sample weight (g)}}
\]

As the amount of peroxide was estimated before the thermal treatment, the amount of peroxide after the thermal treatment was estimated at the mentioned concentrations and times.

**RESULTS AND DISCUSSION**

At the beginning of the work, the peroxide value was estimated for both sample Al-Dar and Altonsa (Iraqi and Turkish origin) respectively. The control samples were low due to the lack of frying process. The peroxide number was measured for both Al-Dar and Altonsa oil during frying in 15, 30 and 45 min of the processing at a fixed temperature. 4.1 and 6.4 respectively, and kept on was rising In the value of peroxide this indicates the formation of free radicals and after continuing frying for 30 minutes the value of peroxide increased more than the first value and after continuing frying for more than 45 minutes the value of peroxide increased more.

The value of peroxide increases to a large degree, from which we conclude that by repeating the frying process of the oil and increasing the time, the value of peroxide is constantly increasing frying and this indicates the formation of free radicals (Hopia, Huang, & Frankel, 1996).

100 ml of oil was used to fry potato slices without adding vitamins, and three samples were taken during different time periods, so the peroxide number was as follows:
100 ml of oil was used to fry potato slices without adding vitamin and we took three samples during different time periods so the peroxide number was as follows.

After that, liquid vitamin E was used with a concentration of 98%. The first use is 10 micro ml of micropipette and was added to 100 ml of Aldar and Tunisa oil.

And the process of frying the oil with the material potato slices for 15 minutes, and there was a decrease in the value of peroxide by a little degree compared to the lack of adding vitamins, as well as the continuation of frying process.

The second use is 20 micro ml of vitamins to 100 ml of Aldar and tuna oil. The oil was used for frying by adding vitamins to it for 15 minutes. It was found that...
there was a noticeable decrease in the value of peroxide and the continuation of the frying process for 30 minutes. The value of peroxide increased, but to a lesser extent than its rise without using the vitamin. Likewise, for the continuation of the frying process for 45 minutes, as the peroxide number has increased, not like the high peroxide value without the vitamin.

The third use is 50 micro ml of vitamins to 100 ml of Aldar and Tunisa oil. The oil was used for frying for the same mentioned periods of time. The results were different to a lesser degree than the results using 20 micro ml of vitamins, as well as for other results, regardless of the numbers, constantly frying. This indicates that No significant change occurred when the vitamin concentration increased and these results were consistent with 10,14 The higher the percentage of the vitamin, there will be no significant change. After that, the vitamin was added in different concentrations. Use the oil by frying the potato slices. The results are as follows:

![Graph](al_dura_oil.png)

**Figure 3. The vitamin was added in different concentrations.**

After that, the vitamin was added with the same aforementioned concentrations. The oil was used by frying the potato slices. The results were as follows:

![Graph](altonsa_oil.png)

**Figure 4. The vitamin was added in different concentrations.**
We conclude from this that the heat leads to an increase in the peroxide number with repeated use and an increase in time and that the use of vitamin E in the amount of 20 microgram per 100 ml of oil has resulted in a significant decrease in the value of peroxide and that the increase in the vitamin is of little effect depending on the amount of oil used and its increase when using A greater amount of oil, this means that there are limits to reducing the number of peroxide in the oil, so that the increase in the vitamin did not show a significant decrease in the number of peroxide. The addition of vitamin to frying oils reduces the number of peroxide and this corresponds to 15

Recommendations

1- Use of originating oils with a low peroxide number, as the Iraqi oil had a lower peroxide number than the Turkish one.

2- Storing oils in places away from sunlight and not storing them in hot places.

3- Not to use oil for frying more than once and for the shortest period of time possible.

4- Use vitamin E and add it to oils before using them to reduce the number of peroxide, according to the mentioned percentage.

Financial Disclosure: There is no financial disclosure.

Correlation between Hormonal and Biochemical Changes with Kidney Function in Newly and Previously Diagnosed Women Diseased with Polycystic Ovary Syndrome

Zahraa Abed al-kareem 1, Jinan Hussein Multag 2, Ban Hoshi Khalaf 3, Amal Umran Mosa4

1M.Sc., Department of Pharmacology and Toxicology, College of Pharmacy, University of Kerbala, Kerbala, Iraq), 2 Lecturer, Dr., Karbala Hospital for Gynneceology and Obstetrics), 3 Lecturer, Dr., Department of Pharmacology and Toxicology, College of Pharmacy, University of Kerbala, Kerbala, Iraq), 4 M.Sc., Department of Pharmacology and Toxicology, College of Pharmacy, University of Kerbala, Kerbala, Iraq

Abstract

The objectives of our work was to identify the effects of insulin resistance and other hormonal changes on kidney function in newly and previously diagnosed women diseased with PCOS.

Method: This prospective study was done by collect serum samples and urine from three group (Control 60), (previously 50), (newly 50) patients. The withdrawal led samples were subsequently assay for hormonal and biochemical changes.

Results: The data of tests were available for both groups. We found significant differences in level of insulin, Homeostatic model assessment Insulin resistance (HOMA-IR), Homeostatic model assessment Beta function (HOMA-B), Progesterone among newly and previous women, also the data indicated a significant correlation between urea and testosterone in newly while direct significant correlation between urea and progesterone. There was significant correlation between Thyroid stimulating hormone (TSH) and creatinine in previously diagnosed PCOS, also direct correlation between uric acid and Body mass index (BMI), Fasting blood glucose (FBS), HOMA IR and inverse correlation with Triiodothyronine (T3) in new PCOS while in previously diagnosed PCOS there is inverse correlation between uric acid and T3. Finally, significant correlation between FBS, insulin, HOMA B and HOMA IR in previously diagnosed patients while correlation is seen between FBS, insulin and HOMA IR in newly patients.

Keywords: Biochemical changes, kidney, women, polycystic ovary syndrome.

Introduction

Polycystic Ovarian Syndrome: Polycystic ovarian syndrome (PCOS) is metabolic, endocrine and genetic disorders, chronic absence of ovulation of, with clinical and biochemical changes and presentation of hyperandrogenism (1)

PCOS affects as many as 10% of reproductive-age women when using the National institutes of health (NIH) standards in diagnosis. It is convenient that menstrual disturbances, insulin resistance and hyperandrogenism are currently existent, that includes anovulation, hirsutism, irregular and painful menstrual cycles, amenorrhea oligomenorrhea with small cysts in the ovaries, central obesity, and one more presentations related to the insulin resistance (2,3,4).

Epidemiology: The predisposing factors for PCOS include the following:

High maternal androgen: Prenatal exposure and Onset of type 1 diabetes mellitus before menarche, insulin resistance and obesity. Drugs: such as anti-epileptic drugs (e.g., Valproate) (5). Polycystic ovaries develop when the ovaries are stimulated to produce excessive amounts of (androgens), particularly testosterone, by either the release of excessive luteinizing hormone and
high levels of insulin in the blood or change due to levels of sex-hormone binding globulin (SHBG) resulting in increased free androgens\(^6\).

Women affect with PCOS reign elevated level of gonadotropin releasing hormone (GnRH), hence gives rise to a rise in ratio of Luteinizing hormone (LH)/Follicle stimulating hormone (FSH). The preponderance of women affected with PCOS have obesity and/or insulin resistance. The hypothalamic, pituitary and ovarian axis changes in PCOS are caused by insulin levels rises\(^7\).

The state of hyperinsulinemia augments GnRH shoots frequency, LH upon FSH predominance, ovarian androgen output excess, follicles’ maturation reduction and lowering binding of SHBG.\(^8\).

Autosomal dominant method sounds to be the genetic part of PCOS inheritance\(^9, 10\).

**Diagnosis of PCOS:** NIH works proposed that diagnosis of PCOS is performed when patient has pictures of androgen rise in vivo and in vitro, whether patent endures oligoovulation, and when other conditions causing PCOS are excluded\(^11\).

**Standard Diagnostic Assessment:** The diagnosis assessment includes the followings:

**A-History-taking:** women are inquired for menstrual manner, fatness, lack of breast evolution, acne and/or hirsutism, Lifestyle modality such as exercise, diet, and smoking require estimation and whether to consume any drugs and their influence should be scrutinized. Gynecological enquiry has to recognize age of menarche, menstrual disturbance, infertility and presence of relatives’ hirsutism.\(^12\)

**Patients and Methods**

**Selection of patients:**

This work was performed at the Obstetric and Gynecological Teaching Hospital in Karbala. It was carried out from July to November 2018. The age of patients and controls groups was (18-38) years. This study was carried on 100 patients with PCOS and 60 healthy individuals as controls, the patients were allocated into (2) groups:

Groups (A): include 50 patients with PCOS since above 1 year (as previously patients group).

Group (B): include 50 patients recently diagnosed with PCOS (as newly diagnosed group).

All patients were tested for fasting serum glucose and fasting insulin level, FSH, LH, progesterone, estradiol (E2), prolactin, testosterone, thyroid stimulating hormone (TSH), free T3, free T4, urea, creatinine and uric acid were measured by using a ready-made kits and Microalbuminuria was measured by urinalysis reagent strips.

**Statistical Analysis**

Modeling and featuring of data was accomplished by using SPSS 22.0.0 (Chicago, IL), GraphPad Prism version 8.0.0 for Windows, GraphPad Software, San Diego, California USA, software package applied to predict analytic techniques, p value is counted significant if lower than 0.05.

**Results**

**Hormonal and biochemical change in PCOS groups and control**

The data presented in the table (3.1) and in the figures (3.1) indicated serum insulin was significantly elevated in previous PCOS compared to control. The data presented in the figure (3.2), (3.3), indicated a significant different in the HOMA-IR, HOMA-B, among the previous and new PCOS to control patients and in the figure (3.4) the data indicated a significant different in the progesterone among the previous and new PCOS compared to control.

**Relationship between urea and various variables**

The data presented in the table (2) are indicated in the newly diagnosed PCOS; urea is negatively and significantly coorelated with testesterone. While in previous PCOS urea is directly and signifincatly correlated with progesterone.

Discussion

The elevated insulin level in the PCOS women regarding to the table (1) figure (1), (2) indicate that insulin level in the two groups of PCOS women are higher matched to controls. The present study revealed that serum insulin levels in both new and old PCOS were higher than that reported in controls; this attributed to the presence of insulin secretion impairment besides state of insulin resistance. An agent outer to receptor of insulin, supposedly a serine/threonine kinase, impetuses mentioned aberrations and it is a model of paramount neoteric mechanism of resistance of insulin correlated to agents dominating insulin receptor coding. PCOS patients were noted to be insulin resistant, and had beta-cell dysfunction. The data presented in the table (1) figure (3) indicate a significant different in HOMA B function ,HOMA B was significantly higher in old PCOS compared to control.

The homeostasis model assessment (HOMA) is a technique applied to endue an evaluation of beta cell assignment and sensitivity of insulin from glucose levels and serum fasting insulin. In this study also, there is relationship between HOMA-IR with various variables as presented in the table (5):

The results in previously PCOS women showed a significant correlation between HOMA-IR and FBS, insulin and HOMA-B While in newly PCOS women illustrate a significant correlation between HOMA-IR and FBS and insulin. There is a strong association of PCOS with insulin resistance. This can be due to increase process of phosphorylation in insulin receptor proteins, which reduces its protein tyrosine kinase performance leading to abnormal insulin secretion. PCOS patients had significantly higher values of fasting glucose, fasting insulin and HOMA-IR compared with controls. This study clarify a significant elevation in insulin resistance (HOMA -IR) in both newly and previously diabetic patients compared to control and a significant elevation in beta cell assignment (HOMA-B) in previously patients group compared to newly patients group and control group, this increase develops initially to compensate for Hyperinsulinemia, as glucose level increase, beta cell function decreases further but insulin hypersecretion within time lead to beta cell exhaustion.

Conclusion

In newly diagnosed PCOS women the hormones (testosterone, progesterone) may have an effect on the kidney function, while in previous diagnosed PCOS women the hormones (progesterone, TSH) effect on the kidney function.

The Effect of the use of E-Learning Teaching Physiology in the Academic Achievement of Students of the Technical Medical Institute

Mayad Nazim Rashid
Associate Prof., Middle Technical University, Institute of medical Technology –Baghdad

Abstract

Physiology is an important science that is taught at the Technical Medical Institute, where it is taught in most sections and branches, and to know the extent of the student’s understanding and mental abilities by the use of modern technology, and learning may be an immediate or simultaneous learning in the classroom or outside. E-learning is characterized by ease and modification of information provided and increases the possibility of communication to exchange views, experiences and perspectives between students and teachers and overcome the problem of the number of students with narrow classrooms. It is also successful for the “traditional education” that exists at the institute, where it constitutes the collective presence of students and promotes joint work among them. The present research aims to identify the effect of using an e-learning by teaching physiology in the academic achievement of the students of the Technical Medical Institute. They were divided into two groups, the first experimental and the second by twenty students for each group, one of the experimental group that studied e-learning method and the second control, which studied by lecture method.

Keywords: E-Learning, Achievement, Technical Medical Institute

Introduction

Modern education advocates the use of various methods of learning processes, especially the philosophy of distance learning\(^1\), which is consistent with the principles of e-learning, and that the strategy of e-learning is the application of technology in education as a method of self-learning\(^2\). The e-learning strategy is one of the modern strategies in education that integrates technology and technology in distance education\(^3\). The researcher noted that the method of teaching in the medical institute is based on traditional methods of conservation and indoctrination without technology or technology having a role in teaching\(^4\). Hence the researcher felt the problem of her research, and can be summarized in the following question: What is the effect of using e-learning by teaching physiology on the academic achievement of the students of the Technical Medical Institute?

Second: the importance of research

Many educators pointed to the need to train teaching staff on modern scientific techniques and methods and their various applications, which are expected to stimulate the thinking of learners for interaction and self-participation in the classroom, in addition to strengthening the social link between students. It should be noted that the use of an effective teaching method not only has an effect on raising the level of academic achievement of students but beyond that until this method becomes part of the preparation for the teaching staff. To this end, many educational institutions in the world have spent a lot of money and conducted many studies, pursuant to the principle of targeted education, which aims to regulate the thinking of students on the one hand and the introduction of technology in education on the other hand\(^5\).

The importance of research can be summarized in the following:

Theoretical importance

A. The importance of keeping abreast of modern technological developments in the field of education,
especially university education, which prepares graduates to deal with the different work requirements in the field of technology and others.”

B. Educational technology is one of the variables introduced in the field of education, which constituted important steps in the transfer of education from the traditional form to another more sophisticated form.

C. Still, most educational institutions are absent from the use of technology and deal with it, due to the lack of material allocations on the one hand and the lack of knowledge of ways of dealing and employment of this technology on the other.

Practical importance

A. It is expected that there will be an increase in achievement as a result of the use of a new and unconventional method of teaching based on the technology used and fluent students outside the classroom.

B. Highlighting a vital and important subject that did not receive attention and attention - according to the knowledge of the researcher.

C. “The research will come up with a set of conclusions, recommendations, and proposals that are expected to enrich the local library and open the door for other researchers in the same field.”

Third: Research objectives

Current research seeks to identify:

The effect of the use of e-learning teaching physiology in the academic achievement of students of the Technical Medical Institute.

Fourth: Research hypothesis

The current research is based on the following hypothesis:

There are no statistically significant differences between the mean of the experimental group studied by the method of e-learning and the average of the control group studied by the lecture method in physiology in the post-test.

Fifth: Limits of research

The current search is defined by a set of limits:

2. Temporal field: the academic year 2018-2019

Types of E-Learning

A number of sources, including (Al-Allaq, 2004: 7), (Astetah and Sarhan, 2007: 270), (Kittaneh, 2009: 278), and (Al-Wadi, 2011: 338) agree that e-learning is divided into two main parts:

1. Asynchronous e-learning: “This is the kind of education that does not require learners and teachers to be online at the same time, but requires the use of correspondence and communication techniques between learners and teachers such as e-mail or other networks, where information is exchanged at different times and not in At the same time, where the teacher prepares the course material, and then published on the Internet, and students according to the time that suits them to follow this article, and therefore can be counted asynchronous e-learning is the most common and used as a result of flexible use and employment “Among the most important tools are:

1. E-mail: is a program for the exchange of messages and documents using the computer through the Internet.

2. Textile Web: It is an information system that displays different information on the pages.

3. Discussion Groups: is one of the tools of communication via the Internet.

4. CDs: These are discs in which curricula or educational materials are prepared (Zaytoun, 2005, 60).

2. Simultaneous e-learning: is the opposite of the first type, that requires the presence of teachers and learners at the same time in front of computers in order to hold discussions and direct dialogues about the educational material, and this is done through the custom conversation or through the virtual classroom,
meaning that this type of education requires live and direct interaction between learners with each other, and the delivery of cognitive material immediately, and where this is done through the Web and other modern programs, the most important tools are the following:

1. Conversation: The possibility of talking via the Internet with users at another time.

2. Audio Conferences: is an electronic technology based on the Internet.

3. Video Conferences: Conferences through which communication between individuals separated by a distance through a high-capacity television network.

4. Whiteboard: It is a blackboard similar to the traditional blackboard. (Mohsen, 2004)

**Benefits of E-Learning**

E-learning is a set of benefits for educational institutions with its members:

1. Individual’s learners gain the ability to deal with modern technology, which is reflected positively on academic achievement and the lives of learners.

2. E-learning is characterized by the ease of modification of information and data releases through which it is also characterized by the easy transfer of parameters to individuals regardless of the space between them.

3. E-learning is facing some educational problems such as lack of experience and competence of some teachers in addition to the shortage of teachers (Astina and Sarhan, 2007: 288).

4. E-learning reduces the cost of travel to and from educational institutions.

5. Works to exceed the limits of space and time in education (Paulsen, 2009, 1)

6. The possibility of diversifying educational services because of the diversity of the means used.

7. The possibility of teaching and training a large number of students in different places and wide (Tulaiti, 2012: 178).

**Research Methodology and Experimental Design:**

The researcher relied on the use of the experimental method in the research, to suit the objectives of the research, where this approach seeks to use two methods in education and comparison between them, so the research may be from the first two experimental groups and the second control. Design of a randomized pre and post-selection randomized control group.

**Research Community**

The research community was chosen intentionally (intentional) and they are the first-grade students in the Technical Medical Institute for the academic year 2018-2019 and the number (30), students

**The research sample**

The research sample consisted of two divisions (A and B). The experimental and control group were randomly selected by lottery. The experimental group (Division B) was studied by the e-learning method, while the control group (Division A) was studied in the traditional way (lecture). The following illustrates the properties of the two groups:

<table>
<thead>
<tr>
<th>Table 1. Shows the individual sample according to the two research groups</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Group</strong></td>
</tr>
<tr>
<td>Experimental</td>
</tr>
<tr>
<td>Control</td>
</tr>
</tbody>
</table>

**The equivalence of the two research groups:**

In order to achieve parity between the two research groups, the researcher conducted parity between the two groups in a number of variables that they believe could affect the results of the research. Physiology consists of (40) questions.

1. Equal age

To ensure that the experimental and control groups were equal in the estimated life span in months, the
researcher used the T test for two independent samples. The results are as shown in the following table:

**Table (2) Parity between the two groups in the chronological age**

<table>
<thead>
<tr>

</tr>
<tr>
<td>Control</td>
<td>15</td>
<td>218.90</td>
<td>2.26</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

It is noted from the previous table that the experimental and control groups were equal in chronological age by the calculated value which was lower than the tabular.

2. **Parity in the IQ test**

To ensure that the experimental and control groups were equal in the IQ test, the researcher used the T-test for two independent samples. The results are as shown in the following table:

**Table (3) parity between the two groups in the intelligence test**

<table>
<thead>
<tr>

</tr>
<tr>
<td>Control</td>
<td>15</td>
<td>47.10</td>
<td>2.91</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

It is noted from the previous table that the experimental and control groups were equal in the IQ test by the calculated value that was lower than the tabular.

3. **Parity in the preliminary achievement test**

To ensure that the experimental and control groups were equal in the achievement test, the researcher used the T test for two independent samples. The results are as shown in the following table:

**Table (4) parity between the two groups in the achievement test**

<table>
<thead>
<tr>
<th>Total</th>
<th>Number</th>
<th>Arithmetic mean</th>
<th>standard deviation</th>
<th>Value T</th>
<th>Significance level</th>

<tr>
<td>Control</td>
<td>15</td>
<td>23.15</td>
<td>1.38</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

It is noted from the previous table that the experimental and control groups were equal in the pretest achievement test by the calculated value which was lower than the tabular.
Search tool

Achievement test:

A test was constructed in physiology consisting of (40) questions with four alternatives, three false and one correct, including three levels (understanding, application, analysis).

Psychometric properties of the test

1. Sincerity test

The validity of the test was verified by the subject of a group of experts and arbitrators in the field of competence, the researcher relied on the criterion (80%) of the views of experts to accept the paragraph and according to this criterion did not drop any paragraph.

2. Stability test:

To verify the stability of the test, the researcher used the equation (Alfa Kronbach) for each of the test paragraphs, the researcher found that the value of the stability coefficient is (0.90), and (Odeh, 1998: 367) pointed out that the stability of the tests Standardized attainment (0.85) and above. Based on this criterion, the test was considered static.

Apply the final experiment

The experiment was applied to the two research groups, after the equivalence between them in a number of variables mentioned above, the researcher gave the same educational material to the two groups, and was applied (e-learning) on the experimental group, and the lecture method on the control group as follows:

A- Experimental group:

The experimental group studied the way of e-learning.

1. The researcher identified the subject of the lesson and divided the time of the lesson into an introduction, presentation and conclusion

2. Equipped equipment (such as data shop, calculators on the number of students, intelligent patient).

3. Presented the material on the screen and explained, and then asked the students to use the computer to search for answers to questions submitted to them by using the Internet speed requirement in obtaining the answer and accuracy in its formulation.

4. The researcher asked the students to be two groups in the form of two rings, ring A and ring B, to answer a question and the group that succeeds in answering the question is the winner

Control Group:

The teaching material was applied to the students by the method of lecture within the scheduled lesson and at the same times and places set for the experimental group.

Posttest tests

After completing the experiment, the researcher applied the post-achievement test to the experimental and control groups, with the help of two colleagues in the department.

Statistical means:

The researcher used the following statistical methods in data processing:

1. Arithmetic mean
2. Standard deviation
3. Test (T) for two independent samples

Fourth Chapter/ Research results

The research hypothesis states:

There were no statistically significant differences between the mean of the experimental group studied by the e-learning method and the average of the control group studied by the lecture method in post-test physiology. To validate this hypothesis, the researcher applied the subsequent test to the experimental and control groups and used the T test for two independent samples. The results are as shown in the following table:
Table (5) Comparison between the experimental and control group in the post test

It is clear from the previous table that the calculated $T$ value was greater than the tabular $T$ value.

The researcher attributes this result to the effect of the e-learning method in increasing students’ academic achievement, because this method has saved a lot of time and effort on the student in addition to the compatibility of this method with students’ inclinations in information technology, and thus has helped them to overcome some of the achievement problems that they were suffering.

**Conclusions**

1. The impact of the method of e-learning on the achievement of the physiology of students of the Medical Institute

2. The members of the experimental group studied the method of e-learning on the members of the control group, which was studied by a lecture in the test of achievement of physiology.

**Financial Disclosure:** There is no financial disclosure.

**Conflict of Interest:** None to declare.

**Ethical Clearance:** All experimental protocols were approved under the Institute of medical Technology and all experiments were carried out in accordance with approved guidelines.

Impact of Quality of Primary Health Care Centers Upon Adolescents’ Health Status With Chronic Diseases in Kirkuk City

Burhan A. Hama Hussein1, Mohammed F. Khalifa2
1Academic Nurse, Kirkuk Health Directorate, Kirkuk, Iraq, 2Professor, Community Health Nursing Department, College of Nursing, University of Baghdad

Abstract

Background: The primary health care centers initiatives are designed to improve patient care and health outcomes. A process failed to address the impact on health outcomes, patient satisfaction, and costly of chronic diseases expected to adolescents. This study aimed to determine the role of quality of primary health care centers (PHCCs) on adolescents’ health status with chronic diseases in kirkuk city.

Methodology: A descriptive (quantitative design) was conducted through (18) PHCCs in Kirkuk city. Two questionnaires were designed for the purpose of the study. A simple random sample of (180) health professional (manager) were selected through the use of probability sampling approach. The sample of study was divided into two groups which include organization structure (PHC )centers (18) and (162) adolesents with chronic diseases. Data analysis is performed through the use of descriptive statistical data analysis approach.

Results: the overall evaluation for the quality of PHCCs is adequate on (59% ; N=11), and fair on (41% ; N=7) respectively. The quality of PHCCs is adequate relative to all of its dimensions of general health status, tangibles, accreditation, responsiveness, assurance and empathy. The experienced good level for the general, physical, mental, relationships and emotional dimensions of health status with chronic diseases Inadequate on Adequate on (44.%: n=71 ), Fair on (34.% :n= 55 ), and Inadequate (23. % :n= 36 ), level of evaluation. except that of the quality of life dimension of health status Adequate on Fair on (37.%: n = 60 ), Inadequate (30 %: =49 ) ,and Adequate (33.% n=53 ) does not impose any effect on adolescents’ general health status.

Conclusion: The study findings depict that the quality of PHCCs is adequate relative to all of its dimensions of general health status, tangibles, accreditation, responsiveness, assurance, and empathy. Adolescents’ health status is good regardless of their age groups as being early, middle and late age adolescents except that of the quality of life dimension of health status which has a fair level of evaluation. The study confirms that the Impact of quality of PHCCs does not execute an impact on adolescents’ health status.

Keywords: Adolescents’, health status, chronic diseases, primary health care.

Introduction

Primary healthcare centers refer to the first contact-access, continuous, comprehensiveness services available, and coordinated care provided to individuals regardless of gender, race, or diseases. Most PHC services have focused on treating illnesses as and when they arise(1). Primary healthcare centers include a wide variety of services delivered; the diagnosis, treatment, promoting good health, preventing health problems, and managing the ongoing care of people with health problems long-term conditions (2). The PHC system is being placed under immense pressure to perform as well as meet clinical targets, patient needs, and effective care (3). This strategy importance of implementing quality procedures and the continuous improvement of quality services. The fact that these strategies do not always lead to the desired outcome (4). The PHC services initiatives are
designed to improve patient care and health outcomes. A process failed to address the impact on health outcomes, patient satisfaction, and costly of chronic diseases expected to adolescents (5). Adolescents with multiple chronic diseases had substantially more bed days, school absence days, and behavioral problems than adolescents understand the importance of health care, conscious of the main health issues affecting them and therefore, should be engaged in addressing their health care needs and influences are strongly associated with their health outcomes. (6) Today management of chronic diseases for adults populations thus becomes a major focus for quality of PHCCs. Health system is needed strengthening if they are to meet the growing challenge of chronic diseases in low-income and middle-income countries(7). The goals of the current services to increasing availability and improving the quality care of chronic disease, and reducing disparities in the PHC services(8). The health-care team will aim to reduce the impact of the disease and agree to maintain a life as similar as possible to their developmental change to the adolescent period of life, but also by participated young people themselves in developing self-care management(9). In this study aims to help countries develop competency-based and self-management programs for adolescent health status and development in both pre-service and in-service management. In addition, it provides guidance on how to assess and improve the structure, content, and quality health-care services for adolescents with chronic diseases.

Methodology

A descriptive evaluation study is using a quantitative design conducted on a total of (18) PHCCs are selected for the purpose of the study in Kirkuk city. A simple random sample of (180) subject, it is selected throughout the use of probability sampling approach (a questionnaire). It was comprised of two parts and overall items included in the questionnaire were (102) item.

A: Organization Structure: This is comprised of information about socio-demographic characteristics of manager, and (22) item it is comprised such as about:- Tangibles, Accreditation, Responsiveness, Assurance, and Empathy of PHC centers.

B. (Adolescents') with chronic diseases: This part is comprised of information about socio-demographic characteristics of clients, and (12) items related to evaluate the health status in general, and (55) items consists of:- Physical condition, emotional state, the effect stress, evaluate the overall quality of your life, and Life enjoyment adolescents ‘with chronic diseases. The questionnaire provided a three-point scale: (1) Adequate, (2) Fair, (3), Inadequate.

a. Dependent Variable: Adolescents’ Health Status

b. Independent Variable: Quality of Primary Health Care Centers

This table indicates that the quality of primary health care Centers does not impose any effect on adolescents’ health status.

Discussion

Part I: Overall Evaluation of the Quality of Primary Health Care Centers

Analysis indicates that the quality of PHCCs is adequate with respect to its domains of tangibles, accreditation responsiveness, assurance and empathy (Table 1). Such findings can be interpreted in a way that the PHCCs are concerned about adolescents with chronic diseases. So, they are well equipped to present such health care services to this target segment of the population in the community.

These findings are very well-noted in the high mean of scores on items of the domains of such quality (Table 1). Except on 2 items of Tangibles, the nature of the departments, places of waiting, offices, doctors, and other existing staff matches what you expect in your mind and items of Responsiveness 2 on Patients are not expected to receive immediate service from the quality of PHC staff are low. These items have presented the actual state through which the PHCCs are managed and provided.

A sequential exploratory mixed method design is carried out to identify quality determinants for healthcare services for adolescents and young adults with chronic conditions based on the perceptions and the experiences of adolescents and young adults themselves. The study uses the initial qualitative phase employed semi-structured in-depth interviews to elicit the elements and determinants of quality of care as identified by adolescents and young adults living with chronic conditions. The second phase employs a questionnaire developed from the data gathered during the qualitative phase to survey the target population.

This is distributed to a larger sample of adolescents and young adults with chronic conditions to determine and confirm the relevance of the identified care elements and quality determinants.

The global standards are developed through a four-stage process:- (1) conducting needs assessment (2) developing the global standards and their criteria. (3) expert consultations. (4) assessing their usability. The global standards are developed based on the needs assessment in conjunction with the analysis of (26) national standards from (25) countries. The final document is reviewed by experts from the (WHO) regional and country offices, governments, nongovernmental organizations, academia, and development partners. The study has resulted in the development of eight global standards and (79) criteria for measuring them of adolescents’ health. (1).

It has been reported that the care given to all children, including young adolescents, in health facilities is evidence-based, safe, effective, timely, efficient, equitable and appropriate for their age and stage of development (10).

Part II: Evaluation of Overall Dimensions of Adolescents’ with Chronic Diseases

Analysis of such health status presents that most of the early age adolescents have experienced good level for the general, physical, mental, relationships and emotional dimensions of health status for chronic diseases except that of the quality of life dimension of health status which has a fair level of evaluation (Table 2). These findings present empirical evidence that early age adolescents in Kirkuk city are more blessed to gain better health status throughout their lifespan. Furthermore, the quality of their life may be straggling due to the burden of chronic diseases that are imposed upon their life.

All their age groups distinguished health status of the adolescents with chronic diseases is very noticeable in the high mean of scores on items the dimensions of general, physical, mental, relationships, emotional and quality of life of the adolescents with chronic illness health status (Table 2).
It has been reported that at least (12%) of adolescents living with a chronic condition. Some conditions are characterized by increasing incidence (e.g., diabetes and asthmatic) or improving survival rates (e.g., cystic fibrosis), while others are concerning because of differentially poorer outcomes in adolescents in comparison to both children and adults (e.g., cancer). Growing evidence suggests that adolescents’ health status with chronic disease is particularly disadvantaged engaging in risky behaviors to at least similar if not higher rates as healthy peers while having the potential for greater adverse health outcomes from these behaviors (11).

Research studies confirm that chronic disease affects one in ten adolescents worldwide. Outcomes included challenges to adolescent self-management, nature of the parent-adolescent relationship, illness representation, and perceptions of adolescent self-efficacy in compliance, medical decision making, laboratory measures, and adolescent self-management competence (12).

Part III: The Impact of the Quality of Primary Health Care Centers Upon the Adolescents’ Health Status

Throughout the course of data analysis, the study depicts that the quality of PHCCs does not enforce any effect on adolescents’ health status (Table 3). The logically driven interpretation for such findings can be presented in a way that as long as the quality of PHCCs is adequate for adolescents with chronic diseases they definitely maintain a good level of health status.

Due to the originality of the current study, no supportive empirical evidence of these findings is available in the literature. It has been recognized that health care comprises services provided by health professionals, including screening and prevention, treatment and disease management that result in the maintenance of physical and emotional well-being. Improvements in the health of adolescents can be accomplished through the utilization of empowered, efficient and effective public health measures that represent adequate quality health care(13). The report highlights the need to strengthen improving PHC, particularly to better manage the large numbers of patients with multiple chronic conditions (14).

Conclusion:

The study findings depict that the quality of PHCCs is adequate relative to all of its dimensions of general health status, tangibles, accreditation, responsiveness, assurance, and empathy. Adolescents’ health status is good regardless of their age groups as being early, middle and late age adolescents except that of the quality of life dimension of health status which has a fair level of evaluation. The study confirms that the impact of quality of PHCCs does not execute an impact on adolescents’ health status. It is confirmed that male adolescents experience more incidence of chronic diseases than females.

Study of Some Immunological Aspects in Scabietic Patients

Amerah Abdel Hadi1, Alaa Jawad Hassan2
1 Ph.D. Student, 2 Prof. Dr. Department of Biology, College of Sciences, University of Babylon, Iraq

Abstract

Scabies is an important parasitic skin disease that continues to persist all over the world. The current study was designed to assess some immunological parameters that may be related with scabies disease. Blood samples were collected from 60 patients (30 first infestation, 30 re-infestation) with ordinary scabies and 30 healthy individuals as a control group to determine the total and differential WBCs count, in addition sera levels of some immunological parameters including, C3, IgE and Indoleamine 2,3 dioxygenase (IDO). The results revealed that a significant increase (P≤0.05) in total and differential WBCs count of patients groups compared with healthy group, also the levels of immunoglobulin IgE and IDO showed a significant increase (P≤0.05) in patients groups in comparison with healthy group. Concerning with complement components (C3) its levels observed a significant differences (P≤0.05) between patients groups (first infestation and re-infestation), also between patients and healthy group.

Keywords: Sarcoptes scabiei. IDO. IgE. C3. WBCs. Patients.

Introduction

Scabies is a pruritic skin disease caused by Sarcoptes scabiei var. hominis which is characterized by severe itching particularly at night, red papules and often secondary infection. Commonly infested areas are the skin between the fingers, elbows, axillae, groin, penis, and nipples (1). Since, both the cell-mediated immune reaction in the skin and the circulating antibody response act parallels in clearing of the mites, eggs and debris (2). Hypersensitivity reactions in patients infested with scabies caused by secretion of different materials by S. scabiei in the host skin (3-4) and during 4 weeks from infestation of scabies the immunity developed and appears of first symptom (5) The human body is exposed to different pathogens every day, but only few of them causing diseases because of the natural defense that called innate immune system, which represent the first line of host defense (6).

The data concluded that serum levels of C3 and IDO may be play an important role in controlling or persistent of skin parasitic infestation with Sarcoptes scabiei and increased levels of IgE.

Materials and Methods

1. Patients and control:

A total of 60 patients infected with Sarcoptes scabiei var. hominis (25 males and 35 females) and 30 healthy individuals (15 males and 15 females) were included in current study.

2. Blood samples:

The blood samples were drown from each patients and healthy subjects (5ml). The sample was divided into two parts, the first placed in EDTA tube for calculate the total and differential WBCs count, while the other part was kept to clot at room temperature, then centrifuged at 3000 rpm for 10 minutes, after that sera samples were transferred into eppendorf tubes and stored at deep freeze until used.

3. Laboratory investigations:

A. The total and differential WBCs count assay:

The total and differential WBCs count were done according to the

B. Immunological assays:

Serum IgE was measured by Enzyme Linked immuno- Fluorescent Assay technique (ELFA) performed by mini VIDAS, according to the manual procedure in kit provided by bio Mérieux company /
France, while the levels of C3 and IDO were estimated by ELISA according to the manual procedure of kits provided by MyBiosource company/USA and Abcam company/UK respectively.

**Statistical Analysis**

The results were analyzed by using statistical system spss version -24. The data were expressed by means ± standard deviation (±SD). Differences among patients and control groups were assessed using least significant differences (L.S.D.)

**Results**

There was a significant increase (P<0.05) in means of the total WBCs count for patients groups compared with control group which reached to $12.783±1.488 \times 10^9$ and $12.790±1.482 \times 10^9$ (cell /L) for first infestation and re-infestation groups respectively, while it was $8.147±2.403 \times 10^9$ (cell /L) for controls (table 1).

The differential WBCs counts for the first infestation and re-infestation groups of patients were shown a significant increase (P<0.05) in neutrophils, eosinophils, and basophils compared with healthy group, but there was a significant decrease (P<0.05) in monocytes and lymphocytes in patients groups compared with healthy group as shown in table(1).

As notified in table (2) the results revealed that a significant increase(P<0.05) in the levels of IgE in patients groups compared with control group which reached to $524.15±246.59$ and $513.13±251.64$ (IU/ml) for first infestation and re-infestation, whereas it was $73.64±19.21$ (IU/ml) in control group. The data of current study showed statistically significant differences at the level of significance P-value < 0.05 between mean averages in studied groups, as notified in table( 2). In which, there was a significant differences in the levels of C3 between the three groups, which is reached to $2.61±1.49 \mu g/ml$, $64.74±26.8 \mu g/ml$ and $11.68±3.28 \mu g/ml$ in first Infestation, re-infestation and control groups respectively.
The results (table 2) showed that a significant increase (P < 0.05) in the level of Indoleamine 2,3 dioxygenase in patients compared to control groups, which reached to 7.61±2.39, 7.83±2.26 and 0.52±0.28 (ng/ml) in first infestation, re-infestation and control groups respectively.

**Discussion**

There were a significant differences (P<0.05) in the total and differential WBCs counts between patients and healthy subjects groups. (8) and (9) mentioned that the elevated numbers of lymphocytes, monocytes, eosinophils and basophils in scabetic patients compared with healthy group, also (5) reported that occurs of blood eosinophilia and enhanced production of IgE in scabetic patients.

IL-10 and TGF-β cytokines produced by eosinophils may alter the local character of the Th2/Th1 responses by preventing the differentiation of naïve T lymphocytes to either the Th1 or Th2 phenotype, on the other hand producing indoleamine 2,3,−dioxygenase by eosinophils may also drive Th1/Th2 imbalance (10-11).

The mechanisms for the infiltration of mast cells and basophils into the blood and skin remains to be addressed to elucidate their role and importance in scabies inflammatory and allergic responses. (12) and (13) referred that the activated mast cells and basophils rapidly produce TNF-α, IL-6 and Th2 cytokines (IL-4, IL-5 and IL-13) which are the main molecules responsible for the allergic Th2-type inflammation.

There were a significant differences in IgE levels among the patients groups and healthy subjects, in which (14) noted that elevate levels of IgE in patients compared with healthy groups which ranged between 17–1219 (IU/mL) when they studied 50 patients (suspected with scabies) and 20 healthy group. Also, (15) showed a high significant differences in total IgE levels (1.92±0.52 pg/ml) in patients with scabies compared with control group, while (16-17) have been documented a wide variation in serum IgE levels among healthy non-allergic adult populations. (18) explains the hypersensitivity reaction type 1 in patients infested with scabies who is responsible for expelling parasites and products from the borrowing of severe itching and scratching, which in turn leads to a sudden reduction in the density of parasites at the time it began to itch (19). On the other hand, the studies of humoral immune responses in forty scabietic patients and twenty healthy control individuals, showed no significant difference in the levels of IgE between patients and control groups, while other researches have demonstrated a significant increase in IgE levels among patients with scabies (20-21-22-23-24-25).

The cysteine and serine proteases of the dust mite and the serine protease of Aspergillus fumigatus have
all been documented to induce Th2-driven inflammatory responses dominated by elevated IgE, eosinophilia, and Th2 cells, therefore, the author suggests the mites and its products contains on inactivated serine proteases may be leads to elevate level of IgE. 

There are a significant differences in C3 levels between the three groups of the study, found that a significant difference in C3 levels between scabietic patients and control groups, in which there was a high levels of C3 in patients, while pointed out no significant differences in C3 levels between patients(177.71±81.34pg/ml) and controls (160.37±61.22pg/ml). On the other hand, showed no significant differences in the level of C3 in scabietic patients before or after treatment compared with control group, that’s mean a normal levels in the C3 concentration.

The results of current study revealed that a significant increase in IDO level in patients(first infestation, re-infestation) compared to healthy subjects group. illustrated that cutaneous Leishmania major infection stimulated expression of the immune regulatory enzyme indoleamine 2,3 dioxygenase (IDO) in local lymph nodes, therefore, induced IDO attenuated the T cells stimulatory functions of dendritic cells and suppressed local T cells responses to exogenous and nominal parasite antigens.

Recently, IDO-1 enzyme activity were lower in patients with asthma and allergic rhinitis than in control group (P<0.05), while in the same study they found that the patients with atopic dermatitis shows higher IDO-1 activity compared with control group (P<0.05). Meantime, mentioned that the IDO activity in serum of patients with atopic dermatitis and controls considered statistically significant differences.

Evaluation of Aspects of Continuing Nursing Education Programs in Kirkuk Health Directorate Hospitals

Hussein M. Abdulfatah¹, Salma K. Geehad²

¹Community Health Nurse Specialist, Kirkuk Health Directorate, ²Professor, Community Health Nursing, College of Nursing, University of Babylon

Abstract

Objective(s): To evaluate the aspects of the Continuing Nursing Education Programs in Kirkuk Health Directorate Hospitals

Methodology: A descriptive design, using self-evaluation approach, is employed throughout the present study. A non-probability sample of (251) staff nurse are recruited from Kirkuk Health Directorate Hospitals; Kirkuk General Hospital and Azady Hospital. A questionnaire is constructed for the purpose of the study which comprised of (1) part, (6) aspects and (52) item. Content validity and internal consistency reliability are determined for the questionnaire through a pilot study. Data are collected through the use of the questionnaire and structured interview a means of data collection. Data are analyzed through the application of descriptive statistical data analysis approach of frequency, percentage, mean of scores, total scores and range.

Results: The study indicates that the majority of nurses have evaluated the aspects of the continuing nursing education program as poor at Kirkuk Health Directorate.

Conclusion: The study concludes that the evaluation of aspects of the continuing nursing education programs is appraised as poor for the majority of nurses’ self-evaluation.

Recommendations: The study recommends that mandatory, periodic, systematic and effective evaluation of continuing nursing education program can be carried out for the benefit of both staff nurses, these programs and the quality of nursing care. Further research can be carried out on a large sample size, varied range scale of variables, large sample size and nation-wide continuing nursing education programs.

Key wards: Determination, Continuing Nursing Education Program, Kirkuk Health, Directorate

Introduction

Nursing is a thriving profession whose importance continues to grow in a complex healthcare system. Opportunities for continuing education abound and with online resources. While the availability of so many resources may feel overwhelming, it can be good to remember that nurses can tailor their continuing education to fit their particular professional needs (¹). Nursing is a lifetime learning process. Nurses not ever learn everything they want to know in nursing school. However, the greatest important thing that nurses learn is that if they don’t know something, or have not ever accomplished a procedure, they must ask for assistance and, when necessary, supervision. As far as we are concerned, the major reason for continuing education in nursing is the development and improvement in professional practice. Nursing continuing education provides nurses the prospect to learn and improvement of their own practices in secured patient care (²). Nurses in the 21st century will want to be highly skilled in technology and have widespread knowledge of healthcare policy, leadership and research. Nurses of the future will comprehend the value of evidence-based practice and be the leaders who aid implement new research for enhanced patient outcomes. These highly educated nurses will understand the value of collaboration and coordination crosswise multiple interdisciplinary teams. The future is very cheerful for highly educated nurses, especially those entering RN to
MSN programs. The healthcare system requests nurse leaders and visionaries more than ever. Those nurses will manage complex problems and see the impact of decisions on patient care and the healthcare environment in general. All of these topics can be met throughout continuing nursing education (3). Continuing nursing education and the submission of innovative knowledge to practice are progressively important means to advance patient care in today’s health environment. The inclination and aptitude to transmission knowledge, skills, and attitudes are serious to improving patient outcomes. It has been also suggested that continuing education program endorse knowledge, attitude, performance and competency of nurses (4,5). Nursing continuing education affords nurses the opportunity to learn and advance their own techniques in safe patient care. Continuing education, more than a professional requirement, is aimed at improving overall knowledge and career prospects of the nurses. Continuing education is necessary for nurses for such reasons: (1) Professional Requirement: Nurses are required to complete a certain number of hours, in specific or open courses, to get their license renewed; (2) Professional Validation: As a way to validate clinical competence and education, many employers require nurses to complete specific courses; (3) Quality Care: Continuing education helps in staying current in evidence-based practices to assist nurses in providing safe and quality patient care; (4) Promotion: As every course adds to your knowledge and skills, it helps in landing a promotion or a coveted position and (5) Minimize legal risks: Staying up-to-date is a mandatory requirement for the nurses. Failing to do so can have serious consequences. Continuing nursing education helps them keep their practice current and minimize potential legal ramifications (6).

In addition to that nursing continuing education presents nurses the prospect to learn and advance their own techniques in secured patient care, continuing education presents benefits for nurses that include: Remaining up-to-date in evidence based practices in order to provide safe and quality patient care. Many organizations contain continuing education in their employee performance evaluation, professional and personal satisfaction (2).

Based on the early stated evidence, the present study ought to evaluate the Continuing Nursing Education Programs at hospitals in Kirkuk Health Directorate.

**Methodology**

A descriptive design is employed throughout the present study to evaluate the aspects of the continuing nursing education programs in Kirkuk Health Directorate from November 3rd 2018 to April 30th 2020.

After receiving the approval of the Council of Nursing College for the study and prior to data collection, proposal and questionnaire of the study have been submitted to the Ministry of Planning Central Statistical Organization and the Ministry of Health and Environment Kirkuk Health Directorate in order to obtain an official permission to carry out the study. The permission, after being granted, is presented to the hospitals to ensure the agreement and cooperation.

The study is conducted at Kirkuk General Hospital and Azady Teaching Hospital in Kirkuk Health Directorate. These settings are the designated site for data collection, because all of them are representing the classification of hospitals as general and specialized ones.

A purposive “nonprobability” sample of (251) staff nurse is selected for the present study. All staff nurses, who have participated in the study, have presented with consent form and they are asked to sign the form for their agreements for the participation in the study. All participants are introduced with the study objectives and they are presented with the opportunity of being aware of the study affairs. Such action has been implemented to protect the participants’ human rights and facilitate access to them in order to gather the necessary data for the study.

The study instrument consists of the following:

**Part I: Aspects of the Continuing Nursing Education Program**

This part is comprised of six aspects as follows:

1. Program goals:

This part is comprised of (7) items which are concerned with the program goals. It is evaluated as poor (7-12), fair (13-17) and good (18-21).
2. Program Planning:

This part is comprised of (6) items which are concerned with the program planning. It is evaluated as poor (7-12), fair (13-17) and good (18-21).

3. Performance:

This part is comprised of (7) items which are concerned with the program performance. It is evaluated as poor (10-17), fair (18-24) and good (25-30).

4. Operation and Management:

This part is comprised of (8) which are concerned with program’s operation and management. It is evaluated as poor (10-17), fair (18-24) and good (25-30).

5. Program Outcomes:

This part is comprised of (10) item which are concerned with the program outcomes. It is evaluated as poor (10-17), fair (18-24) and good (25-30).

6. Program Effectiveness:

This part is comprised of (8) item which are concerned with the program effectiveness. It is evaluated as poor (8-13), fair (14-18) and good (19-24).

Each one of these aspects is evaluated based on the calculation of the total scores and ranges.

A pilot study is conducted for the determination of the study instrument validity and reliability for the period from February 12th to March 7th 2019.

The content validity of questionnaire is determined by panel of (10) experts who are provided with copy of study instrument and are asked to review and evaluate the instrument for its content clarity and adequacy. Some items are excluded and others are added after taking all the comments and recommendations into consideration. So, the questionnaire is considered adequately valid measure after performing the modifications that are based on the experts’ responses.

Internal consistency reliability of the questionnaire is determined through the use of split-half technique and the computation of Cronbach alpha correlation coefficient on responses of (20) staff nurse. The correlation coefficient is (r=0.85) which indicates that the questionnaire is adequately reliable measure.

Data are collected through the use of the study instrument and the structured interview technique as means of data collection for the period from March 10th 2019 to May 8th 2019.

The data are analyzed through the use of descriptive statistical data analysis approach of frequency, percent, mean and standard deviation, mean of scores, total scores and ranges.

Discussion

Analysis of evaluation of the aspects of the Continuing Nursing Education Program in Kirkuk Health Directorate has revealed that staff nurses have appraised these aspects as poor for the majority of them. Such finding provides empirical evidence that the continuing nursing education program has practiced series of insufficiencies with respect to all aspects of the program.

A study was done, In Korea, to develop a measurement tool for evaluation of continuing nursing education programs and to verify its validity for effective management and quality of education programs. The draft of the evaluation measurement is developed from consultation with professionals, focus group interviews targeting groups of nurses, and individual interviews with education program planners. After (6) professionals examined content validity, 46 items were retained. A pilot-survey is conducted to confirm the time required to complete the questionnaire and the level of understanding of general content and each item in the questionnaire. Construct validity is verified through exploratory factor analysis of data from a survey with (44) items completed by (452) nurses and (59) education program planners. The final evaluation measurement for continuing nursing education programs consisted of (6) evaluation factors and (36) evaluation items. The (6) evaluation factors include identifying program goals and target groups, program planning, performance, operation and management, program outcomes, and program effectiveness. The study concludes that the evaluation measurement for continuing nursing education programs developed in this study is considered suitable to utilize as
an evaluation measurement of the quality of continuing education programs for nurses (7).

**Conclusion**

The study concludes that the evaluation of aspects of the continuing nursing education programs is appraised as poor for the majority of nurses’ self-evaluation.

**Recommendations:**

The study recommends that mandatory, periodic, systematic and effective evaluation of continuing nursing education program can be carried out for the benefit of both staff nurses, these programs and the quality of nursing care. Further research can be carried out on a large sample size, varied range scale of variables, large sample size and nation-wide continuing nursing education programs.

**Financial Disclosure:** There is no financial disclosure.

**Conflict of Interest:** None to declare.

**Ethical Clearance:** All experimental protocols were approved under the Kirkuk Health Directorate and all experiments were carried out in accordance with approved guidelines.

Epidemiology and Seasonal Variation of Ixodid Ticks and Piroplasmida Detection in Cattle of Basrah Province, Iraq

Sabeeh H AL-Mayah1, Ashwaq T. Abdul-Karim2

1Prof., Dr, 2Assist. Lecturer, Department of Biology, College of Education for Pure Sciences, Basrah University

Abstract

Four hundred and twenty cattle belonging to different breed and age groups were investigated for infestation by ticks during the period from October 2018 to September 2019 in Basrah governorate, Iraq. Investigated cattle were found to be infested by four species of hard ticks namely (Hyalomma anatolicum anatolicum, Hyalomma marginatum turanicum Rhipicephalus (Boophilus) annulatus, Rhipicephalus sturanicus). No significant difference in infestation rate was observed according to the method of cattle raising (X²=0.455, p=0.500), however, seasonal variation in infestation with significant difference was found, higher infestation rate reported in June (63.3%) and the lowest was in January (20%) (X² =76.740 ,p = 0.05). In the meantime blood smears samples from the same cattle were also examined by microscopy for hemoprotozoan pathogens. The examination revealed that those cattle are infected by Babesia spp. (27.14%) and Theileria spp. (19.52%). No, significant difference in infection rate was found between male and females, but a significant variation was seen among age groups, however, age group 1-3 years revealed a high rate of infection. Seasonal variation in the infection rates were observed in infected cattle. Higher infection rates of Babesiosis and Theileriosis reported in June (50%) and (36.7%) respectively.

Keywords: Epidemiology, Babesia bovis, Theileria annulata, Hyalomma, Rhipicephalus, Basrah, Iraq.

Introduction

Cattle are most important source of national income for countries. The directorate of animal wealth estimated the number of cattle in Iraq about 2.5 million in 2007. We have no specific information on the races and strains of cattle that are raised in Iraq but are believed to be most of the indigenous cattle breeds and fall within the following races: AL-Janobi cows; AL-Restaki cows, AL-Sharabi cows and AL-Karadi cows; the last two races are confined to the northern region of Iraq, in addition, there are few numbers of the strain Holstein – Friesian introduced to improve local of dairy production. There are a number of obstacles facing the progress and development of livestock industry in Iraq, mainly diseases including ticks and tick-born disease (TBDs) which are most prevalent and exert their huge impact in tropical and sub-tropical regions. TBDs cause enormous losses through mortality, morbidity, productive losses and the cost control and their effect on the immune status of infected animal. The passive impact of ticks does not only acts as vectors for pathogens, but also causes significant effects on animals, such as lack of milk production, weight loss, skin grafting, and predispose animal to other bacterial and fungal diseases. The climatic condition of Iraq is favorable for growth of tick species which is contribute to potential occurrence of Babesiosis and Theileriosis which are caused by Babesia spp. and Theileria spp., respectively. Routine diagnosis of babesiosis and theileriosis is performed by microscopic examination of Giemsa stained blood smears and parasite viewing as well as clinical signs in severe cases, but in subclinical infections parasite microscopically undetectable and lead to relatively high rate of false negative diagnosis. Moreover, Bilgic et al. (2013) pointed out that it is difficult to differentiate between species of Babesia based on morphological characteristics, especially in mixed infection. If animals

recovery from infection, along with lasting carrier status, occurs in which low numbers of erythrocytes remain infected with parasites, and acts as carrier or reservoir for parasites. These carriers have an important role in the transmission of the infection by ticks.  

Materials and Methods

A - Study Area and Field Sampling

The study was accomplished in Basrah province, which is located in the southern part of Iraq, at a latitude of 30°30' and longitude 47°48'. A total number of 420 cattle were randomly sampled during the period from October 2018 to September 2019.

Samples were collected on farms with two different methods. Methods were applied, those that are grazed in unimproved natural pasture and those that are kept in the pens and are hand fed and watering. All cattle without regular acaricide treatment. The sample-level variables included sample size and location (northern, central, east, west, and southern areas). Cattle were categorized into age classes (<1 year old to ≥ 10 years) and divided into two categories: cattle with tick burden and no tick burden.

B - Collection of tick and Blood samples

Ticks were collected using rubbing alcohol pads surrounding the skin of cattle and removed by forceps and kept in labeling screw plastic tubes containing ethanol. All collected ticks were examined under the stereomicroscope. Species, sex, and state of feeding were recorded.

Ticks identification was done according to Hoogostaal et al. (1981) and Shubber (2014). Some of female ticks were frozen at -20˚C for DNA extraction.

Blood samples were collected from the vena jugularis from a total of 420 cattle with a 10ml disposable syringe under aseptic precautions. About 5ml of blood was collected in tubes containing Ethylene Diamine Tetraacetic Acid (EDTA) for DNA extraction and then stored in iceboxes at 4˚C. The samples were transported to the parasitology laboratory at Basrah University, Education College for Pure Sciences, where blood smears were prepared, and fixed by using methanol and stained by Giemsa, then examined under an oil immersion 1000x objective.

C - DNA Extraction

The DNA was extracted from blood and tick samples using DNA extraction kit (GeneiadBiotech, Taiwan) according to the manufacturer instructions. The extracted DNA were tested by Nano drop spectrophotometer (Type Implen) at a wave length 260/280 nm.

D - Polymerase Chain Reaction (PCR)

For the molecular diagnosis of T. annulata, B. microti, B. bovis, B. ovis, and B. motasi in ticks and cattle, PCR reactions were performed using the specific primers for detection T. annulata Cytob1 (F: ACTTTGGCCGTAATGTTAACAC, R: CTCTGGACCAACTGTCTTGG), 312bp (Bilgic et al., 2010); B. microti ISSrRNA (F: CTTAGTATAAGCTTTTATACAGC, R: ATAGGTCAGAAACTTGAATGATACA), 238bp (Inoue et al., 2015); B. bovis SSrRNA (F: CTGTCGTACCGTGGTTGAC, R: CGCACGGACCGGAGACCGA), 541bp (Chaudhry et al., 2010); B. ovis SSrRNA (F: TGGGCAGGACCTGGTTGAC, R: CCACGGGTTGCRAGACCGA), 565bp (Aktas, 2005); and B. motasi Rap1b (F: TGGGCAGGACCTGGTTGAC, R: CCACGGGTTGCRAGACCGA), 565bp (Ni, 2016).

The amplification protocol was as follows: initial denaturation at 95˚C for 1 minute followed by 35 cycles of 95˚C for 50 sec for T. annulata, 40 cycles of 94˚C for 1 min. for B. microti, 35 cycles of 94˚C for 30 sec. for B. bovis, and B. motasi, and 35 cycles of 94˚C for 1 min. for B. ovis, annealing 35 cycles at 55˚C for 50 sec. for T. annulata, 40 cycles of 54˚C for 1 min. for B. microti, 35 cycles of 50˚C for 30 sec. for B. bovis, and 35 cycles of 62˚C for 1 min. for B. ovis, and 35 cycles of 58˚C for 30 sec. for B. motasi. Extension at 72˚C for 1 min. for T. annulata and 72˚C for 90 sec. for B. microti, 72˚C for 45 sec. for B. bovis, and 72˚C for 1 min. for B. ovis and B. motasi with final extension at 72˚C for 10 min. for all pathogens (except for B. bovis at 72˚C for 7 min.) in the MiniAmp plus thermocycler. The amplification products were separated on 1.5 agarose gel stained with ethidium bromide.
E- Statistical analysis:

Chi-square test was used according to the SPSS statistical program (software, Version 23).

Results

Out of 420 cattle examined in Basrah governorate, an overall 42.5% cattle were infested by *Hyalomma anatolicum anatolicum*, 32.5% with *H.turanicum*, 23.1% with *Rhipicephalus turanicua*, 21.8% with *R.(Boophilus) annulatus*, and 6.2% with mixed infestation. 485 specimens of ticks were collected from 160 animals that mean the intensity of infestation for each animal was 3.0 ticks. Cattle raised in pens recorded the highest prevalence of ticks reaching 39.5%, while cattle grazing in pastures recorded a lower prevalence (34.9%), but the differences were insignificant ($X^2 = 0.455, P=0.500$). No marked differences were observed between sex or between age groups regarding the prevalence of ticks infestation. However, the monthly prevalence of infestation in cattle, *H. a. anatolicum*, *H. turanicum*, *R. turanicus* and *R.B. annulatus* was highest in June (63.3%) and the lowest in January (20%). There were significant differences ($X^2 = 76.7, P=0.05$) in monthly prevalence (Table 1).

$X^2 = 76.740, P=0.05$

Microscopic examination of 420 blood smears showed that 114 (27.1%) and 82 (19.5%) of cattle were positive for *Babesia spp.* and *Theileria spp.* respectively, according to the sex of cattle, however, there were no significant differences in the prevalence of infection.

Higher prevalence of infection with bovine babesiosis and theileriosis were recorded in cattle of 1-3 years age group 32.3% (50/155) and 22% (34/155) respectively, while lower prevalence recorded in ≥10 years for babesiosis 0.1% (1/11) and 0% (0/11) for theileriosis. There were significant differences between age groups ($X^2=19.88, P=0.001$) and ($X^2=24.81, P=0.00$) respectively.

The seasonal variation of infection showed that the highest rate of infection were found in June, represented by 50% for Babesiosis and 36.7% for Theileriosis, while lower rates recorded in October 8% and 4% respectively (Table 2). There were significant differences ($X^2=$
88.6, \( P = 0.00; X^2 = 116.69, P = 0.00 \) and \( X^2 = 71.5, P = 0.00 \) respectively.

Discussion

Iraq is located in the southern part of the northern temperate zone, and this location has significant impact on its climate, which is similar to the climate of the tropical region in terms of temperatures, as it is subtropical.

The current study provides preliminary epizootiological data on ticks and ticks borne diseases (TBDs) in south region of Iraq. However, this study provides useful information about the species of parasitoid ticks in cattle of this area. Cattle were infested with H. a. anatolicum, H. m. turanicum, R. turanicus and Rh. B. annulatus. Thus, it does not differ in terms of diversity with the study of Abdul Hussein(2006) and Muhammad(2013) in middle and southern Iraq. Infestation rate in the present study (38.1%) differs from 48.2% recorded by Tuama et al. (2007), 54.3% of AL-Ramahi (2011) and 62% of Mohammad(2015) from other parts of Iraq. These differences in infestation prevalence may be due to the animal raising practices and using or not using of acaricides, difference in vegetation, rainfall rate from year to year and availability of other appropriate host.

There was no significant difference in the rate of infestation of cattle raised in pens and that grazing in the pastures, although the cattle raised in the pens recorded a higher rate of infestation (39.5%).

Although variation was observed in H.a.anatolicum population in different seasons, the result indicates that is the predominant tick in all season in Basrah cattle. This population dynamic pattern may be attribute to the fact that hot and dry weather is conducive for the development of H.a.anatolicum ticks.

Aktas et al.(2004) have referred the abundance and diversity of ticks as well as the intensity of infestation in animals when studying the epidemiology of the diseases it transmits and this is what the current study has.
The life cycles of *Babesia* and *Theileria* parasites are very similar and closely related to them in that they are transmitted by the same vector which are ticks, but the latter differs by having a development stage in its life cycle, which is the infection of lymphocytes before the erythrocytes are infected, so it is possible to explain the epidemiological picture of both diseases as it is correct on the first can be correct in the second.

Abstract

Background: Measles remains a major public health problem in many developing countries including Iraq.

Objective: To describe the epidemiological and clinical profiles of measles among children admitted to Babylon Teaching Hospital for Maternity and Children.

Methodology: A descriptive observational cross-sectional epidemiologic study was conducted on children diagnosed and admitted to Babylon teaching hospital for Maternity and Children. using the (person, place, time epidemiological model) during the period from 1st of January 2019 to the 1st of September 2019. The total number patients was 157. The independent variables studied include; age, gender, residence, time of admission, nutritional status, vaccination status, any co morbidities, clinical presentations and complications.

Results: One hundred fifty seven clinically and serologically diagnosed measles cases who were admitted to Babylon Teaching Hospital for Maternity and Children. The male to female ratio was 1.4:1 the mean age of the patients 35.15±38.5 months (ranging between one month to 11 years). In this study Children under years were most affected. Seventy four percent patients were from rural districts and sub districts. The disease took the profile of epidemic and was seen most often during the hot season, with a peak in July. Majority of cases stayed in the hospital for three days and more. Only one death was reported with a a case fatality rate (0.63%).The most common complications in this study was pneumonia.

Conclusion: Measles remains a common, endemic illness mostly due to inadequate vaccination coverage, further analytic studies are strongly requested in Iraq to identify the real potential risk factors of the occurrence of this serious endemic diseases.

Keywords: Clinical Characteristics, Children, Measles

Introduction

Measles remains a common disease in many countries, especially in parts of Africa and Asia. People from both developed and developing countries are seen to be targeted from this medical problem. Although the incidence rate of this disease was significantly decreased during the period from 2000 until 20171. recent studies conducted in the USA and other countries indicated the level has started to grow up2. Measles is usually associated with fever and rashes3 that could be more dangerous among children came from developing countries and potentially leading to increase the mortality rate up to 15 percent4. Despite undertaken efforts on the issue of measles elimination in Europe by 2015, the goal was not achieved yet5. In some cases, the patients are urgently admitted to the hospital due to the severe complications6. In 2017, There were about 110,000 individuals who passed way from measles worldwide and most of the cases were seen to be among children7. The spread of this disease could be reflected by a significant demand of vaccination being used over the countries8-11. Epidemiological information is necessary to assess progress and document, measles elimination12-13.
Epidemiological studies about this contagious disease in Iraq are limited. This manuscript aims to describe the epidemiological features of measles cases admitted to Babylon maternity and children hospital during the year 2019.

**Methodology**

A descriptive observational cross sectional hospital based epidemiologic study was conducted on children with measles admitted and diagnosed clinically in Babylon teaching hospital for Maternity and children. This study covered the period from January until September 2019.

Data were collected retrospectively from Medical case sheets of children aged from 1 month till 11 years.

The independent variables studied include; age, gender, residence, time of admission, nutritional status, vaccination status, any co morbidities, clinical presentations and complications. We approached registered data in the hospital records on measles cases.

The collection of data were made by collaborative group of students of 6th stage of Babylon medical College After obtaining ethical clearance from the health authority. Data were presented in tables and figures, Spss version 21 was used to analyze data, Chi square was performed to assess the significance differences among the categorized variables, P values less than 0.05 were considered significant.

**Ethical Considerations:** This study was approved by the Research Ethical Committee in Babylon University –Hammurabi College of Medicine.

**Results**

Table (1) shows that about half of patients are below one year (45.2%).

Only (19.1%) of children above nine months were vaccinated as shown in table(2).

**Table (2): Distribution of measles cases by status of vaccination**

Chi Square = 24.685, df= 12, P-value = 0.016

**Discussion**

The current study shows that measles is still recurrent endemic viral disease in our country with evidence of epidemic on the endemic situation. The transmission of the endemic measles could be referred to the presence of continuous indigenous of measles virus for about 12 months and onwards targeting a specific area. Despite the fact that measles infection has been significantly reduced over the last decades, measles is still a big contributor for mortality among children living in low income countries. This study shows that males are infected slightly more than females this finding goes in line with the finding of another local study conducted in Baghdad province by Aziz HA et al but disagrees with the results of other studies. About one third of infection occurred before the age of one year this finding is similar to the finding of a local study and to the reported result by Choe YJ et al. in Republic of Korea. Large proportion of measles cases occurred among unvaccinated children in urban area. Measles is still attacking vaccinated children in our
society this may be to many factors including vaccine failure, this finding is similar to the finding of another studies \(^\text{19}\). These findings could be explained due to the vaccine failure. This failure could be caused by several factors like vaccine’s dosage being used, cold-chain system being applied. In addition to that, host-specific factors like persistence of maternally acquired immunity could also be accounted for such failure \(^\text{20}\).

The occurrence of this small epidemic of measles in our province was found to be higher in the beginning of summer months with a peak in July this result is in agreement with Hirfanoglu et al. in Turkey \(^\text{21}\) but disagrees with the results of other study \(^\text{13}\). This difference in timing may be explained by the time of occurrence of epidemics. The present study reveals that more than half of patients are moderately or severely malnourished, this result is higher than the proportion of malnourishments children with measles reported by other similar studies. In the present study about half of the study group were malnourished while 32.12% of children were malnourished in a local research \(^\text{13}\), while Ur-Rehman et al. reported 40% as malnourished \(^\text{22}\). The major complication in the present study is pneumonia and bronchiolitis (about 27%) followed by diarrhea, this finding is similar to the finding reported by Khan I et al.2013 in Peshawar –Pakistan \(^\text{23}\). In this study the majority of measles cases (nine in tenth) have typical presentations, studies indicated that both fever, maculopapular (hyper pigmented) rash are among other symptoms that can be effectively used as a monitoring tool for this disease in an epidemic area. More confirmation could also be established from the titter of anti-measles Ig M. \(^\text{24,25}\). Moreover, few patients showed some less typical features. More than two thirds of measles patients in this study stayed in the hospital more than three days duration of admission there is a significant association between younger age (<one year) and increasing the duration of hospitalization, this finding is in accordance with other study \(^\text{26}\), in Italy commonest age for admission was below one year \(^\text{27}\). Measles still threaten the health status of our community, a strategy for control and elimination of measles should be planned to get rid of this serious viral disease similar to countries in the Middle East. In 2019, the regional verification commission for measles and rubella announced that some of Eastern Mediterranean countries like Oman, Bahrain, and Iran are absolutely clear from both measles and rubella and this big achievement could therefore participate in the global efforts for reducing such diseases worldwide. \(^\text{28}\)

**Conclusions**

The study shows that measles still endemic in our country with evidence of recurrent epidemics, males are affected slightly more than females and about, affecting young children below five years mainly infants. Large proportion of measles cases occurred among unvaccinated children in urban area. Measles is still attacking vaccinated children in our society, the disease is associated with malnutrition and the vast majority of cases have typical presentation, the majority of patients were hospitalized for three years and more.

**Limitations:**

1- There may be inaccuracies in the data of the file system.

2- The study did not look at the measles laboratory performance indicators or the quality of serological specimens.

3- The weaknesses in surveillance performance and the gaps in the investigation of cases and outbreaks may conceal the true incidence and epidemiological pattern of measles in the province since it is hospital based, in this cross sectional study design cause and effects associations cannot be determined.

**Competing Interest:** The authors declare that they have no competing interests

**Financial Disclosure:** There is no financial disclosure.

**Conflict of Interest:** None to declare.

**Ethical Clearance:** All experimental protocols were approved under the University of Babylon and all experiments were carried out in accordance with approved guidelines.

Bacterial Infection and Seminal Fluid Parameters in Iraqi Sub Fertile Men

Mamdooh A. Al_Nasrawi1, Loqman J. Tawfiq2
1Assist Prof., 2 Lac. Prof., Ministry of Higher Education & Scientific Research, Meddle University of Technology, Medical Technical Institute/Baghdad, Nursing Dept

Abstract
Semen samples of 60 sub fertile men that aged from 25 and 45 years that attending an Al-Sammrai infertility hospital from 10-10-2017 to 5-12-2018 and were examined for bacteriological culture. The patients divide to negative group (A) the second as positive group (B). Semen were chaked from the groups and analyzed for viscosity, sperm morphology, semen volume, sperm concentration, and motility percent. The results for cultures was negative in 15% and positive in 85% of patients. The isolated organisms were as the following percentage ( Escherichia coli 11%, Staph. aureus (16%), B-hemolytic streptococcus 30%, Staphylococcus epidermidis 43 %). The semen characteristics in infected samples showed that the motility and viability of spermatozoa were lower when compared to noninfected semen sample. That are means, the infections have a direct effect on seminal fluid quality and subsequently negative effects on human fertility. The results showed that there are a highly significant difference (p˂0.001) between fertility power in noninfected men and infected cases.

Keywords: spermatozoon, seminal fluid, microorganisms, infection, human infertility.

Introduction
Infections of semen may affect male fertility power in different and methods. The mechanism of infertility is not understood completely and for some researchers the possible effect of infection in human sub fertility is debatable 24, 25. Chronic bacterial infection of semen is uncommon, but may be a cause of male infertility 5,23. The bacterial pathologies of the genital tract are the same to those infected the urinary tract 22,28. More studies found the correlation between seminal fluid infection and sperm quality. Fertile men have less microorganism in their seminal fluid when compared to sub fertile patients 14,22. These bacterial infections may effects directly on the sperm, or indirectly on the seminal fluid which may include antisperm antibodies forming 7,26. In the developing countries, the infections of semen is the most important factors that may cause human sub fertility 27. Gdoura R. et al, (2007) 6 and Hannachi H. et al, (2015) demonstrated that genital mycoplasmas and ureaplasmas seem to be widespread among the male partners of infertile couples in Tunisia which could influence semen quality negatively. The results also found that assay of PCR-microtiter plate hybridization method takes a rapid and good effective technique to determine human genital mycoplasmas and ureaplasmas which is very useful for epidemiological and etiological studies of these pathogens.

Materials and Method
Seminal fluid samples were evaluated from 60 men (25 to 45 years of age (average of 35 f 5.9) that they were no symptoms of genitourinary system. All selected men expatriate any medication in the past 3 months. The elect sub fertile men were refused if they had a varicocele and groin injury in genital tract. At the time of insertion, the sub fertile men were tested for urethral discharge and if it was present it will be excluded. Before they visited the hospital, the men will abstain for 3-4 days. Penis and hands were washed with bactericidal effect substance (exa. Soap), then by masturbation semen samples were obtained, then it will put into a sterile specimen container. During collection of the specimen, the sub fertile patients were not to use any lubricants.
One milliliter of the seminal fluid will be used for culture and sensitivity examination for microorganisms growth within short time. After liquefaction of seminal fluid, we examined it for other semen parameters (concentration of sperms, percentage of motile sperms, morphology and others). Morphology was performed as Eliasson procedure in 1971. Depending on [WHO 2010] criteria, seminal fluid analysis were performed. Bacterial culture of seminal fluid was performed as described by [12]. The data was statistically evaluated by using (Student t test) with the Minitab computer program.

**Results**

**Seminal fluid Characteristic**

The sub fertile patients were 25 years to 45 years old with (average of 35 ± 5.9). The sub fertility infertility duration was 2-6 years. This study inclusive 60 patients, 20 men were normal sperm concentration (35.6 %), azoospermia were 8 (12.12 %), and oligozoospermic were 12 (20 %), in 15 (25 %) were primary infertility and 5 (8.3 %) was secondary infertility. Depending on the result of bacteriological analysis, the samples were divided in two groups. The samples that did were Group A which were not show positive culture (n = 15 (25 %) and group B (n = 45) (75%) that with bacteriological positive cases. Table (1) is a summary of seminal fluid characteristics. Regarding motility percent, volume and viability, there were statistically significant differences between the two groups A and B. In group A, the motility of sperm and viability were higher in comparison to group B.

**Semen Bacteriology:**

Table 2 identified bacterial infection (anaerobic and aerobic) that present in the seminal fluid of sub fertile patients. The 60 samples were divided as following categories: 35 were aerobic positive bacteria and 10 were for anaerobic positive bacteria. 43% Staph. epidermidis, 11 %, E. coli, 16 %, Staph. Aureus and P-hemolytic streptococcus in 30 %.

Discussion

Our study is fastened on the subclinical non-symptomatic infection and its relationship to sub-fertility. Male accessory genital inflammation diagnosis is not easy and its causes on sub-fertility is questionable. The variability in more researches is very great that the effects of microorganisms infection and seminal fluid parameters of sub-fertile and fertile patients. The variation is 10 and 60% of positive cultures of fertile men and varied between 20 and 100% in sub-fertile men (2, 3, 8, 11, 13, 15, 19, 20, 22, 27). We try to determine the effects of infection by microorganism on the semen parameters. Staphylococcus has been reported to have a prevalence in semen of 24-100% [7] found that Staph epidermidis. have prevalence of 24 – 100%, but in our study is 63%. Besides in 28% of cases was recovered Strept. viridans of semen specimens in comparisons to 15 – 74% in another researches [19]. From 7% of the samples, non-aerobic gram-positive cocci were recovered in comparisons to 15 – 20% in those of another studies [19]. Depending on our study, we find that the infection by microorganisms, make changes of seminal fluid parameters such as sperm motility percent, semen volume, and status of viability. The fail of in spermatozoon motility percent may due to fixation of mobility ability of human sperm [6], or make spermatozoon to be dead by making harmful poisons produced by the infected microorganisms [10]. Degeneration of the morphology of human spermatozoon may happen due to infection by infectious microorganisms [1], also our present study find the same effect of infection on human spermatozoon by making deep structural effect in the morphology. Other study describe that there is no difference in parameters of seminal fluid for presence of infection or not in cases of study [27]. Kenny (2018) [13] established that there were no effects of any types of microbe that present in human
semen fluid on characteristics of sperm. In 1980, Jacques et al., established that the motility percent was decreased. The reason of variability of results may be due to seminal fluid collection ways and deference of investigation.

Daily Living Activities of School Age Children with Acute Lymphocytic Leukemia at Welfare Pediatric Teaching Hospital

Khatam M. Al-Musawi1, Nuhad Aldoori1, Zaid W. Ajil 2, Russell Qasem3, Hadeer Ali3 ,Sahar Ammar3

1Assistant Prof., 2Instructor, 3Academic Nurse, Pediatric Nursing Department, College of Nursing, University of Baghdad, Iraq

Abstract

Objective(s): The study aims to assess daily living activities domain of school age children with acute lymphocytic.

Methods: A descriptive study, conducted in Baghdad City from 13 of February to 20 of May 2016. A purposive sample of 50 children with acute lymphocytic leukemia at welfare pediatric teaching hospital and child central pediatric hospital. The study instrument was consists of three parts, the first was demographic data demographic characteristics of the child, the second part is related to the symptoms and clinical signs and complications phenomenon on the child, and the third part related to the daily activities for school age children.. Data was analyzed using (SPSS) version 25. The data analysis for this study included descriptive and inferential statistical analysis.

Results: The results of our study showed that (50%) within age groups (6-7)years , (60%) were males, (66%) of them were continuing school attendance, (56%) within class level (1-2) , the highest percentage (58%) of the study sample are not miss school. there is significant association between participants DLA and their demographic characteristics such as age, gender, school situation and education level, at p-value of (0.007, 0.004, 0.013,and 0.001) respectively, (96%) of them complain from yellowing and pale skin , (70%) complain from anemia, vast majority of them have moderate daily activities. that there is significant association between participants’ DAL and their Symptoms and Clinical Signs and Complications of the Child with Acute Lymphocytic Leukemia of, breathing difficulties , Yellowing and pale skin, bleeding and bruising and Anemia, at p-value of (0.003, 0.002, 0.001,and 0.005) respectively

Keywords: Children, Acute Lymphocytic Leukemia, Welfare Pediatric Teaching Hospital

Introduction

Leukemia is one of the most prevalent kinds of cancer in children, includes more than one third of all cases of cancer in the childhood 12. According to the International Society of Pediatric Oncology (2015), approximately 25000 cancer cases are diagnosed each year with estimates that suggest 90000 annual deaths due to cancer. Cancer is the third-leading cause of death after congenital heart disease 5. Acute lymphoblastic leukemia (ALL) is an aggressive neoplastic characterized by the uncontrolled proliferation of lymphocytes, and represents the most common childhood cancer. , several efforts have been made for the best treatment approach, such as combination of chemotherapy and radiotherapy

13 Diagnosis, hospitalization, and cancer treatment can cause distress for the child and family that lead to physical, psychological, and social problems. means living with disruptions to daily roles and routines due to the long protocols of chemotherapy usually last 2.5-3.5 years. Life, These problem involve motor skills and balance; social functioning especially in relating to their friends, and in their ability to learn 7. The main role of the nurse is to provide the children with adequate information about the planned procedure. The physical care of children with leukemia is usually complicated and risk of functional limitations and participation restrictions. General areas of nursing care include the assessment, management and prevention of infections, pain, side effects of chemotherapy and nutritional
problems 9. ALL refers to life threatening diseases among school age children can cause many physical health problems, which may affect their life process. is extremely stressful, and variety of school functioning. In addition to physical health problems, may also affect the psychosocial aspects.

Materials and Method

Design of the Study

Descriptive study was carried out in order to achieve the stated objectives.

Objectives of the study:

The study aims at: 1. Assess daily living activities domain of school age children with acute lymphocytic leukemia 2- find out relationships between daily living activities domain of school age children with ALL and their demographic characteristics such as (age, gender, school performance).

Setting of the Study

The study was conducted in Baghdad city; oncology ward at Welfare Pediatric Teaching Hospital

Sample of Study

Non-probability (purposive) sample of (50) school age children with ages of (6-12) year old are selected and their diagnosis with acute lymphocytic leukemia, as well as hospitalized for management

Study Instrument

An assessment tool has been adopted and developed by researcher design for purpose at the study: Part One Demographic Characteristics of the Child. The demographic characteristics of the child such as (age, gender, grade, Residency, Scholastic Case, child in the family order).Part Two Symptoms and Clinical Signs and Complications Phenomenon on the Patient the symptoms and clinical signs and complications phenomenon on the child such as (Skin problems, hair loss, anemia, breathing difficulties, Yellowing and pale skin, bleeding and bruising, abdominal pain, joints and bones pain, anorexia, inflammatory frequent, severe insomnia lethargy)

Rating and Scoring

The items have been rated and scored according to the following two points of likert scales are used for rating the items of activities as yes = 2, no = 1, for all items.

Data Collection.

The collection of data has been performed out of the utilization of questionnaire, and by means of direct interview with child. Data were collected from 13 of February 2016 to 20 of April 2016.

Statistical Analysis

The statistical data analysis using (SPSS-ver.20) in order to analyze and evaluate the data of the study. A descriptive statistical data analysis used in the study: which include frequencies, percentages; and Inferential statistical data analysis: used the Chi-square test.

Conclusions

According to the findings of the present study, the researcher concluded the following: Acute lymphocytic leukemia mostly occurs in males more than in females. Most of the study sample are at age group (6-7). The study confirms that ALL mostly common occurs among patients in urban residential area more than in rural. The vast majority of the ALL the children are continuing their school condition within educational level (Grade) (1-2). The vast majority of children complain about symptoms and clinical signs and complications of ALL. The vast majority of the ALL the children have moderate affected on daily activities.

Assessment of Primary School Teachers’ Knowledge about Stuttering of School-Age Children at First Al-Karkh Education Directorate in Baghdad City

Rafea Qadri Meteab Al-Qaisi1, Eqbal Ghanim Ali2, Ali Kareem Khudhair3

1Ph.D. Academic Nurse, Ministry of Health, 2Professor and Academic Supervisor, College of Nursing, University of Baghdad, 3Professor and Academic Supervisor, College of Nursing, University of Karbala

Abstract

Objective(s): To assess knowledge of primary school teachers’ about the stuttering of school-age children at first al-karkh education directorate in Baghdad city, and find out the relationships between primary school teachers’ knowledge and their demographic characteristics.

Methodology: The study started from the period of 20th September 2018 to the 1st of March 2020. Probability samples of 370 primary school teachers were chosen randomly. The questionnaire was designed and composed of two parts: the first part deals with the teachers’ demographic data; the second part includes a stuttering knowledge scale. Determined reliability of the questionnaire through a pilot study and determined validity through a panel of (31) experts. The data was collected through the self-administration method was used by asking the participants to complete the format of the questionnaire and fulfill the questions, and it described statistically and analyzed through the use of descriptive and inferential statistical analysis procedures.

Results: The findings of the present study indicate that (53.5%) of the study sample have poor knowledge about stuttering of school-age children, and the no-significant relationship between teachers’ demographical characteristics and their knowledge about stuttering.

Conclusions: The study concludes that most of the teachers’ had poor knowledge about the stuttering of school-age children, and there are no effects of socio-demographic characteristics of teachers’ on their knowledge about stuttering.

Recommendations: The study recommended an education program for primary school teachers about stuttering to improving their knowledge about stuttering in the school environment.

Keywords: Primary School Teachers, Knowledge, Stuttering, School Age Children.

Introduction

Stuttering is the most prevalent fluency disorder; it is a disruption in the flow of talking characterized by the repetitions of sounds or words, sound prolongations, and blocks, that may affect the rate and rhythm of speech, these core behaviors may be accompanied by avoidance of words, or speaking situations, physical tension, and negative reactions 17, 29, 31. It is a complex problem, also known as stammering.6,10,15,18,19,20. Stuttering is a common disorder that exists worldwide and in all cultures and races 1,4,12,21, is indiscriminate of intelligence, income, and occupation, it affects people of all ages and both gender, despite the difference in prevalence rates. Nearly 5% of all children stuttering for a period of their life, although there is no known cure for stuttering, 75% of children who stutter (CWS) will outgrow or recover spontaneously without any treatment by late childhood, and remaining about 1% with lifetime disorder 25. This can be attributed to factors such as the age of onset, gender, duration of stuttering moments, and family history 25.
Although there are many theories and abundant research about the stuttering, the specific etiology of stuttering remains unknown\(^5\), most scholars agree that stuttering has a multifactorial etiology. This means that stuttering is most likely the result of the interaction of genetics, environmental factors (such as stressful life events, parent attitudes), and developmental factors (such as physical, cognitive, speech-language skills)\(^21\). These factors are typically combined and can be the deciding factor in a child spontaneously recovering or becoming a person who stutters their entire life\(^29\).

Teachers carry a large share of the responsibility for children’s educational development, this responsibility may be greater when it comes to children with disabilities\(^24\). Moreover, teachers’ empathy and behavior as their interactions with CWS can have an effect on the way these children are viewed and treated by their peers\(^14\).

School-age children spend a significant amount of time at school, and there is no doubt that teachers are authority figures who can have a significant influence on their lives during early years of life\(^1,2,3,22\) also, teachers play an important role in the educational development of CWS, their attitudes can significantly affect the performance of school-age children in the classroom, as well as their progression, Many CWS testify that stuttering negatively impacted their self-confidence in school, academic capacity, and relationships with teachers and peers.

**Materials and Method**

**Study Design:** Descriptive cross-sectional study design was conducted on teachers working in governmental primary schools at first Al-Karkh education directorate in Baghdad city, the study started from the period of 20\(^{th}\) September 2018 to 1\(^{st}\) March 2020 and aims to assess knowledge of primary school teachers’ about the stuttering of school-age children, and find out the relationships between primary school teachers’ knowledge about stuttering and their demographic characteristics.

**Study Sample:** Probability samples of 370 primary school teachers and currently works in government primary schools were selected from 30 primary schools at first Al-Karkh education directorate in Baghdad City, they were chosen randomly from each school.

**The Study Instruments:** The instrument was constructed by the investigators to measure the primary school teachers’ knowledge about stuttering, the questionnaire format consists of two parts:

**Part I: Teacher’s Demographic Characteristics:** This section includes (6) items concerning the respondents’ general characteristics: age of teacher, gender, residency, marital status, education level, and their teaching experience years.

**Part II: Stuttering Knowledge Scale:** This part of questionnaire format comprised of a multi choices questions (26 items) concerning the teacher knowledge about stuttering, true and false choices have been scored and rated on two levels dichotomous scale true answer and false answer, (2) points for the true answer and (1) point for the false answer. The total score ranged from a maximum score of 52 to a minimum 26 with the higher score indicated of more complete knowledge of stuttering while the lowest score indicated poor knowledge.

**Data collection:** The data collected by the investigators, Participants were asked to complete a self-administered questionnaire, after taking the initial consent of each teacher to participate in the study, the process started from the 20\(^{th}\) of February until the 30\(^{th}\) of May 2019.

**Data Analyses:** This analysis was performed through the computation frequencies, percentages, standard deviation (SD), mean of the score (MS) and relative sufficiency (RS %). Also, the Contingency Coefficients (C.C.) test was used to the assessment of the relationship between the overall knowledge of participants and other variables.

**Results**

This result indicates that most of the study sample were represented (34.1%) within age groups of (40-49) years, and (83.8%) were females. Also, the highest percentage (93.2%) of the study sample are living in an urban residential area, (71.9%) of the study sample were married, (40.3%) were graduates from (Institute/2 year Diploma degree), and (35.9%) have (10-19) years’ experience in teaching.
The results in figure (1) illustrate that more than half (53.5%) of the study sample represents poor knowledge.

**Discussion**

Totally, the result of the current study revealed that overall knowledge about stuttering of school-age children of the majority of teachers was poor knowledge, which represented more than half of study sample, and over a third of the sample had fair knowledge, and only (3.5%) had good knowledge about stuttering (figure 1). The findings and evaluation of the teachers’ knowledge in the present study, lead to consider teachers’ responses as unsatisfactory, especially if take into account that the majority of questions were not practical but theoretical. The findings of this study were in agreement with previous study conducted by St. Louis, (2005) they reported that study sample had poor knowledge about stuttering and agree with (de Britto Pereira et al., 2008) they mention that study sample had poor knowledge about stuttering. Also agree with 13 who mention that teachers demonstrate an overall poor knowledge about stuttering.

**Conclusions**

Most of the primary school teachers were poor knowledge about the stuttering of school-age children, and there is no significant association between teachers’ attitudes toward stuttering and their demographic characteristics.

**Recommendations:**

Education program about stuttering is fundamental to increase the teachers’ knowledge about stuttering, and using mass media for educating the community as a whole and not teachers only.

**Financial Disclosure:** There is no financial disclosure.

**Conflict of Interest:** None to declare.

**Ethical Clearance**

All experimental protocols were approved under the College of Nursing and all experiments were carried out in accordance with approved guidelines.

Effect of Preheating on Micro-hardness of different Composite Resins

1M.Sc. (Baghdad), 2 Ph.D. (London), Department of Restorative and Aesthetic Dentistry, College of Dentistry, University of Baghdad, Iraq.

Abstract

Aim: The aim of this study was to assess the effect of preheating on the surface microhardness of different commercially available composite resins (G-aenial, Filtek Z350 and Tetric-N-Ceram).

Materials and Methods: Tubes of the composite resins were either kept at room temperature (24±1°C) or preheated for 40 min in a commercially preheating device to 40°C, 50°C and 60°C, respectively. From composite resin tubes, a total of 120 disk-shaped specimens (40 specimens of each composite resin, 10 disks from each temperature setting) were prepared by inserting uncured preheated composite resin into cylindrical nylon moulds (5 mm diameter × 2 mm height); before light polymerized for 40s with a light-emitting diode curing unit. The Vicker’s microhardness number (VHN) of each specimen was measured. Two-way ANOVA and Tukey test were used to analyze the collected data at a significance level of 0.05.

Results: In comparison to the room temperature, there was a significant increase in the mean VHNs of each composite resin by preheating to 40°C, 50°C and 60°C, respectively (p<0.05). For G-aenial posterior, Filtek Z350XT and Tetric-N-Ceram, at room temperature, the mean VHNs were 51±4.3, 60.6±3.7 and 76.6±1.4, respectively with significant difference between G-aenial posterior and Tetric-N-Ceram (p<0.05), while at 40°C, the mean VHNs were 65.7±2.5, 86.8±2.3 and 88.4±1.8, respectively with significant differences (p<0.05) between G-aenial posterior and the other two composites. At 50°C, the mean VHNs were 109.4±0.9, 104.4±3.4 and 114±0.71, respectively with no significant difference between composite resins. At 60°C, the mean VHNs were 122±3.2, 129±3.4 and 136±2, respectively with significant difference between G-aenial posterior and Tetric-N-Ceram (p<0.05).

Conclusions: Preheating significantly increased the surface microhardness of all tested composite resins with the highest value observed for Tetric N-Ceram at 60°C preheating temperature.

Keywords: Composite resins, Preheating, Vicker’s microhardness.

Introduction

Composite resin restorations placement in anterior and in particular, posterior teeth has increased dramatically over the past 5 years.1 The driving factors for such an increase might be the patient’s aesthetic demand, an increased desire for more conservative restorations and more predictable dental adhesive systems.2 In posterior teeth, load-bearing composite resin restorations may have a longevity comparable to that of amalgam.3 However, the use of conventional compositions, such as high-filler content densified or hybrid composite resin materials, may result in poor adaptation to the prepared cavity walls because of high viscosity.4 In such a framework, the marginal integrity of the final composite resin restoration might be affected because of the subsequent voids entrapment and the microleakage between the composite and the underlying tooth surface.5 However, composite preheating to a
temperature of approximately 68⁰C has been introduced as a method to increase the initial flow of the high viscous conventional composite resin materials prior to their placement and curing. An improvement in polymerization parameters such as curing depth, reaction rate and degree of conversion was found to be the coincidental aspect of such pre-heating procedure. Thus, a positive effect on mechanical properties of composite resin materials might be expected as a consequence to pre-heating, before polymerization, and such an effect has also been reported. Moreover, a mutual relationship has been reported between the degree of polymerization and surface microhardness. Vickers microhardness number (VHN) may be appropriated as a simple monitor of the conversion rate of composite, wear resistance and surface stability of composite, thus it may be identified as being one the best parameters to evaluate mechanical strength. Pre-heating resin composite reduces its pre-cured viscosity and enhances its subsequent surface hardness. These effects may translate as easier placement together with an increased degree of polymerization and depth-of-cure.

Chairside warming of composite resin is achieved by placing capsules, or syringes, of the material in a composite warming tray or a water bath. A number of manufacturers present commercial heating devices for this purpose. Calset composite warmer (AdDent, Inc., Dandury, CT, USA) is the most popular and effective preheating device; it can heat the resin to 37⁰C, 54⁰C and 68⁰C, and maintains a constant temperature as needed by the clinician. Another device called ThermaFlo™ composite warmer has introduced by Vista dental (USA) with a specially designed applicator to keep the material warm for optimal flow and added the advantage of extended length for access in deeper areas.

Warming composite resin has also shown to improved manipulation and resulted in less microleakage, which reduced the film thickness of some conventional materials. Testing the kinetic parameters of resin monomers polymerization revealed an Arrhenius-type behaviour such that a relatively simple increase in temperature may promote a large increase in reaction rate.

The aim of this study was to measure the surface microhardness of three commercially available conventional composite resin materials (G-aenial, Filtek Z350, and Tetric-N-Ceram) at room temperature and after preheating procedure to 40⁰C, 50⁰C and 60⁰C. These materials are usually used for direct composites posterior restorations. The null hypothesis stated that there is no difference in surface microhardness of the three composite resins at room temperature from that gained after preheating procedure.

**Materials and Method**

Three commercially available composite resin materials were used in this study. Tubes of each composite type were preheated as follow, the control tube of each type of composite resin material was kept at room temperature (24⁰C ± 1⁰C) without preheating and the other three tubes were preheated to 40⁰C, 50⁰C and 60⁰C in a commercially available preheating device (Figure 1) (Foshan, Stardent, Equipment Co., Limited, China), respectively. Preheated composite resins were used to prepare a total of 120 disk-shaped specimens (40 specimens of each composite resin). The specimens were prepared by inserting the uncured preheated composite resin into the cylindrical nylon moulds (5 mm diameter × 2 mm height). The moulds covered with a Mylar strip and held firmly between two microscopic glass slides (Micro Slides, Gold Seal) on both upper and lower surfaces to remove excess material and standardize surface finishing and to prevent leakage of thermally softened materials, as shown in (Figure 2).

Light was applied to the top surface of each specimen for 40 seconds with a light-emitting diode curing unit (Valo, Ultradent, Cologne, Germany). The light intensity was nominally 1200 mW/cm² checked with a radiometer (Patterson curing light meter, Patterson Dental Supply, St. Paul, MN, USA). For the three preheated groups, the composite resin tubes placed in the heating device for 40 minutes before light curing. This time was required for initially warming the device and maintaining the composite resin inside the tube at a constant temperature.

The temperature of each preheated composite material was monitored by inserting a thermocouple probe (1.3 mm diameter) inside the tube of composite resin immediately after removing it from the heating device; the probe fitted to a high-sensitivity temperature recorder (Geratherm medical AG, Gschwend, Germany). Each composite resin material inserted into the mould
within 45 seconds after removal from the heating device. The nylon moulds, clear glass slides, and the plastic filling instrument were warmed to 37°C before insertion of the materials. The composite resin discs stored in a dry opaque box for 24 hours. The surface microhardness analysis was performed with an HVS 1000 digital vickers microhardness tester (Leader precision instruments Co., Shenzhen, China), as shown in Figure 3, using a 100g load for 15 seconds. The microhardness machine provided with Vickers indenter produced a diagonal indentation on the on the top smooth surface of the specimens calculating the VHN at higher magnification. Three randomly selected points for each specimen was measured and averaged.

Statistics performed using SPSS software (SPSS Statistics 17.0, SPSS Inc., Chicago, IL, USA). Two-way analysis of variance (ANOVA) and Tukey test were used for multiple comparisons.

Results

The preheated composite resin showed higher Vicker’s hardness numbers than that of composite resins at room-temperature. Differences in VHNs were significant between the three composite resin materials at each temperature setting (p<0.05), except at 50°C, there was no significant difference in VHNs between the three composite resins. Also, there was continuous increase in VHNs of each composite resin material at different temperatures settings (p<0.05).

At room temperature, the mean VHNs were 51±4.3, 60.6±3.7 and 76.6±1.4 for G-aenial posterior, Filtek Z350XT and Tetric-N-Ceram, respectively with significant difference in VHNs between G-aenial posterior and Tetric-N-Ceram (p<0.05). At 40°C, the mean VHNs were 65.7±2.5, 86.8±2.3 and 88.4±1.8 for G-aenial posterior, Filtek Z350XT and Tetric-N-Ceram, respectively with significant differences (p<0.05) between G-aenial posterior and both Filtek Z350XT and Tetric-N-Ceram, respectively. At 50°C, the mean VHNs were 109.4±0.9, 104.4±3.4 and 114±0.71 for G-aenial posterior, Filtek Z350XT and Tetric-N-Ceram, respectively with no significant difference between composite resins. At 50°C, the mean VHNs were 122±3.2, 129±3.4 and 136±2 for G-aenial posterior, Filtek Z350XT and Tetric-N-Ceram, respectively with significant difference between G-aenial posterior and Tetric-N-Ceram (p<0.05).

Discussion

Based on the results reported here, the null hypothesis, stating that there is no significant correlation between pre-curing warming of composite resin and post-curing microhardness should be rejected. The three types of composite resin tested in the current study showed increased values of microhardness as a direct response to pre-curing warming. For all the three resin composites used in the current study, surface microhardness increased with preheating, these findings are in accordance with the results of previous studies.11, 15-18

In order to explain these results, it is important to understand that during polymerization, as soon as exposure to light, the process of monomer conversion will be initiated. With the progression of the reaction, composite will become more viscous with the formation and growing of the polymer chains. The increased in viscosity will limit the movement of molecules at this vitrified state, and prevents the completion of the polymerization.14, 19 Contrariwise, as a result of higher thermal energy, preheated composites exhibit an increase in monomer mobility, reducing the viscosity and augmented the molecular motion.15, 19, 20

Studies showed that, light curing of warmed composite resin even for a shorter period of time demonstrated a higher degree of conversion than light-curing at room temperature.8 On the other hand, refrigerated composite resin illustrated lower conversion rate.14 The increased viscosity of the refrigerated material resulted in slower propagation and subsequently decreased in monomer conversion. A correlation between monomer conversion and surface microhardness values has been reported in several studies.9, 17, 21, 22 In the current study, this might explain the significant rise in surface microhardness among all tested composite resin materials. It is important to note that all composites tested were light activated type, the polymerization reaction is initiated by light only, pre-curing warming of composite resin showed no evidence of polymerization until the material exposed to light.

Dental composites can be defined three-dimensionally by filler, organic matrix and coupling
agent. The hardness of composite resins reflects their molecular chain flexibility and degree of polymerisation\(^9,17\) and is affected by other factors such as resin matrix type, filler type and filler volume fraction. According to the results of this study, the chemical composition of each composite may have a significant effect on the microhardness of each tested material. Tetric-N-Ceram resin composite exhibited the highest mean microhardness under the various experimental conditions investigated, followed by Filtek Z350XT and G-aenial posterior. The high microhardness values achieved by both Tetric-N-Ceram and Filtek Z350XT resin composites may be related to the amount and type of fillers. These materials have high filler contents (63.5\%, and 78.5\% by weight, respectively) and employ the nano-filler technology, no significant difference was found between these two materials in surface microhardness. Filler content has been also correlated with depth of polymerization, hardness, compressive strength, and stiffness\(^23\). The presence of fillers enhances the resistance of the composite to abrasion, improves its mechanical strength and resistance to indentation.

The presence of different filler particle size could be another factor that affects the microhardness. As the light beam is scattered and reflected within the composite material during light-curing this can affect the degree of composite conversion, leading to lower microhardness values. Larger filler size variation in G-aenial posterior (16-200nm) might explain the lesser microhardness value when compared with Filtek Z350XT (4-20nm) and Tetric-N-Ceram (40-160nm).

**Conclusion**

within the limits of this study, warming of the resin composite materials significantly increased their surface microhardness; the greatest increase occurred at 60\(^\circ\)C, which may be recommended as suitable preheating temperature for all materials tested. This recent trend in composite application is promising, improving the mechanical properties, and thus enhance the durability of the restorations.

Antibiotic Effect on Pseudomonas Aeruginosa Isolated From Patient In Hila City

Murtadha Hamza AjeeL1, Fatma Moeen Abbas2, Amer Jassim Al-Khafaji3
1M.Sc., College of Science for women, University of Babylon, Iraq, 2 Department of Microbiology, College of Science for women, University of Babylon, Iraq, 3Department of Biology, Organic Geochemistry, College of Science for women, University of Babylon, Iraq

Abstract

In this study, a total of 400 clinical samples were collected from patients different hospitals in hilla city((13.51%) Margin teaching hospital, (27.03%)Al-Hilla teaching hospital,( 43.24%) Babylon hospital for maternity and pediatric and (16.22%)Chest Disease Center) , ( 37 ) isolates were identified as to P. aeroginosa, from 9 (18%) isolates from burn specimen, 7 (14%) isolates from otitis , 5 (10%)isolates from UTI , 4 (8%) isolates from wound , 3(7.5%) was isolated from blood specimen where as 6 (6%)was isolated sputum and only 3 (5%)isolates were detected from skin. The period of collection was extended from January 2019 to June 2019. Also antibiotic susceptibility were preformed using disk employed diffusion and agar utilizing dilution processes. Furthermore , the resistance of isolate to a variety of antibiotics has been investigated and found that these isolate have been resistance to more than one antibiotic : 37(100%) resistance to Cloxacilin , 37(100%) to Amoxicillin /Clavulanic acid, 37(100%) to cefotaxime, 36(97%) to ceftizoxone, 34(92%) to Ceftazidime, 14(37%) to Levofloxacin, 18(49%) to Gentamicin, , 3(8%) to Norfloxacin and 1(3%) to Azetronam.

Keywords: Pseudomonas aeruginosa, Different sources, Antibiotic susceptibility, Resistant, Gram-negative bacteria.

Introduction

Pseudomonas aeruginosa is a Gram-negative bacterium, an aerobe rod belongs to the Pseudomonadaceae bacterial family and so taxonomic classification relies on preserved substances, including 16srRNA which is a range of members of the Pseudomonas genus, divided into eight classes 17. Pseudomonas aeruginosa infection allowed the incorporation of the constituents of the outer membrane, namely secretary toxins like Lipopolysaccharides (LPs), general endotoxin, which is a protein, toxoids, mutant reacting toxins or nontoxic substances, Pilli, and Flagella 23,35. P. aeruginosa allows β-Lactamases; enzymes to deactivate the antibiotics by hydrolyzing the peptide attachment of the Ring β-Lactam. P.aeruginosa is capable of producing numerous β-lactamases, such as extended-spectrum β-lactamases (ESBL), chromosomal cephalosporinase (AmpC), and metallo-β-lactamases (MBL). Different kinds of MBLs were previously identified and brought on integrated products. Earlier researches have shown that high levels of morbidity and mortality are connected with MBL-generating P.aeruginosa in bloodstream diseases. the ampC gene mutation generates such resistance which unlike other β-lactamases 1,9,10,13.

Material and Methods

1- Patients:

A total of 37 Pseudomonas aeruginosa isolates were collected from different clinical specimens in Babylon province during the period from January to June 2019. These specimens were collected from 400 specimens obtained from inpatients suffering from different infections by taking swabs from Burn, wound, ear, UTI, blood, urine ,sputum and skin. MacConkey and Nutrient agars were utilized in aerobic conditions with a temperature at 42°C for 24 to 48hrs. Later, the bacteria were characterized using traditional biochemical tests depending on protocols from MacFaddin, (2000).
2- Antibiotic susceptibility tests:

The susceptibility of P. aeruginosa isolates were determined by disk diffusion method (Kirby–Bauer standardized disk method).

The Mueller–Hinton medium was employed for this test. The medium was cooled to 45–50°C and with a sterile wire loop, the 4–5 pure colonies were transferred to a tube containing broth at 5ml of BHI 37°C-incubated until its turbidity standard. This usually required at least 4–6 hours incubation. The cells density was compared with McFarland standard tube No. 0.5. Sterile swab made of wood and cotton was standardized-suspension-dipped streaking it onto the Mueller–Hinton medium dry surface with three different directions to obtain an even distribution of the inoculums. Using a flat and even surface, the plates were let to stay without distribution for 3 to mins for better dryness. The disks were inserted on the surface using gentle pressing with a sterile forceps within 15mins and incubated for 18hrs at 37°C with inverted position. The inhibition zones later were ruler-measured (millimeter) using CLSI (2012) as guidelines for deciding the sensitivity or resistance of the bacteria to the antibiotics used.

Result and Discussion

1) Isolation of Pseudomonas aeruginosa

During the period of study, 400 hospital-patient-based specimens were collected in hilla city, only 37 (9.25%) isolates from P. aeroginosa bacterium, 9 (18%) isolates burn specimen, 7 (14%) from otitis , 5 (10%) isolates, 4 (8%) isolates from wound ; 3 (7.5%) was isolated from blood specimen whereas 6 (6%) was belong to sputum and only 3 (5%) isolates were detected from skin . The outcomes were identified, table (1).

The second Gram negative HAP bacterium isolated from health care centers is P. aeruginosa with leveled up incidence and fatality rates 22,27 with highly risky illnesses, such as septic burns, in patients with low defense of the immune system 11,34 .

The P. aeruginosa incidence findings, here, assured 9.25 % (37/400) of the hospital samples with lower rates than that, 39.1%, uncovered by Okon et al.,2009 from Nigerian patients with infected wounds and, 25.5%, revealed by Ndip et al., (2005) in Cameroon, in Al-Sulaimania City Hospital, Iraq, at 17.85%, and in Egypt at 18.6%. Sample size and geographical distribution may have induced variations in the collected findings 30,14,15.
P. aeruginosa is well-revealed as HAP antimicrobial and chemical resistant gene carrying as unveiled of those genetically transferred materials such as via plasmids Nordmann (1993).

2. Properties of P. aeruginosa

Smooth and irregular looking colonies on nutrient agar with aromatic sweetish odor. Pseudomonas aeruginosa appear on Pseudomonas base agar Shiny, opaque, shiny, convex smooth, greenish-yellow colony Medium turned light blue. as shown in figure (1), a wide collection of the bacterium isolates unveiled colonies with green-blue fluorescent color with pyocyanin of medium diffusion in nature.

Figure (1) Pseudomonas aeruginosa on Pseudomonas base agar.

β-hemolysin was recorded to be released by certain isolates on blood agar. The growing on MacConkey agar was the dominant feature of all isolates; however, a limited number claimed positive lactose fermentation properties. Positive oxidase with Gram negative non-fermenting bacterial rods was uncovered for the survey isolates.

3. Antibiotic susceptibility test of P. aeruginosa:

Disk diffusion method:

The results of presents study showed resistant and sensitive isolates, so the effects of different antibiotics on P. aeruginosa isolates were investigated, and the results were similar to locally and worldly studies and the drug susceptibility patterns of P. aeruginosa isolates were varied as shown in table (2).

</tbody>
</table>

As shown above antibiotic susceptibility to P. aeruginosa results showed 97% resistance to ceftizoxone (30 μg), 63% to Norfloxacin, 100% to Cloxacilin, 100% to Amoxicilin /Clavulan acid, 37% to Levofloxacin, 49% to Gentamicin (10 μg), 92% to Ceftazidime (30 μg), 100% to cefotaxime (30 μg) and 71% to Azetronam, the results of presents study in line with results of were locally studies conducted by Al-Maamori (2011), Al-saffar (2005), Al-Gibouri (2006) and Zeki (2006). In presents study P. aeruginosa isolates showed resistant to aminoglycoside antibiotics, gentamicin (49%) to be disagreed with Lee et al in (2007) who was detected aminoglycoside-resistant in (47%) of aeruginosal reported variants and Alammary, (2013) declared resistant to aminoglycoside antibiotics, gentamicin (45%) in Hilla teaching hospital because the appearance of aminoglycoside resistant as acquired.

Resistance of P. aeruginosa to antibiotics of aminoglycosidic nature shows geographical variation as highest in Southern Europe with Greece, 49.8%, and the United Kingdom, 96.6%, of non-susceptibility to gentamicin.
The greatest antibiotic resistance rates were observed in ceftizoxime (100%), Cloxacilin (100%), Amoxicillin/Clavulan acid (100%) followed by Ceftriaxone (97%) which was agreement with other studies in ceftizoxime (99.2%), Cloxacilin (91%) and Amoxicillin/Clavulan acid (94%) (Amini and Mobasseri, 2017) and Kerman (95%) ceftizoxime, Cloxacilin (88%) and Amoxicillin/Clavulan acid (95%) (Moosavian and Rahimzadeh, 2015) This can make ceftizoxime, Cloxacilin and Amoxicillin/Clavulan acid a bad choice for further prescription against P. aeruginosa. (ICA, 2016). Show in Figure (2).

![Figure (2) Antibiotics on Pseudomonas aeruginosa](image)

Strains of P. aeruginosa have evolved increased resistance rates against in ceftizoxime (100%), Cloxacilin (100%), Amoxicillin/Clavulan acid (100%) and Ceftriaxone (97%) (Sofianou et al., 1997 and Snydman, 2010), The super bacterial resistance may be due the incidence of genetic modifications via mutations and gene moving between strains of P. auroginosa. 7, 32

The result of present study was disagreement with Babaeekhou et al., (2018) who showed 78.9% resistance to ceftizoxime, 68.1% to Amoxicillin/Clavulan acid, 67.3% to Ceftriaxone, 67.3% to carbenicillin, 65.2% to Cloxacilin, 63.7% to ceftazidime, 63.04% to gentamicin, 53.6%.

Azetronam and Norfloxacin had been recorded the lowest rate of resistance in the present study (3%) and (8%) respectively. It shows relatively low frequencies in other studies, the current findings from this work in line with Saderi and Owlia (2015) findings in Tehran (10.4%) resistance to Azetronam and (13.6%) resistance to Norfloxacin.

Levofloxacin had been recorded resistance rate in present study (37%) was agreement with study concluded by Peymani et al., (2015) in iran showed resistance of p. aeruginosa to levofloxacin (33.7%).

Geographical and time criteria may apply critical alterations in the status of resistance to those drugs. However, MDR of the bacterium is a featured property narrowing the antibiotic options available for managing related diseases. De novo occurrence of elevated rates of MDR was ensured via drug exposure with circulating of MDR strains between individuals. 2, 18, 21

**Conclusion**

Pseudomonas aeruginosa recovering from patients’ infected burns constitute a serious therapeutic problem. Pseudomonas aeruginosa isolates were resistant to Cloxacilin, Amoxicillin/Clavulanic acid and Cefotaxime, where as Pseudomonas aeruginosa isolates were susceptible to Azetronam.

Genetic Survey of Enteroaggregative E.coli in Diarrheic Children under 5 years in Thi-qar governorate

Sanaa Ghali Jabur¹, Murtada Hasan Abed²
¹Assist. Prof., ²Student, Pathological analysis/ College of Science/ University of Thi-Qar

Abstract

The study aimed to investigate the prevalence of Enteroaggregative E.coli obtained from children of Thi-qar suffered from diarrhea through PCR detection of virulence factors (aggR, astA, pic) antibiotic resistance and extended spectrum β-lactamase (ESBL) production. The investigation included collection 430 stool samples from diarrheic children under five years involved both gender and 40 samples as a control from healthy children , were consulted in (Bint al- Huda Hospital for Gynecology obstetrics and pediatrics , Al-Mousawi hospital and private clinics laboratory ) at a period extended from 10th December 2018 -21th July 2019. A total of the isolates were diagnosed by different laboratory and molecular method. PCR diagnosis confirmed the distribution of genes (aggR and astA) within EAEC were (66% and 53%), respectively. The highest resistance to antibiotics was (100%) to ceftazidime and cefpodoxime , (97% ) to ceftriaxone, followed by (96%) for Ampicillin, Sulfa-Trimethoprim and cefuroxime, respectively, and cefixime, amoxiclav, Cefotaxim and Tetracycline (94.8%), (92.3%), (85%) and (78.2%), respectively. While the medium resistance was (55.13%) for each of ciprofloxacin , pipercillin-tazobactam, respectively, and Amikacin (51%). While the lowest resistance was to Gentamicin (30.7%) and Imipenem (26.9%). EAEC isolates were multidrug resistance in average 64/66 (96.97%).

Key words: Enteroaggregative E.coli, virulence genes, antibiotic resistance, ESBL.

Introduction

Diarrheal diseases are still a global problem around the world especially in children under five years and are among the commonest causes of death among infants and children in developing countries, where poor hygiene and the absence of access to fundamental sanitation enable their dissemination. Worldwide diarrhea takes Order advanced on average death and UNICEF still considers diarrhea as one of the causes of death in young children under 5 years of age, it comes second after death rates of pneumonia (¹). Diarrhoeagenic Escherichia coli (DEC) is a common bacterial cause of acute and persistent infectious diarrhea, play a major role in children under 5 years of age. DECs are classified into six groups based on clinical associations, phenotypic assays and factors of virulence: Enteroaggregative E. coli, Enteropathogenic E. coli, Enterotoxigenic E. coli, Enteroinvasive E. coli , Shiga toxin-producing E. coli, and Diffusily adherence E. coli (²-³). Enteroaggregative E.coli is important one that has been implicated as an emerging cause of traveler’s diarrhea and persistent diarrhea among children and immunocompromised patients in both developing and developed countries. Enteroaggregative E.coli characterize by the primary infection mechanism start with attachment to intestinal mucosa by aggregate fimbriae and is controlled by the agg gene , as well as other secreted proteins that play a major part in pathogenicity. Culture and biochemical test can’t distinguished between commensal or pathogenic strains of E.coli in stool so PCR used to detect the virulence genes in pathogenic strains (⁴). PCR provide detection to many Diarrhoeagenic E.coli strains virulence genes with high sensitivity and specificity (⁵).

Materials and Method

Collection of samples

During the period from 10th December / 2018-21th July/ 2019, a total of 430 stool samples were collected from both gender of diarrheic children under five years had been admitted at hospitals and attended at
private clinics in Thi-Qar province, Iraq. Otherwise, 40 samples of stools from healthy children were obtained as control. The stool samples transported on Carry Blair swabs and cultured on MacConkey agar, Blood agar, XLD and EMB, incubated aerobically at 37 °C for 24 hours, the isolated bacteria were identified according to morphological, biochemical tests, API 20E and VITIK-2 system.

**Antibiotic susceptibility test:** performed by Kirby-Bauer procedure on Muller Hinton agar and results interpreted according to Clinical and Laboratory Standards Institute. All isolates were tested for ESBL production using the combined-disk test using ceftazidime (30 μg) and cefotaxime (30 μg) disks and combination with clavulanic acid (10 μg) disk and interpreted findings according to the Institute for Clinical and Laboratory Standards (6).

**Genetic diagnosis:** It preformed by PCR technique that was used for amplifying the virulence genes. The mixture reaction was performed in a total volume 20 μl of PCR Mastermix Gold Monoplex 5x (Mastermix 5 μl, DNA Template 2 μl, Forward primer 1 μl for each primer, Reverse primer 1 μl for each primer, free water ddH2O 11μl). PCR cycling program parameters used in this reaction for detection of (aggR , astA, pic) genes, the thermal cycling program(Initial denaturation 95°C for 3 min. 1cycle), ( Denaturation 94°C for 45 sec 30 cycle ), (Annealing 58°C for (aggR ,astA) and 59°C for (pic) 45 sec. 30 cycle ), ( Extension 72°C for 50 sec.. 30cycle), (Final extension 72° C for 10min. 1 cycle) (Holding 4° C 1 cycle). The amplification products were electrophoresed through a 2 % agarose gel and visualized with UV transilluminator after RedSafe™ staining. A 5 μl of 100 bp DNA ladder was used as a molecular size marker in a gel. Statistical analysis of all variables and comparisons was performed with Excel application (version 2010), Windows 7 and Statistical Package for the Social Sciences (SPSS) (version 22). Chi-square test was used for independent under P-value ≤ 0.05 was considered statistically significant (7).

**Results**

The percentage of positive bacterial infections were 180 (41.86%) while the rate of 250 (58.14%) represented other causes of diarrhea E.coli were isolated in 100(23.26%) of 430 collection samples followed by 80(18.60%) represented of other gram-negative bacteria (Salmonella, Klebsiella, Proteus, Pseudomonas, Enterobacter, Serratia, Cronobacter). Enteroaggregative E.coli occurred as the most present strain when reached 66/100 (66.0%), especially in children under two years while it not appeared in healthy children (control patients).

The appearance of aggR, astA and pic virulence genes EAEC isolates were rate 66 (66%), 53 (53%), and 6 (6%), respectively. The fact of aggR gene appearance in all EAEC isolates may be means all of them were
The distribution of patients infected with E.coli according to gender which were 53(53.00%) in males and 47(47.00%) in females, while the patients infected with strain Enteroaggregative E.coli were 37(37.00%) in males and 29(29.00%) in females. This results show no statistical significant differences between both gender.

The highest rate of infection exhibited artificial fed with rate 31/100(31.00%) while breast fed and mixed fed reduced to 15/100(15.00%) and 20/100(20.00%), respectively. Show table (1).

|                   | Calx² = 9.737 | Tabx² = 5.99 | DF = 2 | P. Value = 0.008 |

The high incidence of EAEC infection was recorded in first and second age group flowed by third and fourth age group, but there were no cases recorded in fifth age group as shown in figure (1).

**Antibiotic resistance patterns**

The results of antimicrobial susceptibility testing of the 66 EAEC isolates against 15 antibiotics are summarized in Table (5). All isolates (100%) were resistant to Ceftazidime and Cefpodoxime, followed by Sulfamethoxazole, Ampicillin and Ceftriaxone 63 (95.5%) then 61 (92.4%) for Amoxiclav and Cefixime, 56 (84.9%) Cefotaxime, 36 (54.6%) Ciprofloxacin, Piperacillin –tazobactam and Amikacin 34 (51.5%). While the lowest resistance was to Gentamycin and Imipenem that was 20(30.3%) and 18 (27.3%) respectively.

**ESBLs Phenotype**

The overall occurrence of ESBL-producing EAEC isolates was 56.06% (37/66). All isolates that were tested positive for ESBLs were also MDR.

**Discussion**

In present study, the most common type of diarrheagenic E.coli was EAEC, which may be largely responsible for diarrhea in children.

The most common type of diarrheagenic E.coli was EAEC, which was prospect largely responsible for diarrhea in children with prevalence 66%, this result near with globally studies such as by Abimiku et al (8) in Nigeria (68.67%), Mandal et al(10) in India (69%). The out result more than local and globally studies such as Abdul-Hussein et al (5) in Kut who showed incidence of EAEC was (40.5%) and Zhou et al(11) in China reported (20%), that reported a high a frequency of EPEC pathotypes associated with pediatric diarrhea.

Three predominant genes detected in EAEC from diarrheic children in Thi-qar were aggR (66%), astA
(53%), and pic (6.0%). This results corresponding with Ali et al (12), they were reported relatively similar findings for aggR (90%), astA (52.6%) and pic (5.3%).

The present study with PCR showed no-statistical significant according to gender. The current study agreed with Ammary and Pediatrics (13) in Baghdad, Aslani et al (14) in Iran, when was detect differences between males and females infection rate, males was higher than females. The virtual but not statistical high rate of infection in males may be due to males are more active, and more mixing in society Thi-qar than females.

Molecular analysis proved statistical significant according to type of feeding where the infection rate in artificial fed more than mixed fed and breast fed. These results corresponded with some previous studies as the study by Ali et al (12) in Egypt and Ammary and Pediatrics (13) in Baghdad. The high incidence of infection in artificial fed and mixed fed may be due to several factors including; poor hygiene, sanitation, Contamination, the widespread spread of bacteria, particularly in low-birth communities social and economic (14).

Habitation did not excite statistical significant in infection rate that was (56.06%) in rural while decreased in urban (43.94%). These results consistent with some previous studies Gutiérrez-Jiménez et al (15) in Mexico whose noticed infection rate of EAEC in rural (52%) compared with urban (48%), also the current results were comparable to the results of Ammary and Pediatrics (13) in Baghdad, were said (64%) positive samples from rural and (36%) positive samples in urban.

Enteroaggregative E. coli pathotype were detected in each one of 4 age group, but the most cases infection were occurred among children in first and second years, this result consistent with local study reported by Khalil (3) in Baghdad showed high prevalence of EAEC in children less than 2 years. Some researches close agreement with this results involved Nguyen et al (16) in Vietnam who showed that EAEC was more frequently isolated in children less than 2 years.

**Antimicrobial Susceptibility Pattern**

Our study for Cefpodoxime and Cefuroxime was agreement with global studies by, Amin et al (3) 81.3%, Karami et al (17) 97 % and Rodriguez-Baño et al (18) 97.3. Resistance to Ceftriaxone and Cefotaxime (100,85%), respectively agreement with another study had been reported high resistance in studies done by Sakhi (19) 85.7% and AL-Hilali (20) 68%.

Resistance to Amoxiclave (92.32%), was agreement with another studies as done by Al-Hilali (20) in Al-Najaf who motioned resistance 83.4 % and also with the study of Khoshvaght et al (21) in Iran with rate 86.11% . Resistance to ampicillin and sulfa-Trimethoprim (96.1%), were agrees with Aslani et al (14) and Amin et al (3), hose reported 100% resistance for each one.

Similar study by Sakhi (19) in Thi-qar indicated highest resistance in E.coli isolates to Tetracycline 78%. Another studies involved Konate et al (22) in Burkina Faso whose revealed that 85 % of E. coli isolates were resistance to tetracycline. Therefore tetracycline should not be used without first performing culture and sensitivity (23).

Piperacillin-tazobactam showed resistance similar with global study by Konaté et al (22) whose reported resistance (64.5%). locally Shamki (24) where pointed resistance in rate (60%).

Ciprofloxacin showed medium resistance corresponding with globally study by Cassier et al (25) and Khoshvaght et al (21) whose marked out resistance about (61%) and (47%), respectively.

Amikacin, this result corresponds a study performed by Shamkhi (24). Globally in lined with Zhou et al (11) found that vast majority of E. coli were susceptible to Amikacin, in 7.4%

Gentamycin showed low resistance agreemented with 34% reported Cassier et al (25) and Khoshvaght et al (21) 41%.

Imipenem belong to carbapenem antibiotic binds to different penicillin binding protein. It is from the most active drug against gram negative bacteria, the sensitivity of Enteroaggregative E.coli to imipenem was (44.87%).

The current study found all Enteroaggregative E.coli isolates were multidrug resistance in rate 96.97%. This results agreed with Dembélé (23) in Burkina Faso and each study of Khoshvaght et al (21) and Aslani et al

Prothrombotic Changes in Patients with End-Stage Renal Disease and its Relation to Thrombotic Cardiovascular Complication

Enass Abdul Kareem Al-saadi,1 Haithem A Al-Rubaie2, Raid A Al-Rubaye3

1FIBMS, Lecturer of Hematopathology, Department of Pathology, College of Medicine, University of Karbala, Iraq, 2FICMS, Assistant Professor, Department of Pathology, College of Medicine, University of Baghdad, 3CABM, Consultant physician and nephrologist, Al-Karama Teaching Hospital, Baghdad, Iraq

Abstract

Background: There is a great risk of cardiovascular disease (CVD) and vascular thrombosis in patients with End-Stage Renal Disease (ESRD). These patients exhibit numerous abnormalities in coagulation, fibrinolytic, inhibitory protein abnormalities in multiple levels.

Aim: To assess hypercoagulable changes by measuring the levels of Antithrombin, plasma fibrinogen and FXII activity in patients with ESRD, and to found correlation between and hematological parameters including: Hb level, WBC count, reticulocyte percentage and platelet count.

Method: A case control study conducted at Al-Hayat center, Al Karama teaching hospital during the period from the 1 of February to the 30 of October 2014 and 50 patients aged < 60 years of both genders with (ESRD) in addition to 20 apparently healthy controls were included in this study.

Results: Patients and controls were matched for age and gender. The mean hemoglobin level, total WBC count, absolute neutrophil count, reticulocyte percentage and platelets count were significantly lower in ESRD patients than controls, P<0.05. The mean values of the coagulation parameters, Prothrombin time (PT), Activated Partial Thromboplastin Time (APTT), Plasma Fibrinogen and Factor XII activity were significantly higher in patients than controls. Anti-thrombin activity was significantly lower in patients group than controls, (P<0.001). Cardiovascular complications and vascular thrombosis included Deep Venous Thrombosis (DVT), Cerebro-Vascular-Accident (CVA), Myocardial Infarction (MI), angina or heart failure reported in 62% of the patients. Patients with cardiovascular complication and vascular thrombosis had significantly higher PT, APTT, and factor XII activity, lower anti-thrombin activity as compared to those without cardiovascular complication and vascular thrombosis.

Conclusion: (ESRD) patients had coagulation abnormalities render them more liable to have cardiovascular complications and vascular thrombosis.

Keywords: End stage renal disease, Antithrombin, Factor XII activity, plasma Fibrinogen, coagulation parameters.

Introduction

The chance of occurrence of cardiovascular disease and vascular thrombosis is far greater in patients with ESRD than in general population.(1) CVD was significantly more prevalent in uremic patients treated by hemodialysis (HD) or peritoneal dialysis (PD) compared with other populations of a similar age as proved by many studies.(1,2) ESRD poses a great cardiovascular fatality rate as it has been established. Cardiovascular consequences provide a mortality
rate of about 10- to 100- fold higher among patients on dialysis than persons matched for age and sex in the general population.\(^{(3)}\) Vascular sequelae caused by atherosclerosis are the main cause of death in patients undergoing HD.\(^{(4)}\) A modification in the coagulation pathway and in fibrinolysis are the major cause of hyprocoagulability and these modifications may result from endothelial cell activation and damage.\(^{(5)}\) Most of the traditional risk factors detected in the general population increase the risk of CVD in chronic kidney diseases (CKD) patients. In fact, numerous Framingham risk factors are more prevalent among CKD patients as compared to those with normal kidney function. Additionally, non-traditional risk factors which are related to CKD patients also contribute to the CVD burden.\(^{(6)}\) CVDs are the leading cause of death among patients on HaemoDialysis HD.\(^{(7)}\) Elevated levels of fibrinogen and D-dimer were associated with the presence of atherosclerotic disease independent of renal function and other risk factors. Changes in hemostatic parameters occur early in the course of renal failure in patients with arteriolar nephrosclerosis, suggesting a prothrombotic state that may contribute to the risk for atherosclerotic disease at all levels of renal function.\(^{(8)}\) Persons with elevated plasma fibrinogen concentration in those with risk factors may further increase the risk of the development of atherothrombosis and subsequent CVD through the blood coagulation system.\(^{(9, 10)}\)

**Patients and Method**

**Study design setting and time:**

This case-control study was conducted at Al-Hayat center in Al-Karama teaching hospital during the period from 1 February to 30 October 2014

**Patients:** After approval of study protocol from the scientific council of the Iraqi Board of Pathology and patients consents, a total of 50 adult patients aged < 60 years of both genders (35 males and 15 females) with ESRD on repeated sessions of HD, 2-3 times per week, were included in this case-control study.

**Exclusion criteria:**

- Patients aged above 60 years to avoid the risk of thrombosis.
- Patients with congenital or acquired thrombotic disorders, e.g. malignancy, DIC, liver disease or deranged liver enzymes, systemic lupus erythematosus or other immunologic diseases and pregnancy.
- Recent major surgery within the last 3 months.
- Active inflammation.
- Patients taking any type of anticoagulant therapy during the preceding one week.
- Women using oral contraceptives pills.
- Inability to give informed consent.
- Those who did not want to participate.

**Control group:** A 20 apparently-healthy participants aged (22-50) years, 14 males and 6 females were enrolled as controls and pre-constructed data collection sheet was filled for each participant (patients and controls) and included: personal information, and clinical and laboratory data.

**Methods:** This study test the hematological parameters including: Hb,WBC count, absolute neutrophil count and platelet count by using an automated electronic counter (Hematology auto-analyzer - BECKMAN COULTER, ACT. 5 diff. USA) and reticulocyte percentage by standard method using new methylene blue solution. While Coagulation Tests which were done in current study include:

- **Prothrombin time (PT)**
- **Activated partial thromboplastin time (APTT).**
- **Fibrinogen assay (clauss technique) by using commercially available kit FIBRI- PREST® 2 (DIAGNOSTICA STAGO, France).\(^{(11)}\)**
- **Coagulation factor XII activity:** was done using coagulation factor XII (STA Deficient XII) kit where the assay consists of measurements of the clotting time in the presence of cephalin and activator of a system in which all the factors are present and in excess except factor XII which is derived from the sample being tested.\(^{(12)}\)
- **Antithrombin activity (AT):** LIATEST® AT Kit was used using antigenic assay of AT
concentration by the immunoturbidimetric method which based on the change in turbidity of a micro-particle suspension that is measured by photometry and the suspension is mixed with the test plasma whose AT antigen level is to be assayed. An antigen-antibody reaction takes place, leading to an agglutination of the latex micro-particles which induces an increase in turbidity of the reaction medium. This increase in turbidity is reflected by an increase in absorbance, the latter being measured photometrically.\(^{(13)}\)

**Statistical Analysis**

Data of patients and participant were transformed and entered to the computer by using data base software with statistical utilities; The IBM statistical package for social sciences (SPSS), Chicago, USA, software version 20 was used for entering and analyzing the data. Level of significance (\(P\) value) was set at < 0.05 as cutoff point to be considered as significant difference. Results and findings presented in tables and figures with explanatory paragraphs.

**Results**

The hematological parameters of patients were significantly lower than that of the controls with a statistically significant differences with \(P\) value <0.001 for Hb, total WBC count and reticulocyte percentage, and \(P= 0.005\) regarding platelet count while there was no statistically significant difference found in absolute neutrophil count between both groups (Table 1).

The mean PT, APTT, fibrinogen and factor XII were significantly higher in patients than in control group with \(P\)-values of 0.008, 0.026, <0.001 and 0.001, respectively. While antithrombin was significantly lower in partent’s group with \(P\)-value of <0.001 (Table 2).

Cardiovascular disease (CVD) and vascular thrombosis was present in 62% of patients (31/50): deep venous thrombosis, cerebrovascular accident, angina, myocardial infarction, and heart failure were noticed in 20%, 16%, 16%, 8% and 8% respectively. Interestingly, 3 patients had 2 CVD at the same time.

The correlation between coagulation parameters and hemoglobin revealed a significant inverse relation between PT, APTT, fibrinogen and factor XII activity with Hb (\(P\)-values= 0.02, 0.001, 0.001 and 0.001 respectively), a significant direct relation between AT activity and Hb with \(P=0.001\) (Table 3).

The comparison of the mean values of the coagulation parameters with CVD and vascular thrombosis had significantly prolonged mean PT, APTT, higher factor XII activity and lower anti-thrombin activity than the 19/50 patients with no CVD and vascular thrombosis as follows: the mean PT was 17.49 ± 6.06 versus 14.32±2.31 with \(P=0.013\) (Figure 1); APTT 45.38 ± 23.90 versus 33.56 ± 9.51 with \(P=0.017\) (Figure 2) and factor XII activity (%) 205.94 ± 110.99 versus 136.59 ± 65.82 with \(P=0.008\) (Figure 3).

Discussion

In general ESRD patients not only experience an excess morbidity and mortality due to arteriosclerotic cardiovascular disease, but also thrombosis of the vascular access.(14) The ESRD patients exhibited numerous abnormalities of coagulation, fibrinolytic, and inhibitory proteins at multiple levels which involved in the pathogenesis of cardiovascular complications and vascular thrombosis in those patients. (15)

The current study found that the mean values of Hb level, total WBC count, reticulocyte percentage and platelets count of the 50 ESRD patients were significantly lower than their corresponding values of the controls (P<0.05). The mean value of the absolute neutrophil count was also lower in ESRD patients than controls in this study but the difference didn’t reach the statistical significance. Anemia is a common complication of CKD which is associated with increased morbidity and mortality and this finding is supported by that of Al-Nozha et al.(16) The frequency of occurrence of anemia correlates with the severity of Renal Failure, and is forming about 1% in stage 2 of CKD to almost 100% in ESRD or chronic HD patients. (17, 18)

Patients with ESRD in this study had a lower total leukocytes and differential counts when compared to that of control group and this finding was explained by Agarwal and Light who mentioned in their study that leukocyte counts change over time in people with CKD, and there was a decrease in lymphocytes and eosinophils. (19)

The current study found that PT and APTT were significantly elevated in patients as compared to controls (P<0.05). These findings were consistent with that reported by Alghythan and Al Saeed (20) who found that PT and APTT were significantly increased after-HD when compared to the before-HD levels and controls. The present study documented that mean plasma fibrinogen of ESRD patients was significantly higher than that of controls, (P<0.001), in line with the findings of a recent Egyptian study in 2013 which found a significant increase in plasma fibrinogen which might contribute to the hypercoagulability in ESRD patients.(21) The present study found that AT activity was significantly lower in ESRD patients than controls, (P<0.001). This finding agreed the findings of previous studies, Vaziri and his colleagues (23) which found that AT activity and concentration were significantly reduced in ESRD patients. Regarding factor XII activity, the current study reported that the mean factor XII activity of the ESRD patients was higher than that of controls (P=0.001). These findings were consistent with another study was conducted by Svensson et al involving ESRD patients on hemodialysis, it was reported that FXII activity in those patients was higher compared to normal subjects. (24)

Conclusions

End stage renal disease patients had significantly lower Hb levels (anemic), lower total WBC count, lower Reticulocyte count and lower platelets count as compared to healthy controls. Also we conclude that PT, APTT, plasma fibrinogen and factor XII activity levels were elevated in ESRD patients compared to healthy controls, while Anti-thrombin activity was reduced. Another conclusion we found in this study is that Higher levels of PT, APTT, Plasma Fibrinogen and Factor XII activity and the lower Anti-thrombin activity associated with higher prevalence of cardiovascular disorders and vascular thrombosis.

Relationship of Sex Hormon Binding Globulin, Thyroid Stimulating Hormone, Testosterone and Prolactine with Body Mass Index (BMI) Value among Iraqi Females in Reproductive Age

Abbas Mehsen Gata¹, Jaleel Samanje², Ammer Abd. Mohammed¹, Saman Jumaah³

¹Lecturer, ²Dr. Lecturer; Middle Technical University, College of Health and Medical Technology / Baghdad, Iraq, ³M.Sc. Medical Biochemistry, Kirkuk health directorate, Kirkuk, Iraq

Abstract

Background: The purpose of this study was to determine the relation between increasing in the body mass index (BMI) value and sex hormones level represented by sex hormon binding globulin (SHBG), Thyroid stimulating hormone (TSH), testosterone and prolactine in 51 women in reproductive age aiming following the life quality of these females.

Method: Participants were 51 women from center of Baghdad city. Every female full a questionnaire and sex hormone concentration from each female were measured. Level of FBS and HbA1c test was estimated and designed as exclusion criteria for diabetic mellitus and other metabolic disorders. Body mass index value was compared by demographic properties, Pearson’s correlation coefficient and A stepwise method in linear regression statistic test was applied to detect the association of BMI (kg/m²) with serum sex hormon binding globulin (SHBG), Thyroid stimulating hormone (TSH), testosterone and prolactine and predict the most affected factor.

Results: The mean and standard deviation level of most studied parameter were not differences between case study and control females group (obese vs non-obese) in compared with normal value of each test. BMI value were negatively correlated with age and SHBG (nmol/l) level (r = 0.156; P= 0.274) and (r = 0.578; P = 0.00) respectively. While BMI were moderately positive correlated with testosterone (nmol/l), TSH (μIU/mL) and prolactin (ng/ml) (r = 0.388; P = 0.005), (0.354; P = 0.011) and (0.37; P = 0.006) respectively. Depending on the stepwise method in linear regression analyses, the SHBG (nmol/l) and testosterone (nmol/l) were the most independent predictor factors for BMI in the studied groups (β = 0,484; P = 0.001) and (β = 0.348; P = 0.001) respectively.

Conclusions: The most factors affecting obesity identified in the study were SHBG, Testosterone. However, other variables such as age, did not impact the BMI value of participants.

Keywords: Iraq; Sex hormone binding globulin, Testosterone; obesity.

Introduction

Obesity can be defined a complicated and multifactorial disease that occurs due to the interaction of social, behavioural, metabolic, genetic and impact of cultural behavioral. Obesity offers a cause for many health problems, reduces life’s duration, effect the quality of life and increased mortality. As a result, it has become an important public health affair on a global scale (1). Gender specific issues in female with obesity start with initial puberty, menstrual disturbances and dysovulation, and then they go forward with polycystic ovary syndrome (PCOS), obstetric problems, infertility, endometrial and breast cancer incidence which rise after

Corresponding authors:
Jaleel Samanje
Jaleel.najah@mtu.edu.iq
menopause (2). Hormonal changes are associated with gradually increasing BMI are slow, therefore a certain “adaptation mechanism” could improve and might clarify why the BMI-associated sex hormone alterations were not proven to be a significant role in anxiety pathogenesis in overweight individuals. Hormonal changes which were associated with obesity could be “protective” against anxiety.

The term “sex steroid-binding globulin (SSBG)” are also called “Sex hormone-binding globulin (SHBG)” structurally are homodimer glycoprotein which are able to binds both estrogens and androgens hormones (1). SHBG structurally are synthesis from the liver with different binding affinity values for different hormones such as five high affinity with dihydrotestosterone (DHT), testosterone (T) while less bindings values with 17β -estradiol (E2) hormones (2). Therefore, (SHBG) regarded as the major vehicles for transporting these sex steroids hormones, also to non-specific carriers such as albumin, primarily the concentration of SHBG control the availability of the aforementioned steroids hormone (3). The literature indicated that the influence of genetic, different hormonal, and lifestyle-related factors on circulating SHBG levels. The estrogen/ androgen balance was typically the key feature in the regulation of SHBG synthesis. SHBG regulation is considered currently as multifactorial and other non-steroidal factors have a significant character in the circulating levels of this binding protein. (4). The rise in body fat ratio in premenopausal women, can lead to an imbalance in sex steroids. Estrogen aromatization of androgens rises the estrogen amount in stromal vascular cells in fatty tissue. On the other hand, the estrogen/androgen ratio rises in obese individuals, there is a fall in sex hormone- binding globulin (SHBG).

**Materials and Method**

**Participant**

The present study was a cross-sectional types of cases and control. The studied population included female patients with gynecological health problems in Baghdad teaching hospital department of gynecology in Iraq between September 2018 and February 2019. The age of participants was 19 years or greater. The participants in the present study were chosen by simple random sampling method from among female patients with gynecological health problems. Thirty-one female patients were chosen as cases (BMI 30 and above) and twenty female patients (BMI ≤ 29.9) were chosen as controls. Inclusion criteria were being females free from some health problems such as polycystic ovary disease, thyroid disorder, chronic renal diseases, chronic hepatopathy, and tumors and any metabolic syndrome (MetS.). As well as, females who were undergoing to hormone treatment. The sample size was calculated by this formula:

\[ n = \frac{2(z_1 + z_2)^2 \cdot s^2}{d^2} \]

=51 participants The research council and ethics committee of Baghdad health directorate in Iraq approved this study. Written informed consent was completed by all the patients before starting this study. The data collection tools in this study included: demographic characteristics, anthropometric measurements and Biochemical tests. Each participant woman in this study was undergoes to biochemical tests. **Hormonal and another parameter assay**

A blood sample for biochemical test was drawn from each participant at day of experiment and after 12 hours overnight fasting. Blood samples were divide into two tubes one for serum collection the other was transferred in test tubes containing EDTA substances. Questionaries’ was obtained from the participants before starting this study. All samples were sent to the medical city complex for teaching laboratories institute for assessments. The SHBG, testosterone, prolactin and TSH were detected by using IMMULITE® 2000 immune assay system (IMMULITE, SIMENS, USA). While the FBS and HbA1c were assessed by using (Dimension® RxL Max®, USA) integrated system, and analyzer by using (Arkay, ADAMS, JAPAN) respectively.

**Statistical Analyses**

Statistical analyses were calculated using the Statistical Package for Social Sciences (SPSS) software (SPSS version 22. Inc., Chicago, IL, USA, 2013) and the level of significance was established at a p-value 0.05 or less. Descriptive analysis was conducted to determine the means, standard deviations, percentages and frequencies. Shapiro walk test for normality was
carried out on each continuous variable because of the sample size less than 100.

**Result**

**Frequency and biochemical test descriptive of studies groups**

The demographic properties of participants’ biochemical measurement were summarized in Table 1 and Table 2. The frequency of obese group was 31 in number which account (60.8 %) in comparison with non-obese groups females which has normal body mass values which account 20 cases (39.2%) of total participants from total study count. When categorized the BMI (kg/m2) values of studied groups the resulted group were (obese vs overweight normal weight) the mean value was (35.7±4.2 vs 19.35±1.26) as arranged in (Table 1). There are no obvious differences in the mean values of the four types of sex hormones level which includes SHBG (nmol/l), Testosterone (nmol/l), TSH (μIU/mL) and Prolactin (ng/ml) for both groups when compared with normal value of each test. The result of this study also revealed the level of both test FBS (mg/dl) and HBA1c level % which designed primarily as exclusion criteria for studied the normal health status of both groups were within normal range (97.6±7.05 vs96.3±7.1) and (5, 14±0, 3 vs 5, 1±0, 5) respectively when compared with normal value of each test as arranged in (Table 2). Subsequently, on bivariate correlation analysis, the BMI of participants was found to be significant associated with the independent variables which include SHBG, Testosterone, TSH, prolactin and which are significant predictors as declared in (Table 3). The results revealed that correlation of BMI (kg/m2) had strong negative significant correlation with SHBG (nmol/l) hormone (r= -0.578, P= 0.00). While the rest hormones such as Testosterone (nmol/l), TSH (μIU/mL) and Prolactin (ng/ml) were showed moderate positive significant correlation (r= 0.388, P=0.005), (0.354, P= 0.011) and (0.37, 7, P= 0.006) respectively as shown in (Table 4). We excluded the HbA1c and FBS tests from predicator test because we regarded it in the design of our study as exclusion tests of diabetic status. Four-predictor multiple linear regression models are proposed to explain the variation of BMI(Y). The four-predictor variables proposed are SHBG (X1), Testosterone (X2), TSH (X3), and Prolactin (X4). A stepwise method in linear regression has been used (Table 5). Therefore, the variables already in the equation are removed if their p-value becomes larger than the default limit due to the inclusion of another variable. The result of regression revealed highly significant model (p < 0.001). For addressing the multicollinearity, the researcher has been used collinearity statistics to remove the offending variables, where they represented clearly multicollinears, which indicated a problem in the statistics. The result of regression revealed significant model \{F =25, df = (3, 47) p < 0.001\}.

Dependent Variable: BMI (Kg/m²)

Discussion

Hepatocyte SHBG production is under the influence of several factors which can either increase (thyroid hormones, estrogens) or reduce its levels (obesity, progestogen, growth hormone, prolactin) 4,5. The mechanism by which obesity is associated with decreased SHBG has not been fully explained, but may involve inhibition of hepatic source of SHBG due to increased levels of insulin hormone (7, 8). Sex hormone-binding globulin (SHBG), are regarded as a major transporter protein of testosterone hormone, the level of (SHBG) are one indicator of risk for metabolic syndrome in both men and women 9. Another publisher who indicated that a low circulating level of SHBG was not associated with high concentration of insulin level( 10) but was associated with dyslipidemia and obesity conditions that are strongly associated with fatty liver in humans 11-13. Women with MS showed increased testosterone and lower SHBG independently of menopausal status (9). Our result was disagreement with previous study, so the level of the FBS level (mg/dl) and HbA1c % range was within normal range (97.6±7.05, 96.3±7.1,5,14±0,3,5,1±0,5%) respectively. Obesity is documented as one causes which lead to insulin resistance state which in turn lead to development of diabetes mellitus disease 10, increase the risk of Metabolic syndrom state 11 also associated with hypercortisolism condition 12, and elevated level of estrogen hormones 13. The result of regression analysis represented by stepwise method revealed the SHBG (nmol/l) and testosterone (nmol/l) were the most independent predictor factors affected due to increased in the BMI (kg/m²) value in the studied groups (β = -0.484; P = 0.001) and (β = 0.348; P= 0.001) respectively. Obesity is linked with lower serum levels of SHBG in both men and women 14,15. Some studies, that has been applied on typically small samples of peri-menopausal women, indicate either a decrease in or no substantial age-related changes in SHBG concentration 16-18. There is increasing evidence that low SHBG levels are strongly associated with metabolic syndrome and also an independent risk factor for development for diabetes, especially in postmenopausal women 19,20.

Conclusion

The main objective of this study, are to follow the healthy status of obese females under reproductive stage aiming to protect them from and metabolic syndrome which may lead to impair their quality of life also to predict the most biochemical test which may predict the hormonal disturbances for those females who are not married.

Impact of Juvenile Diabetes Long-Term Treatment upon Adolescents Physical Activities at Al Nasiriya Diabetic and Endocrinology Center

Adil Ali Hussein¹, Khetam Mutasher Hatab²
¹Assistant Lect, College of Nursing, University of Basrah,
²Assistant Prof. Dr., College of Nursing, University of Baghdad

Abstract

Introduction: Exercise has a positive effect on health, strength gain, weight control, social activity and self-development, contribute to the development of healthy habits in adults, but can also cause hypoglycemia. The variety, weight and duration of administration can cause various hormones (insulin, glucagon, catecholamine glucocorticoid), mediated metabolism. when the administration of insulin derived from insulin and / or an increase in anti-regulatory hormones increase glucose production in the liver and damage glucose in skeletal muscles. Although potential hyperglycemia can scare patients and their families, recipient fear of hypoglycemia can be a serious problem for clinical attention.

Objectives: To determine impact of juvenile diabetes long-term treatment upon adolescents’ physical activity and to discovery out the relationship between impact of long-term treatment with adolescents specific demographic data.

Methodology: A descriptive study design was performed to determine the impact of juvenile diabetes long-treatment upon adolescent’s physical activity in Al Nasiriya diabetic and endocrinology center. The study had started from February 6th, 2019 to June 7th, 2019. Non – probability (accidental) sample of (100) adolescents were selected.

Conclusion: The present study concludes that the greatest impact of long-term treatment of diabetes on the adolescents lifestyle was on physical activity; in addition the statistical test shows that the significant association between the adolescents’ physical activity and their age, socio-economic status.

Key words: impact, juvenile diabetes, adolescents, physical activities.

Introduction

Diabetes Mellitus Type 1, present in 5 to 10% of the cases of diabetes, results from the destruction of pancreatic beta cells, consequently leading to insulin deficiency. The main immunological markers of pancreatic compromise are the anti-islet, anti-insulin and anti-glutamic acid decarboxylase (GAD) antibody levels present in 90% of patients at the time of diagnosis. Diabetes type 1 habitually occurs in children and adolescents, however, it may also manifest in adults, generally in a more insidious manner. Patients with this type of diabetes necessarily depend on insulin administration. The main goal of treatment is to prevent the appearance or progression of chronic complications, such as microvascular (diabetic retinopathy, nephropathy and neuropathy) and macrovascular (cerebral vascular accident and peripheral arterial disease) complications, simultaneously minimizing the risks of acute complications such as severe hypoglycemia (1).

Lifestyle is an important determinant of glycemic control in diabetic type 1 and 2 patients. The treatment of DM1 interferes in the lifestyle, is complicated, painful, depends on self-discipline and is essential to the patient’s survival. The therapeutic approach involves various levels of action, such as insulin therapy, dietary guidance, acquisition of knowledge about the disease,
the ability to self-apply insulin, and self-monitoring of glycemia, maintenance of regular physical activity and psychosocial support. Due to the many beneficial effects, regular physical activity is indicated for patients with DM1, because it improves metabolic control and diminishes cardiovascular risk, in addition to adding an important effect on preventing the chronic complications of this pathology (2).

**Methodology**

**Design of the Study:**

A descriptive study design was performed to determine the impact of juvenile diabetes long-treatment upon adolescent’s physical activities in Al Nasiriya diabetic and endocrinology center. The study had started from February 6th, 2019 to June 7th, 2019.

**Setting of the Study:**

The study was conducted in Al Nasiriya Diabetic and Endocrinology Center This study was conducted on the adolescents who treated as a juvenile or type 1 diabetes mellitus.

**Sample of the Study:**

Non-probability (accidental) sample of (100) adolescents were selected. All patients diagnosed as having juvenile diabetes (DM type 1). They selection of patients was built on the following criteria:

**Method Data Collection:**

The data was collected through the use of a developed questionnaire (Arabic version), the researcher assumed full responsibility for interviewing the study sample after explaining and clarifying the objectives of the study for the adolescent, after obtaining the initial approval of each adolescent to participate in the study.

Data collection was carried out from February 6th, 2019 to June 7th, 2019.

Spend approximately (25-35) minutes with each adolescent to the interview and complete the questionnaire.

**The Study Instrument:**

The study tool is a questionnaire that was designed for the purpose of the study after extensive reviews of accessible literature and related studies. The study tool consists of three parts. The first part includes the demographic characteristics of the participants in the study, the second part includes physical activities.

**Part I: Socio-demographic Characteristics of the Sample of the Study**

This part deals with demographic characteristics of the sample consists of student’s age, gender, parents educational level, parents occupation, and family economic status.

**Part II: Physical Activities of Child**

This part constitute the activity domain consisting of (8) elements.

**Data Analysis**

Data from this study were analyzed using SPSS version 20. The following statistical data analysis methods were used to analyze and evaluate the results of the study (Frequencies, percent Mean of score (MS), Relative sufficiency (R.S), Standard Deviation and Chi-square).

**Results**

</table>

The study results indicate that there is a significant association between the adolescents’ physical activities and their age and socio-economic status at p-value less than 0.05.

**Discussion**

**Part I: Discussion of the Socio-Demographic Characteristics for the Study Sample**

Finding results in (table 1) shows that the common of the study subject age is (11-13) years old (48%), these finding agree with Hapunda et al,. (3) that found the great age group representative his study was (12-15) years. Anderson et al,. (4) supported present study by the gender is equally distributed by males and females who participant in their study.

With regard to the child order, the results indicate that the majority of subjects ranked first (54%). This conclusion is supported by et al,. Cardwell (5) who concluded that children who were second or highest in the birth order had a lower risk of Diabetes in children by 10% on average, the cause of any decreased risk of diabetes in children with a high birth order, but may reflect increased exposure to siblings at an early age.

As regards the school absence and performance, (66%) of the study sample absent from the school for one time, and (61%) of them have times of no failed this findings match with Cooper et al,. (6) who declared the impact of type 1 diabetes on a child’s ability to achieve it in school is a common concern for people with type 1 diabetes and their families. Low school attendance, cognitive deficits associated with diabetes, hypoglycemia, hyperglycemia and the psychosocial effects of chronic diseases are all possible factors that can lead to poor school performance for a child with diabetes compared to peers.

**Part II: Discussion of the Physical Activities of Adolescents with Juvenile Diabetes**

Regarding physical activity the present study found (58%) of total sample responses was bad that indicate affected, these finding agree with Jabbour et al,. (7) that concluded adolescent with type 1 diabetes, when exercising at high temperatures, dehydration develops more rapidly than non-diabetic couples and, therefore, suffers from poor performance and muscle cramps, which limits their physical activities.

**Part III: Discussion of the Association between the Study Subjects Lifestyle and Their Demographic Data**
Lawrence et al., (8) declared the age was to demonstrate statistically significant association with physical activities this finding support present study results as shown in (table 4) results indicate that there is a significant association between the adolescents’ activities and their age.

Regarding the socio-economic status there is a significant association with adolescents’ physical activities ($P= 0.04$) as shown in (table 4) this finding agree with Cho et al., (9) that stated there was a significant relationship between physical activity and socio-economic status and increase changes on it in higher socio-economic status.

Conclusions

The present study concludes that the greatest impact of long-term treatment of diabetes on the adolescents (physical activity) in addition the statistical test shows that the significant association between the adolescents’ physical activity and their age and socio-economic status.

Recommendation:

- Encourage adolescents with juvenile diabetes to regular exercise to reduce the risks of emerging complications in the long period, and monitor blood glucose regularly before and after exercise.
- Because much of a child’s day is spent at school, communication with school staff is important for optimum diabetes control and school performance.
- Most health promotion programs are needed to be implemented at schools, to increase the awareness of students and their teachers and improve their healthy behaviors.

Evaluation of Nurses’ Burnout among Nurses at Hospitals in Nasiriyah City Iraq

Alaa M. Tuama¹, Mohammed Fadhil Ali², Gossoon Juma Elywy²

¹Instructor Doctor, Community Health Nursing Department, College of Nursing, University of Thi-Qar, 
²University of Thi_Qar, Faculty of Nursing, Department of Community Health Nursing - Nasiriyah – Iraq

Abstract

Objective: To evaluate burnout among Nurses at Hospitals in Nasiriyah City,

Methodology: The sample of the study was purposeful and included (216) nurses, who were selected from hospitals from October 2, 2016, to June 28, 2017 CE.

Results: The study’s results have showed (63.9%) of the sample were (19 - 28) years, (74.1%) of the sample have experience of year (<10), (41.7%) were preparatory, (95.8%) of the sample were Urban, (47.2%) of the sample were Sometime enough of Economic status, the results have revealed that there is a moderate assessment in for an overall satisfied related to job satisfaction (128, 59.3%).

Recommendations: The study recommends an Establish laws that protect nurses from abuse and stress at work. Commitment by the ethics of the profession and work according to the policy of the institution.

Keywords: Evaluation; Burnout ; Nurses, Hospitals, Nasiriyah City.

Introduction

Reported was shows that 40% of nurses in the hospitals experience burnout and about every five hospital nurses there is one of them think of quit work over the next year, nurses suffered from burnout because they have a wide range of tasks and long working hours, and contacts with doctors, other co-workers, the patients, and patients’ families. (⁴)

Also, nurses are particularly vulnerable to stress. About 25% of all nurses suffer from stress, as shown by the results of two European epidemiological studies (⁵)

High levels of absence among healthcare professionals and poor mental health may lead to a lowered goodness of patient care (¹⁰)

Stress often comes from your work, but anyone who feels overworked or undervalued is at risk of overwork, the characteristics of your lifestyle and personality traits can contribute to overwork, what do you do when you stop working and how you look at the world can play a big role in causing stress like Requirements for work or home, fatigue is a gradual process, signs, and symptoms are hidden at first but get worse over time, think of the early symptoms as red signs that there is an error that must be addressed if you pay attention and work to reduce stress, you can prevent a major breakdown, if Ignore them, it will burn in the end (³¹)

A chronic condition of emotional and physical exhaustion that results from excessive work and/or personal demands and constant stress, and it describes feelings of emotional exhaustion and fatigue caused by work. It manifests itself in both physical fatigue and a sense of emotional and psychological drained (³²)

Studies have been isolated from occupational stress among health workers, especially in Nigeria at best, there has not been a sufficient comparison study between professionals on stress among health workers, police personnel and teachers. (³⁴)

A review of staff pressure in healthcare settings in 17 countries found that nurses in most countries experienced high levels of stress. Many researchers have described the nurses’ work as stressful work. (²)
Nurses are the largest health profession in Canada, with over 300,000 regulated nurses. Nurses have been identified as experiencing high levels of occupational stress, due to work overload, role conflict, aggression and working with traumatized patients. An adverse consequence to occupational stress in nurses is absenteeism (taking days off work), low job satisfaction and leaving the job (turnover). (8)

**Methodology**

A descriptive study was conducted at Thi-Qar Governorate in Al- Hussein Teaching Hospital, Bent AL_Huda Hospital, Al-Musawy Hospital and Al-Haboby Hospital from the period of the October 2nd 2016 to June 28th of 2017.

The sample is purposive “Non-probability” of 216 nurses who work in the units from which the study sample was recruited, in the above mentioned hospitals.

The questionnaire has been adopted after an extensive review of available literature and related studies. The study instrument consists of three parts. The first part includes participants’ demographic characteristics of age, gender, level of education,…etc. The second part is related to burnout.

Data collected by the researcher are from nurses who work in the above mentioned hospitals by interview and through filling a tool.

Truth of the tool is determined through pilot study Cornbach’s alpha which has been (0.80), while the validity obtained by experts in the field.

Statistical analysis was performed using the Microsoft office excel 2007 and SPSS package (version 19).

Discussion

The participants’ mean age of more than half of them is within (19-28) years-old. This result is consistent with the study of Tziaferi S, et.al. (2010) who have found that most medical services and nurses were graduated from the technological foundation, having working experience for the general hospital, there an age at a mean of 30 years old. I agree with the study of (Tuama, 2019) who found that more than half of the nurses are within 18-27 years-old. This can be attributed to that most nurses who are participants in this study are newly employed; they are small in age. Besides, the researcher targeted certain units and departments in the hospitals like the emergency department, operation room, intensive care unit, and medical and surgical wards, and most of the newly employed nurses are assigned in this unit to get the required skills and experience.\(^{16}\);\(^{17}\)

Regarding the years of experience, the majority of the sample has (\(\leq 10\) ) years of experience in work, this result is consistent with the study of Velonakis MG and Tsalikoglou F, (2010) who have found that The greatest proportion of respondents have less than 10 years of clinical experience (51%). This can be attributed to that most nurses are newly employed, and have less than 5 years of working experience. It was the criteria of the study.\(^{18}\)

Less than half of them have a Preparatory Nursing School at the level of Education. This result is consistent with the study of M. H. P. Marziale and O. S. Hong, (2005) who have found that in relation to the level of schooling, most nurses have a high school education prevailing (54.3%) which is the minimum requirement to carry out the function. This can be attributed that the number of nursing institutes and colleges has been very limited in the last years, in comparison to the huge number of preparatory nursing schools.\(^{19}\)

The majority of them live in urban areas. This result agree with Amare et. al., (2013), indicated that the majority of the study participants were living in urban areas (61.8%). This can be attributed that most hospitals lie in the city center where they are more close to nurses. Moreover, most of rural men prefer to work in their farms rather than looking for other jobs.\(^{20}\)

Finally, regarding socio-economic status, less than half of them report that their monthly income is somewhat sufficient. This can be referred to, as mentioned earlier, most of those nurses are newly employed and the higher the years of working, the higher the monthly wages.

Concerning to the burnout, the study subjects responses were moderate at the burnout. This can be attributed that, over time work in the work place and shortage in the nursing staff.

Recommendations:

The study recommends an Establish laws that protect nurses from abuse and stress at work. Commitment by the ethics of the profession and work according to the policy of the institution.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the College of Nursing and all experiments were carried out in accordance with approved guidelines.

Prevalence of Toxoplasmosis and Relationships With Estradiol Hormone and Vascular Cells Adhesion Molecular-1 (VCAM-1)

Zahraa Ismail Abdul Al-Ameer¹, Ahmed Khudhair Al-Hamairy², Dakel Ghani Omran²
¹M.Sc. Student, ²Prof. Dr., College of Science for Women, University of Babylon, Hilla, Iraq

Abstract
Sero-epidemiological study were conducted for pregnant and aborted women to investigate the infection person with toxoplasmosis in Babylon province during the period from December 2018 till March 2019, ELISA technique for 53 serum samples for pregnant and 67 serum sample for aborted women, according to epidemiological criteria (Residence area, age group, existence of cats in houses, times number of abortion status, number of children, collection samples monthly, trimesters period of pregnancy). Concerning biochemical parameters, the present included determination of estradiol hormone and vascular cell adhesion molecule -1 (VCAM-1) in aborted and healthy women that their ages ranged between 20 to 49 years old. it has been found a significant increase (P<0.05) in the levels of estradiol hormone in women affected with toxoplasmosis compared to healthy women . VCAM-1 results indicated a significant increase (P<0.05) in a comparison with those of healthy women it can be concluded that infection with Toxoplasma gondii is associated with estradiol hormone and vascular cell adhesion molecules.

Keyword: Toxoplasmosis, Estradiol, VCAM-1

Introduction
Toxoplasma gondii is protozoan parasite a compulsory intracellular, which results toxoplasmosis. Its distributed worldwide, and capable infecting virtually all warm-blooded animals. Its ability of causing acute and life-threatening qualifications in pregnant females (women) and immunocompromised persons. In many statuses, the laboratory identification of severe and latent toxoplasmosis depends upon the identification of T. gondii especially IgG and IgM antibodies. Most serological tests like ELISA, have been used for the detection of antibodies against the infection that takes place in pregnant women. Ecumenically, the distribution of this disease is extremely variable even inside the countries. In all host species, including humans, Toxoplasmosis is generally acquired either vertically from mother to fetus (congenital infection), or through ingestion of oocysts in contaminated food or water. Rarely, T. gondii can transmit through organ transplantation and the transfusion of infected blood. In many cases, laboratory diagnosis of latent and acute T. gondii is based on detecting T. gondii specific IgM and IgG antibodies, there are several serologic tests for anti-toxoplasma IgM and IgG, among which ELISA has maximum sensitivity and specificity. In Arab and regional countries, the prevalence of toxoplasmosis was ranged between 26-81.4%. In Iraq toxoplasmosis studies have reported different prevalence rates, ranged between 19.1-25.2%. VCAM-1 is expressed and located on luminal and lateral sides of endothelial cells. During inflammations or infections, VCAM-1 act to enhance rolling and adhesion of white blood cells before they migrate from blood circulation into affected tissues.

**Materials & Method**

**Blood Samples Collection**

1. It had been taking five milliliter of venous blood for both pregnant women and aborted women
2. By using syringe five milliliters as 3 ml. for serological and biochemical tests.
3. Three ml. of the blood samples were put in a gel tube and left standing for 20 minutes at room temperature for a clot, and then the tube was centrifuged at 3000 rpm for five minutes to collect serum.
4. The serum obtained was divided into many portions for different serological tests to avoid the melting of the samples and repeat the freeze because this will affect the quality of the result.
5. All sera were stored in the deep freezing -20°C until being analyzed *Toxoplasma* antibodies.

**Enzyme Linked Immunosorbent assay (ELISA)**

This assay was performed by using two kits, One for detection of IgG antibodies, and the other for detection of IgM specific antibodies against *Toxoplasma* antigen in the patient’s serum.

- **Detection of anti-*T. gondii* antibody (IgG)** by Enzyme linked Immunosorbent Assay (ELISA) technique.

  The bioCheck *Toxoplasma* IgG ELISA (BC-1087) kit was used. The *Toxoplasma* IgG ELISA is intended to evaluate a patient serologic status to *T.gondii* infection.

  **Principle:**

  Serum samples were added to patients to dig the plate covered with the pure *Toxoplasma* antigen. In the case of IgG antibodies to Toxoplasmosis in the serum, they will bind to the antigen. All non-washable substances are removed after the addition of the conjugate enzyme is linked to the anti-antigen complex, and remove conjugate enzyme by washing and the base material is added. The plate is incubated to allow hydrolysis of the base material to produce the absorption coefficient of the infected samples.

- **Detection of anti-*Toxoplasma gondii* antibody (IgM)** by Enzyme linked Immunosorbent Assay (ELISA) technique.

  The bioCheck *Toxoplasma* IgM ELISA (BC-1087) kits were used. The Toxoplasma IgM ELISA is intended for use in detecting IgM status to *T.gondii* in human serum and the procedure of IgM antibodies ELISA it’s the same methods that used above in IgG procedure.

**Biochemical tests**:

**Blood Samples Collection**:

A total number of subjects in this was 65 women of these, 50 women were infected with *Toxoplasma gondii* and suffering from abortion at a least five month ago. The ages of women ranged between 20 to 49 years old. Fifteen healthy fertile women were selected to serve as a control group. The infected women were classified according to their ages into three groups, First group 20-29 years old, Second 30-39 years old, Third group 40-49 years old. All women of this study were free from other chronic diseases and diagnosed by consultant physicians. Five milliliters of blood were withdrawn and then divided into two parts, The first part (2 milliliters) were put in EDTA tubes to complete hematological analyses. The second part of blood sample (3ml) was brought into gel plain tubes and left for 15 minutes to complete blood coagulation. After complete coagulation the samples were transferred into centrifugation at 3000 rpm for 10 minutes and then sera were a spirited by micropipette and transported into Eppendorf tubes for storage at 20°C for future biochemical analysis.

**Estimation of estradiol hormone concentration**

Estradiol hormone was estimated by kit supplied from Monobind company (USA)\(^1\)

**Estimation of vascular cell adhesion molecular-1 (VCAM-1)**

The concentration of VCAM-1 factor was estimation according to instructions Monobind company (USA)\(^1\).

**Results**

A total of 120 blood samples (67 pregnant and 53 aborted) women that attending to Maternity and Children’s Hospital in the Al-Hilla city, Babylon province, during the period from December 2018 till
March 2019, their age groups between (20 years to 49 years) and more than years.

Figure (1): Shows the correlation between estradiol hormone and vascular cell adhesion molecule-1 (VCAM-1) in women affected with *Toxoplasma gondii*
Prevalence of toxoplasmosis among pregnant and aborted women.

The results of a positive sample by using ELISA technique for IgG and IgM and mixed (IgG & IgM) among aborted women 25.8 %, 8.9 %, and 4.4 %, respectively, but the pregnant women that lowest than compared with aborted woman for IgG, IgM and mixed (IgG & IgM) 15.1 %, 5.6 %, and 1.8 % respectively, these results shows the percentage of infection in the aborted women has high level but do not reveal significant differences (p>0.05). The present study agreement with the study of the 15 in both (IgG&IgM) was 3.7% in aborted women and study of 16 agree in aborted women for IgG and IgM was 20%, 5% respectively, also the study 17 for IgM was 6.04%.

While present study disagree with the 18 for it is antibodies IgG and IgM which were 40%, 29% respectively, in aborted women and also 17 percentage infection in the aborted women for IgM only it was 6.04%, as well as study 19 in aborted and pregnant women for IgG were 41.8%, 40.0% respectively and 16 do not show the percentage IgM in the pregnant women was 0%.

The reason for this fluctuations for the rates of infection may be explain as the antibodies IgM level have been in the first weeks to three weeks from infection are very high and then begin to reduced its concentration and high increased concentration for antibody IgG significantly and that too those seen in aborted women where they have been subjected to infection, , predecessor and thus stimulate the immune system in advance which increases of high concentrations of these antibodies no these fall into chronic infections or may be confirmed the most patients in this study have chronic infection (IgG) or sub-acute infection (IgG&IgM) and acute infection (IgM).

Prevalence of toxoplasmosis among pregnant and aborted Women according to the residence area

By using ELISA test IgG, IgM and mixed (IgG,IgM) in rural area where 22.2% ,11.1% 4.4% respectively, compared to urban area 18.6 %, 5.3%, 1.3% ,respectively any rural more susceptible of urban area to infection , these results shows the rural area have high level but do not reveal significant differences (P>0.05). The current study agreement with study 15 where had percentage infection IgG and mixed (IgG &IgM) 18.2% , 5.5% in rural area while in urban area 13.8%, 4.5% respectively , and the study 20 showed that IgM in rural area was 10% and the urban area for IgG was 28% and agree with 21 in rural area for IgM was 9.7%, also, study 22 has percentage IgG and IgM were 23%, 1% in rural area respectively, as well as study 23 agree with present study where has IgM in rural area and urban area were (4%) and (1.5%) respectively.

The present study disagreement with 24 in Babylon province showed that urban area more than rural area for IgG were 73.1%,26.9% , respectively, but significant differences did not appear in urban areas compared to rural areas. And 18 who found for (IgG & IgM) 44.8% urban area and 39.6% rural area and as well as study 25 disagree with current where has percentage infection of IgG was (68%) in rural area and (32%) in urban area.

Biochemical Parameters :

Data obtained from the present study indicated significant elevation (p< 0.05) of estradiol hormone level in first and second groups of women affected with toxoplasmosis the association between sex-hormone and toxoplasmosis infection is a particular problem in public health 29. The present results were not consistent which indicated that acut infection with Toxoplasmosis is related with significant increase in the levels of estrogen of pregnant and non -pregnant women 30.

Conclusions

The current study demonstrated increase titer of IgG, IgM in cases of rural area more than of urban area also all the cases fall in the chronic infection because high frequency of IgG and also showed increase levels of cell adhesion molecules VCAM-1 associated with increase estradiol hormone of infected women.

Antibacterial applications and Comparative Study for Adsorption Phenol Red Dye Using Spinel Co1-xMxFe2O4 Nano Composites (M= Cd, Ag)

Waleed Abbas Jawad1, Nada Y Fairooz2
1Assistant lecturer, University Teacher, Babylon Education Directorate, Ministry of Education,
2Prof. Department of Chemistry, College of Science, University of Babylon, Hilla-Iraq

Abstract
This work concerned with the study of adsorption of phenol red dye by using spinel Co1-xMxFe2O4 was prepared by Co-precipitation method at different ratios of (0.2:0.8, 0.5:0.5, 0.8:0.2) and calcinations at temperature 600 °C for three hours. The conclusion showed that (0.5:0.5) percentage has high activity than other ratio at different temperature. The prepared powder was differentiated by X-ray diffraction, Fourier Transform Technique (FT-IR), UV-Visible Spectroscopy, Scanning Electron Microscopy (SEM), Energy Dispersive Spectroscopy (EDS), Atomic Force Microscope (AFM), high performance liquid chromatography (HPLC) were also studied for all spinel. X-ray and Electron Microscopy studies showed the average size of the granules prepared for the composite in this manner (17.44 for Cd and 37.55 for Ag).

Introduction
The expanding enthusiasm for nanotechnology is expected to the nanostructured material with measurements for example grain estimate, layer thickness or shapes beneath 100 nm1. The bizarre properties of nanomaterials are explicit to the Nano-measurements. Nanomaterials are the materials having something like one measurement under2. In the previous two decades, overall endeavors in both the hypothesis and the exploratory examination of development, portrayal and utilizations of inorganic nanostructures including metal oxides, earthenware production and composites have brought about a develop, multidisciplinary field. Nanostructured materials are noted for their security, green science and find assorted specialized application3. Late research concentrated on the utilization of nanomaterials to tackle natural issues and to clean the earth for what’s to come. Nano-sized materials are new useful materials, which offer high explicit surface region to volume proportion and surface-dynamic locales, accordingly, can be utilized as compelling adsorbents. Besides, nanomaterials have been utilized in different natural applications, for example, in green science, photograph synergist debasement of natural color, remediation of dirtied water, toxin detecting and discovery, antibacterial action, etc. The got nanomaterials and their composites have been utilized in natural applications, for example, adsorption investigations of poisonous metal particles, expulsion of natural color from fluid arrangement and antibacterial applications. In this investigation, we have concentrated on iron oxide and Cd and Ag nanomaterials and furthermore about iron oxide-cadmium and silver blended nanocomposite. Cadmium or silver and iron oxide are the most vital clay materials. Compact disc and Ag demonstrates countless substance and physical properties. It is broadly utilized as an electrical protector, displaying extraordinarily high protection from substance specialists, just as giving superb execution as an impetus for some compound responses, in microelectronics, layer applications, and wastewater treatment. In addition, press oxide assumes an essential job in natural and organic procedures and is additionally broadly utilized in various mechanical applications.

Experimental part.
Preparation of solution.

Chemical materials used in this work were prepared by the Co-precipitation method with ratios (X = 0.0, 0.2, 0.5 and 0.8). During the synthesis, Fe(NO$_3$)$_3$·9H$_2$O, Co(NO$_3$)$_2$, Cd(NO$_3$)$_2$, Ag(NO$_3$)$_2$ and NaOH were used as the oxidizing agent. All the metal nitrates were weighed in desired stoichiometric proportions and dissolved separately in amount of distilled water. After the complete dissolution, the metal nitrates were mixed together. Afterward, entire solution was kept with constant stirring at 80°C on a magnetic stirrer for 1 hour to assure removal of NaNO$_3$ from the powder.

The produced precipitate was washed 10 times with hot deionized water to maintain the pH of the solution to about 7 (4-5). Due to the continuous evaporation of water, the solution becomes viscous. The sample was put at the ignition temperature of 120°C to form a fluffy mass. These masses were crushed and the resultant material was annealed at 600°C in a muffle furnace for 3 h for the pellet formation.

Adsorption studies.

To decide the equilibrium relationship of sum adsorbed by a unit load of adsorbent (qe) with the grouping of adsorbent staying in the medium at balance (Ce), investigations of different adsorption isotherm models are required, which can enhance the plan of a sorption framework. There is different sort of adsorption models grew, for example, Freundlich, Langmuir isothermal models, etc. The most widely recognized models, for example, Freundlich and Langmuir conditions are utilized to examination of this investigation. The underlying color focuses were differed from 5 to 70 mg/L utilizing (0.15 Cd and 0.1 Ag) g of every adsorbent in 100 ml of phenol red arrangement (normal pH) with fomentation time 60 min.

Adsorption Isotherms.

Adsorption tests were led utilizing 50 ml stoppered conical flasks at room temperature 25°C. (0.15 Cd and 0.1 Ag) mg of adsorbent was added to every flask which comprised of 10ml phenol red arrangement of different beginning focuses from color. All flasks were shaken at 6000rpm in a thermostated shaker for (120min). After decantation and filtration, the color focus was broke down by utilizing UV-obvious spectrophotometer the measure of color adsorbed was determined from the accompanying condition.

**Langmuir Isotherm.**

The Langmuir isotherm show expect monolayer inclusion of adsorbate on a homogeneous adsorbent surface. This model does not think about surface heterogeneity of the sorbent. It accept adsorption will happen just at specific site on the adsorbent. The Langmuir condition is given as:

\[
\frac{q_e a_L}{K_L} = \frac{K_L C_e}{(1+K_L C_e)}
\]

The linear form of the Langmuir isotherm is:

\[
\frac{C_e}{q_e} = \frac{1}{K_L q_{max}} + \frac{C_e}{q_{max}}
\]

where aL (Lmg-1) and KL (Lg-1) are the Langmuir constants, qmax (=KL/aL) is the most extreme adsorption limit comparing to finish monolayer inclusion (mg g-1), which relies on the quantity of adsorption locales. The values of qmax and KL are calculated from the slopes and intercepts of the straight lines of plot of Ce/qe versus Ce.

**Freundlich isotherm.**

The Freundlich isotherm demonstrate is an observational condition that depicts the surface heterogeneity of the sorbent. It considers multilayer adsorption with a heterogeneous enthusiastic circulation of dynamic destinations, joined by communications between adsorbed atoms. The Freundlich isotherm equation is given as:

\[
q_e = K_F C_e^{1/n}
\]

The linear form of the Freundlich isotherm is:

\[
\ln q_e = \ln K_F + \frac{1}{n} \ln C_e
\]

where Ce is the balance fixation (mg L-1), qe is the sum adsorbed at harmony (mg g-1) and KF and n are Freundlich constants, identified with the degree of
the adsorption and the level of nonlinearity between arrangement focus and adsorption, separately. KF and \((1/n)\) can be resolved from the direct plot of \(\ln qe\) versus \(\ln Ce\).

The essential characteristics of Langmuir isotherm can be expressed by a dimensionless constant called equilibrium parameter (RL) that is defined by the following equation\(^{(7, 12-13)}\):

\[
RL = \frac{1}{1 + aL C_0}
\]

where \(aL\) and \(C_0\) are the parameters as characterized beforehand. The estimation of RL determined from the above articulation. The idea of the adsorption procedure to be either ominous (\(RL > 1\)), direct (\(RL = 1\)), great (\(0 < RL < 1\)) or irreversible (\(RL = 0\)) (Lian et al., 2009). Here RL values acquired are recorded in table 3.2. The direct Langmuir and Freundlich plots for the adsorption of CR onto the three nanorod adsorbents are gotten by plotting \(Ce/qe\) versus \(Ce\) and \(\ln qe\) versus \(\ln Ce\), separately (given in figure 3.8). The isotherm constants and connection coefficients were determined and recorded in table 3.2. By looking at the connection coefficients \(rL^2\), it tends to be found that the exploratory harmony adsorption information are all around depicted by both the Langmuir and Freundlich models, however the Langmuir show is progressively appropriate.

Result and Discussion

X-ray diffraction patterns.

Solid semiconductor at crystalline state was studied by using XRD technique. In this work, X-Ray diffraction was used to study Co$_{1-x}$MX$_x$Fe$_2$O$_4$. Table 3.2 illustrates the spinel of Co$_{1-x}$Cd$_x$Fe$_2$O$_4$; the best from spinel Co$_{1-x}$Ag$_x$Fe$_2$O$_4$ in photocatalytic degradation. The characterization of spinel Co$_{1-x}$MX$_x$Fe$_2$O$_4$ at ratio 0.5:0.5 by using x-ray diffraction radiation ($\lambda = 1.54 \text{ Å}$) were characterized after treatment in the alike condition of preparing catalyst that calcination at 600 °C for four hours from fig. 3.1. Find dissimilar peaks apparent in the figure of the spectrum represent 2$\theta$ (17.44) back for spinel material.

Fourier Transition for Infrared spectrum (FT-IR).

A study of the double prepared catalyst was achieved by using Fourier Transform Infrared (FTIR). All spectra were recorded at the wavenumber ranged from 400-4000 cm$^{-1}$. Fig. 3.2. is characteristic of the sample Co$_{1-x}$MX$_x$Fe$_2$O$_4$ that appearance the peaks at (1506.46–1651.12) cm$^{-1}$ and (412.78 – 667.39) cm$^{-1}$, respectively. In the range of 800 – 400 cm$^{-1}$, two main
absorption bands with very low intensity are observed around 412.78 and 667.39 cm\(^{-1}\) and may be is caused by metal oxygen vibration in the octahedral side.

### 2.4.3. Atomic Force Microscopy.

Atomic Force Microscope (AFM) is a technique used to analyze the morphology of surface. AFM is used to characterize the surface of catalyst by determining the force between tip and surface of catalyst.

**Fig. 7** AFM 2-D, 3-D images of a:Co\(_{0.5}\)Cd\(_{0.5}\)Fe\(_2\)O\(_4\), b:Co\(_{0.5}\)Ag\(_{0.5}\)Fe\(_2\)O\(_4\).  

**Scanning Electron Microscopy**

This technique was used to study the structures of the prepared photocatalysts from the aspect of the morphology of crystals of the semiconductors using the SEM. Microscopy techniques help us to analyze the particle size distribution and the nanocrystalline size distribution. The prepared photocatalysts spinel Co\(_{0.5}\)M\(_{0.5}\)Fe\(_2\)O\(_4\).

Factors influencing Adsorption process.

Effect of adsorbent dose.

Adsorbent measurements is a standout amongst the most vital parameter that has been considered to decide the ideal condition for the execution of adsorption. Basically, insufficient measurement or overdosing would result in the poor execution in adsorption. Accordingly, it is significant to decide the ideal measurements so as to limit the dosing cost and slime development and furthermore to acquire the ideal execution in treatment. The impact of adsorbent portions on the expulsion of phenol red utilizing Co\(_{0.5}\)Cd\(_{0.5}\)Fe\(_2\)O\(_4\)and Co\(_{0.5}\)Ag\(_{0.5}\)Fe\(_2\)O\(_4\)was performed by blending the examples of various load to 100 ml of phenol red color, looking after pH=7 (pH at ordinary condition) for 60 min contact time.

The heaviness of the adsorbents was shifted in the range 0.01-0.3 g. demonstrates the UV–vis retention spectra of phenol red arrangements in the wake of being treated with various doses of the readied spinel adsorbents utilizing an underlying color convergence of 100 mg L\(^{-1}\). It is seen there is a ceaseless expulsion of phenol red with increment in adsorbent portion up to (0.15 for Cd and 0.1 for Ag) g.

This may be due to an increase in number of active sites of the adsorbent material with increasing amount of the adsorbent. Further increase in the amount of the adsorbent does not bring any considerable change in the adsorption i.e. approximately straight line is obtained. Therefore (0.15 Cd and 0.1 Ag) g was chosen as the optimum amount for all studies of the adsorbents.

**Effect of pH of phenol red solution.**

Impact of pH of phenol red arrangement pH influences both watery science and surface restricting locales of the adsorbents. To examine the impact of pH on the adsorption of phenol red color the pH extend 3–11 was picked. The pH of the test arrangements was balanced by utilizing HCl and NaOH arrangements. (0.15 Cd or 0.1 Ag) g of every adsorbent utilized in 100 ml of phenol red arrangement of every pH esteem with 60 min disturbance time. From figure 3. it is discovered that, forCo\(_{0.5}\)M\(_{0.5}\)Fe\(_2\)O\(_4\), there is no huge change in the rate adsorption by expanding pH from 3-9 and achieved most extreme at pH = 9 and after that marginally diminished at higher pH. This is expected to for higher pH arrangement; the high adversely charged adsorbent surface locales did not support the adsorption of deprotonated CR because of electrostatic repugnance 12.

**Effect of initial dye concentration on adsorption.**

The underlying focus gives essential data that defeats the mass exchange opposition of all atoms between the watery and strong phases14. The adsorption is incredibly influenced by the centralization of the arrangement, as the adsorptive responses are specifically relative to the convergence of the solute6. It this segment, (0.15 Cd and 0.1 Ag) g of every adsorbent utilized every 100 ml of phenol red arrangement (common pH) with fixation going from 5ppm to 70ppm and the unsettling time was kept 60 min. It is discovered that with the expansion in beginning color fixation, rate adsorption diminishes while the harmony adsorption limit of the adsorbent for phenol red increments with expanding starting color focus for example the more focused the color arrangement, the higher the adsorption limit. This is most likely because of a high main impetus for mass move in high color focus.
D) Effect of temperature of spinel.

Adsorption process were performed in indistinguishable way from referenced in the above passage at temperature (20, 25, 30, 45, 50) C0 to appraise the thermodynamic conduct of adsorption process, this depends in the event that the adsorption diminishes with expanding temperature, the procedure is exothermic and the other way around.

A) Effect of recovery of spinel.

Desorption of colors from adsorbent and re-age of the adsorbent is a critical issue in perspective of re-use of use of the adsorbent. With rising costs of crude materials and wastewater treatment forms, the appeal of item recuperation forms has expanded essentially. The fundamental target of the recovery procedure is to reestablish the adsorption limit of depleted adsorbent and to recoup profitable parts present in the adsorbed stage. Desorption think about was performed by blending (0.15 Cd and 0.1 Ag) g phenol red stacked CoMFe2O4(Fe: Cd or Ag = 0.5: 0.5) nanocomposite with 100 ml of phenol red arrangement and desorption was completed for 1 hours. At that point the centralization of eluted phenol red was estimated to figure the measure of phenol red desorbed. For recovery considers, progressive adsorption– desorption forms were done for three back to back cycle. The figure demonstrates that about 84.2% of Cd and 75.2% of Ag phenol red viably expelled on the primary cycle. From that point forward, the expulsion limit of the adsorbent reductions as the quantity of cycles increases15.

Conclusion

The primary object of the present work is to investigate the likelihood of utilizing spinel Co1-xMxFe2O4 as adsorbents. The procedure is unconstrained and exothermic the impact of different working parameters, for example, pH, adsorbent dose and temperature was assessed. The thermodynamic capacities are exceptionally valuable if the present outcomes are to be used on huge scale.

Abstract

In this study, prepared nanocomposite materials made of polyester were prepared with a fixation hardener ratio of 0.1 g per 10 ml of polyester. This percentage was constant in all samples and addition of both chlorophyll(Cll) and lead oxide (PbO<100nm) as well as lead oxide with chlorophyll by weight percentage (0.2 ,0.5, 0.2 (Cll) with 0.5(PbO)wt.% receptivity, then study coefficient of loss of reflectivity of all samples where the results indicated that most prepared materials correct for use attenuation materials of microwaves where is reflection coefficient of all samples larger than (10dB) this show that absorption of composite materials consistence larger than 90%, then study reflection coefficient and also definition complex permittivity in the range frequencies (3-5)GHz where observed that value of the complex permittivity larger than one $\varepsilon_r > 1$.

Keywords: Nano-composite, Microwave Sensor, Application

Introduction

One of the most important uses of nanoparticles with a polymeric basis is to protect people from the side effects of radiation emitted from the mobile because the radiation caused by the excessive use of mobile phones is very dangerous, because the radio signals from cellular phones are considered carcinogens - that can cause cancer and there are symptoms And disturbances occur as a result of mobile phone radiation such as dizziness, insomnia, Parkinson’s disease, brain tumors, and many more 1,2. Mobile phones use electromagnetic radiation in the microwave or microwave range, and other digital wireless systems, such as data and communications networks, produce similar beams. The International Agency for Research on Cancer (IARC) classifies mobile radiation based on the IARC scale into category 2b (may cause cancer). Which means they may pose a risk of cancer 3,4. The constant consideration of smart phones is full of damage, but looking at smart phones continuously causes an internal headache which causes lack of sleep. According to optics specialist Andy Hepworth, ultraviolet radiation from smartphones can cause damage to the back of the eye, and continuous exposure to these rays turns on the mood, causing discomfort and lack of sleep 5. The 2012 study found that 66% of people are worried or afraid to lose their phones or move away for a short period, which leads to the use of smart phone on the charger and may cause radiation from the charger to the phone damage in the long term brain and brain 6,7. Mobile phone is one of the basics of the present day, has spread around the world speed of the missile, and gradually developed to become a laptop, you can use throughout your day tirelessly and tired. But for all the price and science also a double-edged weapon 8. Phones Portable as a time bomb unfortunately due to its great effects Harmful to our health, mobile devices open in the bedrooms cause insomnia and excessive use leads to brain damage and heart weakness The mobile inventor of the German chemist Friedhelm Weinhurst warned of the risk of leaving mobile devices open in the bedrooms on the human brain , Said in a private meeting
with him in Munich, that keeping these devices or any transmitters or receiving space in the bedrooms cause a state of insomnia, anxiety and lack of sleep and damage to the brain, which in the long term to destroy the immune system in the body. He stressed in a press statement that there are two values for the frequency of radiation emitted from the initial mobile 900 MHz and 1.8 MHz second, which puts the human body to many risks, pointing to mobile power stations equivalent to the power of radiation from a small nuclear reactor, and the electromagnetic waves resulting from the mobile Stronger than x-rays that penetrate all organs of the body. On the one hand, a group of scientists in Sweden, Germany, Australia and the United States confirm the damage caused by these waves, On the skin, on semen, on the immunity of the body and on the disappearance of insects. In our analysis the microwave loss materials have been characterized in terms of the electrical permittivity, which describes the interaction of a material with an electric field and in general is complex quantity. According to the theory of complex permittivity, when an electromagnetic field propagates within dielectric material, the electric field induces two types of electrical effects, i.e. conduction and displacement currents. The effect arising from free electrons (conduction current) gives rise to powerless, which is related to the imaginary permittivity ($\varepsilon''$); the interaction with bound charges (displacement current) induces the polarization effect, which is described by the real permittivity ($\varepsilon'$). Therefore, an increase of the real part of the complex permittivity can be mainly ascribed to dielectric relaxation and space charge polarization effect, whereas an increase of the imaginary part of the complex permittivity can be attributed to the enhanced electrical conductivity of the material. The paper is arranged in four main sections. the experimental part, Vector Network Analyzer(VNA) as shown in (Section 2), the result and discussion as shown in (Section 3), the results for optical microscope as shown in (Section 3.1), FT-IR measurements as shown in (Section 3.2), microwave absorption properties as shown in (Section4),Loss Reflectivity as shown in (Section 4.1), Reflection Coefficient as shown in (Section 4.2), complex permittivity($\varepsilon''$) as shown in (Section 4.3),complex permittivity($\varepsilon'$) as shown in (Section 4.3).

**Experimental Part**

In order to measure the microwave properties of the composite materials by means of Vector Network Analyzer (N5230C Agilent PNA-L) in the waveguide method for (3-5) GHz. In this research, the following materials have been used where you work on selecting the best ratio of hardener by selecting 10 ml of polyester to be fixed for all samples and add a percentage from hardener of polyester where the number of samples to the college in this work is (4) samples, is hardener in fixed percentage (0.1,0.2,0.3,0.4) wt.% . To choose the best ratio to be fixing in all samples After completing the samples required to select the appropriate ratio, the hardness of the samples was measured using the hardness measuring device (Shore-A)[16,17] ,Where the hardness of the samples was (71, 70, 69, 68) so the first ratio was chosen based on the hardness measurements to be constant in all samples a first sample was then two step for work the second sample by adding a chlorophyll with different weight ratios (0.2, 0.4, 0.6, 0.8) wt.% where the best chlorophyll was selected based on optical characteristic measurements using a device(UV-Spectrophotometer) to select a sample with high absorption and transmittance of up to 60% for visible light where selection of the first sample with a concentration (0.2)wt.% of chlorophyll was then three step for work the three sample by adding a Lead oxide (PbO,>100nm) with different weight ratios (0.1, 0.3, 0.5) wt.% where the best PbO ratio was selected based on optical characteristic measurements using a device (UV-Spectrophotometer) to select a sample with high absorption and transmittance of up to 60% for visible light where selection of the three sample with a concentration (0.5)wt.% of PbO was then four step for work the four sample by adding a best ratio of chlorophyll with best ratio of PbO and then The samples were then prepared and configured to test the microwave absorption using a device Vector Network Analyzer (N5230C Agilent PNA-L) where the samples were cut by 1 cm based on the size of the required waveguide.

**Vector Network Analyzer(VNA)**

Before the network analyzer, determining the reflection coefficient of a circuit required you to manually calculate the phase of the reflection coefficient one frequency at a time on a piece of paper. This manual
process required youth first find the maxima and minima of the standing voltage wave in a slotted line and repeat this process for all frequencies of interest. It is safe to say that if the vector network analyzer (VNA) had not been created, the high frequency community would look very different today. Today, the VNA characterizes high-frequency passive and active devices in their linear mode of operation by measuring their network parameters, called S-parameters, as a function of frequency. Over time, VNAs have been extended in hardware and in capability to also measure noise parameters and nonlinear characteristics, including compression, intermodulation, and hot S22 measurements. As a result, the VNA evolved into.

**Result and Discussion**

**The optical microscope**

Figure (1) show the images of (Pure, Cl, PbO, Cl+ PbO) nanocomposites materials by two magnification power, taken for samples at magnification power(10x). However, shows a clear difference to the samples as shown in the pictures. When addition proportions of Cl in films composites, the chlorophyll form a continuous network inside the polymers. When addition proportion of (PbO) nanoparticle continuous network inside the polymers and best film. This network has paths where charge carriers are allowed to pass through the paths, causing a change in the material properties. This is consistent with the results of researchers.

Fig. 1: Photomicrographs (10X) for (Pure, Cl, PbO, Cl+ PbO) composite materials

3.2 Fourier Transforms Infrared Spectroscopy Testing (FT-IR)
The Fourier transforms infrared spectroscopy (FT-IR) spectra of pure (pure, pure-Cll, pure-PbO, pure-Cll-PbO) and doped films are shown as Table (1).

**Table 1: (FT-IR) spectra of pure (pure, pure-Cll, pure-PbO, pure-Cll-PbO)**

<table>
<thead>
<tr>
<th>1- pure (polyester-hardener)</th>
<th>10ml- 0.1 wt.%</th>
<th>Fig.3(A)</th>
</tr>
</thead>
<tbody>
<tr>
<td>2- pure-Cll</td>
<td>0.2 wt.%</td>
<td>Fig.3(B)</td>
</tr>
<tr>
<td>3- pure-PbO</td>
<td>0.5 wt.%</td>
<td>Fig.3(C)</td>
</tr>
<tr>
<td>4- pure-Cll-PbO</td>
<td>(0.2,0.5) wt.%</td>
<td>Fig.3(D)</td>
</tr>
</tbody>
</table>

All spectra exhibit the characteristic absorption bands of pure. It can be noticed that some observable changes in the spectral features of the samples in the range (1718–1068) cm\(^{-1}\) (fingerprint region) apart from new absorption bands and slight changes in the intensities of some absorption bands. The new bands may be correlated likewise with defects induced by the charge transfer reaction between the polymer chain and the nanomaterials. The vibrational peaks for pure at (3254.63, 2907.09, 2852.73, and 1083.93) cm\(^{-1}\) are assigned to O–H stretching, C–H stretching, C=O stretching, C–H bend of CH\(_2\), and CH rocking of (pure-Cll), respectively and another vibrational peaks for concentrations of nanocomposites. further, the vibrational peaks found in the range (1718-1068) cm\(^{-1}\) may be attributed to nanoparticles with polymers which indicate that nanoparticles doped in the (Cll, PbO) polymers matrix.
Loss Reflectivity

Fig. (4), show that the loss of reflectivity in the first sample without the addition (pure) of the fries are few the greatest loss of reflectivity is confined to frequencies (3-3.2) GHz is limited ((-50- (-39) dB) but after the addition of chlorophyll(II) for the Sample in the case observed The energy of reflection at frequency (4.5-3.5) GHz equal ((-30 - (-43) dB). The greatest loss of reflection energy is limited ((-30- (-43) dB)

The greatest loss of reflection energy is limited (-43dB) at frequency (3.15) GHz There are values ranging (-24dB, -15dB) at frequencies (3.5-3.8) GHz and add the addition of lead oxide(PbO) The greatest loss of reflectivity is confined to frequencies (3-4) GHz is limited ((-33- (-35)) dB and add the addition of lead oxide(PbO) with chlorophyll(CII) The greatest loss of reflectivity is confined to frequency (3.7) GHz is limited (-49) dB .This means that there is high absorption of microwaves in range (3-5) GHz.

Fig. 4: Shows the reflection Coefficient with frequency when (pure, CII, PbO, PbO+CII) receptivity

Reflection Coefficient

In order to obtain materials with high attenuation of the electromagnetic waves, the coefficient of reflection should be reduced to the lowest possible value. As shown in Figure (5), the relationship between the reflection coefficient of the prepared materials where we observe that the behavior of the reflection coefficient is similar to the extent A large measure between the loss of energy reflection and frequency where we note that the lowest value of the reflection coefficient corresponds to the highest value of the loss of reflection energy and this is the axioms because the coefficient of reflection is calculated through the relationship.

\[ RC = 20 \log (\Gamma), \] where \( \Gamma \) represents the loss of reflective energy of the fallen beam. Thus, we have obtained materials with low reflection coefficients that can be used as electromagnetic wave modifiers in the (3-5) GHz package.
Fig. 5: Shows the loss of reflection energy with frequency when (pure, CII, PbO, PbO+CII) receptivity

Complex permittivity ($\varepsilon_R \varepsilon'_R$)

Fig. (6), show the behavior of complex Permittivity with frequency in the restricted range of (3-5) GHz where we observe that the behavior is similar to the behavior of the attenuation coefficient because the calculation of compound permutation was calculated using the attenuation coefficient. Where we note the values at frequency (4) GHz when (pure, CII, PbO, CII+PbO) is ($\varepsilon_r = (10.26, 13.12, 9.2)\varepsilon'_r = (10.26, 13.12, 9.2)$) respective.
Conclusions

In this study, it is possible to use composite materials to attenuate the microwave waves and absorb them completely. The results showed that the susceptibility of these materials to the absorption of microwaves is large, up to 90% observed and obtained high absorption so that the material is used to disperse these waves and reduce the impact on people, which can be used for screen mobile and as is known, the mobile produces electromagnetic radiation may be harmful to humans because of thermal effects, especially on the eye as well as mobile towers And the towers of the Internet and wireless communications send these waves within the range of frequencies (3-5)GHz so the use of this material for screen mobile to absorbs all these waves and attenuate, which is reflected positively on human life.

Knowledge, Attitudes, Practices, and the Factors that Influence Breastfeeding among Mothers attending a Primary Health Center in Sulaimani City

Bestun Ibrahim Hama Rahim1, Niaz Mustafa Kamal2, Bekhal Abdalwahid Amin3

1Lecturer, 2Assistant lecturer, Community Health Department, 3Assistant lecturer, Midwifery Department, Sulaimani Technical Institute, Sulaimani Polytechnic University, Sulaimani, Iraq

Abstract

This study was performed to assess knowledge, attitudes, and practices towards breastfeeding and identify factors impacting this practice among mothers. A descriptive case-series study was carried out among 220 mothers who had a child less than 2 years, in Ibrahim Pasha Health Center in Sulaimani city, between the 9th of August 2018 and 20th of November 2018. The convenience sampling method was used to select the subjects. Mean age of the mothers was 29.37 years. More than half (56.8%) of the mothers were encouraged for breastfeeding, the main encouragement factors were husbands, medical staff, and other families (45%, 22%, and 15% respectively). More than one third (37.7%) of the mothers ceased breastfeeding, the main motives were producing insufficient milk, child refusal and child’s disease (31%, 25%, and 17% respectively). The association between mode of delivery and types of feeding was statistically significant (P=0.028); exclusive breastfeeding was high in the normal delivery group. Overall, the mothers had a good knowledge and a positive attitude toward breastfeeding. Only 30.5% of the mothers started breastfeeding within the first hour after labour. An extreme number (95%) of the mothers fed colostrum to their baby. Merely 30.5% of the participants fed their babies exclusively.

Keywords: Breastfeeding, Knowledge, Attitudes, Practices, Factors, Primary health center.

Introduction

Breastfeeding is an essential public health approach for improving infant and child morbidity and mortality, reducing maternal morbidity, and supporting to control health care costs (1). Breast milk is a complex, living ideal nutritional fluid that contains antibodies, enzymes, hormones, and perfect nutrients for healthy growth and development (2). In newborns, it promotes the growth, development of cognitive skills and the immune system. Furthermore, it diminishes the risk of sudden infant death syndrome (SIDS), type 1 diabetes, and many other diseases. Besides, it decreases the mother’s risk of developing breast cancer (3). Studies have revealed that breastfeeding during the initial stages of a child’s development, motivates the immune system and enhances the child’s responses to vaccination. Reduction in the incidence of respiratory infections, gastrointestinal diseases, ear infections and improvements in teething have been noticed in children who have been breastfed exclusively for six months or more (4).

Breastfeeding should be begun within the first hour after birth, and it contains the feeding of colostrum that is recommended by world health organization (WHO) as the ideal food for the newborn (5). Breastfeeding should be introduced exclusively in the first 6 months, and to be prolonged for 2 years and beyond with other sufficient sources of nutrition. However, the practice of breastfeeding, particularly exclusive breastfeeding in the first 6 months, stays very low in most countries (3).
In the western countries, there have been risen trends of breastfeeding in the last few years. On the other hand, there has been a drop in breastfeeding in the developing countries \(^5\). Additionally, little is known about breastfeeding and obstacles women experience in the Middle East \(^6\). This study was conducted to assess knowledge, attitudes, and practices of the respondent mothers as well as to identify the factors that influence women’s decision and ability toward breastfeeding.

**Subjects and Method**

**Subjects and study design**

A descriptive case-series study was undertaken from the 9th of August 2018 to 20th of November 2018 in Ibrahim Pasha Health Centre in Sulaimani city which was highly visited by mothers. The convenience sampling method was used for the selection of the subjects. The current study involved 220 mothers. The sample size was dictated by depending on the obtainable time for conducting the study, and the number of eligible cases who visited the set of the study. Mothers who had children less than 24 months of age and visited the Ibrahim Pasha Primary Health Centre/Sulaimani were eligible to participate in this study, except the conditions which breastfeeding is contraindicated; like mother suffering from cancer, galactosemia, active tuberculosis, and psychoses.

**Statistical Analysis**

Data were analyzed using the Statistical Package for the Social Science (SPSS version 22, IBM Statistics. inc) with consideration procedures to confirm the high quality of data and minimizing error. These included testing questionnaires, data entry, regularity checked all data collection and entry. The Chi-square \((\chi^2)\) test was used for comparisons among subgroups. P-value \(\leq 0.05\) was used to prove a level of significance. Quantitative and qualitative variables were respectively expressed as mean\(\pm\) 95% confidence intervals (CI) and percentage. Texts, Tables, and Figures, were used for describing the results.

**Ethical considerations**

Ethical clearance was obtained from both Sulaimani Technical Institute and General Directorate of Health in Sulaimani city for carrying out this study. The mothers were recruited for this study informed in detail about the objective of the study and they were free to participate in the study also participation was voluntary. Verbal consent was taken from the mothers. The confidentiality of the collected data was guaranteed.

**Results**

**Factors influencing breastfeeding**

Roughly three fifths (56.8%) of mothers were encouraged for breastfeeding, while (43.2%) of the mothers were not encouraged. Several factors had a role in encouraging breastfeeding; the figure demonstrates the main factors in this study were husbands, followed by medical staff, and other families (45%, 22%, and 15% respectively) (Figure 1)

**Results**

**Factors influencing breastfeeding**

Among mothers nearly two fifths (37.7%) stopped breastfeeding, several factors influenced on stopping breastfeeding; the figure illustrates that the main reasons in the current study were producing insufficient milk, the child refused, and child’s disease (31%, 25%, and 17% respectively) (Figure 2).

**Maternal practices towards breastfeeding**

The result reported that 32.5% of the mothers started breastfeeding within the first hour after birth. Maximum number (95%) of mothers fed colostrum to their baby. Only 30.5% of the participants fed their babies exclusively in first six months. The range of breastfeeding frequency was between 3-26 times per day, half (50.2%) of mothers fed breast milk to their baby 8-12 times per day. Minority (12.3%) of the respondents consumed drugs for improving breast milk production (Table 4).

Discussion

Factors influencing breastfeeding

Approximately three fifths (56.8%) of mothers were encouraged for breastfeeding. Likewise, another study was indicated that the majority of the mothers were encouraged for this practice (7). Furthermore, another study demonstrated that nearly three-quarters of mothers received health education on breastfeeding benefits (3). In the present study, several factors had affected in encouraging breastfeeding; main factors were husbands, medical staff, and other families, while a study showed the main sources of health education on breastfeeding were physicians and nurses (3). Similarly, a result of a study revealed that mothers were encouraged for breastfeeding by medical staff, another family, and husbands (7). Moreover, a result of a study revealed that the main source of information was health institution, friends and mass media (8).

Association between mothers’ background and type of children feeding

The present study showed that there was no statistically significant association between age of mothers and methods of children feeding, this finding is consistent with the results of two other studies were conducted in Nigeria, and Morocco (9, 10). However, the frequency of exclusive breastfeeding higher among mothers with high education level in comparing with other education levels, but this relationship was not statistically significant. Conversely, two studies found a significant association between exclusive breastfeeding and the mother’s education (9, 10).

Mother’s knowledge regarding breastfeeding

The bulk of the study participants were aware of breastfeeding and their benefits for both children and their mothers, our finding is in agreement with the results of two former studies were conducted in Saudi Arabia, and India (3, 11).

Maternal attitudes towards breastfeeding

Totally, the mothers had a positive attitude toward breastfeeding; this result is consistent with the result of a study was conducted in Saudi Arabia (1). While more than half of the mothers believed that breastfeeding prevents going to work. Likewise, a study found that roughly two-fifths of mothers believed that formula feeding is the better choice than breastfeeding if the mother plans to return to work (11). Approximately two-fifths of the respondents believed that breastfeeding will make mother’s breast sag. Similarly, two prior studies
reported that more than half of mothers believed that breastfeeding cause breast sag.\(^{4,12}\)

**Maternal practices towards breastfeeding**

The result reported that merely 32.5% of the participants initiated breastfeeding within the first hour after birth. Likewise, a study indicated that 28.7% of mothers started breastfeeding immediately after delivery\(^ {8}\). While another study reported that 71.2% of mothers initiated breastfeeding within the first hour after delivery\(^ {13}\). Our result could be explained from the fact that more than three fifths of mothers delivered their baby through caesarean section. A study revealed that mothers delivering their infants through caesarean section run a 1.38 times greater risk of having difficulties with breastfeeding in comparison to mothers delivering their neonates vaginally\(^ {14}\).

**Conclusions**

The main encouragement factors for breastfeeding in this study were husbands, medical staff, and other families, while the main discouraging factors were producing inadequate milk, child refusal, and the child’s disease. The minority of the respondents used drugs for improving their breast milk production. Caesarean delivery negatively affected breastfeeding practices. Nevertheless, the majority of the mothers had a good level of knowledge and positive attitude toward breastfeeding, but they were not translated into practices, less than one third of the participants fed their babies exclusively.

Molecular Typing of *Malassezia* and *Histoplasma* in Bronchoalveolar Lavage Fluid from Patients with Pulmonary Respiratory Infections

Zahraa Muhyi Al Shareefy¹, Zaidan Khlaif Imran²

¹ M.Sc., ² Prof. Dr. Biology Department, College of Science for Women, University of Babylon, Babylon Province, Hilla, Iraq

Abstract

Pulmonary infections caused by fungal infection is one of the general serious lung disease. Its symptoms and risk vary from controlled to fatal if not treated early. The aim study isolation and identification of *Histoplasma* and *Malassezia* inhabitant lung of patients pulmonary respiratory infections. A total of 103 clinical samples were collected from the patients who attenuated the Thoracic and Respiratory Diseases Center, Tebba National Hospital and Morjan Educational Hospital in Babylon province. The samples were taken under the supervision of the physician after diagnosis of pulmonary diseases such as Tuberculosis, Pulmonary fibrosis, lung cancer, asthma, Thoracic Allergy. Lop full of bronchoalveolar lavage fluid (BAL) were Direct cultured on Sabouraud’s Dextrose Agar (SDA), microscopically and molecular identification was performed based on used specific primer pairs for *Histoplasma* and *Malassezia*. The results shown identification many yeast and molds based on cultural and molecular assay shown: A 438 out of 500 isolates of yeast were identified as *Candida* spp., 27 isolates of *Malassezia* spp. and other filamentous fungi such as Zasmidium cellare, *Aspergillus* spp., *Penicillium* spp., *Fusarium* spp., *Mucor* sp., *Alternaria* spp., *Acremonium* sp. and *Cochliobolus kusanoi*.

Key wards: Pulmonary diseases, lavage samples, molecular assay, Histoplasma, Malassezia.

Introduction

The lung exposes of chronic infection with some fungi such as *Candida*, *Histoplasma*, *Malassezia* and others molds, these fungi are capable of causing self-limiting pneumonia when inhaled. *Malassezia* species and pneumonitis have been described in children and adults with central venous catheters and in patients with preceding surgery⁸. Thus, they exist at the vary interface between commensal and pathogen such as, their interaction with the human immune system is of great interest.³. Histoplasmosis is a pulmonary fungal disease that inhales the airborne infectious conidia of the dimorphic fungus, *Histoplasma capsulatum*⁶. This yeast may causes acute pulmonary disease, disseminated disease, chronic pulmonary disease and fibrosing mediastinitis¹⁰. The aim of the study was to determine the lung fungal infections, particularly pathogenic yeast, in patients with chronic pulmonary diseases based in lavage samples and molecular diagnosis of fungal isolates based on culturing sample methods.

Material and Method

A total of 103 samples of sputum and bronchoalveolar lavage fluid (BAL) (39 sputum, 64 lavage) were collected over an approximate 6 months era from October 2018 to April 2019. Clinical samples was collected from patients who were consulted for chest respiratory diseases from Morjan educational hospital, Tebba respiratory center, advisory clinical for respiratory disease in Babylon province, Iraq. All samples were taken...
from the patient under the supervision of the concerned physician. After diagnosis of respiratory infection of the patient, an aspiration sample was taken from patients with pulmonary allergies, asthma, cancer, pulmonary fibrosis, Tuberculosis (Tb) patients. The questionnaire was used for each patient and included some important information. Questioners: Age, Gender, Nature of work, Housing, Chronic diseases, Smoking, drugs uptake were performed. The samples were collected in sterile containers and the samples were directly transferred to the laboratory for culture. Each specimen was inoculated into Sabouraud’s Dextrose Agar, by stricken on SDA, with chloramphenicol, streptomycin and erythromycin then incubated at 28 °C for 2 - 7 days. The gDNA was extracted according to the PCR procedure were as previously described by The universal primer pair used in this study was ITS5/ITS4 Forward: (5'-GGAAGTAAAAGTCGTAACAAGG-3') and Reverse (5'-TCCTCCGCTTTATTGATATGC-3'), the specific primer pairs for Malassezia: Malup (5'-AGCGGAGGAAA AGAAACT-3'), Mal down primer (5'-GCACGAAAGCTCCGGAAG-3'), and For Histoplasma: HistoAF 5’-CACGCCGTGGGGGCCTGGGAGCCT-3’, HistoAR: 5’-CGGGTGTCGCCGGACACCGGGCC-3’.20

Results and Discussion

The majority of patient samples were females 53.39% (55/103), while 46.60% (48/103) males samples. The average of patients age were ranged from (11-90) in both genders. The high infection percentage was 28.72% of the total positive samples occur between (51-60 years) and the lowest percentage of infection were 1.06% occur between (81-90 years), the high incidence percentage of fungus infection was calculated in Table (1).

These molds isolated in this results Table (3) referred to roles in infection and causes Fusariosis,18. The experiment had been given us that Aspergillus spp. were high frequently such as A. fumigatus, A. niger, A. oryzae, A. flavus and A. ochraceas, and its compatible with9. Several scientist(5, 17) spotted that most repeated species which effect and lead to pulmonary infection were A. fumigatus, A. flavus, A. niger and A. terreus which we disagree with them too for having A. niger as a second frequent species. Penicilliosis high frequency was and this is consonant with the study of 15.

PCR Ribotyping of fungi depending on ITS region:

The results have successfully identified the targeted fungi and yeast based on amplification part of rDNA region by the primer pair ITS5 and ITS4 as in Figure (1).
Identification results of Histoplasmosis using PCR technique

The targeted species have been successfully identified using *Histoplasma* spp. primer pair: HistoAF, HistoAR. The species have been identified on a molecular weight (516bp). (data not shown).

PCR typing of the LSU rDNA region by using Mal primer pair

The results of PCR amplification of DNA from colonies of *Malassezia* species were successfully accomplished PCR-typing method for part of the LSU rDNA region by using the *Malassezia* specific primers. All *Malassezia* spp. gave monomorphic bands, approximate 605bp of PCR products Figure (2). This results similar to same results of 14 and 2.

As we mentioned that *Malassezia* spp. is not well described or discovered only view studies explained it such as
as we mentioned explained it in infants and Aguirre (2011) explained the fungemia of *Malassezia* spp. in Iraq there were no studies described it as a lung infection, patients with *Malassezia* spp. were in chronic conditions such as lung cancer or TB infection or were in a long term of drugs or antibiotics therapy such as antibacterial and antifungals.

Frequency of this yeast (*Malassezia*) in our patients samples were high as a second frequent yeast isolate and it was higher than the observation of the mentioned researchers. Infected with many lung infections leads to long terms of therapy which leads to weakness of patients immunity and this leads to the wide spread of fungal infection more widely and more dangerous and leads to one of the patient’s death causes, beside many of these fungi causes fungemia and as the lung fluid is enrich with materials that help increase growth and infection.

At the final, this study had been faced many problems; like collecting the samples was on a level of difficulty specially for BAL samples like suffering the unavailability of samples easily and quickly, sometimes the lack of response of medical staff, the presence of patients with these diseases, waiting for long time, required the presence of surgical intervention to obtain these samples, sometimes not responding to the patient and not giving samples or information about his or her illness or health status, the risk of dealing with this type of samples in relation to patients with Tuberculosis (TB) as well as BAL samples for the presence of blood and bodily fluids that are likely to carry viruses or dangerous bacteria that causes series infections like Hepatitis etc.

Likewise the interference and coexistence between yeast species leads to the difficulty of purifying and isolating the yeasts from each other and identification or diagnosing it accurately. Finally the lung diseases that occur due to fungi need to have a higher concentration and give it more importance especially within the Iraqi medical field because all of these infections lead to serious troubles (infections) besides in many cases lead to death.

**Ethical approval**: Both authors hereby declare that all actions have been examined and approved by the appropriate ethics committee and have therefore been performed in accordance with the ethical standards laid down in the 1964 Declaration of Helsinki.

**Conflict of Interests**: The authors did not declare any conflict of interest.

Genotyping Tinea Capitis Fungi and Evaluate the Antifungal Activity of Plant Extract in Vitro

Hiba Jabur Sallal1, Zaidan Khlaif Imran2
1 M.Sc. 2 Prof. Dr. Biology Department, College of Science for Women, University of Babylon, Babylon Province, Hilla, Iraq

Abstract

Tinea capitis is a prevalent superficial fungal infection seen in developing nations predominantly in child, the aim of this study included isolating and identification of Tinea capitis fungi isolated from clinical samples who attenuate the outpatient clinics and other samples were collected from soils of barber shops, homes and mosques in Babylon / Hilla Province. 120 hairs, scales and soil were 80 clinical samples (hairs and scales), 30 soil samples, and 10 hair samples as control group. The results showed that: numbers of dermatophytes fungi were identified based on microscopic and Molecular criteria. T. mentagrophytes, T. tonsurans, M. audounii, M. canis. Also non dermatophytes fungus was Chaetomium globosum. Also three yeast species were identified: Candida albicans, Candida parapsilosis, Malassezia spp. based on molecular assays. The antimicrobial activity of plant extract antifungal shown, Capparis spinosa plant has highly antifungal activity shown inhibition on dermatophytes, followed by Furcraea foetida shown inhibition compare with activity of Fluconazole in vitro.

Key wards: Genotyping, Tinea capitis, Dermatophytes, Antifungal activity, Plant extract

Introduction

Dermatophytes are known as ring worm, dermatophytosis and Tinea (9,5). Approximately 10-15% of the world’s population has been found to have fungal infections 22. Tinea capitis is a scalp skin-attacking disease that attacks hair follicles and shafts and causes eyebrow infection. The disease is regarded a shallow mycosis or dermatophytosis form.

Tinea capitis ‘ epidemiology differs across distinct geographic regions around the globe, and the species may alter in any specified region. Hot tropical humid climates, low socioeconomic status, crowded living conditions, and bad hygiene lead to Tinea capitis ‘ enhanced incidence. It is highly communicable and may reach epidemic proportions especially in overcrowded setups (16,8). The aim of study conduct molecular typing of suspected fungi were associated with Tinea capitis samples, and those isolated from patients, and from soils of barber shops, Assessment of the effectiveness of plant extract antifungal activities and assessment of the effectiveness of conventional antifungals.

Material and Method

Collection of Specimens:

1. Hair and scalps: A 80 hair and scalps samples were collected in this study from all patients diagnosed with head lesions (clinical and barber shops). After that, the infection area was sterilized with 70% alcohol to remove the bacteria. Hair samples were collected using forceps and skin scraps from the scaly edge of the area using a surgical blade. The sample was transferred to the laboratory in sterile filter paper.

2. Soil: The soil of the barbers shops, house and mosques was collected and transported to the laboratory in sterile paper to be examined.

Corresponding author:
Zaidan Khlaif Imran
Biology department, College of Science for Women, University of Babylon, Babylon province, Hilla, Iraq; E-mail: zaidan.omran@yahoo.com
3. Cultivation of Samples:

All clinical samples collected were cultured on SDA agar media that containing chloramphenicol (250mg/l), Streptomycin (150mg/l) and cyclohexomide (250mg/l) then all samples incubated at (28-30°C) for two weeks. Then after the result of culture appeared the samples were examined morphologically from where the color of colony, shape, texture and reverse pigment. Then maintained the samples by using a screw-cup slant on SDA and preserved while the study 20.

All samples that give positive results of Tinea capitis purified by taking a pure colony from culture media that obtain a mixed culture.

DNA extraction:

The isolates of yeast and filamentous fungi under interest were subjected to DNA extraction. In brief; a loop full of yeast colonies and tiny portion of mycelia were suspended in the lysis buffer supplemented by Favrogen Yeast Extraction Kit (Korea) and following up the extraction steps based on the instruction of this Kit. A dry DNA pellet dissolved in diluted rinse and preserved in - 20 °C until use (13, 12, 1).

The genomic DNA was extracted according to 13, The PCR procedure was as previously described by (13,12,1). The universal primer pair used in this study was ITS5/ITS4 Forward: (5′-GGAAGTAAAAGTCGTAACAAGG-3′) and Reverse (5′-TCCTCCGCTTATTGATATGC-3′), the specific primer pairs for Malassezia: Malup (5′-AGCGGAGGAAA AGAAACT-3′), Mal down primer (5′-GCGCGAAGGTGTCCGAAG-3′) 17,

Sequencing of Selected PRC Product

A 10 dermatophyte isolates PCR products were sent to Korea’s Macrogen Laboratory and obtained the positive sequence information for various species. The sequencing findings were subjected to those deposits in GenBank for sequence species identification for alignment with reference strains 11.

The Plant Extract Samples

Plant samples that used in this study, which comprised plant parts from the local markets for center of Babylon province. Then cleaned the plant from dust and impurities, Put in a flat bowl and leave to dry at room temperature, take a while, after the plants completely dry, then crashed by electric grinder well crashes 1.

Static Analysis

Statistical analysis was performed with the use of SPSS version20. ANOVA test was used to compare distinctions between variables, at a probability level (≤ 0.05).

Results and Discussion

Prevalence of dermatophytes among Tinea capitis sufferers:

A total of 120 samples, 110 samples were (80 hairs and scales and 30 soils) were collected from different age and genders of patients with Tinea capitis and 10 samples were collected by the same techniques from like healthy persons (as control samples), the clinical specimens were collected from private clinics in Babylon province and from barbers shops, the soil specimens were collected from the dust of the ground shops of barbers, houses and mosques. Identification results based on cultural and microscopic methods showed that 48 (60%) of 80 clinical samples were positive cases. The majority of the patients were males 38.75% (31/ 80) while, 21.25% (17/ 80) specimen from females. The samples of soils were 30 samples (27.27%), the results were 1(3.33%) out of 30 samples were positive case. While only one specimen shown positive out of 10 samples from control group.

The relations between the infection and age for both genders:

It had been registered the number and percentage of infected patients by Tinea capitis, depending on gender and age ,table (1) had shown the significant difference between genders and infection with this disease, the number of males (31)(64.58%) and the number of females reached (17)(27.08%) to the consultative of the dermatology.

It was clear from the current study, males infection with Tinea capitis was (64.58%) while in females (27.08%) it was found existence of significant differences of the infection in both sexes agreed with results of other researchers outside of Iraq, including 15 who concluded that the Tinea capitis is a disease common in children
and occurs in males more than females, and 19 in the city of New Delhi, India, 3 in Kenya and 2 in Palestine and 18 in South Africa, 23 in Kashmir, who found that Tinea capitis affects males more than females in their studies.

Males’ sensitivity to tinea capitis. The elevated rate of tinea capitis in males can also be ascribed to simple sporal implantation owing to short hair and frequency sharing of comb, brushes and caps.

**The Identified fungi:**

A total of 11 fungal isolates have currently been identified based on evidence of morphological, microscopic, and molecular analysis. The dermatophytes were: *T. mentagrophytes, T. quinckeanum, T. tonsurans, M. audonii, M. persicolor, M. canis,* and non dermatophytes was: *Chaetomium globosum.* Also, two Candida spp. were *C. albicans, C. parapsilosis,* and *Malassezia* spp.

Table 2 shows the types of dermatophytes isolated from the human, the most common isolate predominant was *M. audonii* which represent 21 (45.65%) of cases followed by *T. persicolor* 9 (19.56%). It showed the presence of differences between sex and species of the fungi isolated.

**Molecular identification**

**A. Molecular typing by ITS region:**

The particular results were 12 dermatophytes and non-dermatophytes based on the rDNA region ITS1-5.8S-ITS2, 28S partial sequence). The dermatophytes were: *Microsporum* spp; *Trichophyton* spp.; *Cheatomum* spp., *Candida* spp.; and *Malassezia* spp. Also, some isolates of molds Figure (1).

![Figure (1): Profile gel electrophoresis of PCR products of 12 dermatophyte and non-dermatophyte isolates of fungi amplified by ITS5/ITS4 primer: Lanes (left to right): isolate of 1- *M. audouinii* (800 bp); 2, 6, 7- *Chaetomium globosum*; 3, 4 unidentified fungi (600 bp); 5- *T. mentagrophytes* (780 bp); 8, 9- *T. queckanum* (700 bp); 10- unidentified fungi; 11- *T. tonsurans* (700 bp); 12- *M. persicolor* (700 bp), these results according to sequence analysis; 13, 14 *Candida albicans* (500, 510 bp); 15- *Candida parapsilosis* Molecular M (100bp for each step.). 1.6% agarose gel at 70 volt for one hour.](image1)

There are high variations in PCR products among of fungi under interest as in used ITS5 / ITS4 as primer pair for amplification of ITS region. ITS region consider good barcoding region due to high variation for another ward the amplification of this region show high polymorphism in PCR product. (*Chaetomium globosum*, *M. audouinii*, *M. canis*, *M. ferrugineum*, *M. persicolor*, *T. mentagrophytes*, *T. quinckeaneum*, *T. tonsurans*) these range not always require for other specific genetic analysis.

Shown that all *Malassezia* spp., shown monomorphic bands, approximate 605bp of PCR products. Figure (2), these results consistent with 17.

![Figure (2): Electrophoresis gel profile of PCR amplification products. All samples yielded a single band of approximately 605 bp.:1-3 isolates of *Malassezia* spp. Molecular marker: M1= (100bp).](image2)

The current study agreed with 7 concluding that *M. Globosa* appears to be the most prevalent pathogen responsible for Tinea capitis, as well as, also *M.furfur* identified one of causative agent to cause Tinea capitis 21.

**DNA sequence analysis:**

About 16 μl of PCR products were sent to Macrogen Laboratory in Korea for sequencing analysis. After the sequence results had been obtained, each sequence alignment with the sent isolate’s nitrogen bases sequence. They correspond to reference sequencing samples in the gene bank using NCBI Blast Nucleotide.

![Figure (3): Phylogeny construction for all identified isolates based on sequence charts with one reference strain (marked with the accession number, while our isolates have full names).](image3)
Antifungal Activity of Some Plant aqueous extracts against dermatophytes spp.

Figure (4): Inhibition growth of aqueous plant extracts compared with the antifungal fluconazole, A. Water as control treatment, B. Effect of Capparis plant, C. effect of Furcraea plant, D. effect of the antifungal Fluconazole.

In recent study 3 isolates of dermatophytes are used to study the effectively of this plants extracts, the concentration of plant aqueous extracts was (5%). The plant extracts showed inhibition of dermatophyte growth, the aqueous plant extract from Capparis gives the highest inhibition zone respectively followed by plant extract from Furcraea, while the antifungal fluconazole was less inhibited compared to those plants. The sensitivity of fungus Figure (5).

Figure (5) Comparison of antifungal agents activity between plant type (Capparis, Furcraea) and Fluconazole dermatophytes growth. The species of dermatophytes were (f1: T. tonsurans, f2: M. ferrugineum, f3: M. audonii).
Figure (5) shown that the dermatophytes strains shown significant difference of response, the highest effect of inhibition was *Capparis* and *T. tonsurans* the most fungus in response to the extract was the mean (4 cm) followed by *M. ferrugineum* (3.8 cm) and *M. audonii* (3.2 cm). *Furcraea* was less inhibited than *Capparis*; *M. audonii* was the highest fungus in response to (2.4 cm) of the plant while *T. tonsurans* and *M. ferrugineum* equal response (1.7 cm). Fluconazole was the least fungal response compared to plants and *T. tonsurans* was the highest fungus in response to antifungal (1.8 cm), followed by *M. audonii* (1.7 cm) *M. ferrugineum* the lowest fungus (11.6 cm). There were significant differences between *Capparis* plant and *Furcraea* and Fluconazole, while *Furcraea* showed no significant differences between it and the antifungal.

The conclusion of this study gave attention that particular study about Tinea capitis more producible in their result compared with survey studies of dermatophytes and non dermatophytes fungi in whole human body. The results of our study after isolated and identified 8 dermatophyte and non-dermatophyte fungi and 3 yeasts. The antifungal activity of plant extract of *Capparis* and *Furcraea* plants shown highly inhibition compared with Fluconazole, this result was light on uses natural product more effective and revealed rise of Fluconazole resistance by dermatophytes.

Nurse’s Practices toward Nursing Intervention of Diagnostic Procedures at Neuro Surgical Hospitals in Baghdad City

Wafaa Abd Ali1, Widad K. Mohammod2

1 Lecturer, Adult Nursing Department, College of Nursing, Baghdad University; 2 Assist Professor, Adults Health Department, College of Nursing, Baghdad University

Abstract

The study aims to evaluate nurses’ practices toward nursing intervention of diagnostic procedures at Neuro Surgical Hospitals, and to find-out the relationship between Nurses’ practices with their Socio-demographic characteristic of age, gender, and education level. A quantitative research approach has been used for this study design starting from December 7th, 2017 to September 2nd, 2019. A purposive sample was adopted including (50) male and female nurses as participants. They were working at Neuro surgical Hospitals. The study Instrument was composed of two Parts: The First Part is concerned with the socio-demographic characteristics, and the second Part includes Nurses’ Practices. Content validity of the instrument was established through a panel of (11) experts. Results have been analyzed through the use of SPSS “Statistical Package for Social Sciences” model 24.0 by using descriptive and inferential statistical methods. Findings of the present study revealed that most of the samples were within the age of (35-44) years who were accounted (34%). The age group of (25-34 years) represent (32%). 24 percent of the study sample were (45-54) years old, and only five nurses were within the age group of (18-24) years old.

Key word: Nurses, practice, diagnostic procedures, neurosurgical.

Introduction

Patients with various neurological dysfunctions can perform several diagnostic studies to detect health problems, such as EEG, EMG, MRI, and CT scan. Nurses have several roles to deliver healthcare services for neurological patients, including educating patients about the aims, to be expectations, and the side effects preceding testing. Moreover, other healthcare conditions required special considerations before performing neurological exams, including women using contraception breast-feeding women. Nurses should note results, disease progression, and patients’ response to therapy (1,2,3).

Material and Method

A quantitative research approach has been used for this study. The quasi-experimental design (pre-test and post-test) was conducted on nurses who work at neurosurgical hospitals towards selected educational program. It was conducted with application of pre-test and post-test approach to evaluate nurses’ practices regarding impact of educational program upon nursing intervention of diagnostic procedures, in addition to the application of education program. It was carried out in order to achieve the initial stated objectives. The study started from December 7th, 2017 to September 2nd, 2019. Participants were verbally informed about the aims of the study and had been asked to participate voluntarily. They also had been informed that they could refuse to answer a certain question or withdraw from the study at any time. Emphasis was placed on creating a suitable environment during interview using good communication skills with participants. The researcher constructed the questionnaire thorough reviewing of previous literature and related studies. The study instrument comprised of two parts; Socio-Demographic Data which was comprised of six items relative to the gender, age, educational status, years of experience, training of program, and number of training courses; and Nurses’ practices Form which was comprised of (35) items that concerned with nurses’ practices to evaluate nursing intervention of diagnostic Procedures at neurosurgical hospitals. Content validity for the early
developed program and the study instruments were determined using panel of (11) experts. A preliminary copy of the program and questionnaire was designed and presented to (11) experts for the determination of its validity. They were (8) faculty members from College of Nursing – University of Baghdad, (3) faculty members from Neuro Surgical Hospitals in Baghdad city. A purposive sample of (10) nurses was selected from diagnostic procedure units of working in neuro surgical hospitals to achieve the purpose of pilot study. It was applied on the nurses who had the same criteria of the original study sample and started from December 9th, 2018 to December 23th, 2018 to determine the internal consistency of questionnaire related practices of nurses concerning nursing intervention of diagnostic procedure at neuro surgical hospital. The researcher determined the internal consistency by using test – retest through the computation of Pearson correlation coefficient of the scale which was \( r = 0.88 \) for nurse’s practices \(^4\). Data were collected through direct interview with the study sample by using a constructed questionnaire. Nurses were observed while they were working in their units to provide care concerning nursing intervention by using concealed observational technique. Data were collected from February 4th, 2019 to April 3rd, 2019. The data were analyzed by using SPSS (Statistical Package for Social Sciences) version 24.0 application of the statistical analysis system. The descriptive data analysis includes Frequency (f), Percentage (%), Mean, and Standard Deviation. The inferential data analysis includes Pearson Correlation Coefficient, t-test, and ANOVA Table test with significance of p value \( \leq 0.05 \).

It is clear from the table (1) of demographic characteristics for nurses, that the majority of the study sample are females (52%) and the remaining are male. According to their age group, the majority of the sample within the age group of (35-44) years who are accounted (34%). The age group of (25-34) years accounted for (32%). Twelve’s of the study sample are (45-54) years old who are accounted (24%), and only five nurses are within the age group of (18-24) year who are accounted (10%). Relative to their education level, equal number are graduate from medical institute and nursing secondary school who are accounted (26%), college (12%) graduate and (36%) primary school graduate (Table 1). According to the subject’s years of experiences, 30% have (11-15) years of experiences, 24% have (16-20) years of experiences, 20% have (6-10) years of experiences, 18% have (5-10) years of experiences, while the remaining 8% have (21 and more) years of experiences. Concerning training session, the majority of nurses have no training session who are accounted (74%). The remaining have training session who are accounted 26% and have one session only.

Ass.=Asymptomatic significant; A.=Always (2.5 - 3); S.=Sometimes (1.50 – 2.5); N.=Never (1. – 1.50).
Results in table (1) presented that the sample of the study were (24) males whom accounted for (48) percent, and the remaining were females with (52) percent of the study sample. A highest proportion of the study sample (34) percent, were within age group (35 – 44) years old, and the remaining (32) percent were within age group (25 – 34), (24) percent within age group (45 – 54), and (10) percent within age group (18 – 24) respectively. Number of employees with a diploma in nursing reached (13) with (26) percent; while, 12 percent of the study sample have bachelor’s degree in nursing. Moreover, nurses who have secondary certificates were accounted for (26) percent. Those who have Primary certificates were accounted for (2) percent, and those with other certificates were accounted for (34) percent. The number of employees with years of experience (1-5) reached (9) a percentage (18%), while those with years of experience (6-10) reached (10) a percentage (20%), who had years of experience (11-15) and reached (15) a percentage (30%), and for the years of experience (16-20) reached (12) and by percentage (24%), and the last with years of experience (21 and more) reached (4) and by percentage (8%). The number of employees who took part in training session was (13) and percentage (26%), while those who did not take part in any training session reached (37) a percentage (74%). The staff who participated in training session were divided into those who participated in one session reached (7) and percentage (14%), while those who participated in two sessions reached (4) percentage (8%) , and the last with those who participated in three sessions reached (2) percentage (4%). Iannotti (2015) established a study in 12 neurocritical units on registered nurses and found that (54.54) percent of the study sample were within age group of (22 – 33) years old, and (36.36) percent were within age group of (34- 44) years old . Moreover, Iannotti (2015) reported that (90.91) percent of the study sample have (0 – 10) years of experience in neurocritical units . Table (2) presents that there are significant differences in the mean of study sample between the pre and posttest procedure, revealing a significant improvement in nurses’, practices regarding CT scan. Table (5) presents that there are significant differences in the mean of study sample between the pre and posttest procedure, which reveals that there is a significant improvement in nurses’, practices regarding EEG. The Mean knowledge related to all domain of the study for the study group participants has increased significantly in the post-test stage. In contrast, there is a minor difference in the Mean knowledge for the control group participants between pretest and posttest stage. Shehab, Ibrahim, and Abd-Elkader (2018) indicated a positive impact of an Educational Program on Nurses’ Knowledge and practice Regarding Care of neurocritical ill patients at Intensive Care Unit at Suez Canal University Hospital . The authors of this study reported a positive impact of an educational program on the total score of nurses at various concepts (p value = .001) . Elf, Carlsson, Rivas, Widnersson, and Nyholm (2019) declared that nurses play a significant role in providing care for patients undergoing EEG, which might impact the health status of patients with neurological disturbances or illnesses .

**Conclusions**

Nurses’ practices in general were poor before the implementation of an educational program in pre-test, which included their practices during the procedures. There were significant improvement in Nurses practices after the implementation of an educational program in post-test. The findings of this study indicate that the educational program for nurses was effective after the exposure to such a program, (their practice toward nursing intervention of Diagnostic procedures). Emphasis should be put on the managers of hospitals, and nursing affairs managers to monitor and follow-up, support and supervise nurses while they are working in their units. Giving the nurses of the patients’ knowledge and practices for good preparing before and after any procedure in the neurological hospitals. Emphasis is necessary on hospital managers and administrators on nursing to reward and incentive nursing staffs that are efficient and loyal in their work and to reward the good ones and punish the careless in their duties.

Antimicrobial Study against Seven Cycles Compounds Derivatives from Pyrimidine

Aseel Fadhil Kareem¹, Hasan Thamer Ghanim²

¹Lecturer, ²Assistant prof., Department of pharmaceutical Chemistry/ College of Pharmacy /University of Babylon, Iraq

Abstract

The current study involves preparing newly pyrimidine derivative compound with seven membrane rings and used it to explain the antimicrobial activity of it against four isolates of four types of G+ & G– pathogenic bacteria (Staphylococcus aureus, Staphylococcus epidermidis, Escherichia coli and Klebsiella pneumonia) respectively, with two types of fungi (Aspergilus niger & Penicillium chrysogenum) by using four different concentrations (5, 10, 15 & 20 mg/ml⁻¹). The characterizations and properties of this compound have biological and pharmacological functions through the inhibition the growth of many types of organisms.

Key words: Antimicrobial activity, Schiff base, Pyrimidine.

Introduction

Heterocyclic derivatives have effective antimicrobial, anti-inflammatory and anticancer activity with different pharmacological effects. Two atoms of imine group (two-membered component) was added to maleic or phthalic anhydrides (five-membered component) lead to form a seven-membered heterocyclic compound(1,14). These products contain the seven rings with functional groups (R-N=N-R⁻) the Schiff bases have aromatic azo group are colored therefore we used them as dyes that considered as an organic compound with many antimicrobial activity ². The seven membered rings are widely present in nature with nitrogen and oxygen atoms that have medicinal activity because of their structural similarities between them and natural substances. In the industrial field, they used in polymer processes and antioxidant (3,4).

Pyrimidine is a cyclic amine with a large group of heterocyclic compounds that plays an important role in many biological functions. It is found in nucleic acids, several vitamins, co-enzymes and purines ⁵.

Azo dyes one of the important and the largest groups of synthetic organic dyes that mainly used as coloring agents for foods and cosmetics, besides to their applications in modern technology ¹.

These compounds have the ability to inhibit the replication of nucleic acid and protein synthesis that may be used against many of multidrug resistant organisms among the world (6,14).

Objectives

This study was designed to determine the antibacterial and antifungal activities of a newly synthesized compound at different concentrations against four types of pathogenic bacteria with two types of fungi in vitro laboratory conditions.

Materials and Method

1- Chemical study:

We prepared A1 compound [-2, 6 diamino-5-((4-hydroxycyclohexyl) diazenyl) pyrimidin-4-ol ] by dissolving (0.03 mol) from p-aminophenol in (0.03 ml) of concentrated HCl with (10 ml) of distilled water. Then we cooled the mixture to (0-5) °C in ice water bath. (0.03 mol) of sodium nitrate was dissolved in (10 ml) of cool distilled water and this solution was added to the mixture above step by step with continuous shaking for (15 min). The diazonium solution was added to solution contain (0.03 mol ) from Pyrimidine that dissolved in (25 ml) of ethanol and sodium hydroxide the result was formation light purple solution at pH (6-7) then we left it for one
hour, filtrated the mixture and washed the precipitate with distilled water then we recrystallized from absolute ethanol.

The S1 Schiff base \[ 4,4'-(1Z,1'Z)-((6-hydroxy-5-(4-hydroxycyclohexyl) diazenyl) pyrimidine2,4diyl) bis (azaneylylidene)) bis (methaneylylidene)) bis (2-methoxycyclohexan-1-ol) \] was prepared as following: 0.03 moles of vanillin (3-methoxy-4-hydroxy benzenes aldehyde) was dissolved in (25 ml) in absolute ethanol, then we added 1-2 drops of Glacial acetic acid with continuous shaking for (20 min) on magnetic stirrer. Then, we treated it with (0.03 mole) from A1 compound gradually to complete the process at 70 ᵒC in 7 hr. The mixture was evaporated and dried the solution for recrystallized from absolute ethanol as in scheme (1).

The B1 compound \[4,4'-(6-hydroxy-5-(4-hydroxycyclohexyl) diazenyl) pyrimidine-2,4-diy) bis(3-(4-hydroxy-3-methoxycyclohexyl) octahydrobenzo[e][1,3]oxazepine-1,5-dione) \] was prepared by dissolved of 0.03 mol from Schiff bases (S1) in (25 ml) dry benzene with continuous shaking to complete solving . Then we added (0.03 mol) from phathalic anhydride gradually to complete the process at 65 ᵒC in 15 hr. The solution was dried for recrystallized by absolute ethanol as in scheme (2).

2- Microbiological study:

The antimicrobial activity of the newly synthesized compound was examined by using 4 isolates of four types of G+ & G– pathogenic bacteria that include the following (S. aureus, S. epidermidis, E. coli and K. pneumonia) respectively, with two types of fungi A. niger & P. chrysogenum at four different concentrations (5, 10 , 15 & 20 mg/ml⁻¹) after dissolving these compounds in DMSO as solvent as in\(^7\). The antimicrobial activity was measured by minimum inhibitory concentrations in (mm).
Results and Discussion:

In this study we prepared B1 compound from the S1 Schiff base that was confirmed by IR & HNMR as in scheme (2) to determine the antibacterial and antifungal activities of it against G+ & G– bacteria with fungi by measuring the minimum inhibitory concentration (MIC) in (mm) at four different concentrations (5, 10, 15 & 20 mg/ml⁻¹) as in table (1) and figure (1).

This compound had good activity against all types of bacteria and fungi that used in this study with a significant increased against G+ especially S. aurous at (20 mg/ml⁻¹) concentration compared with others microorganisms and this is may be occurring due to their ability to damage the cell wall of the microorganisms and inhibit their function or stopping microbial replication and these results were agreements with many researches (10,11,12,13).

The presents of central ring separator play an important role in the noncovalent DNA cooperation through intermolecular interaction as formation of hydrogen bonds, which can increase the antimicrobial activity and that depend on the nature of hetero atoms in their structures and the presence of phenyloxy moiety with NH₂ as an electron releasing group(6,11,13).

Table (1) Antibacterial and antifungal activity against B1 compound at four different concentrations (5, 10, 15 &20 mg/ml⁻¹)

Conclusions

The present research focused on the synthesis of novel chemical derivatives to explain their antibacterial and antifungal activity that be safely used in future towered many infectious diseases.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the College of Pharmacy, Iraq and all experiments were carried out in accordance with approved guidelines.

Effect of Cupping (Al-Hijima) on Hematological and Biochemical Parameters for some Volunteers in Missan Province

Abbas Ch. Mraisel 1, Mustafa A. Nama2, Ahmed, A. Habeeb3

1 Assistant Prof., Toxopathology, 2 Lecturer, Basic Medical Science Department / Nursing College / Missan University, Iraq, 3 Lecturer, Biochemistry / Clinical pathology Department /Al-Manara for Medical Science / Missan, Iraq

Abstract

Objective: The aim of Cupping is to extract the blood which is believed to be harmful for the body which in turn rids the body of potential harm from symptoms leading to a reduction in stressful condition. The study was performed to evaluate the effects of cupping (Hijama) on the hematological and the biochemical parameters in the patients before and after making the cupping.

Subjects and Method: The study was performed in period between (first November -2018 to May- 2019) and conducted on (30) volunteers coming to Hijama centers in different parts of Missan province in ages between (30-50) years with . Five (5ml) of venous blood samples were collected the first sample was taken before and after one week of cupping and two weeks later after cupping . Each sample of blood was separated into two tubes for hematological assessment and the serum was stored in -20°C freezer till handled for biochemical analysis ,determined lipid profile and serum electrolytes level. These parameters were performed in laboratories of Al- Sadder Teaching Hospital – Amarah City according to the standard methods that described in the Analysis Kits that used in this study was products of Spinach Company Spin react.

Results: The obtained results for hematological analysis observed significant increase in (RBCs) after one and two week of making Hijima in (p< 0.05),as compared results before making hijjama ,significant decrease in hematocrit(HCT) ,hemoglobin (Hb) ,Platelets (Plt) , neutrophiles and lymphocytes percentages after one and two week of making Hijama as compared results before making hijama . Total cholesterol were observed significant decrease in (P>0.05) after one and two weeks of hijima in compared with the total cholesterol before making the hijima ,decrease in (LDL) , (vLDL) and Triglyceride after one week and two week of hijima as compared before making the hijima .High density lipoprotein (HDL-ch) observed significant increase in (P>0.05) after one week and two weeks of making hijima as compared with (HDL-ch) before making the hijima. The biochemical analysis observed significant decrease in levels of ALP enzyme,creatine ,blood urea nitrogen and blood glucose in(P>0.05) after one and two weeks of Hijima, significant increase in levels of total proteins , AST and ALT in(P>0.05) after one and two weeks of making Al-hijima as compared with levels before making the hijima. Serum electrolytes level showed an significant decline in serum Calcium ions (Ca+2) in (P>0.05) after one and two weeks of making Al-hijima as compared to the serum calcium level before making of Al- hijama. Also observed insignificant decline in serum sodium(Na+2), chloride ions (Cl-) and potassium ions(K+) as compared to level of sodium ,chloride and potassium ions before making of Al- hijama.

Key Words: Cupping, volunteers, hematological, biochemical parameters, Hijama centers.
Introduction

In the Arab and Muslim world, Al-Hijamah is a deeply rooted religious technique supported by many authenticated sayings (hadiths) of Prophet Mohammad (PBUH) who recommended its use in human ailments more than 1400 years ago. There are three types of cupping include dry, wet, and massage cupping. In dry cupping stationary cups are placed on the skin and left for a period of five to 15 minutes in one location without incisions, while in wet cupping (hijama) the process of using a vacuum at different points on the body but with incisions in order to remove ‘harmful’ blood which lies just beneath the surface of the skin. In massage cupping, oil is applied on the skin to facilitate smooth movement and discover the areas of tension and congestion prior to applying the cup. Cupping therapy can be divided into two broad categories; dry cupping and wet cupping. Dry cupping simply pulls the local underlying tissue up into the suctioning cup, whereas wet cupping uses the same technique, but adds scarification and bloodletting. Many theories explain the mechanism of action of cupping, suggested the immunemodulation theory, cupping and acupuncture had the same mechanisms of action. Immunemodulation theory suggests that changing the microenvironment by skin stimulation could transform into biological signals and activate the neuroendocrine immune system. Suggested that skin’s mechanical stress (due to subatmospheric pressure) and local anaerobic metabolism (partial deprivation of O2), during cupping suction could produce physiological and mechanical signals which could activate or inhibit gene expression. In wet cupping therapy, superficial scarifications could activate the wound-healing mechanism and gene expression program.

Cupping therapy has reported benefits in the treatment of lower back pain, neck and shoulder pain, headache and migraine, knee pain, facial paralysis, brachialgia, carpal tunnel syndrome, hypertension, diabetes mellitus, rheumatoid arthritis, and asthma. These diseases can be categorized into localized diseases (neck pain, lower back pain, and knee pain) and systematic diseases such as diabetes mellitus, hypertension, and rheumatoid arthritis.

Material and Method

The study was performed in period between (first November -2018 to May- 2019) and conducted on (30) volunteers in ages between (30-50) years with average age (40) years contact with Hijjama centers in different parts of Missan province. Five (5ml) of venous blood samples were collected from each volunteer, the first sample was taken before cupping and second sample was taken after one week of cupping ,while the third sample was taken in two weeks later after cupping . Each sample of blood was separated into two tubes. The first tube with EDTA for hematological assessment and second blood tube was centrifugation for 10 minutes at 3000rpm, the serum was stored in -20°C freezer till handled for biochemical analysis for determined lipid profile and serum electrolytes level.

Complete blood picture were shown from the collected blood samples by automatic methods (System X kx-21n automated hematology analyzer; JAPAN CARE CO., LTD) including hemoglobin (Hb), white blood cells (WBCs), red blood cells (RBCs), Platelets and Haematocrit or packed cell volume (PCV).

Statistical Analysis

The results were expressed as mean ± standard error (SE). Statistical analyses were made with one-way analysis of variance (ANOVA) using SPSS 17. The criterion for statistical significance was (P<0.05).

Results

The obtained results for hematological analysis the blood samples collected form (30) volunteers in Hijjama centers before and after one and two week of hijjama,observed significant which increased (RBCs) after one and two week of making Hijjama as compared results before making hijjama (p<0.05),also observed significant decrease in haematocrit(HCT) ,hemoglobin (Hb) ,Platelets (Plt) , neutrophiles and lymphocytes percentages after one and two week of making Hijjama as compared with the results before making hijjama (p<0.05), Tab(1).

Lipid profile values were detected in blood samples that obtained from volunteers before and after one week and two weeks of hijjama which include total cholesterol ,LDL-ch,HDL-ch ,Triglyceride and VLDL-ch where
the total cholesterol levels were observed significant decrease in (P>0.05) after one and two weeks of hijima in compared with levels of the total cholesterol before making the hijima ,also the results observed significant decrease in Low-density lipoprotein (LDL), very Low density lipoprotein (vLDL) and Triglyceride in(P>0.05) after one week and two week of hijima as compared with the levels before making the hijima,Tab(2).

While the high density lipoprotein (HDL-ch) observed significant increase in (P>0.05) after one week and two weeks of making hijima as compared with the levels of (HDL-ch) before making the hijima,Tab(2).

Table-2: Show lipid profile parameters for the patients before and after one and two weeks of Hijima. (N:30 volunteers).

The biochemical analysis of the blood serum that obtained from volunteers before and after making Al-hijima observed significant decrease in levels of alkalinephosphatase enzyme, creatinine ,blood urea nitrogen and blood glucose in(P>0.05) after one and two weeks of making Al-hijima as compared with level of these biochemical parameters before making the hijima, Tab(3). On other hand there was significant increase in levels of total proteins , Aspartate aminotransferase and Alanin anino tranferase in(P>0.05) after one and two weeks of making Al-hijima as compared with levels of total proteins , Aspartate aminotransferase and Alanin anino tranferase before making the hijima, Tab(3).

Table (4) and figure (1) shows the comparison of serum electrolytes level before and after one and two weeks of hijama. Blood samples obtained after hijama showed an significant decline in serum Calcium ions (Ca+2) in (P>0.05) after one and two weeks of making Al-hijama as compared to the serum calcium level before making of Al- hijama.

The results also observed insignificant decline in serum sodium(Na+2), chloride ions (Cl-) and potassium ions(K+) as compared to level of sodium, chloride and potassium ions before making of Al-hijama.

![Figure 1](image)

Discussion

Hematological analysis of the blood samples that collected from (30) volunteers in different Hijama centers in Missan province before and after one and two week of Hijama, observed significant increase in (RBCs) and decrease in haematocrit(HCT) ,hemoglobin (Hb) ,Platelets (Plt) , neutrophiles and lymphocytes percentages after one and two week of making Hijama as compared with results of these parameters before making hijama.

The results of this study were agreed with 6 who stated that RBCS will increase gradually after two weeks of cupping with significant decrease in the percentage of WBCs ,lymphocytes ,monocytes , HGB, and HCT and platelets in the human venous blood, while Abdullah et al. (2014) were found insignificantly changes in hematological levels after cupping.

1 were found slight improvement in hemoglobin levels ,RBCs,while WBCs observed with normal values duet to improvement in erythropoietin production after cupping and produced in adequate which make
hemoglobin to return to the normal values and increase production of RBCs and suggested that renal function has improved which may be related to the improved metabolism, electrolytes and appetite.
