A meta-analysis from 55 countries also showed that the standard deviation score (SDS) of European children in general are +0.5 SD, while children from Saudi Arabia and India are -0.5 SD compared to the WHO 2006 chart reference population. 20 Research by Batubara et al (2006) also shows that Indonesian children have lower SDS than the 2000 CDC chart reference population. This data shows that there are different characteristics of child growth in various regions.

The different interpretations of two growth chart in this study indicate that estimation of children malnutrition in Indonesia using 2006 WHO-CGS is exaggerated, and perhaps Indonesian children have grown in accordance with their genetic potential. This can lead to unnecessary examination and intervention which can interfere exclusive breastfeeding and cause excessive supplemental feeding. 7 Formula milk and excessive supplementation of food can cause excess weight which will be accompanied by long-term complications in the future. It must be considered in the national policy of malnutrition management in Indonesia. However, because children’s growth is not only influenced by race or genetic factors, good environmental factors must also be considered. Interventions to correct problems that affect the nutritional status of the population such as lack of breast milk, low or high calorie food, lack of health facilities, sanitation, and poverty must be continued. 17

This study also has several limitations. Our study analyzed secondary data collected from integrated healthcare center, hence anthropometric measurements tend to vary in each center. Nutrient intake including breast milk and parent socioeconomic status were not evaluated. This might lead to some bias in evaluating differences in interpretation of nutritional status. Application of growth chart that developed from Indonesian children as standard population should be considered in estimating children with malnutrition. Further study is needed to confirm whether the interpretation of child nutritional status using growth chart is consistent with their clinical condition and also to determine whether Indonesian children have grown.
according to their genetic potential.

**Conclusion**

2005 GDIC detects fewer children with malnutrition than 2006 WHO-CGS. The significant difference on interpretation between two growth charts was particularly found in height-for-age.

Association between Blood Total Testosterone Levels and Consolidated Memory on Eldery Men at Veterans Institution

Muhammad Hamdan¹, Raini Wisnujono¹, Yudha Haryono¹, Abdulloh Machin², Euginia Putri Permata P.²

¹Lecturer in Department of Neurology, Faculty of Medicine, Dr. Soetomo Teaching Hospital, Universitas Airlangga, Surabaya, East Java, Indonesia, ²Department Student of Neurology, Faculty of Medicine, Dr. Soetomo Teaching Hospital, Universitas Airlangga, Surabaya, East Java, Indonesia

Abstract

Background: Decreased total testosterone levels in the blood will disrupt memory consolidation. In this phase, one could still function normally even though it is difficult to recall the information that has been learned.

Methods: The subjects were taken consecutively and conducted by interview, generalist, and neurological physical examination, Word List Memory Task examination twice as well as measurement of total testosterone in the blood. The subjects were grouped into total blood testosterone levels of less than 298 ng/dl and more than equal to 298 ng/dl.

Results: Fifty-four subjects studied obtained that total blood testosterone levels <298 ng/dl in the Word List Memory Task (WLMT) group <21 (62.5%) were higher than the WLMT group ≥21 (37.5%). Furthermore, Total Testosterone in the blood more ≥298 ng/dl in the WLMT group <21 (15.2%) was less than in the WLMT group ≥21 (84.8%).

Conclusion: There was a correlation between total testosterone levels in the blood and memory consolidation in elderly men at the Veterans' Institute of Republic Indonesia in Surabaya.

Keywords: Elderly men, Total Testosterone in the Blood, Consolidation of Memory, Neurology

Introduction

It is estimated that the world population is 7 billion, up from 6.5 billion in 2006. The increase in number is followed by an increase in people aged 60 years and over. Between 1970 and 2025, the number of elderly people is expected to increase by 223% or about 694 million. In the year 2025, there will be about 1.2 billion people in the world aged 60 years and over. Then soon will be 2 billion in 2050. Increases occur in many developing countries, including Indonesia. The increasing number of elderly people in the world brings several problems in the health field. Health problems of decline in cognitive function will affect the pattern of interaction with the elderly living environment, with family members and social activities. This will add to the burden of families, the environment, and society.

In the aging process, there will be a circadian rhythm disorder that is a biological process that shows endogenous oscillations and recurs every 24 hours, including sleep-wake cycle, heart rate, blood pressure, hormone secretion, sensory ability, and mood are all governed by the hypothalamus.

Disorders of hormone secretion possibility cause a decrease in total testosterone levels in men resulting in some symptoms and complaints such as cognitive and mood disorders as well as disorders of virility.
Cognitive impairment is much complained by 39% of the population aged 50-59 years and increased to more than 85% at the age of over 80 years. Men (6,7) will experience a decrease in total blood testosterone levels of about 0.8-1.6% every year starting when entering the age of about 40 years. The decrease in total testosterone levels will disrupt the consolidation of memory so that there possibility complaints of forgetfulness. In this phase, one could still function normally even though it is difficult to recall the information that has been learned. However until now, the correlation between total testosterone levels and memory consolidation remains unclear.

Research on total testosterone levels with memory consolidation disorder in elderly men will be conducted at the Community of Veterans of Republic Indonesia8. This community consists of the struggle retired veteran (before independence), retired armed forces of Republic Indonesia (after Indonesian independence) and retired police9. The selection of Veterans Institution of the Republic of Indonesia in its population has a high well being educated, has the spirit to move and socialize and still pay attention to the importance of health problems10. So hopefully this community could help the smoothness of this research.

Examination of total blood testosterone levels needs to be performed, as the total blood testosterone levels could affect the formation of consolidated memory and the learning process, leaving the elderly easily to forget their memories.11 Until now in Indonesia there is no research on this topic, therefore the authors are interested to determine the correlation between total blood testosterone levels and memory consolidation in the elderly male.

**Methods**

Fifty-four elderly men in Veterans of Republic Indonesia in Surabaya were enrolled from November 2014 to October 2015, attention function (Digit Span) >5, concentration function (Vigilance) >10, Mini-Mental State Examination (MMSE) >24, minimum level of senior secondary education or equivalent, willing to participated the research (informed consent). The method was performed according to consecutive cases (sampling from consecutive admission) until the sample number has been reached to set. Then, it was conducted an interview, performed memory check word list memory task twice and laboratory on participants who meet the criteria for inclusion.

This was an observational analytic with the cross-sectional approach and has obtained the approval of ethical clearance from the ethics committee of Dr. Soetomo General Hospital, Surabaya Indonesia. The dependent and independent variable data will be analyzed analytically by using chi-square. Data analysis results will be displayed in graphical form. The entire process of data analysis will be processed using the SPSS 21 computer program. (SPSS, Inc., Chicago, IL)

**Results**

**Basic Characteristics of Research Subject**

A total of 54 study subjects consisting of 8 subjects with total testosterone less than 298 ng/dl and 46 subjects with testosterone more than or equal to 298 ng/dl. Characteristics age of the subjects obtained; 60-65 years was 25 people (46.3%) and age 66-70 years was 29 people (53.7%). Educational Characteristics was high school graduate level by 52 (96.3%) and university graduate by two (3.7%).

The subjects with hypertension were 17 (31.5%) people, and those who not suffer were 37 (68.5%) people. Subjects with diabetes mellitus were 19 (35.2%) people and those without was 11 (35.8%) people. Subjects with dyslipidemia were 11 (20.4%) people, and those who did not suffer were 43 (79.6%) people. Active subjects smoked was 22 (40.7%) people, and who did not smoke was 32 (59.3%) people. Subjects with memory consolidation disorder were 12 (22.2%) people, and those with no memory consolidation problems were 42 (77.8%) people. Subjects with total testosterone levels less than 298 ng/dl were 8 people (14.8%), and subjects with total testosterone levels more than or equal to 298 ng/dl were 46 people (85.2%).

**The correlation between Hypertension and Memory Consolidation**

In subjects with uninterrupted consolidation who experienced hypertension was fewer by 2 people (11.8%) than non-hypertensive by 10 people (27.0%). This difference was not statistically significant or clinical, with p = 0.300 and odds ratio (RO) of 0.360 (CI 95% 0.070-1.864).

**Correlation between Diabetes Mellitus and Memory Consolidation**
In the subjects with consolidated disruption who had diabetes was 6 (31.6%) people more than those who did not have diabetes by 6 (17.1%) people. This difference was not statistically significant or clinical, with $p = 0.307$ and odds ratio (RO) of 2.231 (CI 95% 0.604-8.224)

The correlation between Dyslipidemia and Consolidation of Memory

In subjects with uninterrupted consolidation who experienced dyslipidemia was 2 (18.2%) people fewer than non-dyslipidemia by 10 (23.3%) people. This difference was not statistically significant or clinical, with $p = 1.000$ and odds ratio (RO) of 0.733 (CI 95% 0.136-3.965)

Correlation between Smoking and Memory Consolidation

In subjects with uninterrupted consolidation who smoked was 5 (22.7%) people more than non-smokers by 7 (21.9%) people. This difference was not statistically significant or clinical, with $p = 1.000$ and odds ratio (RO) of 1.050 (CI 95% 0.286-3.864)

Correlation between Education and Memory Consolidation

In the subjects experiencing the consolidation that interrupted with senior high school education was 11 (21.2%) people less than college education by 1 (50.0%) people. This difference was not statistically significant or clinical, with $p = 0.398$ and odds ratio (RO) of 0.268 (CI 95% 0.016-4.641)

Correlation between Total Testosterone Levels and Memory Consolidation

In subjects with impaired consolidation having total testosterone levels less than 298 ng/dl for 5 (62.5%) people, it more than those with testosterone levels greater than or equal to 298 ng/dl by 7 (15.2%) people. This difference was statistically and clinically significant with $p = 0.01$ and odds ratio (RO) of 9.286 (CI 95% 1.798-47.964). This means that subjects with a total testosterone level less than 298 ng/dl have a risk for memory consolidation disorder 9.286 times greater than subjects with testosterone levels greater than or equal to 298 ng/dl.

**Discussion**

In this study, there was a difference in the proportion of memory consolidation disorders in subjects with total testosterone levels less than 298 ng/dl and greater than or equal to 298 ng/dl. It was tested by chi-square test with $p = 0.01$ and odds ratio (RO) of 9.286 (CI 95% 1.798-47.964). Based on these data, it could be stated that there was a significant correlation between total testosterone levels and memory consolidation, where subjects with total testosterone levels less than 298 ng/dl have a risk for memory consolidation disorder 9.286 times greater than subjects with testosterone levels more or equal to 298 ng/dl.

Based on data, there was no statistically significant difference with $p = 0.307$ and the odds ratio (RO) 2.231 (CI 95% 0.604-8.243). Therefore, the status of diabetes mellitus was not a meaningful confounding factor for the occurrence of memory consolidation disorder. This possibly due to the good control of blood glucose in subjects suffering from Diabetes Mellitus. All subjects who suffer from Diabetes have received adequate therapy so that blood glucose levels during examination have been controlled. This was in accordance with the assertion that the correlation of intensive decreased blood glucose levels in diabetics to memory function impairment. The study concluded that intensive blood glucose control could be slowing the decline in cognitive function (CI 95% 1.02 to 1.19; $p <0.0156$). While the condition of chronic hyperglycemia accelerates the decline in cognitive function.

Hypertension was one of the confounding factors in this study. Some literature says that there is a correlation between hypertension and memory impairment. Hypertension often did not cause actual clinical symptoms so many hypertensive people did not realize it. If not treated, hypertension could cause coronary heart disease, heart failure, stroke, kidney failure and other problems such as memory function impairment. Hypertension causes narrowing of the blood vessels. Decreased blood flow to the brain due to the narrowing could cause the brain to become inefficient.

Measures of cognitive function in 288 hypertensive patients were produced high blood pressure (mean systolic 154.7 ± 21.3 and diastolic mean 88.6 ± 92) that had the significant role to cognitive function, including memory function with $p <0.001$.15
In data there was no significant difference between a statistic and clinical with \( p = 0.300 \) and the odds ratio (RO) 0.360 (CI 95% 0.070-1.864). So it could be stated that the status of hypertension was not a meaningful confounding factor for the occurrence of memory consolidation disorder. The study of 50 elderly patients with hypertension who performed cognitive examination using MMSE obtained the result of no difference in the cognitive disturbance between elderly and hypertension \( (p = 0.331) \). In contrast, other studies provide different results due to differences in subject research factors included in the inclusion criteria. Giordano included inclusion criteria ranging in age from 53 years to 94 years and male or female sex. While in this study the subject of research was aged 60 years to 70 years and all are male sex.

In data there was no statistically significant difference in the value of \( p = 1.000 \) and the odds ratio (RO) of 0.733 (CI 95% 0.136-3.965). So it could be stated that in this study, dyslipidemia was not a significant confounding factor for memory consolidation disorder. This was in contrast to prospective longitudinal community studies of LDL cholesterol with the risk of dementia in elderly people. The result of increased LDL cholesterol correlates with the risk of dementia with an odds ratio of 3.1 (CI 95% 1.5 - 6.1). In other studies provide a controversial result that there was a weak correlation between levels of High-Density Lipoprotein Cholesterol (HDL-C) and Low-Density Lipoprotein Cholesterol (LDL-C) with dementia disorders. This result was similar to Table 2. In Table 2, there was no statistically significant difference in the value of \( p = 1.000 \) and the odds ratio (RO) of 1.050 (CI 95% 0.286-3.864).

There have been several studies on the correlation of nicotine to cognitive function especially attention, learning, and memory. The effects of nicotine on neuroplasticity are controversial. Even some research on the effects of nicotine on attention, learning, and memory provide heterogeneous results. Subject who smoked had improved performance in motor responses, good attention, and memory recognition, but had a disruption to learning and memory recall. There have been several studies on the correlation of nicotine to cognitive function especially attention, learning, and memory.

In data, there was no statistically significant difference with \( p = 0.398 \) and odd ratio (RO) 0.268 (CI 95% 0.016-4.641). So it could be stated that in this study, the level of education was not a confounding factor that meaningful for the occurrence of memory consolidation disorder. These results not in accordance with some studies on the correlation between education level and cognitive impairment to the risk of dementia. Previous studies mentioned that the level of education was a predisposing factor of cognitive impairment and dementia. While the research using MMSE (Mini-Mental State Examination) and CDT (Clock Drawing Test) on elderly cognitive function profile over 60 years showed significant result, that subjects who received more than nine years of education (senior high school, diploma or bachelor), has a cognitive function that classified as normal while the elderly who only educated 9 years more experienced a decrease in cognitive function.

Based on the activity theory proposed Stanley to achieve successful aging, the elderly must remain active in both mental and physical activity. One of the mental activities is by undergoing formal education up to the highest level.

Results from previous studies were different from current research. In the previous study, there was no significant correlation between MMSE score and testosterone levels. Most patients have had low MMSE results although testosterone levels are within the normal limits. While in this study the factors (attention, concentration, MMSE and sleep disorders also depressive disorders) will be inserted into the subject of research when getting a bad result. Therefore, the memory consolidation disorder could be concluded as a result of low levels of testosterone alone.

Conclusion

There was a correlation between total testosterone levels and memory consolidation in elderly men at the Veterans’ Institute of Republic Indonesia in Surabaya.

The Analysis of Workload and Safety Communication Against Burnout Syndrome in Inpatient Nurses

Yulia Purnawati¹, Tri Martiana², Rachmat Hargono³, Firman Suryadi Rahman⁴

¹Student of Magister Program of Occupational Health and Safety Department, ²Lecture in Department Occupational Health and Safety Department, ³Lecture in Department Health Promotion and Behavioral Science, Department Faculty of Public Health, Universitas Airlangga, Campus C Mulyorejo 60115, Surabaya-Indonesia, ⁴Student of Doctoral Program of Public Health, Universitas Airlangga

Abstract

Introduction: Burnout is a psychological problem that attacks nurses and is one of the risks causes nurses to do unsafe actions. Nurses suffering from burnout and have a less safe environment will implement inefficient care systems. Generally, high workload is directly proportional to the incident of burnout. This research study aimed to find the effect of workload and safety communication on the level of burnout in inpatient nurse services.

Method: This research was a cross-sectional study implemented at Rumah Sakit Umum Haji and Rumah sakit Islam Jemursari Surabaya, Indonesia. This implementation of research study was started in April to June 2019. The samples were collected using two populations of sampling method and got 138 nurses as samples. To analyze the effect of workload and safety communication on burnout syndrome, the researcher used multinomial logistics.

Results: The results of Multinomial logistic test showed that workload affected the incidence of burnout with a value of p = 0.037 and safety communication did not affect the incidence of burnout syndrome with a value of p = 0.274.

Conclusion: Workload affected the burnout syndrome incidence, while safety communication had no notable effect on burnout syndrome. The researcher suggests the hospitals to provide mental and physical health services, as well as stress coping training for nurses.

Keywords: Workload, Safety communication, Burnout

Introduction

Nurses who work in hospitals faced many difficult situations every day. At the same time, nurses are part of the public who are concerned with economic problems. They often work more than one burden and are constantly under emotional, physical and mental pressure.

The facts in the field, not all nurses can do their duties and functions properly because they often experience mental and emotional exhaustion due to their duties, which must always be ready to provide maximum service for others. If this problem is not resolved immediately by the hospital, of course, the nurses’ stamina and emotions will be drained and generating pressure that creates in nurse’s burnout.

The fact that nurses have a high risk of experiencing burnout was discovered long ago. An imbalance between workload and number of nurses causes an overload of workload. The emergency department, orthopedics & traumatology, oncology, and advanced care are the work environment, which possesses the highest-pressure levels. If the nurses experience continuous overload workload, they will experience burnout. One sign of burnout on nurses is the expression of nurses who rarely smile to patients.
Nurses experienced burnout and have an uncomfortable environment triggered them to provide inefficient care compared to nurses who suffer from burnout. Safety climate is defined as the description or perception of nurses on safety practices, regulations, and procedures so that they act effectively in the work environment; associated with other priorities such as productivity. One dimension of safety climate is safety communication. This communication is very important, so dangerous situations could be prevented or avoided and the management may take the necessary initial action to dodge the dangerous situation and problems of environmental exposures.

There has been a lot of research on burnout and climate safety, but only a few researchers have studied in a comprehensive and detailed to investigate the effect of safety communication on the incidence of burnout syndrome, especially in health care organizations such as hospitals.

Therefore, the researcher was interested to analyze the effect of workload and safety communication on the burnout syndrome occurrence in inpatient nurses.

**Method**

This research study is a cross-sectional study. It was applied at Rumah Sakit Umum Haji and Rumah Sakit Islam Jemursari Surabaya, Indonesia started from April to June 2019.

The population in this research study was nurses in Rumah Sakit Umum Haji and Rumah Sakit Islam Jemursari Surabaya, Indonesia. The samples were 138 nurses and collected utilizing two population sampling methods.

The researcher collected primary and secondary data. Primary data in this research study were obtained by observing work sampling and questionnaires. Secondary data were from interviews and standard operating procedure documents.

Independent variables in this research study were workload and safety communication, while the dependent variable was burnout syndrome.

The multinomial logistic test was adopted to analyze the effect of workload and safety communication on burnout syndrome. There were three categories of burnout syndromes; those are low, medium, and high.

**Results**

**Workload**

The technique used in observing workload was work sampling, which was an observation of nursing care activities conducted by nurses in doing their daily tasks.

The calculation of nurse workload on 138 samples of nurses was based on the percentage of productive time used for direct and indirect nursing activities of total working hours.

**Safety Communication**

Safety communication measurements functioned part of the safety climate questionnaire from Naghavi et.al. The results of safety communication measurements are described in the table below:
Based on the questionnaire results, most respondents (64%) declared the organization had high safety communication. This revealed, in general, respondents believed the organization had tried to communicate about work safety like safety talk. However, some respondents viewed the lack of safety communication from the head of the room.

**Burnout Syndrome**

Burnout syndrome measurement used a questionnaire from the Maslach Burnout Inventory (MBI). Based on the questionnaire results, respondents experienced high category burnout syndrome of 4%. Burnout-syndrome measurement results are described in the table below:

The Effect of Workload and Safety Communication on Burnout Syndrome

The researcher implemented statistical testing using multinomial logistic regression. It showed that there was a significant effect of the workload on burnout syndrome, (p = 0.037) and p <0.05. Safety communication did not affect burnout syndrome, (p = 0.274) and p> 0.05. The higher the workload of nurses might raise the chance of burnout syndrome incident.

**Discussion**

**Workload**

The observation results on workload analysis suggested the average value of 86.59 % of the total working hours per person. It indicated the workload of nurses had exceeded productive time. The maximum productive work time was only 80% of total work hours and 20 % was for non-productive activities. The excessive workload could cause physical or mental fatigue and emotional reactions such as headaches, indigestion, and irritability.

**Safety Communication**

On the questionnaire results, most respondents (64%) perceived that the organization possessed high safety communication. This explained in general, respondents assumed the organization tried to communicate about work safety such as safety talk. Nevertheless, some respondents considered the lack of safety communication from the head of the room. Safety communication is an influential contributor in improving safety at work. Regular communication about safety issues between managers, supervisors, and workers is an operative habit in improving health and safety in the workplace.

**Burnout Syndrome**

Questionnaire analysis presented respondents experienced low burnout (42%), moderate (54%), and high (4%) syndrome. Burnout syndrome means a condition encountered by someone in the form of physical, mental, and emotional fatigue that lasts for a long time. It potentially is likely to attack nurses and to increase in nurses implementing services, since they often meet with a variety of characters and illnesses suffered by patients. Hence, the nurses are at risk of having fatigue, both physically and mentally.

The data obtained from questionnaires analysis indicated the nurses frequently experienced burnout syndrome several times a month; it happened on which they worked with other people. They felt that working made them tired. Besides, nurses sensed responsible for some patient problems occurred several times a month, and this responsibility was considered as a burden.

**The Effect of Workload on Burnout Syndrome**

The results of this study showed there was a notable effect of workload on burnout syndrome. The
high workload triggered nurses to endure burnout and fatigue. This would have an impact that the nurses gave less quality of services. Another study conducted by Kiekkas presented burnout syndrome had a significant relationship with nurses’ workload. Kiekkas also stated high workload specifically affected one of the burnout-syndrome dimensions, namely physical and emotional exhaustion.

The high workload prompts the nurses to feel fatigued or burnout. Consequently, it produces job stress and influences on the decreasing job satisfaction. The excessive work stress on nurses led to burnout syndrome. Physical fatigue happened continuously for a long period will have an impact on psychological fatigue.

**The Effect of Safety Communication on Burnout Syndrome**

Safety communication did not affect burnout syndrome because safety communication between management and nurses was considered good. Good management communication reduced stress on workers.

**Conclusion**

The workload value per person was 86.59% of the total working hours. Based on the results of the questionnaire analysis, most respondents (64%) perceived that management had high safety communication.

Workload positively affected on the burnout syndrome incidence, while safety communication did not influence the burnout syndrome.

The researcher suggests the hospital’s management instill nursing care values so that work the nurses’ motivation increases. It also needs to provide refreshment to the nursing tasks. Thus, the subjective workload can be reduced, improve safety communication such as safety talks, provide mental and physical health services, and training coping with stress to the nurse.

Effectiveness of *Garra Rufa Care* Toward Pruritus Elderly Who Live in Indonesian Village

Zagad Budhi Dharma¹, Joni Haryanto², Elida Ulfiana²

¹Student Faculty of Nursing, ²Lecturer Faculty of Nursing, Universitas Airlangga, Kampus C Mulyorejo, 60115, Surabaya, Indonesia

Abstract

Pruritus is a neurodegeneratif disease that attacks the peripheral skin. It is not infrequently the elderly experience these health problems with itching complaint, so that it cause a feeling of wanting to scratch. High itching complaint can also cause the anxiety level increased. The purpose of this study was to determine the effectiveness of Garra Rufa Care pruritus elderly who live in the village area, Indonesia. This study was designed as a quasi experiment using non-probability techniques with a simple random sampling method. The respondents of this study consisted of 40 elderly people who had pruritus caused by dermatology and were divided into an experimental group and a control group. The independent variable was Garra Rufa Care, and the dependent variable was elderly with pruritus. This instrument of the study used the Numeric Rating Scale (NRS), Geriatric Anxiety Inventory (GAI) and used the Wilcoxon and Mann Whitney test with α <0.05 as data analysis. The results showed the effect of Garra Rufa Care on itching complaint (p = 0.000) and there was a significant low (α = 0.014). The results showed the effect of Garra Rufa Care on anxiety level (p = 0.000) and there was a significant significance (α = 0.000). Psychological effect have given “micro massage” and decreased the anxiety level which have physically reduced itching scores. Garra Rufa was effectively used as an intervention in the elderly with pruritus by decreasing itching complaint and anxiety level. Further study was expected to replicate similar studies with more samples and carried out observation after making intervention.

Keywords: Anxiety, Elderly, Garra Rufa, Itching, Pruritus.

Introduction

Pruritus is an unpleasant sensory perception that causes a strong desire to scratch and has a high impact on the quality of life¹. Chronic pruritus (CP) is a symptom with a negative impact on quality of life and it is known to be associated with anxiety². The elderly is one of the patients who often experience pruritus skin disorders. This is due to pruritus being one of the neurodegeneratif diseases that attacks peripheral skin³. Patient with the high pruritus intensity is more susceptible to experience anxiety⁴.

Pruritus can be found all over the world. According to a cross-sectional study in Oslo, Norway, pruritus affects 8.4% of the general population⁵. While in a French study a survey was sent to 10,000 randomly selected households ⁶. From the 7,500, 87% reported skin problems since their born and 43% of patients with skin diseases stated that they had experienced pruritus¹. According to a study in Turkey which involving 4099 elderly dermatological patients, 11.5% reported pruritus, and the highest prevalence was recorded in patient who aged over 85 years. From a study in Thailand which involving 149 elderly patients, pruritus was the most common in 41% of the total patients involved ¹. The results of the preliminary study conducted in one of the Villages, Indonesia, there were 40 elderly out of 521 elderly who experienced pruritus or 7.6% of the number of elderly people.

The number of elderly people in Indonesia is 7.6% or 18 million out of 237 million inhabitants. In East Java, there are elderly with 11.6% or 4.4 million inhabitants as the highest number ³ after the Daerah Istimewa
Yogyakarta (DIY) and Central Java. Based on the data from the population in the village there are 10.9% elderly or 521 out of 4810 inhabitants.

Skin aging comes from a combination of chronological and environmental factors. This involves intrinsic, hormonal, biological and genetic factors as well as extrinsic and dangerous stimuli such as accumulation of UV radiation, pollution or nicotine for life. Ageing skin will be characterized by epidermal and dermal atrophy, due to the loss of collagen, degeneration of elastic fiber tissue and loss of hydration. The characteristics of intrinsic and extrinsic aging are progressive loss of function, structural integrity and physiological function of the skin, which involves impaired immune responses and skin barrier function, vascular atrophy, metabolic imbalance of reactive oxygen species and extracellular matrix component. Therefore, the molecular mechanism that protects and defends against extrinsic factor decreases progressively over a lifetime.

While the problem of pruritus continues to be left and it is not immediately treated in the elderly, then the negative impact that will arise such as a scratching scar that can cause ulceration in the legs. Then the ulcer can develop into an infection and worsen the skin condition of the elderly. Therefore a special nursing intervention is needed to overcome this.

Garra Rufa Care is an action in the form of nursing intervention using Garra Rufa fish. Garra Rufa is a fish species that is beneficial for skin health by releasing the enzyme ditranol (anthralin) which can decrease the inflammatory process and increase skin moisture. Garra Rufa can also be used for aesthetic purposes and as a medical treatment of patient with psoriasis. The function of the ditranol enzyme released by Garra Rufa fish produces a therapeutic effect to improve blood circulation, the skin becomes smoother, reduces and blurring of the scars and increases skin regeneration. This study was conducted to determine the effectiveness of Garra Rufa Care Toward Pruritus Elderly in Village Areas of Indonesia.

**Material and Method**

Quantitative approach with the Quasy Experimental design and pre-post control design research was conducted to determine the effectiveness of garra rufa care toward pruritus elderly who live in the villages of Indonesia. This study was carried out in Pagerejo Village, Pacitan Regency, East Java, Indonesia. The population in this study was 521 elderly who aged more than 60 years. Calculation of the large sample using the application G * Power 3.1.9.2. A sample of 40 elderly is obtained, that is 20 samples from the control group and 20 samples from the treatment group (nursalam).

The instrument in this study used the Geriatric Anxiety Inventory (GAI) and Numeric Rating Scale (NRS). The study process began with pre-test activities to determine itching complaint and anxiety level, then intervening with Garra Rufa fish in accordance with SOP (Standard Operating Procedure). After the intervention, it was carried out a post-test to determine the final condition of itching complaint and anxiety level.

The collected data was then analyzed using the Wilcoxon test to determine whether there was difference between the 2 samples. Then, it also performed a non-parametric test using the Mann-Whitney statistical test. Finally the data were analyzed using the SPSS windows program.

**Result**

Characteristic of respondent in the gender category were dominated by women in both the control group (60%) and the treatment group (60%), if it was counted, the total female respondent were 24 respondents (52.5%).

The pretest results of the elderly itching complaint in treated group before being given Garra Rufa Care showed that 17 respondents felt moderate itching, and 3 respondents felt severe itching. The posttest results of the treatment group after being given Garra Rufa Care showed 18 respondents felt moderate itching, and each respondent in mild itching and normal/not itchy.

P = 0.000 Wilcoxon
P ≤ 0.05

The Decrease Average
\[ \frac{44}{20} = 2.2 \]

The Decrease Average
\[ \frac{35}{20} = 1.95 \]

α = 0.014
Mann Whitney
α ≤ 0.05
The results of statistical tests using the Wilcoxon Test in the treatment group found a decrease in itching complaint of the elderly with pruritus after being given Garra Rufa Care with p value = 0.000 which means p <0.05, then H1 was accepted, it means that there was an effect of Garra Rufa Care in itching complaint of the elderly with psoriasis by an increase average in the treatment group of 2.2 points. Mann Whitney test results in the control and treatment group obtained a value \( a = 0.014 \), which means there were significant differences in the treatment group and the control group. So it was said that there was an influence of Garra Rufa Care on itching complaint of the elderly with significant pruritus.

**Discussion**

Pruritus was caused by a number of causes, including dry skin, immunosuppression and nerve degeneration and also it can caused by skin diseases, systemic condition, and psychogenic condition\(^20\). As we got older, changes of skin structure and loss of cell function gradually cause the skin to become more sensitive which was susceptible to disease. Pruritic skin disorder that occurred in the elderly was the result of normal skin aging due to the decrease of mobility\(^21\).

Function changes of the Stratum Corneum (SC) barrier, lipid matrix cell and intercellular (ILM); pH variations; SC protease changes; the decrease of sebaceous and sweat gland activity; and the decrease of estrogen level. All of these factors can cause itching induction\(^20\). As we got older, the decrease of cell function gradually causes the skin to become more sensitive and at risk of itching.

After being given the Garra Rufa Care therapy there was a change in the decrease of itching complaint. Garra Rufa fish was known as “nibble fish” or “doctor fish of Kangal” which was an effective therapy to reduce itching complaint and it was used as ichthyotherapy for medical treatment of psoriasis\(^22,23\). By Ichthyotherapy, itching complaints that often arises will not relapse although it has been for some time\(^23\). Plaque psoriasis patient with severe pruritus report the higher scores for depression and anxiety\(^4\). A decrease in anxiety can occur due to a decrease in itching complaint with Garra Rufa Care which provided the effect of psoriasis spa therapy in the form of a relaxation sensation that results a comfortable feeling\(^27\).

The treatment of pruritus was very complex and depends on the underlying condition and the accompanying disorders\(^19\). Skin disease was often suffered by the elderly, and therefore there was a necessity for special nursing intervention to handle it\(^28\). Types of treatment in pruritus were creams and ointments that contain anti-pruritic substances such as urea, menthol, or polydocanol\(^19\).

The intervention using Garra Rufa fish works spontaneously, that was the condition of fish that will swarm around the skin which contains many dead skin cells and simultaneously the fish will secrete the enzyme ditranol\(^29\). Other benefits can also improve blood circulation, eliminate bacteria, and also reduce foot odor. Moreover to the benefits above, Garra Rufa Care provides a “micro-massage” therapeutic effect providing psychological comfort when the fish bites produce a feeling of comfort\(^20\).

**Conclusion**

Garra Rufa Care intervention was effective in reducing itching complaint in the elderly with pruritus, without any side effects. Providing Garra Rufa Care intervention was also effective in reducing anxiety level in the elderly with pruritus, on the other hand, decreasing anxiety level was obtained without any side effects. There was an influence of Garra Rufa Care in the reduction of itching complaint and the anxiety level of the elderly with significant pruritus. Garra Rufa Care can reduce itching complaint, so that reducing anxiety after the intervention.

**Ethical Clearance:** This research has passed the ethics test with number 501-KEPK by the health research ethics commission of the Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia.

Effectiveness of Audio-Visual Media in Health Education about Fruits and Vegetables Consumption in Early Adolescents at Palangka Raya Elementary School

Untung Halajur

Abstract

Consumption of fruits and vegetables in Indonesia is still lacking (5%), even though fruits and vegetables play a role in maintaining the condition of blood pressure, blood sugar and cholesterol levels to prevent non-infectious diseases. One way to increase public awareness to consume fruits and vegetables is through health education. Health education through audiovisual media is considered important because it displays elements of moving images and sounds that stimulate more senses. This study aims to determine the effectiveness of audiovisual health education media to increase knowledge, attitudes, and behavior of adolescents in the consumption of vegetables and fruit every day. This research uses quasi experiment method. The sample of this research is grade 6 students of Menteng State 5, Elementary School in Palangka Raya. The results showed an increase in the proportion of knowledge and good attitude after the intervention period (p-value: 0.008 and 0.002). There is no significant relationship between sex with students’ knowledge and attitudes towards vegetable and fruit consumption (p-value: 1.0 and 0.71).

Keywords: fruit and vegetable, knowledge, attitude, gender

Introduction

The results of basic health research 2010, there are still many people who do not consume enough vegetables and fruits. In 2013, 93.5% of the population aged> 10 years consume vegetables and fruits under the recommendation. In 2018, the consumption of fruits and vegetables that were quite new reached 5 percent.1,2,3 Various studies show that the consumption of vegetables and fruits that are sufficient to play a role in maintaining normal blood pressure, blood sugar and cholesterol levels. Consumption of enough vegetables and fruit also reduces the risk of difficulty defecating (constipation) and obesity. This shows that adequate consumption of vegetables and fruits also plays a role in the prevention of chronic non-communicable diseases. Consumption of adequate vegetables and fruits is one simple indicator of balanced nutrition. The ripe fruit containing carbohydrates, the higher the fructose and glucose content, which is characterized by a sweeter taste. In the eating culture of the Indonesian urban society at this time, increasingly known sugary juice drinks. In a glass of sugary fruit juice containing 150-300 calories, about half comes from added sugar. Therefore, consumption of overripe fruit and sugary juice drinks need to be limited in order to help control blood sugar levels.

Daily consumption of vegetables and fruit is a government program through the Ministry of Health which is stated in the community movement to increase public awareness of the importance of consuming fruits and vegetables every day. Increasing public awareness especially teenagers one of which is to provide knowledge through health education about the consumption of vegetables and fruit every day, both in schools and directly to the wider community. Health education in schools about the consumption of vegetables and fruits...
each day as well as education in general consisting of students, teachers, teaching media, teaching methods, teaching aids and materials to be taught.

Audiovisual media is media that has sound elements and picture elements. This type of media has better capabilities because it combines audio and visual media. There are 2 types of audiovisual media namely silent audiovisual and motion audiovisual. Audiovisual still is a media that displays sound and still images such as sound slides, sound chain films and sound prints. While audiovisual motion is a media that can display sound elements and moving images such as video cassette sound films. The senses that channel much knowledge into the brain are the eyes (approximately 75% to 87%), while 13% to 25%, human knowledge is obtained and transmitted through other senses.

Based on the description above, this research is important to be done to find out the effectiveness of audiovisual health education media to increase knowledge, attitudes, and behavior of adolescents in the consumption of vegetables and fruit every day.

Materials and Method

This research uses quasi-experiment method. The pretest-posttest group design is described as follows: (1) give an experiment to one group that is a group that is treated using audiovisual media (video) (2) provide initial tests for groups and calculate the mean of achievement; (3) providing treatment using audiovisual learning media (video); (4) give a final test for one group and calculate the mean group achievement; (5) calculate the difference between the average value of the initial test and the final test (improvement in learning outcomes) of the group then compare with statistics. In this study, audiovisual media about the consumption of vegetables and fruit every day as an independent variable. Knowledge variable, the attitude of consumption of vegetables and fruits every day as the dependent variable. Characteristics of respondents viewed were age and sex, and favorite food. The research sample was Grade 6 students of Menteng 5 Elementary School in Palangka Raya. The time for conducting research is in the range of May 2019 to August 2019.

Audiovisual media is media that has sound elements and picture elements. This type of media has better capabilities because it combines audio and visual media. There are 2 types of audiovisual media namely silent audiovisual and motion audiovisual. Audiovisual still is a media that displays sound and still images such as sound slides, sound chain films and sound prints. While audiovisual motion is media that can display sound elements and moving images such as video cassette sound films.4 The senses that channel much of the knowledge into the brain are eyes (approximately 75% to 87%), while 13% to 25%, human knowledge is obtained and transmitted through other senses.5

In the learning process until learning outcomes are obtained, there is a process that requires learning media. The learning process becomes more interesting because of the use of media so that it encourages students to love science and likes to search for their own sources of knowledge, students’ habits to learn from various sources will be able to instill an attitude to students to always take the initiative to find a variety of learning resources needed. Learning media are all forms and channels used to convey information or messages. Media is one of the communication tools in conveying messages which is certainly very useful if implemented in the learning process, the media used in the learning process is called learning media.6

Attractive learning media can increase student interest in the learning process, learning media can also provide stimulation in student learning activities.7 The principles that have been used in the media in this study are the effectiveness (accuracy) in achieving learning objectives, relevance: the suitability of the media used with the goals, efficiency: selection and use of media must properly pay attention that the media is cheap and cost-effective, can convey the purpose of purpose, can be used and applied in learning so as to increase student understanding and improve the quality of learning, contextual: the selection and use of learning media must prioritize aspects of the student’s social and social environment.6

The learning method used is audiovisual, audiovisual media is an intermediary or visual aid used by researchers in learning activities that use material absorption through sight (pictures) and hearing (sound). The use of audio visual media takes into account the duration, with the duration of the learning meal will be more efficient in the use of time, if learning is planned with the right time then the success rate of learning will also be greater.8

Consumption of fruit and vegetable by students can not be separated from the behavior of people who carry out these activities, because the behavior of these people will affect food products to be selected or purchased. Behavior arises because of a driving factor that causes a force to arise so that the individual acts. The driving factor in behavior is determined by two things namely the driving factor from within the individual which includes beliefs, motivation, emotional level and gender. Encouraging factors from outside the individual include knowledge, education, experience, environment, and so on.9 Knowledge is more an introduction to an object or thing objectively.10

Knowledge and attitude are internal factors that influence student behavior. In detail human behavior (which in this case is the consumption of vegetables and fruit) is actually a reflection of various symptoms such as knowledge, desires, desires, interests, motivation, perceptions, attitudes and so on. Knowledge is the result of knowing, and this happens after someone senses a certain object. Most of human knowledge is obtained through the eyes and ears.11 Know is defined as remembering a material that has been studied previously and is the lowest level of knowledge. Before someone behaves he must know in advance what the meaning and benefits of the behavior are for him, so that it can be interpreted that before students behave to consume vegetables and fruit, students must know what information about vegetables and fruit is like.

Attitude is a reaction or response that is still closed from someone to a stimulus or object. One of the social psychologists, states that the attitude is the readiness or willingness to act and not the implementation of certain motives. Attitude is a readiness to react to objects in a particular environment as an appreciation of the object. Attitude is one of the psychological or mental aspects that is formed through the learning process along with one’s growth and development. So that what is meant by student attitudes in the consumption of vegetables and fruit is the views or responses of students who
are still closed to the consumption of vegetables and fruit. The formation of attitudes is influenced by internal factors and external factors. Internal factors include physiological and psychological. While external factors are experience, culture, mass media, others that are considered important and the learning process.\(^\text{11}\)

The results showed that there was an influence of audio-visual media on students’ knowledge and attitudes between before and after and between the intervention and control groups. Audio-visual media is a medium that involves the sense of hearing and vision as well as in a process that is able to stimulate the sense of sight and sense of hearing together, because this media has sound elements and picture elements.\(^\text{4}\) There was an increase in student knowledge. This type of media has a better ability, because it includes both types of auditive (listening) and visual (seeing) media, which means materials or tools used in learning situations to help writing and words spoken in transmitting knowledge, attitudes, and ideas.\(^\text{12}\)

Based on the results of the study, researchers assume that health education using media that involves the sense of hearing and vision as well as in a process that can stimulate the sense of sight and sense of hearing together can affect the level of knowledge and attitudes of adolescents about consumption of vegetables and fruit. Thus, health education is needed by using audio-visual media that can stimulate the sense of sight and sense of hearing together, because this media has sound elements and picture elements that can affect the level of knowledge. The goal is that teenagers can understand vegetables and fruit.

The attitude of growth begins with the knowledge that is perceived as a good or bad thing, and then internalized into him. Knowledge is one of the factors that influence attitude. The better the knowledge the better the attitude, on the contrary the less knowledge, the less good (less) attitude. Someone’s experience related to an object can influence the formation of one’s attitude towards the object.\(^\text{13}\) By paying attention to attitude we get a tendency to choose whether to accept or reject a suggestion that is accepted as something good or not good. Attitude is an internal ability that plays a role before someone takes action.\(^\text{14}\)

**Conclusion**

Percentage and number of respondents based on gender, female gender as many as 57.33% or as many as 43 people and male students as much as 42.67% or 32 people. Before the intervention of students ‘knowledge of vegetable and fruit consumption by 81.3% was well knowledge, after the intervention, students’ knowledge of vegetable and fruit consumption by 92% was good knowledge. There is an increase in the proportion of knowledge both after the intervention period. The attitude of students before the intervention that is equal to 76% being good, after the intervention as much as 89.3% of students being good. There is an increase in the proportion of good attitudes after the intervention period. As many as 95% of female students are well-informed and 90.6% of male students are well-informed. There is no significant relationship between sex with students’ knowledge of the consumption of vegetables and fruit. As many as 90.7% of female students behaved well and 87.5% of male students behaved well. There is no significant relationship between gender and students’ attitudes towards consumption of vegetables and fruit.

The Effect of Research Project Course on Nursing Students’ Attitudes toward Research Process

Selman Hussain Faris¹, Fatma Makee Mahmood ², Ali Kareem Khudhair ³

¹Community Health Nursing Department / College of Nursing/ University of Kerbala, Iraq, ²Adult Department / College of Nursing/ University of Kerbala, Iraq, ³Psychatric and Mental Health Nursing Department / College of Nursing/ University of Kerbala, Iraq

Abstract

Objective: Investigate the effect of research project course on nursing students’ attitude toward research at a college of nursing in Kerbala University and identify the relationship between nursing student’s attitude and demographic variables. A pre-experimental design (One-group Pretest-Posttest design) was utilized to determine the effect of research project course on nursing students’ attitude toward research at a college of nursing in Kerbala University. All participants were exposed to assess of attitudes regarding research before and after the implementation of the research project course in order to detect the effect of the course. The current study results revealed that; the majority (74.2%) of nursing students were within age groups (20-22) years old the mean age of the all students was (22.27) years. 82.3% of total students were female. the majority (82.3%) of subjects were single, most of sample (80.6%) were urban resident, the mean of score of the positive attitude of respondents in posttest of the research project course was significantly higher than the pretest of the research project course in all aspects of attitude regarding research project course, and no significant difference between the nursing students’ demographic variables and attitude responses in the posttest of research project course.

Key words: Nursing students, Attitudes, research project course, research

Introduction

Nursing research is characterized as the integrating, and dispersing procedure to have effect on the current nursing practice by utilizing research produced information. Additionally, nursing research application has been connected with enhance nature of nursing practice. According to Chien, et., al. (2013) and Nieswiadomy (2011), Applying research prove amid day by day clinical practice help to upgrade the; nature of nursing care, medical attendants’ close to home and expert execution and additionally to enhance the responsibility for training, and documentation of the cost-adequacy of nursing care. So, the nursing research acts to give a base to confirm base practice by approve and refine existing information (science) and growing new learning that is connected to nursing practice. What’s more, when you are connected the nursing research finding in nursing practice prompt abatement expenses of medicinal services, expands individual profitability, long more advantageous lives for patients, and lessening torment and enduring of patients. The act of nursing care needs particular information and clinical aptitudes to take care of real or potential issues that influence wellbeing of people. Therefore, the enthusiasm for nursing research is considered as a need for medical attendants instructors and school of nursing, in light of the fact that the utilization of research is of extraordinary significance to the up and coming age of nursing staff in aptitudes, for example, leading examination, settling on free clinical choices perusing logical articles, and critical thinking approaches. Baccalaureate programs get ready understudies for section level nursing positions. The center is to nurture all people through the human life expectancy. Information is procured from course books, classroom and Web-based direction, recreation,
and clinical encounters. The objective of all projects is for understudies to graduate as protected, section level experts, have gotten a balanced introduction to the nursing field. Understudies are presented to prove based nursing practice all through their educational programs; nonetheless, the apportioned time for nursing research is frequently constrained. Nursing research is significance of its incorporation amid undergrad guideline can’t be overemphasized. Just with introduction and experience students would be able to start to comprehend the idea and significance of nursing research. Hence, a basic research course wound up obligatory in most baccalaureate nursing programs the world over to build understudies’ interest in research and usage of research discoveries practically speaking. Working on nursing understudies, is tested to stay up with the latest via searching for recovering and scrutinizing research articles that apply to hone issues that are encountered in their clinical setting. Also, it is essential to outfit understudies with a solid establishment in research to enable them to assess inquire about judge explore discoveries for conceivable application to clinical settings and to take an interest in investigate ponders. Undergraduate research project program aims to facilitate quality undergraduate research between students and mentors and to bring students into a community of scholars within their field. They urge medical caretakers to use and be effectively engaged with investigate. Undergraduate education positively affects understudies to gain an essential perspective about research and encourage them to undertake research. The initial step into compelling use of research, which makes incredible commitments to change of nursing, is preparing for look into amid undergrad training. The exploration course ought to be joined into all undergrad training projects and educational program. With the goal that undergrad medical attendants can turn into a compelling exploration per user and set research discoveries in motion, they ought to have the capacity to comprehend look into reports, reprimand them and comprehend phases of research. Among investigate exercises anticipated from nursing understudies are; perusing research articles fundamentally, gathering and announcing solid and legitimate information, going to nursing meetings, utilizing library assets, and plan theoretical or paper introduction. A nursing research course is viable in expanding learning about strides of research and getting the capacity to assess after effects of research and in addition having a positive attitude towards research. Students’ attitudes are connected with their inclusion in inquire about as future nurses. Positive students’ attitudes toward research encourages students to contribute in research, and increases effective application of research findings as well as, improving healthcare outcomes.

**Methodology**

A pre-experimental design (One-group Pretest-Posttest design) was conducted on nursing students’ attitudes toward research in nursing college. During the period from October 25th 2017 to April 15th, 2018 a non-probability (purposive) sample of (62) nursing students in nursing college was participated in the research project course which are selected after taking their consent. All of the students in the fourth undergraduate academic year 2017-2018, were invited to participate in this study. The aims of the study was clarified before achievement the participants’ consents. Only 62 students were participated and returned the questionnaires. All subjects participated in the research project course at the same time, place, and environment; All participants nursing students exposed to posttest assessment of attitudes regarding research after the implementation of the research project in order to detect the effect of the research project. The tool of this study was adapted from a study by Larson (1989), Halabi and Hamdan (2010) and Halabi, (2016). Several statements of this questionnaire were modified and developed to increase the validity of this instrument and to be more appropriate for achieving the aims of the present study. After reviewing the related literatures and relevant studies, and prior to implementation of the research project, the researchers constructed the attitudes test questionnaire to assess the nursing students attitudes respondents pre and post the implementation of the research project, in order to identify the difference in attitudes of the respondents toward research. The study instrument consisted of (2) parts as the following: Demographic data (which include nursing students’ gender, age, marital status, and residence) and nursing students’ attitudes which is comprised of (22 items): section one is related to usefulness of research (4 items), section two is related personal interest in research (4 items), section three is related to research abilities (7 items), and section four
is related to using research in clinical practice (7 items). Likert Scale was used to assess the level of student’s attitude towards research pre/post research project. It was adopted from Likert Scale (2006) and modified by the researchers according to the aims of the study. The overall number of the items included in the nursing students’ attitudes were measured in a three levels scale; Agree, uncertain and disagree, and rated as 3, 2, and 1, respectively with a cut-off point=2. Assessment of nursing students’ attitudes was based on: Mean score for attitudes items equal to 2 or more is considered as a positive. While Mean score for attitudes items below (2) is considered as an negative. The researchers calculated the score percentages of attitudes response for each nursing student in the two related period of the course, and then calculated the difference between the posttest and pretest for each study sample to achieve the attitudes improvement effect for each nursing student.

**Data Analysis**

SPSS version 20 was used to analyze of the data. Statistical analysis was made using Chi-square and paired T-test, have been used to identify the significant change in attitudes before and after research project. The level of significance was set at \( P \leq 0.05 \).

**Ethical Considerations:** The study was approved by the research department of the participating college of nursing. Students were assured anonymity and confidentiality as well as the right to refuse participation and to withdraw from the study without penalty.

**Results and Discussion**

Table 1 reveals that the majority ((n=46) 74.2%) of nursing students participant in study sample were (20-22) years old with mean age of the all students was 22.27 (20-41) years. 82.3% (51) of total students were female and 17.7% (n=11) were male. Regarding to the nursing students marital status, the majority ((n=51) 82.3%) of the subjects were single. Also, this table shows most of sample ((n=50) 80.6%) of the residents were urban. Results related to attitude respondents regarding to research project, were presented in this table, indicate that the mean of score of the attitude respondents in posttest of the research project course was higher than the pretest of the research project course in all aspects of attitude regarding research project course (positive attitude respondents in comparison between pretest and posttest of the research project course). This table also indicates that a significant difference between pretest and posttest of the attitude of respondents at p-value (0.001). The study results reveal that there is a high significant difference between the nursing students’ attitude responses in the two tests (pretest and posttest) of research project course. Table 4 shows that there is no significant difference between the nursing students’ demographic variables and attitude responses in the posttest of research project course. Nursing research is fundamental to the practice of nursing staff, and the significance of its incorporation during undergraduate direction can’t be overemphasized. Just with presentation what’s more experience nursing students can be able to start to comprehend the concept and significance of nursing research. After the analysis of demographic characteristics as shown in table (Table 1) it was revealed that the majority of subjects (74.2 %) were at age 20-22 years old with mean age of the all students was 22.27. Regarding to the nursing students gender the findings indicate that slightly more than three quarters (82.3%) of the students (82.3%) were females and the other (17.7%) were males. According to marital status of nursing students, the study results reveal that more than half (51%) of samples were single and 49% were married. Concerning resident place, the study findings indicate that more than three quarters (80.6%) of the sample were urban. This finding is consistent with Erkin et al. (2017) who revealed that the mean age of the nursing students was 20.72 years . 86.3 % of nursing students were females and 13.7% were males (17).While, other study which was done by Hasan (2016) , to assess students’ attitudes towards research at mazandaran university of medical sciences shows that approximately half (61%) of students were females and (39%) were males, this result was inconsistent with the findings of the present study. After participating the nursing students in the graduation research project course the results of analysis indicate a significant improvement in nursing students’ positive attitudes regarding research in comparison with the two periods (pretest and posttest), when the results of current study revealed that the nursing students’ attitudes about research; Usefulness of research in pretest 11.145 while in posttest 11.467 ; Personal interest in research is pretest 10.129 while in posttest 10.612; Research abilities in pretest 14.919 while in posttest 16.871; and
Using research in clinical practice in pretest 13.919 while in posttest 17.112.

**Conclusion**

According to the findings of this study, the nursing students’ attitudes toward research were increasing significantly after exposing to the research project course and the demographic variables (gender, age, marital status and resident) of the nursing students had no significant effect on their attitudes toward research.

**Financial Disclosure:** There is no financial disclosure.

**Conflict of Interest:** None to declare.

**Ethical Clearance:** All experimental protocols were approved under the Community Health Nursing Department / College of Nursing/ University of Kerbala, Iraq and all experiments were carried out in accordance with approved guidelines.

The Effectiveness of Mobile Application as an Alternative of Health Education Media for Adolescents in the Middle School

Noordiati1, Erina Eka Hatini1, Greiny Arisani1
1Lecturer on Department of Midwifery, Polytechnic of Health, Ministry of Health, Palangka Raya, Indonesia

Abstract

Adolescent health problems are still becoming major issues in health issues such as smoking behavior, drugs, and free sex. Improving health school age and adolescent is prioritized in promotive and preventive efforts. One of them is done through the school health effort. The purpose of this study was to determine the effectiveness of mobile applications as a health education media for adolescents in secondary schools towards adolescent knowledge and attitudes about health, compared to printed media. This type of research is quasi experimental research with a two group comparison pretest-posttest design. There were significant mean differences in knowledge, attitudes and skills before and after getting an intervention using the mobile application media (p = 0.000). There were significant mean differences in knowledge, attitudes and skills before and after getting an intervention using the My Health Report Card (p = 0.000). There was a significant mean difference in knowledge, where the mean score of knowledge was higher in the group using the mobile application media compared to using the My Health Report Card (p = 0.000). There are no differences in the attitudes and attitudes of groups who use the mobile application media and who use the My Health Report Card.

Keywords: mobile application, adolescent, health school

Introduction

Based on the results of the 2015 School-Based Health Survey in Indonesia, it can be seen health risk factors for students aged 12-18 years (junior and senior high) nationally. As many as 41.8% of men and 4.1% of women claimed to have smoked, 32.82% of those who smoked for the first time at the age of ≤ 13 years. The same data also shows 14.4% of men and 5.6% of women have consumed alcohol, then also found 2.6% of men have ever consumed drugs. Another illustration of health risk factors is sexual behavior in which 8.26% of male students and 4.17% of female students aged 12-18 years have had sexual relations. Premarital sexual behavior certainly has a broad impact on adolescents, especially related to the transmission of infectious diseases and unwanted pregnancy and abortion. 1

Seeing the existing problems, improving school-age and adolescent health is prioritized on promotive and preventive efforts. One of them is done through the health school effort which aims to improve the ability to live healthy and student learning achievements so that healthy and quality human resources can be produced. One of the efforts to improve the health of students through the health school program, since 2013 my Health Report Card has been developed for students. In 2015 the book received support and approval from the Minister of Education and Culture to be implemented in schools. My Health Report Card consisted of 2 types of books namely Information Books and Health Record Books, Information Books containing health knowledge about clean and healthy living behavior, dental and oral health, balanced nutrition, eye health, ear health, prevention of infectious and non-communicable diseases, reproductive health, prevention of violence, mental health, accident prevention. Whereas the Health Record Book contains a sheet recording the results of health services: health screening and periodic examinations, giving blood-added tablets, administering
worm medicine, health checks at health facilities.  

The results of a preliminary study conducted in the City of Palangka Raya, obtained information that not all junior high schools and senior high schools received the books, although there were those who received but the number was very small and did not reach all students. Data collected from health school program in several Palangka Raya Community Health Centers states that the number of books received from the Palangka Raya City Health Office is very limited, so that only a few books are distributed to each school and it is recommended to increase their respective schools. The existence of different schools certainly led to different decision-making processes, only a few schools were willing to reproduce the book, and the rest said they could not because of the limited availability of funds.

Currently advances in information technology play a very effective role in helping the health system and allows removing time and place barriers to providing high quality services. In the last few years significant growth has been observed in cell phone use. This portable device provides the impact of fast access to information and easy communication between individuals.

Based on the above, researchers intend to make alternative media other than printed books to expand the reach of the utilization of Information Books and Health Records through a mobile application that can be accessed by students, teachers and parents, so that they can support government programs in improving adolescent health. To find out the effectiveness of mobile applications as a medium for health education for adolescents in secondary schools towards adolescent knowledge and attitudes about health, compared to printed text media.

### Materials and Method

This type of research is a quasi-experimental research, with a two-group comparison pretest-posttest design, the approach used is quantitative. The study was conducted at senior high schools in the Menteng Sub-District, namely ISIE Vocational School and Karsa Mulya Vocational School.

The population in this study are all high school or equivalent students in the Langkai Village and Panarung Village which are the work areas of the Panarung Community Health Center. The sample in this study were students who met the inclusion criteria, namely Grade X High School students or equivalent, for intervention groups using mobile application students had an android mobile phone, got permission from their parents or guardians, were willing to attend an explanation meeting using printed books and mobile application. Exclusion criteria are students do not follow the meeting and explanation of the use of a printed book mobile application, students are exposed to the information book/book notes into health and not follow the post-test.

The method of taking samples in this study is by consecutive sampling. The independent variable, which is the variable that influences or is the cause of change, is the Mobile application media and the Health Information Book for high school students. Dependent variable, is a variable that is affected or that is due to the presence of independent variables, namely knowledge, attitudes and skills of high school students about health (clean and health behavior, oral health, balanced nutrition, eye health, ear health, prevention of infectious diseases, reproductive health, prevention of violence, mental health and accident prevention).

Differences in changes in the mean score of knowledge, attitudes and skills in each of the mobile application and My Health Report Card groups

Based on the results of the analysis, it was found that there were significant mean differences in knowledge before and after getting health education in groups using the mobile application and My Health Report Card, with the difference in mean scores higher in the groups using the Health Application My Health Report Card. In conducting research, each group has obtained the same health information about adolescent health through different media.

My Health Report Card for junior high or high school students is equivalent to a book that contains health information about puberty, balanced nutrition, reproductive health, STI and HIV/AIDS, drugs, mental health and myths. This book has been developed since 2013. In 2015 received support from the Ministry of Education and Culture to be applied in schools. Students are asked to read the My Health Report Card, communicate with parents and as a media for health education to peers.

Nowadays information technology is developing more rapidly, many people are helped by various facilities produced by the advancement of technology. One technology that is developing is an Android-based smartphone (smartphone), because it is considered to provide convenience and benefits for its users, many practitioners and academics who develop the application. Technology development may to help health workers role in the socialization of MCH Handbook, Pre Scrinning Child Development Questionnaire and monitoring the nutritional status of children.

Most mobile phone users are teenagers, so it becomes an opportunity in the health sector to use mobile phones as a medium in them his health information and services. The development of technology is very possible to be used to help in the dissemination of information and socialization of several health programs. In this study the application that was made and used as a health education media in the form of the My Health Report Card had an impact on meaningful knowledge enhancement for high school students.

The results of this study are in line with the results of Pratiwi and Restanty’s (2018) research on the application of android-based applications to mother’s knowledge in monitoring the nutritional status of children. The results showed that there were significant differences in the knowledge of mothers before and after applying an android-based application “nutritional status of children”.

The attitudes and skills of adolescents in this study indicate that there is an equally increase in the average score of attitudes and skills in groups using the mobile application and My Health Report Card, with differences in mean scores higher in groups using the
Some research abroad related to improving attitudes and skills in health through application was shown by Denghani et.al. (2019) regarding the prevention of high-risk sexual behavior using a mobile application shows an increase in students’ attitudes compared to previous risky sexual behavior, so the use of a mobile application plays a role in preventing high-risk sexual behavior and can increase sexual attitudes in students. The results of this study are in line with the results of research conducted by Bull (2012) who conducted research on sexual health interventions through social media to send sexual health messages through the Facebook network to reduce STIs, the results show that social networks are effective for health interventions.

**Differences in changes in the mean score of knowledge, attitudes and skills between the Mobile Application My Health Report Card and the My Health Report Card.**

The difference in knowledge scores in the pre-test and post-test results for the two groups showed a significant difference with the increase in knowledge in the mobile application group was higher than those using the My Health Report Card. From the results of this analysis it can be concluded that the mobile application is more effective towards increasing knowledge.

Research conducted by Novaeni et.al (2018) shows that 85% of adolescents said that very good about android-based adolescent health applications, can increase understanding of reproductive health, interesting, easy to remember and understand material, add motivation and in accordance with adolescent needs.

The results of other studies that show the same results as this study are studies conducted by Novianto, Suryoputro and Widjanarko (2019) about the influence of the application of “Smart Mobile Teenagers” on the knowledge, attitudes and self-efficacy of adolescents about the prevention of prediabetes, showing a significant influence on the improvement knowledge, attitude and self-efficacy in the prevention of prediabetes. Clever Teen Mobile Application can be an alternative in the use of health promotion media as a means of communication of educational information in adolescents in the prevention of prediabetes.

**Conclusion**

There are significant mean differences in knowledge, attitudes and skills before and after getting an intervention using the mobile application media. There are significant mean differences in knowledge, attitudes and skills before and after getting an intervention using the My Health Report Card. There is a significant mean difference in knowledge, where the average score of knowledge is higher in groups using the mobile application media than those using the My Health Report Card. There are no differences in the attitudes and attitudes of groups who use the mobile application media and who use the My Health Report Card.

Detect of Phylogenetic Relationships by RAPD_PCR among *Staphylococcus aureus* Isolated from Different Sources in Hilla City

Amal Raqib Shamran¹, Zainab A.Tolaifeh¹

¹University of Babylon /Collage Of Science For Women, Iraq

**Abstract**

*Staphylococcus aureus* (brilliant staphylococcus) is a Gram-positive, cocci–shape, it is an individual from the typical verdure of the body, oftentimes found in the nose, respiratory tract, and on the skin. Usually positive for catalase and nitrate decrease. We can portrayed *S. aureus* strains that are across the board in hospitals in Hilla city.60 clinical and condition tests were gathered from numerous parts of patients like injuries, skin, nails and urinary tract disease taken from general doctor’s facilities of Hilla city. Strategies for segregation and distinguishing *S. aureus* dependent on culture strategies with biochemical tests, A sum of 17 enhanced DNA sections from 250 to 1K base match) were watched utilizing the 2 ground works, and every one of preliminary that fruitful giving intensification groups uncovered distinctive hereditary example. End: RAPD-Polymerase Chain Reaction investigation it used to discover an incentive in structuring an assortment of sub-atomic DNA unique finger impression dependent on epidemiological examinations that centers around the recognizable proof and portrayal of *S. aureus*.

**Key words:** Phylogenetic, RAPD_PCR, Staphylococcus aureus

**Introduction**

*Staphylococcus aureus* is an opportunistic pathogen that causes a nosocomial infections ranging from self-limiting to lifethreatening in both developing and developed countries. It is critical in the study of disease transmission and nature to have the capacity to distinguish bacterial species and strains precisely. Fast distinguishing proof and order of microscopic organisms is ordinarily completed by morphology, healthful prerequisites, anti-microbial obstruction, isoenzyme examinations, phage affectability. Meanwhile, a few strains of *S. aureus* have mecA quality which presents protection from methicillin and the greater part of the regularly utilized antimicrobial operators including β-lactams and cephalosporins. These strains are called methicillin-safe Staphylococcus aureus (MRSA) and they thought to be more destructive than methicillin-powerless Staphylococcus aureus (MSSA) strains. The expanding rates of nosocomial and network related MRSA diseases and their capacity to exchange between people, ox-like, and nourishment of creature birthplaces have turned into a worldwide hazard. Recognition and distinguishing proof techniques utilizing the PCR to enhance DNA have been utilized for different creatures, yet these require sequence information for particular preliminaries. In any case, PCR utilizing discretionary groundworks (AP-PCR) requiring no earlier arrangement data has uncovered DNA polymorphisms that might be valuable for fingerprint (Welsh and McClelland, 1990; Williams et al., 1990). Haphazardly Amplified Polymorphic DNA (RAPD), a straightforward PCR based procedure, has been broadly utilized for epidemiological examination. In addition, RAPD preliminaries can successfully examines the entire chromosomal DNA for the nearness of little reversed rehashes and intensifies the interceding DNA portions of variable length that can be utilized for distinguishing hereditary variety and setting up strain-particular fingerprints. Likewise the test can be performed with low convergence of DNA utilizing short

**Corresponding author:** Amal Raqib Shamran.
University of Babylon /collage of science for women, Iraq.
engineered oligonucleotide groundworks long.

**Methodology**

**Sampling**

Sixty samples were collected from clinical and environmental cases. Samples were taken from out and inpatients who admitted to AL-Hilla General Teaching Hospital and Babylon Hospital for Maternity and Pediatric Hospital. Between October 2016 and May 2017.

**Bacterial Isolation**

Around 250 ml S. aureus detach was enraptured into a 100 ml of supplement soup (pH seven.5) and command underneath consistent shaking at thirty seven C for twenty-four h. The microorganism cell was expelled o by action, washed with zero.1mM Tris EDTA and unbroken at - 20oC for DNA extraction.

**Genotypic identification**

**DNA Extraction**

DNA of *staphylocus aureus* isolates was extracted and purified using Extraction and purification Kit from Geneaid company (UK).

**Primers**

Two arbitrary or random primers (OPB-10, OPX-01) obtained from Bioneer, IDTDNA (USA). Bacterial isolates were tested for single primers for RAPD-PCR technique (table 1).

**RAPD-PCR amplification**

Final product of 30μl reaction volumes containing ten ul of single primer, 12.5 ul of inexperienced Master combine, .5 ul of Genomic DNA and therefore the volume of reaction was completed up to thirty ul by adding a pair of.5 ul of enzyme free water Amplification was applied during a thermo-cycler (Eppendorf) programmed for 2 minutes at 94°C; for 45cycles one minute at 94°C, one minute at 35°C and 2 minutes at 72°C; and a final extension of 5 minutes at 72°C. Amplification product were electrophoresed in one.8% agarose gels so pictured by staining with ethidium bromide. commonplace molecular markers were conjointly enclosed in every action run. Ultraviolet trans-illuminated gels were photographed.

**Phylogenetic Analysis:**

Positions of unequivocally scorable RAPD bands were transformed into a binary characters matrix (‘1’ for the presence and ‘0’ for the absence of a band at a particular position). Phylogenetic tree was created by the unweighted pair-group method arithmetic (UPGMA) average cluster analysis.

**Results and Discussion**

**RAPD analysis of staphylococcus aureus**

Polymorphism assay for *staphylocous aureus* isolates was carried out using two primers. Random amplification of the DNA of *S. areus* isolates reveals the efficacy of these selected nucleotides sequences in determination the similarity or variations among all isolates.

*S. aureus* isolates by RAPD:

A total of 9 amplified DNA fragments ranging in size from 250 to 1 Kpb were observed using two random amplified polymorphic DNA (RAPD) primers (opX-10, opB-01) where as17 polymorphic amplified fragments were commonly detected among the 9 *S. aureus* isolates (table 1) and each of primer give different genetic profiles. UPGMA analysis for the dendrogram made based on the RAPD data generated by primer OPX-10 were performed and shown in figure 3. Analysis showed that the 9 s. aureus strains were grouped into two and clustered into three classes. The large cluster comprised the Stap4, Stap5, Stap9, Stap7, and Stap8; a second cluster included strains of the S2, S8 and S9; and the third remaining clusters corresponded to the Stap1, Stap3, Stap2 and Stap6. While primer OPX-01 were performed and shown in figure 4. Analysis showed that the 9 *S. aureus* strains were grouped into two and clustered into three classes also. Genetic fingerprint and process diversity between Staphyllococcus aureus isolates were determined by ever-changing RAPD data into a Jaccard similarity analysed by UPGMA to produce a organic process tree. The compound band pattern obtained is equivalent to a Universal Product Code, allowing the identification of each individual. as Associate in Nursing example, isolate Sa1 presents distinctive bands once its compound amplified with most of the primers tested
It’s well documented that RAPD-PCR is one of the most widely used method to investigate the genetic variability of any given nosocomial pathogen, moreover in RAPD the power of designated and discriminatory primers can be been easily assessed. Phenotypes consist of isolates that less related and such identification isolates using cultural and morphological techniques often lack consistency and precision. In the current examination, we have discovered that distinguishing proof of hereditary assorted variety in S. aureus relies upon wellsprings of segregates, diverse host cells and event of freaks. RAPD markers uncovered conceivable association between host start line, amendment and hereditary selection among S. aureus separates, and this shown its process and symptomatic potential. Clearly, for these deoxyribonucleic acid teams examples to possess a helpful significance within the zones of prescription, people science and also the study of illness transmission, explicit deoxyribonucleic acid teams should be known with host beginning points, transformation and quality qualities. Rapd-pcr is important to possess fast and solid epidemiologic composing method to screen the bury or intra-spread of multidrug safe MRSA strains. this might be practiced by a organized correlation of deoxyribonucleic acid band styles among microorganisms differentiating for the varied host birthplaces, transformation and quality qualities gift. Comparative methodology has been utilised to separate forceful from non-forceful disengages of the seed assault microorganism Phoma symbol. The DNA mark characterized for each race of S. aureus ought to be valuable for epidemiological reviews, medicinal analyses, and in the distinguishing proof of new destructive strains and detaches and their birthplace.

Figure 1. RAPD –PCR using the primer OPX-10. {M Line (ladder) , the isolates numbered (1,2,3,4,5,6,7,8,9) were positive for OPX10 primer}
Figure 2. RAPD–PCR using the primer OPX-01 (M Line (ladder), the isolates numbered 1, 2, 4, 6, 8, 9) were positive for OPX-01 primer, while 3, 5, 7 were negative.

Conclusion

Strategies for segregation and distinguishing *S. aureus* dependent on culture strategies with biochemical tests, A sum of 17 enhanced DNA sections from 25s0 to 1K base match) were watched utilizing the 2 ground works, and every one of preliminary that fruitful giving intensification groups uncovered distinctive hereditary example . End: RAPD-Polymerase Chain Reaction investigation it used to discover an incentive in structuring an assortment of sub-atomic DNA unique finger impression dependent on epidemiological examinations that centers around the recognizable proof and portrayal of *S. aureus*.

Blood pressure, Blood Sugar, Smokers and their Relationship with Physiological Variables of Some Risk Factors

Nada Saad Naji Al-Taee

Department of Environmental pollution, Faculty of Environmental Sciences, AL-Qasium green University, Iraq

Abstract

This study deals with the physiological measurements of fasting blood sugar (FBG), clinical blood pressure (CBP) and smokers and their association with risk factors (obesity, gender and age) among university students. A total of 257 students (77 females and 180 males) were registered. Including 41 healthy and 42 students who were FBG; 33 were healthy and 69 were suffering from CBP; 39 non smokers and 33 students who were smokers; aged 19-26 years. A statistically not-significant connection was found between FBG, CBP and smoking with obesity rates; but a significant difference between smoking and CBP with age and gender, respectively. These findings highlight the prevalence of FBG and CBP also smoking in students and its relation to certain risk factors such as obesity, sex and age among selected student groups.

Keywords: blood glucose, blood pressure, smoking, risk factors.

Introduction

It is important to prove now that many factors such as obesity, sex and age are linked to BG, BP and smoking. The obesity is a hazard factor to many diseases, as diabetes and hypertension\(^1\). In 2030, around 438 million people worldwide (7.8%) in adult population are suffering from diabetes. This global rise in the propagation of diabetes is attributed to urbanization, population growth, aging and obesity\(^2\). According to\(^3\) there is a significant impact of diabetes with gender, and women are more probability to develop diabetes than men. A study in Iraq found that the diabetes prevalence was 15.2% in female compared with 11.8% in males\(^4\). Despite the increasing burden of obesity and HBP in growing countries, there was limited information about BMI contribution in BP in these populations, especially among students. BMI is independently and positively connected with mortality and morbidity due to HBP, cardiovascular disease CVD and diabetes II\(^5\). For all BMI categories in study\(^6\), age was higher with HBP and HBP in men than in women. The systolic-BP and diastolic-BP increased with age, both for men and women\(^7\). Smoking is one of the leading causes of death as well as the main challenge to public health all over the world\(^8\). Smoking is connected with low weight\(^9\). Lack of smoking propagation has been proposed as one of the agents connected with a high in obesity\(^10\). There may be a causal impact of smoking on weight because nicotine is a metabolic stimulant as well as appetite suppressant\(^11\). The difference in CVD risk among smokers and non-smokers is significant in middle age, particularly for men\(^12\).

Materials and Method

Criteria of participants

A sample of 257 students was selected randomly among students. About 83 participants of FBG with mean(X)±standard deviation (SD) of age were divided to: health (<100 mg/100cm\(^3\); 21.97±1.49), pre-diabetes (100-125 mg/100cm\(^3\); 21.83±1.59), diabetes (≥126 mg/100cm\(^3\); 21.77±1.09), and hypoglycemia (≤70 mg/100cm\(^3\); 21.66±2.30). In addition, 102 participants of a CBP-level with X±SD of age, systolic blood pressure (mmHg), diastolic blood pressure (mmHg) and pulse pressure (Min) were divided as: normotensive (<120/<80; 21.38±1.706, 110.87±5.129, 72.16±6.126, 86.29±11.07), EPB, elevated blood pressure (120-129/<80 mmHg; 21.96±2.007, 124.78±2.848, 75.71±4.767, 86.40±11.09), hypertension (130-139/80-89 or ≥140/90 mmHg; 22.00±1.647, 144.68±10.90, 90.41±6.873, 84.82±9.26), and hypotension (<90/60 mmHg; 20.28±1.603, 84.57±6.160, 56.57±3.101, 84.28±8.76). In addition, only 72 men were employed
for smoking and the periods of cigarette smoking of 2-3 year with X±SD of age were divided into 39 non-smokers (control; 22.25±1.91), 9 light-Smokers (≤10 cigarette daily; 22.11±1.96), 16 moderate-smokers (11-20 cigarette daily; 22.06±1.80), and 8 heavy-smokers (≥20 cigarette daily; 22.25±1.90).

Collection of data and measurement

The data were gathered utilizing a self-administered questionnaire. It is built on several axes such as: age, smoking case, duration of smoking, the number of cigarettes smoked per day, the family history of diabetes and physical activities. The criteria for selecting students were that no one should suffer any medical complication such as heart disease, stroke or any other disorder. BG was measured in the morning after fasting for at least 8-10 hours, using the active glucose Accu-chek meter. BP was measured by the electronic pressure device by taking the pressure rate while students rested for at least 10-15 minutes.

Measurement of obesity.

The obesity was estimated using body mass (BMI) index, measured by weight in kilograms (kg) divided by a height in the meters squared [kg/m²]; BMI classification was based on WHO as: normal weight, 18.5-24.9; underweight, less than 18.5; and overweight 25-29.9. The waist circumference, (WC), is measured by placing the measurement meter tightly on the waist (cm) and the WC/risk level are classified as follows: Low (Women <80 and Men <90), high (Women 80-88 and men 94-102), and very high>102 for smokers men.

Statistical analysis

The descriptive analysis was also used to show the X±SD of the results. Gender, age and obesity were statistically tested by Chi-square (c²) test at p<0.05.

Results and Discussion

Fasting blood glucose and obesity, sex and age

In Table 1: A statistically insignificant in BMI with BMI c²= 5.652 among smoking status. A statistically not-significant in CW risk level of smokers compared to non-smokers. And a significant in age in which the high percentage was appeared at age (21-22) years of light-smokers followed by low percentage appeared at age (23-24) years of moderate-smoker compared to non-smokers. In addition to high percentage that noted at age (21-22) years in light-smokers, moderate-smokers, and heavy-smokers compared to control, and heavy-smokers has been shown in age 25-26 years compared with non-smokers of a same age. Obesity is connected with poorer control of BP-levels and BG-levels making people with diabetes more susceptible to micro-vascular and cardiovascular diseases. Other studies have shown a strong epidemiological link between the development of diabetes and obesity. When the study trends were studied by BMI groups, disease increased only among those who have obese (18.0% to 20.1%), indicating that much of the rise in the prevalence of diabetes is due to the growing prevalence of obesity, and diabetes was less

Clinical blood pressure level and obesity, gender and age

In Table 2: No-significant relationship between the level of CBP and obesity measured by BMI and WC, although the highest rate of EBP and hypertension was overweight and obese compared to normotensive, respectively. Hypertension and EBP are the highest in low and high of WC risk level compared with normotensive, respectively. The male had a high percentage of hypertension (82.76) and a high percentage of hypotension (85.71) in female compared with normotensive. EBP and hypertension appeared 21-22 and 23-24 years of age, compared to normotensive, respectively.

Smoking status with obesity (BMI and WC) and age.

In Table 3: A statistically not-significant in obesity with BMI c²= 5.652 among smoking status. A statistically not-significant in CW risk level of smokers compared to non-smokers. And a significant in age in which the high percentage was appeared at age (21-22) years of light-smokers followed by low percentage appeared at age (23-24) years of moderate-smoker compared to non-smokers. In addition to high percentage that noted at age (21-22) years in light-smokers, moderate-smokers, and heavy-smokers compared to control, and heavy-smokers has been shown in age 25-26 years compared with non-smokers of a same age. Obesity is connected with poorer control of BP-levels and BG-levels making people with diabetes more susceptible to micro-vascular and cardiovascular diseases. Other studies have shown a strong epidemiological link between the development of diabetes and obesity. When the study trends were studied by BMI groups, disease increased only among those who have obese (18.0% to 20.1%), indicating that much of the rise in the prevalence of diabetes is due to the growing prevalence of obesity, and diabetes was less
prevalent in males than in females in Iraq community\textsuperscript{17}. In Turkey, there was a statistically non-significant relation between BP and sex\textsuperscript{18}. Although this study was statistically insignificant in age with FBG, the results were favorable with\textsuperscript{19} the prevalence of disease and hazard factors among people aged 15 Years and older in Ethiopia. A significant connection was also found\textsuperscript{20} on college students between age, overweight, and sex, as well as between BG elevation with gender. Many people own a classification of BP without knowing it. The results of the current study were consistent with\textsuperscript{21}, where a positive relationship was absorbed between obesity and hypertension, also\textsuperscript{22} which observed a positive connection between hypertension and BMI. The current study shows that male students had a high percentage of hypertension compared with a healthy and female students, and is close to\textsuperscript{23}. It is also appropriate with\textsuperscript{24} that there is a positive connection with BP and increasing age.

The low prevalence of smoking has little impact, often less than 1%, on increasing the prevalence of obesity and reducing the healthy weight of the population\textsuperscript{25}. The BMI of smokers appeared a diminishing trend compared with nonsmokers\textsuperscript{26}. No-significant variation in the physical mean parameters such as obesity are found when calculating X±SD in smokers and passive-smoker\textsuperscript{27}; but my results do not identical the results of\textsuperscript{28}, it was observed that both cigarette consumption and smoking frequency had positive effects with weight loss in adolescents. There has been a significant elevate over the past decade in the numbers of smokers of college age\textsuperscript{29}. Various studies have reported that the spread of smoking raises between the first to last year among college students, confirming the fact that the early years of the university are important to target anti-smoking activities\textsuperscript{30}. The University of Karbala, smokers (45.7%) smoked before the age of 18 years, and were positively correlated with male sex and growing age\textsuperscript{31}.

**Conclusion**

There was insignificant association between obesity and cases, but significant differences between age and sex with smoking rate and CBP level among students.

The Relationship of Self-Motivation in Diabetes Mellitus Management with Blood Sugar Levels of Diabetes Mellitus Type II Clients

Berthiana T 1, Noordiati 1

1 Lecturer on Department of Nursing, Polytechnic of Health, Ministry of Health, Palangka Raya Indonesia

Abstract

The purpose of this study was to determine the relationship of self-motivation to diabetes mellitus (DM) management with blood sugar levels of DM type ii clients in Outpatient Polyclinic Installation in Dr. Doris Sylvanus Hospital Palangka Raya. The research uses descriptive correlational with cross sectional research design. The sampling technique uses purposive sampling. The respondents of this study were 40 people. Data collection using a questionnaire and recording the value of blood sugar from the results of laboratory tests in the client report status. Statistical tests use the Chi-Square test. The results of statistical analysis revealed that self-motivation on clients was in the unfavorable category of 32 people (80%), blood sugar levels were in the high category of 26 people (65%) with a p-value of 0.001 (p <0.05). There is a significant relationship between self-motivation to DM management with blood sugar levels of DM type II clients in the Outpatient Polyclinic Installation of Dr. Doris Sylvanus Hospital Palangka Raya.

Keywords: self-motivation, blood sugar level, diabetes mellitus

Introduction

Diabetes mellitus is a group of metabolic diseases with characteristic hyperglycemia that occurs due to abnormal insulin secretion, insulin action or both.1

Based on a preliminary study in the medical record section of Dr. Doris Sylvanus Hospital Palangka Raya which was conducted on January 24, 2018, obtained data on the number of patients with Type II DM in 2016 the number of DM cases was 4111 cases with an average monthly of 343 cases and increased to 4942 cases in 2017 with an average monthly to 412 cases. The increase in cases of Type II DM is accompanied by an increase in the occurrence of cases of Type II DM complications, based on the medical record of complications that often occur is hyperglycemia which is the forerunner to the growth of various other diseases to the point of death. If hyperglycemia in people with Type II diabetes can be controlled properly, then all these chronic complications can be prevented, at least inhibited.1

The goal of diabetes mellitus management for the short term is to eliminate complaints/symptoms and maintain a sense of comfort and health, while in the long run to prevent complications, both macroangiopathy and neuropathy with the ultimate goal of reducing diabetes morbidity and mortality.

Management of diabetes mellitus with 5 main pillars, namely first, meal planning by making dietary arrangements based on the nutritional status of diabetes. Second, physical exercise so that muscle contraction when doing physical exercise will make the membrane permeability to glucose increase. Third, pharmacological therapy. Fourth, counseling. The fifth routine and independent monitoring of blood sugar with sugar control can reduce the number of complications in patients with diabetes mellitus

DM management problems that often occur in Dr. Doris Sylvanus Hospital Palangka Raya based on the results of a survey on January 24, 2018 in people with
DM is the lack of self-motivation related to carrying out the four pillars of DM. One of the factors that influence a person’s behavior in improving and maintaining their health is motivation, including in managing DM regularly as an effort to prevent complications in diabetes mellitus patients. One of the DM management is regular blood sugar control, which is one of the treatments for diabetes mellitus patients to support stable blood sugar and prevent complications, therefore there is a need for self-motivation in carrying out the examination and management of diabetes mellitus.

**Materials and Method**

This type of research is quantitative in the form of descriptive correlation which is research that aims to reveal the correlative relationship between the independent variables and the dependent variable, with the cross-sectional approach which is a study to study the dynamics of the correlation between factors and risks with effects by approaching, observing or collecting data at once in one when.

The population in this study is type II diabetes mellitus clients who seek treatment at the Internal Medicine Outpatient Clinic of Dr. Doris Sylvanus Hospital Palangka Raya. The sample used in this study with a sampling technique using purposive sampling with a total sampling of 40 respondents. This research was conducted on April 20-May 12, 2018. The time was used to collect data through a questionnaire that was filled in completely and returned to the researcher.

**Findings and Discussion**

Chi-square correlation test results obtained p-value of 0.001 \((p < 0.005)\). The results showed that only 8 people (20%) were good in self-motivation and had blood sugar levels in the normal range of 7 people (87.5%) while respondents in the good self-motivation category with high blood sugar levels were 1 person (12.5%). While the remaining 32 people (80%) with poor self-motivation category, where most of the blood sugar levels in the high category are as many as 25 people (78.1%) and as many as 7 respondents (21.9%) with self-motivation not good to have a value of blood sugar levels within normal limits. The results of the analysis of the motivational questionnaire items found that the highest score on statement number 6 is the statement “I am happy if my blood sugar is in the normal range” with a score of 138 with 19 answer choices answered “agree” and 21 respondents answered “strongly agree”. This means that the majority of respondents actually feel happy and want their sugar levels within the normal range. While the analysis of motivation questionnaire items with the lowest score on statement number 2 is the statement “I am challenged to undergo treatment” with a score of 99. It shows that most respondents feel less challenged in undergoing treatment so that is one of the factors that can affect client motivation.

Odds Ratio (OR) value is 25.00, that is \(OR > 1\), this shows that a person with DM with low self-motivation has a 25.00-fold risk of having uncontrolled blood sugar levels, the lowest has a risk of 2,617 times and the greatest risk is 238,787 times that of having an uncontrolled blood sugar level compared to someone with good self-motivation. The results of this study indicate the less motivation of clients in managing DM the more uncontrolled or high blood sugar levels. From the results of the study the researchers concluded that the self-motivation of Type II DM clients in the Outpatient Clinic of the Internal Medicine Polyclinic of Dr. Doris Sylvanus Hospital Palangka Raya is in the unfavorable category. This is influenced by several factors such as age, gender, level of education, occupation, marital status, and length of time with DM.

The results showed that the majority of respondents were early elderly, aged between 46-55 years. As a person ages, changes in function and composition in the body can affect one’s ability to carry out activities including one’s motivation. The results showed that the majority of respondents who came to control the disease in poly disease in the female sex. Gender also influences a person’s motivation and behavior. This is because women tend to be more obedient to the rules than men.

Most of the respondents studied had a high school education level. The level of education is an indicator that someone has taken formal education in certain fields. The higher the level of education a person will usually have more knowledge including about health and the presence of this knowledge will affect someone to have awareness in maintaining their health.

People who work tend to have less time to visit health facilities so that there will be less time available and opportunities for treatment. Whereas in this study the results were obtained that the majority of respondents were housewives/not working which means that respondents had plenty of time to visit health facilities including managing DM.

The marital status of most respondents is married and has a spouse. This is one of the factors that can affect a person’s motivation, including respondents in managing DM, because respondents get support from their husband or wife. The length of time with DM is also one of the factors that influence a person’s willingness to manage DM. The longer a person with DM, the better the coping and self-efficacy of a person and the more experienced in managing the disease.

This study is in accordance with previous research conducted by Yesi Ariani (2011) about the Relationship between Motivation and Self-Efficacy of Type II DM Patients in the Context of Nursing Care at H. Adam Malik Hospital Medan, stated that with the results of 45 respondents had poor motivation in conducting self-efficacy. Motivation the majority of patients lack self-care so it is advisable for nurses and physicians to increase patient motivation in the context of DM by increasing patient autonomy intrinsically.

Social environment, family, and health workers influence in increasing motivation and changes in patient behavior. Someone who has the support of the family, and surrounding and support from health workers who are not pressing, controlling tight or authoritarian will increase motivation in checking blood sugar levels.
Conclusion

There is a significant relationship between self-motivation and blood sugar levels of DM Type II clients in the Outpatient Polyclinic Installation of Dr. Doris Sylvanus Hospital Palangka Raya.

Ethical Clearance: This research has gone ethical feasibility testing by the Ethical Research Commission of the Polytechnic of Health, Ministry of Health, Palangka Raya.

Abstract

Introduction: In South Sorong Districts in 2013 there were 47.6% cases of malnourished and underweight children under five; short and very short toddler cases (stunting) of 60.7%. In 2017 South Sorong Districts was one of the 100 districts that were the priority in handling stunting problems. Where the problem of stunting is chronic malnutrition in the period ranging from uterus to toddlers.

Purpose: this research aims to find the socio-cultural potential and local wisdom in overcoming nutritional problems in these children under five.

Method: this riset mix methods by looking for quantitative and qualitative data. Quantitative data with anthroprometry and qualitative data conduct in-depth interviews and village community consultations in finding solutions that are appropriate to the conditions of the community.

Result: It was found as many as 49.41% of malnutrition, while stunting was 54.1%. Natural potential in the form of food ingredients, fish, sea shrimp, chicken, sago and various vegetables already exists in the community. The community made an agreement in dealing with the nutritional problems of these children with child care, nutrition, nutrition and sanitation.

Conclusion: that in handling nutritional problems of children there is involvement of the community, traditional leaders, religious leaders, support from the village head and the support of the regional government in the form of special team formation and additional budgets on children under five nutrition programs

Keywords: malnutritions, children under five, local wisdom

Introduction

Preparing future generations who are resilient for the welfare of the Indonesian nation is common responsibility, and health care must be prioritized from pre-marriage phase, fetus to teenagers. Health problems are often specific local health problems related to local socio-culture that need to be explored in order to find out basic problems so that repairs can be made or empowered for a culture that has a positive impact on health. An understanding of the culture of the community related to health issues is very important to note as a determining factor towards the success of health programs aimed at improving the quality of life of individuals and communities. The description can be used by health workers for knowing, learning, and understanding what applies in the community¹,².

Specific local health problems related to the local socio-culture need to be explored in order to find out the basic problems so that it needs to be improved or empowered for a culture that has a positive impact on health. Thus a good wealth of Indonesian culture can continue to be developed, conserved and utilized locally even if possible nationally. Health programs can be designed to improve the nutritional status of children under five according to specific local problems. In this process the cultural approach is one of the important
and cannot be ignored ways. Understanding the cultural potential and local wisdom is very important in solving the nutrition of children under five\(^3,4\). The existence of churches and religious leaders and community leaders is important in resolving these problems. In addition, the sustainability of the approach that is in accordance with the culture of the community and local wisdom can be maintained and improved, so that the community will be better and minimize health problems in the nutrition of children under five and increase the level of public health in general\(^5\).

The aim of this cultural-based research that will be carried out in South Sorong District is to make an interventional model by utilizing local wisdom involving community leaders, religious leaders, figures and health workers related to overcoming the problem of malnutrition in children under fifth by exploring all the potential that exists in the community to make models that are in accordance with regional culture in overcoming the nutritional problems of children under five in that area.

**Method**

The research conducted was a mixed methods research which is the method combines two research methods at once, qualitative and quantitative in a research activity, so that more comprehensive, valid, reliable, and objective data will be obtained. Exploring the value system and community behavior related to health phenomena using ethnographic methods, researchers and stakeholders and the community conduct social construction to resolve existing health problems.

The researcher updated the nutritional status data for children under five in Konda and Wamargege villages, in South Sorong, West Papua Province Indonesia. The research team conducted discussions internally, then advocated the results of the research to the community, both in the church and village office.

The ethical approval was taken from Health Research and Development Agency (Balitbangkes) of Ministry of Health Indonesia (No: LB.02.01/KE.237/2018). This research was funded by Health Research and Development Agency (Balitbangkes) of Ministry of Health Indonesia.

**Result**

Konda and Wamargege villages are part of the Konda Sub-District in South Sorong District. It is located about 35 km from the capital city of Teminabuan, South Sorong District. The transportation to reach the area uses land vehicles with a travel time of around 2 hours, while if using a river lane it takes about 45 minutes. On the outline, these two villages 3 major tribes namely the Yaben tribe, the Tehit tribe and the Nakma tribe. In these two villages, the three tribes have intermingled, both in residential and inter-tribal marriages. Most people’s lives are fishermen and farmers or gardening. The location of the village of Konda and Wamargege is close to the beach which is flowed by the Teminabuan river and adjacent to the sea estuary\(^6,7\).

The existence of children under fifth in Konda and Wamargege is pretty much. In the village of Konda there are around 90 children under five, while in the village of Wamargege there are more than 150 children. The research team saw many children under fifth in these two villages, and at first glance the children were small (short) and thin. According to some of their experiences there are those who weigh weight and some who don’t. There is even a tendency for children over 2 years not to go to the posyandu. Every family has many children, on average they have 5 to 7 children. There are also in one family having more than one children under fifth, some even have 3 children under fifth\(^8\). The existence of schools in this village has elementary and junior high schools, but there are still many children who are not in school and the reasons are unclear. This is very important to reduce illiteracy rates in the community with obligate all school children up to 9 years of study/school (to graduate from elementary and junior high school)\(^9,10\).

Measurement of the nutritional status of children under five in Konda and Wamargege villages by measuring height and weight, and age of children under five. The number of children under five is 85 children consisting of 36 children under fifth from Konda village and 49 children under fifth from Wamargege village. Data is seen in the diagram below.
Measurement Of Weight/Age On Children Under Fifth

From 85 children under fifth who have measured body weight per age, it was found that there were 49.1 percent of good nutritional status, there were 28.23 percent of malnutrition status and there were 23.35 percent with poor nutritional status. Data can be seen in the following diagram.

Graph 2: Nutritional Status Children Under Fifth Weight/Age

Measurement Body Height/ Age on Children Under Fifth

Stunting conditions for Children under fifth were 54.1% (sum of stunting and severely stunting), the normal was 44.7% and tall was 1.2%.
Discussion

Based on environmental health science, good community potential that can be developed as a source of family nutrition intake, especially the nutrition of children under five among them is the location of the village by the sea. This makes the main work of the community in both villages is fishermen. The captured seafood such as fish, shrimp, crabs are types of foods that contain high protein nutrition which are very good for toddlers to consume. However, sea products so far have always been sold, the results of which are to meet the daily needs of life. For the sake of fulfilling the nutrition of children under five, it is necessary for each family to allocate family income to buy the nutritional needs of children under five such as milk, chicken eggs, chicken, and vegetables.

Related to the availability of garden land for each family. The garden land owned by each family is very broad, but it is still not well taken care of. The garden is still full of grass and perennials, such as durian, rambutan, coconut and sago palm (Fa or sago), but there are no kitchen plants. The main nutrient consumption of the family from these hard plants is sago, because sago is a typical food type of Papua, which is generally processed into a staple food called papeda. The existing sago, which is still limited to papeda, has not been processed well with various variations to adjust the fulfillment of toddlers’ meals.

The existence of Posyandu in the village is also a potential village that is useful to help provide health services for toddlers and pregnant women. But the use of posyandu is still not maximized. Posyandu has not yet played a role in the transfer of knowledge. This can be seen when weighing toddlers, mothers who come do not carry cards to health (KMS) or MCH books, so babies are weighed only as notes in cadre books. There is no explanation of the results of weighing up or down if it goes up how and if it goes down what should be done by the mother. Posyandu in both villages is also used for supplementary feeding (PMT) by PKK mothers which is held every month in the first week.

Broadly speaking, the potential of the community in Kampung Konda and Wamargege are as follows:

1. The community has a social structure, namely the Village Chief Konda and Wamargege, the Chairperson of the Village Representative Body Konda and Wamargege, religious leaders, the administration of village administrators, community leaders, traditional leaders

2. The existence of customary law that is obeyed, for example regarding marriage, which must be obeyed
by all the ringal communities in Kampung Konda and Wamargege.

3. Community compliance with religious leaders, village administration, community, and traditional leaders.

4. The wife’s obedience to her husband, given the customary marriage process that requires her husband to buy or dowry around 10 million or even more and as much as 200 bunches of cloth. After the traditional marriage, the church marriage continues.

5. Occupations of residents in Wamargege are generally fishermen and in the village of Konda they generally do farming, raising livestock

6. Most of the fishermen’s products are shrimp, and are sold to middlemen who have been subscribed to fishermen in Kampung Konda and Wamargege. Some fish are sold to local people, and eaten by fishermen themselves.

7. The results of gardening are generally sago, cassava, banana, spinach.

8. Livestock: chickens raised by the local community do not have special pens. The chickens are wild and find food in their home pages or in their neighbors. For pigs, there are wild animals and there are cages near the house.

9. Hunting results: Deer, wild boar, birds, forest rats and others.

10. There is a helper health center 1, Pudtu Konda. consisting of 4 nurses, 3 midwives and also there is a monthly attendance at the local health center staff for posyandu activities.

11. There are two Posyandu, one in Kampung Konda and one in Kampung Wamargege. Elderly Posyandu only 1 piece.

The implementation of the research during 2018 was carried out with the preparation stage, continued at the data collection stage and made the intervention plan that was most appropriate to the conditions of the Konda and Wamargege Village communities. First data collection by measuring height or length of body and weight of children under five. It was found that children under fifth who were malnourished were 49.4% while those who were stunting (short and very short) were 54.1%. Furthermore, a clinical examination by a health center doctor was found that there were acute respiratory infections, pneumonia, diarrhea and suspected pulmonary tuberculosis.

From the field findings, the research team carried out awareness and advocacy for people on Sunday church services, in Kampung Konda to have a dialogue with the community in overcoming the problem of malnutrition children under fifth in Konda and Wamargege Village. The results obtained, from the village meeting were community agreement in overcoming the problem of malnutrition and lack of these are as follows: (1) the mother or wife who has children less than 2 years old, are not permitted to join the husband go to the sea (2) Nutrition House, where there is a special place for cooking and gathering menus with local raw materials, then the results of the cooking are given to children under five who are malnourished and lacking in Konda and Wamargege Village, and (3) Nutrition Reef, where every house has plants that are eaten as a source of vitamins from food ingredients.

Conclusion

The average family has more than 2 children, in fact most families have children 6 to 8 children. Interventions and recommendations for overcoming the problem of malnutrition in South Sorong Regency are the use of natural resources and local wisdom. in addition, community participation and collaboration with local community leaders can be used as a step to overcome the problem of malnutrition in children.

Source of Funding: This research was completely funded by Ministry of Health, Indonesia.

Conflict of Interest: There is no conflict of interest.

Abstract

This paper deals with the unique FORTIS system for parametrization of injuries, which allows one to make the scoring of injuries resulting from accidents, while it offers possibilities for its utilisation for the needs of the road transportation experts or biomechanics during the analysis of vehicle - pedestrian accident cases or for forensic biomechanical assessment of a course of other accidents. The work presents forensic investigation of fatal injuries of pedestrians and an assessment carried out via the FORTIS system in comparison with AIS. The output is a complex parametrization of accident consequences that can be used for the needs of traffic accident analysts and experts in other forensic sciences in calculations in a simulation program or using other forensic exact methods.

Key Words: Injury, description of injuries, injury parametrization system, injury localization, collision analysis

Introduction

Nowadays, an expert in the field of road transport as well as an expert in the field of forensic biomechanics has considerably limited possibilities to use the information on a type, extent or exact location of an injury in the assessment of an accident or an injury case. This is due to the fact that usually it is only a verbal description of injuries carried out by a doctor, but the form of such information is only a small help to expand the necessary knowledge about a movement of an injured person and a particular way the injury was caused.

For further investigation of the possibilities to use the injury parametrization and localization of injuries in practice the „Theory of injury and contact signatures“ was used, which was prepared by forensic engineers in cooperation with the (Institute of Forensic Medicine of P. J. Šafárik University in Košice, Slovakia) in the past years (since 2002) based on the theoretical evaluation of the simulation results of 250 traffic injuries and about 200 actual accidents.

Pedestrian injuries as an information on the course of the collision

In this respect, the primary parameters were particularly

- location on pedestrian’s body (injury location), resulting from the first contact with the vehicle
- extent of injuries (consequence of collisions) determined on the basis experts forensic assessment

It is obvious that the distinctness of every injury or accident plays a decisive role here as the localization, the type and extent of injuries in connection with the localization and the type and extent of damage to a vehicle provide a specific picture of a collision, the „reading“ or recognition of which would, together with other data, significantly improve the collision analysis, eliminate the current inaccuracies and scholastic phenomena.

The following question may be raised in relation to the above:

Corresponding Author:
Ing. Ján Mandelík, PhD.,
e-mail: emg@dodo.sk
“How to use the information on injuries sustained by the pedestrian during the sequence of impact, after “throwing” and movement to final position in the crash analysis, provided that the injuries cannot be sufficiently measured at the level acceptable for calculation purposes“

Additional two methodological questions arise when we attempt to answer the question:

1. How to express the location, extent and type of pedestrian injuries (in general – consequences of violence acting upon human body resulting in the injury), to enable any degree of quantification, whereas the quantification should be correct especially from medical viewpoint, as performed by forensic specialists?

2. How to make use of this forensic quantification to assist in the analysis of traffic accidents?, i.e. how to transmit and subsequently use the knowledge from the two fields – forensic medicine and forensic engineering to analyse the sequence of the accident?

Provided that a collision and an injury are, physically speaking, a unique and unrepeatable set of phenomena, which is affected by an undefined number of influences, out of which many are specific for a particular collision, we may predict that in order to achieve the best solution for its analysis it is vital that we make use of all known circumstances and facts.

Parametrization and determination of injury extent from medical point of view – current state

The effort to standardize injuries to a human body (including pedestrian injuries in traffic accidents) is motivated by a need to define causes and consequences of injuries. During an interaction of a human body part and a vehicle (or a vehicle interior, a road, a motorcycle, etc.) there are mechanical and physiological changes of the contacting human body parts due to the action of force. These changes are called a biomechanical response to an external load[5].

To describe the dependence between a mechanical (time and force) action and a biomechanical response for the needs of technical experts it is necessary to define the criteria that express a degree of an estimated biomechanical response to a mechanical load. The extent of injuries may help to reconstruct the course of an accident and it also may be a very useful control value.

The AIS/ISS injury scale is currently considered a classic injury parameter evaluation system from the medical point of view. The mentioned parametrization is based on the medical esvaluation of injury type and extent.

Methodology of injury severity score AIS/ISS

The point values according to Abbreviated Injury Score (AIS) and Injury Severity Score (ISS) for injuries (adapted according to Baker et al., 1974, 1984, Moore et al., 1998):

<table>
<thead>
<tr>
<th>AIS point value of one body part</th>
<th>Injury description</th>
<th>ISS value (AIS2)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No injury</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>Minor injury</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>Moderate injury</td>
<td>4</td>
</tr>
<tr>
<td>3</td>
<td>Serious injury</td>
<td>9</td>
</tr>
<tr>
<td>4</td>
<td>Severe injury</td>
<td>16</td>
</tr>
<tr>
<td>5</td>
<td>Life-threatening injury</td>
<td>25</td>
</tr>
<tr>
<td>6</td>
<td>Fatal injury</td>
<td>36</td>
</tr>
</tbody>
</table>

ISS = AIS2 max1 + AIS2 max2 + AIS2 max3  (0 … 75 points)

Among other well-known there are GSI (Gadd Severity Index), HIC (Head Injury Criterion – a head injury parameter), 3MS, TTI (Thoracic Trauma Index – a trunk injury parameter), VC (a soft tissue injury parameter), EIC (Extended Injury Criterion – an extended injury parameter), which are the ways of injury parametrization, but they provide a universal information means neither for the entire body of an injured person nor for all types of injuries.

Parameterization of injuries in crashes involving pedestrian injuries – FORTIS system (Forensic Traumatology Injury Scale)

Nowadays, a forensic analysis of injuries, especially traffic injuries, is not always standard, mainly due to the lack of an established, precisely defined procedure of injury parameter standardization. The proposed
procedure for the assessment of traffic injuries, including
the key element of injury parameter standardization
according to internationally accepted AIS/ISS scale
(abbreviated Injury Scale/Injury Severity Score) as
follows:

Materials and Methods

➢ Investigated circumstances, accompanying
documentation, autopsy reports, image documentation
and results of supplementary investigation evidence
from traffic accidents involving pedestrian fatalities

➢ Completed autopsy report in accordance with
the requirements of International Disease Classification
(10th revision)

➢ Assessment of injury parameters using
proprietary modified FORTIS system, comparison of
FORTIS values with AIS/ISS values

The modified FORTIS system

The result is the modified FORTIS system – a range
of injuries in forensic traumatology, the use of which
enables a more complex expression of the severity of
an injury, thus enabling its further use to solve traffic
accidents and other injury events resulting in damage to
health. The FORTIS system uses a proprietary modified
point value system, which besides determining the
basic injury to health (ZPZ), proposes classification
of accompanying complications in two groups: Ko1 -
primary post-injury complications - such as traumatic
shock, haemorrhagic shock, cardiac tamponade,
haemothorax, pneumothorax) and secondary
complications Ko2 – such as inflammatory changes,
oedema of non-traumatic origin, thromboses, conditions
arising from surgeries, etc.

Such division provides an opportunity to indirectly
assess quality of healthcare provision in case of a
surviving injured. To verify the proprietary modified
FORTIS system, 12 fatal traffic accidents were subjected
to assessment by forensic pathologists, evaluating each
case as a single event and subsequently each relevant
item in the autopsy report was assessed in a similar
way. The results acquired through above analysis were
compared to standard assessment of injury parameters –
AIS/ISS in order to demonstrate new possibilities of the
FORTIS system in quantification of injury parameters.

Point values of the 12 assessed pedestrian fatalities
using standard AIS/ISS method and the modified

FORTIS system can be seen in Table 1.

</table>
It is undeniable that the possibilities of the point injury evaluation by the FORTIS system are wider; the system is more flexible, more accurate and it differentiates a degree of damage to health caused by the injury, which was fully confirmed by a research focused on the possibilities of using the proposed system.

Illustrative examples of scoring of forensic examination of fatal injuries with a different ratio ZPZ, Ko1 and Ko2

A. Results - case No.4

Investigated circumstances: involving motor vehicle VW Passat, whereas the vehicle with its right side collided with underage pedestrian who entered its trajectory from the right side, causing him head injury to which he succumbed shortly after the accident.

Immediate cause of death: Rupture of the connection between medulla oblongata and cerebral pons and contusion and laceration of brain and intracranial haemorrhage resulting from fragmented fractures of cranial calvaria and base.

Fig. 1 Documentation of finding - illustration to case no. 4

Fig. 2: Evaluation of parameters of injuries in the case no. 4 via custom modified FORTIS system and comparison of FORTIS values with AIS/ISS values
B. Results - case No.11

Investigated circumstances: involving a collision between passenger vehicle and pedestrian. The injured pedestrian was subsequently hospitalized at the traumatology department with bilateral fracture of pelvis (treated by conservative – Kirschner’s extension of left leg). On the 12th day of hospitalization, F.K. died.

Immediate cause of death: Bilateral focal catarrhal-purulent broncho-pneumonia.

Fig. 3 Documentation of the finding - illustration to case no. 11

Fig. 4 Evaluation of parameters of injuries in case no. 11 via custom modified FORTIS system and comparison of FORTIS values with AIS/ISS values
EVALUATION AND BENEFITS OF FORTIS SYSTEM

The informative value of the modified FORTIS system according to the extent of the damage to health in connection with the immediate consequences of the actuating violence (ZPZ – basic damage to health) and associated complications (Ko1, Ko2) in the selected cases, case No.4 and case No. 11, in relation to the survival period of the injured persons is shown in Fig.5 and Fig.6:

Fig. 5 Relationship of FORTIS ZPZ, Ko1 and Ko2 in the event of death on the spot DN- case no. 4

Fig. 6 Relationship of FORTIS ZPZ, Ko1 and Ko2 in the event of survival - case no. 11

The research conducted so far, outcomes of which are presented herein, enables us to state that the technique of standardization of pedestrian injury parameters in case of traffic accidents (quantification of injuries) requires the application of the proprietary modified scoring system FORTIS, that enables (subject to good quality of input parameters) to calculate the degree of the basic injury to health, primary post-injury complications and secondary complications, including painful treatment procedures and poor quality of healthcare and in case of fatal injuries it enables to determine the immediate cause of death.

The modified system of injury scoring differs from the existing systems in the following aspects:
FORTIS vs. AIS/ISS

Scoring of injuries and their complications using modified tables Injury Score in Forensic Medicine

- Special scoring of the basic injury to health (ZPZ)
- The complications are divided in two categories:
  1) primary post-injury complications (Ko1)
  2) secondary complications (Ko2)
- The score values include decimal positions
- Maximum score of FORTIS is not limited

It is clear that the above mentioned differences between FORTIS and the scale of the AIA/ISS system significantly increase FORTIS’s utility, accuracy resulting in certain parameter of the injury expressed in the form of a number, enabling the generation of characteristic signatures with respect to the parameters of the collision between the vehicle and the pedestrian, or in general to the mechanism of injuries.

Currently, the total number of 39 tables of individual body parts is being processed with regard to decisive health consequences in relation to the extent and location of the actuating violence, which are gradually verified and completed with others. The stated methodology continues to be constantly improved.

In order to manage a full use of FORTIS system for the needs of the accident course analysis (or the injury course analysis) it is necessary to display the localization of the spot on the body surface, where the violence resulting in an injury actuated. Then, we may compare this localization with the localization of the contact according to a calculation in the simulation program, as shown in Fig.7.

![Examples of visual identification of contacts in PC Crash program](image1)

Fig. 7 Examples of visual identification of contacts in PC Crash program [3]
Conclusion

It is apparent that in such way we created an opportunity, for the needs of analysts of traffic accidents at solving the vehicle-pedestrian collision, sto compare a level of concordance of localisation of injuries at own calculations, and even by comparing the concordance of distribution of total energy acting upon collision to the pedestrian’s body, using calculation program. The said FORTIS system has considerably greater possibilities of use within forensic medicine and traumatology as it includes not only the area of evaluation of road traffic injuries, but also all injury phenomena (railway accidents, aviation accidents, violent criminal acts, etc.), during the analysis of which it is possible to obtain the information on severity of individual traumatic contacts for individual calculations, than the simulation programs used to analyse traffic accidents. We may presume that the FORTIS system should be already used in the first contact between a doctor and a patient suffering an injury and that it should accompany the patient until he/she recovers and that it should also be used to investigate the accident/injury as well as for a legal assessment of all its aspects, for which it provides all available information for the mentioned said purpose.

Citrus Hystrix D.C Fluid Inhibits the Growth of Escherichia Coli, Pseudomonas aerogenosa, and Bacillus subtilis

Haitami1, Leka Lutpiatina1, Akhmad Muhlisin1
1Lecturer, Medical Laboratory Technology Poltekkes Kemenkes Banjarmasin, Indonesia

Abstract

Background: Citrus hystrix D.C is a plant traditionally used for herbs and medicinal plants in Indonesia. Citrus hystrix D.C fluid is proven to inhibit the growth of Staphylococcus aureus. The purpose of this study was to determine the ability of the fluid of Citrus hystrix D.C concentrations of 25%, 50%, 75%, and 100% in inhibiting the growth of Escherichia Coli, Pseudomonas aerogenosa, Bacillus subtilis.

Material and Method: This research is experimental with Posttest Only Control Group Design. The material used was local Citrus hystrix D.C, fresh and clean green, obtained from the Astambul area, Banjar Regency, South Kalimantan Indonesia.

Results: The results showed that there was a zone of inhibition of Citrus hystrix D.C fluid at a concentration of 25%, 50%, 75%, and 100% on the growth of Escherichia Coli, amounting to 7mm, 10mm, 13mm, 15mm. Pseudomonas aerogenosa, amounting to 6mm, 9mm, 13mm, 14mm. Bacillus subtilis, amounting to 6mm, 8mm, 11mm, 14mm.

Conclusion: It concluded that the fluid of Citrus hystrix D.C affected the growth of Escherichia Coli, Pseudomonas aerogenosa, Bacillus subtilis with the most significant inhibition zones respectively 15mm, 14mm, and 14mm.

Keywords: Citrus hystrix D.C; Antibacterial; Escherichia Coli; Pseudomonas aerogenosa; Bacillus subtilis

Introduction

Unhealthy lifestyles and poor sanitation are factors that support bacterial infections. The bacterial infection is still a health problem in Indonesia. Bacterial diseases such as tuberculosis1,2,3 and Staphylococcus aureus4,5. There are also problems with bacterial environmental contaminants such as Salmonella6, E. coli7, Staphylococcus aureus8,9 and Bacillus10,11.

Gram-positive Bacillus subtilis can cause bacteremia, septicemia, and endocarditis12. E. coli bacteria are Gram-negative bacteria that cause infections of the urinary tract and digestive disorders such as diarrhea13 whereas P. aeruginosa is a Gram-negative bacterium that causes urinary tract infections, meningitis, diarrhea, necrosis of enterocolitis and pneumonia14.

We are handling bacterial infections, in general, using synthetic bacteria. Synthetic antibacterial has side effects that can cause allergic reactions for users who are not suitable to use the antibacterial. So the manufacture of natural antibacterial originating from plants began to be investigated15.

Indonesia is a country rich in herbal plants as medicinal plants such as Anredera cordifolia16, Cananga odorata (Lamk). Hook17, lime18, Syzygium polyanthum19, Carica papaya Linn20, Jatropha curcas21, Kaempferia galanga L.22, Cinnamomum burmannii23, Eleutherine palmifolia (L) Merr24, Hibiscus sabdariffa L.25 Ocimum basilicum Linn26, Citrus hystrix D.C.27. Citrus hystrix D.C. is an Indonesian endemic plant originating from the family Rutaceae, genus Citrus. The community has commonly used plants belonging to the genus Citrus for the treatment of various diseases28.

Citrus hystrix D.C fruit fluid has a pH of 1.62, which shows very acidic, compared with lime (Citrus aurantifolia swingle) Research that has carried out on the fluid owned by the plant genus Citrus proves its activity
as an antioxidant and antibacterial (male). Citrus hystrix D.C fluid contains flavonoids which play a significant role in inhibiting bacterial growth.

The results of Kusumawardhani (2019) Citrus hystrix D.C fluid can inhibit the growth of *Staphylococcus aureus* at concentrations of 25%, 50%, 75%, and 100%, respectively 13.75mm, 17.25mm, 19.75mm, and 21.75mm. The inhibitory water of Citrus hystrix D.C against *Staphylococcus aureus* has known, but the inhibition has not been identified yet on *Escherichia Coli, Pseudomonas aerogenosa, Bacillus subtilis*. The purpose of this study was to determine the antibacterial ability of Citrus hystrix D.C fluid against *Escherichia Coli, Pseudomonas aerogenosa, Bacillus subtilis*.

**Subjects and Method**

The research carried out was an experimental study by examining the inhibitory power of Citrus hystrix D.C fluid with concentrations of 25%, 50%, 75%, and 100% when compared with the control group.

The material used in this study was Citrus hystrix D.C fluid with the criteria of local fruit, fresh and clean green, obtained from Astambul, Banjar Regency, South Kalimantan Indonesia.

The independent variable used is Citrus hystrix D.C. The Bound Variable used is the diameter of the bacterial inhibitory zone on Muller Hinton (MH). Determination test of Citrus hystrix D.C conducted at the Laboratory of Basic Mathematics, and Natural Sciences University of Lambung Mangkurat Banjarbaru Antibacterial activity test carried out using the diffusion method in a well with repeated work three times. This study uses sterile aqua dest as a thinner in various concentrations of Citrus hystrix D.C. The results obtained were read by measuring the inhibitory zone of Citrus hystrix D.C fluid against bacteria using a ruler.

**Results**

Testing the antibacterial activity of Citrus hystrix D.C fluid on bacteria showed variations in the inhibition zone. Data of Citrus hystrix D.C fluid inhibition zone data for bacteria presented in Table 1-3.

### Discussion

Based on the data obtained in tables 1-3, it known that *Citrus hystrix* D.C. fluid can inhibit the growth of *Escherichia Coli*, *Pseudomonas aerogenosa*, *Bacillus subtilis*. The higher the concentration of *Citrus hystrix* D.C. fluid, the greater the diameter of the inhibition zone formed. This result shows that by increasing the level of *Citrus hystrix* D.C. fluid, the higher the content of active ingredients contained in *Citrus hystrix* D.C. fluid, which functions as an antibacterial, so the higher its ability to inhibit bacteria.

*Citrus hystrix* D.C. fruit fluid has a pH of 1.62, which shows very acidic so that when oxidized, the structure will change, and its function will decrease and even disappear. In general, pathogenic bacteria cannot grow very slowly at pH below 4.6. The limitation of this study is that no phytochemical tests carried out on the research material. The unknown chemical content of *Citrus hystrix* D.C., such as flavonoids, saponins, tannins, alkaloids, and others, is hidden.

Chowdhury et al. (2009) stated that the methanol extract of *Citrus hystrix* fruit and some of its fractions had moderate to healthy antibacterial activity against some Gram-positive and Gram-negative bacteria. The ethyl acetate extract and essential oil of *Citrus hystrix* rind have more effect on *S. aureus* than *E. coli*. *Citrus hystrix* D.C. fluid used in this study also proved that the inhibition zone of *E. Coli* at a concentration of 100% was only 15mm, compared to the inhibition zone of *Staphylococcus aureus* in Kusumawardhani’s study (2019) resulting in a higher inhibition zone at the same concentration of 21.75mm.

The limitation of this study is that no phytochemical tests carried out on the research material. The unknown chemical content of *Citrus hystrix* D.C., such as flavonoids, saponins, tannins, alkaloids, and others, is hidden.

### Conclusion

There is a zone of inhibition of *Citrus hystrix* D.C. fluid at concentrations of 25%, 50%, 75%, and 100% on the growth of *Escherichia Coli*, amounting to 7mm, 10mm, 13mm, 15mm. *Pseudomonas aerogenosa*, amounting to 6mm, 9mm, 13mm, 14mm. *Bacillus subtilis*, amounting to 6mm, 8mm, 11mm, 14mm.

Study of Analytical Characterization and Antibacterial Activity of Silver Nanoparticles Synthesized by Using Pineapple Juice as a Reducing Agent

Wahran M. Saod¹, Dhelal Abdul Ghafoor², Laith M Najeeb³, Mohammed J. Mansoor Al-Taee⁴
¹University of Anbar, College of Science, Department of Chemistry, Iraq, ²Department of Chemistry, General Directorate of Education in Anbar, Ministry of Education, Iraq, ³University of Anbar, College of Science, Department of Biology, Iraq, ⁴Anbar Water Directorate, Quality Control Department, Iraq

Abstract

In the past years, various phytosynthetic processes have been utilised of silver nanoparticles for the low cost and environmentally friendly comparing to the chemical and physical methods. These unique metal nanoparticles are used in several applications which are including pharmaceuticals, antimicrobial and biomedical applications. Wherefore, the object of this work is biosynthesizing AgNPs from extracts of pineapple juice as reducing studying their characteristics by Ultraviolet-Visible (UV-vis) Spectrometer, Atomic Force Microscope (AFM), SEM Scanning Electron Microscope and Transmission Electron Microscope (TEM) The UV-Vis spectra results show a strong resonance centered on the surface of silver nanoparticles (AgNPs) at 410 nm. the presenting study is involved the preparation of (AgNPs) from natural source, which confirmed by UV-Visible spectral analysis in 410nm and the synergism effects with some antibiotic to increase the sensitivity to some pathogenic bacterial isolate as *E. coli*. In addition, our study is presented results of the minimum inhibitory concentration (MIC) that MIC for AgNPs is 25 while other antibiotics are (32,64,128). Finally, the synergism activity shows a significant difference in the sensitivity of some antibiotics used against *E. coli* bacteria, especially with levofloxacin and increased the inhibition form 419 mm to 1657.2 mm.

Keywords: AgNPs, pineapple juice, UV-Vis, *E. coli*, synergistic role.

Introduction

Nanoparticles (NP) are atomic or molecular aggregates with dimensions between 1 nm and 100 nm (¹,²). NPs great Have a great scientific interesting because have a bridge between bulk material and atomic or molecular structure (³). There are different processes to prepare silver nanoparticles (AgNPs), such as conventional temperature assisted process, controlled reaction at high temperatures, and microwave assisted process (⁴). Green method for the synthesis of AgNPS with plant extracts plays a very important role in nanotechnology without any harmful chemicals (⁵). Recently, some plants were used to synthesize silver nanoparticles including Ziziphus mauritiana (⁶) and Cyperus sp. (⁷). The Green synthesized is by using pineapple juice. Pineapple [Ananas comosus (L.) Merr.], is the third most important fruit crop in the tropical and subtropical regions of the world, it is only preceded by banana and citrus (⁸). Pineapple has an important source of sugars, organic acids and the most important is considering as an antioxidant, such as ascorbic acid, flavonoids, and other phenolic compounds related to antioxidant activities (⁹,¹⁰). UV-vis spectroscopy is rapid, easy, sensitive, selective technique for various types of NPs and the measurements of this technique are consuming short times (¹¹, ¹²).

Experimental section

Materials: Research chemicals were supplied by MERCK Company-Germany.

Instruments: UV-Vis spectroscopy (Shimadzu, Japan), Atomic force microscope (AFM);
Synthesis of silver nanoparticles using pineapple juice

Only, 440 ml of pineapple juice aqueous was added to 240 ml distilled water in conical flask, the solution was heated to 50 - 60 °C. 10 ml of aqueous solution was added to 1mM AgNO₃ with stirring. the color of the solution will change to orange after 15 min. This indicates for the formation of AgNP₅.

Antibacterial activity

Isolate

E. coli isolates were obtained from microbiology laboratories at the Faculty of Science, Anbar University. the isolation was confirmed by using some of the biochemical investigations that included with growth of the nutritious broth and Macconky agar. In addition to carrying out some special tests including Gram stain and some biochemical tests after that the isolation was diagnosed using VITEK 2.

Sensitivity test

A number of antibiotics were used by Bioanalyse company. Where they were followed the method of spreading around the tables on Mueller Hinton Agar fertilized with E. coli bacteria (13).

The minimum inhibitory concentration (MIC).

The values of the minimum inhibitory concentrations (MIC) were determined by broth dilution technique in microtiter plates and this technique is based on the Clinical and Laboratory Standards Institute (CLSI) guidelines (14) for each compound: Ag⁺ ion, AgNPs, chitosan, and the antimicrobial drugs (Gentamycin,Amikacin, Doxycycline, Levofoxcacin, Trimethoprim,Cefixime) against Grum-positive bacteria E.coli. The MIC investigations, the bacterial suspension 0.5 McFarland (approximately 108 colony forming units per mL) were prepared from E. coli bacteria in Mueller Hinton agar, at 37 °C, for 24 h. It was added 150 µL of bacteria suspension and 150 µL of the antibacterial agent solution in a polystyrene microtiter plate, both solution was diluted in Mueller Hinton broth. The concentrations of the compound are ranged between (0.03-64 µg mL⁻¹). The plates were incubated for 24 h and the bacteria growth was determined by turbidity and color change in the system by adding the non-enzymatic marker (resazurin aqueous solution 0.01 g L⁻¹). Resazurin turns from dark blue to colorless under the metabolism of bacteria (15).

Results and Discussion

Characterization

The formation of silver particles (AgNPs) was confirmed after 15 min at 50-60 °C by the color change of the solution and the surface plasmon resonance (SPR) band which obtained by UV-Visible spectrum with 410 nm (13). The optical absorption spectra are normally determined by a UV-visible spectrophotometer. The function of UV-visible absorption is based on measuring the intensities of two transmitted beams, one beam transmitted from the sample and another transmitted from the reference cavity. UV-Visible spectral analysis of the bio-synthesized AgNPs from pineapple juice and their color were checked in this test to confirm the formation of AgNPs (16). The color change of the mixture solution from yellow to the brown color at peak 410 nm, and that agree with results of (6, 7).

The atomic force microscope (AFM) is used to differentiation the NPs. It supplies the ability of 3D visual image and both qualitative and quantitative information about different actual features such as size, roughness, morphology and surface texture (17). AgNP₅ that formed from pineapple juice as reducing agent have smooth a surface and small particles diameter. distribution, the average particle of AgNPs is measured by AFM images was (32 nm),

SEM analysis in most of measurements s that specialized with nano particles. This study gave image for synthesized silver nano particles was shown high-resolution. Average of size particles around between 20 -30 nm with spherical shape.

Transmission electron microscopic (TEM) is one of the most popular characterization techniques for NPs (18). In this technique, a real image of NPs is taken; different magnifications can be used to show more detailed or general shape of NPs. These images are containing a
lot of information regarding shape and size distribution, and even crystallographic structure and characteristics of nanoparticles. TEM images data clearly shows that the structure and nature of reducing agent play an important role to reduce the Ag ion into Ag atom. This method provides highly stable water-soluble. Mono dispersion and Spherical Shape only particles, average size between (18- 30) nm 

The EDX spectrum of the biosynthesized AgNPs (figure 1) shows finding silver element as an indicator for the formation of silver nanoparticles from the. Also, it exhibits the C, O, N, Al Si, and Sr elements have been presented in the used sample. Si element has been presented from deposition of AgNPs on the bottom

Biological Applications of AgNPs

AgNPs have been used in applications of AgNPs in different biological and biomedical applications, example antibacterial, antifungal, antiviral, anti-inflammatory, anti-cancer, and anti-angiogenic. In our study, we focused on the efficacy of AgNPs as an antibacterial agent using a number of common antibacterial against E. coli bacteria. Antimicrobial Activity of AgNPs

One of the most typical model organisms is E. coli which is used in medical and biology researchs as well as drug mechanisms and drug targets studies. The nature of E. coli is Gram-negative bacteria which has the same structure of any cell by using the minimum inhibitory concentration.

The MIC value of AgNPs tested against E. coli was found to be high (in the range of (32 -128) (µg/ml) table (1).

(Table 1) Antibiotics and (AgNPs) MIC (µg/ml) determination by micro-titer plate

Therefore, we investigated the mechanism of synergistic influence of combination between AgNPs and antibiotics against E. coli. The synergism was presented with E. coli when AgNPs combined with Gentamycin, Amikacin, Levofoxacin, Trimethoprim, Cefixime, if found the highest value of MIC at Trimethoprim, Cefixime. AgNPs were effective in inhibiting bacterial growth Therefore, it can be said that AgNPs are broad spectrum agents whose performance is not blocked by the drug-resistant mechanisms of the bacteria. (23)

The combination test between antibiotics and silver nanoparticles (Synergistic role)

Ten microliters colloidal AgNPs was injected into wells in media which containing antibiotics. The plates were cultured by bacteria and then incubated at 37°C for 18-24 h. The diameter of inhibition zone was measured by the ruler compared with the control; antibiotics and AgNPs alone. AgNPs have utilised in medicine field, and in this work, it was used the synthesised AgNPs as antibacterial agent through simple technique called well
diffusion assay. The potential of anti-bacterial properties for AgNPs was shown against *E. coli*. The synthesised AgNPs has ability to inhibit *E. coli* growth with various types of antibiotics. The empty spaces were significantly increased with using AgNPs-antibiotics as shown in table 2.

The increasing of inhibition zone relates with the combination of the Ag nanoparticle with antibiotics which increase methods of killing bacteria *in vitro* and that is called synergistic effect between AgNPs and antibiotics (24). The role of silver nanoparticles biosynthesized from natural organic compounds in fruits extracts may be play an important agent against microbes (7), referred to that silver nanoparticle which produced in the green chemistry method is considered potential nano-drug against human microbes’ pathogens *in vitro*.

**Conclusion**

In this study, we used green method to synthesis AgNPs by using pineapple extract as reducing and stabilising agent which proved by UV-Visible spectral analysis, EDX, SEM, and AFM analyses. we tested activity of synthesized Ag NPs as anti-bacterial against *E. coli* by using well diffusion assay technique. The study showed that Ag NPs were anti-bacterial very active with different type of antibiotics against *E. coli* and we found sliver nanoparticles has the synergism effect with some antibiotic such as (Gentamycin, Amikacin and Doxycycline, Levofloxacin, Trimethoprim and Cefixime) in increase its activity towards *E. coli*.

Adolescents’ Knowledge and Attitude Before and After Exposure to Media of Youth Sexual Behavior in Indonesia

Setyafanny Santoso1, Pulung Siswanta1

1Department of Health Promotion and Behavioral Science, Faculty of Public Health, Airlangga University, 60115 Surabaya, East Java, Indonesia;

Abstract

The increasing number of cases regarding adolescent free sex is due to a lack understanding of reproductive health. Someone’s knowledge about reproductive health is believed to be closely related to what action they take. In the context of adolescence, their knowledge of reproductive health undoubtedly influences their attitude toward premarital sex. Most of premarital sex cases occur because they are lacking of knowlegde about its impact. This quasi-experiment was conducted on a senior high school in Indonesia. Subjects were 144 nine grade students, selected using purposive random sampling from a total population of 229 students. For each control and experiment groups, 72 students each were selected. The experiment group participated in the treatment of the study. Data was analyzed using paired t-test to find the differences of control and experiment groups’ knowledge and attitude. Both groups showed an increase of knowledge. However, the increase in experiment groups were more than one of the control group. There were only 10 students (14%) of experiment groups reached the category of having good understanding on the pre test and the number increased on the post to 39 students (54%).

Keywords: Knowledge, Attitude, Video, Leaflet.

Introduction

Health is a good condition physically, mentally, spiritually and socially, which enables everyone to live productively socially and economically. Health is among the most important thing for anyone no matter how old they are. Health is a serious matter, which is related to one person to another in the national development. Therefore, everyone must fight for the highest level of health. Everyone should promote health life style ranging from digestion, exercise to sex.

Many of teenagers exhibit behaviors that tend to lead to free sex. This is due to their ignorance about proper sex. Free sex behavior in adolescents is mostly caused by their association, which is now very alarming(1).

Premarital sexual behavior lead to disastrous consequences for health. It can lead to transmission of sexually transmitted diseases and unwanted pregnancies, which later can result in these teenagers dropping out of school, getting social sanctions or suffering complications during the pregnancy to the postpartum.

The increasing number of cases regarding adolescent free sex is due to a lack understanding of reproductive health. Nurhayati (2011) stated that someone’s knowledge is closely related to his/her action. In the context of adolescence, their knowledge of reproductive health influences their attitude toward premarital sex(2). As they are lacking of comprehensive knowledge about the effect of their sexual behavior, the premarital sex in adolescents depends on their how their knowledge and attitude towards it. Among numbers of effort we can take to increase their understanding is by conducting health promotion program using audio-visual media.

There are three kinds of health promotion media, namely audio, visual and audio-visual. One of visual media is a leaflet. It is good to stimulate adolescents vision sense during the promotion program. For the
audio-visual media, the common known media is video. It is widely used to increase people knowledge by stimulating their hearing and vision sense so that the knowledge can be acquire well and maximum(3).

Another research (Furqoni, 2015) about the effectivity of health promotion program using leaflet and video toward adolescents’ knowledge and attitude found that there were an increase of youth knowledge, comparing before and after experiments(5). The use of leaflet increased subjects knowledge score from 6.75 to 10.8, while the use of video increased it to 11.6 from the average score of 6.50. Another research (Pratama, 2014) also found that increasing knowledge gained by adolescents using audio-visual and leaflet. The average score of the use of leaflet increased significantly youth understanding from 33.3% doubled to 75.4%. On the other hand, the use of audio-visual media showed an increase, but not significant. from 60.6 to 63.6(6).

Research by Tindaon (2017) supports the finding above. It found that health promotion using leaflet can increase adolescent knowledge of reproductive health by 9.62%. It is because message and information conveyed in the leaflets are concise, interesting, solid and clear so that it can attract readers to learn and therefore have better understanding about the problem(7).

Audio-visual public service advertisments are believed to be an effective tool in delivering information and messages, especially in the purpose of education. Research by Dewi (2017) found that adolescents who watch audio-visual public service advertisement showed marked increase in their knowledge by 24.9% by demonstrating 75.1% understanding of all conveyed messages(8). Aeni (2018) also argued that audio-visual media can increase student knowledge. Her post-test result showed that there were significant improvement of student knowledge after health promotion using video(9).

Material and Method

This is a quasi-experimental study with pre-test post-test Control Group Design, which is an experiment where measurements are taken both before and after treatment to see the effect of the treatment. Samples were selected using purposive random sampling. Data of knowledge and attitude were collected using a 30-questions questionnaire asking adolescent knowledge and attitude towards adolescent sex behavior. The treatment participated in an sex education session using video and leaflet, while the control group participated in different sex education session, which is only using a leaflet. The post-test were given after the treatment. Data were analyzed using SPSS version 21. To find the differences, mean score before and after treatment were compared and analyzed using paired t-test.

This study was conducted on April 2019 in one of senior high school in Indonesia. Total population was 229 students, with selected sample of 144 students using below formula. The sample were divided into two group, 72 students for each control and treatment group.

\[ s = \frac{\lambda^2 N P Q}{d^2(N-1) + \lambda^2 P Q} \]

Annotation:

s = number of sample

N = number of population

\(\lambda^2\) = Chi Square, with df = 1, with margin of error of 1%, 5% and 10%

P = Q = 0.5

d = 0.05

During the experiment, the treatment group watched video about the impact of premarital sex of teenagers aged 16-19 years old. After the video, they were given leaflet containing the same topic and the leaflet were read to them. Total duration for the video and leaflet reading was 15 minutes. Twenty minutes after the treatment, the group answered the questionnaire as the post-test 1 containing the same question from the pre-test questionnaire. The post-test 2 was carried out 4 days after the treatment.

Findings

Each experiment and control group consisted of 72 students. There were 28 boys and 44 girls in the experiment group and 38 boys and 34 girls in the control group. Subjects were 16 – 19 years old. The frequency of respondents in the treatment group and control group who had been exposed to health promotion media about adolescent sexual behavior was 26% and 29% respectively. Those who had never been exposed to the media about sexual sexual behavior were 74% and 71%, respectively.
The analysis results found that the average score of subject knowledge about adolescent sexual behavior before treatment for the control group was 18.21 with the lowest score of 14 and the highest score of 23, while of the treatment group was 18.74 with the lowest value of 14 and the highest value of 24. According to the results of the independent-test results, the average value of the control and the treatment group was not different, with a significant value \( p = 0.271 < \alpha \) (0.05).

The analysis results on the value of adolescent attitudes about adolescent sexual behavior before treatment showed that the control group had an average value of 51.61 and the treatment group had an average value of 53.21, with a significant value of \( p = 0.105 < \alpha \) (0.05). It can be interpreted that the attitude values of the two groups have no difference.

The normality test was used to test whether the data obtained was normal or not. To find it out, the Kolmogorov-Smirnov (K-S) was employed. Data is said to be normal if the significance value is more than 0.05. This value means that there is no significant difference, which also means that the data is normally distributed. If the significance value is less than 0.05, the data has a significant difference, which means that the data is not normally distributed.

<table>

</tbody>
</table>

Table 2 shows that the average value of knowledge on post test for control and treatment group were 18, 21 and 18.74 respectively with \( p \)-value of 0.271 > \( \alpha \) (0.05). This result shows that there were no significant differences of knowledge between the two groups before the treatment. On the post test I, the average score for control group and treatment group were 19.49 and 23.11 respectively with \( p \)-value of 0.000.

In post test II, the average score for the control and treatment group were 19.15 and 22.08 respectively with \( p \)-value of 0.000. From these results, it is clearly seen that the \( p \)-value for both post tests were 0.000 < \( \alpha \) (0.05), so it can be concluded that there was a difference in knowledge of the control group and treatment group after the treatment.

</table>

Table 3 shows the analysis result for subjects’ attitude during this experiment. Pre-test result shows \( p \)-value of 0.105 < \( \alpha \) (0.05). This shows that there was no significant difference between the control and treatment group before the treatment regarding their attitude toward the topic. The result of post test I and post test 2 obtained \( p \)-value of 0.000 and 0.006 < \( \alpha \) (0.05). So, it can be concluded that was a difference in attitude of the control group and treatment group after the treatment.

Discussion

Respondents knowledge of before treatment was in the category of sufficient. The control group score was in the category with an average value of 18.21. The treatment group was also in the same category with an average score of 18.74. Knowledge of respondents in the control group and treatment group is classified as sufficient because it was between the values of 18-22.

In the treatment group, there were 39 people (54%) who scored well. The increase occurred in the treatment group. Their initial average score of 18.74 (sufficient category) increased to 23.11 (good category). It can be concluded that the two groups experienced an increase after the intervention. This is also supported by the research of Furqoni (2015) who stated that there was an increase in knowledge before and after the treatment was given.

The treatment group experienced a greater increase compared to the control group. This is because the treatment group received treatment in the form of video public service advertisements and leaflets, while the control group only received intervention in the form of leaflets.

This result proves that audio-visual media in the form of public service video ads and visual media in the form of leaflets can increase the knowledge of respondents as seen in both groups in this experiment. This result is also supported by Aeni (2018) who stated that video media can increase adolescent knowledge, and improve the learning system of students, especially teenagers.

It can be concluded that video media is able to stimulate people in improving their level of knowledge and attitude. Changes that occur are significant at the time before and after the intervention is given. So that, it can be concluded that the public service ads in form of video media created by BKKBN is effective in increasing people’s knowledge and attitudes toward the topic, especially for adolescents.

Conclusion

There was a difference in knowledge after the health promotion program using videos and leaflets. The increase of knowledge for respondents was found in both groups. However, the increased in the treatment group is much better than one in the control group. In the treatment group, there were 10 people (14%) in the pre-test who were in the category of good. The number increased to 39 people (54%) after the treatment.

Differences in attitudes of respondents after the experiment were clearly seen. After the treatment, the number of subjects who were in the category of good were 15 respondents (21%) and 30 respondents (42%) for the control group and treatment group respectively. However, the subject in the treatment group were more likely to have better attitude than the control group.

Based on the results of paired t-test, which obtained p-value of 0.000 < α (0.05), it is clearly seen that there are differences in the level of knowledge and values of attitudes of respondents before and after intervention. Video media about adolescent sexual behavior is proven to be effective in increasing knowledge and changing attitudes of respondents.

It is strongly recommended for the public service ads makers to increase the intensity of broadcasting the video through television stations or any other programs involving a lot of teenagers. By inserting advertisements on the such events, the messages will more likely to be easily seen and remembered by teenagers as they attend those events. Schools are strongly suggested to provide this kind information or health promotion program and education like this in a regular basis. It is due to the fact that most respondents feel more pleased to have the information conveyed through these methods.

Conflict of Interest: All authors have no conflicts of interest to declare.

Effect of Methamphetamine Addiction on Brain Chemistry Through the Adoption of Fractalkine as an Indicator

Mushtaq T. Abood¹, Lamia A. Almashhedy¹
¹Msc. Student/ Ministry of interior/Federal security agency/ Border Guard Force Command, Baghdad, Iraq

Abstract

Methamphetamine (METH), a highly addictive drug and a strong stimulant of the central nervous system. METH abuse is increasing, especially among young people and adolescents, and therefore we wanted in this research to shed light on some of the problems resulting from meth use, especially its effect on the central nervous system, the blood-brain barrier, and Fractalkine (CX3CL1).

CX3CL1 is the only member of the CX3C subcategory of chemokines, which have a major role in the central nervous system by regulating interactions between neurons, glial cells, and immune cells. It is also considered heavily involved in traumatic brain injury (TBI) and spinal cord injury (SCI).

The study was conducted on eighty people divided into three groups, thirty non-addicted men as a control group (G1), taking into account and excluding, cigarette smoking, age, social and cultural conditions, and chronic diseases, also thirty people addicted to methamphetamine (G2), and twenty people addicted to methamphetamine and other narcotic substances (mix) (G3), whose ages ranged between (15-45) years and the period of methamphetamine abuse ranged between (1-7) years.

The results of study showed that CX3CL1 values were higher among addicted persons compared to non-addicts (G1), this difference in values shows us the effect of meth on the total values of CX3CL1.

Keywords: CX3CL1, Fractalkine, CX3CR1, Chemokines, Methamphetamine, blood–brain barrier (BBB).

Introduction

Methamphetamine (Meth) is an amphetamine derivative that is abused increasingly world-wide (¹). And it is a widely abused psychostimulant contributes to altered neuronal function, addiction, and cellular damage (², ³).

Meth affects glial cell activity, and glial cell activity that lead to modulate the neurotoxic and addictive effects of methamphetamine. Microglia are the major antigen-presenting cells in brain and when activated, they secrete an array of signaling molecules (e.g., proinflammatory cytokines and chemokines) that can cause neuronal damage.

Astrocytes are the most numerous and diverse glial cells in the CNS, with a variety of functions including, but not limited to maintenance of brain homeostasis, storage and distribution of energy substrates, synaptogenesis, and brain defense.

Like microglia, astrocytes can also secrete a number of signaling molecules that play a putative role in methamphetamine-induced neurotoxicity, such as pro- and anti-inflammatory cytokines including interleukins (ILs), interferons (IFNs), and tumor necrosis factors (TNFs), as well as chemokines (⁴).

Activation of microglia and astrocytes are normal compensatory reactions to brain injury, but excess neuro inflammation can lead to further brain damage. Indeed, repeated or neurotoxic (i.e., high dose) Meth
exposure induces alterations in glial cell functions that contribute to a complex cascade of events, leading to neuroinflammation, neuronal damage, and behavioral impairments (Fig. 1)\(^5\).

Pre-clinical in vivo studies and cultured human brain microvascular endothelial cell in vitro experiments show that methamphetamine contributes to inflammation-induced BBB dysfunction in a dose- and time-dependent manner\(^6\).

Methamphetamine exposure, in combination with stress, can synergistically exacerbate BBB damage via inflammatory mechanisms that persist for at least 7 days following methamphetamine\(^7\). Collectively, these methamphetamine-induced effects on BBB contribute to immune dysfunction, such as increased leukocyte/monocyte transmigration across the endothelium and into the CNS\(^8,9\) as shown in (Fig. 1).

(Figure 1): simplified schematic of brain and periphery the blood–brain barrier (BBB)\(^5\)

Fractalkine is a large cytokine protein of 373 amino acids, that has a chemokine domain located on top of a mucin-like stalk\(^10,11\), it contains multiple domains and is the only known member of the CX\(_3\)C chemokine family. It is also commonly known under the names fractalkine (in humans) and neurotactin (in mice)\(^10\).

The main source of chemokines is white blood cells (WBC), but CX3CL1 is mainly produced in endothelial cells and neurons\(^12\). It is not surprising that CX3CL1 expression is elevated in highly vascularized and well-innervated organs and also in locations with an increased concentration of immune system cells, such as the CNS,
lungs, cardiac muscle, liver, intestines, and placenta \textsuperscript{(13, 14)}

Soluble CX3CL1 potently chemo-attracts T cells and monocytes, while the cell-bound chemokine promotes strong adhesion of leukocytes to activated endothelial cells, where it is primarily expressed.\textsuperscript{(10)} CX3CL1 elicits its adhesive and migratory functions by interacting with the chemokine receptor CX3CR1.\textsuperscript{(15)}

Fractalkine is found commonly throughout the brain, particularly in neural cells, and its receptor is known to be present on microglial cells. It has also been found to be essential for microglial cell migration.\textsuperscript{(16)}

CX3CL1 is also up-regulated in the hippocampus during a brief temporal window following spatial learning, the purpose of which may be to regulate glutamate-mediated neurotransmission tone. This indicates a possible role for the chemokine in the protective plasticity process of synaptic scaling.\textsuperscript{(17)}

The disruption of homeostatic paracrine and autocrine interactions of the CX3CL1/CX3CR1 axis in the context of neuron-microglia communication may be seen as one of fundamental elements in the pathogenesis of CNS related diseases \textsuperscript{(18)}. One inducer through which neurons and microglia can communicate to regulate inflammation is fractalkine (CX3CL1) (Fig 2).\textsuperscript{(19)}

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{image.png}
\caption{The scheme shows intraneuronal protein accumulation. \textsuperscript{(19)}}
\end{figure}

\textbf{Material and Method}

The study was conducted on eighty people divided into three groups, thirty non addicted men as a control group (G1), taking into account and excluding, cigarette smoking, age, social and cultural conditions, and chronic diseases, also thirty people addicted to methamphetamine (G2), and twenty people addicted to methamphetamine and other narcotic substances (mix) (G3), whose ages ranged between (15-45) years and the period of methamphetamine abuse ranged between (1-7) years.

This study was conducted at the University of Babylon / College of Science / Chemistry Department, and also in Baghdad Governorate, Ibn Rushd Teaching Hospital for Psychiatry.

The addicted persons were chosen for study after being clinically examined and diagnosed by
the laboratories of Ibn Rushd Teaching Hospital for Psychiatry. The results of the screening of people taking methamphetamine during the past (24-48) hours were positive.

Determination of Fractalkine: Human Fractalkine (CX3CL1) (Chemokine C-X3-C-Motif Ligand 1) measured according to method that described in ELISA Kit.

Results and Discussion

The current study included fifty addicted males their ages were 26.7±7.4 years who had a history they of meth abuse for 1-7 years as test group, While the control group was thirty persons non addicted males their ages 27.9±6.9 years as shown in Table (1).

</table>
Table (2) show that CX3CL1 levels were higher among addicted compared to non-addicts (control group), and this results explained the effect of meth on the CX3CL1 levels.

METH abuse is also shown to exert neurotoxic effects by increasing the secretion of pro-inflammatory cytokines IL-6 and TNF-alpha in the brain (20, 21). METH abuse appears to impair blood-brain barrier (BBB) vascular function (22, 23).

These myriad effects of METH on cardio-neurovascular function and on astrogliosis-related neurotoxicity clearly emphasize the importance of the blood and brain interface. The blood-brain barrier, principally composed of the brain endothelium tight junction proteins, is a dynamic interface. BBB function is maintained at the expense of huge bio-energy consumption (24-26).

Fluctuations in CX3CL1 levels are also observed in many neurodegenerative diseases. Increased levels of serum CX3CL1 are reported in patients with multiple sclerosis (27, 28), traumatic brain injury (29), and human immunodeficiency virus (HIV) with CNS complications (30).

The CX3CL1/CX3CR1 axis acts in many physiological phenomena including those occurring in the central nervous system (CNS), by regulating the interactions between neurons, microglia, and immune cells. CNS injuries represent a serious public health problem, despite improvements in therapeutic management. To date, no effective treatment has been determined, so they constitute a leading cause of death and severe disability. Recent evidence implicated the role of the CX3CL1/CX3CR1 axis in neuro inflammatory processes occurring after CNS injuries (31).

there are numerous newly discovered phenomena as regards the influence of the CX3CL1/CX3CR1 axis on CNS physiology and pathology, such as the effect on the synaptic plasticity, maturation, activity and a marked effect on the functioning of hippocampal formation (32).

**Conclusion**

The study showed an increase in the levels of Fractalkine among meth addicts. This increase may lead to infection with various diseases such as traumatic brain injury (TBI) and spinal cord injury (SCI).

Also, the study shows us that the Fractalkine levels increase with age, which increases the risk of developing various diseases directly related to the Fractalkine.

Abstract

The objectives were to find out the alterations in serum lipid status among adult male smokers and non-smokers in Maysan Province, south of Iraq, as well as to evaluate the relationship between the heaviness of smoking and dyslipidemia in smoker subjects. A comparative study was achieved on 160 men with aged 30-63 years which were grouped to smokers and nonsmokers, among them 120 individuals were smokers and the other 40 were nonsmokers. According to the intensity of smoking, the smoker group is divided again into three subgroups: mild (A), moderate (B), and heavy (C) smokers. The concentrations of total cholesterol (TC), high density lipoprotein-c (HDL-c), triglycerides (TG), low density lipoprotein-c (LDL-c) and very low density lipoprotein-c (VLDL-c) were measured and calculated. The results revealed that concentrations of serum lipid profiles in smokers were significantly higher than that of nonsmokers except in case of high density lipoprotein-c which was significantly reduced among smokers. In addition to that the lipid profile had a significant correlation with the cigarette numbers of that smoked daily; the mean values of all lipid fractions except HDL-c were noticeably increased from group A to group C, while they were decreased in the case of HDL-C. There were significantly different between nonsmokers and different groups of the smoker, the values of TC of groups A, B, and group C were (178.6, 181.7, and 183.5) mg/dl respectively. According to similar arrangement of above smoker groups, the mean values of TG were (238.4, 245.2, and 248.7) mg/dl. In case of HDL-c, they were (31.5, 28.4, and 26.8) mg/dl. Among LDL-c level, they were (194.8, 203.8, and 204.9) mg/dl. In VLDL-c level, they were (47.7, 48.2, and 50.5) mg/dl. The findings of the study showed that smokers (especially heavy smokers) are at much greater risk of initiating atherosclerotic plaques and various heart diseases than non-smokers.

Keywords: Lipid Profile, smokers, non-smokers, TC, HDL-c, TG, LDL-c, and LDL-c, Maysan.

Introduction

The lipids are playing a crucial role in all parts of biological life. Some roles involve acting as hormones and hormone precursor, using in digestion, producing energy, storing functions, and metabolic fuel; serving as structural and functional substances in biological membranes and forming padding to permit neuron transfer or to prevent the losing of heat [1]. The blood test that used to investigate the levels of serum Tc, TGs, LDL-c, HDL-c, and VLDL-c is called lipid profiles [2]. The smoking is an essential risk factor causing atherosclerosis, and the disease of coronary artery [3].

Several studies have recorded increase in blood TC levels among people who repeatedly having smoking and decrease in TC levels among individuals leaving smoking. Further researches also showed that smoking decreases HDL-c levels, causing increased risks of heart disease. Smoking leads to an elevate in LDL-c and TG levels. Several studies have shown a dose-dependent relationship between smoking and serum lipid profile [4]. The mechanism by which the smoking changes the metabolism of lipoprotein is not completely understood. Numerous mechanisms assumed are stimulation of the sympathoadrenal system by nicotine leading to lipolysis and raised serum free fatty acid level which is causing an increase the synthesis of VLDL from the liver. A high intake of free fatty acid by heart leads to increased myocardial oxygen demand. Depressive acting of smoking on estrogen levels leads to decreased HDL-c. Smokers are thought to eat a diet that rich in fat and
lipids and lesser in fibers as well as cereals\cite{5}. Nicotine stimulates the releasing of catecholamine leading to activate the adenyl cyclase of the adipose tissue causing an increase in lipolysis, elevated concentration of free fatty acids of plasma, secreting hepatic triglycerides and hepatic free fatty acids along with VLDL-c in bloodstream\cite{6}. Although the exact mechanism of tobacco smoke that having role in the process of atherosclerotic and coronary artery disease remains not wholly clear, many chemicals that is found in tobacco smoke cause risky effects on the health\cite{7}. In the World Health Organization’s Western Pacific Region (WHO WPR), being born males is the unique highest risky indicator for tobacco usage \cite{8}. The prevalence of male smoking was (62.3\%) and the rates of increasing are the greatest in world \cite{9}. Atherosclerotic alterations that found in the middle of age initiate in childhood and the mechanisms may linked to irregular levels of risky factors such as serum lipid profiles and smoking, which are supposed to be associated with initially stages of atherosclerosis and coronary artery disease. In adults, increased level of LDL-c and decreased level of HDL-c and its main subfractions are correlated with myocardial infarction or risk factors for coronary heart disease (MI)\cite{10,17&19}. Although many researches have been achieved globally to investigate the lipid profile status in smokers, there were a little data concerning the influence of smoking on lipid profiles in Iraqi smokers \cite{11}. The current study has been achieved to reveal the correlation between smoking and lipid profiles among smoker persons in Maysan Province, south of Iraq and to estimate the p-value between lipid profile tests of smokers and nonsmokers based on the intensity of smoking.

Materials and Method

The present study was a comparative study, carried out from October 2019 to February 2020 at Al. Sadr Teaching Hospital in Maysan Province. The total samples of this study were consisting of 160 adult males; out of them 40 individuals were non-smokers and the other 120 were smokers since at least 15 years duration, aged between 30-63 years. The smokers were divided into three groups: (mild, moderate, and heavy smokers) depending on heaviness (intensity) of their smoking.

Group A: Mild smokers = 20-34 cigarettes per day (N =40)

Group B: Moderate smokers = 35-49 cigarettes / day (N =40)

Group C: Heavy smokers = 50-64 cigarettes / day (N =40)

Under the aseptic condition, about five ml of fasting (12-14 hours) venous antecubital blood samples were collected from each individual in a test tube and waiting for at least 30 minute until blood were clotting. Then the sera were centrifuged up to 4000 round per minute for 10 minutes. Sera were stored at -20°C until tested. Total cholesterol, triglycerides and high density lipoprotein-c were tested by standard enzymatic kit of Human Ltd while low density lipoprotein-c and very low density lipoprotein-c were estimation by calculated method of Friedewald. All data were analyzed by using (SPSS) version (V. 18.0).

Results

Table 1 demonstrates the difference in means ± standard deviation (SD) of lipid levels between smokers and nonsmokers. All the levels of lipid profile were found to be higher with significant values among the smokers compared to the nonsmokers (p <0.05) except HDL-c levels, it was lower among smokers with significant p-value (p <0.05).

LDL-c: One way ANOVA (F = 22.3, P <0.000), Ns: Non significant

VLDL-c: One way ANOVA (F = 13.9, P <0.000), Ns: Non significant

**Discussion**

The present study has shown that the mean values of total cholesterol, triglycerides, low density lipoprotein-c, and very low density lipoprotein-c were expressively higher in smokers when compared to nonsmokers. Simultaneously the levels of HDL-c were considerably lower in smokers comparing to nonsmokers (Table 1), these findings in accordance with this study [1, 11, & 12]. Among the various groups of total cholesterol in nonsmokers, the mean values of groups A, B, and C were in the range of (150.4, 178.6, 181.7, and 183.5) respectively. The values of TG were in the range of (163.4, 238.4, 245.2, and 248.7) among nonsmokers, group A, B and group C respectively. Further parallel raise is seen in LDL-c level from nonsmokers, group A, B and C in the range of (132.5, 194.8, 203.8, and 204.9) respectively. VLDL-c level also increased substantially in nonsmokers, group A, group B and group C, in the range of (32.7, 47.7, 48.2, and 50.5) respectively. Inversely, mean value of HDL-c level was decreased in the range: (50.6, 31.5, 28.4, and 26.8) mg/dl from nonsmoking groups A, B and C respectively. The decrease in HDL-c in smokers explained by the smoking-induced increase
catecholamine release, causing an increase in VLDL-C and a decrease in HDL-c concentrations also promotes Coronary Heart Disease and atherosclerosis by lowering HDL-c and increasing the LDL-C which further may lead to vascular endothelium damage[18]. As above results, there was a significant elevation in the level of TC, TG, LDL-c, VLDL-c and decline in HDL-c level among different groups of smoking in regarding to increase in the intensity of the smoking (Table 2). These findings were agreed with the several studies [1, 12, 14 &15]. From table3 to table 6, p-value was with highly significant(P <.000) between nonsmoker and various groups of smokers in all lipid values, while there was no significant within the smoking groups except in HDL-c levels, It was found to be significant between group A and group C (P <.01). These results were in line with the findings of many studies [1,11,12, & 16]. The mechanisms by which smoking causes the above observed dyslipidemic alterations are still not fully understood. High serum low density lipoprotein-c and low serum High density lipoprotein-c are correlated with an increased risk of atherosclerosis. Raised levels of HDL-c are indicative of decrease efflux of cholesterol from arterial wall thus favoring atherosclerosis and Chronic Heart Diseases (CHD)[12]. The rise in lipid levels in smokers explained by the mechanism: Cigarette smoking causes absorption of nicotine into the body which leads to lipolysis and release of free fatty acids into the bloodstream via activation of adenyl cyclase in adipose tissue by nicotine stimulated secretion of catecholamines, increased of free fatty acids in the liver give rise to increased hepatic Triglyceride and VLDL synthesis, so thus increasing the concentration of Triglyceride and VLDL-C in blood[18].

**Conclusion**

The study clearly showed a considerable correlation between the elevation of lipid levels and smoking. It has been found that the alterations in the serum lipid profiles tend to be elevated with the increase in the heaviness of smoking. The risk of an increase in serum levels of TC with an increase in low-density lipoprotein-c and a reduced in levels of high-density lipoprotein-c assumes great importance since it has been the patterns correlated with CHD. The declined levels of high-density lipoprotein-c in smokers and the raised exposure of the vascular endothelium to actively atherogenic lipids as a result of impairment of clearance of triglyceride-rich lipoproteins could produce a mechanism whereby smoking predisposes to a larger risk of developing atherosclerotic plaques and CHD.

Abstract

Background: ABUSE is among the meaning of deprivation of human rights and grandeur that appear as negligence, authority negation, financial exploitation, physical and psychological vexations, and rejection. This study was done to investigate the ABUSE of family with rural elderly in the city of Ivan in 2019.

Methods: 92 elderlies who lived in two villages of the city of Ivan in 2019 were selected by stage cluster sampling in this descriptive cross-sectional study. An 8-point Iranian questionnaire of ABUSE related to the elderly in the family and with scores ranging from 0 to 100 was the research tool. Data were analyzed using descriptive statistics in SPSS-16 software.

Results: There was no physical ABUSE and rejection, but the highest level of ABUSE was emotional negligence. The mean scores of financial ABUSES were less than 10%, authority negation less than 15%, financial neglect less than 20%, caring neglect and psychological ABUSE less than 25%, and emotional negligence less than 55% in both villages.

Conclusion: It is suggested that the ABUSE level be measured using the elderly in homes and centers such as hospitals, nursing homes, etc. the injured elderly should be screened and receive necessary consultation and support services.

Keywords: Abuse, Rural, Elderly

Introduction

The population of the elderly has grown nowadays (1, 2), and the elderly are affected by various diseases at this age that these diseases have negative effects on the elderly (3). ABUSE is one of the problems affecting this group. Elderly ABUSE means that a career or trustee deliberately or unintentionally does or does not a specific behavior that increases the risk and harm or violates human rights and decreases the quality of life of the elderly (over 60 years). This ABUSE includes physical, sexual, and emo-psychological ABUSE, negligence, rejection, or financial ill-use (4-6). Some factors such as no readiness of family to take care of the elderly or specific social conditions such as modernism, change, and conflict in the value system make the elderly at risk of ABUSE by family members (7).

The likelihood that a person being abused in the family is far higher than outside the family (8).
family members neglect deliberately or unintentionally by insouciance to provide emotional, caring, and safety needs, neglecting to help them to do their indoors and outdoors works and providing a decent living for the elderly. Different degrees of ABUSE have a significant impact on reducing the health and safety of the elderly. ABUSE is not a new issue and is among substantial public and social health problems around the world. Socio-economic and geographical factors in different age groups influence social support. Sometimes, family members ABUSE weak the social base of the elderly due to not reach the stage of filial puberty or compulsory responsibility, as well as changing the roles of family, the existence of the crisis, the psychological stresses of modern life, and unfaithfully.

the results of various studies have confirmed the presence of elder abuse in Iran. ABUSE, regardless of its type, is often hidden, especially if ABUSE is psychological. The effects of elderly ABUSE include decreased self-confidence, feelings of hopelessness, inadequacy, disability, and even reduced quality of life and increased mortality. The rate of elderly ABUSE at the home account from 67 to 73.3% of all elderly ABUSE cases in Europe. Providing proper solutions to reduce elderly ABUSE helps to improve their quality of life. Educating how to communicate and care for the elderly in families and promoting a culture of family respect for the elderly is too vital in preventing elderly ABUSE and is effective in improving the quality of life of the elderly. This study was done to investigate the ABUSE of family with rural elderly in the city of Ivan in 2019.

Material and Method

92 elderlies who lived in two villages of the city of Ivan in 2019 were selected by stage cluster sampling in this descriptive cross-sectional study. Inclusion criteria included being at the age of 60 and older, ability to answer questions, no severe hearing impairment, no psychological illness and cognitive disorders (MMSE score of 6 or higher), informed consent of the elderly to participate in research and do not participate in other studies.

Then, the aims of the study were explained to the participants and were completed the written consent form, demographic information, and the questionnaire of elderly ABUSE in the family. Heravi Karimvi et al designed this questionnaire, and in 2009, then validated for the Iranian community, which includes 49 items in 8 sub-scales: Caring negligence, psychological ABUSE, physical ABUSE, financial ABUSE, authority negation, rejection, financial neglect and emotional negligence. Scores ranging from 0 to 100 and higher scores indicate more abuse. The mean duration of each questionnaire answering was 30 minutes. Data were analyzed using descriptive statistics and in SPSS-22 software.

Findings

Tables 1 provide demographic information of the elderly in the two villages, and Table 5 shows the mean and standard deviation of the dimensions of elderly ABUSE in the two villages.

Discussion

Based on the results of the present study, there was no physical ABUSE and rejection. Physical ABUSE in studies by Va’ezil et al. was 3.12% (20), Hervey et al. 4.7% (11), in studies by Burji et al. in rural regions, was 1.5% (26), and Skirbekk et al. 5.3% (22). Elderly rejection in the studies by Burji et al. in rural regions was 8.5% (23), and studies by Rohani et al. were 9.3% (24). The results of these studies are in line with the results of the present study.

Emotional negligence had the highest level of ABUSE with almost 55%. Emotional neglect in the study by Va’ezi’s et al. was 42% (20), which is consistent with the present study. In the study by Hervey Karimvi et al., the level of elderly ABUSE in the dimension of emotional negligence was 17.4% (11) that is not in line with the present study that it could be caused by the cultural and social differences in the life of the elderly in urban and rural regions.

The mean scores of financial ABUSES were less than 10% in both villages, and financial negligence was less than 20%. Financial ABUSE in studies by Hervey et al. was 7.9% (11), in the studies by Skirbekk et al., was 5.4% (22), and in the studies by Amstader et al., was 6.6% (25), which are consistent with the results of the present study. Financial negligence of the elderly in the study by Va’ezi et al. was 28.7% (20), which is higher than the present study. In the study by Hosseini, financial abuse was 14.3% (26). The authority negation was less than 15% in this study. The authority negation of the elderly was 10% in the survey by Karimvi et al. (11) and in the study by Va’ezi et al. was 12.5% (20) which is consistent with the present study. Caring negligence and psychological abuse were less than 25% in this study. The psychological abuse in the survey by Va’ezil et al. was 22.18% (20), and in the study by Nasiri et al. was 53.3% (12). Also, in the study of Rahimi et al., Psychological ABUSE is the second most common familial elderly ABUSE (27). In the study by Nanjing in China, 35% of older adults were abusive and neglected. (28). In the study of Abdi et al., The prevalence of abuse in the elderly was equal to one percent (1). In old age, this group of people may be abused in viral diseases such as Covid-19, which requires preventive measures to prevent (29).

Conclusion

According to the results of the present study, there was no physical ABUSE and rejection. Although the elderly was assured of confidentiality, they may report less to ABUSE because of being confident, shame in disclosing abuse, fear of losing caregivers, and fear of diminishing social status. Emotional negligence had the highest level of ABUSE, and there were some aspects of the ABUSE in behavior with the elderly. It is suggested that the ABUSE level be measured using the elderly in homes and centers such as hospitals, nursing homes, etc. the injured elderly should be screened and receive necessary consultation and support services.

Electrodiagnostic Studies Role in Diagnosis and Management of Thoracic Outlet Syndrome

Mohammad Reza Kalantar Motamedi 1, Niki Tadayon2, Mohammad Karimian3
1Professor of Surgery Department of General Surgery, School of Medicine Shohada-e-Tajrish Hospital Shahid Beheshti University of Medical Sciences, 2Professor Vascular and Endovascular Surgery, Shohade-e-Tajrish Hospital, Shahid Beheshti University of Medical Sciences, Tehran, Iran, 3Assistant Professor of Vascular Surgery, Clinical Research Development Center of Imam Khomeini Hospital, Ilam University of Medical Sciences, Ilam, Iran

Abstract

Introduction: Thoracic outlet syndrome (TOS) is caused by the compressive effect on brachial plexus or subclavian vessels at the thoracic outlet. The symptoms are usually neurologic, arterial or venous or the combination of them.

Method: From these patients we chose 70 patients whom underwent surgery (resection of first rib, with neurolysis with trans axillary approach) and we had the complete data on EMG -NCV and could follow postoperative course and were completely satisfied by the operation and their symptoms was relieved according the quick DASH Questionnaire and thereby the diagnosis of TOS was proved by the result.

Result: The electro diagnostic tests of 6 patients (1.5%) were completely normal. The lower trunk symptoms which should be more frequent in TOS was purely present in 7.1%. Fibrillation and fasciculation along the course of ulnar nerve was present in 10% of cases. The middle trunk abnormal motor NCV was the pure pathology in 2.9%. Fibrillation and fasciculation along the course of median nerve (abductor pollicis brevis) 2.4% and for Brachioradialis (radial nerve) NCV was abnormal in 1.8%.

Conclusion: To prove this fact, we selected only the patients who were completely satisfied by the operation and their symptoms was relieved according the quick DASH Questionnaire and thereby we were sure that the diagnosis of TOS has been correct. Retrospectively we evaluated the electrodiagnostic findings in these patients.

Keywords: Diagnosis, Thoracic outlet syndrome, Management, Iran

Introduction

Thoracic outlet syndrome (TOS) is a condition caused by compression of nerves or blood vessels at the thoracic outlet. (1) Pain, paresthesia, and weakness in the hand, arm, and shoulder, plus neck pain and occipital headaches, are the classical symptoms of neurogenic (NTOS). Other names according to presumed etiologies such as scalenus anticus, costoclavicular, hyperabduction, cervical rib, and first rib syndromes was assigned to this syndrome. (1) The various syndromes are similar and the specific compression mechanism is often difficult to identify.

The symptoms are usually a neurologic, venous or arterial or a combination of them. Occasionally, the pain is atypical in distribution and severity and is experienced predominantly in the chest wall and parascapular area, simulating angina pectoris. (1)
Diagnosis of the nerve compression can be objectively substantiated by determining the nerve conduction velocity.

The ulnar nerve conduction velocity (UNCV) test, as described by Jebson(4) and by Caldwell and associates,(3) has widened the clinical recognition of this syndrome and improved diagnosis, selection of treatment, and assessment of therapeutic results.

Although in mild cases with no sign of nerve palsy physiotherapy to improve posture and stretch neck muscles is used primarily, in cases without improvement and the sever cases surgery is advised.

Surgical treatment involves resection of the first rib neurolysis of brachial plexus and scalenectomy, usually through the transaxillary approach except for arterial procedures, which may employ the supraclavicular approach.

**Material and Method**

We have probably one of the largest series of TOS patients. From these patients we chose 70 patients whom underwent surgery (resection of first rib, with neurolysis with trans axillary approach) and we had the complete data on EMG -NCV and could follow postoperative course and were completely satisfied by the operation and their symptoms was relieved according the quick DASH Questionnaire and thereby the diagnosis of TOS was proved by the result.

58 were female and 12 patients were male (83%-17%) median age was 40.5 years old with the range of 15-62 years.

According to the disabilities of the arm shoulder and hand score (quite DASH) the median score preoperative was 63.6 and median post-operative score with the follow up at least 24 months (2-6 years) was 13.6.

**Results**

The electro diagnostic tests of 6 patients (1.5%) were completely normal. The lower trunk symptoms which should be more frequent in TOS was purely present in 7.1%. Fibrillation and fasciculation along the course of ulnar nerve was present in 10% of cases. The middle trunk abnormal motor NCV was the pure pathology in2.9%. Fibrillation and fasciculation along the course of median nerve (abductor policis berevis) 2.4% and for Brachioradialis (radial nerve) NCV was abnormal in 1.8%.

**Discussion**

As the electro diagnostic reports are performed according the most frequent pathology compatible with the findings, TOS was only reported in 22 patients (in 31%) of our cases.

The mainstay diagnostic consideration for thoracic outlet syndrome includes the history and physical examination and although EMG-NCV findings are not necessary to confirm the diagnosis and cannot reliably rule out this diagnosis. These test are performed to show the extent of nerve damage before the surgery and save the surgeon from legal issues concerning the intraoperative nerve damage.

The subclavian vessels and brachial plexus traverse the cervicoaxillary canal to reach the upper extremity. The outer border of the first rib divides this canal into a proximal division triangle. This proximal division is composed of the scalene triangle and the space bounded by the clavicle and the first rib (the costoclavicular space (1))

The proximal division is the critical space in which the neurovascular compression happens. This space is
bounded superiorly by the clavicle and the subclavius muscle; inferiorly by the first rib; anteromedially by the border of the sternum, the clavi pectoral fascia, and the costoclavicular ligament; and posterolaterally by the scalenus medius muscle and the long thoracic nerve. (1)

The scalenus anticus, inserting on the scalene tubercle of the first rib, divides the costoclavicular space into two compartments: an anterior compartment, containing the subclavian vein, and a posterior compartment, containing the subclavian artery and brachial plexus. (1)

Many factors can cause compression of the neurovascular bundle at the thoracic outlet. The basic factor, which was pointed out by Rosati and Lord (5) is deranged anatomy, to which congenital, traumatic, and atherosclerotic factors may contribute. Bony abnormalities are present in approximately 30% of patients, either as a cervical rib, a bifid first rib, and fusion of first and second ribs, clavicular deformities, or previous thoracoplasty.

Pathologic changes in the configuration of the cervicoaxillary canal alter the normal functional dynamics and serve as the basis of the clinical maneuvers used in the diagnosis of thoracic outlet syndrome.(1)

The mainstay diagnostic consideration for thoracic outlet syndrome includes the history and physical examination. Radiographs of the chest and cervical spine, EMG-NCV, cervical myelography, magnetic resonance imaging (MRI), computed tomography (CT), coronary angiography, venography, or arteriography are not necessary to confirm the diagnosis.(1)

The symptoms and signs of thoracic outlet syndrome depend on whether the nerves, blood vessels, or both are compressed at the thoracic outlet.

Signs and symptoms of nerve compression occur most frequently; arm pain and paresthesias are present in about 95% of patients and motor weakness in <10%. Pain and paresthesias are segmented in 75% of cases, with the ulnar nerve distribution involvement more prominent. Pain is usually insidious in onset and commonly involves the neck, shoulder, arm, and hand. (1)

In some patients the pain is atypical, involving the anterior chest wall or the parascapular area; it is then termed pseudoangina because it simulates angina pectoris (1)

Urschel and associates (7) reported that these patients have normal coronary arteriograms and decreased ulnar nerve conduction velocities, strongly suggesting the diagnosis of thoracic outlet syndrome.

This atypical manifestation of the thoracic outlet syndrome is due to the neuroanatomy, innervation, and pain pathways of the arm, chest wall, and heart.

To confirm the diagnosis, we can use the compression tests from which Adson or Scalene Test is the most helpful one.

The Adson test, described by Adson in 1951(2) tightens the anterior and middle scalene muscles, thus decreasing the interscalene space and magnifying any preexisting compression of the subclavian artery and brachial plexus. The patient is instructed to take and hold a deep breath, extend his or her neck fully, and turn his or her face toward the side. Obliteration or diminution in the radial pulse suggests compression.

There is no single diagnostic test that can confirm the presence of a NTOS (1) Variable presenting symptoms, complicated by multiple anatomical anomalies, present a diagnostic dilemma to the physician. Diagnosis is usually confirmed by a combination of a proper history and physical examination and electrophysiological studies are only performed to rule out other pathologies and to have a confirmation of the extent of disease before the operation.

Electrodiagnostic studies fall under two categories: electromyography (EMG) and nerve conduction studies (NCS). EMG studies have been found useful in the diagnosis of neurogenic TOS, but may not be sensitive enough in patients with a milder form of the disease. Motor NCS can test the brachial plexus motor component at the root or cord level. Any decrease in amplitude of response is suggestive of axonal loss. Delayed conduction may implicate a demyelinating disease. (13,14) Motor conduction velocities of the ulnar, median, radial, and musculocutaneous nerves can be reliably measured, as described by Jebson. Caldwell and associates(3) improved and adapted to clinical use the technique of measuring UNCV in evaluating patients
with thoracic outlet compression. Conduction velocities over proximal and distal segments of the ulnar and median nerves are determined by recording the action potentials generated in the hypothenar or first dorsal interosseous muscles. The points of stimulation are the supraclavicular fossa, mid-upper arm, area below the elbow, and wrist.

Urschel and colleagues reported that the normal UNCV values are 85 m/s across the thoracic outlet, 55 m/s around the elbow, 59 m/s in the forearm, and 2.5 to 3.5 m/s at the wrist.

In patients with thoracic outlet syndrome, the average UNCV value was reduced to 53 m/s across the outlet (range of 32-65 m/s). (6-10)

Somatosensory-evoked potential studies have been utilized to diagnose neurogenic TOS (17,18) but may be nonspecific. (15,19)

Electromyography (EMG) and nerve conduction velocity (NCV) tests are normal in the large majority of patients with clinical signs of NTOS. When positive, the changes are usually nonspecific. In a small number of patients, usually those with cervical ribs and hand atrophy, electrodiagnostic studies reveal typical changes of ulnar neuropathy.

Assessment of Serum Visfatin Levels in Patients with Chronic Obstructive Pulmonary Diseases in Babylon-Iraq

Hamood Hathala Salman¹, Ban Mahmood Shaker Al-joda², Monem Makki Abdulridh Alshok³
¹Al-Karama Teaching Hospital in Kut, Wasit Health Department, ²Chemistry & Biochemistry Department, College of Medicine, University of Babylon, ³College of Medicine, University of Babylon

Summary

The presented study aims to evaluate the levels of serum Visfatin, in patients with chronic obstructive Pulmonary diseases in Babylon-Iraq, to find the correlation of Visfatin, with lipid profile in these patients and compared with apparently healthy as case-control study. The study included (50) patients as patients group diagnosed with COPD (G1) and (50) as apparently control group (G2). The age of all studied groups ranged between (40-65) years and BMI with (18.8-24.4) Kg/m². Serum was used in determination of FBS, lipid profile (Ch, TG, HDL-c, LDL-c and VLDL-c), insulin, CRP and Visfatin. Whole blood was used for determination of HbA1C. The results revealed significant elevation in FBG and HbA1c levels were seen in patients groups when comparing to healthy control. The results indicates a significant elevation in TC, TG, LDL-c and VLDL-c in G1 comparing to G2. Also, HDL-c significant decreased in G1 comparing to G2. Also, the results showed significant increased in CRP levels in G1, when comparing to G2. A non significant visfatin and insulin level in G1 when compared with G2 (p value = 0.486). A non significant correlation was found in G1 between visfatin, TC, TG, HDL-c and VLDL-c.

The conclusion from this study indicate that G1 which HDL-c is low in this group has the highest value for FBS, HbA1c, TC, TG, LDL and VLDL. Also, the study found non correlation between lipid profile parameters in G1.

Keywords: COPD, visfatin, Lipid profile, CRP.

Introduction

Chronic obstructive pulmonary disease (COPD) is a common, preventable, and treatable disease characterized by persistent respiratory symptoms and airflow limitation that is due to airway and or alveolar abnormalities, usually caused by significant exposure to noxious particles or gases. The chronic airflow limitation that characterizes COPD is caused by a mixture of small airway disease (e.g., obstructive bronchiolitis) and parenchymal destruction (emphysema), the relative contributions of which vary from person to person. Chronic inflammation causes structural changes, small airway narrowing, and destruction of lung parenchyma. A loss of small airways may contribute to airflow limitation and mucociliary dysfunction, a characteristic feature of the disease. Chronic respiratory symptoms may precede the development of airflow limitation and be associated with acute respiratory events (1). Visfatin, also called nicotinamide phosphoribosyltransferase (NAMPT) and previously identified as pre-B cell colony-enhancing factor (PBEF) is a 52 kDa protein encoded by the PBEF gene located on chromosome 7. It was originally discovered in lymphocytes, bone marrow, liver and muscles (2), but later identified in many other organs including the lungs (3). Leucocytes, especially granulocytes and monocytes, are the major sources of visfatin (4).

Materials and Methods

This study included one hundred with aged ranged (40-65) years and BMI ranged between (18.8-24.4) Kg/m². Subjects were divided into two groups:

Corresponding author:
ahmodlab17@Gmail.com.
Group (1) consist of (50) as Patient group diagnosed with COPD.

Group (2): consist of (50) as apparently healthy control group.

The patients attended the Marjan Medical City in Babylon Province, Hilla city, from November 2018 till March 2019. Ten milliliters of blood were collected after an overnight fasting from all subjects by venipuncture. A liquate of (0.5 ml) of whole blood was used in determination of HbA1C. The other part was left in 37°C for (15min) to clot then centrifuged at (3000 rpm) for (5min). The serum which obtained was freeze at (-20°C) until analysis of lipid profile, visfatin, insulin and CRP.

**Laboratory Tests**

Glucose was determined after enzymatic oxidation in the presence of glucose oxidase (GOD)\(^{(5)}\). Total serum cholesterol determined by utilizing a kit based on the enzymatic hydrolysis \(^{(6)}\). The absorbance was recorded for the quinonimine (red complex) at 500 nm. The determination of TG based on the enzymatic hydrolysis. The intensity of the color formed is proportional to the triglycerides concentration in the sample. The lipoproteins of VLDL, and LDL contained in the serum sample were precipitates by the addition of (4%) phosphotungstic acid solution, which contain (10%) magnesium chloride (PH 6.2). The supernatant obtained after centrifugation contains the HDL, from which the cholesterol can be determined by complementary kit used in determination of total serum cholesterol as described in reference \(^{(7)}\). LDL-cholesterol and VLDL-cholesterol were estimated indirectly by using Fried Ewald formula \(^{(8)}\):

\[
LDL-c = \text{Total Cholesterol} - (\text{HDL-c} + \text{VLDL-c})
\]

\[
VLDL-c(\text{mg/dl}) = \frac{\text{TG}}{5}
\]

Insulin and visfatin were determined by using ELIZA technique based on the sandwich method \(^{(9)}\), CRP were determined by using NycoCard CRP single test of solid phase, Sandwich-Format, immunometric assay, HOMA-IR insulin resistance calculated by using the following formula \(^{(10)}\):

\[
\text{HOMA-IR}: \frac{\text{fasting glucose} \times \text{fasting insulin}}{22.5}
\]

This work was done in the Department of Biochemistry, College of Medicine /University of Babylon and in Hilla city Iraq.

**Statistical Analysis**

The results expressed as mean ± SD. Students t-test was applied to compare the significance of the difference between all the studied groups. P-value \((p<0.05)\), \((p<0.001)\) and \((p>0.05)\) considered statistically significant, highly significant and non-significant respectively. The correlation coefficient \((r)\) test is used for describing the association between the different studied parameter.

**Ethical Issues:**

**A-Approval** by scientific committee of the Clinical Biochemistry Department, College of Medicine/ University of Babylon, Iraq.

**B-Approval** by Babylon Health Directorate, Ministry of Health and Information Centre for Research and Development of Babylon Province.

**C**-The objectives and methodology were explained to all subjects and verbal consent had been taken.

**-Study Design**

This study design was a case – control study.

**The Results**

The mean ± SD and T-test of descriptive parameters for COPD in the studied groups with aged ranged (40-65) years and BMI ranged between (18.8-24.4) Kg/m\(^2\) are presented in table (1).

*(S) significant differences.

The results in table (1) revealed significant elevation in FBS and HbA1C levels was found in patients groups when comparing to healthy control. The results indicate significant elevation in TC, TG, LDL and VLDL in G1 comparing to G2. Also, the results also illustrated significant decreased in HDL in G1 when comparing to G2.

Systemic inflammation and steroid use could be important contributory factors responsible for both COPD and hyperglycemia. Similarly, Mannino et al., also found out that COPD patients with severe and very severe airflow obstruction had a higher prevalence of diabetes. Dyslipidemia, a major risk factor for CHD and metabolic syndrome, is characterized by a cluster of lipid abnormalities such as an elevated level of triglyceride (TG), a reduced level of high-density lipoprotein cholesterol (HDL) and an increased level of low-density lipoprotein cholesterol (LDL). A number of studies have evaluated the relationship between COPD and blood lipid profiles with inconsistent results. While some authors reported reduced serum levels of HDL or increased serum levels of TG in COPD patients, the objective of the present study was to investigate the association between COPD and the serum levels of FBS, total cholesterol (TC), triglyceride (TG), HDL, LDL and VLDL. The prevalence of lipid profile abnormalities in COPD are different in studies and range of 9-50% have been reported. Smoking affects the lipid profile in the following ways. The plasma β-lipoprotein, cholesterol and triglycerides concentration are higher and HDL is lower in smoker than in nonsmokers.

Nicotine stimulates the release of adrenaline from the adrenal cortex leading to increased serum concentration of free fatty acids (FFA) which further stimulates hepatic synthesis and secretion of cholesterol as well as hepatic secretion of very low density lipoprotein (VLDL) and hence increased TGL.

Smoking decreases estrogen levels and further leads to decreased HDL cholesterol concentration. Also, HDL concentration was inversely related to VLDL concentration in serum.

Smoking increases insulin resistance and thus, causes hyperinsulinemia. LDL, VLDL and TGL are elevated in hyperinsulinemic conditions due to decreased activity of lipoprotein lipase. R. Gupta et al. study shows significantly higher LDL and significantly lower VLDL levels when compared to controls.
Table (2) showed (mean ± SD) and (T-Test) of insulin, HOMA-IR, visfatin, for studied groups. The results in table (2) showed a non-significant elevation in insulin for G1 when compared with G2, while HOMA-IR highly significant elevation was noticed in G1 when comparing to G2.

Table (2): Levels of insulin, HOMA-IR, hs-CRP & Visfatin in patients and controls.

*(S) Significant differences, (HS) highly significant differences, (NS) No significant differences.

The results in table (2), also, showed significant increase in CRP levels for G1 when comparing to G1, but visfatin levels non-significant elevation was found in G1 when comparing to G2.

The HOMA-IR is a condition in which the body’s cells become resistance to the effects of insulin. That is the normal response to a given amount of insulin is reduced. Other study results suggest that increased HOMA-IR index has significant association with COPD\(^{(17)}\), this study agreement with our result.

Results also showed highly a significant increase in hs-CRP levels in G1 when compared with G2 (p value = 0.0001). The patients with COPD had significantly higher leukocytes and CRP levels. Pinto-Plata et al. showed that CRP levels in COPD patients are significantly higher compared to the control group and the CRP level\(^{(18)}\). Two studies, one each reported by Smith et al. and Varma et al. have suggested that the serum visfatin levels are not associated with parameters of body composition or the insulin resistance. Taken together, it would appear that there is no relation between visfatin and insulin resistance\(^{(19,20)}\) this study agreement with our result.

Relationships and correlation coefficients:

Part of the study was to investigate the relationships and correlation coefficients: Relationship between visfatin, TC, TG, HDL, LDL, insulin, HOMA-IR and CRP were studied for studied groups which shown in table (3).

Table (3): Correlation coefficient and p-value between visfatin levels and other parameters for patients and controls.

A non-significant correlation was found between visfatin levels and (TC) in G1 ($r = 0.106$), as shown in figure (1), and negative significant between visfatin with G2 ($r = -0.320$).

**Figure (1): Correlation between visfatin & TC in G1**

A non significant correlation coefficients was found between visfatin and TG in two studied groups ($r = 0.130$, $r = -0.049$) respectively.

**Figure (2): Correlation between visfatin and TG in G1**
Results also showed a non-significant correlation between visfatin levels and HDL for all studied groups ($r_1 = 0.207$, $r_2 = 0.095$) respectively. Results in table (3-3) illustrated a non-significant correlation in visfatin levels with LDL in G1 ($r = 0.054$) and also in G2 ($r = 0.244$). Also, non-significant correlation was found between visfatin levels with VLDL in G1 ($r = -0.054$) and also in G2 ($r = 0.130$). Also, non-significant correlation was found between visfatin levels with VLDL in G1 ($r = 0.054$) and also in G2 ($r = 0.244$). Also, non-significant correlation was found between visfatin levels with VLDL in G1 ($r = 0.130$) and G2 ($r = 0.049$).

A non-significant correlation between visfatin and insulin levels was found in G1 ($r = 0.093$) as shown in figures (3). A significant negative correlation between visfatin and insulin levels was found in G2 which ($r = -0.026$).

A non-significant correlation between visfatin and HOMA-IR levels are shown in G1 which ($r = 0.119$), while positive significant correlation between visfatin and HOMA-IR levels are shown in G2 which ($r = 0.016$). A non-significant correlation was found in visfatin and hs-CRP levels in all studied groups which ($r = 0.204$, $r = -0.253$) respectively.

Conclusion

The conclusion could be drawn from this study that visfatin non changed in G1 comparing to G2. Also, there are non-significant correlation between visfatin levels with insulin and CRP, while positive significant correlation between visfatin and HOMA-IR levels are shown in G2 which ($r = 0.016$). As far as to our knowledge this is the first study determined the levels of visfatin in COPD patient with normal BMI and find its non-relation with lipid profile in patients with COPD.

Use Markers of Short Tandem Repeats (STR) for Samples of Bone in the Forensic Diagnosis of the Human Being in the Kerbala Governorate

Hussein Majid Mahmood1, Yasamine Khudiar Alganimi2

1Post Graduate/Biology Department, College of Education for Pure Sciences, Kerbala University/Iraq, 2Prof. Dr. Biology Department, College of Education for Pure Sciences, Kerbala University/Iraq

Abstract

STR’s analysis of DNA from bone samples plays an important role in identifying missing persons. We present a method for DNA extraction from bone samples that involve complete demineralization and digestion of the sample, followed by purification by silica binding. This method, along with the multiple STR typing approach, has also proven highly successful in recovering DNA profiles from bone samples from a wide range of contexts. These methodological steps include bone cutting and grinding, DNA extraction, Repurification in case of highly inhibited samples, quantification, amplification multiplex STR, Data Analysis of the DNA Typing and The guidelines for the preparation of personal reports. the total number of study samples reached 48, whose ages ranged between (14 to 33) years divided into 3 groups, group (1) in which (16) bone samples from the son, group (2) in which (16) blood samples from the father and group (3) It contains (16) blood samples from the mother. Conformity was carried out in the identification tests for persons in the forensic evidence laboratories of the Iraqi Ministry of the Interior, according to the protocols in the Kits used and by forensic experts.

Keywords: Forensic Sciences, Identification Human, STR typing.

Introduction

Forensic science is an area that solves legal cases in civil and criminal cases (1). Forensic is a mixture of different branches of science that can provide information to the legal courts that are imposed by investigative bodies in the criminal justice system worldwide (2).

Forensic science is a multidisciplinary field, which helps rebuild a crime scene based on the collection, analysis, and interpretation of scientific evidence. Each crime is unique in its own way. This is because the nature of the crime that was carried out, the location of the crime scene, the people involved in the crime, and the things that were used, all differ from one crime scene to the next (3).

The availability of DNA samples is absolutely essential to determine the DNA pattern in a forensic study. DNA pattern determination is a method in which genetic differences at the DNA level are used to determine an individual (4).

The DNA samples present at the crime scene or mass disasters may be insufficient in quality and quantity, because they may often contain very small amounts of DNA or may be very degraded due to prolonged exposure to various environmental conditions such as heat, light, moisture, and microorganisms (5). It is common in the forensic study to have highly degraded DNA samples from a variety of sources. Therefore, it is preferable for the collection of samples to be proper, and to handle carefully during the identification of the DNA pattern to reduce the chances of external contamination (6).
Bones are often the primary source of samples in person identification and criminal investigations. Bones are often used in forensic study because they have the ability to demonstrate resistance to extreme and severe conditions such as high temperature, humidity, and bacteriological action(7)(8).

Bones is one of the important evidence that is often found at the crime scene related to mass disasters, terrorism, human trafficking and missing persons. Morphological observations can be used by forensic scientists to determine the age, gender, residence, and race of a human individual(9).

Defining a forensic DNA pattern has a significant impact on society by providing reliable evidence to convict violators or exonerate innocent suspects. Another area for applying DNA pattern determination is paternity testing using autosomal, mitochondrial or Y chromosome markers(10)(11).

DNA is often referred to as the “genetic blueprint for life” as the individual whose genetic makeup is coded into the DNA. This is intended to mean that DNA is passed from parents to their offspring(12).

The signs currently used are known as Short Tandem Repeat (STR), and they are length polymorphs. STR are short repeating sequences that are mostly found in the not encoded areas of DNA, either within or between genes(13).

**Materials and Method**

**Sample collection:** Samples were collected from Al-Shaheed Ghazi Hospital and Al-Kindi Teaching Hospital from sick and injured people from Kerbala governorate, after their approval was obtained. The total of 16 bone samples obtained was as follows (femur: 4, hip bone: 2, tibia: 2, ulna: 1, instep: 2, hand comb: 1, radius bone: 2, Humerus: 2). 16 blood samples were obtained from the father and mother of the person.

Samples were obtained directly from the operating theaters and placed in the (Cup Tube) and saved directly in the storage box, which contains ice bags, so that they can be kept cool until they are transferred to the laboratory.

Blood samples were collected and stored on FTA Cards and kept at room temperature.

**Sample preparation:** A portion of the calcium was removed using an emery machine (Dremel, Racine, WI, USA) to ensure the sample was cleaned properly and that there were no other tissues on the bone. Then cut the large bones into small pieces and wash twice with 10% sodium hypochlorite for 15 minutes, then wash twice with deionized water for 15 minutes, once rinsed in 96% ethanol. Allow samples to dry overnight at room temperature. It is placed in marmeric slurry and liquid nitrogen is poured on it until the sample is immersed and begins to move the slurry stick in a continuous circular motion until the nitrogen dries and this process is repeated until a fine-grained powder is obtained because the more accurate the flour, the more pure the DNA is. Each bone sample is prepared separately using sterile instruments in a specially designed room(15).

**DNA extraction:** The extraction of bone samples was performed using the EZ1 DNA Investigator Kit (48) by the EZ1 Advanced XL device and extracted according to the protocol for the EZ1 DNA Investigator Kit (48) DNA extraction kit supplied with the kit and as approved by the forensic laboratories.

As for blood samples collected by FTA™ Mini Card, they are used directly with the process of DNA amplification (PCR), which will be mentioned later.

**DNA quantification:** The quantification of DNA was estimated using a 7500 REAL-TIME PCR using the Quantifier™ Trio DNA Quantification Kit with the HID Real-Time PCR software for v1.2 analyses to determine the isolated DNA. The samples were diluted according to the amplitude of the relevant short tandem frequency group (STR) amplified, while the samples that specified a small quantity of the recommended concentration were amplified using the maximum size of the DNA extract.

This group was used to evaluate the quantification of human DNA, the presence of PCR inhibitors and the level of DNA degradation (via the degradation index (DI) for each sample at one time. Data were accepted with R2 values from 0.99 or higher.

**PCR amplification**

**Bone samples:** PowerPlex® Fusion 6C System (PC) was used to amplify bone samples according to the Promega Corporation (2017) manual and according to the method used in forensic laboratories. A mixture of reaction solution was prepared for each sample in a 1.5 ml PCR reaction tube:

\[
\text{Master Mix} = 5.0\mu l; \text{ Primer Pair Mix} = 5.0\mu l; \text{ template DNA} = 15.0\mu l \quad \text{“Total reaction volume} = 25.0\mu l”
\]
The Thermal Reaction and cycling setup was performed according to the procedures described in the PowerPlex® Fusion 6C System user manuals. Reaction products were kept at 4°C until use.

**Blood samples:** A small piece (punch) with a diameter of 1.2 mm was taken from the dried spots from each of the samples saved on the FTA™ cards. The punch was cleaned with alcohol to prevent cross contamination. The punch was processed according to the manufacturer’s instructions. The punch was washed three times using the FTA™ purification reagent for 5 minutes at room temperature, followed by two washes with the TE (10 mm Tris pH 8.0, 0.1 mm EDTA). Washed punches were dried for 30 minutes at 60 °C.

FTA™ punches are placed in PCR tubes, with the following components added and final volume adjusted to 50µL with sterile dual distilled water: 200 nM per primer, 800µM DNTPs, 1.5 mM MgCl2 and 2.5 U Taq polymerase. The Thermal Reaction and cycling setup was performed according to the procedures described in the PowerPlex® Fusion 6C System user manuals. Reaction products were kept at 4 °C until use.

**Capillary electrophoresis separation:** PCR products were detected and separated by capillary electrophoresis on 3550 Applied Genetic Analyzer (Thermo Fisher Scientific, Oyster Point, CA). A mixture of 0.5 µl of GeneScan™ 600 LIZ® Size Standard v2, 9.5 µl of Hi-Di™ Formamide, was dispensed and 1.0 µl of PCR products was added to each well. The Capillary electrophoresis was performed with run settings as indicated by the manufacturer for PowerPlex® Fusion System - Promega Corporation.

**Data analysis:** Genotypes and electrical diagrams obtained after DNA separation were obtained using the Gene Mapper ID-X version 1.4 (Applied Biosystems, USA). Data were statistically analyzed using GenoProof 3 SoftwareKinship Examination (Qualitype GmbH, Dresden, Germany) (Dumache, 2017).

**Results and Discussion**

The paternity test is based on the alleles matching at STR 24 loci between the child, mother and father (Trio Cases). In this case, no genetic discrepancy was observed for the alleged relationship between the father and the child in any of the STR 24 loci. Results are shown in Table 1.

The combined parenting index was calculated (CPI) and Paternity Probability (W) for standard trio cases using GenoProof3 software. The paternity index (PI), the Combined paternity index (CPI), is then calculated by multiplying the individual PIs across, obtained from each loci tested. Using a CPI and a prior probability of 0.5, the parenting probability (W) is calculated according to the following equation:

\[ W = \frac{CPI}{CPI + 1} \]

**Table 1: The value of the paternity index father-son and the maternity index mother-son for each locus**

In the eleventh case, the results were as follows: combined parenting index was Calculated (CPI) 1,093,931,389,095 and Paternity Probability (W) 99.9999999994% and also (CPE) calculated 99.9999999995% (Paternity practically proven). In the twelfth case, the results were as follows: combined parenting index was Calculated (CPI) 76,047,184,748 and Paternity Probability (W) 99.9999999986% and also (CPE) calculated 99.9999999986% (Paternity practically proven). In the thirteenth case, the results were as follows: combined parenting index was Calculated (CPI) 194,517,436,486 and Paternity Probability (W) 99.9999999994% and also (CPE) calculated 99.9999999974% (Paternity practically proven). In the fourteenth case, the results were as follows: combined parenting index was Calculated (CPI) 176,512,622,425 and Paternity Probability (W) 99.9999999994% and also (CPE) calculated 99.9999999995% (Paternity practically proven). In the fifteenth case, the results were as follows: combined parenting index was Calculated...
(CPI) 51,637,272,228,769 and Paternity Probability (W) 99.9999999999% and also (CPE) calculated 99.9999999999% (Paternity practically proven). In the sixteenth case, the results were as follows: combined parenting index was Calculated (CPI) 69,762,623,876 and Paternity Probability (W) 99.9999999985% and also (CPE) calculated 99.9999999974% (Paternity practically proven).

The current study has shown that 24 loci of STR technology have sufficient discriminatory ability to exclude or include the alleged father in disputed parenting cases. This is consistent with many reports describing the strength of interest and discrimination of STR markers. In the paternity and identity test. The calculated paternity index values and the probability of paternity that are important in applying the paternity test DNA typing method, were high with the current STR typing, and the paternity index measures the strength of the genetic match between the alleged father and a specific child. If the alleged father and child share a low frequency allele, they will be considered strong and will give a high parenting index\(^{(13-15)}\).

When the child’s biological parent is questionable, the PCR-based STR test is the accurate choice available for paternity testing, in relation to crime issues in the current study, STR’s analysis was very useful for personal identification.

Data from this study leads to the conclusion that STR genotyping is a powerful tool for analyzing conflicts between parents. From a practical point of view, standardized methodology with high reproducibility and low cost plus the availability of STR loci in the human genome is easy to implement, making it ideal genome markers for parenting/maternity evaluation.

Specifically, in all cases of trio paternity, 24 forensic loci were effective exclusion of paternity or to provide sufficient positive evidence (strong evidence) on paternity, and to provide a high discriminatory power at a rate ranging between W 99.999999996% to 99.9999999999%, by Using a database qualified well.

**Conclusion**

Successful, STR typing is a tool genetic reliable and powerful have an important central role in the community to solve the problems of family relationships and judicial studies.

Abstract

Background: The emptied sheep’s ovarian follicles recently used as a container for spermatozoa during cryopreservation, it was found a proper carrier to cryopreserving spermatoza in vapor-dependent cryopreservation. The aim of this study was to evaluate the effect of two periods of exposure to liquid nitrogen (LN₂) vapor on the parameter of spermatozoa during cryopreservation in this technique.

Method: The study was conducted on 30 semen samples from patients with oligozoospermia diagnosed by semen analysis according to the standard criteria of World Health Organization (WHO) 2010. Sheep’s ovarian follicles obtained from local slaughterhouse and prepared by slicing the ovaries and evacuating the follicular fluid and oocyte. Each semen sample diluted 1:1 with cryosolution (glycerol 10%) and injected within eight emptied sheep’s ovarian follicles. The first four follicles represent P1; exposed to LN₂ vapor for 7.5 minutes and the other four follicles represent P2; exposed to LN₂ vapor for 15 minutes before emerged in liquid nitrogen. Sperm progressive motility, total motility, normal morphology and DNA fragmentation index (DFI) were analyzed for all samples pre-freezing and post-thawing.

Results: After two months of cryopreservation, sperm progressive motility and total motility significantly (P<0.01) increased post-thawing in P2 as compared with P1, while both of P1 and P2 significantly (P<0.01) decreased as compared with pre-freezing. Normal morphology significantly (P<0.01) decreased post-thawing in both P1 and P2 as compared with pre-freezing, while no significantly difference found between P1 and P2. DFI significantly (P<0.01) increased post-thawing in P1 and P2 as compared with pre-freezing, while in P2 DFI was significantly lower than in P1.

Conclusions: The exposure to liquid nitrogen vapor for 15 minutes in emptied ovarian follicles technique gives a better result than exposure to the vapor for 7.5 minutes regarding sperm progressive motility, total motility and DFI.

Keywords: ART; cryopreservation; human spermatozoa; LN₂ vapor; ovarian follicles; sperm cryopreservation.

Introduction

Cryopreservation of human spermatozoa is a widespread routine work in clinics of assisted reproductive technologies (ART) (¹). It is used for preserving male fertility in many cases such as prior to undergoing chemotherapy or radiotherapy, vasectomy and other activities that may affect male fertility (²). It also can be used in cases of
sperm donors to prevent the distribution of infectious diseases from donor to recipient couples (3). It is found that cryopreservation cause damage to spermatozoa and reduce its viability and motility and even the fertilization ability(4). More than 40% of sperm motility found to loss after cryopreservation (2), this may due to the damage of plasma membrane, loss of acrosome function and or DNA fragmentation (5). Cryopreservation of spermatozoa not only affect sperm motility and viability, but also the concentration of sperms decreased post-thawing due to the dilutions and washing steps (6). However, this may not appropriate for low concentrations of spermatozoa because it may loss during washing steps (7,8). This reason spur many researchers to experimented different techniques for cryopreserving the low concentrations of spermatozoa(7–12).In our recent under-publication techniques for cryopreserving the low concentrations of spermatozoa, we succeeded in cryopreserving different concentrations of spermatozoa using sheep’s emptied ovarian follicles as a vehicle to carry spermatozoa during cryopreservation in order to minimize the loss of cryopreserved spermatozoa. In emptied ovarian follicles technique, spermatozoa cryopreserved by exposing to Liquid Nitrogen($\text{LN}_2$) vapor before immersed into $\text{LN}_2$. Therefore, this study builds on our prior results, to determine the best time of exposure to $\text{LN}_2$ vapor during cryopreservation of spermatozoa in this newly invented cryopreservation technique.

**Materials and Method**

**Subjects and samples collection:** Thirty semen samples were collected from oligozoospermic patients (their sperm concentration $\leq 15 \times 10^6 \text{mL}^{-1}$) their ages ranged from 22 to 57 years old. They attended to the Fertility Center Clinic at Al-Sadr Medical City, Najaf, Iraq, during the period from February 2019 to November 2019. The samples collected from the subjects by masturbation after 3 days sexual abstinence and analyzed according to the World Health Organization (WHO) 2010 standard guidelines using a light microscope (Optica, Italy) to determine the sperm parameters (sperm concentration, total motility, progressive motility, normal morphology). Each sample was analyzed twice by only one experienced biologist to avoid any personal variations.

**Ethical approval:** This study was ethically approved by the medical ethics committee in Jabir Ibn Hayyan Medical University, Iraq (Approval No: 19-0003). All the patients gave their informed agreement for research before they gave the semen samples.

**Experimental design:** After seminal fluid analysis (SFA) and DFI assay, each semen sample diluted 1:1 with cryosolution using SMART medium (14) with (10%glycerol) and injected within eight emptied sheep’s ovarian follicles. The first four follicles represent P1; exposed to $\text{LN}_2$ vapor for 7.5 minutes and the other four follicles represent P2; exposed to $\text{LN}_2$ vapor for 15 minutes before emerged in liquid nitrogen. Sperm progressive motility, total motility, normal morphology and DFI were analyzed for all samples pre-freezing and post-thawing.

**Collection and preparation of sheep ovarian follicles:** A total of 240 ovarian follicles were sliced from 186 sheep’s ovary used in this study. The sheep ovaries were collected from local slaughterhouse in Najaf city. The ovaries were collected directly from the ewes after slaughtered and kept at 32-35°C with normal saline solution (0.9%NaCl) supplemented with two types of antibiotics (100mg/ml penicillin and 100mg/ml streptomycin). The ovaries then, transported to the laboratory within 1 hour. In the Laboratory, ovaries washed three times using normal saline solution (37 °C) to remove the clotted blood and reduce contamination on the ovarian surface (15). After washing, the ovaries differentiated according to the size of ovarian follicles. The ovaries that contain follicles less than 0.3 mm in diameter were excluded, and those contain follicles larger than 0.3 mm in size sliced to remove the medulla and allows the follicles to be fit inside the cryotube. Then, the ovarian pieces that contain the follicles were stored at 4°C till the semen prepared.

**Process of sperm cryopreservation:** The prepared ovarian follicles emptied from the oocyte and follicular fluid using 23-gage sterile hypodermic needle with a disposable 2mL syringe. Then, each part of all the semen samples injected in 8 emptied follicles and inserted into two cryotubes (Thermo-scientific 1.8mL) (4 follicles in each cryotube) and covered with cryosolution. One cryotube exposed to $\text{LN}_2$ vapor for 7.5 minutes and the other exposed to $\text{LN}_2$ vapor for 15 minutes (2cm above the surface of $\text{LN}_2$), then, the cryotubes plunged inside $\text{LN}_2$ and stored at -196°C for two months using cryopreservation $\text{LN}_2$ tank (MVE SC series $\text{LN}_2$ tank 40L).

**Thawing Process:** After two months of cryopreservation, each cryotube was taken out from the $\text{LN}_2$ and immersed inside water bath at 35°C for 5 minutes, then, by using forcipes, the ovarian follicles
transferred from the cryotube to a clean Petri dish and the samples withdrawn from the follicles using 23-gage sterile hypodermic needle with a disposable 3mL syringe. The volume measured and the sample diluted 1:1 with the thawing solution (SMART medium plus 0.25M sucrose) and then utilized for analyzing the sample’s parameters (sperm concentration, motility, normal morphology and DFI).

**DNA fragmentation assay:** Sperm DFI was determined in both fresh and thawed semen using Acridine Orange (AO) fluorescence stain. The AO stain was prepared according to Tejada et al. (16). The evaluation of DFI done using fluorescent microscope with excitation at 450–490 nm to count sperms in at least 5 fields. The normal spermatozoa with intact double-stranded DNA stained green while spermatozoa with fragmented DNA showed red or orange fluorescence (Figure 1). The DFI was calculated by measuring the percentage of DNA Fragmented spermatozoa (16).

**Statistical analysis:** The statistical analysis system (SAS) program (2012) was used to analyzed the data. Parameters in this study were expressed as the means and standard deviations (mean ± SD). The least significant difference (LSD) test and analysis of variation (ANOVA) were used to analyze the differences between groups. The p-value of less than (0.01) was considered significantly different.

![Figure (1): DNA fragmentation assay using Acridine orange stain under fluorescent microscope (magnification power 40X). Green sperms ranked as spermatozoa with intact DNA, orange and yellow sperms ranked as DNA fragmented spermatozoa.](image)

**Results**

Sperm concentration was significantly (P<0.01) decreased in both post-thawing groups when compared to pre-freezing, meanwhile, no significant difference were observed in sperm concentration post-thawing between P1 and P2.

Progressive sperm motility (%) and total motility (%) found to be significantly (P<0.01) higher in samples exposed to LN$_2$ vapor for 15 minutes(11.91±3.56) (22.07±4.36) respectively as compared with samples exposed to LN$_2$ vapor for 7.5 minutes (8.23±3.05) (14.08±4.73) respectively, while both groups significantly (P<0.01) decreased as compared with pre-freezing (26.22±5.18) (34.92±6.25) respectively.

Normal sperm morphology (%) significantly (P<0.01) decreased in both post-thawing groups when compared with pre-freezing (25.19±3.79), meanwhile, in samples exposed to LN$_2$ vapor for 15 minutes, normal sperm morphology (23.02±0.35) observed to be slightly but not significantly higher than in those exposed to LN$_2$ vapor for 7.5 minutes(22.20±0.39).
DFI significantly (P<0.01) increased post-thawing both in P1 (42.91±2.18) and in P2 (39.6±3.01) as compared with pre-freezing (35.75±3.41), while in P2 (samples exposed to LN2 vapor for 15 minutes) DFI significantly decreased as compared with P1 (samples exposed to LN2 vapor for 7.5 minutes) (Table 1).

**Discussion**

Human spermatozoa can be cryopreserved by one of three main protocols: slow freezing\(^{(17)}\), rapid or vapor-dependent freezing \(^{(18)}\) and ultra-rapid freezing (vitrification) \(^{(19)}\). In this study, samples were cryopreserved using the direct contact between the cryotube that contain the samples and the LN\(_2\) vapor for two periods of exposure (7.5 and 15 minutes) in view to determine the effect of the two periodson the parameters of cryopreserved spermatozoa. This method is one of the most popular method in human sperm cryopreservation \(^{(20)}\). Esteves et al.\(^{(6)}\) confirmed that this method preferable than slow graduating cryopreservation for human spermatozoa. Rahiminia et al. in 2017\(^{(21)}\) concluded that human sperm DNA, chromatin and acrosome integrity status were more tolerable during cryopreservation with LN\(_2\) vapor rather than in vitrification.

In comparison between the two periods of exposure to LN\(_2\) vapor in this study, the recovery of progressive and total motility increased significantly (P < 0.01) in 15 minutes than in 7.5 minutes. This reflect that the extend period of exposure to LN\(_2\) vapor may reduce the plasma membrane damage of the cryopreserved spermatozoa during freezing process, and this in turn increase the recovery rate of sperm motility post-thawing. For the same reason, normal sperm morphology slightly improved with the exposure to LN\(_2\) vapor for 15 minutes.

In addition to conventional sperm parameters, DFI gives more information on men’s reproductive potential. Spermatozoa with fragmented DNA have been reported to be contributed in failure of fertility and loss of pregnancy \(^{(22)}\). Although the negative effect of cryopreservation on sperm motility, morphology, and viability post-thawing has been studied widely \(^{(19)}\). The effect of various cryopreservation method on sperm DNA integrity still controversy \(^{(23)}\). Several studies demonstrated that cryopreservation increase sperm DNA fragmentation post-thawing \(^{(18,24)}\) and other studies indicated that cryopreservation did not affect sperm chromatin integrity and not increase sperm DNA fragmentation \(^{(25,26)}\).

The main causes of DNA fragmentation seemed to be the increase in reactive oxygen species (ROS) during sperm cryopreservation as well as the formation of intracellular ice crystals \(^{(27,28)}\). The results of this study found that DFI significantly decreased with the exposure to LN\(_2\) vapor for 15 minutes when compared with the exposure to LN\(_2\) vapor for 7.5 minutes. This may refer to the positively role of the exposure to LN\(_2\) vapor for 15 minutes in reducing the formation of intracellular ice crystal and reducing the formation of ROS during freezing process. Exposure to LN\(_2\) vapor for 15 minutes previously used in human sperm cryopreservation. In conclusion, the exposure to LN\(_2\) vapor for 15 minutes before emerging the samples directly into LN\(_2\) gave better results regarding sperm motility, morphology and DFI than the exposure to LN\(_2\) vapor for 7.5 minutes in this technique of sperm cryopreservation.

Abstract

Somatosensory evoked potential (SSEP) usually done using bipolar surface stimulator of peripheral nerve and recorded by cortical surface or subdermal needle electrodes, in this study we modify an adhesive large surface area, surface stimulator using the same montage and method then compare the result between them. We took nineteen patients of median nerve SSEP, locate and identify the shape of dermatom assigned according to text using large square adhesive surface electrode. The same as the shape of dermatom, this is the cathode electrode, for the anode, a strip has the same length of the cathode with a width of two centimetres placed beneath the cathode, the circular ground band between stimulated and recording electrode. The subjects In this study prepared for routine SSEP study the result obtained of both study compared using statistical method and we found there was a significant different between two method and the modified as higher amplitude using lesser stimulated threshold but not significant different between latency. That’s happened because we increased the surface area of stimulation which means more the motor nerve was stimulated.

Keyword: Somatosensory, evoked potential, electrode, electrical charge.

Introduction

Definition and review: The electrical signals were a response by evoked potentials that formed by nerves that work as receiver for stimulation.¹ Nerves disorder was diagnosed by computer testes, site and type of nerve damage, and provided a clear view about patient’s condition after and during the surgery, wherever several types of evoked potential tests that used for that purpose. The all used to induce mild stimulation the nerves to receive and send the impulse to and from the brain. The electrodes polar put on several sites on the skin for recording the work nature of the brain and spinal cord.

Type and degree the responses are recorded and analyzed by specialized computer software and the results are printed on paper as a chart. (2,3)

Prior to the production of muscle force, ion exchange across muscle fiber membranes, results in production of small electrical currents, which is generated by muscle fibers to produce muscle action. These currents represent the main part of the signaling process for the muscle fiber contraction. EMG can be measured by using specific elements to conduct the signals either superficially by applying electrodes to the skin or invasive intramuscular elements. Surface EMG method of measurement are the most common method, It is non-invasive, and it doesn’t need medical heath professional to conduct it. Surface EMG measurement, depending on many factors including UV and low mV range (5). The properties of the sEMG are affected by many factors such as⁴,⁵

• The time needs for muscle contraction
• The strength of muscle contraction
• The space between the electrode and the active muscle area

The elements of the underlying tissue (e.g. thickness of underlying skin and adipose tissue)

- The character of electrode and amplifier
- The electrode and skin connection quality

In many situations the data of the time and muscle contraction strength is required, the other factors increased the variation in the EMG records, which makes the result analysis more complicated process. However, the influence of the non-muscular factors on the sEMG can be reduced by:

- Using the same parameters (electrodes and amplifier)
- Maintain consistency of the electrodes- skin contact

The Importance of Skin – Electrode Impedance:
The constant impedance is a very important factor for the EMG measurement accuracy. Recent design of the pre-amplifier has minimized the importance of EMG measuring with low level of electrode –skin impedance. The level of muscle impedance is not a significant factor, while the impedance stability with the time and the impedance balance between electrode sites has a significant effect on the signal to noise ratio of the sEMG measurement. To minimize the noise components, it is very important to ensure the balance in impedance between electrodes sites. The perfect balance of the impedance at each site doesn’t require, but the relative similarity is required. The impedance balance level is not arbitrary it depends on the pre-amplifier. The energy levels of the electrical signals determine by the impedance at each electrode sites. The signal strength gets in the process of differential amplification, as a consequence of the impedance differences between electrode sites. The common signal components canceled by differential amplification. In a similar way the D/C voltage potential will not be cancelled. Pre-amplifier instability and inaccuracy occurs when the pre-amplifier doesn’t have sufficient D/C noise suppression in the residual D/C component.

Skin Preparation: The electrode – skin bind results in a D/C voltage potential, generated by impedance increment from the outermost layer of skin, including dead skin material and oil secretions. This D/C potential, common to all electrodes, can be minimized with proper skin preparation.

Types of Electrodes: The most common surface electrodes include:

- Dry electrodes in direct contact with the skin
- Gelled electrodes using an electrolytic gel as a chemical interface between the skin and the metallic part of the electrode

Recommendations for Bipolar sEMG Electrodes has recommendations for construction of bipolar EMG electrodes (sensors) including:

- Electrode form
- Electrode size
- Inter-electrode dimension
- Electrode components
- Electrode structure

Electrode Shape:

- The “electrode shape is defined as the shape of the conductive area”. There are different shapes of electrodes, varies as circular, square, and bar shaped electrodes. Each electrode site must have the same surface area.

Electrode Size:

- Electrode size is defined as the size of the surface of a conductive area of a sEMG electrode. Upon an increase of the size area of a sEMG electrode, Upon an increase of the size area of a sEMG electrode, it is expected that the view of the electrodes increases. No quantitative data on the extent of this effect on the EMG characteristics is available at the moment. For bipolar sensors, in general, the size of the electrodes should be large enough to record a reasonable pool of motor units, but small enough to avoid crosstalk from other muscles.”

Material and Method

During eleven months (10th January 2018 till 19th of December 2018), twenty five cases of the median nerve, located and identified the shaped of dermatom assigned according to text using large square adhesive surface electrode the shape of dermatom. This is the cathode electrode for the anode a strip has the same length of the cathode with a width of two centimetres placed beneath the cathode, the circular ground band between the stimulated and recording electrode; the study was conducted at Erbil teaching hospital. The data collected was from random simple cases fulfilling the above
criteria SSEP, with a comparison groups analysis data done based on the reading of old and modified method for the median nerve.(8) SSEPs are usually used electrical stimulations into either dermatomes or significant nerve trunks. dermalomal SSEPs (DSSEPs) are meaning responses that done by dermatomal stimulation.

DSSEPs are used needle electrodes in the dermal and subdermal surface. Theoretically, the sites that stimulated by electrodes will produce responses into a nerve root. The responses are done medically in more than one nerve root. Dermatomal maps are included the best location for the best dermatomal responses (9)

Stimulating of the median nerve in the wrist is done for recording the response electricity by two polar the anode in proximal of the palmar, and the cathode set at three cm proximal to the anode polar, between the tendons of muscle.

Stimulating the median nerve is at the wrist region by placing the cathode pair at (2-4) centimetres of the wrist between the muscle of flexor carpi radialis and the palmaris longus. The used current uses square wave has 20 mA- 5.1 Hz and during 200 msec. Stimulation and recording are done by using a disposable intradermal needle. The reading starts and recorded gradually, and the stimulation increases to reach simple twitching in the muscle. (Macdonald DB, 2006) CPz, CP1, CPE are the location of the active electrodes at FPz depend on the international 10-20 system as figure (1). While on the forehead, the ground electrode was put between the recording sites and stimulating. The electrodes stayed less than five KOhm and required time is (50-100) msec(11).

Stimulation of nerves is done by using monophasic square pulses for (0.1-0.3) seconds. The stimulus is done either by steady constant current or constant voltage. See Figure 1

The contact should be without resistance for following causes:

• For decrease patient discomfort.
• The nerve become effective when the voltage constant.
• To decreasing the electrical stimulus in the recorded information.

The stimuli should be high in the intensity at accepted ranged where the patient should be anesthetized during making the process. The high intensity stimulus is favorite advisable for giving safety margin in decreasing nerve stimulation during operation surgery. Ischemia of the nerves and limb edema are Factors results in reducing the efficacy of nerve stimulation.

**Stimulus Rate:** Avoiding rapid stimulus delivery rates, wherever, the normal rate is (3-6) stimuli each second. And should avoid low rates such as frequency (5.0) Hz, the signal decrease the noise. If the stimulus ratio is under harmonic of the recurrence, the frequency noise must be same phase in each data time.

The characteristics of SEPs that should detected such as component amplitudes, peak latencies and waveform morphology. Wherever, component amplitudes are status during several tests of SEP recordings. Peak latencies are consistent across subjects, while the amplitudes demonstrate great contrast. Therefore, analysis of SEP diagnostic studies is based on peak latencies and measures derived from them.

![Figure 1: Median nerve SSEP recorded](image-url)
Result and Discussion

A total of 15 cases were meeting the inclusion criteria between two kinds of electrodes, no studies involved randomized comparisons, and all were simple case series. Patient age were (20-63) years, and the ratio was 2.12:1 and we excluded the value in the table 1 because we take the normal cases.

Table 1: Value of latency and amplitude don’t including in this study

<table>
<thead>
<tr>
<th>Cortex</th>
<th>P14</th>
<th>N20</th>
<th>P25</th>
</tr>
</thead>
<tbody>
<tr>
<td>Latency (msec)</td>
<td>14.8±1.2</td>
<td>18.9±0.4</td>
<td>23.6±0.32</td>
</tr>
<tr>
<td>Amplitude (uV)</td>
<td>3.0±1.4</td>
<td>2.8±0.3</td>
<td>1.85±0.69</td>
</tr>
</tbody>
</table>

For most techniques, an acute 50% amplitude drop or 5% to 10% latency increase is considered clinically significant. Smaller degrees of background variability in latency and amplitude are common but not generally of clinical significant.

That is the main problem in all patients, the traditionally used test is very painful, and in most cases the pain is unbearable. To solve this problem the area of the examination was expanded which in return reduce electrical charge and reduce the level of pain for the patients.

Statistically when increased the area that is mean decreased the electrical charge and the pain with less time.

In this study we are changed in the electrode from 1 cm in the old electrode and to modified electrode to 7 cm and then increased the stimulated with low electricity and stimulated the same region in the brain by nerve or by skin, and we found the decreased of pain when increased the surface is that mean more area was stimulated.

Advantages of the new method:

1. The traditional procedure is extremely painful causing the patient to move to make the results more valid.

2. The new test is available on the market at reasonable prices.

Charge density is the amount of electric charge per unit length, surface area, or volume at any point in a volume. Surface charge density is the quantity of charge per unit area, measured in coulombs per square meter (C∙m⁻²).

Electric charge is the physical property of matter that causes it to experience a force when placed in an electromagnetic field.

\[
\text{Charge density (C/m}^{-2}\text{)} = \frac{\text{current}}{\text{Area}}
\]

In brief, figure (2) shows a scatter plot XY, in which the Y axis shows the difference between the two paired measurements (Old electrode – modified electrode) and the X axis represents the average of these measures ((Old electrode + modified electrode/2). In other words, the difference of the two paired measurements is plotted against the mean of the two measurements. B & A recommended that 95% of the data points should lie within ± 2SD.

The figure shows that the average discrepancy between two method is not large enough to be important which support that there is a good agreement between the two used method. Thus, we can say that there is a clear relationship between Old electrode and modified electrode.
Figure 2: The correlation between pressures estimated by Old electrode and modified electrode, the blue line is mean, the red line is + 2SD

Conclusion

This study has investigated the difference in results between applying Old electrode and modified electrode in patients with different neurosurgery exam. It has shown some aspects that must be considered during doing the exam. I recommended studying the difference between the two techniques in other diseases to know the effect of the nerve which is obviously has an important effect. We also recommend to give more attention to the type and size of electrode depended on the different area investigation.

Investigation the Association of the VEGFR-2 and -2578C\A Polymorphism as a Risk Factor for Incidence of Lung Cancer in Babylon Province

Ali K. Dahir¹, Alaa S. Al-Awad², Moaed E. Al-Gazally³

¹College of Medicine, Babylon University, Iraq, ²Prof. Dr., Oncology Center, Merjan Teaching Hospital, Babylon, Iraq, ³Prof. Dr., College of Medicine, Babylon University, Work Now at University of Al-Ameed, Iraq

Abstract

Background: VEGF gene polymorphisms can induce either increase or inhibition of VEGF secretion, with altered promoter activity.

Aim: We investigated the association of the VEGFR-2 and -2578C\A polymorphism in the VEGF gene with Lung cancer risk in Babylon province. Methodology: VEGFR-2 level was measured by Enzyme Linked Immunoabsorbant Assay ELISA and Genotyping of the VEGF-gene variation (-2578A\C) was performed using the amplification refractory mutation system PCR. We investigated the association of VEGF gene variants with different clinicopathological features of lung cancer patients.

Results: No significant difference was seen of the VEGFR-2 levels in lung cancer patients when compared with control group (P=0.92), the allelic frequency of -2578 A\C VEGF gene no difference was seen in patients lung cancer (p=0.652). Hardy-Weinberg equilibrium showed a significant difference cases group (p=0.016), also revealed A allele exhibits a pathological behavior and it appears in over-dominant model (p=0.05), this proves that there is significant association of -2578A\C VEGF gene in lung cancer patients.

Conclusion: Our results showed no significant association of the VEGFR-2 in lung cancer patients while showed a significant association of the VEGF -2578C\A polymorphism with LC susceptibility in Babylon province. The VEGF -2578C\A heterozygote significantly increases the risk and can be useful as a predisposing genetic marker.

Keywords: Lung cancer, VEGFR-2, polymorphism, dominant model.

Introduction

Lung cancer (LC) is the main cause of cancer-related deaths worldwide, it is a complex and highly heterogeneous disease[1]. About two million person are diagnosed with lung carcinoma each year and most of them diagnosed at an advanced stage[2]. Iraqi cancer broad reports that Lung cancer is the second most common cancer in the Iraq province[3]. The lack of effective treatment choice and high mortality make lung cancer a major public health challenge all over the world[4]. With the advent of next-generation genotyping and in-depth understanding of the molecular biology of lung cancer, genotyping of single-nucleotide polymorphisms (SNPs) may be pivotal in the personalized treatment for patients with lung cancer[5]. Angiogenesis it is known as complex process of the formation of new networks of blood vessels. Angiogenesis has a major role in tumor progression and metastasis[6]. VEGF plays a major role in the progress and prognosis of malignancy[7]. VEGF is an important in establishing a vascular supply within the tumor in lung carcinoma[8]. The VEGF/VEGF-receptor axis is composed of multiple ligands and receptors with overlapping and distinct ligand–receptor binding
specificities, cell-type expression, and function[9]. VEGFR-2 is a type V receptor tyrosine kinase mainly known to be expressed in vascular endothelial cells and encoded by the KDR gene[10]. This receptor responds to the signal of VEGF binding, which initiates a phosphorylation cascade that ultimately involves nuclear regulatory targets resulting in enhancement of endothelial proliferation, angiogenesis and cell migration[11]. The VEGF gene is located at chromosome 6p21.3, covering 14 kb in length with 8 exons and 7 introns [12]. Being highly polymorphic, about 30 single SNPs have been identified and described [13]. Several SNPs of VEGF have been reported to be associated with individual susceptibility to cancer and can alter the VEGF expression and protein production[14-20].

Materials and Method

Determination of Serum VEGFR-2 Concentration: The VEGFR-2 concentration is measured by enzyme linked immune-absorbent assay kit (Sandwich-ELISA) type as the method[20].

DNA Extraction: DNA were extracted by the procedure depending on manufacture protocol and was detected by using agarose gel electrophoresis technique[15].

VEGF -2578C/A (rs699947) genotyping: VEGF -2578C/A genotyping was detected by using amplification-refractory mutation system –PCR (ARMS-PCR). ARM Systems are based on the use of sequence-specific PCR primers that allow amplification of test DNA only when the target allele is contained within the sample. Following an ARMS reaction the presence or absence of a PCR product is diagnostic for the presence or absence of the target allele. The VEGF -2578C/A genotyping primers were designed by using primer3 software as showed in table(1)[25]. The ARMS-PCR done in a reaction volume of 20µL containing MgCl$_2$ (0.5µL), FO- 1µL, RO- 1µL, RI-1µL, RI-1µL of 10pmol of each primers and 8µL from Master Mixof2.5X(Cyntol, Russian). The final volume of 18µL has been modified by adding nuclease free ddH$_2$O (5.5 µL). Finally, the DNA template (2µL), was added from each cases.

Amplification conditions of VEGF genotyping: The amplification conditions used were at 94 C for 5 minutes followed by 35 cycles of 94C for 35 sec, 63 C for 40 sec, 72 C for 45 sec followed by the final extension at 72 C for 5 minutes. The amplification products were separated by electrophoresis through 2% agarose gel stained with 3µL ethidium bromide and visualized on a UV transilluminator. Primers FO and RO flank the exon of the VEGF -2578C/A gene, resulting a band of 353bp to act as a control for DNA quality and quantity. Primers FI and RO amplify a wild-type allele (C allele), generating a band of 229 bp, and primers FO and RI generate a band of 149bp from the mutant allele (A allele). The best temperature was determined to be 58°C in the temperature range of 55°C to 63°C tested with a gradient PCR thermocycler. The annealing temperature was lowered from 60 to 58°C to favor the binding of both forward wild and reverse mutant primers that contain mismatches to the templates. The number of cycles was increased from 30 to 35 cycles, significantly enhancing the yields of all three PCR products. Together, these changes resulted in a more robust amplification of the mutant allele and a less competing reaction from the control, as shown by the relative intensities of the corresponding bands on agarose gel electrophoresis.

Results

The present results on patients showed that high age frequency of cancer occurred between (45-80) years old. The mean and standard deviation of age for lung cancer patients when compared with control group, as showed in table(2). The current results on patients showed that high age frequency of cancer occurred between (45-80) years old, this due to the lung cancer incidence is very low before age 25 years and increases with increasing age up to 40 years due to several causes such as environmental factors, the nutrition, poor health education, radiation exposure, smoking, repeated injuries, and previous lung disease[16]. The current results agree with many studies in Iraq performed on lung cancer[17-19], they expected that the risk of lung cancer is higher in middle age and elderly Men and women than in younger, this risk increase as a woman and Men ages, rising sharply after the age of 50 years old.

VEGFR-2 concentration in the serum: This results showed no significant difference for VEGFR-2 serum concentration in lung cancer patients when compared with control groups, P-value=0.92, as shown in the table(3).

Genotyping of the VEGF gene variation(-2578A/C)rs699947: The Hardy-Weinberg Equilibrium Analysis: The genotype distributions and allele frequencies of the SNPs -2578C/A located in the VEGF gene showed a deviation from HWE(P=0.016) in the
patients group while the genotype distributions and allele frequencies of the SNPs-2578C\A showed no deviation from HWE (p=1) in the control group.

**Study population:** All demographic characteristic of the subjects are showed as follows a total of 45 Lung cancer patients and the same number of gender matched healthy control were analyzed. This research was confirmed by the Research ethics committee, University of Babylon college of medicine. Blood(5ml) samples were collected from participants in EDTA and gel tubes.

The VEGFR-2 level in different genotype individual of the -2578 C\A VEGF gene: This study has shown no association of the VEGFR-2 levels in different individual that carry different genotype of the -2578C\AVEGF gene. P-values>0.05.

**Discussion**

Several studies detect a significant increase in VEGFR-2 in Lung cancer patients as a result of angiogenesis process because of the increased need for oxygen. This study did not show the significant difference in the VEGFR-2 levels of the two groups, and this does not agree with [20-22], that revealed a significant difference in regards to VEGFR-2 levels in lung cancer patients when compared to control groups. VEGF plays a paramount role in an angiogenesis through different mechanisms[23]. High VEGF expression is associated with tumor growth and metastatic process, while the inhibited VEGF expression results in suppressed growth of cancer[24]. Several functional polymorphisms of the VEGF gene that may affect serum VEGF expression level, included −634G\C, −1154G\A, 936C\T, −1498C\T, −2578C\A, and −460C\T [25]. The −2578C/A of VEGF gene, have been demonstrated to modulate the levels of VEGF expression in tumor growth especially with lung cancer[26]. Recently, the effects of the VEGF gene polymorphism on the Lung cancer risk have been extensively studied; however, the results of these studies were conflicting and ambiguous. The findings of our study proposed that VEGF -2578C\A variant significantly increased the risk of Lung cancer. These results indicate that relative risk of lung cancer associated with −2578C/A of the VEGF gene lung carcinoma in their patients. The present results agreement with[27-29], all of which demonstrated a high significant correlation of the-2578C\A VEGF with lung carcinomas, and not agreement with Liu C et al 2015 and Yang F et al 2018[30] these studies were conducted on Asians, Caucasians and Indians it did not show a significant association of the -2578C\A VEGF gene and lung cancer. In conclusion, our result showed no significant correlation with regards to levels of VEGFR-2 in lung cancer patients while showed a significant associations of VEGF -2578C\A polymorphism with LC susceptibility in Babylon population. VEGF -2578C\A in over dominant model significantly increases the risk of Lung cancer and can be useful as predisposing genetic marker for LC.

Psychological Stress among Dental Students at Al-Iraqia University after Corona Virus Pandemic

Mohammad M. Abdulrazzaq¹, Marwah M. Adnan², Zeena T. Abdulhadi Al-Ani³

¹Lecturer, ²Assist. Lecturer, ³Lecturer, Department of Conservative Dentistry, College of Dentistry, Al-Iraqia University, Baghdad, Iraq

Abstract

Aim of the Study: Among undergraduate dental students at Al-Iraqia University after “Covid-19” pandemic, this study was done in order to evaluate the amount of psychological stress between them.

Materials and Method: By the use of the General Health Questionnaire (GHQ-12), Psychological stress was evaluated among (305) students who asked to fill completely the supplied questionnaires.

Results: The highest level (22.3%) was found at the 1st stage, and generally among female higher than male, (60.9%) scored more than 3 on the (GHQ- 12) vs. (38.8%) for male, at p=0.05 which was considered to be statistically significant.

Conclusion: Despite the changes in the curriculum and the gradual increase in the number of students. The different sources of stress from the year 2020 were mostly unaltered in our study. To minimize stress among dental students during certain conditions further studies is needed.

Keywords: “Covid-19”, Stress, Dental Students.

Introduction

One of the most stressful health professions was Dentistry (1-5). Since the survey of Kay and Lowe, in the United Kingdom among the dental practitioners, observed that this risky demanding profession and continually dentists appear to be pleased as participants of profession companies (6).

From all over the world, the subject of interest for most searchers was the stress among this group of students in this field (7-20), which was considered to be a higher level if compared with medical students, even they might also have a little bit psychiatric signs which may also lead to consider them psychiatrically sick and may also be in some cases the want for psychiatric remedy is indicated (20). This occupation because of its stress may negatively affect their performance (21,22), this relation was found by Sanders and Lushington (23).

In our college the machine of find out about for undergraduate is a dental regimen of 5 years. The (first and second years) were the preclinical while the mainly preclinical is the (third year) otherwise the (fourth and fifth years) the performance of the clinical portion of our study. It was supposed that anxiety because of the “Covid-19” was experienced in about 24.9% of college students (24).

Aim of the study: The purpose of this study was to determine the stress in undergraduate dental students at Al-Iraqia University, during 1st peak of “Covid-19” pandemic the level of stress among dental students. In addition, we also liked to locate if gender and stages has effect on the results of this study.

Materials and Method

All undergraduate (460) college students at our dental university enrolled at Al-Iraqia University at some point of the educational year 2019–2020 and after 6 months of pandemic attack of “Covid-19”. Our college students had been contacted electronically via this method, and the questionnaires had been stuffed and return to us except extend on line with the aid of the usage of Google sorts and documents had been gathered by way of sheet sorts immediately.

In this article, one of the questions was about the first choice of the student that he prefers whether medicine or dentistry, the first question asked for students’ demographic data, age, sex. (GHQ-12) represent the questionnaires which was delivered to the students (General Heath Questioner) and the administration had been well-known by means of the dean’s place of business of our dental college.

In the beginning it was explained to the students the aim of this study, and they realized that participation was voluntary, nameless, and with illustrative pictures. Not more than 10 minutes was required to fill these questioners, students at virtual classes were all invited to participate. It was all in English Language. This questioner will measure psychological distress (25). In number of studies its reliability and validity have been proven (26). An enlarge in psychological distress as evaluated from first- to fifth-year university college students (27).

It is a twelve-item questionnaire, with 5 solutions to each question. The man or woman is requested to think about the ultimate two months in answering the questions. “Have you felt constantly under stress?” and “Have you been losing confidence in yourself?” are Examples of these questions. The present solutions are no greater than usual. The scoring strategies have been used for the (GHQ-12), yielding a specific (high vs. low stress) result variable.

The (GHQ-12) was first scored using the 1-5 scoring method as in the investigation by Guthrie et al (28). A rating of 1 means two low stress objects and a rating of 5 means two excessive stress objects from the 5 feasible solutions. The whole for the twelve questions was once then calculated when the scoring technique is used. It has a clear crossing factor of extra than three, and individuals who were more than score 3, are considered to have an evidence of psychological stress. The crossing element of increased than three used to be arrived at with the useful resource of Guthrie et al (29).

We reached a whole score by scoring the responses and summing it. The imply rating for the questioner was once then calculated.

Results

This descriptive study had been applied in Al-Iraqia University of dentistry with about 305 college students from university had been participated in this on-line types questioners to give an explanation for the relation between the stress occurs during education with of undergraduate student in the duration of “Covid-19” pandemic (Table 2).

Frequency distribution means, and standard deviation had been calculated for the (GHQ-12). The arrangement of the questionnaires depends on (Cronbach’s alpha). Chi square test of independence had been utilized to test the association between demographic and questions asked. P-value < 0.05 considered statistically significant.

This table describes the stress and the variation of it according to the gender male and female (table1).

**Discussion**

This descriptive research had been done in the 1st peak of “Covid -19” with undergraduate dental students from Al-Iraqia University, this research has been taken apart with different 5 stages to explain the level of stress which effect the undergraduate students at the period of the pandemic.

This research have been done with the aid of Google forms and then these forms had been sent to the students by an email due to the spread of viral infection and to reduce face to face contact so depend on social media in filling the questioners via all participated undergraduate students30, these questioners had been answered by a 305 undergraduate students whom seems to be at different stages 98 students were male in the collage and 207 were female, and the result indicated that the female greater stressed than male 60.9% during this period of the infection (figure 1) the variation of the study may additionally be associated to the truth that female had been more in all likelihood than male in responding to emotional stress31.

The effect of this investigation had been confirmed that the peak of stress level which was measured via Chi square test used to be related to the first year 22.3% (fig 3) whilst the lowest level of stress value used to be related to the second year 18.4%, in the meantime the third year stress level represent 18.7% and the fourth year stress level in about 21% whilst the fifth year which consider the last year for undergraduate student in dentistry collage were 19% .Several studies indicated agreement with this research which had been discovered that the first year student had been regarded the highest level of stress for which may additionally be related to the young age of this stage which had been extremely great relation with the emotional exhaustion 32,33, moreover the first
year students might also observed the new study topics vary from the secondary school studies topics, course clinical necessities, full schedule and lack of time for interest or leisure all of these reasons would possibly be lead to elevate the level of stress on first year students.34

This study had been located that the other highly level of stress had been observed at the fourth stage, whilst the second and the third stage had been sort of steady. The high level of stress at fourth stage might also be due to the transition from preclinical stages to clinical stages and the close contact to actual patient instead of manikin as in the previous stages.35,36

the Variations between stages in the level of stress can also moreover affected with the unique education method of the lecturers and the new approach they have been observed in talk about the concern with the student and the approach they relay to reduce the confusion and stress on the student.37

Whilst, the result of this study had been indicated disagreement with Gorter et al which found that the Fifth year students had been relatively high stress level when compared with first year and this may also be explained to that the dental education at the final level had been focused on the clinical works extra more than the other educational years.38

Conclusion

As a result of this study, there is a strong relationship between stresses during dental study (online) and “Covid-19”, also this stress differs from stage to stage, ranging from high stress at 1st stage to lowest at 2nd stage.

Recent Root Canal Instruments and Techniques: A Review

Zeena T. Abdulhadi Alani

Dr. Lecturer, B.D.S., M.Sc., Conservative Dentist, College of Dentistry, AL-Iraqia University/Iraq

Abstract

In this article the properties and advantages of NITI alloy were presented with the development of new types of endodontic files and instrumentation techniques. Each new one was designed to solve disadvantages present in older one. NITI files always considered suitable for negotiation of curved canals, this automatically will reduce any possibility of some problems like transportation, ledge formation and zipping within the canal. Cleaning and shaping of the root canal space is the most important to create a sterile area, organisms free. In order to reach this goal (sufficient information of current development of instruments and instrumentation techniques is needed). With the new versions which are rapidly becoming available, the Dentist may find it a little bit difficult to choose the most suitable file and technique for an individual case. Practitioners must always keep in mind that benefits and weaknesses is present in most file systems. In other hand clinical experience, usage safety, handling properties and outcomes of the case, should decide a particular design fate.

Conclusion: Endodontic treatment files and techniques are very rapidly developed and this is the most important point, since each new design or technique will supply advantages which improve the endodontic treatment work and prognosis.

Keywords: NITI, instrumentation technique, health; canal; roots.

Introduction

IN the 19th and early part of the 20th century, hand Instruments were the only choice. The first endodontic (handpiece) for automated root canal preparation was developed in 1889 by William Rollins. This automated handpiece used full rotation and to lessen instrument breakage, the rotational speed was limited to 100 rpm. The next improvement appeared in 1928 when the Austrian company W & H (Burmoos, Austria) brought out the —Cursor filing contra-angle. This handpiece used a combined rotational and vertical motion of the file. Eventually, endodontic handpieces became popular in Europe with the marketing of the Racer handpiece (W & H) in 1958 and the Giromatic (Micro-Mega) in 1964. The Racer handpiece worked with a vertical motion, the Giromatic with an equal reciprocal 90° rotation

In the 1980s, sonic and ultrasonic hand pieces were introduced to the dental marketplace and are still being used in various degrees today. The late 1980s to the early 1990s saw the introduction of the first rotary Ni-Ti files and corresponding hand pieces to drive them.

Generally, Ni–Ti instruments have:

1. Effective cleaning ability.
2. Can preserve the root canal anatomy (shape).

To prevent the breakage that may happen to the rotary instruments due to fatigue and appropriate speeds, continuous pecking motion in most canals is recommended

Techniques using stainless steel hand file always require:

1. Numerous files.
4. Limited flexibility ➔ canal transportation
5. Permanent plastic deformation (file breakage).
Properties of (NiTi) files:
- Flexibility, shape memory
- Also have a low modulus of elasticity (about 1/4 to 1/5 that of stainless steel files),
- Higher strength.

NiTi files always considered suitable for negotiating curved canals and reduce the risk of transportation, zipping and ledge formation within the canal\(^3\). High incidence of unexpected failure of rotary nickel–titanium instruments during use represents some limitations. These instruments frequently may fracture and may be lodged in narrow and canals with apical curvature\(^4,5\). Nowadays, greatest numbers of commercially available Ni-Ti files utilized to shape root canals are driven in a continuous rotation. Any repetitive back-and-forth motion can be defined as reciprocation which used with stainless steel files in the past. From inception, most hand pieces used equal to 90° reciprocation both clockwise and counterclockwise. Throughout time, most reciprocating systems have reduced the envelope of motion to 30° arcs of reciprocation. Now a days, the M4, Endo-Eze AET and the Endo-Express use small, equal, 30° angles of clockwise and counterclockwise reciprocation\(^1\).

Metallurgy of rotary instruments:

Nickel-titanium alloy:
1. Corrosion resistance is high,
2. Super elasticity,
3. Shape memory. This is because of the arrangement of the atoms in steel can move against each other by a small specific amount before the occurrence of plastic deformation\(^6\).

Electro polishing: The purpose of this process is to reduce irregularities in the file surfaces such as flash and milling marks, this also improve properties of the material, specifically fatigue and corrosion resistance. The resulting instruments appear to have better cutting efficiency and corrosion resistance. Changes in the alloy material have been introduced in order to make it with more resistance to cyclic fatigue. In manufacturing endodontic instruments the alloy:

1. Composed of 56 % (wt.) nickel, 44 % (wt.) titanium and is generically known as 55-Nitinol\(^7\).
2. In addition to the fact that it possesses higher amount of flexibility and highly resistant to fracture\(^8\).
3. NiTi has inherent ability of shape memory (SM) and superelasticity (SE) also called pseudoelasticity, (PE); the transition between the —austenitic and —martensitic phases in the NiTi alloy is a function of temperature and stress\(^7\).

Super elasticity (SE): The austenitic phase transforms into the martensitic phase when subjected to stress.

Shape memory (SM): The shape-memory undergo transformation when cooled from the high temperature (austenite) to the low temperature (martensitic)\(^9\).

Blue treatment: "Vortex Blue and ProTaper Gold rotary files"; are new modalities of instruments they can undergo a complex heating-cooling property treatment.
that results in the formation of a visible titanium oxide layer in the surface of the instrument which keep a shape memory alloy by controlling transition temperatures (10).

Glide path: The root canal system should first be explored with a small, pre-curved stainless steel files then enlarged by a larger hand files so we get glide path before introducing the first crown-down rotary instrument. PathFile Root Canal Drills, G-FilesTM, ScoutRace files are examples of new rotary systems used specially in severely curved canals to get the glide path (11).

Path FileTM: In order to create a glide path rapidly and safely this new rotary instrument was designed. It comes in 3 sizes and made up of NiTi alloy with a very slight taper of .02 so it can resist the cyclic fatigue (12).

Scout Race: To mechanically prepare root canals that are with sever curvature this new design appeared with3 different lengths. They have rounded safety tips to guide and cutting edges to eliminate screwing (12).

ProTaper Universal: ProTaper rotary instruments have been shown to create more regular canal diameters when compared with FlexMaster, HERO and 25 Race file systems. They have a continues ability to change helical angle and pitch over the cutting area that will prevent it from being screwed through the root canal space.

ProTaper Gold: Have the identical geometry of PTU instruments but are manufactured from a proprietary heat treated NiTi alloy. It still produces the same PTU shapes, but they are considered to be with better safety and actually better. The shapes will be more precisely replicate the original root canal system flow. The gold technology will provide better canal shapes, safer and greater efficiency.

Retreatment with ProTaper: ProTaper D1 - for coronal filling removal, ProTaper D2 - for middle filling removal, ProTaper D3 - for apical filling removal. By using very slight apical pressure during file penetration within the canal also withdraw the file frequently, inspection done for the file then cleaning from the debris, we can use a hand file to overcome if there is any resistance and confirm the canal permeability.

ProTaper NEXT: It comes as 5 instruments but mostly we can prepare by the first two. The Protaper Next X1, the Protaper Next X2 which can be considered as the first finishing instrument for optimal irrigation and root canal obturation. Protaper Next X3,Protaper Next X4 and the Protaper Next X5 .Those will be used to create tapering in the root canal or to prepare wide and large root canal systems (13).

---

**Figure 2: PROTAPER NEXT, complete system with five instruments.**
This system has several properties which include flexibility, safety and because of its bilateral symmetrical rectangular cross section it will create asymmetric rotary motion\textsuperscript{(13,14)}.

**Twisted Files (TF):** It has a raised flexibility, fracture resistance and slower crack initiation and propagation. Special surface conditioning and twisting is used during the manufacturing process which will lead to increase in the resistance of the instrument to cyclic fatigue and flexibility\textsuperscript{(15)}.

**TF Adaptive:** Most clinical cases will be easy to be treated effectively and safely by the selfiles. This file when it is used without stress it can allow better cutting efficiency and caries removal because it works in a continuous rotation movement. This will allow better brushing or circumferential filing for better debris removal in oval canals and reducing the tendency of screwing that minimizes errors that is commonly seen with other NiTi instruments of great taper and used in continuous rotation. The angles depending on the anatomical variations and intracanal stresses forced on the instrument so they vary according to these. Therefore there is reduction in the risk of intracanal failure but not affecting performance of the work\textsuperscript{(16)}.

**Hyflex CM and Hyflex EDM:**

This new instrument has: Improved flexibility, resistance to cyclic fatigue and good adaptation to the canal space anatomy reducing the risk of ledging, transportation, or perforation. This file appears to regain its shape after sterilization and can be reused, if not returned back to their original shape then they should be discarded\textsuperscript{(9)}.

**Reciproc:** These files are currently designed to allow root canal preparation without glidepath preparation, not like above mentioned systems. In order not to get root canal straightening, preparation faults and preparation time mechanical root canal preparation systems are better compared to hand instrumentation. This system is very comfortable to the dentist and the patient. Reciproc system also includes three instruments (R25, R40 and R50) and is driven by the VDW Silver Reciproc Motor (VDW) or the X-Smart Plus motor (Dentsply/Maillefer). When it rotates in the cutting direction it will advance and engage dentine to cut it before the instrument will rotate in the opposite direction to ensure disengagement\textsuperscript{(17)}.

**Reciproc Blue:** It is a single instrument required to prepare a root canal. Simple, but effective, it has enhanced safety in root canal preparation and retreatment for patients. Made from Nickel- Titanium (NiTi) undergoes innovative heat treatment, increased resistance to cyclic fatigue and additional flexibility and blue color. It provides more effective irrigation and obturation. This instrument designed specifically to be used in reciprocation. It has better properties because of specific s-shaped cross-section, the taper, the cutting angles and the thermally improved raw material.

![Figure 3: Reciproc blue, This instrument designed specifically to be used in reciprocation.](image-url)
One Shape: It is also a single file instrument which made of austenite NiTi alloy. Tip size of 25 and a constant taper of 0.06, it have different cross sectional designs over the length of the working part. It has a very good advantage of faster treatment than conventional techniques.

2Shape: It has:
1. Better cyclic fatigue resistance.
2. Better and more flexibility.
3. We insert the rotating instrument into the canal until feel resistance.
4. When the file is removed from the canal, it must be cleaned by cleaning the grooves and do irrigation through the canal, after that continuous progressive downward movement.
5. To reach the working length two to three cycles are usually sufficient. This file is suitable for about all different treatments.

Self Adjusting File (SAF): It adapts itself to the three dimensional anatomy of root canals will lead to removal of dentin uniformly, remaining wall thickness and prevention of canal transportation (18).

Properties:(19,20):
• This file has the ability to be Adapted to the root canal with three Dimensional Anatomy.
• Uniform thickness of Dentin and Remaining Wall Thickness can be removed.
• Canal Transportation prevention.
• Durable
• Irrigate the canal with Sodium Hypochlorite in continuous manner.
• In the Apical Part of the Canal Removal of the Smear Layer.

Wave One: It is a single-file system to shape the root canal completely from start to finish. One hand file only required in this technique followed by one single Wave one file to shape the canal completely. In fine canals the Wave One Small file is used. These files are designed in a manner so it works with a reverse cutting action (21).

How we can select the suitable file?:
1. We Use Wave One Small file, If size 10 K-file is very resistant to movement.
2. We use Wave One Primary file, if size 10 K-file moves to length easily loosely.
3. We use Wave One Large file, if size 20 hand file or larger goes to length.

WaveOne GOLD: The ground NiTi files are heat-treated and slowly cooled and this has a positive effect on the instrument properties and gives the file its distinctive gold finish, improves its strength and flexibility far in excess of its predecessor.

The followings have been shown:
1. Cyclic fatigue resistance of this type of files 50% greater than Wave One Primary.
2. The flexibility of this type of files Primary is 80% greater than that of Wave One Primary.

This single-file reciprocating system has four tip sizes Small, Primary, Medium and Large, in lengths of 21, 25 and 31mm lengths. Preparation of the canal is ideal for the irrigant exchange and removal of debris. A design feature present in this file result in a reciprocating movement that is very smooth, eliminating the need to push on the file promotes safety and improves cutting efficiency (21).

Gentile file: This file is made from SS. The single-use files, It enlarge the canal walls by gently scraping the dentinal walls since that it has a rough surface after undergoing particle blasting. They are operated by a special fully automated handpiece at a maximum speed of 6500 rpm. The GF system consists of files, an orifice opener 18 mm long and 5 preparation files 25 mm long. canals should be prepared by using 2 to 3 files According to manufacturer’s instructions. This will allow the dentist to choose the most appropriate file combination according to the canal anatomy (22) single file rotary and reciprocating systems also ensure ease of use and reduced preparation time (23).

Detection Antibodies IgM, IgG and Determination Levels of IL-33 in Iraqi Diabetic Type 2 Patients Infected with Toxoplasma Gondii

Sarah Ali Saeed¹, Israa Kasim Al-Aubaidi²

¹Post Graduate/Department of Biology, College of Education for pure science (Ibn- Al- Haitham), University of Baghdad, Baghdad, Iraq, ²Assist. Prof. Department of Biology, College of Education for Pure Science (Ibn- Al-Haitham), University of Baghdad, Baghdad, Iraq

Abstract

Toxoplasma gondii is an obligate intracellular protozoan that causes a disease called toxoplasmosis which has the capability to pass its both life cycle parts asexual and sexual in the final host (cats) and also through intermediate vertebrate hosts including humans. Diabetes mellitus is a metabolic disorder that there is high blood sugar level over a prolonged period. This research included one hundred and twenty blood samples that collected from diabetic patients after diagnosing them by endocrinologist at the Imamene Kadhimein Medical City during August until the end of December 2016 with age ranging 12-76 years with mean 50.9 ± 13.8. Toxoplasmosis diagnoses was occurred by using Toxo IgG and IgM antibodies immulite torch assay while diabetes diagnosis by fasting blood sugar tests also measuring level of IL-33 in samples was done by sandwich ELISA method that showed a group of diabetic patients infected with toxoplasmosis have the highest level of IL-33. The results showed that a group of diabetic patients have the highest level of glucose in diabetes test (188.31 pg/ml) while a group of diabetic patients infected with toxoplasmosis have the highest level of IgG (106.17 IU/ml) while all samples have seronegative results for Toxo IgM also the highest level of IL-33 showed in a group of diabetic patients infected with toxoplasmosis (858.84 pg/ml) while a group of diabetic patients not infected with toxoplasmosis have (556.67 pg/ml) and control group have (315.58 pg/ml).

Keywords: Toxoplasma gondii, IgM, IgG, Diabetes mellitus type 2, IL-33.

Introduction

Toxoplasma gondii is an obligate intracellular protozoan that causes a disease called toxoplasmosis. It has the ability to pass both asexual and sexual parts of it life cycle in feline (cat) as the final host, and a wide spectrum of warm-blooded vertebrate hosts including humans as intermediate hosts. It is a zoonotic disease according to T. gondii is one of the most common parasites of animals. T. gondii passes through three shapes: tachyzoites responsible for active infection, bradyzoites found in tissue cysts and sporozoites found in environmentally resistant oocysts formed after the sexual part of the life cycle.

Diabetes Mellitus (DM), commonly referred to as diabetes, is a group of metabolic disorders in which there are high blood sugar levels over a prolonged period. Type 2 is representing about 90% of all cases of the disease; it is characterized by the coexistence of insulin deficiency and the peripheral effects of the hormone.

Diabetic patients are more amenability to infect with T. gondii due to their low level immune response, toxoplasmosis and diabetes may pave the way to each

Corresponding Author:
Israa Kasim Al-Aubaidi
Assist. Prof. Department of Biology, College of Education for Pure Science (Ibn- Al- Haitham), University of Baghdad, Baghdad, Iraq
e-mail: israakasem@gmail.com
other; the occurrence of necrotic lesions in the pancreas of the experimental animals infected with *T. gondii* may indicate that toxoplasmosis paves the way to diabetes as the involvement of the pancreas can lead to the inhibition of insulin secretion and consequently the establishment of diabetes (7).

**The object of this research as the following:**

1. Determine levels of glucose by using FBS test.
2. Detection antibodies IgM and IgG of *T. gondii* infection.
3. Determine levels of interleukin-33 in Iraqi diabetic type 2 patients infected and control uninfected individuals in order to understand the relationship between these diseases.

**Materials and Method**

**Selection of Patients:** This research included one hundred and twenty blood samples collected from diabetic patients after diagnosed by endocrinologist at the Imam Kadhimein Medical City during August until the end of December 2016 with age ranging 12-76 years with mean 50.9 ± 13.8. Six milliliter of venous blood was gathered by using 10 ml disposable syringe. These samples were immediately carried to gel tube and left to clot at room temperature (20-25°C) for 15 – 20 minutes, after cloting it was centrifuged at 2500 to 3000 rpm for 10 min period to separate serum that used for fast blood sugar diagnoses (Glucose MR, Linear, Spain) then immulite torch assay used for *T.gondii* diagnosis (Flex reagent cartridge IgG, Siemens, Germany) while the remaining serum distributed in tightly closed eppendrof tubes by micropipette, each eppendrof included (0.25 ml) and then the tubes were stored at -20°C until used. For detection cytokines levels by Sandwich ELISA method, one hundred diabetic samples used and divided as: a group of 50 samples of diabetic patients infected with toxoplasmosis and a group of 50 samples of diabetic patients only as well as a group of 25 samples of healthy individuals selected as control.

**Sandwich ELISA method:** Sandwich ELISA technique enzyme immunoassay used for measuring the levels of interleukin-33 by using the manufacturer directives as provide with the kit from peprotech, USA.

**Statistical Analysis:** Chi-square test was used to analyze the results, also least significant difference (LSD) test used for significant compare. Statistical significant that used for this study was a P-value < 0.05.

**Results and Discussion**

*T. gondii* can infect and grow in any nucleated host cells which leading to the production of various inflammatory markers by the innate acute inflammatory responses and antigen-specific adaptive immunity which facilitates a state of chronic inflammation at various anatomical sites in the host (8). In a meta-analysis of studies on the relation between chronic toxoplasmosis and diabetes mellitus, researchers found that chronic toxoplasmosis was a possible risk factor for type 2 diabetes mellitus (9).

Table (1) showed that a group of diabetic patients only has the highest level of fasting blood sugar as compared with other groups with highly significant differences.

The shown results similar to results of Modrek et al. (10) results that investigate of IgG and IgM in 205 serum samples of diabetics in Ali Asghar Hospital in Zahedan (southeastern Iran) with age (13 – 60) years that found 131 diabetic patients had fasting blood sugar levels between 121-300 mg/dL that 79 diabetics
have anti-\textit{Toxoplasma} IgG (63.2%) and 52 diabetics have anti-\textit{Toxoplasma} IgM (71.3%) with significant differences (P < 0.05).

Several experimental evidences have been evaluated and suggested as plausible pathophysiological mechanisms to explain this relation, including:

1. Infected white blood cells assimilate improved migratory feature, causing the easier distribution of \textit{Toxoplasma} in body organs, such pancreas\textsuperscript{(11)}.

2. A clinically visible autoimmune procedure could be ignited by \textit{Toxoplasma} infection, trending immune machinery across auto antibody production, for example against Langerhans islets cells\textsuperscript{(12)}.

3. A probability, is that \textit{T.gondii} itself may attack and destroy pancreatic cells directly, initiating pancreatitis and more importantly, diabetes\textsuperscript{(11)}.

4. Creation of reactive oxygen species (ROS) and nitric oxide (NO) is stimulated by diabetes, and these agents, as stimulant for intracellular pathogens, can reactivate latent, cysts of parasites, over starting acute infection\textsuperscript{(12)}.

5. Given the incapability of neutrophils to correctly achieve phagocytosis and intracellular killing in progressive stage of diabetes, there may be raise in responsiveness to intracellular pathogens like \textit{Candida} and \textit{Toxoplasma}\textsuperscript{(13)}.

6. The opsonization activity and leukocyte cytotoxicity of diabetic patients need for removal of pathogens are extensively subsided; therefore they would be more prone for opportunistic infections\textsuperscript{(13)}.

While table (2) revealed that all samples of research have seronegative for anti-\textit{Toxoplasma} IgM with highly significant differences as well as showed that 50 samples of diabetes have seropositive for anti-\textit{Toxoplasma} IgG and 70 samples have seronegative for IgG Abs in addition, a group of diabetic patients infected with toxoplasmosis has highest levels of IgG Abs that compared with other groups with highly significant differences as clarified in table (3).

\end{table}
Lately, the immulite 2000 torch assay measure Toxo IgM and IgG in International Units per milliliter (IU/ml) of serum; this assay is simple, rapid and comparatively inexpensive needful 60–90 minutes for completion (14).

The previous results of IgM and IgG Abs matched with the research of El-Awady et al. (14) that include seroprevalence of toxoplasmosis in 110 diabetic pregnant women and 110 non diabetic pregnant women which found 47 (42.7%) of diabetic pregnant women were seropositive for anti-Toxoplasma IgG and 3 (2.7%) seropositive for IgM Ab as well as 24 (21.81%) of healthy non diabetic pregnant women were seropositive for IgG Ab and seronegative for IgM Ab. Although matched with results of Shirbazou et al. (15) that clarified the prevalence of IgG and IgM Abs in diabetic patients were (56.6%) and (2.4%) as well as in control were (22.4%) and (1.6%) respectively, in addition matched with results of Gokce et al. study (16) that include serologic detection of anti-Toxoplasma infection in 91 diabetic patients and 93 healthy control which found the prevalence of IgG Ab of T. gondii was 55 (60.43%) while in healthy control was 36 (38.7%).

These returns discovered that the prevalence rate of IgG Ab was directly associated with duration of diabetes because of the weakened immune system of diabetic patients which also proposed that toxoplasmosis patients are more capable to be diabetics than those without. Demolition of the pancreas occurs in three stages of T. gondii:

1. Hyperactive stage (hyper-period) in which β-cell obliteration of nerve cells and less interference in the insect in a hyperactive state of the pancreas, sometimes insulin secretion is excessive, frequently resulting in low or a too low blood sugar, this stage is often occurs during adolescence.

2. Disordered stage (compensatory stage), in which neurons and pancreatic β-cells have a great amount of damage, under normal conditions, insulin secretion will be insufficient, the body will begin the compensative function. So, when few in the disordered state, this stage of insulin secretion over time.

3. Decline stage (recession), in which nerve cells and β-cells destruction of more compensatory function reach to its limits (11).

The results of table (4) referred to serum levels of IL-33 in studied groups and explained that a group of diabetic patients infected with toxoplasmosis only has the highest level of IL-33 in comparison with other groups although significant differences showed in these results.

### Table 4. Concentrations of IL-33 (pg/ml) in sera of studied groups.

Interleukin-33 is a new member of the IL-1 superfamily of cytokines that is expressed by mainly stromal cells, such as epithelial and endothelial cells, and its expression is upregulated following pro-inflammatory stimulation\(^{(17)}\). It functions both as a traditional cytokine and as a nuclear factor regulating gene transcription. It increases concentration in serum of toxoplasmosis (IgG) patients due to interleukins that regulate information transfer among different types of leukocytes during various stages of immune or inflammatory response\(^{(18)}\). This is assured by increase IgG, IgA and IgM, this return may indicate that autoimmune disease like toxoplasmosis might influence cytokine production in toxoplamosis patients\(^{(19)}\). The reduction in IL-33 levels in diabetic patients may due to the protective effect of IL-33 by reducing adiposity and improving glucose tolerance and insulin resistance, this interleukin strongly induces Th2 cytokine production from these cells and can promote the pathogenesis of Th2 related disease such as asthma, atopic dermatitis and anaphylaxis\(^{(18)}\). However, IL-33 has shown various protective effects in cardiovascular diseases such as atherosclerosis, obesity, diabetes type 2 and cardiac remodeling. Thus, the effects of IL-33 are either pro- or anti-inflammatory depending on the disease and the model\(^{(19)}\).

**Conclusion**

This research has reached to the following conclusions:

1. Fifty samples of this research are diabetic patients type 2 infected with toxoplasmosis, this illustrate the relationship between diabetes and *T. gondii* which relates to depression of immune response of type 2 diabetic patients, that make them more susceptible to toxoplasmosis infection.
2. Diabetic type 2 patients infected with toxoplasmosis have the highest level of glucose in their blood as FBS test clarified.
3. Some of Diabetic type 2 patients infected have chronic toxoplasmosis infection (IgG antibodies appeared) while there is no appearance for acute toxoplasmosis (IgM antibodies).
4. Levels of IL-33 rise in diabetic type 2 patients infected with chronic toxoplasmosis.

In Vivo Genotoxicity Assessment of Gold Nanoparticles of Different Doses by Comet Assays

Zainab Ahmad Hassan1, Hind Hussein Obaid2, Mustafa Nuhad al-Darraji3

1Ph.D. Student, Science College, Anbar of University/Iraq, 2Assist. Prof., Science College, University of Baghdad/Iraq, 3Assist. Prof. Science College, Anbar of University/Iraq

Abstract

Gold nanoparticles were synthesis by green method using the soaked orange peels (citrus Sinensis) as reducing and stabilizing agent. The gold nanoparticles were diagnosed using the approved method, including the transmission electron microscope and the visible UV spectroscopy. Thus, the results of the diagnosis showed the formation of spherical particles with a size of 36 nanometers. Their biological effects on the bone marrow cells of albino mice were studied.

Male albino mice were used in this study and randomly divided into seven groups. The first group was the control group injected with the physiological solution (Normal Saline) and the other six groups were injected with different doses of the solution of the gold nanoparticles (1, 2, 4, 6, 8 and 10) Mg/kg. The effect of gold nanoparticles on the DNA damage by bone marrow cells was studied using comet assay according to the following criteria:

(DNA in Head%, Comet Length, Tail Length, DNA in Tail%, Olive Moment), the results showed a significant decrease (P≤0.01) in the rate of DNA in Head%, while it showed a significant increase in Comet Length, Tail Length, DNA in Tail%, Olive Moment compared to the control group and all Doses studied. The effect of gold nanoparticles was directly proportional to the increase in the studied doses. The dose was 10 mg/kg, which was the highest toxicity, followed by the dose of 8 mg/kg, then the rest of the doses was descending.

Keywords: Gold nanoparticles, Comet assay, Orange peel, toxicity.

Introduction

Nano molecules have been designed and widely used in various technologies. Nanoparticles are generally defined as molecules sized range between 1-100 nanometers. It is believed to be within this size. They gain unique characteristics that differ from their properties when they are the largest size. (1) The evaluation of the cellular toxicity for gold nanoparticles is very important because it has a potential impact on DNA damage. This can lead to cancer and mutations in the long-term.

(2) The comet assay or single cell gel electrophoresis (SCGE) assay assesses the DNA damage resulting from the breakage of one or two double strand. Besides, this shows increasing DNA migration in the electric field. The method has become one of the standard method for assessing the DNA damage of cells (3). It is preferable to use gold nanoparticles in the medical field because these molecules have unique properties that distinguish them from other minerals, including high biological compatibility with cells and living tissues (4), the affluence of attachment to biomolecules such as polyethylene sugars that have wide medical applications, groups of carboxyl, amine, DNA, RNA, antibodies, Peptides and others (5) and chemical stability (6) have the ability to form geometries (7).

Gold nanoparticles may cause stimulation for the immune system due to their size close to the size of proteins and even the sizes of viruses \(^{(8)}\). There is little information about the inflammatory properties of gold nanoparticles and their role as antibodies. Some studies have shown that nanoparticles of gold nanoparticles can accumulate in the reticuloendothelial system of the liver and spleen, causing thus poisoning them. \(^{(9)}\)

**Materials and Method**

- **Synthesis of gold nanoparticles:** Gold nanoparticles synthesis in an environmentally friendly green method by soaking the orange peels as a reducing agent and stabilizer\(^{(10)}\). The gold nanoparticles produced using the visible UV spectroscopy\(^{(11)}\) and the transmission electron microscope\(^{(12)}\) were described.

- **Determination of Lethal Dose LD50:** The median lethal dose was determined in male albino mice using the Dixon method\(^{(13)}\).

- **The effect of gold nanoparticles on the DNA damage by bone marrow cells:** Depending on Allen’s method\(^{(14)}\), 6 different doses of the solution of gold nanoparticles (1, 2, 4, 6, 8, and 10) were prepared mg/kg in a volume of 0.3 ml and injected under the peritoneum of the mice of the studied groups by 3 mice per group. As well as, the control group was injected with a volume of 0.3 ml of normal Saline. After 18 hours, the groups studied were injected with a solution of cholchicine (prepared at a concentration of 1 mg/ml) with a volume of 0.3 ml. After 2 hours, the mice were drugged with chlorofum and then dissected to obtain bone marrow from the femur. To determine the effect of gold nanoparticles synthesized according to the present study on the level of the genetic material of the cell, tests were conducted of the effect of gold nanoparticle on the DNA damage of bone marrow cells using Comet assay via the following criteria (DNA in Head%, Comet Length, Tail Length, DNA in Tail%, Olive Moment. The results were extracted based on the comet score program. In addition, this test was performed according to the method followed by\(^{(15)}\).

**Results and Discussions**

**Characterization of produced gold nanoparticles:**

The first way to describe the biosynthesis of gold nanoparticles was to measure ultraviolet light spectrum. After 12 hours of manufacture, the color of the solution changed from yellow to light pink, then absorbance was measured. Also, a peak appeared at wavelength (533 nm) and absorbance (0.710).

The results showed that color change plays an important role in detecting the formation of nanoparticles. This is confirmed by the appearance of the peak in conjunction with absorbance after 12 hours. The peak gave a spectral evidence for the formation of surface plasmon resonance of the golden nanoparticles \(^{(16)}\). This is consistent with \(^{(17)}\) who concluded that the color change of the solution from blue to pink light rosy is evidence of the reduction of gold salts and the formation of gold nanoparticles. This reduction and color change can be attributed to the presence of phytochemicals reduced in the soak plant. This agreed with \(^{(18)}\) who resulted that phyto-chemicals have high ability to rapidly reduce mineral solutions to nanoparticles. Citrus sinensis contains proteins and glucose molecules in addition to vitamin C, which are reducing agents for the manufacture of gold nanoparticles \(^{(19)}\).

Figure (1) shows a picture of the electron microscope for produced gold nanoparticles using soaked orange peels (Citrus Sinensis). The results showed that spherical nanoparticles of 36 nm with no clusters or conglomerations of these particles. Due to the repulsive nature of the reducing agent that enclosed the surface of the gold nanoparticles, they stabilize as well as biomolecules helped to form spherical molecules\(^{(20)}\).
The genotoxic effect in bone marrow of albino mice:

- **DNA in Head%**: The toxic effect of gold particles was directly proportional to the increase in dose in the percentage of DNA head. (Figure 2).

  ![Figure 2. The effect of Goldnanoparticles on DNA in head% in albino mice bone marrow cells.](image)

  Doses 10 and 8 mg/kg showed the highest toxicity effect in the genetic material of bone marrow cells. The ratio of DNA in head (50.48 ±3.04 and 51.87±2.89)% respectively, compared to the control group that reached (84.98±2.02)% . Significant differences (P≤0.01) were found among the different doses, except for doses 1 and 2 mg/kg. While the percentage of head DNA ratio was (2.09 ± 84.55 and 2.31 ± 84.83)% respectively.

- **Comet Length (px)**: The results (Figure 3) showed a significant increase in comet length, and significantly (P≤0.01) was directly proportional to the increase in the dose used. Obviously, the dose of 10 mg/kg showed the longest comet, reaching (95.44 ± 3.92) px compared to the control group (39.82 ±1.69)px.

  ![Figure 3. The effect of Goldnanoparticles on Comet Length (px) in albino mice bone marrow cells.](image)
Then the effect decreased by diminishing the dose (4,6,8) mg/kg at a rate of (78.70 ±1.04) and (73.63±1.84) and (80.96 ± 3.59) px, respectively. A significant difference did not indicate between them (P> 0.01), while it increased significantly for the two doses (1,2) mg/kg and the control group.

For the two doses (1,2) mg/kg, they did not show a significant difference between them, nor did they show a significant difference when compared to the control group at the rate of (39.15±1.09) and (45.57 ± 2.01) px, respectively.

**DNA in Tail %:** Gold nanoparticles caused a toxic effect on bone marrow cells, depending on the DNA in the tail at the (P≤0.01) level compared to the control group. The DNA break increased with a higher concentration (Figure 5). The doses 10 and 8 mg/kg showed the highest DNA percentage in the tail reached (49.52 ±3.04) and (48.12±2.89)%, respectively, compared to the control group (15.17±2.31)%.

**Tail Length:** The results of the Tail Length (figure 4) showed a significant height (P≤0.01) when using high doses 6, 8 and 10 mg/kg. The tail length reached (13.32 ±1.62), (13.78±1.33), (22.20±1.95) px, respectively, compared to a control group of (4.36±1.47)px. The doses 1, 2 and 4 mg/kg did not have a significant effect (P> 0.01) compared to the control group. When comparing the concentrations between them, the results showed that the length of the tail increased with an increase in the doses used.
Olive Moment: The results in Figure (6) showed a significant increase (P≤0.01) for all studied doses compared to the control treatment. The increase in the value of Olive Moment increases with increasing dose value. The dose 10 mg/kg showed the highest toxic effect on the genetic material of marrow cells, as the value of Olive Moment (11.19±0.91) compared to the control group which reached (4.05±0.52). According to this study, low doses 1, 2 and 4 mg/kg, however, did not show a significant effect compared Control group.
The results of the present study agreed with Olive (15) who studied a modified method to reduce the toxicity of gold nanoparticles for DNA damage by encapsulating these nanoparticles with glucose molecules. This indicates the toxic effect of nanoparticles on the DNA.

According to the results obtained, it was found that gold nanoparticles synthesized by the environmentally friendly biological method using soaked orange peel had a toxic effect on the DNA. It could be directly proportional to the high dose used.

The toxic effect of synthesized gold nanoparticles may induce mutations (21) and DNA strand damage (22) by stimulating the production of free oxygen radicals, causing destruction of cell membranes, proteins, and DNA (23) and stimulating DNA damage signals (24). Toxicity may also be caused by the direct association of these nanoparticles with the DNA strand due to their small size, where are able to cross cellular barriers or by stimulating oxidation systems, repairing proteins of the DNA strand and causing damage to the DNA strand in addition to its ability to stimulate apoptosis of the cells (26). It can be the size of the nanoparticles used in the study (36 nanometers) has a great role in the toxicity of these molecules. The sizes of 30-50 nanometers consider the most toxic ones compared to other sizes because of their high ability to cross cell membranes (27). The accumulation within the lysosome stimulates the mechanism of autophagosome, causing cell death (28). Besides, the spherical shape of these molecules is five times more toxic than other forms (29).

**Conclusion:**

The soaked orange peels contain reducing agents and stabilizer for making spherical nanoparticles in an environmentally friendly green method. The results of the visible UV spectroscopy and the Transmission electron microscopy for characterization of synthesized nanoparticles are the reductive ability of the soaked orange peels. The gold nanoparticleless synthesized have a toxic effect on the DNA of bone marrow of albino mice. Thus, the toxic effect depended on the doses used in this study. It showed a direct increase with the rise in the studied doses. Its toxicity was evaluated according to the comet assay test.

Histological Evaluation of the Effect of Metronidazole on the Brain Tissue in Adult Female White Rats

Yaseen Khalaf Mohammed1, Ayad Hameed Ibrahim2, Aziz Khalid Hameed3

1Researcher: Department of Biology-College of Science, Tikrit University/Iraq, 2Prof. Dr: Department of Anatomy and Histology-College of Veterinary Medicine- Tikrit University/Iraq, 3Prof. Dr: Department of Biology-College of Science- Tikrit University/Iraq

Abstract

The present study was undertaken to assess the neurotoxic effect of metronidazole in pregnant female rats. Twenty adult pregnant female rats were randomly divided into four groups treatment with oral metronidazole at the therapeutic dose 250 mg/kg, 500 mg/kg and 1000 mg/kg from the eight day of pregnant to the twenty day of pregnant (every eight hour), whereas the last group serve as a control. Routine Histological Techniques were done and stained by Hematoxylin and Eosin (H & E). The histopathological examination of brain show the lesion was characterized by a wide spongy cavitation and cavitation was observed around the nerve and glial cells along with atrophy of some of its nuclei and around the axonal and vascular axons with the presence of nuclear thickening of some glia cells, as well as hyperplasia of the glial cells supporting, disintegration and degeneration of nerve fibers, with damage to the meninges. In addition to the presence of bloody congestion. This study revealed that metronidazole have a neurotoxic effect in adult female rats with a severity depended on its dose and duration of administration.

Keywords: Metronidazole, Brain, Pregnant, Neurotoxic, Hyperplasia, Vacuolation, pyknosis.

Introduction

Metronidazole is an injectable and oral synthetic(1). Metronidazole is an antimicrobial agent commonly used in the treatment of several protozoal and anaerobic infections(2). Its main indications are trichomonal infection, amoebiasis, Helicobacter Pylori infection and Clostridium difficile associated diarrhea. Additionally, it is often used in Crohin disease, Rosacea and hepatic encephalopathy. Though it is well tolerated in common setting, patient may experience serious neurologic side effects in both long term and short term use. This includes peripheral neuropathy, cerebellar dysfunction, visual impairment, vestibulotoxicity, cochleotoxicity, ataxic gait, dysarthria, seizures and encephalopathy(3;4;5;6;7).

Despite of the passage of sixty years of research, metronidazole metabolism and its cellular toxicity are not clearly known. Metronidazole is considered a primary drug, Prodrug, not in the active formula. It is activated by reducing (reducing the nitro group) when there is a lack of oxygen concentration, which leads to breaking down amidazole and causing cellular toxicity. This is a currency basis for treating anaerobic infection. It has not yet been established whether the reduced (active) metronidazole is responsible for cellular toxicity or some of its metabolic derivatives that are responsible for the events of cellular toxicity(8; 9).

Metronidazole crosses the blood-brain barrier, and its induction of cerebral cytotoxicity does not depend on how it is administered orally or intravenously(10). Several studies have been conducted on the neurotoxic mechanism of metronidazole, but until now the mechanism has not been clearly defined by the hypotheses developed by researchers(11). In many experiments were conducted on animals (rats), which showed the occurrence of neuronal modulation after treatment with metronidazole.
with damage to the cerebellum, metronidazole and its metabolic derivatives are associated with RNA in the nucleus of the neuron and inhibit the production of proteins and the occurrence of bulging and breakdown of the axon.\(^{(12)}\)

Since then several cases have been reported and awareness of this entity among clinicians have substantially increased especially in the last decade. But still many questions remain unanswered and hence this entity needs further research and clarifications. Therefore, the present study was carried to investigate brain histopathological alteration associated with metronidazole administration in female rats.

**Material and Method**

Twenty Sprague-Dawley females rats were used for the purpose of this study. It was purchased from Animal House, Faculty of Veterinary Medicine, Tikrit University. The average weights were (167 grams), and were in a good health. The rats were kept in the animal house, as they were randomly distributed, at the rate of five animals for each group inside the cages intended for breeding with a floor furnished with sawdust. (27 ° C) and a 12-hour light cycle: 12-hour darkness, and give the diet feed (plate) and water in sufficient quantities to feed it throughout the breeding and livestock treatment period. Adult females were placed with adult males rats and by the rate of every two females with one male in each breeding cage for the purpose of mating, and animals were monitored until fertilization occurred by observing the vaginal plug on the next day and the day on which fertilization occurred was considered zero of pregnancy and the day after that was considered The first day of pregnancy. Used metronidazole as a tablet, and one tablet contains 250 or 500 mg/kg of metronidazole. The pharmaceutical industry used in the UAE was Julphar. Doses used for rats were calculated using the following method.\(^{(13)}\):

The pregnant animals group divided into four groups and each consist of five pregnant female.

**Pregnant Group:**

1. **Group 1 (Control group):** Given normal feeding and water.
2. **Group 2:** Given the concentration 250 mg/kg from the metronidazole medicine form the eight day to the twenty day from pregnant (every eight hour).
3. **Group 3:** Given the concentration 500 mg/kg from the metronidazole medicine form the eight day to the twenty day from pregnant (every eight hour).
4. **Group 4:** Given the concentration 1000 mg/kg from the metronidazole medicine form the eight day to the twenty day from pregnant (every eight hour).

After the end of the specified period of experiments, the histological technique of the samples was performed according to the method, and then samples were performed on the techniques of preparing the microscopic tissue sections, which were fixation and hardening, washing, and dehydration, clearing, infiltration, embedding, and trimming the mold. Cutting the paraffin sections by using a rotary microtome with thickness (6µm), Mounting and Staining. Hematoxylin and Eosin stain (H & E) used to study the histological changes caused by metronidazole. After completing the preparation of the microscopic tissue sections, they were examined by optical microscopy.

**Result**

**Group 1 (Control group):** The meningeal pia mater around the cerebral cortex contained a loose connective tissue with the presented of fibroblasts with blood vessels and appeared beneath it a pale colored Molecular layer that appeared to be spongy with a number of glial cells extending downward with the Granular layer as larger cells continuously connected with the pyramidal neuron layer (Fig.1).

**Group 2 (Pregnancy):** The cerebral cortex tissue is surrounded by the inner meningeal tissue (pia mater) with another outer membrane, Erachnoid membrane, where the presence of the Subarachnoid space in which the Cerebro-Spinal fluid occurs, the Molecular layer under the membranes of the meninges appeared pale due to the vaculation of many places Glial and neuron cells, especially with large numbers of glial cells in the lower layers of the cerebral cortex (Fig.2).

**Group 3 (Pregnancy):** The meningeal layer of the brain has damage and loss of continuity of the membrane to the pia mater as well as an increase in the penetration of the molecular and granular layer beneath it, as well as in the area of pyramidal neurons. Glial cells and nerve fibers swell around the glia and nerve cells, which degenerate and disintegrate, which showed frequent Vacuolation and Cavitation in brain tissue (Fig.3).
**Group 4 (Pregnancy):** The cerebral cortex has an extensive necrosis and necrosis that has extended to the deepest layers of the brain. This enlargement has surrounded all the supporting and nerve cells, extending from under the meninges that have lost the continuity of the coated surface of the brain to the deepest large nervous layers (Fig. 4). The middle of the brain contained nerve fibers in the form of degenerative bundles, missing continuity, i.e., disintegrated surrounding large numbers of inflammatory cells and debris of glial and neuronal cells in their midst and the lesion and cavitation regions of the cerebral cortex were surrounded by degenerated and degraded nerve fibers and there were large numbers of glial and neuronal cells that lost the cytoplasm as their nuclei appeared inside the cavitation sinuses (Fig. 5).

Discussion

Metronidazole crosses the blood-brain barrier, and its induction of cerebral cytotoxicity does not depend on how it is administered orally or intravenously (10). Several studies have been conducted on the neurotoxic mechanism of metronidazole, but until now the mechanism has not been clearly defined by the hypotheses developed by researchers (11). If many experiments were conducted on animals (rats), which showed the occurrence of neuronal modulation after treatment with metronidazole with damage to the cerebellum, metronidazole and its metabolic derivatives are associated with RNA in the nucleus of the neuron and inhibit the production of proteins and the occurrence of bulging and breakdown of the axon (12).

The results of the study showed the occurrence of cavitation and widespread cavitation in the brain tissue with the occurrence of a breakdown of the axons and the occurrence of hemorrhage, and this increased with the increase in the dose given. The concentration of metronidazole is high in the extracellular space in the brain that is likely to cause toxicity to the brain (15). This is consistent with what the researcher (16) found through histological microscopy, and it was found that the treatment of cats with metronidazole at a dose of 73.5-147 mg/kg for forty days, leaders lead to a loss of the medulla of some cranial nerve axons with necrosis and degeneration of some neurons, an increase in the number of glial cells and swelling of the axons with the presence of large macrophages in the Brainstem. Also, the treatment of rabbits with metronidazole at a dose of 20 and 40 mg/kg, and through microscopic histological examination of the brain and sciatic nerve, led to cavitations in the brain, spongy changes and degeneration of nerve bundles in the sciatic nerve with cell degeneration and the loss of Burkinji cells with severe congestion in the brain with loss of the covering Myeloma of the sciatic nerve axons (17), (18) also indicated that the treatment of male rats with metronidazole in doses of 135 mg/kg and 540 mg/kg for sixty days, and through histological examination found in brain tissue the occurrence of blood congestion within the blood vessels, hemorrhage, Burkinji cells necrosis and hemorrhage in the granular layer and epidermis around Supper neuron and glial cells Metronidazole metabolic products may be associated with DNA or RNA in neurons (19).

The association of metronidazole or its metabolic derivatives with RNA inhibits the construction of proteins and consequently breaks the axons in nerve.
fibers (20; 21; 6). Metronidazole also induces the oxidation of norepinephrine, dopamine, and all catecholamine derivatives to form nitro-ion roots that reduce tissue oxygen, the superoxide roots, which increase the water content causing swelling of the axons (22). It may also induce vascular spasm, which may result in a lack of localized oxygen, in which case it leads to any tissue breakdown.(23).

Reducing metronidazole as a result of metabolic processes produces a synthetic anti-inflammatory, thiamine, as metronidazole turns into a vitamin B1 analog, and therefore it can be a base substance for the enzyme thiamine, which leads to competition vitamin B1, so metronidazole is converted into a counterpart of thiamine. It leads to harmful feeding of the nerves, which causes neurological diseases. Vitamin B1 is a key coenzyme in the mitochondria of the alpha-ketoclutarite and pyrophite metabolites which are part of the biochemical pathway to produce ATP which is the most basic energy in the cell (25). In the lobule cells, the metabolic metabolites of metronidazole are associated with RNA instead of the deoxyribonucleic acid (DNA). Therefore, the construction of cellular proteins will be inhibited due to the metronidazole binding to the RNA and thus lead to the breakdown of neuronal modulators (26). Whereas (11) stated that the neurotoxicity of metronidazole occurs through its inhibitory effect of the-aminobutyric acid neurotransmitter.

An Analytical Study of Deviations of the Foot and the Way to Put it While Walking Using the Force Sensor

Wissam Shallal Mohamed1, Basem Naji Al-Fatlawi2, Israalaffta Salem3, Hayder Naji Habash Alshawi4

1Assistant Prof., University of Al-Muthanna/Faculty of Physical Education and Sports Sciences/IRAQ, 2Assistant Prof., University of Kufa/Faculty of Physical Education and Sports Sciences/IRAQ, 3Assistant Lecturer, 4Prof., University of Kufa/Faculty of Education for Girls/Department of Physical Education and Sports Sciences/IRAQ

Abstract

The importance of the research lies in knowing the deviations of the foot from the position of the gait and the extent of the relationship of these deviations and the conditions in the pain that occur at the top and bottom of the back, as the method of placing the foot on the ground and areas of strength centring is important and affects the human skeleton, especially the areas of the spine above and below the back, As for the research problem, it was represented by following and informing the researchers. Many people suffer from the pain that arises in the areas of the back. As a specialist in this field, the researchers decided to study and analyze the variables of a force-sensitive device for a sample of students from the College of Basic Education, if this device is through the results that It extracts it can contribute to the knowledge of the many problems that these individuals suffer from at the back level. The research aimed to identify the areas of strength and foot deviations through the force sensor in the research sample, where the researchers used the descriptive method in the survey method as the research community identified the students of the College of Basic Education At the University of Kufa, who are (170) students, and the researchers chose a sample of (20) students who suffer from back pain, and after the presentation and discussion of the results came the most important conclusions The results showed that the research sample rested while walking on the outer part of the foot, and the results showed that the rest of the strength areas of the force were uneven and few.

Keywords: Foot deflections, the force sensor; analytical studies; back pain.

Introduction

The importance of the research lies in the possibility of exploiting and benefiting from lactic acid during training in the speed of transfer of information to the brain because the presence of this substance in the body leads to the release of certain hormones that help in the speed of information transfer to the brain in knowing the deviations of the foot from the position of walking and the relationship of these deviations and conditions in the pain that occurs at the top and bottom of the back, as the way to place the foot on the ground and the areas of strength attachment is important and affects the human skeleton, especially the areas of the spine above and below the back, and the research problem was that the current scientific progress depends on techniques and modern method when applied in various aspects And the use of modern scientific devices, in order to access the scientific facts that serve this progress, therefore, through the follow-up and briefing of researchers, there were many people who suffer from pain that arises in the areas of the back and as a specialist in this field, the researchers decided to study and analyze the variables of a device that feels the strength of a sample of the students of the College of Basic Education, if this device, through the results it extracts, can contribute to knowing the many problems that it suffers from. Individual loyalty at the level of the back and the research aimed to identify

areas of strength and foot deviations through the force sensor in the research sample.

**Practical Part:** The researchers used the descriptive method in the survey method on the students of the College of Basic Education at the University of Kufa, who are (170) students, and the researchers chose a sample consisting of (20) students who suffer from back pain.

**Field Research Procedures**

**Exploratory Experience:** The researchers conducted the exploratory experiment 12/20/2016 at ten o’clock in the morning on a group of students whose number reached (3) students outside the original sample in the College of Basic Education and were aimed at identifying work obstacles to avoid them in the main experiment, because “the exploratory experiment procedures lead to Avoid shortcomings, specifying the location, time and duration of the experiment.”

Through the exploratory experiment, the following observations were identified:

- The validity and working of the Dynafoot device.
- The extent of providing the necessary equipment and tools.
- The adequacy of the number of assistant team members and its role in performing its duties correctly.

**Main Experience:** The main experiment was conducted 1/5/2017 at ten o’clock in the morning in the College of Basic Education at the University of Kufa, where a device (Dynafoot) was used to extract its variables from the areas of strength and leg deviations.

**Strength sensor (Dynafoot)**: A system for measuring force changes on the ground during each running step, which is made up of four parts that are the data delivery base (a foot pedal that is placed in the shoe with a wired connection to the force calculator that connects to the leg of the laboratory) and the signal receiver device connects with the laptop and receives the signal. After 20 meters for closed halls and 10 meters for outdoor playgrounds, the system operates after placing the steps sensor in the player’s laboratory shoe and fixing the conveyor device to point on his leg and entering data about the player’s age, length, weight, and gender, and the device measures the highest strength, lowest strength, power distribution areas in the foot, and foot deviations And other variables.

**Statistical Means:** To identify the results of the study, the researchers used the Excel system to extract the following statistical method:

1. Arithmetic mean.
2. Standard deviation.

**Presentation, analysis and discussion of results:**

Presenting, analyzing and discussing the results of the variables of the (Dina foot) device.

From Table (1), and through the results that have emerged, it is clear that the research sample was anchored while walking on the outer part of the right foot and also the deviation of the right foot to the outside side, and this action leads to the birth of the mother in the back at the sample since the force is supposed to be centred in the middle. The foot because the skeleton is an interconnected structure and any defect in one of its parts leads to pain and these pain due to the imbalance of this structure and the shedding of force in its correct place.

As for the left foot, most of the strength was concentrated in the inner part of the foot, due to the concentration of force in the right foot in the outer part, that is, it caused a malfunction in the position of the force, which led to its gathering in the inner part of the foot, and this resulted in a deviation of the foot by (2) degrees, which is less than the right foot, which it deviated by (7) degrees.

From the previous results, it becomes clear to the researcher that the basis of the pain experienced by the students is in the way of putting the foot on the ground and getting used to the wrong way of walking from a young age, which leads to an imbalance of the skeleton and an imbalance in one of its parts, which causes the pain.(10)

Conclusion

1. The results showed that the research sample rested while walking on the outside of the foot.
2. The results showed that the remaining areas of the force’s focus were mixed and few.
3. The results showed that the degree of right foot deflection was great.

Isolation and Diagnosis of Multi Drug Resistance *Pseudomonas Aeruginosa* from Wound and Burn patients in Baghdad City

Mustafa Riyadh Salman AL-Rubaye¹, Taghreed Khudhur Mohammed², Hanaa N. Abdullah³

¹Researcher, Selçuk University Fen Fakülteleri/Biyoteknoloji Bölümü Kampus/KONYA/Turkey; ²Professor, Institute of Medical Technology/Al-Mansour/Middle Technical University/Baghdad-Iraq, ³Professor, College of Health and Medical Technology-baghdad/Middle Technical University/Iraq

Abstract

**Background:** *Pseudomonas* is a common bacteria found all over the world; in soil, water, and plants, and it is one of the most common pathogens in hospital-acquired infections.

**Aims:** The aims of this study were isolation of *P. aeruginosa* bacteria from patients with inflammation of burns, Diagnosis and identification of *P. aeruginosa* using chemical tests and VITEK2 system and also study of antibiotic resistance in *P. aeruginosa* using the VITEK2 system.

**Method:** (206) swabs were collected from wounds and burns; (139) samples from burns and (67) samples from wounds; from different clinical cases for both sexes and ages (1-70) years, the patients coming and sleeping in Baghdad Teaching Hospital and Burns Hospital in the City of Medicine at Baghdad city; the duration from January to the end of March 2019. Samples were cultured on the variety of culture media (MacConkey agar, Blood agar and Cetrimide agar) in order to obtain the bacterial isolates of *P. aeruginosa* depending on their phenotypic characteristics. VITEK2 system were used for identification *P. aeruginosa* and to study their resistance to the antibiotics.

**Results:** Out of the 206 samples, 50 *Pseudomonas aeruginosa* were isolated from swabs. 31 (62%) isolates were isolated from burn and 19 (38%) from wound swabs. The isolates were subjected to a series of biochemical tests as diagnosed with Api 20E; and VITEK2 system to increase confirmation of isolation yield for *P. aeruginosa* bacteria. The results showed that the majority of isolates were (92%) resistant to Amoxicillin while the isolates differed between sensitive and moderate sensitivity and resistance to other types of antibiotics.

**Conclusion:** The study showed that the percentage of isolation of *Pseudomonas aeruginosa* bacteria from wound infections is relatively higher than the rate of isolation from burn swabs. Most of *Pseudomonas aeruginosa* isolates showed high resistance to most types of antibiotics used in the present study, especially the antibiotic Amoxicillin where the resistance rate was 92%.

**Keywords:** *Pseudomonas aeruginosa; VITEK 2 system; resistance to antibiotics.*

Introduction

*P. aeruginosa* is a Gram-negative and ubiquitous environmental bacterium. It is an opportunistic human pathogen capable of causing a wide array of life-threatening acute and chronic infections, particularly in patients with compromised immune defense. It has been of particular importance since it is the main cause of morbidity and mortality in cystic fibrosis (CF) patients and one of the leading nosocomial pathogens affecting hospitalized patients while being intrinsically resistant to a widerange of antibiotics(1).
This Gram negative bacteria structure includes a 0.5 – 0.8 μm by 1.5-3 μm rod shape, and has one flagellum for mobilization. Individualizing itself from most Gram-negative bacteria, P. aeruginosa is positive for an oxidase reaction. Moreover, it is permanently unable to ferment lactose. P. aeruginosa is found in water, plants, soil, and on the epidermis of animals. In nature, it is commonly found as a plankton swimming through water or as a biofilm, clusters of bacteria sharing the same phenotype and common chemical properties\(^2\). Uniquely, P. aeruginosa can thrive and survive in a variety of temperature and infrequent nutrition. The bacterium has been observed in previous studies to grow in distilled water giving P. aeruginosa an advantage in adapting to changing environments\(^3\). Being an opportunistic pathogen, P. aeruginosa requires a lack of immunity to infect its host\(^4\). Moreover, this is the explanation as to why P. aeruginosa is such a sizeable nosocomial threat for patients with ventilation machines, cancers, and burns. Colonization of P. aeruginosa in the respiratory tract is associated with sepsis and death. Any patient that is immunosuppressed or has experienced significant amounts of trauma are at risk for the colonisation of an infection. The mortality rate approximates 50% for said patients who obtain an infection\(^5\)(\(^6\)). The aims of this study were isolation of P. aeruginosa bacteria from patients with inflammation of burns, diagnosis and identification of P. aeruginosa using biochemical tests and VITEK2 system and also study of antibiotic resistance in P. aeruginosa using the VITEK 2 system.

Materials and Method

I. Collection of Samples: 206 swab samples were collected from clinical sources including 67 burns and 139 wounds from patients suffering from burns and wounds infections and under the supervision of a medical specialist at City Medicine Hospital/department of burns in Baghdad city, in the period beginning from January to the end of March 2019.

II. Identification of bacterial isolates:

A. Morphological examination: Blood agar, MacConkey agar and Cetrimide agar were used to study the phenotypes of P. aeruginosa colonies which including colonial form, shape and color, size, and aroma. Readymade media were used, Nutrient Broth, Mueller- Hinton agar medium, Brain heart infusion broth, Pseudomonas agar, Voges - Proskauer reagent, Urea agar medium, King A medium, King B medium and Indole test medium\(^7\).

B. Microscope examination: The Gram stain was used for identification of P. aeruginosa in the samples\(^8\).

C. Chemical Tests: The following biochemical tests were performed for the diagnosis of isolated P. aeruginosa bacteria: Catalase test, Oxidase test, Motility test, IMVIC test (Indole test, MR-VP, Simmons’ citrate agar, Citrate utilization test)\(^7\)(\(^8\)), and API 20E identification system.

D. API 20E identification system: API 20E is standardized system for identification the Enterobacteriaceae and other non- fastidious, by depending on using 20 biochemical tests. It was done according to the instructions of BioMerieux.

E. Determination of minimal inhibitory concentration of antibiotics using the VITEK2 compact system: The isolates were identified as P. aeruginosa by conventional method as well as by the VITEK2 system\(^9\). The VITEK2 is a fully automated system that performs bacterial identification\(^10\). In VITEK2 compact system, the Antibiotic Sensitivity Test Card (AST C) Supplement 2 was used to determine the values of the (MICs) for P. aeruginosa isolates. There are 18 to 20 antibiotics distributed over 64 holes in the Antibiotic Test Card. The device recorded the turbidity changes following the growth of the bacteria, this is done according to the instructions of BioMerieux.

F. Antibiotic susceptibility test (AST): The sensitivity of bacterial isolates to many antibiotics was studied according to the Kirby-Bauer method and WHO\(^11\)(\(^12\)).

Results and Discussion

The study included the collection of 206 swabs of burn injuries and wounds of both sexes, males and females, ranging in age from 1-70 years for the period from January to the end of March 2019, from burns hospital in the city of medicine and Baghdad Teaching Hospital. After the final diagnosis of samples obtained 50 isolates of P. aeruginosa (24.27%) were shown in Table 1.

On MacConkey agar, the bacterial colonies appeared pale yellow because they had not fermented lactose, and this compatible with the results of previous researches\(^{10}\). On Nutrient agar, the growing of *P. aeruginosa* colonies were identified depending on the pigments and odor production (grape like odor). On the blood agar medium, the bacterial colonies gave Beta-hemolysis (β). On the Cetrimide agar, the bacterial colonies appeared in greenish yellow, on the King A agar, they produced a blue and green pigment (pyocyanin), while all isolates grow on King B agar did not produce pyocyanin.

Microscopic examination showed that they were Gram negative bacilli. In the biochemical tests, all isolates showed positive results for Catalase test, which explained the bacterium’s ability to break down hydrogen peroxide into water and oxygen gas. The score IMViC tests was Indole (−), Methyl red (−), Voges-Proskauer (VP) (−), positive (+) result for Citrate consumption, as shown in Table 2. Kligler’s Iron Agar (KIA) have alkaline interaction (cannot ferment glucose and lactose), \( \text{H}_2\text{S} \) production (−). Growth temperature is 37°C and 42°C, and negative results were obtained for urease test; they were positive for motility test because the bacteria have flagella, these results corresponds positive for motility test because the bacteria have flagella, these results corresponds to\(^{11}\)(\(^{12}\)).

All isolates of *P. aeruginosa* showed a clear variation in the resistance of the antibiotics used in this study. The resistance rate determined against Gentamicin was 81%, Ciprofloxacin was 79%, Tetracycline was 74%, and Nalidixic acid and Norfloxacin were 72%, Imipenem 66%.

Figure 1. The results showed that the minimum inhibitory concentration (MIC) of the antibiotic: the VITEK2 Compact system was used to determine the values of the lowest inhibitory concentrations (MICs) for 13 antibiotics namely Ticarcillin, Piperacillin/ Tazobactum, Ticarcillin/clavulanic acid, Pipracillin, Cefepime, Gentamicin, Imipenem, Meropenem, Tobramycinin, Cipodoxacin, Ciprofycin. The results showed that the value of the MIC of Ticarcillin antagonist is 32 µg/ml at 87%, anti-Pipracillin/Tazobactum 8-16 µg/ml at 85.5%, Ticarcillin/clavulanic acid 16-64 µg/ml at 85.5%, anti-Pipracillin ≥ 4 -16 µg/ml 85.5%, Anti-Cefepime 2-8 µg/ml 76.8%, Gentamicin ≤ 1-4 µg/ml 73.9%, Imipenem 0.5-2µg/ml 71%, and anti-Meropenem ≤ 0.25 µg/ml 63.8%, anti-Tobramycin ≤ 1-2 µg/ml 71%, anti-ciprofloxacin ≤ 0.5-0.25 µg/ml 68.1%, anti-Amikacin ≤ 8-2 µg/ml 60.9%, anti-ceftazidime 2 -8µg/ml 60.9% were shown in Table 3.

Ceftazidime | 22 - 63.8% | 2 - 7.2% | 10 - 29%

A percentage (%) of the total isolates were calculated.*

The current results reports that the percentages of *P. aeruginosa* in both wounds and burns swabs are 50 isolates of (24.27%), and this result is higher than in other Iraqi results of researchers. Zainulabdeen in 2016\(^{(13)}\) recorded that the percentage of *P. aeruginosa* in patients suffering from burn and wound infections in AL-Samawah General and teaching Hospitals in the South of Iraq was (8.2%) between 2014 and 2015. Whereas, in the North of Iraq, Kirkuk governorate, the percentage of *P. aeruginosa* in burns was (32.55%)\(^{(14)}\).

The difference in isolation rate may be due to the degree of health care, which includes the arrival of the patient to the hospital before bacterial growth or the possibility that the patient had taken antibiotics in advance, and on the other hand may lead to a long hospitalization in the hospital increase the rate of isolation, especially in patients with burns. The intensity may increase to 20% within 72 hours as a result of an infection acquired from hospital infection and nosocomial infection directly as a result of contact with patients or indirectly through the use of contaminated surgical instruments and tools that help to spread these bacterial\(^{(14)}\). Also, the reasons for the difference in isolation rates are due to the difference in the sample source, number of samples, geographical location, and method of antisepsis of wounds or burns, frequency of antisepsis, as well as the common and random use of antibiotics which had a significant role in the emergence of resistance to these bacteria.

Recent study showed that *P. aeruginosa* isolates were 100% resistant to (Amoxicillin, Ampicillin), 93% to the (Cefotaxime, Carbenicillin and Imipenem)\(^{(15)}\); this compatible to the current results. In Baghdad city, AL-Shamaa et al. 2016 [16] were isolated 31 *P. aeruginosa* isolates from 111 burn and wound swabs. All isolates were resistance 100% to Carbenicillin, 61% Ticarcillin, and Colistin to 84%. In Pakistan, the most common bacterial isolate from burn patients was *P. aeruginosa*; it was 41 isolates (24.91%). All isolates showed highly resistance to different antibiotics including Augmentin, ceftazidime, cefotaxime, ceftriaxone, meropenem, and piperacillin+tazobactam \(^{(17)}\). In United States, most *P. aeruginosa* isolates had resistance to Penicillins, Cephalosporins, and Carbapenems\(^{(18)}\).

It is noted that the results of the present study recorded high resistance of bacterial isolates towards the group Penicillin- β-lactam including Ampicillin and Amoxicillin as these antagonists work to prevent the synthesis of the bacterial cell wall by binding to special sites in the bacterial cell and thus inhibits the work of the enzyme transpeptidase which forms peptide bridges in the peptidoglycan layer, which is an important component of the cell wall. The results of the present study showed that the resistance of *P. aeruginosa* bacteria to the antibiotic Ampicillin and Amoxicillin, which is a medium-spectrum antibiotic, was very high (92 and 89%, respectively), this ratio is high and this result is consistent with the result obtained by Al-Qasi, 2012\(^{(19)}\). The results of antibiotic resistance were consistent with those of Reishet et al., 1993\(^{(20)}\); it was 90.47%. In another study, all isolates of *P. aeruginosa* were resistant to penicillin and amoxicillin\(^{(21)}\). It is clear that the most important characteristic of *P. aeruginosabacteria* is their low sensitivity to antibiotics. In addition to the lowpermeability of the cellular membranes of bacteria and the ability of *P. aeruginosa* bacteria to develop their readily acquired resistance either by mutation in coded genes or by horizontal transmission of antibiotic-resistant gene markers. The multiple resistance of many antibiotics may be attributed to different virulence factors of bacterial isolates that increase resistance to different antibiotics\(^{(21)}\).

**Conclusion**

The study showed that the percentage of isolation of *Pseudomonasaeruginosa* bacteria from wound infections is relatively higher than the rate of isolation from burn swabs, reaching 28.35%. Most isolates of *P. aeruginosa* showed high resistance to most types
of antibiotics used in the present study, especially the antibiotic Amoxicillin where the resistance rate was 92%. Also Imipenem was the most effective antibiotics against isolates of P. aeruginosa bacteria with a resistance rate of 66% followed by Nalidixic and Norfloxacin with a rate of 72%.

Epidemiological Study of Common Cancer Cases in Baghdad City

Taghreed Khudhur Mohammed¹, Alaaabdulkhaliq Jabbar², Anam Aziz Jasim³, Hanaa N. Abdullah⁴

¹Professor, Ph.D., Institute of Medical Technology/Al – Mansour/Baghdad/Iraq, ²Assistant Lecture, M.Tech., Institute of Medical Technology/Al – Mansour/Baghdad/Iraq, ³Lecture, Master in Biotechnology/Institute of Medical Technology/Al – Mansour/Baghdad/Iraq, ⁴Professor, Ph.D. College of Health and Medical Technology-Baghdad/Middle Technical University/Iraq

Abstract

Background: It is possible to notice the increase in the incidence of cancer during the recent years in Iraq, particularly in Basrah, Al - Anbar and Baghdad. Different types of cancers like Lung cancer, Breast cancer, Bladder cancer, Colorectal cancer and Pancreas tumors.

Objectives: The objective of the current research was to study the most common cancer cases in Baghdad city.

Method: The current study was conducted in the oncology teaching hospital/medical city/Baghdad, for the period from January 2019 until October 2019. The data of 139 patients were collected from official records in the hospital clinics which included gender, age and the types of cancer.

Results: The highest percentage of cancers was found in patients with breast cancer (54.67 %); followed by colon cancer (16.54 %), ovarian cancer (8.63 %), liver cancer (5.75 %) and prostate cancer (5.03 %). The highest incidence of breast cancer appeared in the age group (40 – 49) years with the percentage of 35.52%. Of the total number of studied cases, 80 (63.30%) of patients with different types of cancer suffered from chronic diseases.

Conclusion: Breast cancer most common types of cancers in Baghdad city, and increased cases in the last year, 2019. Both sexes suffered from cancers especially in age above 40 years.

Keywords: Breast cancer, colon, ovary, liver, prostate, epidemiology.

Introduction

Epidemiology of cancers is important to study the distribution and frequency of different types of cancer diseases among specific area⁵. There are different types of cancers in Iraq like breast; colorectal; lung; lymph nodes; ovarian and gastrointestinal cancers⁶.

The highest frequency of cancers are related with breast cancer. In Iraq, 855 patients with breast cancer were observed in 2016. Thirty-five percent of women with breast cancer was present in the 45 – 54 year age group⁷. Interpretation of cancer results indicates that there is a noticeable increase in cancer incidence in all regions of Iraq. The reason may be due to the weapons used during wars, as well as due to enormous environmental pollution and accumulation of waste of all kinds in the Iraqi environment, increased unemployment, poverty and eating unhealthy food and others⁸⁹.

In Tikrit, during (1995 – 2005), the prostate carcinoma recorded the third type of cancers in males. The most risk factors may be causing cancers are: aging,
smoking tobacco, drugs, radiation exposure, infection with some viruses and bacteria, alcohol drinking, genetic factors, immunosuppression and exposure to some environmental factors ex. Sunlight and heavy metals[4]. So, the objective of the current research is to study the common cancer cases in Baghdad city.

**Method**

The current study was conducted in the oncology teaching hospital/medical city/Baghdad, for the period from January 2019 until October 2019. The data of 139 patients were collected from official records in hospital clinics which included gender, age and the types of cancer.

**Ethical Approval:** This study has conducted with ethical approval from oncology teaching hospital/medical city/Baghdad, in order to facilitate the obtaining of information from the medical clinics arriving to it, a number of patients have different types of cancer.

**Results**

The total of 139 patients with different types of cancer were shown in (Table 1). The highest incidence rates were in breast cancer (54.67 %); followed by colon, ovary, liver and prostate cancers (16.54%, 8.63%, 5.75% and 5.03% respectively).

According to table (2), the highest percentage of cancer appeared in women more than in men, as it was 112 (80.57%) and 27(19.42%) respectively. From the current results, it was found that the highest incidence of type of cancer in men was prostate cancer 7(100%), followed by colon cancer 6(26.08%). In women the highest percentage of one type of cancer was breast cancer 76(100%) followed by colon cancer 17(73.91%).

From table (3), the highest incidence of breast cancer appeared in the age group (40 – 49) years and in percentage of (35.52%); it is followed by ovarian cancer within the same age group with a percentage of (75%). While the highest incidence of prostate cancer was within the age group (70 – 79) years with the percentage of (71.42%). The results of liver cancer showed that it was almost evenly distributed across age groups (40 – 49), (50 – 59) and (60 – 69) years in percentages that ranged from 25%to 37.5%. As well as colon cancer, it was present in all age groups under study in almost equal percentages.

Discussion

The world is witnessing a large increase in the incidence of different types of cancer and this is due to various reasons. The most reasons include exposure to some microorganisms that cause genetic mutations such as infection with EBV; eating unhealthy food or genetically modified foods.

Breast cancers and other types of cancer may be happening as a result of aging and genetic factors. The possibility of infection increases if there are other patients in the same family who had cancer. Ali et al, found that the highest prevalence of cancer in Iraqi patients with different types of cancer was breast cancer. It was 33.1% in women attended in Al - Yarmook hospital whereas the bladder and colorectal cancers were 13.5% and 3.7% respectively. This is compatible with the current study; in which the breast cancer incidence was 76 (100%), followed by colon cancer 17 (73.91)%.

In Tikrit city, the prostate tumor recorded the third solid tumor in men. It was seen in 75 (9.1%) cases in a period from January 1995 to December 2005 which was diagnosed by histopathological method. The highest frequency appeared in men with age > 70 years. The result of the current study is compatible with the study of researchers in Tikrit. The prostate cancer recorded (5.03%) (Table 1) with age ranged (70 – 79) years with percentage 71.42% (Table 3).

The results of the current study relating with lung cancer is incompatible with the study of Al – Rahim in 2007. The researcher revealed that 71.8% of males
with a mean age of 63 years attended to medical city hospital at Baghdad had lung cancer\(^8\) and this does not match with the current research results in which the lung cancers recorded 2.15% (Table 1).

Other studies related with the distribution of breast cancer in different governorates of Iraq. The data obtained from the cancer registries at many hospitals in Basrah which containing the number cases of breast cancer in a period from 2009 to 2012. The incidence rate was 24.49/100000 females\(^9\). While the percentage of breast cancer in Karbala in (3634) suspected cases (suffering from nipple discharge and breast mass with presence of ulcers during the period from 2001 – 2005 was 9.5\(^{(10)}\).

A study in Erbil/Kurdistan showed that despite of facts related with the majority of women have a good knowledge of breast and cervical cancers; however, most women had an average knowledge of the importance of mammography, Pap smear and early breast cancer detection. Therefore, there is an urgent need to explain the screening program in primary health care hospitals and educational hospitals to raise awareness among women as well as in the media such as television, radio and newspapers\(^{(11)}\).

In 2017, the incidence of all types of cancer was higher in females than in males in a period from 2008 to 2015 in Karbala\(^{(12)}\) and this similar to the current study. The mortality rate according to infection with different types of cancer increase in Basrah governorate during the period from 2008 to 2016. Lung and bronchus cancer caused the death in 752 (13.2\%) from 5719 patients who suffered from different types of cancer, followed by breast cancer which lead to death 606 (10.6\%) of patients during 2008 – 2013\(^{(13)}\). In 2018, 75\% of Iraqi women with breast cancer, suffered from deficiency of vitamin D3 and calcium. So these two factors may have an impact on the incidence of cancer in women\(^{(14)}\).

Iraqi children, aged less than (15) years had acute lymphoblastic leukemia (ALL) in a percentage of 72.5\%, whereas acute myeloblastic leukemia in adult was 27.5\%(15). All types of cancer increased in the world. Breast cancer incidence ranged from 27 per 100000\^-2 in (Asia, Africa) and (Australia, North America and Europe) respectively\(^{(16)}\). In United States, the colorectal cancer incidence had spread in patients aged from (49–50) years in percentage 46.1\% (50 per 100000 of population)\(^{(17)}\).

**Conclusion**

Breast cancer most common types in Baghdad city and increased in the last year, 2019. Also, Female more than male suffered from Breast cancer, specifically in age between third and fourth decades years.

Investigation of the Hydrolytic Enzyme Activities of *Candida Parapsilosis* Isolated From Milk Samples of Bovine Mastitis by API ZYM and Molecular Method

Hawraa F.H. AL- Abedi, Azhar A.F. AL-Attraqchi, Bassam Y. Khudaie

1Lecturer Dr. Department of Microbiology, PhD student in College of Veterinary Medicine/the University of Basrah/Iraq, 2Assistant Prof. Dr. Department of Medical Microbiology/College of Medicine, Al-Nahrain University/Iraq, 3Prof. Dr. Department of Microbiology/College of Veterinary Medicine, University of Basrah/Iraq

**Abstract**

Two hundred and fifty milk samples were collected from cows suffering from mastitis, these samples were tested for mycotic mastitis using culture and conventional PCR method. The results showed 116 isolates of *Candida* spp. were recovered with a prevalence of (46.4%), hence *C. parapsilosis* was the dominating species 15/116 (12.9%). Fifteen isolates (100%) belong *C.parapsilosis* was confirmed by PCR using a species-specific primer for the 18S rRNA gene. Some randomly chose isolates of *C. parapsilosis* were used for detection of their hydrolytic enzymatic activity by API ZYM test and PCR. The method used to evaluate their enzymatic activity was API ZYM (BioMerieux). The highest activity was observed for leucine arylamidase, acid phosphatase, naphthol-AS-BI-phosphohydrolase and α-glucosidase as 10/10 (100%) for each, followed by esterase lipase (C8) 9/10 (90%), valine arylamidase and alkaline phosphatase 8/10 (80%) for both and esterase (C4) 7/10 (70%). Conventional PCR was done for partial amplification of sterol esterase, alkaline phosphates and alpha-glucosidase genes by specific primer sequences, The results of the PCR amplification of these genes was 8/10 (80%) for sterol esterase gene. Concerning the alkaline phosphatase gene, it was present in 10/10 (100%). Regarding alpha-glucosidase gene was present in 10/10 (100%). This work aims at evaluating enzymatic activities of *C. parapsilosis* isolated from cow’s milk with mastitis.

**Keywords:** Candida parapsilosis, Bovine mastitis, Hydrolytic enzymes, Conventional PCR, API ZYM test.

**Introduction**

Bovine mastitis is the most devastating state of the epidemic in terms of the worldwide economic losses. The etiological agents can vary from place to place depending on climate, animal species and animal husbandry, and include a wide variety of gram-positive and gram-negative bacteria and fungi(1). Mycotic mastitis had been documented to be caused by various genera of moulds and yeasts beside bacterial mastitis,

The most commonly observed fungi are *Candida* spp, *Aspergillus* spp, *Trichosporon* spp, *Cryptococcus* spp(2). Mycotic mastitis is classified into two large groups based on the moment of diagnosis, primary mycotic mastitis (bacterial preliminary mastitis) and secondary mycotic mastitis that often occur immediately without antibiotic treatment (3). For timely, effective management, early, rapid and accurate identification of the pathogenic fungus is important. In the clinical microbiology laboratory, traditional detection of pathogenic fungi is based on morphological and physiological tests that often take 3 days or more and may be inaccurate. A traditional PCR and multiplex PCR approach was developed in recent years to classify multiple fungal pathogens simultaneously in a single reaction(4). The fungi have virulence factors such as adapted cell morphology, adhesion factors, phenotypic switching, biofilm formation and enzymatic activity to
colonize, invade and evade host defence mechanisms. One particularly effective factor is the production of extracellular hydrolytic enzymes which facilitate the destruction of the cellular membranes and thus allow the host tissue to penetrate the fungal cells(5).

Material and Method

Sample Collection: Two hundred and fifty samples of bovine milk with mastitis according to California mastitis test from different areas of Basrah province, had been collected during the period from March 2018 up to September 2019.

Isolation and identification of Candida spp.: Milk samples were inoculated in Sabouraud’s Dextrose agar supplemented with 0.05 mg/ml chloramphenicol and then incubated at 37°C for 24h up to 1 week. Macroscopic and microscopic morphology tests have been performed after incubation yeast identification was conducted according to(6).

Detection of hydrolytic enzymes by API ZYM Kit: The enzymatic activity was measured using a semi-quantitative micromethod API ZYM test (BioMerieux, France) (API Laboratories and Analytab products). The substrate was available for 19 hydrolytic enzymes(7), for evaluating the followings: Alkaline phosphatase, esterase, esterase lipase, lipase, leucine arylamidase, valine arylamidase, cystine arylamidase, trypsin, α-chymotrypsin, acid phosphatase, naphthol – AS-BI-phosphohydrolase, α-galactosidase, β-galactosidase, β-glucosidase, α-glucosidase, α-mannosidase and α-fucosidase.

Specimen suspension was expected from culture media on Sabouraud’s dextrose agar in 2 ml of distilled water, then suspended in API medium the turbidity was concordant with McFarland tube No. 5. Inoculation of the strip using a pipette was done by dispensing 65 ml specimen into each cupule, the plastic lid was placed on the tray and incubated at 4 h for 37°C, the inoculated strip was not placed in bright light. One reduction of ZYM A, after incubation (tensioactive agent) and 1 reduction of reactive ZYM B (diazonium salt) was added to every cupule. Strips had been placed under a strong source of light (1000 W bulb) for about 10 seconds. Reactions were read and the results recorded on the result sheet. A value of 0-5 assigned corresponding to the established colours: 0 corresponds to a negative reaction; 5 corresponds to the maximum intensity; values 1, 2, 3, 4 are considered to be intermediate reactions depending on the intensity level.

Molecular identification of C. parapsilosis:

A. Primer Design: DNA extraction yeast culture was done with G-spin extraction DNA kit according to the manufacturer protocol identification of C.parapsilosis isolates were conducted by using conventional PCR for the amplification of a partial gene of 18S rRNA by specific primer sequences was used. The hydrolytic enzymes detected were of genes encoding sterol esterase, alkaline phosphatase and alpha-glucosidase. The PCR primers were designed and funded by the company (Macrogen, South Korea) using the NCBI- Gene Bank online database and primer design., table (1).

B. DNA extraction: According to the manufacturer procedure, yeast genomic DNA from the milk samples was extracted using G-spin DNA extraction kit. Candida culture as 200 μl was pipetted into 1,5 ml sterile microcentrifuge tubes, then added 50 mg glass beads with 20 μl of proteinase K and homogenized for 5 min by cell disruptor vortex mixer. Then 200 μl of BL cell lysis buffer was added to each tube and mixed with a vortex mixer, all tubes were incubated for 10 min for 56°C with mixing every 3 min, 200 μl of absolute ethanol was applied to lysate and immediately mixed by shaking vigorously. Spin column put in a 2 ml collection tube and transferred the mixture (including any precipitate) to the column, and then centrifuged for 1 min at 13,000 rpm. The filtrate was discarded and the spin column was inserted into a new 2 ml collection tube, 400 μl W1 buffer was added to the spin column and centrifuged at 13,000 rpm for 1 min, the flow-through was discarded and the collection tube was reused. Six hundred μl wash buffer was applied to each column and centrifuged at 13,000 rpm for 1 min, the flow-through was removed, the column was put in a new 2 ml collection tube, then all the tubes were centrifuged at 13,000 rpm for 1 min to dry the column membrane. Spin column was placed in a new 1.5 ml tube, and 50 μl of the CE buffer was added directly to the membrane and incubated at room temperature for 1 min, then centrifuged at 13,000 rpm for 1 min. Instead all the tubes left stand for 1 min to ensure that the matrix absorbed the elution buffer, then centrifuged at 10,000 rpm for 30 seconds to elute the purified DNA. NanoDrop spectrophotometer was used to check the concentration of the extracted DNA according to the formula: 1OD260 = 50ng, purity = 260/280.

C. PCR amplification: PCR master mix reaction by using (Master mix PCR PreMix kit). The master mix was prepared according to company instructions by inserting 3 μl of template DNA, 1 μl of forward and reverse primers (10 pmol), and 20 μl of nuclease-free water was completed. Reactions were as follows: initial denaturation at 95°C for 2 min, followed by 30 cycles of denaturation at 95°C for 30 s, annealing at 57°C for 18S rRNA, 60.3°C for forsterol esterase, 59.3°C for each alkaline phosphatase and alpha-glucosidase for 30 sec, and extension at 72°C for 50-60 sec, with a final extension at 72°C for 5 min. Amplification products were separated by electrophoresis on 1.5 % agarose gel containing 3 μg/mL ethidium bromide using a 2000-bp ladder (Amersham Biosciences) as molecular weight marker. Tested on agarose gel electrophoresis for 1 hour (100V).

Results

1. Prevalence of C. albicans in dairy cows with mastitis: Out of 250 milk samples analyzed from cows with mastitis, 116 Candida isolates were recovered (46.4%). Based on cultural and morphological aspects, C. parapsilosis was the predominant 15/116 (12.9%).

2. API- ZYM enzymatic activities: Some random selected C.parapsilosis isolates were used for determination of 19 hydrolases activities. Regarding C. parapsilosis 10 isolates were generated highly activated leucine arylamidase, acid phosphatase, naphthol-AS-BI-phosphohydrolase, and α-glucosidase when the percentage was (100%), followed by esterase lipase nine isolates produce this enzyme strongly (90%) meanwhile only 1 isolate (10%) showed no activity of this enzyme. Eight isolates (80%) found to be producers for each of alkaline phosphatase and valine arylamidase with high activity and only 2 isolates (20%) produce alkaline phosphatase with moderate activity, while 2 isolates (20%) with no activity for valine arylamidase enzyme. In case of esterase, it was found that 7 isolates only (70%) produce this enzyme with strong activity, meanwhile, 2 isolates only (20%) produce this enzyme in moderate activity and only 1 isolate (10%) showed no activity at all, table (2).

3. **Molecular identification of C. parapsilosis:**

Molecular identification of *C. parapsilosis* in this study relied on conventional PCR for the amplification of a partial gene of 18S rRNA by specific primer sequences. This gene was present in fifteen samples of *C. parapsilosis* with PCR product size of 507 bp, as shown in figure (1). Using NanoDrop spectrophotometer, DNA concentration was ranging from (5.9 – 70.2) ng/ml with a purity of (1.8–2.08).

![Figure (1): Agarose gel electrophoresis shows PCR product analysis of pathogenic *C. parapsilosis*. Lane M Marker ladder (2000 bp), lane (1-7): 18S rRNA gene of *C. parapsilosis* isolate at 507 bp. Lane (NTC): None template (negative control).](image-url)
3. **Conventional PCR assay for enzyme production by *C. parapsilosis***: The results of PCR amplification of these genes was 8/10 (80%) for sterol esterase with a PCR product size of approximately 489 bp, as shown in figure (2). Concerning the alkaline phosphatase gene, it was present in 10/10 (100%) with a PCR product size of approximately 598 bp, as shown in figure (3). Regarding the alpha-glucosidase gene, it was present in 10/10 (100%) with a PCR product size of approximately 550 bp, as shown in figure (4).

Discussion

Yeasts are single-celled organisms that are ubiquitous in the environment and they are considered prospective pathogens of the mammary gland that produce disease when natural defense mechanism is lowered(8 and 9).

A total of 116 (46.4%) Candida isolates out of 250 milk samples were taken from cows with mastitis based on cultural, morphological aspects were carried out in various setting phenotyping identification tests for Candida spp. The highest percentage among isolated Candida spp was belong C.parapsilosis 15/116 (12.9%). In the present study, the percentage of C.parapsilosis was higher than those obtained in a study done in India (7.69%) isolated from cows with clinical mastitis(10). The presence of C. parapsilosis were also incompatible with those reported in Poland which was (45%) and in Turkey as (12.7%)(11 and 12). The geographical variation may be considered one of the reasons for the discrepancy in the distribution of species, or due to the number of included samples or may due to the differences in the method used for diagnosis.

In the present study C.parapsilosis (N=10) isolates and regarding hydrolases API ZYM test showed strong leucine arylamidase, acid phosphatase, naphthol-AS-BI-phosphohydrolase and α-glucosidase among 10/10 (100%), esterase lipase (C8) 9/10 (90%), valine arylamidase and alkaline phosphatase 8/10 (80%), and esterase (C4) in only 7/10 (70%). Hydrolytic leucine arylamidase enzymes was produced strongly in both tested species of Candida which similar to those reported in Poland by(7). And the isolates of C. parapsilosis examined did not produce trypsin, chymotrypsin, α-galactosidase, β-glucuronidase, α-mannosidase, and α-fucosidase which is similar to those reported by(13). In the current results and regarding the enzymatic activity of the isolated Candida spp. showed some differences from those detected by(14), who studied 12 enzymes of trypsin, α-chymotrypsin, α-galactosidase, β-glucuronidase, α-mannosidase, and α-fucosidase which is similar to those reported by(13). In the current study the reasons of choosing these enzymes out of the previously 19 studied ones is that the gene sequence of the other 16 enzymes are not found in gene bank i.e. the sequences of the three studied enzymes were obtained only. Furthermore, and concerning other studies in this field were not found as published research to compare the current results with them.

Conventional PCR was done for partial amplification of sterol esterase, alkaline phosphates and alpha-glucosidase genes by specific primer sequences. The results of the PCR amplification of these genes was 8/10 (80%) for sterol esterase. Concerning alkaline phosphatase, it was present in 10/10 (100%). Regarding alpha-glucosidase, it was present in 10/10 (100%).

In the current study the reasons of choosing these enzymes out of the previously 19 studied ones is that the gene sequence of the other 16 enzymes are not found in gene bank i.e. the sequences of the three studied enzymes were obtained only. Furthermore, and concerning other studies in this field were not found as published research to compare the current results with them.

Conclusion

1. This study proved the presence of C. parapsilosis in cow milk sample with mastitis in Basrah province.
2. API ZYM test is a good and more specific test than conventional PCR for detection of hydrolytic enzymes activities

Incidence of *Entamoeba Gingivalis* and *Trichomonas Tenax* in the Oral Cavity of Periodontal and Patients Under Chemotherapy, Confirmed with *in Vivo* Study

Dhilal Mahdi Al-Muathen¹, Luma Amer Yasir², Hayat Ghaith Sachit³

¹Lecturer/Basic Science Department- Biology, College of Dentistry, Mustanasiriyah University, Baghdad-Iraq, ²Lecturer/Dr. National Center of Hematology/Iraq, ³Assist. Prof. Dr. Basic Science Department-Microbiology, College of Dentistry, Mustanasiriyah University, Baghdad-Iraq

Abstract

**Aim:** The study aimed to evaluate the impact of occurrences *Entamoeba gingivalis*, and *Trichomonas tenax* with periodontal in one hand and patients receiving chemotherapy on the other hand and compared to normal subjects. And evaluate the pathogenicity of these parasites *In Vivo*.

**Materials and Method:** A total of 80 patients, 30 with Periodontitis attending AL-Karama dentistry center, and 20 patients under chemotherapy referred to the national center of hematology- Mustanasiriyah University, Iraq, were involved in this study. And the last 30 subjects were considered as control with good oral condition. Scrapings of gums were taken and examined immediately microscopically, once by wet-mount smear, and the other stained with Giemsa-Romanowsky. The positive samples were cultured on special cultures for the experimental part and then spread on the gingival margins of three groups of rats (for each parasite), the first was given immunosuppressive drug, while the other two groups were not given it.

**Results:** The results show that the higher frequency of *Entamoeba gingivalis* in patients with Periodontitis 36.7%. Patients receiving chemotherapy showed higher frequency of *E. gingivalis* and *Trichomonas tenax* comparing with the control group 30% and 10%, 15% and 3.333% respectively. All rats which were dealt with *T. tenax* still alive and with healthy gingiva, in the other hand, all rats in the 1st group that dealt with *E. gingivalis* have been showed periodontal ulcers and two of them died after 10 days, while one rat of the 2nd group has been showed mild gingival inflammation with no death, and no ulceration, inflammation or death have been occurred in the control group.

**Conclusion:** These findings suggest that: 1- Periodontal patients showed higher frequencies of *E. gingivalis*. 2- Patients receiving chemotherapy showed higher frequencies than the normal control. 3- *In Vivo Entamoeba gingivalis* may become pathogenic in individuals under chemotherapy.

**Keywords:** Oral cavity; toxicity; patients; chemotherapy; *in Vivo*; health.

Introduction

Though the saliva contains low nutrient concentrations and antimicrobial defense systems, the human oral cavity is still a home to numerous microorganisms, oral hygiene alone has little effect on subgingival microflora in deep pockets. Periodontitis is a handicapping disease, WHO (world health organization) calculated that 0.132% of the world wide are disability-adjusted life years, a measure of disease burden as the loss of healthy life years (DALYs). Risk factors for this disease have been identified: alcohol consumption, poor mouth hygiene and smoking.
Trichomonas tenax and Entamoeba gingivalis are human buccal protozoan parasites. T. tenax is an anaerobic, commensal, and can live only in the mouth, they are most abundant between the teeth and gums and in pus pockets, tooth cavities and crypts of the tonsils. Transmission, then, is direct usually through kissing or common use of eating or drinking utensils\(^8\). There are studies that relate to its prevalence in patients with marginal chronic Periodontitis.\(^9\)

Entamoeba gingivalis lives on the surface of teeth and gums, in gingival pockets near the base of teeth, and sometimes in the crypts of tonsils. Because no cyst is formed, transmission most be direct from one person to another by kissing, by droplet spray, or by sharing eating utensils\(^8\). It has been noted in publication that the increased prevalence of *E. gingivalis* is connected with diseases of the oral cavity, and particular with periodontal diseases\(^10\). Chomize et al\(^11\) have, however, demonstrated the pathogenicity of *E. gingivalis* in the following groups of patients: those receiving immunosuppressive, with genetic diseases and with lowered body immunity.

**Materials and Method**

**Survey Part:** Study subjects: The present sample consists of 80 individuals aged 20-60 year, and comprised 35 females and 45 males. No of the study subjects were completely edentulous\(^12\). Thirty of patients were with advanced Periodontitis who referred to AL-Karama dentistry center, and 20 patient who are under chemotherapy were selected from the national center of hematology/Mustanasiriya university/Baghdad, Iraq. The rest 30 subjects were considered as control group with no systemic disease and with good oral condition.

**Samples Collection:** A temporary laboratory was set up in both sites of the study, identification of *E. gingivalis* and *T. tenax* are made by the finding of trophozoites in scrapings the gums and teeth with sterile swab rubbed. Samples are taken from deep pockets surrounding the teeth of patient.

**Microscopic Examination:** The deposit was suspended in a drop of physiological saline solution, and two slides were performed for each sample, light microscope examination by original wet-mount smear is performed immediately for presence of *T. tenax*, due to its motility\(^13\). And the other was stained with Giemsa-Romanovsky\(^14\) after the samples were fixed examined immediately under light microscope (40 x)\(^15\) to detect the *E. gingivalis*. The parasite of *T. tenax* was identified by their flagella and characteristic locomotion, while *E. gingivalis* was identified by its shape depending on the expansion of the pseudopodia formation and presence of vacuoles\(^16\).

**Experimental Study:**

**Parasites Culturing:**

1. **Entamoeba Gingivalis:** After the isolation of *E. gingivalis* from periodontal patients, the organism cultured on (Cleveland and collier medium) for 72 hour, filtered, washed with physiological normal saline for 3 times\(^17\).

2. **Trichomonas Tenax:** The samples that positive of *T. tenax* were inoculated in the broth selective Kupferberg, used for the growth of *T. tenax* (Kuperberg Trichomonas Broth), to which 0.1g of chloramphenicol was added to prevent the growth of bacteria and other microorganisms. Seeded culture media were taken to the oven at 37\(^\circ\)C for 72 hour.\(^18\)

**The Animals:** Two suspensions of *Entamoeba gingivalis* and *Trichomonas tenax* were prepared for experimental application by using 24 rats about (200-250 g/rat) provided by animal house of the Biological Chemical Pharmaceutical Control, the rats had normal teeth and periodontal tissue.\(^17\)

For each parasite, 12 rats are divided into three groups (4 rats for each). The first group injected with prednisolone acetate (0.25 mg/rat) daily for one week before animal test\(^19\), while the other two groups of rats are not given immunosuppressive drug. Parasites suspension spreaded on the gingival margin of the rats (first and second groups only), the third group is the control in which their gingival margins are spreaded by normal saline free from parasites\(^17\).

**Results and Discussion**

Cross sectional study designed of 80 subjects were selected as a study samples, 30 with advanced Periodontitis, 20 under chemotherapy, and the latest 30 were control group with no systemic disease and with good oral condition. Out of 30 Periodontal examined patients, 11(36.7\%) were infected with *E. gingivalis*, while 3(10\%) were harbored *T. tenax* as illustrated in table (1). In addition to that, results shows that occurrence of *E. gingivalis* and *T. tenax* in the 20 patients under chemotherapy are accounted 6(30\%) and 3 (15\%)
respectively, while their occurrence in the controlled group were 3(10%) and 1 (3.33%) respectively fig. (1).

Comparisons significant shows that with periodontitis group in light of positive E. gingivalis outcomes compared with controlled group recorded significant different at P<0.05, with more than three times occurrences (Cohort=3.375)\(^{20}\). In addition to that, with respect to T. tenax positive outcomes compared with controlled group, no significant different at P>0.05 was obtained, but it’s more informative for that result to be reported rather than simply that p-value was not achieved to 0.05, as well as under chemotherapy group with respect to T. tenax parasite are reported more than four times (Cohort=4.5) of positive outcomes compared with controlled group. And these results are the same as the findings of\(^{(23)}\), who revealed that when the immunity level decreases or when immunosuppressive drug is used the infection may occur in the oral cavity.

Finally, comparisons significant shows that with periodontitis and under chemotherapy groups in light of positive E. gingivalis outcomes, had no significant different at P>0.05, with a similar times occurred (Cohort=1.22). In addition to that, with respect to T. tenax positive outcomes, no significant different at P>0.05 was obtained, but according to related ratios (Cohort=0.667) of positive outcomes, it could be conclude that under chemotherapy group had one and a half times of reported positive outcomes more than those reported with Periodontitis group. Figure (1) represent graphically by cluster bar charts distribution of Entamoeba gingivalis and Trichomonas tenax sensitive to positive outcomes among studied groups (periodontitis, under chemotherapy, and control) groups.

(*) HS: Highly Sig. at P<0.01; S: Sig. at P<0.05; NS: Non Sig. at P>0.05; Testing based on Contingency Coefficient test and measuring ratio related rates (Cohort +ve)

Figure (1): Distribution of *Entamoeba gingivalis* and *Trichomonas tenax* sensitive at the studied groups

According to experimental part of this study, table (2) explains that, each of the twelve rats which were deals with *Trichomonas tenax*, and *Entamoeba gingivalis* reported the following results:

**Trichomonas tenax**: Dealing with *Trichomonas tenax*, twelve rats stilled a life and with healthy gingival, and that’s remained with the same responses in view of 2nd and 3rd groups.

**Entamoeba gingivalis**: Dealing with *Entamoeba gingivalis*, twelve rats had reversed behavior with their a life and with healthy gingival, and that’s given in each groups, as follows:

**First group**: All rats injected with immunosuppressive drug have been shown periodontal ulcers after 7 days of dealing with *E. gingivalis*, and two of them died after 10 days of dealing.

**Second group**: One of the rats has been shown Gingival Erythematous and swollen after 6 days of dealing with *E. gingivalis*. No periodontal ulcers and no death occurs to the rats.
Third group: All the 4 rats were still healthy, and no death occurs to them.

In addition to that, statistically, and comparing between Trichomonas tenax, and Entamoeba gingivalis, a significant different at P<0.05 are accounted according to test distribution of multiple ratio’s infections (+ve) in contrasts of different groups, and it could be indicating that Entamoeba gingivalis had reported the worst type of studied parasite resulted either with number of infection, or with dead status of rates. And these results are in agreement with (17).

Relation of Serum Level of Lipocalin 2 to Her2/neu in Women with Breast Cancer

Atheer R. Atia1, Salam S. Ahmed2

1Asst. Lec. Kirkuk General Hospital, Kirkuk Governorate/Iraq, 2Prof Dr. Professor of Clinical & Medical Biochemistry–A General Pediatrician, College of Medicine–University of Tikrit/Iraq

Abstract

Background: Breast cancer is the most common type of cancer worldwide, being one of the leading causes morbidity in the female.(1) Lipocalin is a neutrophil gelatinase-associated lipocalin (NGAL) or lipocalin 2 that is a 25 KDa glycoprotein, which was originally identified as a covalent complex with matrix metalloproteinase-9 (MMP-9) in human neutrophil.(2) Lipocalin acts as bone-derived hormone which crosses the blood brain barrier (BBB) and acts on the hypothalamus in the brain. The human epidermal growth factor receptor 2 (HER-2/neu), has shown to have a prognostic value for the treatment with the monoclonal antibody in breast cancer.(3)

Material and Method: This is a cross sectional, hospital based study. This study was carried out at the Oncology Center in Kirkuk City-Iraq from the 1st of November 2018 to the end of June 2019. Forty-two women with breast cancer were considered as a study group. Forty-four apparently healthy women without breast cancer (relative of patients) and with a negative family history for the first and second degree relatives of breast cancer were consider as a control group, their ages were from 23 to 70 year. By using a sterile disposable syringe 10 mls of venous blood sample was drawn from each woman at morning and was kept in a plain tube and allowed to clot at room temperature, then each sample was centrifuged at 6000 rpm to obtain serum. Serum of the patients and controls had assay for lipocalin 2 and Her2/neu by ELISA.

Results: The mean serum level of lipocalin 2 was significantly elevated in breast cancer women compared to control women (62.77 ± 6.1 and 23.98 ± 5.9 ng/l) respectively at a P value of 0.001. This study also reveals that the mean serum level of Her2/neu was higher in breast cancer women (33.96 ± 2.7 ng/ml) as compared with the control group (9.76 ± 1.6 ng/ml). This result was highly significant at a P value of 0.001. This study found that there was a moderate positive correlation between lipocalin with Her2/neu in breast cancer women (R: 0.33), which means that lipocalin 2 was proportionally elevated with increasing of Her2/neu level.

Conclusion: This study reveals that there was a significant positive correlation between lipocalin and Her2/neu in breast cancer women, the r value was 0.33.

Keywords: Breast cancer, lipocalin 2, and Her2/neu.

Introduction

Breast cancer is the most dangerous disease that threatens women lives in Iraq for the last twenty years ago.

Every year 1000-1200 new cases are recorded, 98% of which affect women, and 2% of which affect men. Breast cancer occupies 14% of the whole disease in different cancers and a rate of 1-6 of women are affected from every 100000 women.(4) It is important to distinguish the biochemical profiles of cells that have been transformed to malignant cells. Generally these cells, are different from that of normal, tend to concentrate almost upon growth by maximizing the anabolic processes and put down the catabolic functions.(5)
Lipocalin (LCN2), a member of the lipocalin protein family, is a secreted as a glycoprotein that transports small lipophilic ligands. The protein part of lipocalin are part of a group of more than 20 diverse proteins that exhibit limited amino acid sequence similarity but share a highly conserved 3D-structure. LCN2 is a prominent member of the lipocalin super family and was originally identified as a 25-kDa neutrophil glycoprotein based on its covalent binding to matrix metalloproteinase-9 (MMP-9) in human neutrophils.\(^7\),\(^8\) LCN2 has gained attention as a potential biomarker and a modulator of human cancer. LCN2 protein expression levels have been demonstrated to be increased in various human epithelial cancer types, including breast cancer.\(^10\),\(^11\)

The human epidermal growth factor receptor 2, is a transmembrane tyrosine kinase receptor. This protein is encoded by the HER2gene, which is located on the long arm of chromosome 17 (17q12–21.32). Clinically, HER2-positive breast cancer occurs in 15–20% of breast cancer patients and is characterized by the over expression of the HER2 receptor and/or HER2 gene amplification.\(^12\) HER2-positive breast cancer patients have a particular worse prognosis.\(^9\)

**Patients Materials and Method:**

A cross sectional, hospital based study. The protocol of this study was approved by the scientific committee of Tikrit University-College of Medicine, and the agreement of the attendance to Kirkuk Oncology Center to collect the sample from the patients was approved by the Kirkuk Health Directorate. This study was carried out at the Oncology Center in Kirkuk City- Iraq from the 1st of November 2018 to the end of June 2019. A verbal consent was taken from each women included in this study whether considered as a case or control. Forty-two women with breast cancer were considered as a study group, their ages were between 23 to 70 years, and they were from the center and periphery of Kirkuk City, while 44 apparently healthy women without breast cancer and with negative family history for the first and second degree relatives of breast cancer were consider as a control group, their ages were from 23 to 70 year.

By using a sterile disposable syringe 10 mls of venous blood sample was drawn from each woman included in this study at the morning and was kept in a plain tube and allowed to clot at room temperature, then each sample was centrifuged at 6000 rpm to obtain serum. The serum was aspirated then divided into aliquots in plastic tubes and stored at -20°C until the time of estimation. Serum of the patients and controls had assay:

1. Lipocalin 2 by ELISA.
2. Her2/neu by ELISA.

**Statistical Analysis:** All the date collected in this study were analyzed by using the student t-test, the mean, standard deviation, and P-value was also considered. The significance was considered at a P value of less than 0.05. While the correlation was considered as follow:

**Interpretation of R value (correlation coefficient)**
- 0.70. A strong negative correlation.
- 0.50. A moderate negative correlation.
- 0.30. A weak negative correlation.
- 0.3 < R < 0.3: no correlation.
+ 0.30. A weak positive correlation.
+ 0.50. A moderate positive correlation.
+ 0.70. A strong positive correlation.

Results

The total number of a subject that participate are 88 (42 patient and 44 control). The highest rate of breast cancer women (42.86%) was within the age group 41 - 50 years, followed by those within the age group of 51 - 60 years (21.44%). The least rate of breast cancer women (9.52%) was within the age group of more than 60 years, as see in the Figure 2.

![Figure (2): Relation of breast cancer with age.](image)

This study show that the mean of BMI was recorded in breast cancer women when compared with healthy women was 28.5±2.19 versus 24.12±0.99 Kg/m² at a P value P: 0.01, as shown in the following figure 3

![Figure 3: Relation of BMI to breast cancer](image)

The mean serum level of lipocalin 2 was significantly elevated in breast cancer women compared to control women (62.77 ± 6.1 and 23.98 ± 5.9 ng/l) respectively at a P value of 0.001.
Table (1): The mean and standard deviation (SD) of lipocalin 2 level in breast cancer women and the control group.

This study found that there was a moderate positive correlation between lipocalin 2 with Her2/neu in breast cancer women (r: 0.33), which means that lipocalin 2 was proportionally elevated with increasing of Her2/neu level, see the figure 4.

![Figure (4): Correlation of lipocalin 2 with Her2/neu in breast cancer women.](image)

**Discussion**

This study reveals that, he highest rate of breast cancer in women was within the age group 43 - 52 years and the least was within the age group of more than 63 years. Numerous results obtained by other studies were focused on the age of women with breast cancer, e.g. the study that carried by Ghanim H et al(13), who found that the mean age of breast cancer women was 42.2 ± 10.41 years, while the study by Armstrong K(14) who found that the mean age was 50.4± 12.45 years with range of 22 to 80 years.
The study showed that 76.19% of breast cancer women in this study were belonged to urban area comparing with 23.81% were from rural area, this finding could be attributed to that the majority of cases included in this study were from the urban area. Previous study found that malignant lesions of breast cancer were more common in rural areas as compared to urban. This could be due to poor medical aid in rural areas, lower socioeconomic status, and illiteracy. These studies not agree with the present study, this disagreement may be related to a non-homogenous samples.

Body mass index is known to be a modify risk factor for breast cancer. In current study malignant case with BMI > 30.0 kg/m² represent 50% of malignant tumor that agree with other studies. Epidemiological studies have shown that postmenopausal obesity causes an increase in the risk for breast cancer. Since obesity has a close relationship with increased levels of insulin and insulin like growth factors, although increased BMI, elevated blood glucose, dyslipidemia and hypertension are components of metabolic syndrome. Insulin resistance reduces sex hormone-binding globulin levels, causing an increase in free estrogen and androgen levels, hence increasing proliferation of breast epithelial cells.

In the present study the mean serum level of lipocalin 2 for patients with malignant tumor was higher than the control at a P value of 0.001. LCN2 has gained attention as a potential biomarker and a modulator of human cancer, its protein expression levels have been demonstrated to be increased in various human epithelial cancer types, including breast cancer. The finding of Hu et al. were in agreement with finding of this study, who found that there was a significant relation between LCN2 and breast cancer and provided strong evidence for the role of LCN2 in aggressive subtypes of breast cancer. Additionally, Yang et al. reported that lipocalin 2 promoted breast cancer progression, and found that LCN2 level was consistently associated with invasive breast cancer in human tissue. Ören et al. also demonstrated that LCN2 was highly related to breast cancer as compared with healthy women. Bratt also reported that level of LCN2 also significantly higher in breast cancer women than normal breast stroma.

The present study showed that the mean serum level of Her2/neu was higher in breast cancer women compared to the control women. Previous study performed on 64 women with breast cancer; 25 (39.1%) had elevated serum HER2/neu levels accompanied with increased tissue expression of HER2/neu receptors, their results was in a greement with the present study. These results suggest that the elevated in serum Her2/neu level was associated with a clinicopathological aggressive phenotype of breast carcinoma and was related to tissue Her2/neu overexpression. Therefore, serum Her2/neu may be useful for monitoring the course of the disease and response to treatment. Other studies found that, patients with distant metastases (liver, lung and ovary) had markedly elevated serum HER2/neu levels as compared to those without metastases.

The positive correlation between lipocalin 2 and Her2/neu, this finding could be attributed to that both of them were elevated in the sera of women with breast cancer.

**Conclusion**

There were an increase in serum levels of lipocalin 2 and Her2/neu in women with breast cancer.

Estimation Some Antioxidants Enzymes in Stress Patients in Babylon City

Sahar Saadi¹, Rasha Hashim Hussein², Saadi Mohammed³

¹Assist. Lecture, Islamic University; Babylon Campus/Iraq, ²Biolate: Department of Biology, College of Science, University of Babylon, Al-Hillah City, Babel, Iraq, ³Professor, Islamic University; Babylon Campus/Iraq

Abstract

Oxidative stress can be defined as an increase in oxidative parameters or a decline in antioxidant defense mechanisms. Superoxide dismutase (SOD) and catalase (CAT) are antioxidant enzymes. They are responsible for eliminating free radicals like superoxide and hydrogen peroxide, and they stand for antioxidant defense mechanisms. An entire of fifty patients and twenty-five control subjects were collected between April to August 2019. Several physiological parameters were calculable similar to (SOD, and CAT). The results of present study illustrated that the patients groups, had greater significant differences (P≤ 0.05) levels of SOD, and CAT in contrast with control groups result at significant differences (P≤ 0.05).

Conclusion: We found increased SOD and CAT levels were significantly increased in stress patients.

Keywords: Antioxidant, SOD2, stress, Oxidative; health; toxicity.

Introduction

Stress is a physical and a psychological state always present in a human being, and forming an integral part of his everyday life. An event may be perceived by an individual as stressful, whereas another individual may not see it as such, for example, the experience of travelling by plane may be perceived as marvellous whereas for somebody else it might prove to be severe and anxiety-causing(1).

On the other hand, the same person may find that the same event causes stress in one situation, whereas in another it causes little or no emotional involvement. There are, of course, situations affecting most people (e.g., unemployment, sudden death, earthquake, separation) but each person interprets and assesses every experience based on his subjective criteria and deals with it in his own, unique way(3).

Stress causing stimuli may be: biological (disease, surgery), chemical (drugs, toxic substances), microbial (viruses, bacteria, parasites), psychological (illness, death, separation, divorce, failure), developmental (premature birth, anatomical defects), socio-cultural (inharmonious interpersonal relationships, financial difficulties), environmental (unemployment, atmospheric pollution)(2).

Reactive oxygen species (ROS), reactive nitrogen species (RNS), other free radicals, and their related molecules are produced during many physiological and pathological processes taking place in different brain regions and in the periphery(4).

The main sources of ROS generation are environmental pollution, harmful ultraviolet rays, and metabolism, phagocyte cells etc. These sources generate free oxygen radicals and further the oxidative stress in the human body. The theory of oxidative stress suggests that the stress leads to cellular degradation which causes a cascade of apoptotic events and finally to the cell death. Oxidative damage caused by free radicals induce the generation of superoxide radical, peroxynitrite and many more radicals that are the major cause how we age and also age related disorders like Alzheimer’s,
Parkinson’s, neurodegenerative diseases and other related disorders (5).

SOD change superoxide (O2) to hydrogen peroxide (H2O2) and 3 isoformings are known. SOD1 (CuZnSOD) is current in red blood cells (RBCs), SOD2 (MnSOD) is first and foremost mitochondrial and SOD3 is extracellular (7).

Catalase (CAT) is an important endogenous antioxidant enzyme that catalyzes H2O2 detoxification. A number of CAT gene single-nucleotide polymorphisms (SNPs) and mutations have been associated with disease manifestations (8).

Material and Method

Sampling: Fifty blood samples were collected from patient under go stress disease and twenty five samples as control.

Determination of superoxide dismutase (SOD) activity: 50 ul of serum was mixed with 0.2 ml of 0.1 M EDTA [containing 0.0015% NaCN], 0.1 ml of 1.5 mM NBT and phosphate buffer (67 mM, pH 7.8) in a total volume of 2.6 ml. After adding 0.05 ml of riboflavin, the absorbance of the solution was measured against distilled water at 420 nm (6).

Determination of Catalase Activity: CAT activities were determined by measuring the decrease in hydrogen peroxide concentration at 230 nm by the method of Beutler (9). The assay medium consisted of 1 mol/L Tris HCl-5 mmol/L disodium ethylenediamine tetraacetic acid (EDTA) buffer solution (pH 8.0), 1.0 mol/L phosphate buffer solution (pH 7.0), and 10 mmol/L H2O2. CAT activity was expressed as U/mg protein.

Results

The data demonstrated that the patients groups, had greater significant differences (P ≤ 0.05) levels of SOD and catalase in contrast with control groups result as show in table (1) (2), (3).

Discussion

The consequences of estimation physiological parameters (SOD, CAT) illustrated that the patients groups, had greater levels in contrast with control groups result at significant differences (P ≤ 0.05).

This study evaluated the SOD and CAT activity in patients with stress. The main finding of our study has indicated that there was an increase in SOD and CAT activity in men with stress compared to the female.

Oxidative stress is a condition associated with an increased rate of cellular damage induced by oxygen and oxygen-derived oxidants commonly known as reactive oxygen species(10). Reactive oxygen species (ROS) have been implicated in over a hundred of disease states which range from arthritis and connective tissue disorders to carcinogenesis, aging, toxin exposure, physical injury, infection, and acquired immunodeficiency syndrome11). The role of oxidative stress in infertility and method for counteracting its impact on reproductive tissues with antioxidants is still in its infancy.

SOD is the enzyme that catalyzes the conversion of superoxide anion radicals (O2•−) to hydrogen peroxide and molecular oxygen, functioning as a controller of cellular reactive oxygen species levels(12). Past reports denote increased SOD levels in patients with stress and anxiety; however, we found that SOD levels were significantly increased in stress and anxiety patients(13).

Oxidative stress plays a crucial role in the pathophysiology of stress. In addition, poor appetite, psychological stressors, obesity, metabolic syndrome, sleep disorders, cigarette smoking and unhealthy lifestyle may also contribute to it(14).

Catalase is a crucial enzyme for antioxidant mechanisms and decomposes hydrogen peroxide into water and oxygen.(15) Among stress people, CAT is reported to be increased in patients compared to controls(16).

Catalase guards the cells from hydrogen peroxide generated with in them. It plays a role in tolerance acquisition to oxidative stress in the adaptive response of cells. Lower catalase levels are seen in periodontitis(17).

There are some limitations of our study. First The sample size was relatively small, and future studies should be performed in larger samples. On the other hand, the homogeneity of groups is the main strength of our research.

In conclusion, we found increased and SOD and CAT levels were significantly increased in stress patients. These findings should be considered preliminary and needing verification by further studies. Our results should also be considered preliminary and needing confirmation by future studies.

Abstract

Nowadays, Heavy metal pollution is one of the most important environmental problems. All metals occurring in the biosphere originated in the earth’s crust; however, the toxic metal pollution of the biosphere has intensified rapidly since the onset of the industrial revolution, posing major environmental and health problems. Several studies have demonstrated the effect of metals on microbial diversity, biomass and activity. It is believed that metal Microbial activity is responsible for the bioremediation of the third elements in the periodic table. Selenium is an important trace element that required for in trace amounts for growth and metabolism but toxic at elevated concentration. The ability of a single mutant *Pseudomonas putida* sp.12 (mariner transposon) has been used to search for genes involved in the biotransformation of selenite to red elemental selenium. This study aims to develop a transposon mutagenesis system for the model *P. putida* sp.12 to investigate the gene(s) that involved in selenite reduction. The conjugative plasmid pSAM_R1 containing the mariner transposon was used for transposon mutagenesis. A single mutant reliably impaired in selenite transformation, found that the mutant clones, contained an inactivation within *pmoB*, one of two copies of the gene encoding the largest subunit of particulate selenite-reduction. Physiological analysis of this “white mutant” indicated that the selenite-reducing activity, which was located primarily in the cytoplasm of the cells, could be rescued by adding format as an alternative source of electrons.

**Keywords:** Whole genome sequences, Selenium reducing bacteria; transposon; Bioremediation.

Introduction

Microorganisms often keep metal haemostasis by pumping toxic metals out of cells using primary and secondary transporters [¹]. The best mechanism of avoiding an excess of metal ions is active transport by cation-transporting ATPases (Fig. 1). Selenium (Se) has both metallic and non metallic prosperities. It is an essential micronutrient for both prokaryotes and eukaryotes at low concentrations, but it can be toxic at higher levels. Se exists in nature in multiple organic and inorganic forms, Se can act as an antioxidant and protect against the cellular damage caused by oxygen radicals; however, an overdose of Se can disrupt the integrity of proteins and decrease the enzymatic activity, resulting in chronic or acute selenosis [²].

Many resistance determinants on chromosomes and mobile genetic elements encode a range of membrane transporters that transport specific toxic metals out of the cell. Some microorganisms use plasmid-encoded energy-dependent metal efflux systems to remove metals from the cell [³]. For instance, in response to exposition to toxic metals, metal resistance comes mostly in plasmid-encoded bacteria. Resistance genes encode genetic information of microorganisms that is charged by external or internal conditions [⁴].

**Pseudomonas putida** sp. genetic manipulation has proven a challenge because of the natural transformable. Electroporation of *P. putida* sp. has been found effective only with small plasmids. There are slow growing means that some forms of antibiotic selection cannot be used and vectors used with *E. coli* are often not functional. An earlier work has shown that conjugation can be used to introduce plasmids into *P. putida* sp.12, and vectors have been developed to allow mutagenesis of the soluble methane monoxygenase (S) and heterologous protein expression. Because of *P. putida* sp.12 adaptability to toxic chemicals, the model soil bacterium *P. putida* sp. was developed via develop a transposon mutagenesis system for the model *P. putida* sp.and to use this to investigate the gene(s) involved in reduction and remediation of selenite to elemental selenium. The conjugative plasmid pSAM_R1 containing the mariner transposon, which was developed for transposon mutagenesis in the *Rhizobiaceae*. This study aimed to was chosen to construct a transposon library to enable screening for mutants altered in specific metabolic functions including reduction of selenite.

**Materials and Method**

**Bacterial strains and growth conditions:** The *Pseudomonas putida* sp.12 was obtained from the biotechnology laboratory of Diyala University. The strain was growth routinely in LB medium. M9 minimal medium, amended with carbon source was incubated at of 30 °C, while *E. coli* was grown at of 37°C.

The experiments were performed in 150 mL liquid cultures in 250 mL conical Quickfit® flasks cultures were incubated at the optimum growth temperature, on a shaker at 170 rpm, and allowed to grow to an OD600 of between 0.5-0.8. Under the conditions used in these experiments.

**DNA techniques, plasmid concentrations and Conjugation process:** To create the transposon library for *P. putida* sp.12, Plasmid pSAM_R1 has four unique restriction sites (*Nde*I, *Bam*HI, *Xba*I and *Xho*I) was obtained from *E. coli* DH5α using. The plasmid was extracted and digested using QIAGEN kit (Qiagen, MD, USA). Agarose gel analysis was used to confirm its integrity.

The conjugation was used following the method of Lloyd and co-workers. The progeny from the conjugation were resistant to kanamycin (15 μg/ml). Subsequent plating on LB medium also containing nalidixic acid (25 μg/ml final concentration) was performed in order to eliminated the donor *E. coli* strain.

**DNA Sequencing:** The mutants strains were grown on the LB agar with kanamycin (15 μg/ml), and *P. putida* sp.12 grown on separate plates of the same medium without antibiotic was used as a control. Plates were incubated at 30°C. The bacteria were harvested by scraping from the plates and sent for sequences. To detect the number of inserted DNA segments and the transposon position, Mauve sequence analysis package and Mauve Contig Mover (MCM) were employed to re-order contigs for each new draft genome based on comparison to *P.putida*KT2440genome from the Genbank (accession number NZ_JBOP00000000).
The position of the inserted transposon was detected in each contig and compared with the transposon sequence using BLAST to find the location of the transposon[11].

Characterization of mutant strains: The LB plates with 15 µg/ml final concentrations of kanamycin and 10 µg/ml of (Se selenite were used to re-grown white colonies carried the transposon library. The positive control was a kanamycin-resistant clone from the transposon library that gave red colonies on selenite-containing medium. The plates were incubated in 30°C for 24 hrs.

Results

To transfer pSAM_R1 into *P. putida* sp.12, the selected cells were plated on LB agar with kanamycin. Figure 2 confirmed the plasmid pSAM_R1 conjugation, presumably the conjugated plasmid showed antibiotic resistance; while the cells of *P. putida* sp.3 without conjugation (WT) did not grow and no colonies were observed (Fig 3). Around 500 colonies were obtained when the suspension (50 µl) of the conjugated cell was plated on the selective agar. However, non-conjugated cells were grown on medium without kanamycin which conformed strongly the conjugation theory of pSAM-R1 into *P. putida* sp.12 was successful.

![Figure 2. Positions of transposon insertions in the genome of *P. putida* sp.12](image-url)
Figure 3: Triplicate experiment to show selenite reduction by the “white mutant” (*P. putida* sp.12) (A1, A2, A3), wild-type *P. putida* sp.3 (B1, B2, B3) and the selenite reduction-positive (“red”) mutant (C1, C2, C3) in LB liquid media containing selenite (containing 10 g/mL of Se) and grown on c as the carbon and energy source.

**Whole Genome Sequencing:** To check the position of the transposon on the genomic DNA, nine samples were prepared: eight putative transposon mutants and one sample of wild-type of *P. putida* sp.3. The subjected sequences comparison to the reference genome displayed additional segments indicated that there was a region within the genomes from the putative transposon mutants that displayed no similarity to the reference genome. The added segments were conserved among all putative mutant draft genomes but were not present in the genome data obtained in parallel for the wild-type strains. BLAST searches of the added DNA present in the chromosomes of the putative transposon mutants were performed. The confirmed that the extra DNA was the mariner transposon.

**Gene involved in selenite reduction:** The “white” transposon mutant 2T5 (which is inactivated in one of the two copies of *pmoB*) must still be able to grow using carbon as growth substrate and may be impaired in the supply of carbon-derived electrons for reduction of selenite. If this were correct, it may be possible to restore selenite reduction in the mutant by supplying format, which the carbon can use as an electron source via format dehydrogenase.

**Discussion**

This study used transposon mutagenesis to identify the role of *P. putida* sp. in the remediation of selenite (*SeO₃²⁻*). To screen very large number of transposon
insertion clones (≥100,000), well-developed genetic systems have recently been used to obtain high coverage of the selected genome\(^{[12]}\). The mutant colonies are presumably able to assemble fully functional pMMO because the strain retains the other copy of the pMMO operon\(^{[13]}\). Similarly, study aimed to transfer transposon IS-O-Km/hah from *E. coli S17* to *Pseudomonas* strains Pph 1302A and 1448A to screen the progeny for their plant colonization ability\(^{[14]}\). Gene interruption by transposon in this mutant was one of the copies of *pmoB*, encoding the large subunit of pMMO\(^{[15]}\). However, in this study the appearance of selected colonies on LB agar plates could simply be the result of slow growth. Further analysis in liquid media after growth to OD\(_{600}\) with appropriate controls confirmed that the mutant was impaired in reduction of selenite. Earlier studies confirmed that the phenotype of mutants is not due to inactivation of an enzyme which is specifically involved in reducing selenite to elemental selenium, but due to a more general lesion in the metabolism of the methanotroph. When electrons were fed via another route from formate via formate dehydrogenase, reduction of selenite to red elemental selenium was restored, indicating that this route for feeding electrons into the reduction of selenite is also possible\(^{[16]}\). To conclude, transposon mutagenesis by using mariner transposon in pSAM_R1 has been used to impair the gene that is involved in remediation of selenite (SeO\(_3^{2-}\)).

Evaluation of HPRT Gene mutation and Comet Assay in Some Breast Cancer Patients Undergoing Radiotherapy

Rafid A, Abdul Kareem1, Abdul Sahib, K. Ali2, Amel, J. Muttar2

1Assist. Prof./Institute of Genetic Engineering and Biotechnology for Postgraduate Studies, University of Baghdad, Iraq, 2Researcher/Ministry of Science and Technology/Central Laboratories Directorate/Iraq

Abstract

Introduction: Radiotherapy is a toxic cellular treatment that destroys rapidly dividing cells such as cancer cells. The strategy for HPRT mutation examination in human’s cells was commonly used to establish in vivo history along with mutation rates in children and adults inhabitants subjected to experienced and unfamiliar external mutagens. As just a practical approach to human biosurveillance studies, the comet assay has been introduced over the past years as biomarker to identify ionizing radiation Consequences with Patients undergoing radiotherapy in breast cancer.

Materials and Method: This study was carried out on thirty Iraqi women patients with BC patients undergoing radiotherapy about 20-30 Gy locally gamma cells at Al-Amel National Hospital for cancer Management in Baghdad during time 2-13 years, non-smokers and non- alcoholic, aged (35-55 year), with stage (grade) I-III, as well as thirty apparently healthy individuals females collected randomly from population living Baghdad, Old age (35-55) Which are non-alcoholic non-smokers as group of control. Around the ongoing research comet-test and hprt mutation test could be applied to study damages in DNA for genetic two endpoints For patients with cancer throughout radiation therapy.

Results: The present study showed significant increase (p<0.05) in the HPRT gene mutation assay for the in breast cancer patients undergoing radiotherapy as compared with the control group. Also there were found that the values of comet tail moment and tail length was increased significantly (p<0.05) in the human lymphocyte in these for breast cancer patients undergoing radiotherapy as compared with the control group.

Conclusions: Present results revealed that there is a probability of utilizing human lymphocytes changes as useful biodosimetric markers for the detection of human exposure to ionizing radiation, the data gathered also demonstrated the utility of the HPRT gene mutation and (Alkaline) comet test as just a precise alternative biological marker for routine preventative care of cancer patients receiving radiation therapy.

Introduction

Approximately (1 million) reported cases diagnosed globally each year; breast cancer has become the most commonly reported cancer, accounting for about 20 percent of all new female cancers. Radiation is a functional therapy for cancer treatment but in 5%-10% of patients it results in extreme late radiation toxicity. In oncology Ionizing radiation has been effectively and widely used.

Recent developments in cancer radiation therapy have enhanced the diagnosis of cancer victims, but have led to health problems(1). Radiotherapy kills cells in the exposed position by destroys their DNA material.(2). Radiation therapy is still the most common technique
of treating cancers victims. About eighty percent of cancer sufferers receive radiation therapy at a certain time, either for therapeutic or curative reasons. Since radiation exposure neither distinguishes for either normal or even malignant cells, symptoms can grow in patients throughout therapy course for several weeks following treatment or months or years later. The exposure to radiotherapy causes more damage to cells of the body, particularly DNA, and the level of damage to cells relies on the dose of radiation received. Radiation therapy is among the most successful options for treatments of cancer. The prevalence of breast cancer becomes significant, but after several years of radiation treatment, most patients will again be cured or free of cancer indications.

Hypoxanthine guanine phosphoribosyl transferase (HPRT) is a purine rescue enzyme which induces the transformation of hypoxanthine and guanine onto the corresponding nucleotides 5'-monophosphate and 5'-monophosphate guanosine. Numerous in vivo studies of mutations HPRT gene in human cell cultured have presented evidence for, exposure level, age and genetic effect on mutation rate. Enhanced frequency of mutations with advancing age in healthy human individuals is typically demonstrated.

Comet test is really sensitive and needs a geneticist who is able to interpret the outcomes. This test is commonly performed in the search for DNA material damage. From the last few years; comet assay has been adopted as a valuable method for human biomonitoring analyses. Thus biomonitoring research using cytogenetic tools are restricted to distributing lymphocytes and include propagating cell population groups, Comet testing may be introduced to propagating and non-propagating cells as well as tissue cells which are the first hotspots for touch with mutagenic factor. The objective of the study is to use HPRT gene mutation and comet as a biological Markers to identify the negative impacts of ionizing radiation susceptibility in victims with breast cancer having receiving radiation therapy.

**Materials and Methodologies**

**Collection of subjects and blood samples:** During the period January 2018 till January 2019, this study was carried out on thirty Iraqi women patients with breast cancer after radiotherapy treatment, non-smokers and non-alcoholic, aged (30 - 59 year), with stage (grade) II, breast cancer patients treated at Al-Amel National Hospital for cancer Management in Baghdad during time 2-13 years, As well as thirty apparently healthy individuals females collected randomly from population living Baghdad, aged (30 - 59 year) which are non-smokers, non-alcoholic as control group, all of them (100 %) were females. Samples of Blood were obtained from healthy control and cancer sufferers previous to radiation therapy and upon progressive doses of radiation of 20-30 Gy. Locally gamma cells. Five ml of human peripheral blood from all select subjects were collected and placed into sterile plain tube that contained lithium heparin. The blood was placed in a cool - box under aseptic conditions and transfer to the laboratory.

**Assay procedure:** Mutation of HPRT gene test has been conducted as mentioned by Coa et al. The DNA (comet) test was operated as mentioned by Moller et al.

**Microscopic examination:** Binucleated as well as multinucleated cell types from each 1000 lymphocytes have been record under microscopy illumination in the two sets of cultures. Microscopy (magnification 1000X), the Mutant Hprt Gene Frequency “Mf-hprt” has been measured with the use of formulation below:

\[ \text{Mf-HPRT} (‰) = \frac{\text{binucleated and multinucleated cells for every 1000 lymphocytes while grown with 6TG}}{\text{binucleated & multinucleated cells for 1000 lymphocytes if grown without 6-TG}} \times 1000. \]

A maximum of 100 seemingly at random captured comets (100 of each slide) have been investigated using only a luminescent microscope linked to an image processing system via a camera. The following comet criteria have been examined to measure actually damage to DNA: the length of the tail (TL) and the moment of the tail.

Tail length (DNA migration size) is closely linked to the Dimensions of a fragment of DNA and is described In to the micrometers. This has been measured cell midpoint. The tail moment was measured as product of just the length of the tail and the comet-tail DNA portion.

**Data Analysis and Statistics:** The information for these research have been assembled in to the computerized database as well as the frequency. Distribution and statistical explanation (mean, SE) were
dissolved utilizing SPSS statistical program statistical tests of the variability (ANOVA) test as well as the least significant difference (LDS) test has been used with a likelihood of less than 0.05 (p<0.05) variability.

**Results and Discussions**

Mf-HPRT mutated gene frequent test has been conducted on blood lymphocytes cells which have been gained from 30 Iraqi breast cancer patients women, aged (30–59) year and duration of radiotherapy is more than 2-13 years, as well as 30 healthy individuals women as control group which age ranged (30-59 years). Table 1. showed (hprt) for 30 patients with cancer throughout radiation therapy for each patient Mf - hprt expanded with the dose of radiation therapy. mutation assay of MfHPRT gene was conducted according to explanation by (11). Mutant frequency of HPRT gene has been determined as (binucleated), (trinucleated) as well as (quadrinucleated) CB lymphocyte cells for each 1000 lymphocytes. In tissue culture with and without 6-thioguanine were identified by Giemsa staining (Fig. 1).

![Image](https://example.com/fig1.jpg)

**Figure (1): Human lymphocyte cell, blocked by Cytokinesis (A):binucleated (B): trinucleated and (C) qudrinucleated (1000X). genetically determined.**

The outcome of Mfs- HPRT gene mutation for breast cancer patients after radiotherapy and control can be seen in Table (1) The Mf-HPRT rate for patients with breast cancer and controls were 0.91–1.21 and 0.82–0.96, accordingly. Difference of MF- HPRT between patients of breast cancer after radiotherapy and controls has been significantly high (P.< 0.05). Result of HPRT gene analysis in breast cancer high frequency about 1.088 ± 0.0211 ‰ from control 0.890 ± 0.0089 ‰. Table (1) So the frequency of HPRT test had to identify the genetically hazard Among breast cancer survivors after radiotherapy into current Inquiries.

The findings of the HPRT assay in our study demonstrated a significant difference between patients with breast cancer as well as individual in control groups. In current study; breast cancer patients chronically affected to anticancer radiotherapy drag were studied cytogenetically to evaluate the frequencies of HPRT gene mutation, in comparison with control individuals.

- The least significant difference (HPRT 0.05) = 0.0263
- The latter in the column (for comparison of study groups) means that there is no significant difference (p < 0.05).
There are many agents that damage gene and made somatic mutations, HPRT gene analysis widely test in many studies to know mutations frequency (MF) in vivo by T-lymphocytes culturing in media have 6-thioguanine if cell resistance and have colony that mean lymphocytes have mutant at the hypoxanthine-guanine ribosyltransferase (HPRT). HPRT used to understand radiotherapy effect in patients or radiations or any genotoxic factor that effect on populations and cancerpatients (11,16,17). HPRT gene is used in this work as a reporter for such mutations. If an appropriate reporter is present; its susceptibility to mutation initiation must be similar to the MF. HPRT gene essential to tumorigenesis (18).

The findings of this study indicate that perhaps HPRT lymphocyte test is a valuable biomarker For evaluating the possible carcinogenicity of radiation therapy as a cytotoxic cancer agents. Alkaline comet analysis was used as an application biomarker of exposure to assess genotoxic consequences of radiotherapy on peripheral blood cells of 30 Iraqi breast cancers Patients and control groups.

Figure 2 illustrates the usual ordinary and damaged DNACells examined underneath a fluorescent microscope. The results of the alkaline comet assay as tail length, tail moment and % DNA (Mean ± SE) in cancer patients during radiotherapy and control groups, illustrated in Table 2.

The median of comet tail lengths in breast cancer patients, via radiotherapy were 19.21 ± 0.7612 μm, when compared with the control were 16.410 ± 4.031 μm, the observed value was increased significantly in compared with the experimental control group (p < 0.05).

Table (2) Exhibits the findings of the tail moment in comet test for controls and breast cancer patients undergoing radiotherapy. Throughout the comet test, Damage of DNA in Lymphocyte has been shown by tail moment and tail length. The average tail moment (Mean ± SE) of breast cancer patients undergoing radiotherapy was 12.451 ± 0.551, And that was considerably higher than that (8.310 ± 0.281 of healthy controls (P < 0.05). Mean of comet Tail DNA % (Mean ± SE) of patients with breast cancer undergoing radiotherapy and healthy controls were 0.1120 ± 0.0061 and 0.00450 ± 0.0005, respectively. Moreover MCR mean for patients with breast cancer was higher significantly than healthy control. (P < 0.01). The percentage of DNA tail was high after radiation therapy in the BC patients compared to the healthy control group. (P < 0.05). According to the results obtained here, the breast cancer patients are highly significant (P < 0.05) compared with healthy control groups.

Victims suffering from breast cancer were exposed to radiotherapy, the therapeutically radiation genotoxic effects has been examined in lymphocytes that circulating across the body and verified as valuable biodosimeters in a number of radiation research (19, 20). Alkaline comet test this was chosen as a versatile tool for identifying the damage in DNA caused by proven or possibly genotoxic compounds (21).
The present work has shown that radiation therapy is followed by a marked increase in DNA destruction in the lymphocytes cells of patients with breast cancer, this finding was not unexpected as radiation therapy induces a wide range of DNA disruption, varying from double- and singled breaks in DNA strands (11).

Effect of addition of Magnesium Oxide Nanoparticles on surface hardness and tensile bond strength of denture soft liner

Hoshang Khalid Abdelrahman¹, Salem A.L. Salem Al-Sammarayi²

¹Lecturer Dr Hawler Medical University, College of Dentistry, Department of Prosthodontics/Iraq,
²Prof. Dr. Hawler Medical University, College of Dentistry, Department of Prosthodontics/Iraq

Abstract

Background and objective: This study was aimed to determine the effect of addition of 3% of Magnesium Oxide Nanoparticles (MgONPs) on the surface hardness (SH) and tensile bond strength (TBS) of a silicone based denture liner at various time intervals.

Method: The SH and TBS of a silicone denture liner were studied after addition of 3% by weight of MgONPs. A total of 140 samples were constructed. The samples were divided into two main groups, control group and test group to which 3% of MgONPs were added.

Results: The SH of all the samples for both groups was significantly higher after a period of 6 months. For TBS the pattern was reversed in which there was a decrease in the mean of TBS for both control and test groups significantly. Conclusion: The addition of 3%(MgONPs) to Silicone denture liner causes a non-significant effect in the SH but significantly improves TBS.

Keywords: Soft liner, Nanoparticles, Magnesium Oxide.

Introduction

The resilient denture lining materials bonded to the removable dentures are usually used to decrease the amount of the forces transmitted to denture supporting tissues. These materials are able to form an absorbing layer on the part of the denture in contact with the oral mucosa and this allows less traumatic transmission of occlusal forces. The result is that wearing the prosthesis becomes more comfortable for the patient.

The resilient liners used for prosthetic purposes are available either as resin based or silicone based. Both types are present in autopolymerized or heatpolymerizedform.

Despite numerous advantages of this material, soft liners have some shortcoming such as high porosity that increases plaque accumulation, colonization of Candida strains and development of denture stomatitis.

Bacterial contamination continues to draw public attention. Generally, antibacterial agents can be categorized as organic or inorganic antibacterial agent. Organic antibacterial agents have low resistance to processing conditions, which limit their applications. As a result, inorganic antibacterial agents have attracted much interest for bacterial control. The main advantages of inorganic antibacterial agents over the organic antibacterial agents, are the improved stability under harsh processing conditions. In medicine, inorganic antibacterial agents such as MgO are used for the relief of heartburn, sore stomach, and for bone regeneration. Huang et al. demonstrated that MgONPs had an antibacterial effect they also determined that the antibacterial efficacy increased with decreasing particle size.

Material and Method

A total of 140 samples were constructed and divided into two main groups, control (n=70) and test (n=70).

The study was done to evaluate the SH and TBS of
a silicone denture liner after addition of 3% MgONPs depending on a pilot study which was done earlier in which different concentrations of MgONPs (2%, 3%, 4%, 5% and 6%) by weight were added to the soft liner and evaluated to determine which concentration provide best anti-microbial effect. Also a Scanning electron microscopic (SEM) evaluation was performed to determine the distribution of the (MgONPs).

**Preparation of the Samples:** Mollosil, which is a silicone based soft denture lining material is supplied in a two- pastes (base and catalyst), it is an auto polymerizing material, the material is mixed manually at ratio 1:1 base/catalyst according to manufacturer instructions. The base and catalyst parts were weighed by digital weight scale. Then the (MgONPs) was weighed and added in small trace amount to the base part of the material at concentration of (3%) by weight, and mixed together for one minute in a circular motion (120 cycles/minute), after that the catalyst part was added to them and mixed for 30 seconds according to manufacturer instructions all of the samples were made at a constant room temperature 25 °C.

**Hardness Test:** A total of 70 samples divided into two main groups, control n=35 and test n=35 were constructed using abrasion mold(diameter 45 mm, 6 mm thickness) according to ASTM: D-2240-5). The samples were further subdivided into five subgroups (n=7) according to the storage time in distilled water (24 hours, 1 week, 4 weeks, 3 months and 6 months), each subgroup was tested separately because the SH measurement test does not allow reusing the samples.

The SH was measured after 24 hrs, 1 w, 4 w, 3 m and 6 m of aging in distilled water at 37 ± 1 °C. The SH of every sample was measured at five measurement points, that were at least 5 mm away from the edge of each sample and spaced at least 3 mm away from each other’s and then the average was taken

The measurements were performed after 5 seconds of loading using a Shore A Digital Durometer under 1 kilogram.

**Tensile bond strength test:** The TBS was measured according to the ISO standard. 140 Heat-cured Polymethyl methacrylate (PMMA) acrylic plates (25mm X 25mm X 3.5 mm) were prepared(2 plates for each TBS sample).

The surface of acrylic plate coated with adhesive bonding agent supplied by the soft liner material manufacturer. The adhesive was applied to one surface of both acrylic plates simultaneously with a brush, the first acrylic plate was placed on flat floor. A polyethylene O-ring with an internal diameter of 10 mm and a thickness of 3 mm was placed in the middle of the acrylic plate. Next, the test material was poured into the O-ring by the use of disposable syringe to prevent air bubble intrusion. Then, the second acrylic plate was placed over the ring and the testing material.

A weight of 1 Kg was placed over the whole assembly, when the material was set the weight was removed, after that, the ring was removed gently by cutting it with a sharp surgical blade. Fig 1

Lastly, the prepared 70 specimens were conditioned in distilled water at 37 ± 1 °C for 24 ± 1 hour, 1 week ±1 °C, 4 weeks ± 1 h, 3 months ± 1 hour and 6 months ± 1 hour.

**Figure 1: TBS sample**

The specimens were tested using a software programmed universal testing machine. To ensure the specimen assembly pulled at a right angle to the denture base soft liner interfaces a specially designed metal
sample holders were used to grasp the specimens to the universal testing machine grip.

The holders have a 3 mm extension lip to ensure adequate grasping and prevent possible movement of the specimens during testing Fig 2.

Then the sample with the holders were secured into the testing device jaws and stretched at constant cross head speed 10 mm/min, the force which caused deboning was recorded.

![Custom made sample holder](image)

The values of TBS were calculated automatically as the force at debonding divided by a cross-sectional area of interface according to the following formula:

\[
\text{Tensile strength} = \frac{F}{A} \text{ (N/mm}^2\text{)}
\]

\(F = \text{force of failure. (N)}\)

\(A = \text{Original surface area of the cross section. (mm}^2\text{)}\)

**Results and Discussion**

The addition of MgONPs to the soft liner resulted in an increase in the mean SH but this increase was non-significant for all groups (table.1)

The test group was harder than the control group. This group is likely to have highly cross linked network in combination with the added MgONPs. A material with a very high cross link density produces a very dense and hard material, also adding the fillers which have a very small size and the uniform distribution within the material may increase polymer/filler interactions and therefore reduces the mobility of the polymer chains. Furthermore, as the particle size decreases the number of the boundaries of these particle increases, therefore the dislocation movements by these boundaries may cause an increase in the SH.\(^{13}\)

The control group showed lower SH value. This may be due to no MgONPs content, therefore increase polymer chain mobility between cross links. The results from the present study is in agreement with Aziz et al as they found the same result for maxillofacial silicon.\(^{14}\) also agreed with results of other studies on denture soft lining materials.\(^{15,16}\) furthermore, the increase in silicone SH of the modified group in the present study may be due to continued polymerisation and cross linking of this materials throughout the experiment.\(^{17}\) Also, may be due to formation of new bonds between the fillers and the polymer chains, or because of reduction in the interstitial spaces in the matrix of the polymer chain. It has been stated that silicone denture lining materials contain no plasticizer but contain filler\(^{18}\) and absorption of water by the filler could lead to decreased softness.

Note: Groups with the same uppercase superscript letters for each row and lowercase superscript letters for each column are not significantly different at the $p < 0.05$ level.

Aging process showed a significant effect on the SH of the material for both control and modified group, this result is in line with previous studies. This increase in the SH could be due to the gradual leaching of the soluble contents from the materials when undergoes aging for a long periods of time.

The TBS value among different studies vary occasionally owing to using different testing variables, the chemical formula of the tested materials influences the results. Also, the different specimen treatment method such as conditioning or storage before testing need to be standardized. Finally, the TBS values differ according to the specimen fixation method, alignment of loading points, and crosshead speed.

The TBS (table. 2) in this study were dropped from 1.087 MPa after 1 day to 0.446 MPa after six months for control group and 1.097 MPa to 0.462 MPa for test group respectively. Minami et al. obtained similar range values for another brand of silicone denture liner, using similar tensile test specimen assembly.

</tr>
</tbody>
</table>

Note: Groups with the same uppercase superscript letters for each row and lowercase superscript letters for each column are not significantly different at the $p < 0.05$ level.

In this study, it was observed that within the same group, different soft liners showed difference TBS values. This was in agreement with the results obtained in other studies where similar test standardization was used in which their studies showed different TBS results for similar chemically silicone lining materials.

The lowest TBS values were shown by control group which was statistically significant when compared to test group at all period intervals.

This increase in the TBS for the modified group may be due to the low concentration and a very small size of MgONPs used which may have led to less tendency for agglomeration with in the matrix, or possibly the added MgONPs may have been increased the surface area of adhesion between the acrylic resin and the soft denture lining material.

On the other hand, the present study disagrees with the results of Sampaio when found that there is no difference in the TBS after sealant application to the tissue conditioner, this could be explanted by the use of different material formula, shape and size of the specimens or testing parameter in each study.
Finally, the SEM revealed a homogenous distribution without any agglomeration of the MgONPs within the matrix of the tested material, also the EDX revealed the presence of accurate concentration of MgONPs in the test group. Figure 3 and 4 shows the SEM of control and modified samples.
Conclusion

Addition of 3% MgONPs to Siliconedenture liner causes a non-significant effect in the SH, but significantly improves TBS.

Efficacy of Silymarin on Aflatoxin Residues in Eggs and Health Status of Laying Hens

Hussein Ali Rashid¹, Mushtaq Talib Abdulwahid²

¹Post Graduate/Ministry of Agriculture/Veterinary of Directorate/Diyala/Iraq, ²Assistant Prof./Department of Veterinary Public Health, College of Veterinary Medicine, University of Baghdad, Iraq

Abstract
The study aimed to evaluate the silymarin in reducing the aflatoxin (AF) residues in eggs and health status of laying hens. A total of 120 laying hens at the age of 240 days were randomly divided into three equal groups fed on diet with or without AF and 0.5% of silymarin. The residues of AF in the eggs were measured at the age of 260 and 280 days by using HPLC technique as well as, physiological tests. The results of the 3rd group showed a significant (P≤0.05) increase in RBCs, PCV% and Hb, AST, ALT concentrations and Ab titer against ND and IB diseases as compared with the 2nd group and the control. Also, there was a significant (P≤0.05) decrease in the concentrations of AF (B1) and (G1) in eggs at the age of 260 days as compared with the 2nd and the control.

Keywords: Aflatoxin residue, Silymarin, HPLC technique.

Introduction
The main problem in poultry industry represented via contamination with different mycotoxin(1). Aflatoxin (AF) contaminated grains are a worldwide problem that leads to immunosuppression and an altered response to vaccination programs in poultry. These effects result in a decline in animal performance and ultimately minor profitability(2). High levels of AF in feed results decrease in production performance, and the prevalence of residues in poultry meat and eggs(3). The toxicity of AF mainly depends on the quantity and duration of ingestion and immune status, as well as environmental factors(4).

Silymarin (SM) an extractededas of the kernels of milk thistle (*Silybum marianum*), is a composite of flavonolignans that has activity of free radical scavenging. Silymarin is affect positively on the digestibility in the birds that enhance the feed efficiency(5). Milk thistle seed has been identified as protective nutrient of poultry from adverse effects of AFB1(6,7) described that the supplementation of SM by 0.5% of feed had a positive effect to reduce negative effect of mycotoxins with improved of the performance and health status for broilers. Muhammad(8) reported that SM enhanced liver cell protein synthesis also inhibited oxidation of glutathione. The goal of the present study is evaluate the Silymarin to reduce the AF residue in eggs and health status of laying hens.

Materials and Method
A total of 120 hens (ISA Brown) were randomly divided into three equal groups at 40 hens aged 240 days old were obtained from commercial farm in Diyala province. All birds were offered feed adjusted at a rate of 4400 gm/day/group(9) (table 1) with water (*ad libitum*). The 1st group (control) was fed a diet free of mycotoxin. The 2nd group fed contaminated diet by aflatoxin (14.6 ppb) while the 3rd group fed the same diet with 0.5% of silymarin. At aged 242 the birds were vaccinated with attenuated IB(4/91) + ND Clone 30 viadrinking water.

*Animal feed premix for hens (Laymix-2.5 W) Holland made. Inclusion rate: 2.50%. Chemical contains: Crude Protein 11%, Crude Fat 2.18%, and Crude Fiber 0.84. **Dicalcium phosphate Iraq made contains: Ca 23% and P 18%.

Blood samples were taken from each group for physiological tests\(^{10,11}\) at aged 280 days, as well as, the residues of AF in the eggs were measured at the age of 260 and 280 days by using high-performance liquid chromatography (HPLC) technique. The egg samples collected randomly to test in the laboratories of ministry of science and technology. Data was analyzed with SAS software\(^{12}\) using LSD and ANOVA to compare between treatments.

**Results and Discussion**

The results showed significant (P≤0.05) increased in RBCs of the 3\(^{rd}\) group as compared with the 2\(^{nd}\) and control (Table 1) whiles the count of WBCs recorded lower values in 2\(^{nd}\) group than other groups. The increasing of RBCs count may be Silymarin (SM) ‘s ability to keep blood cells from any damage caused by free radicals in the body that may be damaging to cell membranes and their internal components in the body by acting as an antioxidant. Silymarin has anti-oxidant ability as it works directly or indirectly for cracking and elimination of many compounds such as phenylglyoxylic also radical’sketyl\(^{13}\). Also, that explanation was similar with reported by\(^{14}\).

Nazifi and Asasi\(^{15}\) concluded that Silymarin supplementation at percentage (0.5 and 1%) did not alteration the values of the studied hematological parameters (WBC, RBC) as compared to the control group.\(^{16}\) found that SM significantly helps to keep the blood cells and serum biochemical parameters in normal range. The results of total protein did not record significant differences (P≥0.01) among groups at 40 days of study (Table 2). While, the aspartate aminotransferase (AST) and alanine aminotransferase (ALT) dataenzymes activity of the 2\(^{nd}\) group was recorded significantly (P≤0.01) higher values as compared with those in the 3\(^{rd}\) and control groups. The increased AST and ALT activities detected via feeding polluted diets in the present study may be the effects of AF which cause hepatic degeneration and subsequent leakage of enzymes into circulation. The increasing in liver enzymes activity may be the most sensitive indicator of liver damage\(^{17,18}\) said that any liver enzymes disorder is evidence of stress. The results agreed with\(^{19}\) who referred to the
AF has hepatotoxic effects and the activity of AST and ALT might be increased. While the reduction in the liver enzymes activity may be due to the positive effect of SM in protect the hepatic cells from damage by AF. The antioxidant property of Silymarin against free radicals is what prevented hepatocytes from being damaged\(^{(20)}\). Silymarin as well promotes hepatocytes protein creation also declines the oxidation of glutathione \(^{(8)}\).

Anti-oxidative mediators are crucial for hens nutrition as they decline fat peroxidation, consequently increase the organoleptic features, in addition nutritional value of meathenegg, increased meat and egg shelf life\(^{(21)}\). The most well-known exogenous antioxidant substances like vitamin E\(^{(22)}\), Oligo-elements like, selenium, amino acids, glycine also flavonoids such as SM need been identified\(^{(23)}\).

By using ELISA test, the results of the mean titers of anti-ND and IB vaccines are non-significant (P>0.05) differences among groups at 20 days of study, but there was significant (P≤0.05) increase in Ab titers in the 3rd group as compared with the 1st and 2nd groups at 40 days of the beginning of the study (table 3). The increasing in Ab titer against ND vaccine may be attributed to the amelioration effect after feeding onration treated with the Silymarin which preserves the liver cells from aflatoxin damage, that action enhanced protein synthesis in the body which promotion the immune response of chickens. Humoral immune response was development after added of silymarin is in line with\(^{(8,20)}\). Moreover, the effect of hydrated sodium calcium aluminosilicate on the humeral immune response of quails diet on AFB1 polluted ratio was studied by \(^{(24)}\) also found decrease in the Ab titer induced by ND vaccine, due to AF, was relatively prevented. However, the lowering in Ab titer of the 2nd group attribute to contaminated diet with AF. \(^{(25)}\) take down resistance to diseases revealed that AF also inhibits with vaccine-inducing immunity in animals. Manegar\(^{(26)}\) established that AF destroy prime immune response aimed at ND also Gumboro disease as apparent via drop in the ELISA titers. Table 3 shows the Ab titers of 2nd group were significantly (P≤0.05) the lowers than the 3rd group. It is clear from our observations and those of other researchers that AF causes severe immunosuppression that might be due the depressed the phagocytic activity\(^{(27)}\). The results are supported through\(^{(28)}\) who informed the negative role of contaminated feed in the presence of immune suppressant AF in diet. Whilst feed addition of SM with AF contaminated ration in 3rd groups significantly (P≤0.05) improved the immune response of hens.

Means in the same row with different letters differ significantly (P≤0.05).
Moreover, Silymarin supplementation with AF contaminated diet can reduce the adverse effects of AF on performance and systemic immune response. These findings suggest that SM play as an antioxidant property via to prevent the negative effect on immune system. The researchers Friedman\(^\text{(29)}\) confirmed that estimation Ab titers in birds’ serum give good evidence to appointment immunity of birds against ND virus. Thus, the positive results indicated that the effect of SM in preservation of the immune cells and keep cellular membranes flexibility which have achieve a role in antigen diagnosis\(^\text{(30)}\).

In this study, the concentrations of AF B1 and G1 were evaluated by HPLC, figure 1 illustrates the standard chromatogram of the AF B1 and G1 at retention times from 4.5 to 5 minute.

The results obtained from the analysis the eggs samples of the 2\(^{\text{nd}}\) group during 20 days of the beginning of the study are represented in figure 2. The predominant AF for all analyzed samples was mixed B1 and G1. The test indicated that the transmission is relatively persistent during the processing of eggs formation. Trucksess\(^\text{(31)}\), the residues of AF didn’t seem eggs until the day 4 of feeding polluted diet. Dissimilar recorded by\(^\text{(32)}\), AF residues seem in the eggs when hens feeding with 5 mg/kg AF only also/or in mixture with Ochratoxin at 3 and 5 mg/kg. Also,\(^\text{(33)}\) watched AFB1 also the aflatoxin, in the layer hens eggs after feeding the diet polluted with AF. used immune-affinity column with HPLC.

Figure 1. Standard chromatogram of the AF B1 and G1

Figure 2: Chromatogram of total AF B1 and G1 residues in eggs of the 2\(^{\text{nd}}\) group
Hussain(34) is found direct link between AFB1 in the diet and residues in the eggs and muscles. AFB1 could contaminate the food manufactured from laying hens or eggs raised on AF polluted feed. According to the present study, it can conclude that silymarin reducing the aflatoxin residue in eggs and improving production efficiency and enhance health status of laying hens. So, the use of Silymarin at the level of 0.5% in feed during the production cycle seems to offer the best benefits.

Antitumor Activity of β-glucan Extracted from *Pleurotus Eryngii*

Ali Z. Al-Saffar\(^1\), Noora A. Hadi\(^2\), Hadeel Mohamed Khalaf\(^3\)

\(^1\)Assist. Prof., \(^2\)Lecturer, \(^3\)Lecturer, Al-Nahrain University, College of Biotechnology, Dept. of Molecular and Medical Biotechnology, Baghdad, Iraq

**Abstract**

*Pleurotus eryngii*, a type of edible mushroom that exhibit various pharmacological properties, including antioxidant and anticancer effects. In the present study, extracted β-glucan from the *P. eryngii* was tested as an antioxidant and anti-tumor factor. β-glucan was extracted and analyzed by HPLC and FT-IR. Analytical results showed more than 90% similarity in chemical structure and purity. Potential antioxidant activity of β-glucan was examined using 2, 2-diphenyl-1-picrylhydrazyl (DPPH) and compared with ascorbic acid. β-glucan confirmed a potential scavenging activity. The anticancer activity of the β-glucan was assessed using different concentrations (6.25 to 400 µg mL\(^{-1}\)) on MCF-7 and HepG2 cell lines. *P. eryngii* β-glucan exerted a dose-dependent reduction in MCF-7 and HepG2 cell viability with an IC\(_{50}\) of 280.00 and 539.5 µg mL\(^{-1}\), respectively. At the same time, no significant effect was recorded on normal cell line WRL 68. The obtained results are expected that could be used to develop *P. eryngii* β-glucanas an antitumor drug.

**Keywords:** MTT, *pleurotus eryngii*, Cytotoxicity, β-glucan, Antioxidant, MCF-7, HepG2.

**Introduction**

Mushrooms have attracted a great deal of interest in many areas of food and bio-pharmaceutical research and are well known for their nutritional and medicinal values.\(^1\) Several major components with immunomodulatory and/or antitumor activity have been isolated from mushrooms. These include mainly polysaccharides, such as β-glucans, polysaccharo-peptides, polysaccharide-protein conjugates, and proteins. β-glucans have a wide range of biological activities. Mushroom β-glucan polysaccharides are fibers that mostly present as linear and branched chains with different types of glycosidic linkages, such as (1-3), (1-6)-β-glucans and (1-3)-α-glucans, others are heteroglycans containing glucuronic acid, xylose, galactose, mannose, arabinose or ribose.\(^2\)

*Pleurotus eryngii* is an edible mushroom, considered to be a health food not only for low fat and calories but also being rich in amino acids, vitamins, and dietary fiber.\(^3\) In addition, β-glucans of *P. eryngii* received an increasing interest for its bioactive properties including antitumor, immunomodulator, antioxidant and antiallergic activities. Studies have indicated that the polysaccharides isolated from *P. eryngii* were mostly β-glucans, which exhibited potential activities.\(^4\)

Chemically, β-glucans are heterogeneous, non-starch polysaccharides, which form the structural compounds of the cell wall of certain microorganisms, including yeast and algae, mushrooms, and grains, such as oats and wheat. β-glucans may be insoluble or soluble. Insoluble β-glucans fibers consist of β-(1-3/1-4)-D-linked glucose units, whereas soluble viscous β-glucans fibers consist of β-(1-3/1-6)-D-linked glucose.\(^5\)

Many chemical compounds identified as specific agents for inhibiting cancer cell proliferation were also showed significant toxicity toward normal cells, as well
as their side effects. Many potential anticancer drugs have considerable side effects\(^{(6)}\). Therefore, discovery of new safer drugs with potential activity against tumor has become an important goal of research in biomedical sciences. Polysaccharides from mushroom sources can stimulate immune cells, including macrophages, granulocytes, nature killer cells and monocytes to trigger cytokine production and thus stimulating the immune system\(^{(7)}\).

In same point, this study was conducted first to extract β-glucans from *P. eryngii*, and evaluate the cytotoxic activity of the extracted β-glucan against tumor cell lines HepG2 and MCF-7, as approach in developing a mushroom polysaccharides to use either individually or in combination with medicinal drugs combination in cancer treatment.

**Materials and Method**

**Mushroom Strain:** *Pleurotus eryngii* strain was kindly provided and authenticated by Dr. Ahmed A. Kareem, Department of Organic Farming, Ministry of Agriculture, Baghdad, Iraq.

**β-Glucan Extraction from *P. eryngii*:** β-glucan was extracted using a water extraction method\(^{(8)}\). In brief: dried fruit bodies of *P. eryngii* were powdered. The powder was mixed with ddH\(_2\)O in ratio of 1:20 (wt/v). The pH of the mixture was adjusted to 7.0 using 20% Na\(_2\)CO\(_3\). Mixture heated to 90°C for 6 h with shaking (100 rpm). After heating process, the mixture was centrifuged at 8000 rpm for 10 min at 4°C. The pellet was discarded, and the supernatant was transferred to new container and the pH was further adjusted to 4.5 using 2M HCl. The solution was centrifuged at 8000 rpm for 30 min at 4°C. Pellet which contained proteins was discarded and supernatant was mixed with absolute ethanol in a ratio of 1:1 and left for 12 h at 4°C to precipitate the beta-glucan. The mixture was centrifuged at 3000 rpm for 10 min at 4°C. Finally, the pellet was homogenized with absolute ethanol and then oven-dried at 60°C.

**β-Glucan Analysis by High Performance Liquid Chromatography (HPLC):** The samples and standard were analyzed by HPLC (SYKAM, Germany) supplied with S2100 quaternary gradient pump and fluorescence detector RF-20A (UV280). The condition analysis of β-glucan; mobile phase: dH\(_2\)O and orthophosphoric acid (90:10 v/v); column: C18–ODS (25cm x 4.6 mm); Flow rate = 0.7 mL min\(^{-1}\). Preparation of sample: 1 mg dissolved in 25 mL dH\(_2\)O and then 20 µL was injected into HPLC column for analysis. The separation occurred on liquid chromatography and, the eluted peaks were monitored by UV-Vis 10 A-SPD spectrophotometer.

**FT-IR (Fourier Transformed Infrared) Analysis:** The chemical structure of β-glucan was analyzed using FT-IR spectrometry (Shimadzu IR Prestige-21– Japan). The FTIR spectrum was utilized to detect the functional groups of glucan structure compared with the standard. This was done under FT-IR spectrometry in wavelength range 4000-400 cm\(^{-1}\) and at a resolution of 8 cm\(^{-1}\). This test involved mixing an equal volume of glucan sample and standard (2 mg) with potassium bromide (KBr) (100 mg), then grinding the mixture by special grinder until soft and fine powder obtained. The sample was loaded in target mold and analyzed\(^{(9)}\).

**Determination of Carbohydrate Content:** Carbohydrate content was calculated by multiplying the reducing sugar content which was determined depending on Fehling’s reducing method\(^{(10)}\). Briefly, 10 g sample was mixed with 20 mL sulphuric acid (0.5 M). Reflux was then performed in a sand bath for 2.5 hours. The residue was washed after filtration (Whatman filter No. 1) with warm dH\(_2\)O. The solution was then neutralized with Na\(_2\)CO\(_3\) powder and the mixture’s volume was completed to 100 mL with dH\(_2\)O. Titrations were performed using 5 mL Fehling’s solution (equal volumes of solution A and B) pipetted into a conical flask and aliquot of 5 mL dH\(_2\)O was added. The solution was then boiled for 15 seconds. Methylene blue indicator (a few drops) was then titrated with the solution until the color changed from blue to green. The carbohydrate content was then calculated according to following equation:

\[
\text{Carbohydrate Content (%) } = \frac{5 \times 0.005 \times 100 \times 100}{V \times 10 \times W} \times 0.9%
\]

Where \(V\) = volume of sample solution (titration volume) and \(W\) = weight of powdered sample.

**Antioxidant Activity**

Antioxidant activity of extracted β-glucans was detected using DPPH (Sigma Aldrich, USA) for free radical scavenging assay\(^{(11)}\). Scavenging potential of β-glucan against DPPH radicals was determined spectrophotometrically (Aquarius, Cecil, Italy). Colour change (from deep- violet to light- yellow) when DPPH reduced was measured at 517 nm. In our experiment, set of concentrations (12.5, 25, 50, 100 and 200 µg mL\(^{-1}\))
were used. Ascorbic acid was used as positive control. The inhibition (%) of radicals by β-glucan was calculated according to the formula:

\[
\text{Inhibition (\%)} = \frac{\text{Absorbance of } - \text{ve control} - \text{Absorbance of the sample}}{\text{Absorbance of the } - \text{ve control}} \times 100
\]

**Statistical Analysis:** Data were expressed as means±standard deviation (SD) and analyzed by a one-way analysis of variance (ANOVA) followed with Dunn’s test using GraphPad Prism(Graph Pad Software Inc.). A \( p \leq 0.05 \) was considered to indicate a statistically significant difference between groups.

**Results and Discussions**

Dried fruiting bodies of *P. eryngii* was subjected to β-glucan extraction which depended on heating-acid extraction steps. This method is characterized by its ability to extract glucan from mushrooms with significant quantities, limited use of organic solvents and time saving. The total yield of extracted glucan was 7.9%. Previously reported that the total yield of glucan extracted from *P. eryngii* was 6% (14). The advantages of this procedure were heating, and extensive acid treatment followed by ethanol application which leads to β-glucan precipitation and dissolve or remove most the proteins, mannan, nucleic acids and others. The impurities affect the physical and chemical properties of β-glucan and may cause reducing in its ability to be soluble in water (15). Furthermore, the carbohydrate content for the extracted β-glucan was 54%, indicating purity and method of choice for β-glucan extraction.

Regarding HPLC analysis, results in Fig. (1) revealed one major peak in the extracted β-glucan at retention time 3.16 min (487.633 mAU) with an overall area percentage of 90%, which indicated the purity of the extracted β-glucan by comparing with the standard which exhibited almost the same retention time at 2.94 min (377.215 mAU). Purity of 90% gave an indication for the successful β-glucan extraction method. HPLC was used for detecting the purity of polysaccharides including β-glucan extracted from mushrooms and yeasts (16).
FT-IR analysis of *P. eryngii* β-glucan with absorption range of 4000-400 cm\(^{-1}\) was compared with the resulted functional groups of the standard. Fig. (2A), shows that the band range of ~1027.99 cm\(^{-1}\) is a characteristic feature of polysaccharides and assigned for β-1,4 glucans\(^{(17)}\), the absorbance peak at this band represent the existence of C-O-C group\(^{(18)}\). In addition, hydroxyl groups and carboxyl groups were detected at band 2923.88 cm\(^{-1}\), these groups are features of carbohydrate structure\(^{(19)}\). Moreover, both sample and standard showed high degree of similarity with respect to overall spectra abortion.

Fig. 1: HPLC chromatogram for (Top) β-glucan standard and (Down) the test sample.
The scavenging activity of *P. eryngii* β-glucan was estimated using increasing concentrations of β-glucan. Results in Fig. (3) demonstrate a potential free radical scavenging capability of *P. eryngii* β-glucan with calculated IC₅₀ value of 39.3 µg mL⁻¹. By comparing with ascorbic acid (IC₅₀ 27.47 µg mL⁻¹), *P. eryngii* β-glucan showed no significant differences in the pattern of free radicals reduction among all the tested concentrations. β-glucan are the most abundant forms of polysaccharides which display many biological activities including antioxidant²⁰. Antioxidant activity of β-glucan is highly dependent on mushroom source and method of extraction. Our results are in agreement with Roncero-Ramos et al.,²¹ which described the antioxidant activity of β-glucan from different mushroom sources including *P. eryngii*. Another study involving edible mushrooms revealed that β-glucan exhibited antioxidant activity 64 to 93% reduction of DPPH²².

**Fig. 2: FT-IR Spectra of (A) extracted *P. eryngii* β-glucan sample (B) standard.**
Various concentrations of *P. eryngii* β-glucan were tested against MCF-7 and HepG2 tumor cells. In the present study we used the MTT assay, which is universally used to evaluate the cytotoxic potency of drugs *in vitro*\(^{12}\). Results in Fig. (4) shows that the more increasing in β-glucan dose the more reduction in MCF-7 and HepG2 viability. The effect of MCF-7 and HepG2 viability by *P. eryngii* β-glucan exhibited a dose dependent pattern of reduction with a calculated IC\(_{50}\) of 280.00 and 539.5 µg mL\(^{-1}\), respectively. On the other hand, *P. eryngii* β-glucan had slight toxic effect on the cell viability of normal cells WRL68.

The biological, immunological and pharmacological activities of glucans extracted from edible mushroom are mainly attributed to β-glucan\(^{23}\). The cytotoxic activity of *P. eryngii* β-glucan against different types of tumor cells indicated a significant dose-dependent inhibition of cell proliferation and exerted direct cytotoxicity after 24 h. Many reports indicated the anti-proliferative effect of β-glucan extracted from different mushroom
sources. The effect of β-glucan \textit{in vitro} against different tumor cell lines was well demonstrated \((23)\). In addition, previous finding indicated that the toxicity of β-glucan on human pigmented malignant melanoma (Me45) cell line increased by increasing β-glucan concentration with viability reduction reached up to 19%. Moreover, it was proved that glucans in nature have low toxicity on normal cells and well tolerated by patients treated with glucan combination\((24)\).

**Conclusions**

We can conclude that the extracted \(P. \text{eryngii}\) β-glucan exhibited strong antioxidant capabilities and promising anti-proliferative potential on tumor cells \textit{in vitro}, which needed more investigations regard the mechanism of β-glucan in inducing tumor cell viability reduction.

The Effect of Multiple Glass Beads Sterilization Cycles on Cyclic Fatigue of AF Blue S One File

Bassam Alsheekhly1, Marwah M. Adnan2, Fudhla Sadoon Al- Zubaydi3

1Lecturer, College of Dentistry/Al-Iraqia University/Iraq, 2Assistant Lecturer, College of Dentistry/Al-Iraqia University/Iraq, 3Assistant Lecturer–University of Baghdad/Health Center/Iraq

Abstract

Introduction: Sterilization represent an important and essential aspect, now days Most of the dentists usually use the endodontic files for many times before they discard it, this could increase the need for reliable and fast sterilization method, but without affecting the physical properties of the endodontic files.

Aim of the Study: This study discusses an economic method of sterilization (glass bead) and its effect on the fracture resistance of the AF Blue S one file (Fanta) with multiple reuses of the system.

Method and Materials: A total of 75 AF BLUE S one NiTi Rotary files (FANTA) #25 size with 0.04 taper and 25 millimeter length, were used in this study, divided into three groups to test their cyclic fatigue resistance after multiple sterilization cycles.

Result: The results were statically analyzed using (SPSS) software, Anova test showed a statically high significant differences between the groups. Conclusions: Within the limitation of this study, it can be concluded that AF Blue S one file with 4 time glass bead sterilization cycle was the most fatigue resistant compared to zero and two sterilization cycle.

Keywords: Sterilization, Glass Beads, Endodontic Files; Toxicity; sterilization.

Introduction

Sterilization represent an important and essential aspect and it is a cornerstone in controlling the infection that could easily spread by various instruments which are used in the dental field.(1)

Dentists depends on files in performing root canal treatments, these files come in direct contact with the blood of the patient which can easily spread dangerous diseases like “AIDS and Hepatitis”. Most of the dentists usually use the endodontic files for many times before they discard it, this could increase the need for reliable and fast sterilization method, but without affecting the physical properties of the endodontic files.(2,3)

Wet sterilization as autoclave and dry sterilization as the oven and glass bead sterilizer are the mostly used by the dentists,(4) unfortunately autoclave causes dullness and decrease the sharpness and cutting efficiency of the endodontic files, on the other hand dry heat oven needs time that is long to perform sterilization “sixty minutes at 180ºC”, while glass bead sterilization is a variation of dry heat oven, needs only short time.(5,6)

Nickle Titanium (NiTi) files are appropriate instruments used for negotiation of the canals specially curved canals, The use of these files offers the reliability and possibility to provide a predictable root canal preparation, unfortunately these files are vulnerable to fracture.(7)

Many new NiTi files have been marketed by manufactures with the aim to offer safer and more...
effective file system. The thermomechanical treatment of NiTi alloy resulting in enhancement of the physical properties by changing the crystalline structure of the alloy, reducing the frequency of file fracture.

Repeated and prolonged usage of endodontic file has a negative effect on its physical properties which can lead to fracture. Some reports showed that the majority of file’s separation was due to cyclic fatigue. These files are used for many times by the dentists undergoing repeated cycles of sterilization.

This study discusses an economic method of sterilization (glass bead) and its effect on the fracture resistance of the AF Blue S one file (Fanta) with multiple reuses of the system.

Method and Materials

A total of 75 AF BLUE S one NiTi Rotary files (FANTA) #25 size with 0.04 taper and 25 millimeter length, were used in this study, divided into three groups to test their cyclic fatigue resistance after multiple sterilization cycles:

Group 1: 25 files undergo no sterilization (control).

Group 2: 25 files undergo two cycles of sterilization with ten minutes intervals.

Group 3: 25 files undergo four cycles of sterilization with ten minutes intervals.

Files sterilization was done using glass beads sterilizer for 15 seconds at 425-475 °F (218-246 °C).

In this study cyclic fatigue test has been done in custom made tapered stainless-steel artificial canals with regular (5 mm) radius and angles of curvature (90°), due to the limitation of obtaining standard result on using natural teeth associated with the wide variety of canal shape. The block has been designed according to the dimensions of the files which aimed to check out, Test was carried out in according to the manufacture recommended speed of rotary system (375) Rpm, with 2.6 N torques manipulate setting. The middle of the simulated curvature used to be (5-7) mm from the tip of the file which has been positioned at full working length (19 mm). The whole files have been new and the working section is 25 mm in length. Cyclic fatigue tested used to be conducted with the file rotating freely inside the tapered artificial canal which result in that reproducible simulation of the file restrained in the artificial curved canal.

The dental hand-piece has been mounted on wooden block that allowed manipulate of the hand-piece movement, and easy placement of every file inside the artificial canal, making sure 3-dimensional alignment and positioning the file to the identical depth for standardization. The artificial canal has been covered with transparent plastic sheet to forestall the files from slipping out and to enable the researcher observe the files while it works and when fracture has been occurs, so fracture was detectable due to the fact the files have been seen through the transparent plastic sheet window.

Stainless Steel block was once constant to the wooden block to forestall its movement and to make the relation between the steel block and the hand-piece almost constant. Glycerin has been stuffed totally to inside the artificial canal, earlier than each file to the exacted size (19 mm) inside a canal in order to minimize friction and heat generation. The files have been activated inside the canals by usage of (ENDOMAX PLUS) cordless endodontic hand-piece.

Video recording has been carried out simultaneously for more accurate work and to eliminate human error. This equation describe the (NCF) for every file.

“Number of cycles to failure NCF = Speed RPM X Time (T) to fracture in minute”

The armamentarium used in this study are showed by (fig.1)

Fig: Instruments used to perform the study.

Results

The means and standard deviations of (NCF) for the three groups are shown in (Table 1). The results were statically analyzed using (SPSS) software, Anova test showed a statically high significant differences between the groups (P < 0.001).
Intra group comparison using least significant difference test also showed a statically high significant differences between the means of the three groups (Table 2).

**Discussion**

The control of infection that is spreading by various tools used in dentistry is of great importance as a preventive measure for cross infection.

During procedure of root canal treatment the endodontic files come in direct contact with pulp tissue, oral fluids blood and saliva, these files could be considered “reusable sharps “ making there sterilization as a must mandatory step.(17) several sterilization techniques utilized such as autoclave, dry heat oven, ethylene oxide gas and also glass beads sterilizer which provide dry heat with shorter exposure time (18,19)

Ni-Ti endodontic files are always having the risk of separation because of cyclic fatigue or torsional stress,(20,21,22) To reduce or overcome this mechanical failure, many method have been applied by manufacturers to improve the fatigue resistance of file like electro-polishing the surface of the file: (RaCe), twisting instead of machining: (TF), and geometric characteristics alteration such as asymmetric design (Revo-S). (10,23)

Today, thermal processing could be the main approach to develop the alloy metallurgy properties by affecting its transition temperatures and thus leading to alter the fatigue resistance.(24,25) Any Temperature changes will affect crystalline phases in NiTi alloy. These changes result in enhanced the file physical properties such as cutting efficacy has been increased and the fracture resistance also elevated.(26,27) However, sterilization in some studies has been showed that not necessarily effective on the cyclic fatigue of the files.(28)

The choosing of two or four cycle sterilization cycles in this study based on reports showed that NiTi file can be used to shape up to 10 curved root canals.(3,29)

In this present study statistically significant increase in the life time of the AF Blue S one file with the increase in the number cycle of glass bead sterilization in comparison with the cyclic fatigue of the file with zero and two cycle of glass bead sterilization. This result may be related to the heat treatment of the alloy and the wire intermediate face. A modified phase composition because of the changing transformation temperatures is the essential difference between the conventional NiTi and the thermomechanically treated alloy. As the conventional NiTi alloy contains austenite,(30) while, the thermomechanically treated NiTi alloy moreover contains varying amounts of R℃phase and martensite under clinical conditions(31,32,33). These modifications are supposed to lead to extra flexible endodontic files with a superior resistance to fracture which mean decrease the stress on the file during negotiating the canal which lead to increase fracture resistance(34), so thermomechanical treatments represent a modern technique of developing new endodontic file with enhance mechanical properties.(35)

This result may be similar to research of de Melo et al(36) and Zhao et al(37) showed that sterilization increased the fatigue life of rotary Ni-Ti instruments through the increase in hardness and torsional resistance of the material, also Khalil and Natto(38) in their study shows that cyclic fatigue increase with the modern heat treated file and thus exactly what the present research concluded. The result of this study may be related to the wire of the AF One Blue S file and the AR phase heat treatment of Ni-Ti alloy, While several research had
been shows disagreement with the result of this study as Mize et al.\(^{(39)}\) and Hilt et al.\(^{(40)}\) Also, AbuMelha\(^{(41)}\) and Alshwaimi\(^{(42)}\), which suggested that increase the number of autoclave sterilization of rotary files reduced their cyclic fatigue resistance.

**Conclusions**

Within the limitation of this study, it can be concluded that AF Blue S one file with 4 time glass bead sterilization cycle was the most fatigue resistant compared to zero and two sterilization cycle and so multiple cycles have significant alterations in the cyclic fatigue resistance of rotary AF Blue S one files.

**Recommendation:** According to the result of the present study it’s recommended to sterilize the NiTi files with glass bead before using them.

**Ethical Clearance:** The Research Ethical Committee at scientific research by ethical approval of both MOH and MOHSER in Iraq.

Influence Factors Utilization of Family Planning Services among Reproductive Age Women’s in Primary Health Care

Ali F. Hussain¹, Ridha M. Lefta²

¹Assistance Instructor/Community Health Nursing Department, College of Nursing, University of Al-Ameed/Iraq, ²Ph.D. Assist Prof., Community Health Nursing Department, College of Nursing, University of Al-Ameed/Iraq

Abstract

Background: Family planning services as an essential component of primary health care and reproductive health, contributes to reducing maternal and newborn mortality and morbidity and transmission of HIV. Attitudes and knowledge towards family planning services are role play and consider influence factors on family planning services, assess to the means of fertility regulation and communication between husband and wife about desired family size and timing of pregnancy are essential for family planning.

Objective: To determine the influence factors on family planning services of women in reproductive age. Also to determine the association between influence factors of family planning of women in reproductive age and their demographic characteristic.

Materials of the Study: The study design a quantitative research by descriptive study, the sampling it is non-Probability “purposive” sample was a conducted on 150 females which attended with requirement health care services attained in primary health care centers at AL-Najaf city for period from September 7, 2018 to February 16, 2018 November. A questionnaire it has used as a tool of data collection to fulfill the study. A descriptive and inferential statistics was used to analyze the data.

Results: The study results indicate that the majority of study responses are age (30_37)years with 42.0%, duration marriage the most study sample (6_11)years with 44.0%. Related to number of children more half study sample (3_5) with 49.3%, Level of education most are higher secondary school with 28.0%,Occupation the majority study sample homemaker with 70.7% and live in urban. The study sample utilization of met family planning was oral contraceptive pills with 34.7%. In addition, the study sample are more than half their knowledge are poor and attitude negative about family planning.

Conclusion: The majority of the sample study used contraceptive pills and IUD due easy and do not need to procedures and knowledge. There is a significant relationship between knowledge, attitude and items of family planning. Some of demographic data effect upon knowledge and attitude because different in level of education and residence.

Keywords: Program of family planning services, types of contraceptive, Influence Factors utilization of Family Planning.

Introduction

The influence factors on family planning have women’s of reproductive age maybe know little or incorrect information about family planning services. Also when they know some names of contraceptives they don’t know where to get them or how to use it these women have negative attitude about family planning while some have heard false or misleading information.
The poor correspondence between knowledge and attitude of family planning services has drawn attention to women’s perception about the positive and negative aspect of modern contraception. So consider the factors effect for family planning are knowledge and attitude that use modern method stemmed from fear that uses might cause infertility, producing damaging side effect and forgetting to take contraceptives was a serious risk. Family planning is important and effective in improving the health of mothers and children (1). WHO defined family planning programs as (a program that allows individuals and couples to anticipate and attain their desired number of children and the spacing and timing of their births) (2).

Family planning as an essential component of primary health care center and reproductive health, contributes to reducing maternal and newborn mortality and morbidity and transmission of HIV. Through increase awareness and attitudes towards family planning services that lead to fertility regulation and communication between husband and wife about desired family size and timing of pregnancy are essential for family planning. Its cognitive decisions and behavioral practices that enable women to conceive a wanted pregnancy and avoid unwanted or badly timed pregnancy (3).

Although most people are aware of the benefits of family planning services, they complained that it was difficult to access family planning services as such services were provided by health facilities that were far from their homes (4).

The increase in teenage pregnancies and unsafe abortions as well as the maternal mortalities that occurred could have been prevented if uptake of family planning services were improved. The factors that influence the uptake of family planning services is imperative as very little is known about the factors that influence the decision of people to go for family planning services (5).

Family planning services can bring a wide range of benefit to women in Iraq. Before the Gulf war, Iraq underwent a rapid population growth therefore requested married women to limit their families to 4 offspring. And after the Gulf war Iraq insisted on maintaining a high population because of the total death caused by inflict and sanctions, since thus 1993 Iraq has a national policy on assuring assess to family planning and contraceptives. Consultative meetings and workshops were planned with the objective of strengthening and promoting family planning services in Iraq (6).

(6) that found several factors play an important role in the use of contraceptives among women of childbearing age. The identification of these factors is crucial to the planning and implementation of suitable family planning programmers. Many factors inhibit the use of modern contraceptives among adolescents and considered as barriers include poor knowledge and negative about contraceptive, fears and rumors about side effect, and unsupportive or negative influences of partners and family members.

The utilization that influence family planning services for contraceptives use by teenagers has also been found to be a factors of socio-economic status, knowledge about contraceptives, attitudes about issues related to contraceptives, residential area, educational status, counseling received about contraceptives, attitudes of the contraceptive providers, and cultural values, beliefs and norms (7).

Materials of the study: The study design was quantitative research through descriptive study, the sampling it is non-Probability “purposive” sample was a conducted on 150 females which requirement health care services attained in primary health care centers at AL-Najaf city for period from September 7, 2018 to February 16, 2018 November. A questionnaire it has used as a tool of data collection to fulfill the study, which consist of three parts, include demographic characteristics, types of contraceptive method or family planning method, and influence factors utilization of family planning services. A content validity, which is carried out through 13 panel of experts, while reliability use split half. A descriptive and inferential statistics are used to analyze the data through program spss version 21.

Ethical Consideration: The ethical clearance of the present protocol was obtained from the Health Ethics Committee of the university of AL-Ameed and health directorate in Karbala governorate. The individuals were included in this study were not undergone any invasive medical procedure or surgery. In addition, informed verbal consent was taken from all females client before study inclusion that attained to primary health care center.

</table>
This table show the relationship between knowledge and their demographic data the result show high significant relationship between knowledge and (number of children, education level, occupation, resident and method of family planning) with p.value 0.001 and significant relationship between knowledge and (age, duration marriage) with p. value (0.12,0.22). Also attitude and their demographic data the result indicate is high significant.

**Discussion**

The findings of the study indicate demographic data of study participant was the mean age (30_37) years within age groups and all of the study sample were married who utilization of family planning they are period (6_11) year. These result support by(8) was the most percent 44.0% others result were(>=5 with percent 23.3%, 12_18 with 19.3%, and 19 and more with 13.3%. these result about 19.5% respondents had good knowledge of contraception, 76.4% respondents had average knowledge about contraception and 4% had poor knowledge about contraception.

The study finding indicate regarding have children for study sample were (3_5) children. There are authors (8) that found with 56% have 2 children with 36.7% and 6 and more with 14.0% and same of the study most of the study sample were marriage or couples (31.9%) had 3 children, 25.9% had 4 children, 17.1% had 5 children, 7.5% had 6 children, 10.3% had 2 children, and 2.5 had 1 child.

The women were asked about their level of education of the most 28.0% high secondary other results is unable to read and right was 8.0%, primary 26.0%, secondary 23.3%, and Graduate and housewife and employment most of them living in the city and the others lived in rural areas.

The majority of study sample use oral contraceptive pills with 34.3% other method were IUD 20.0%, withdrawal 18.0%, male condom 12.0%, injection 8.0%, female sterilization 1.3%, calendar method and lactation amenorrhea were 2.7%. These results are disagree with(9) that found the total number of condoms provided by international donors has been relatively low. Between 2000 and 2005, the average number of condoms distributed in Nigeria by donors was (5.9%) man, per year, and in 2002, 75 per cent of health services facilities visited in a survey did not have any condom or contraceptive supplies this in turn does not encourage the utilisation of family planning services due to lack of needed contraceptive method.

The study finding also supported by(10), oral contraceptive were the most predominantly recognized modern method (85.9%;116/135). However, only 28.1% (38/135) heard of implant and injections as modern contraceptive method.

Others studies are related to utilization for family planning is prevalence of contraceptive use in approaching 60% worldwide and in the less developing countries almost 53% of couples are using some form of contraception(11).

Studies done in many countries showed that the most commonly used method of contraception among women in southern Jordan were oral contraceptives, IUD, withdrawal and female sterilization was only used by 4.2% of women. Another study found that Jordan Muslims preferred IUD as contraceptive method and that the believed that the IUD had fewer side effect than oral contraceptive (12).

World health organization which showed that women in many underdeveloped countries don’t have enough knowledge about contraception(2).

The majority of women in this study were unfamiliar with the idea of family planning half of the study sample were poor knowledge about influence factors on utilization on family planning 64.7% percent. These study finding of our study is concerned with study done in Jordan about knowledge of women with 91.4% never heard about types and utilization of family planning services (13). Others study results is inconsistence with or study that indicate women has good knowledge about in duhaks showed that 82.4% of women know about family planning.

The sample of the study show negative attitude toward family planning method. Others studies done by researchers who found positive knowledge and attitude about family planning and family planning services in the district were; spacing of children and the desire of some women to prevent pregnancy and Sexual Transmitted Infections (STIs) due to increase their awareness and attitude about family planning services by (5).

The finding of the study that there is a relationship between influence factors utilization for family planning services and demographic data that indicate
high significant between knowledge and demographic data. These findings were agree with our study by (16), educational attainment and level of knowledge about family planning method were statistical significant to family use. the findings of the current study echoed in many other studies. Found that well educated women are more willing to engage in innovative behaviour than less educated women and in many developing countries, the use of family planning method remains innovative. Another researchers support for our study by (17), also reported a positive association between educational level of both women and their spouses and use of contraceptive method.

Preparation of Nano-Antigen for Brucella Abortus by Ultrasound Technique and Evaluate their Sensitivity by ELISA Technique

Dania Dhafer Hameed1, Siham Sabah Abdullah2, Ali Abdullhussein Mahdi3

1Post Graduate, 2Assist. Prof., Department of Physiology and Medical Physics, college of Medicine, Al-Nahrain University, Baghdad, Iraq, 3Assist. Prof., Department of Pathological Analyzes, College of Health and Medical Technologies University, Baghdad, Iraq

Abstract

Background: The nanoparticle technology, or nanotechnology is the science that studies the treatment of matter on the atomic and molecular scale. Nanotechnology deals with measurements between 1 to 100 nanometers, i.e. deals with atomic clusters ranging from five atoms to a thousand atoms. They are much smaller than bacteria and a living cell palsy.

Method: In this study, it involved the production of a new technique for diagnosing infection with Brucella bacteria. This study included 45 samples of patients suffering from brucellosis (women and men), in addition to 36 samples from other Brucella. All were diagnosed Injuries by hospital medical advisory staff using various tests vitek, ELISA, API20C, Morphology, Brucella media test. The samples were examined using the new technique compared to the routine method of diagnosis. We found that the new technique gave a positive result to the samples infected with Brucella bacteria, while the rest of the samples without infection with Brucella bacteria gave a negative result.

Results: It was found that the tests of Elisa and API20C, Vitek were more sensitive 100% and specialized 100% for the diagnosis of Brucella bacteria than other method morpholgy with allergic 44% and specialized 86%, Brucella media Test, with allergy 88% And specialty 86%. The results of the ELISA kit test were the nano-labs (the new technique) in this study to diagnose more successful bacteria compared to normal system and more allergic and specialized because of the antigen-containing.

Conclusion: The new kit use in nanotechnology is more Sensitivity and Specificity for diagnosis to the brucella, Roads routine to diagnose brucella is not effective compared with API, Vitek and ELISA.

Keywords: Nanotechnology, Brucellosis, ELIZA Technology.

Introduction

Nanotechnology is a term used to deal with the scaling matter at atomic or molecular level. The word Nano means a one to one billion of the physical quantity. Considered one Nano unit length equivalent to one-billionth of a meter. When Nanomaterial’s are manufactured from bulk material. Nanoparticles have emerged as powerful tools to initiate and modulate immune responses due to their inherent capacity to target antigen-presenting cells (APCs) and deliver coordinated signals that can elicit an antigen-specific immune response. Nanotechnology is now a fast and interdisciplinary scientific field, through combining distinctive sciences like biology, physics, medicine, and chemistry with engineering, also removing the conventional borders between them.

nano-technology has the capability of controlling and recognizing molecules and atoms, also dealing with the structures with sizes in range of (1-100nm), 1nm has been equal to billionth of meter. The majority of current nano-materials might be provided into 4 types(5-8): Carbon-based materials, Metal-based materials, Dendrimers Compounds Combine Nano-particles\(^9\)(10). Brucellosis is a bacterial infection caused by Brucella, which is transmitted from animals to humans. In most cases, people are infected by consuming raw or unpasteurized milk products. Sometimes, the bacteria that cause Brucellosis may be transmitted through the air or in direct contact with infected animals\(^11\).

**Material and Method**

The samples were collected from 45 patients. Blood samples and 36 other brucella individual (male and female) as control group. all samples were collected from Al-Kadhimiya Teaching Hospital & Baghdad Teaching Hospital during the period from October 2019–February 2020 and were investigation to diagnosis for Brucellaby many test [Culture, Brucella media Test, Vitek and API 20C].

**Preparing the blood agar:** The medium has been prepared based on the specifications that have been provided by the manufacturing company. 37.50g of the powder has been dissolved in 1 liter of the Distal water (DW), auto-calved for 15 minutes at 121C° (15psi), cooled to 50 -55C° and aseptically 5-7% v/v sterile human blood has been added.

Enterotoxin B Ab Preparation

Based on the manufacturing leaflet, 1ml of the DW has been added into 0.20mg of the enterotoxin B Ab. 500µl has been obtained from the enterotoxin B Ab. and diluted with 9500µl DW for obtaining the 10µg/ml concentration.

**Brucella Diagnosis using the vitek system:**

1. 3 colonies have been utilized for preparing the Brucella suspension in saline tubes (0.50ml). The suspension has been adjusted to McFarland standard (0.50) utilizing Vitek colorimeter (450nm filter, transmittance ranging between 45% and 55%).
2. After the labeling of the Brucella cards with marker, placed card at a transfer tube with filling stand which has been in Brucella suspension.
3. The card has been inoculated by the module of the filling.
4. The cards have been closed by the sealor module, and incubated afterwards, for 25hrs or 56hrs at 36C, according to type of the readings which have been provided by the instrument types.

**The destruction of the cell wall and the isolation of Ag**

- The *Brucella* has been cultured on the blood agar plates and incubated overnight at a temperature of 36°C.
- The growth has been harvested with the use of the microscopic slide via curettage.
- DW has been added into the growth of the bacterial for making 5 ml suspension.
- Brucella suspension has been treated by the lysis buffer (50ml of 50ml of 1% Acetate and 2% SDS). The resultant suspension has been incubated for 20min in the boiling water and vortexed vigorously afterwards.
- One bacterial suspension volume has been mixed with two chloroform volumes. Such suspension has been vigorously vortexed and exposed to the ultrasounds at 50C° for 30min.
- The suspension has been centrifuged 5min at 4,400rpm. Ten volumes of supernatant has been precipitated with the use of 1 saturated ammonium sulfate (NH4)2SO4 volume after that, it has been mixed at 40˚C on hot plate magnetic stirrer.
- The mix has been dialyzed with the use of the dialysis bag (14,000) against the sucrose for obtaining stock (i.e. the concentrated protein)

The dialysis is a commonly utilized approach, it is simple, yet, time consuming due to the fact that separation is dependent on the diffusion. The sample has been placed within a dialysis bag which has been prepared from a tube which is made from semi-permeable membranes. Relying on the dialysis tube which is available commercially, merely small molecules with sizes <10kDa has been eliminated from sample to the medium around. Which is why, this approach is typically utilized for removing the salts from the protein solution. Dialysis can be utilized to concentrate protein solutions as well. The molecules of the water are eliminated from the inside of the dialysis bag with the use of a hydrophilic polymer like the poly-ethylene glycol.
Purifying enterotoxin B using the gel filtration chromatography: 50ml of the sephacryl S300 has been packeted in the column (2.50cm diameter×78cm length, volume of the column: 379.90ml). 5 ml of the specimen which has been concentrated through the ammonium sulfate has been applied to the sephacryl S300 column.

The elution has been accomplished at a 5ml fraction flow rate with the use of the DW as buffer, each fraction’s absorbance has been measured at 280\(\text{nm}\). The peaks have been obtained and concentrated afterwards via the dialysis against the sucrose.

Detecting Ag using the ELISA kit:

**Principles:** The concept has been accomplished based on manufacturing leaflet. This immunoassay of the enzyme has been based on the immuno-capture concept for quantitatively detecting of the enterotoxin B Ag. The micro-well plate has been coated by anti-enterotoxin B Ab. Throughout the test, the sample has been added into the antibody coated micro-well plate and incubated after that. In the case where the sample includes the enterotoxin B Ag, it will be binding to antibody which is coated on micro-well plate for forming immobilized complexes of Ag-Ab. Following the first incubation, the micro-well plate has been washed for removing the unbound materials. Anti-enterotoxin B Ab has been added into micro-well plate and incubated afterwards. This antibody will be binding to complexes of Ag-Ab. The enzyme-conjugated have been added into micro-well plate and incubated afterwards. The enzyme-conjugated will be binding to the present immune complexes. The solution of the sulfuric acid has been added into the micro-well plate for stopping the reaction which produces a change of the colour from the blue to the yellow. The intensity of the color corresponding to the enterotoxin B Ag amount which is present in the sample has been measured by a micro-plate reader at 450/630-700\(\text{nm}\) or 450\(\text{nm}\).

**Process:**

**A-Ab. Coating:**
- To capture Ab. in the wells’ bottoms, 100\(\mu\)l of diluted enterotoxin B Ab. (10\(\mu\)g/ml) has been added into the 96 wells of micro-titre plate.
- The plate has been covered by sealer of the plate and then incubated overnight at room temperature.
- Every one of the wells has been washed three times by 100\(\mu\)l of the working wash buffer for each one of the wells, after that, the liquid has been washed away.

The micro-well plate has been turned upside down for few seconds on an absorbent tissue. Each well was entirely cleaned and dried.

**B-Blocking**
- To block the area in the wells’ bottoms, 100\(\mu\)l of blocking buffer has been added into the wells.
- The plate has been covered by sealer of the plate, then, incubated for 30min ± 2min at room temperature.
- Every one of the wells has been washed three times by 100\(\mu\)l of the working wash buffer for each one of the wells, the liquid has been washed away. The micro-well plate has been turned upside down for a few seconds on an absorbent tissue. Each well was entirely washed then dried.

**C- Assay process:**
- The serial dilutions for Ag have been produced: 0.50ml of Ag has been added into the first one of the eight tubes, every one of which contains 0.50ml DW, 0.50ml has been obtained from the first tube and added into second one, etc.
- Al has been left as a blank well.
- 50 micro-liter of every one of the dilutions has been added into assigned wells and carefully mixed through swirling micro-well plate for 30sec. on flat bench.

The micro-well plate has been covered by a plate sealer and incubated for 30min ± 2min at room temperature.
- Those assigned wells have been washed three times by 100\(\mu\)l of a working wash buffer for each one of the wells.
- 50 micro-liter of the diluted enterotoxin B Ab has been added into specified wells.
- The plate has been covered by the sealer of the plate and incubated for 30min ± 2min at room temperature.
- Those assigned wells have been washed 3 times by 100\(\mu\)l working wash buffer for each one of the wells, the liquid has been washed away.
The micro-well plate has been turned upside down on an absorbent tissue for seconds. Each well has been entirely washed and dried.

- 50 micro-liter of the conjugate has been added into specified wells with the exception of the blank one.
- The plate has been covered by sealer of the plate and incubated for 30min. 2min at a room temperature.
- Those assigned wells have been washed three times by 100µl of the working wash buffer for each one of the wells.
- 50 micro-liter of the TMB has been added into the specified wells.
- Two-three minutes later, 50µl of the stop solution has been added into those specified wells.
- Absorbance has been read at 450nm. The enterotoxin B Ag concentration has been specified through the comparison of absorbance to the Brucella curve (IgG Ab.) ELISA Kit.

Method

1. Isolatione of bacteria by culture of blood sample on Brucella media.
2. Add 0.5 ml from pure colony bacteria to 0.5 ml DW (Mix-bacteria)
3. Exposure Bacteria (Mix-bacteria) of Brucella antigen to ultrasound by sonication bath for (1 min, 5 min and 10 min 30 min). . . . . . . (R1) (this step to Cracking proteins into smaller particles due to collision of high frequency sound waves)
4. Add 100 Ml (10 M/dl concentration) from R1 to plastic wells ELISA (to coating of Ag on basic of plastic wells)
5. Add 100 Ml (10 M/dl concentration) from Bacteria of Brucella antigen without exposure of ultrasound (R2) plastic wells ELISA as control
6. Waiting for 24 h.
7. Add 100 Ml Conjugated reagent to R1 & R2 (Routine work for preparation of ELISA Kit)
8. Wash 3 time all wells by washing reagent
9. Add 100 Ml from TMB and waiting 10 min
10. Add 50 Ml from stop reagent (to Stop Interaction)
11. Read on 450 nm
12. Comparing between R1 & R2 of absorbance

Results

Isolation and Diagnosis of Brucellaisolation:
Table [1] and Figure (1) showed the comparison of some test types that are utilized in the Brucella diagnoses. It has been shown that Vitek and API 20-C of a higher sensitivity 100% and specificity 100% for diagnosing Brucella compared to other approaches (Colonial morphology “culture” 44 % and Brucella media test 88.0%), the Vitek test has been used to diagnose 32 isolates.

*The sensitivity of a test is the ability of the test to identify correctly the affected individuals (111)

**The specificity of a test is the ability of the test to identify correctly non-affected individuals (111)
The results showed in Fig (2) and the figure a high absorbency for the samples that were prepared with nanotechnology and whose absorbance was measured as being more high than the samples prepared by traditional method.
Discussion

Samples have been gathered from 45 patients. Blood sample and 36 others brucella individuals (males and females) as the control group. Every sample has been taken from Al-Kadhimiyya as well as Baghdad Teaching Hospitals during the period from October 2019 – February 2020 and have been investigated by diagnosing for the Brucella by several tests [Culture, Brucella media Test, Vitek and API 20-C].

In Table (1) the results have shown that the percentage of sensitivity in the exams API, Vitek and ELISA were (100%), while the examinations of Morphology (44%) and (88) Brucella media test, respectively, while the Specificity rate (100%) for API, Vitek and ELISA were (100%), while its percentage was lower (86) for the Brucella media test and Morphology test. This is because the tests were dependent on the external appearance, color difference, and morphology of the microorganisms. The results proved that the best way to diagnose bacteria is by means of API 20-C, Vitek and ELISA. This is consistent with the findings of Mahdi[12].

The results proved that the extracted and purified antigen by Nano-technique method was more effective than the purified antigen in the routine way because in the event that the large molecule of the antigen is broken, which contains multiple epitopes on the surface of the large molecule where the precise cracking of the large molecule allows to distribute the space of the epitope more widely and publish it accurately and broadly. When using standard antibodies manufactured specifically for specialized isolates of Brucella by the Nano scale method, the results showed a high correlation with the Nano antigen and was detected by absorbance measurements on wavelength 450 nm. Whereas, there was no reaction interaction between antibodies and normally made antigens, this is consistent with the findings of Kishimoto, Maldonado[13].

Creative Thinking and its Relationship to the Quality of Life for Physical Education Teachers in Najaf

Aqeel Yahya Hashim Abdulaziz¹, Noor Latif Abdul Zahra², Hayder Naji Habash Alshawi³

¹Prof., University of Al-Hamdaniya/IRAQ, ²Assistant Lecturer, ³Prof., University of Kufa/Faculty of Education for Girls/Department of Physical Education and Sports Sciences/IRAQ

Abstract

This type of thinking is considered important for the individual and society, because of the creative outcome that is achieved as a result of the presence of individuals with the ability to be creative in various areas of life, if the individual has the appropriate environment for the growth of his creative thinking, which can be one of the reasons that play a role in assessing the quality of life for education studies Of sports in the province of Najaf, and the research aims to identify the level of reasoning thinking and the level of quality of life for female teachers of physical education affiliated to the director of education for the province of Najaf, and to identify the relationship between the level of creative thinking and the level of quality of life for teaching women Of sports in Najaf governorate, and the researchers assume that there is no correlation between the level of creative thinking and the level of quality of life among the teachers of physical education in the province of Najaf, the researchers used the descriptive method in the survey method and the correlations of its relevance to the nature of the research problem on the studies of physical education in the province of Najaf for the academic year 2019-2020, and the number (35) female teachers belonging to the Directorate of Education in the province of Najaf and were chosen in a simple random manner.

The researchers concluded that the level of creative thinking and the quality of life for physical education teachers in the middle level, and the existence of a significant correlation between creative thinking and quality of life, and the development of creative thinking was reflected in the quality of life for physical education teachers.

Keywords: Creative thinking, quality of life, physical education teachers.

Introduction

The quality of life is of great importance for identifying each person who does not benefit the individual to develop his psychological and mental energies, and the level of quality of life for teachers depends on several variables, including psychological and mental ones that directly affect him in his public life, “it is the individual’s feeling of satisfaction and happiness and his ability to satisfy his needs of During the richness of the environment and the advancement of services that are provided to him in the health, social, educational and psychological fields with good management of time and benefit from it “(1)

And that the quality of life is the satisfaction of the individual with his ability in life and a feeling of comfort and happiness, as well that the quality of life is the individual’s feeling of contentment and happiness and his ability to satisfy his needs through the richness of the environment and the improvement of services that are provided to him in the health, social, educational and psychological fields with good management of time and benefit from it, as well as It, consists of a set of variables that aim to satisfy the individual, and subjective

indicators that measure the degree of saturation with objective indicators that measure the flowing capabilities of the individual, and subjective indicators that measure the amount of satisfaction achieved, and the mental capabilities of the individual have a role in the perception of life and one of these variables A mindset is creative thinking, which is creativity. Not only is mental preparation, but there is a large side that is controlled by environmental and social factors, as it can be developed, taught, and learned, according to the appropriate conditions for its development and creativity. It is not limited to a specific number of people. Rather, the justice of God Almighty required the distribution of creative energies over All his creation, and if every person searches himself, he will find that he can be creative with something (2).

This kind of thinking is of importance for the individual and society, because of the creative outcome that is achieved as a result of the presence of individuals who can be creative in various fields of life if the individual has the appropriate environment for the growth of his creative thinking (3).

Which can be one of the reasons that play a role in assessing the quality of life for physical education teaching in the province of Najaf and the research aims to identify the level of performance thinking and the level of quality of life among the teaching of physical education affiliated to the director of education in the province of Najaf and identify the relationship between the level of creative thinking and the level of Quality of life for physical education teachers in Najaf, and researchers assume that there is no correlation between the level of creative thinking and the level of quality of life among physical education teachers in Najaf.

Practical Part

Field research procedures: The researchers used the descriptive approach to surveying and correlation, as it suits the nature of the research problem on the teaching of physical education in the province of Najaf in the academic year 2019-2020, and the number (35) teaching belonging to the Directorate of Education in the province of Najaf and were chosen in a simple random manner.

Measurements used in the research:

The level of the variables used in the research has been identified according to the following:

First: The creative thinking scale for physical education teachers: After examining the researchers’ several tests related to creative thinking. They found that the Bernstein World Scale (1989) is the most appropriate for research, as the world designed this scale, which originally consists of (74) paragraphs aimed at measuring creative thinking among individuals and the answer to them is through three alternatives (I agree, hesitant, do not agree) As the overall scale of the scale ranges from (74 -222) degrees and the scale was prepared by (Zainab Najeh Hasan) () which is of (48) paragraphs and the answer is on a triple scale so that the highest degree on the scale is (144) and the lowest degree is (48) degrees.

Second: The measure of the quality of life for physical education teachers: After examining the researchers on several tests related to measuring the quality of life, the researcher used a measure of the quality of life for the researcher (confident that the servants are slaves), which consists of alternatives with a five-year scale (it applies to him very much, applies to him to a large degree, applies to him on an average degree, applies to him To a lesser degree, it applies to it to a very small degree) and the number of its paragraphs is (22) items, with the highest degree on the scale (66) degrees and the lowest degree (22) degrees.

Scientific coefficients of the scale:

1. Verify the scale: Researchers used the sincerity of (experts), although the two scales enjoy a high degree of honesty and consistency, but the researchers deliberately carried out a number of scientific transactions for the scale, among which (the sincerity of experts) for the two scales, which is one of the types of honesty and means “the extent to which the test represents the content to be measured as paragraphs were presented The two standards are based on a number of experienced masters in the field of psychological sciences, the field of measurement and evaluation, and sports psychology, as they were asked to express an opinion on the validity of the fields and paragraphs of the scale for their evaluation, and to judge the suitability of the field for which it was set, and to make appropriate adjustments through (delete or return s Adding or adding some fields or a number of paragraphs) to suit the research community who are physical education teachers in Najaf Province, as well as mentioning the validity of the alternatives to the answer, or adding and identifying alternatives
to the answer they see as appropriate for the scale, as (Oweis) indicates that “we can prepare The test is valid after presenting it to a number of specialists and experts in the field that the test measures, and if the experts acknowledge that this test measures the behavior that was set to measure it, the researcher can rely on the experts 'judgment, and after analyzing the responses and observations of the experts, the experts’ sincerity was extracted By percentage of expert agreement h For the validity of its paragraphs, as was accepted paragraphs agreed (75%) or more of their views, as “the researcher to obtain a ratio of agreement to experts in the validity of paragraphs, and the possibility of making adjustments by not less than 75%.”

Exploratory experiment

After developing the instructions for the two scales, the researchers conducted the pilot study to discover the following:

1. To ensure clarity of instructions and paragraphs of the two scales.
2. Knowing the time taken to answer each scale.
3. Knowing the circumstances of applying the two standards and the accompanying difficulties.
4. Ensure that the two scales are clear of the sample.
5. Researchers will have practical training to determine for themselves the negatives and positives that are encountered during the conduct of the main test.
6. Extraction of the scientific basis for the scale.

Statistical Means: The researchers used the Statistical Package for Social Sciences (SPSS).

Results and Discussion

This axis included displaying the results of statistics after statistically processing them and in line with the goals.

View, analyze, and discuss test results for individuals in the research sample.

Table (1) shows the mean, the standard deviation, the calculated correlation coefficient value, and the statistical significance of the measure of creative thinking and quality of life.

<table>
<thead>
<tr>
<th>Variables</th>
<th>Unit of measure</th>
<th>Mean</th>
<th>STD. EV</th>
<th>Correlation coefficient</th>
<th>The significance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Creative thinking</td>
<td>Degree</td>
<td>98.25</td>
<td>9.47</td>

<td>Moral</td>
</tr>
<tr>
<td>Quality of life</td>
<td>Degree</td>
<td>46.32</td>
<td>4.23</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

It is clear from Table (1) that the mean of the measure of creative thinking was (98.25) degrees and the standard deviation was (9.47), the mean of the quality of life scale was (154.32) and the standard deviation (4.23), while the calculated correlation coefficient value reached (0.69), which is a value less than (0.05), and this indicates a significant correlation between the two measures.

Discuss the results of the relationship between the creative thinking scale and the quality of life scale: Through the findings of the researchers, Table (1) shows that there is a significant correlation between the criteria of creative thinking and quality of life, and the researchers see the reason for this moral relationship between the moral relationship between creative thinking and the quality of life for physical education teachers, the research sample, where their creative thinking affects their sense of the quality of life in the academic field, where it becomes clear to us that the higher their creative thinking, the more satisfied they are with life, its quality and its requirements, as the quality of life represents the basic pillar in building society and its progress in general and the teaching field for teachers in particular, and that it provides elements c The life of female teachers through achieving the dimensions of the scale, namely the quality of public health, the quality of family life and emotions, the quality of social relations, the quality of time management and administration and self-care, has led to an increase in the motivation of female teachers towards a quality of life balanced with the reality in which you live(4-6), as well as a feeling Female teachers generally have a good quality of life, and (Ahmed Al-Mash’ani, 2066)(5-7) emphasized that “the quality of life is the extent of personal satisfaction with life and the individual’s sense of quality, and a
reflection of this on the different requirements of life, including education.”(8-12)

**Conclusion**

The researchers reached the following conclusions:

1. The level of creative thinking and quality of life for physical education teachers was at the middle level.
2. There is a significant correlation between creative thinking and quality of life.
3. The development of creative thinking was reflected in the quality of life for physical education teachers.

Comparative Study to Compare the Prevalence of Aspergillus Flavus in Iraq and Some Neighboring Countries

Iman Hadi Alfayyadh¹, Ihsan Hameed Khudhair²

¹Lect. Pathological Analysis Dept. College of Science/University of Thi-Qar/Iraq.
²Asst. Lect. Biology Dept. College of Science/University of Thi-Qar/Iraq

Abstract

Aspergillus is a fungus and toxins produced by fungi that negatively affect patients’ lives, and recent research has focused on the relationship between different diseases caused by inhaling portions of fungi or fungal spores. There are some complete reports that fully reveal the relationship of Aspergillus fungi by determining the percentage of toxins produced by this type of fungi or their frequency in feed, food, or even clinical specimens, as well as the effect of toxins secreted by fungi on people who have been exposed to these fungi. It was purified from clinical samples, which included sputum, edema, wiping, tissue parts of the lung and other samples such as serum. As an immunological study, in addition to samples of cereals, nuts and homemade cheeses, as well as some other foods and vegetables. In this review, research in scientific research engines was conducted through four science-based data bases using the following keywords (Aspergillus fungi and the toxins they produce) (diseases associated with Aspergillus fungi). Scientific criteria were adopted in this review, and 41 subjects were selected. The results were compared in these articles regarding the presence of mushrooms in Iraqi governorates such as Najaf, Dhi Qar and Basra, as well as the frequency of mushrooms in Iraq and some neighboring countries such as Turkey, Saudi Arabia and Egypt.

And Syria during the period 2009-2018 these results were compared with the WHO reports and the permissible proportions in food and feed. It was found that the highest rate of fungi was in Iraq at approximately 89.5%, while in Syria the frequency of fungi was 86.6% isolated, and in Egypt and Jordan it was 70.67% 77.6%, respectively, while in Saudi Arabia the Arabian Peninsula was 50.56% less frequent. The high rate of fungi frequency in Iraq may be due to black storage of foodstuffs, which has led to a high rate of fungi frequency and an increase in the proportion of foodstuffs or in clinical samples, according to the materials under study.

Keywords: Aspergillus fungi, a comparative study; clinical; disease toxicity.

Introduction

Aspergillus is a type of pathogenic fungicide that is spreading all over the world. And in food, feed, stored grains and nuts. It can be found in an environment characterized by humidity and high and medium temperatures[1,2]. A. flavus is an opportunistic fungus of humans and animals. It causes diseases in immunocompromised individuals[3,4]. In general, conditions of increased humidity and elevated temperatures for storage grains and legumes increase the occurrence of mushroom toxins.[5,6] Aspergillus flavus They are distinguished by their complexity in the form, which is classified into two strains based on the size of the resulting hardness in the figure. Both the L and S strains can produce the most common aflatoxins (B1 and B2). As for the type S, it is characterized by its ability to produce aflatoxin of type G1 and G2, which is not usually produced by A. flavus. The L strain is more aggressive than the S strain, but produces less aflatoxin[7]. Aspergillus flavus AF36 is a non-carcinogenic and

Corresponding Author:

University of Thi-Qar/Iraq
e-mail: ihsan1981hameed@gmail.com
Aflatoxin-free strain and is used as an active and essential ingredient in pesticides. [8]. As suggested by [9,10] and [11] Aspergillus is found outdoors and in other environments, which may affect human health, outside the natural clinical features of Aspergillus. Or there may be Aspergillus fungi along with other fungi in the body such as Alternaria, Bipolaris, Cladosporium, Curvularia, Fusarium, Pseudallescheria, Rhizopus, Saccharomyces, Stemphylium, and Trichosporon. [12,13]. An acute fungal toxicity outbreak was reported in developing countries with frequent outbreaks in Kenya in 2001, 2004-2006, and 2008 [14,15,16]. In the period 2004-2005, more than 150 deaths were reported amongst the population due to consumption of maize contaminated with A.flavus S strain [17,18]. It was found that aflatoxin was associated with the components of grains and corn in dog food containing up to 600 mg 1 kg of a type of aflatoxin (B) group 34-40. The permissible limits for aflatoxin in feed according to the Food and Drug Administration were 60 mg-kg of aflatoxin B1 in dog food and about 20 ppm in poultry feed [19,20,21]. This study comes as a comparative study of fungi and their recurrence in Iraq and countries bordering Iraq, which included Saudi Arabia, Turkey, Egypt, the Emirates, Qatar and Syria. Samples that were made compared to the percentage of the presence of fungi contain nuts and grains as in Table No. 3 and comparison of the percentage of fungi in blood samples, sputum, faeces and vagina as in Table No. (4). The percentage of fungi in Iraq and countries was compared as shown in the study and the allowable percentage by the World Health Organization.

**Materials and Method**

The first step was to conduct an electronic research to collect a set of research related to Aspergillus fungi. I collected 41 articles on Aspergillus fungus, and these articles diversified around the diseases caused by fungi, which ranged from being in food and the cause of skin diseases, in addition to having blood in the blood and supplies of the sick group under study in the above-mentioned materials. The percentage of mushrooms in Iraq was compared first, which included a group of governorates (Kufa, Basra, Qadisiyah, and Babil). The samples included food samples as a first comparison of the percentage of the fungi that occurs according to the above mentioned materials as shown in Table No. 1, and then studied the percentage of the fungus. In the clinical samples of the same governorates above as in Table 2, another comparison of Aspergillus fungi was performed as a comparative survey in Iraq and other countries bordering Iraq, which included Saudi Arabia, Turkey, Egypt, the Emirates, Qatar and Syria. Samples that were made compared to the percentage of the presence of fungi contain nuts and grains as in Table No. 3 and comparison of the percentage of fungi in blood samples, sputum, faeces and vagina as in Table No. (4). The percentage of fungi in Iraq and countries was compared as shown in the study and the allowable percentage by the World Health Organization.

**Results**

Table No. (1) shows the frequency of the Aspergillus in different samples of foodstuffs, which include (seeds of leafy plants, milk and local cheese) for some governorates of Iraq, which extended the study period from (2009_2018). While in Dhi Qar Governorate, the frequency of Aspergillus fungi in dairy was 65.8% for the year 2015, while the frequency of local cheese fungi in the same governorate was about 75% for the year 2014. As for canned foods, the frequency of fungi in Al-Qadisiyah Governorate was 56.7% and Babel until 86.6% 2014. For cereals and seeds stored for foliar plants, the frequency of fungi in Karbala Governorate was 9.3% while in Kufa 11.5% for the same year. While in Qadisiyah, the percentage of fungi recurrence in leafy plants, which included lettuce, fennel and fennel in Qadisiyah Governorate in 2017, was 53.3%, while in dried fruit samples of figs and apricots 31% for 2018.

Table [3] shows the frequency of *A.Flavus* in different food samples between the governorates of Iraq and neighboring countries during [2009-2017]. It was noted that the *A.flavus* in Syria and Saudi Arabia showed a noticeable increase in nuts such as pistachios, walnuts and others, Saudi Arabia with 78.5% in some seeds, while the percentage of recurrence of fungus in Iraq was higher than the rest of the countries where it reached 71.2% in some food for stored stocks and cereals. The rate of recurrence of *A.flavus* in some types of grain stored and feed in Syria increased by 20% in grain while it was about 16% of pulses either in 2013 has increased the frequency of *A.flavus* in Saudi Arabia in the seeds of wheat plant by 56.3% We note from Table 3 that The frequency of the fungus was 86.3% in nuts for 2015 in Syria and 25% in Jordan for the same year. The peanuts of the nuts in the UAE had a share of this fungus infection, with an average recurrence rate of 63.1% in the United Arab Emirates. While the highest frequency of fungi in corn and wheat grains was very high at 97.3% in Turkey in 2015. In 2017, the frequency of fungus in sunflower seeds increased by 60% in Egypt in 2017. In Iraq and the same year, the percentage of recurrence of *A.flavus* to some seeds of leafy plants was 53.37%. For dairy products, Egypt in 2010 was 86.7%, while in Iraq canned food was 47.8% for the year 2015 and 73.9% for dried food in Lebanon.

Table[4] shows a comparison of some samples showing the frequency of $A.\text{flavus}$ in some neighboring countries and Arab countries in the study during the academic year 2019, where found the frequency of $A.\text{flavus}$ in samples vaginal fluids in females up to 49.7%, but in blood samples found the frequency of fungus in females were 52.1% in Jordan and 49.7% in Yemen. In the blood samples, the frequency of female fungal infection was found to be 24.21% for males, 25% for Iraq, and 1.06% for Egypt for 2016. For samples Ulcer has been found that the $A.\text{flavus}$ appeared in some respiratory patients recurrence rate of 47.6% for the year 2015 in Egypt rate of recurrence of mushrooms in 2017 rose to 78%. We note from Table (4) that the rate of recurrence of $A.\text{flavus}$ in skin samples infected with fungal ulceration was 67.7% in the United Arab Emirates. As for the exit samples of some intestinal inflammatory patients in the Kingdom of Saudi Arabia, the rate of recurrence of the $A.\text{flavus}$ reached 96.5% in 2018.

Conclusions

The purpose of this study is to conduct a survey of the frequency of fungi Aspergillus in a group of Iraqi governorates, and to compare the frequency of fungicides in Iraq and the group of countries neighboring Iraq in food and clinical samples. Scientific standards were adopted in this review. The results were compared in these articles regarding the presence of mushrooms in Iraqi governorates such as Najaf, Babil, Dhi Qar and Basra, as well as the frequency of mushrooms in Iraq and some countries such as Turkey, Saudi Arabia and Egypt and Syria during the period 2009-2018 these results were compared with the WHO reports and the permissible proportions in food and feed. It was found that the highest rate of fungi was in Iraq at approximately 89.5%, while in Syria the frequency of fungi was 86.6% isolated, and in Egypt and Jordan it was 70.67% 77.6%, respectively, while in Saudi Arabia the Arabian Peninsula was 50.56% less frequent. The high frequency of fungi in Iraq may be due to black storage of foodstuffs, which has led to a high rate of fungi frequency and an increase in the proportion of foodstuffs or in clinical samples, according to the materials under study.

Serum Levels of Alanine Aminopeptidase and Aggrecan in Women with Breast Cancer: A Comparative Study

Saja A. Hussein1, Salam S. Ahmed2

1B.Sc. Medical Technology/Medical Laboratory Technology (Kirkuk)–Samarra City/Iraq,
2Dr. Professor of Clinical & Medical Biochemistry/Pediatrician-College of Medicine–Tikrit University/Iraq

Abstract

Background: The term “breast cancer” refers to a malignant tumor that has developed from cells in the breast and is a major public health problem in women throughout the world. It is the most common cancer among women both in developed and developing countries.1 The aminopeptidases (AP) constitute a group of enzymes with closely related activities.2 Aminopeptidases catalyze the cleavage of amino acids from the amino terminus of protein or peptide substrates. The enzyme exhibited low molecular weight of 58,000 by gel chromatograph.3 Aggrecan is a proteoglycan, or a protein modified with large carbohydrates hormone; the human form of the protein is composed from 2316 amino acids long and can be expressed in multiple isoforms due to alternative splicing.4

Materials and Method: This study was designed as a cross-sectional, hospital based study. Forty-two women with breast cancer were included in this study, their ages were from 24 to 70 years, and they were from the center and the periphery of Salah Al-din Governorate. Forty-four apparently healthy women with negative family history of breast cancer were included in this study as a control group, they ages were of a comparable age. By using a sterile disposable syringe, 10 mls of venous blood sample was drawn in a plain tube from each women included in this study for the serum measurement of alanine aminopeptidase and Aggrecan by using ELIZA technique.

Results: The mean serum level of alanine aminopeptidase was elevated in breast cancer women comparing with the control group (71.73±1.5 versus 15.29±0.9 ng/ml). The result was highly significant at a P value of less than 0.01. While the mean serum level of aggrecan was found among women with breast cancer (41.81±11.5 ng/ml) compared to control group which was 7.27±3.6 ng/ml. The result was highly significant at a P value of less than 0.001. This study also found that there was a moderate positive correlation between S. AAP activity and S. aggrecan in breast cancer women (R<0.7).

Conclusion: There were an increase in serum levels of both the alanine aminopeptidase and aggrecan in women with breast cancer.

Keywords: Breast cancer, alanine aminopeptidase, and aggrecan.

Introduction

Breast cancer is the most common malignancy in women, with incidence rates generally increasing throughout the world and this increase being attributed to socio-economic and demographic changes.5,6 It carries a high incidence and mortality from 27 types of major cancers and for all cancers combined since 2012 and are now available in the Series of the International Agency for Research on Cancer with 1.67 million patients in the world.7 Breast cancer is the most dangerous disease that threatens women lives in Iraq, every year 1000-1200 new cases are recorded, 98% of which affect women, and 2% of which affect men. Breast cancer occupies 14% of the

e-mail: marwan.walady@yahoo.com
whole disease in different cancers and a rate of 1-6 of women are affected from every 100000 women.(8)

Alanine aminopeptidase (AAP) is one of exopeptidase, it is composed of 967 amino acids.(9) Alanine aminopeptidase its function is to release the N-terminal amino acid residues from polypeptides and protein, isolated in a highly purified state from human liver, kidney, and pancreas were investigated with regard to their different electrophoretic mobility. While the molecular weights are identical, different isoelectric points were found.(10) Alanine aminopeptidase may hydrolyze several biologically active peptides. It’s activity was significantly higher in males than in females. (11) Alanine aminopeptidase spreads in various regions of mammalian body, because it is responsible for many physiological functions inside the human body, like kidney, pancreas, liver,(12) and intestine specially in duodenum. (13)

Aggrecan (ACAN) is a proteoglycan that present in all cellular and tissue compartments. It is one of the major structural component of cartilage therefore it is known as cartilage-specific proteoglycan core protein (CSPCP) or chondroitin sulfate proteoglycan 1 (may have >100 chondroitin sulphate chain) which are key to its function in the maintenance of a hydrated, compression-resisting matrix. (14,15) Aggrecan has a molecular mass more than 2,500 kDa. (16) The core protein (~300 kDa), (17) and has around 100 GAG chains attached to it. (18) It is consists of two globular structural domains (G1 and G2) at the N-terminal end and one globular domain (G3) at the C-terminal end, separated by a large extended domain chondroitin sulfate (CS) heavily modified with GAGs. The two main modifier moieties are themselves arranged into distinct regions (N-G1-G2-CS-G3-C), a chondroitin sulfate and a keratin sulfate region. The three globular domains, G1, G2, and G3 are Involved in aggregation, hyaluronan binding, cell adhesion, and chondrocyteapoptosis. Along with type-II collagen, aggrecan forms a major structural component of cartilage, particularly articular cartilage. It’s play an important role in function of joints. (18)

Patients, Materials, and Method

This study was designed as a cross-sectional, hospital based study. The protocol of this study was approved by the scientific committee of Tikrit university college of medicine, and the agreement to collect the samples from patients was approved by the Salah Al-din Health Directorate. The study was carried out at the Gynecology Outpatient and Oncology Unit in Samarra General Hospital-Samarra City-Iraq, from the 14 of November 2018 to the end of June 2019. A verbal consent was taken from each women included in this study whether considered as a case or control. The diagnosis of breast cancer was according to discussion of both the gynecologist and the histopathologist. The total number of women with breast cancer were 42, and their ages were form 24 to 70 years, and they were from the center and the periphery of Salah Al-din Governorate. Forty-four apparently healthy women with negative family history of breast cancer were included in this study as a control group, their ages were comparable to that of the women with breast cancer and they were also from the center and the periphery of Salah Al-din Governorate.

By using a sterile disposable syringe, 10 mls of venous blood sample was drawn in a centrifuge from each women included in this study after morning and allowed to clot at room temperature, then the tubes were centrifuged at 3000 rpm and the supernatant serum was used to estimate the levels of alanine aminopeptidase and aggrecan by ELIZA method.

Statistical Analysis: All the date collected in this study were analyzed by using the student t-test, the mean, standard deviation, and P-value was also considered. The significance was considered at a P value of less than 0.05.

Results

This study showed that the peak age of women with breast cancer was between 44–53 years and its percentage was 35.71%, while the least age group was above 63 years and its percentage which was found to be 9.52%, see table (1).

| Table (1): Distribution of breast cancer women according to age. |
|---------------------|-----|---------|
| Age groups (years)  | No. | Percentage |
| 24-33               | 5   | 11.91   |
| 34-43               | 8   | 19.05   |
| 44-53               | 15  | 35.71   |
| 54-63               | 10  | 23.81   |
| >63                 | 4   | 9.52    |
| Total               | 42  | 100     |

</tbody>
</table>

This study reveals that there was a moderate positive correlation between serumalanine aminopeptidase activity and serum aggrecan in women with breast cancer (R<0.7), figure (1).
Discussion

This study reveals that the peak age of women with breast cancer was between 44-53 years; this finding was in agreement with AL-Hashimi et al. (19) who reported that the median age at diagnosis was 49 and the mean age was 52 years, also this study was in agreement with Majid et al. (20) who reported that the breast cancer increased in post-menopausal Iraqi women, and the rate of incidence in Arabs and its Kurdish region were generally stable between 2000 to 2009.

This study also shows that the breast cancer was more common in women from urban area more than rural as seen in the table (2). This result was agreement with Majid et al. (20), that found in his study that the urban exceeding the rural rate by 2:1, for both Kurdish and Arabic women. This finding could be attributed to the migration of some peoples in Iraq from the rural to the rural area in the last decades.

Body mass index consider one of the modifying risk factor for breast cancer. (21) In the present study it was found that there were an increase in the weight of women with breast cancer more than that of the control group. The mean of BMI in breast cancer women that show in table (3), this finding was consistence with Platel N. et al. (22) and Rebbeck R. et al. (23) who reported a high prevalence of overweight and obesity in women with breast cancer. Epidemiological studies have shown that postmenopausal obesity causes an increase in the risk of breast cancer, (24) since the obesity has a close relationship with increased levels of insulin and insulin like growth factors.

This study show that there was a significant difference between breast cancer women and the control group concerning serum level of alanine aminopeptidase which was found to be significantly higher in women with breast cancer comparing with the control. These results were in agreement with Martinez et al. (25) who found an increase in the activity of this enzyme in neoplastic tissue when compared with unaffected tissue. Also these results were in agreement with Mina-Osorio et al. (26) and Taylor et al. (27) who found an increased AP activity in breast cancer tissue vs surrounding normal tissue. Wickstrom et al. (28) and Bauvois B. et al. (29) noticed an increased APN activity in the serum of women with breast cancer vs its activity in serum of healthy women. These findings could be attributed to that tumors usually
associated with a rapid overgrowth of cells along with cell destruction.

The finding of a significant difference between BC women and the control group concerning serum aggrecan level at a P value of less than 0.01. This result was in agreement with the finding of Nikitovic et al.\(^{(30)}\) who reported that the proteoglycans are important constituents of the intracellular or extra cellular matrix, that have been associated with cancer pathogenesis. These findings could be attributed to that tumors usually associated with a rapid overgrowth of breast cells along with increase production of this hormone.

The positive correlation between alanine aminopeptidase and aggrecan in this study, could be attributed to that both of these biochemical parameters were increased in serum of women with breast cancer in this study.

**Conclusion**

This study reveals an increase in serum levels of alanine aminopeptidase and aggrecan in women with breast cancer.

Using Bioluminescence Assay to Detect Snps Cause Drug Resistant of *Mycobacterium Tuberculosis* in Iraq

Hassan Kadhim Nemir¹, Ismail Aziz¹, Alaa Kareem Mohammed²

¹Institute of Genetic Engineering and Biotechnology for Postgraduate Studies, University of Baghdad, Iraq, ²AL- Khwarizmi Engineering College/Biochemical Engineering department/University of Baghdad, Iraq

Abstract

In this search, a new bioluminescent technique was proved for pyrophosphate which was employed to single- nucleotide polymorphism (SNP) diagnosis using one-base extension reaction. Four *Mycobacterium tuberculosis* genes were chosen (*Rpob, InhA, KatG, GyrA*) genes. Fifty-four specimens were used in this study fifty-three proved as drug-resistant specimens by The Iraqi Institute of Chest and Respiratory Diseases in Baghdad., also one specimen was used as a negative control.

The procedure of this assay was as follows. A specific primer within each aliquot owning a short 3-OH end of the base of the target gene was hybridized to the single-stranded DNA template. Then, (exo-) Klenow DNA polymerase and one of either α-thio-dATP, dTTP, dGTP, or dCTP were supplemented and incubated for 1 min. Pyrophosphate freed by DNA polymerase is altered to ATP by pyruvate phosphate dikinase (PPDK), and the amount of ATP is measured using the firefly luciferase reaction. This technique, which does not demand expensive equipment, can be applied to rapidly monitor one-point mutation in the gene that causes drug resistant in *mycobacterium tuberculosis*. The results showed a high variation in values of ATP formation through matching and mismatch bases added. So, this assay (which required only five minutes), enable to find the gene SNP causes resistant for the specific drug.

Keyword: SNPs, pyrophosphate, ATP, Bioluminescent, genes, drugs.

Introduction

*Mycobacterium tuberculosis* constitute a serious threaten to world, this threaten increase when drug resistant of this bacteria occurred.¹(1).

Traditional method used to detect drug resistant such as Drug Susceptibility test (DST) culture method required long period, of at least two months, that waste time effect on patient treatment²(2). Also other method used to detect SNPs such as electrophoresis of single-strand DNA conformation polymorphism (SSCP)³(3), cleavage fragment length Polymorphism (CFLP), which combined the restriction enzyme and SSCP⁴(4), the TaqMan PCR technique⁵(5), amplification refractory Mutation system (ARMS) method⁶(6), the invaders method⁷(7), and the DNA probe method⁸(8) are used. but, there is a problem with these method in that the procedure is complicated and generally demands electrophoresis apparatus, also special analytical apparatus⁹(9-15).

Material and Method

**Sampling:** Through the study interval (April 2018-May 2019), with the aid of the Institute of Chest and Respiratory diseases in Baghdad, it was received 2945 patients with suspected pulmonary and extrapulmoary TB lesions 1820 (61.7%) males and 1125 (38.2%) females, with age range from (1 year – 85 years). Fifty-four specimens which symboled with (S) letter (from S1 to S54 except S26) confirmed as drug resistant were applied in this study, one specimen(S26) was used as negative control.

**DNA Extraction:** Samples which proved as resistant were isolated and processed with DNA extraction using sonicate bath extraction apparatus¹³(13).

**Optimization:** Four genes and five SNPs (*rpoB, InhA, gyrA C94, gyr A C95*) and *katG S315T* were optimized, the gradient annealing was done by a thermal cycler apparatus⁹(9).
Primer Design:

- Primers were designed for genes (\textit{rpoB}, \textit{inhA}, \textit{katG} and \textit{gyrA}).
- \textit{gyrA} gene had two SNPs at codon C94 and codon C95 as illustrated in Table (1).

Table (1): Primers design according to terminal mismatch nucleotide for four genes and five SNPs.

Material and Method

The procedure was included preparation three solutions M1, M2 and bioluminescent solution (PPDK-luciferase solution) as follow:

1. **Preparation of mixture1 (M1):** 1µ of specific primer (75 µM) hybridized to 1 µl of DNA template (1.50 pmol) in 8 µl of 10 mmol/L Tris-acetate buffer containing 2 mmol/L (CH$_3$COO)$_2$Mg.

   The process was included denaturation at 94°C for 20 Sec., then Annealing at 65°C for 2 min$^{(17)}$.

2. **Preparation of mixture 2 (M2):** Four µl of (Mix1) was added to another tube containing 2 µl of 100 mmol/L NEB buffer containing 5mmol/L (CH$_3$COO)$_2$Mg and 1.6 µl of klenwo DNA pol. And 4 µl of one substrate of either ($\alpha$- dATP- s, dTTP, dGTP, or dCTP) mixed and incubate for 1 min.$^{(15)}$

3. **Preparation of Pyruvate, phosphate dikinase (PPDK)- luciferase solution:** The composition of solution was contained 2.3 U/ml PPDK,0.2 mM luciferin ,5.5 U/ml luciferase, 0.0125mM Adenosine monophosphate (AMP), 0.04mM Phosphoenolpyruvic acid (PEP), 0.005U/ml apyrase, 0.05mM Dithiothreitol (DTT), 5% trehalose, 1mM Ethylenediaminetetraacetic acid (EDTA), 7.5 mM MgSo4, 30 mM Beryllium sulphide (Bes). The added (AMP) incorporated with pyrophosphate (ppi) group to form ATP.$^{(18)}$

   Using Biolumenescent Assay to Diagnosis \textit{Rho}p Gene SNPs: The results showd it was possible to clearly

Method

**Bioluminescence technique Steps:**

1. Hybridization reaction: in this reaction primer hybridize to single stranded DNA of target gene, the first base after hybridized was represented target base, for example adenine base (A). This reaction included denaturation at 94°C for 20s and then annealing at 65°C for 2 min$^{(26)}$ by added M1 solution to PCR tube, thermal cycler was used for this purpose.

2. Bases added reaction: one substrate of either dATPa-S, dTTP, dGTP, or dCTP. $\alpha$-dATP-S was added to M1 solution in present (exo) Klenow enzyme, the composition form M2 solution. $\alpha$ -dATP-S was used rather than dATP to diminish nonspecific luminescence $^{(10)}$.

3. Bioluminescent reaction: the reaction occurred by added MIX2 (extension assay solution) to 10 µl of bioluminescent solution (PPDK- luciferase solution) and 80 µl Luciferin substrate.

Results and Discussion

The new Bioluminescent Assay for Detection Snps Cause Drug Resistant

The results showed very high variation between amount of ATP between the matching base and mismatching one. These results agree with$^{(10)}$ foundaton.

**Optimization of primer optimum temperature for hybridyzation:** The optimum temperature of genes hybridization for (\textit{rpoB}, \textit{gyrA} C94 \textit{gyrA} C95, \textit{Inh A} and \textit{Kat G} ) genes were 60°C,62°C, 58°C, 60°C, 60° C respectively.

Using Biolumenescent Assay to Diagnosis \textit{Rho}p Gene SNPs: The results showd it was possible to clearly
determine the wild type containing C and mutant type containing T at the identical position of the mutation site as shown in Table (2). The results of this assay were rapidly shown in the screen of Glomax illuminator after five minutes of insert microplate 96 wells in Glomax apparatus. The output data represented a relative light unit (RLU), which indicated to Adenosine triphosphate compound (ATP)\(^9\).

The higher ATP amount was with match base sample S16, the value was (198), while the less value was with mismatch sample S20. The variation between the higher amount and less amount is more than 100 units, this variation enables diagnosis easily to detect the wild base or the mutant one. The negative control (sample S26) shows normal wild type TCG codon, subsequently, the wild amino acid is serine, while mutant samples express leucine amino acid because of wild codon converted from TCG to TTG. The (RLU) value of blank control which represented luciferase enzyme only was read indicating the clear ATP in this blank.

### Table (2): Values of ATP amount for each matching and mismatch bases for \(rbop\) gene demonstrated high variation in values. Amino acid was expressed in each case.

**RpoB** genes of DNA Specimens showed an opposite curve when added match and mismatch nucleotide at the same time of bases added as shown in Figure (1).

![Bioluminescent assay curve](image)

**Fig. (1):** The bioluminescent assay showed variation in relative light unit (RLU) through matching incorporation and mismatching bases added at the same time of process.

**Using Bioluminescent Assay to Diagnosis Isoniazid Resistant SNPs:** Two genes play significant roles in Isoniazid resistant *inhA* and *katG* genes\(^{(19)}\). 49.05\%(26/53) of all resistant specimens were diagnosed with the bioluminescence assay. The results showed that 53.84\%(14/26) had snps mutation at codon 21 within *inh* gene region, and 34.61\%(9/26) had mutation with *katG* gene region, 15.38\%(4/26) of specimens had no mutant within *inh A* or *katG* gens regions. only one sample 3.84\%(1/26) exhibited both snps mutation within *inh A* or *katG* gens regions this sample(S3) had XDR behavior\(^{(20)}\). *inhA* gene codon 21 ATG converted to GTC, so the amino acid alters as a result from Leucine to Valine, also within *katG* gene region of codon 315 AGC alter to ACC, then subsequently convert amino acid from serine to therionin\(^{(11)}\). As shown in Table (3). The amount of ATP formation with *inhA* gene demonstrated higher sensitivity than that with *rpoB* gene that disagree with \(^{(21)}\).

**Conclusion**

The study proved strongly that bioluminescent assay can dependable in detection of SNPs cause drug resistant in mycobacterium tuberculosis genome, rapidly and without need to electrophoresis process as other technique, in addition other method demand time and expensive equipment in contrast with new method. The time factor plays a crucial role in treatment of tuberculosis patients, so new method such as bioluminescent assay required urgently in such disease.

Assessment of Caregiver Knowledge Related to the Physiological Changes and Health Problems in Government Geriatric Home at Baghdad City

Shatha Ahmed M.A.¹, Muna Abdul Kadhum Zeidan²

¹Assistant Professor (M.Sc.)/Criminal Evidences Techniques Dep./Medical Technical Institute/(Al-Mansur)/Middle Technical University/Iraq, ²Assistant Professor (M.Sc)/Community Health Dep. College of Health and Medical Technology/Middle Technical University/Iraq

Abstract

Population aging can lead to a larger number of individuals with physical and emotional disorders, which increase demand for caregivers, there is a high prevalence of functional disability in older adults and a variability between the genders, with a 42.8% rate among women and 39.6% among men. A quasi-experimental study, Analytical, cross-sectional, non-probability convenient study done with sampling of 20 caregivers was conducted in the Geriatric Care Home in Baghdad City (the governmental geriatric home) for the period from 12th of October 2018 to 20th of January 2019 to asss their knowledge about physiological changes and health problems. A questionnaire was used to collect caregiver’s data which consist of two parts: The first part is concerned general information of the study Geriatric home, and the second part involves two domains involving items concerning caregiver’s knowledge about physiological changes and health problems and their knowledge about emergency care for elderly persons.

Results: the study presents that a high percentage (60%) of the study sample was nurses as caregivers in AL- Rashad Geriatric Care Home and (80%) of the study sample are males, (60%) of the caregivers were graduated from college in AL- Cyelakh, All caregivers in the study of geriatric homes was married, with barely sufficient income .The study shows that,(90%), (70%) of caregivers in all geriatric care homes have (1-10) year of experiences respectively,(80%) of caregivers in geriatric home answers that they have emergency cases at their work time, (85%) of the emergency cases was saved in all geriatric care homes.

Conclusions: The researcher recommends to increase training courses inside and outside Iraq and encourage employees to use safety measures to avoid injuries of the elderly, and prepare the advanced medical facilities to promote saving lives. As well as a medical test and evaluation of all elderly in geriatric care home to identify their health problems which lead to emergencies.

Keywords: Health; medical treatment; emergency; patients; physiological changes.

Introduction

Population ageing can lead to larger number of individuals with physical, emotional disorders, which increases demand for caregivers. In Brazil, there is high prevalence of functional disability in adults and variability between the genders, with (42.8%) rate among women and (39.6%) among men. Functional incapacity among older adults directly interferes in their family, since their dependence Activity of Daily living (ADL) requires presence of caregiver(1).

The elderly are old age, World Health Organization considers the age of elderly begins at oldness of sixty-five and above usually the activity of individuals at this
stage and their bodies are weak and consider themselves unpleasant after they were basis for tender. All things reflected negatively on their health and mental state, begin the stage of anxiety, thinking about the future and what contains(2).

The percentage of elderly, in world population is predictable to increase rapidly from 9.5% in 1995 to 20.7% in 2050 and 30.5% in 2150. Amongst the elderly, number of people aged 80 and more will increase rapidly over time. According to projections, number of those aged 80 and above will rise seventeen fold from 61 million in 1995 to 1054 million by 2150.(3).

Elderly people at higher risk of cardiac complications in short and long terms. Common morbidity (including diabetes and osteoporosis) forms treatments. Supportive care plays key role, it is suggested to use promoter factor to colonize granule more often than younger patients. Quality of life and maintenance status may be important than survival without progress(4).

Dizziness and imbalance among most common complaints of elderly, they are growing concern for public health because they put elderly at great risk of falling. Although causes of dizziness in older people are multiple factors, peripheral vestibular weakness is one of the most common causes. Benign neoplasm is most common form of vestibular weakness in the elderly, followed by mental disease.(5)

Malnutrition is common but under-diagnosed condition in elderly associated with physical and mental weakening, decreased quality of lifecycle, and mortality. Malnutrition disproportionately affects elderly, results from combination of changes related to aging, comorbidities, medications, and environmental factors(6).

Method

In order to obtain an accurate data and representative sample, purposive Non – probability “ sample consists of (20) caregivers men and women are considered, selected purposively from geriatric care homesat government geriatric care home; (10) caregivers men and women are from Al Cyclakh; (10) caregivers men and women from AL-Rashad (governmental elderly care home) .The instrument constructed according to subject (knowledge) which concerned physiological changes and health problem for elderly to achieve the aims of study, the instrument was deal of four parts.

First part: General information about geriatric home: Its include which the (Name of the House . Location (Kark, and Rusafa) . Number of caregiver. Specialty of caregiver (doctor, nurse, social worker, psychologist).

Second part: General information about caregiver

This part is concerned the with General information for caregiver which consist of

Third part : Knowledge of health caregivers about Health problems of elderly: Part four concerned the with Knowledge of health caregivers about Health problems of elderly consist of (10) items it was rated according to Likert scale which a: know (3), not sure (2), Not know (1) score. Included (constipation, visual impairment, and chronic health conditions such as (diabetes, blood presser, cancer), malnutrition, impaired hearing, sensory disability, lost their balance because of muscle weakness, urinary incontinence, Inactivity due to arthritis and loss of muscle tone and elasticity, memory loss (Alzheimer’s).

Statistical Analysis: Statistical programs SPSS (Statistical Package for Social Science) version 20 and Excel application were used to analyze the data. Frequencies, Percentages and Mean of Scores were used in tables in order to get the total results of the sample and to make a comparison between the variables.

1. \( \% = \frac{\text{Frequencies}}{\text{Sample size}} \times 100 \)

2. Arithmetic Mean (\( \bar{x} \))
   \[ \bar{x} = \frac{\sum xi}{n} \]

3. C. SD : Stander Deviation
   \[ S^2 = \sum \frac{x^2 - \mu^2}{2n} - 1 \]

4. Pearson correlation coefficient was used to find out the relationship between two variables and to determine the direction as well as the strength of this relationship.
   \[ r = \frac{n(\Sigma xy) - (\Sigma x)(\Sigma y)}{\sqrt{[n(\Sigma x^2) - (\Sigma x)^2][n(\Sigma y^2) - (\Sigma y)^2]}} \]
Results and Findings

This presents the research subject which is explained in details through the analysis of its variables’ data and organized systematically in tables in a form to be compatible with the research objectives.

Table (2) shows that, (90%), (70%) of caregivers in the study in all geriatric care homes have (1-10) year of experiences respectively, high percent of them not trained for first aid in all geriatric care homes, high percent (70%), (80%) of caregivers in geriatric home answer have emergency cases that occurred at their work time, in AL-Cyelakh, AL-Rashad, geriatric care homes respectively, and the more common emergency cases which happened were (71.4%) in AL-Cyelakh was Dyspnea, (25%) of cases was dyspnea, choking, fainting, and falls in AL-Rashad geriatric care home, the percentage of dealing the emergency cases was saved in all geriatric care homes which were (85%).

Table (3): Knowledge of Health Caregivers about Physiological Changes and Health Problems of Geriatrics

Table (3): Shows The valuation of caregiver Knowledge about physiological changes and health problems of geriatric which presented that the level of caregiver knowledge was moderate according to total mean which (1.5) for AL-Cyelakh, AL-Rashad geriatric care homes respectively.

Discussion of the Study Results

1. Discussion of the Information of the Study Geriatric Home which are included in present study (Table 1): The researcher included geriatric care homes in Bagdad City which are AL-Rashad and Al Cyelakh in AL-Rusafa, The information of
homes was (60%) of the study sample was nurses as caregivers in AL- Rashad Geriatric Care Home, (40%) of caregivers in AL- Cycelakh (government geriatric care home) were nurses, (20%) were doctors+ work in AL- Cycelakh GCH, (10%) were doctors work in AL- Rashad GCH. Moreira, et al(1) stated in their study which was conducted on (60) caregivers to evaluate the effectiveness of an learning intervention on knowledge-attitude and practice of elderly caregivers in Brazil, they present a study that the nurse can be a key element for a comprehensive care for elderly persons and a confident effect on the care.

2. Discussion of General Information of Caregivers in Geriatric Home (table 2): High percent of caregivers who working in geriatric care home in the present study have shown that, (90%), (70%) of caregivers in the study in all geriatric care homes have (1-10) year of experiences respectively, high percent of them not trained for first aid in allgeriatric care homes, high percent (70%), (80%) of caregivers in geriatric home answer have emergency cases that occurred at their work time, in AL-Cyelakh, AL- Rashad, geriatric care homes respectively, and the more common emergency cases which occurred were (71.4%) in AL- CyelakhitwasDyspnea, (25%) of cases was dyspnea, chocking, fainting, and falls in AL-Rashad geriatric care home, the percentage of dealing the emergency cases was saved in all geriatric care homes which were (85%), (87.5%), respectively, in all geriatric care homes was saved emergency cases , and the number of emergency cases which occur in geriatric care home study was (1-2) cases at four study homes.

The researcher believes that the saving emergency cases of elderly due to found ambulance in geriatric home to transport the elderly to emergency unite to near hospital .

Close, J. et al,(7) stated in their report, that the incidence between 2012-2013 of adults older than 65 who sought emergency care was 12 per 100 persons for injury and 36 per 100 for illness, according to the CDC. The most common complaints that bring elderly patients to emergency departments are falls, abdominal pain, difficulty breathing, fever, chest pain, confusion or other cognitive issues, according to experts.

Vieira, et al(8) stated in their study that (28-35%) of elderly people (≥65 years) fall each year worldwide and prevalence increases with age process. Falls are the chief cause of injury, injury related frailty, and death in elderly people. The severity of subsequent injuries varies, and (40%-60%) of falls result in major lacerations, fractures, or traumatic brain injuries. A longitudinal study found that (68%) of people who fall reported approximately injury; healthcare was wanted in (24%) of cases, functional weakening was reported by(35%), and social and physical activities were reduced for more than (15%). Close to (95%)of completely hip fractures are caused by falls.

Kramarow, et al,(9)stated in their report that 55% of all unintentional accidental deaths among adults aged 65 years or over were caused by falls, and the mortality rate of age-adjusted falls in 65-year-olds more than doubled from 29.6 per 100,000 to 56.7 per 100,000.

3. Discussion of the Knowledge of Health Caregivers about Physiological Changes and Health Problems of Geriatrics (Table 3): Through the evaluation of caregivers’ knowledge about physiological changes and health problems of geriatrics, the researcher found the caregiver have moderate knowledge about physiological changes and health problems of geriatrics, which clear through the total mean which of (1.5), (1.5) for AL- Cyelakh, AL- Rashad geriatric care homes respectively.

Barbara, et al,(10) stated in their study that the knowledge and skills of caregivers, is basic for caregivers to do correct decisions solve problems, and consider the foundation for developing and improving their skills.

Soraas, et al,(11)and Goyal, P.et al(12) reported that geriatric care home persons are at height risk of adverse events. These individuals are predominantly vulnerable due to their age, cognitive impairment, complex several diseases, and non-specific performance of illnesses. There is also an increased risk of fall injuries and errors due to many medication and potential drug interactions, and they originate that the use of eight or more drugs is recurrent in Norwegian geriatric care homes, leading to increased danger of drug-drug interactions, which in turn may lead to falls, cognitive impermanent, medication-related problems, and even increased death . In geriatric care homes, physicians frequently recommend drugs without a proper clinical evaluation of the elderly and staff may not be alert of this.

The researcher believed that the caregivers who did
not participate in the training course related to geriatric care is may be caused for low knowledge.

**Conclusions**

After reviewing the interpretation of the study findings, the study can conclude that:

Most of the caregivers who work in geriatric care home in the present study have years of experience between (1-10) years; High percent of the caregivers did not participate in training courses for being related to first aid for emergency cases; High percent of emergency cases occurs in in AL- Rashad, in AL- Cyelakh GCH; More common emergency cases which occurs in all geriatric care homes were: dyspneafalls, fracture, and fainting; Majority of emergency cases which occur in geriatric care homes is saving; and One to two emergency cases occur in the all geriatric care homes.

Study the Glucose Transport, Angiogenesis and Apoptosis Behavioral through Chemotherapy Treatment According to Receptors Status in Women with Breast Cancer

Hamzah H. Kzar¹, Moshtak A. wtwt², Moaed E. Al-Gazally³

¹Lecturer, Department of Chemistry, Veterinary Medicine Collage, Al-Qasim Green University, Iraq, ²Professor, College of Medicine, University of Babylon, Iraq, ³Prof. Dr., College of Medicine, Babylon University, Work Now at University of Al-Ameed, Iraq

Abstract

Background: Glucose transporting into cells, angiogenesis, and apoptosis are the main factors that inducing the progression of many types of cancers including breast cancer. BC progression was seen as a multi-step process involving progressive changes from normal to hyperplasia with and without atypia, carcinoma in situ, invasive carcinoma, and metastasis.

Aim: Assessment the role of glucose transport-1 (GLUT-1), vascular endothelial growth factor (VEGF), and cluster of differentiation factor (CD44) as a glucose transporting into cells, angiogenesis, and apoptotic factors in women with BC whom receiving chemotherapy.

Method and Subjects: 120 women with BC included in this study as a patients group as well as 120 apparently healthy women as control. The women with BC is divided into sub-groups depending on chemotherapy treatment status. GLUT-1, VEGF, and CD44 were investigated by ELISA method.

Results: This study suggested that highly significant differences in the mean and standard division of GLUT-1 and VEGF in all cases of women with BC compare to control group (P-Value< 0.05). The levels of GLUT-1 was highly significant difference between two subgroup have Her-2 positive and negative (p < 0.001), and the levels of VEGF, and CD44 in patients subgroups were significant (p< 0.05).

Conclusion: The following up of the progression and responding to chemotherapy treatment may be more easy by estimation the glucose transporting, angiogenesis, and apoptotic markers in women with BC.

Keywords: Breast cancer; glucose transport, angiogenesis, apoptosis.

Introduction

The plasma membranes of most mammalian cells, except those of the proximal kidney and small intestine, have a passively mediated transport system for glucose. Facilitative entry of glucose into the cell is controlled by GLUTs, structurally related proteins that are encoded by a gene family and are expressed in a tissue-specific manner⁴,⁵. Most cells contain at least one glucose transporter isoform, and many contain more than one. In most cell types, GLUTs mediate a net uptake of glucose⁶. GLUT1 is the most ubiquitously distributed of the transporter isoforms. It is found in virtually all tissues of the fetus and in many tissues and cell types of the adult⁶. GLUT1 has a very high affinity for glucose⁵. VEGF actions are mediated through binding to two receptor tyrosine kinases, VEGFR-1 and VEGFR-2. Activation of these receptors by VEGF triggers the phosphorylation of a multitude of proteins that are active in signal transduction cascades⁶. VEGF expression is increased in the majority of cancers examined to date. The list is

extensive and includes hematological malignancies(7); colorectal cancers(8); hepatocellular carcinoma(9); lung, thyroid, breast, gastrointestinal tract, kidney, and bladder cancers; ovary and uterine cervix carcinomas(10). CD44 is a family of non-kinase, single span trans-membrane glycoproteins expressed on embryonic stem cells and in various levels on other cell types including connective tissues and bone marrow(11,12). CD44 expression is also up-regulated in subpopulations of cancer cells and is recognized as a molecular marker for cancer stem cells (CSC)(13). In Iraq, breast cancer ranks the first among the top ten malignant neoplasms affecting the community; comprising 19.5% of total (4996 cases) and 34.3% of female cancers (4922 cases)(14). During 2016, 897 women died from that disease which is the registered as the first cause of cancer related mortality among Iraqi females (23.6%) and the second overall among males and females (12.1%) after bronchogenic cancer(15). The aim of this study to investigate the role of glucose transport-1 (GLUT-1), vascular endothelial growth factor (VEGF), and cluster of differentiation factor (CD44) as a glucose transporting into cells, angiogenesis, and apoptotic factors in Iraqi women with BC whom receiving chemotherapy.

Materials and Method

Specimens collection: This study was performed during the period from Dec 2018 to May 2019 in biochemistry laboratory, collage of medicine, Babylon university. One hundred and twenty patients were previous diagnosis with BC and receiving chemotherapy in oncology center in Merjan Teaching hospital.

Estimation of GLUT-1, VEGF, and CD44 by ELISA: GLUT-1, VEGF, and CD44 levels were estimated by sandwich ELISA depending on the instructions of the manufacture provided with kits (Sunlong/China).

Statistical analysis: Statistical analysis for assessment of GLUT-1, VEGF, and CD44 in different groups was performed by ANOVA test with using SPSS software. Significant differences were established at p < 0.05.

Results

The receptors status of women with BC included in this study is shows in table-1:

Discussion

Worldwide, BC is the most common cancer in women. The new cases of women with breast cancer in 2018 were more than 250 000 in the USA, and breast cancer will be diagnosed in 12% of all women in the USA over their lifetimes\(^{(16)}\). Globally, about 2.1 million women were estimated with breast cancer in 2018\(^{(17)}\). Breast cancer is a heterogeneous disease with results from a series of genetic and epigenetic events that lead to dys-regulation of cell growth, circumvention of apoptosis, and development of the ability to invade the underlying tissue through the basement membrane\(^{(18)}\).

In the present study, we investigated the levels of GLUT-1, VEGF, and CD44 as glucose transporter system, angiogenesis, and apoptotic marker, respectively. The results showing highly significant differences in the mean and standard division of GLUT-1 and VEGF in all cases of women with BC compare to control group. GLUT-1 is multi-pass protein located in the cell membrane and it essential for interring the glucose molecules into cells to complete metabolism such as glycolysis to provide energy for cancers cells\(^{(19)}\). GLUT1 is responsible for the low level of basal glucose uptake required to sustain respiration in all cells. Expression levels of GLUT1 in cell membranes are increased by reduced glucose levels and decreased by increased glucose levels. The levels of this protein was found to be more expressed in women with BC compare to control and this increase the supporting hypothesis that say of “the cancers cells fed on sugar”. Through the angiogenesis process, the cancer cells building a new blood vessels and increase the expression of VEGF\(^{(20)}\). The results suggested that highly expression of VEGF in patients group and this increase the probability of building a these vessels and promoting the neovascularization and in results increase the proliferation of tumors and cancer progression. The association between a gradual increase in CD44 isoform expression and tumor progression
from less malignant stages to more advanced stages is another indirect indication of CD44 involvement in the malignant process. This concept is perhaps best illustrated by a report describing CD44 expression in colorectal cancer patients. This study suggested that the expression of GLUT-1 and VEGF in positive status of ER and PR was highly significant in subgroups of patients with breast cancer (BC) whom receiving chemotherapy and the expression of VEGF and CD44 not appear in these subgroups. This indicates that the cells having ER, PR were more suitability to incidence of breast cancer more than negative status. Other finding was obtaining from the results suggested that increasing the proliferation and tumor progression were more in women with Her-2 positive status because it highly expressed of GLUT-1, VEGF, and low expression of apoptotic marker, CD44. In conclusion, the following up of the progression and responding to the chemotherapy treatment may be more easy by estimation the above markers in women with BC.

Histopathological Change and Gene Expression of Heat Shock proteins (Hsp90 & Hsp70) in Snail *Pomacea canaliculata* (Lamarch, 1822) Exposed to Stress by the Pesticide Lannate

Ali A. A. Al-Ali¹, Murtatha Y. M. Al- Abbad¹, Basim K. Al-dhamin²

¹Prof., ²Post. Graduate, Department of Biology, College of Education for Pure sciences, University of Basrah, Iraq.

The current study aimed to investigate the snail’s pathological changes and their relationship with the amount of gene expression of heat shock proteins HSP90 & HSP70 under the influence of lannate pesticide. *P. canaliculata* were collected during the period between 5ᵗʰ-10ᵗʰ May 2018. The laboratory generation snails were divided into 2 groups, the first was exposed to a concentration of 10 µg/L of the pesticide, as the lethal concentration of the pesticide was 12.6 µg/L, and the second was left as a control group. After that, three snails from each group were dissected by the end of the following intervals (10mins, 1hr, 8hrs, 24hrs, 3days, 7days, and 15day). The gene expression was studies using qPCR method. Results of the genetic analysis for the abundance of the HSP70-HSP90 showed a clear effect of the pesticide on the treated snails during the above interval.

On the other hand, the results of the histological study of the gills showed that the pathological changes varied in their intensity during the intervals, while there was no clear effect to variation of concentrations. These changes involve loss of cilia in the epithelial cells, infiltration of granulocytes in the cilia loss regions, hyperplasia, degradation and necrosis of cells as well as the accumulation of non-living brown and grey materials within the epithelial cells. Moreover, it was noticed that the mucous materials secreted from cystic cells has increased.

**Keywords:** *Pomacea canaliculata*, Heat shock proteins, HSP70, HSP90, Lannate.

**Introduction**

As a matter of fact, *Mollusca* has a wide variety of species, including Gastropoda.¹ *P. canaliculata* feeds on aquatic plants and can destroy rice and other aquatic or semi-aquatic plants as in Southeast Asia.²

Subsequently, this snail has spread steadily through its leakage through irrigation and drainage canals until it became an important part of the ecosystem in Taiwan. Hence, its rapid growth in Southeast Asia has turned it into a serious pest that threatened rice fields and inflicted heavy economic losses.³ In 2000, *P. canaliculata* was considered one of the 100 worst pests that invaded the world. This was in terms of the International Union for Conservation of Nature and Natural Resources (IUCN) classification. Such abundance may be attributed to the lack of its enemies in the environments in which it lives and, in most cases, to its exceptional ability to adapt to the environments with high temperatures drought, lack of food sources and water pollution.⁴

As a result of these features, the snail was capable of conquering several countries. It was recently registered in the Iraqi environment for the first time by Al- Abbad in 2015.⁵ It is a pest of multiple botanical species and is viewed as one of the most serious pests on rice in Iraq if it spreads in planting zones.⁶

In 1962, so-called stress proteins or Heat Shock Proteins (HSPs) were discovered. These are one of the stress-affected proteins.⁷ Afterwards, they have been known as Molecular chaperon. They play an active role in preserving the functions of proteins as well as stimulating immune responses against pathogens. In addition, they take part in preserving cellular functions by folding the newly formed amino acid chains into their correct protein forms. They also prevent wrong protein
folding and help the cell get rid of damaged proteins. Moreover, they protect proteins and accompany them on their way to combine with their escorts. They also fulfill a very important function to the immune system, as they act as a presentation antigen to show antigens of the immune system cells in order to weaken or eliminate.\(^{(8)}\) HSPs are normally expressed and their expression increases at stress conditions such as high temperatures, exposure to chemical toxic compounds, heavy metals, infections, and diseases.\(^{(9)}\) They have been classified into several species based on their molecular weight, including HSP100, HSP90, HSP70, HSP60, and HSP40.\(^{(9)}\) This study tried to investigate the snail’s pathological changes and their relationship with the amount of gene expression of heat shock proteins HSP90 & HSP70 under the influence of lannate pesticide.

**Materials and Method**

One hundred 100 *Pomacea canaliculata* snails (Lamarck, 1822) were collected manually from the eastern bank of the Shatt al-Arab in the Salihya area in the Governorate of Basra in southern Iraq between 5\(^{th}\)-10\(^{th}\) of May 2018. The snails were then transported to the breeding laboratory in the animal house of the Department of Biology. They were left in the breeding basins to obtain a laboratory generation. After hatching, newly-hatched snails were left under laboratory conditions. Three months later, the laboratory snails were divided into two groups of equal weights of approximately 21g. Next, histological changes were studied especially in the snails subjected to concentration 10 \(\mu\)g/L for the intervals (24hs, 7days, and 15days). 6 snails were taken from each interval, 3 of which were treated and 3 were untreated. Accordingly, histological sections were prepared according to the Humason method (1972).\(^{(10)}\) Thus, 3 snails from each group were dissected after the end of the following intervals (10mins, 1hr, 8hrs, 24hrs, 3days, 7days, and 15days). Then, 20\(\mu\)g of the soft parts of the body (gastrointestinal gland and kidney) were taken for the extraction of RNA according to the method mentioned in the extraction tools SV Total RNA Isolation System of Promega Company. The concentration of RNA was determined with the use of Nanodrop Technologies. After that, the cDNA was formed using the transformation tools GoTaq® 2-Step RT-qPCR System from Promega company. Moreover, the starters for the HSP90 & HSP70 genes were used.\(^{(11)}\)

Afterwards, SPSS program was adopted in the statistical analysis of results. Finally, the significance of the differences between gene expression for genes and periods were tested using the T test at a significant level of \(p\leq 0.05\).

**Results**

The results of the microscopic examination ME of the tissue sections of the gills of *P. canaliculata* treated with lannate showed the presence of various histopathological effects on most of the components of the gill plates but basically are centered on the epithelial cells lining them. It was also noted that there was no effect of the pesticide concentration on the type and severity of these pathological effects, as the pathological changes in each of the two concentrations \(\mu\)g/L (10 and 5) were similar.

After 24 hours of the experiment: The results showed the presence of histopathological changes in the gills of treated *P. canaliculata* compared to the control group samples (Figure 1). These changes were represented by loss of cilia from the epithelial cells lining the plates. The specific study of the successive histological sections showed that the losses were in small areas distributed on different locations of the single placenta plate. An accumulation of granulocytes was also observed in these small areas. That accumulation followed a pattern, as the microscopic examination showed that granular cells are abundant in the base of the epithelial cells lining the gill plate that lost their cilia or are burst into the epithelial cells, but it was not noticed in the epithelial cells lining the gill plates that still maintain their cilia (Figure 1).
After 7 days of the experiment: The results showed the persistence of conjugation of the immune granulocyte cells in the areas that suffer the loss of cilia in the gill plate. In addition, the accumulation of non-living brown color substances was observed in the epithelial cells. These substances usually accumulate as an oval or spherical mass in the cytoplasm directly above the oval nucleus (Figure 2).

The examination also revealed the presence of hyperplasia in the vertical epithelial tissue lining the gill plates and the appearance of epithelial tissue similar to the papilla, as the cells at the top of the hyperplasia lose their polarity. On the other hand, the original cells still maintain their polarity and have vertical shape. Furthermore, their basal surface resides on the basement membrane. In addition, hyperplasia cells are seen as smaller than the mother cells and their large nuclei. Hyperplasia also presses on the tops of adjacent cells, causing their decline (Figure 2). The degeneration of ciliated epithelial cells has been observed too.

After 15 days of the experiment: Results showed the extension of the area of cilia loss accompanied by the loss of the immune granulocyte infiltration. It was also noticed that in some areas of the granulocyte infiltration, these cells form a cyst-like structure as a result of their aggregation in one area under the lining tissue of the gill epithelium, which leads to the rush of the epithelial tissue outward towards the gill fissure, and sometimes eruption of the epithelial tissue leads to pressure on the adjacent gill epithelial cells and, consequently, changes their vertical shape. It was also noticed that there was an accumulation of non-living brown substances in the cytoplasm of the epithelial cells of the gill plate (Figure 3).
There were also instances of hyperplasia in the form of multiple papilla. In this respect, the histological examination showed the emergence of a number of vertical epithelial cells for the gill plate which suffered from cytoplasm degeneration, so it seemed faded or nonabsorbent to the pigment (Figure 3).

**Gene expression abundance analysis of Heat shock protein:** The results of the genetic analysis for the abundance of heat shock genes HSP70-HSP90 of the control group snail samples showed that each of the two genes is expressed in the natural conditions at different degrees. In this respect, the statistical analysis revealed that there are noticeable differences between the two genes as the gene expression of HSP90 was highly significant, of about 5,000 times more likely than that of HSP70 at a probability level of $P \leq 0.05$.

**Discussion**

High abundance of these genes means an increase in the amount of the production of HSPs, usually at the
expense of the rest of the necessary cell proteins.\(^{(12)}\) This may reveal the causes for the appearance of some histopathological changes in the gills and kidneys of the snail, such as degeneration and necrosis. Therefore, the low gene expression in the intervals (8 hours -3 days -7 days -15 days) may be under those regulatory mechanisms, as the high intensity of HSP after ten minutes may have provided the cell with sufficient amounts of protein necessary to adapt to the stress experienced during this interval.

The gills are the most affected organs by the surrounding environment. Being in direct contact with the surroundings, it is expected that they may experience histopathological effects faster than other organa’s.\(^{(13,14)}\) They provide a very large space for direct and continuous contact with pollutants and toxins in water.\(^{(15)}\)

The results have also showed the high toxicity of the lannate on the organs of \textit{P. canaliculata}. The pathological changes were observed during the snail’s exposure to the pesticide in both groups exposed to a concentration of 10 µg/l and 5 µg/l of the lannate. These changes have increased with the increase of the time of exposure to the pesticide. In this respect, it is worth mentioning that the current study is in line with a previous study that showed the relationship between the intensity of changes occurring in different organisms and the length of time of exposure to toxic substances.\(^{(16)}\) The nature of the synthesis of the pesticide may play a role in that, or perhaps the cell receptors in the snail tissue respond with the same degree in different concentrations to urge the cells to react against the pesticide.\(^{(17)}\)

Perhaps this explains the speed of their infiltration and accumulation in some areas of the epithelial connective gill tissue, as they have infiltrated from the first day of the snail’s exposure to lannate. So, when these substances or free radicals act on the oxidation of fats in the plasma membranes, causing a change in the permeability of those membranes, a swelling for the cells may appear and liquids may accumulation inside.\(^{(18)}\) This was observed in the histological sections of epithelial tissue cells.

It is known that a change in the permeability of membranes or their damage can finally lead – with the continued presence of the causing factor- to greater damages that may contribute to the death of cells.\(^{(19)}\) This explains the large number of tissue areas in the organs which suffer from necrosis and degeneration in the members of the studied snails in all intervals. This indicates the speed of divisions and overgrowth triggering the possibility of cancer with the continued exposure to the pesticide,\(^{(20)}\) as previous study indicated that lannate could be carcinogenic.\(^{(21)}\) Hyperplasia in the organism is a form of reaction to exposure to pathogens. This may lead to cancer with the organism’s continued exposure to these pathogens.\(^{(22)}\)

Increasing the reproduction of cystic cells in the epithelial tissue plate is a primary defensive means for the snail against environmental stress exerted by the pesticide in order to the increase mucous material, this may lead to lessen the area exposed to the water polluted with the lannate.\(^{(17)}\) Mucous material is produced for defensive action in order to protect cells from pollutants

**Conclusion**

The study concluded that the intensity of histopathological changes increases in the gills and kidneys of snails with an increase in the extension of the period of exposure to the pesticide more than the increase in the concentration of the pesticide itself. It became evident that there was a direct relationship between the increase in the intensity of histopathological changes and with increased genetic expression of heat shock proteins during the chronic period upon exposure For the pesticide.

Abstract

Statins are group of drugs utilized to large degree as therapy of hypercholesterolemia, that is a substantial hazard in evolving cardiovascular diseases, like myocardial infarction, this achieved by competitive inhibition of three-hydroxy-three-methyl glutaryl coenzyme A reductase (HMGCR), three-Hydroxy-three-methyl glutaryl coenzyme A (HMG-CoA) reductase inhibitors. Statins are applied widely to control serum cholesterol in an attempt to lower mortality and morbidity related to atherosclerosis.

Method: This study was conducted on 18 Sprague dawley male rats. They were separated into three groups each group consist of six animals each as the following:

- **Control group:** Drenched normal saline for 30 days.
- **Rosuvastatin group:** Drenched 15 mg/kg/day of rosvastatin, for 30 days.
- **Pitavastatin group:** Drenched 0.8 mg/kg/day of pitavastatin for 30 days.

Objective: To determine the hepatic and renal toxicity, and safety of rosvastatin compared with pitavastatin in rats.

Results: Results has revealed considerable rise in serum and ALP in rosvastatin group, while for pitavastatin group the results revealed significant difference in serum ALP and no significant increase in serum ALT and AST.

Also there is significant difference in the serum level of creatinine in pitavastatin group and rosvastatin group when compared between the three groups. and no significant increase in serum TSB and urea in both rosvastatin and pitavastatin groups.

Conclusions: The study concluded that the pitavastatin is more safely used in patients with liver and kidney diseases and the pitavastatin is safer than rosvastatin.

Keywords: Rosuvastatin, Pitavastatin toxicity, liver, kidney.

Introduction

Anti hyperlipidemic drugs (Statins) Statins have excessively utilized in treating hypercholesterolaemia through competitive inhibition of three-hydroxy-three-methyl glutaryl-coenzyme A reductase (HMGCR) that is cholesterol rate limiting enzyme in cholesterol synthesis, intracellular cholesterol shortage is caused by statins, there by prompting activating element bounding proteins by activating photolytic sterol, low density protein receptor expression causing plasma concentration of LDL cholesterol reduction caused by hepatocellular uptake increment1.

Statins are recognized to decrease atherosclerosis catastrophes and minimize morbidity and mortality2. Also statins evince different biological impacts that are designated pleiotropic actions including anti-
inflammatory\(^3\) and antioxidant effects\(^4\), suppression of Platelet derived growth factor, stimulate propagation and up regulation of Tumor Growth Factor-B messaging in cardiac cells cultures and renal mesangial cells\(^5-^6\).

**Pitavastatin:** The construction of Pitavastatin reserves upgraded pharmacokinetics, comprising typical action as inhibition of HMG-CoA reductase and superior medicine imbibition. Pitavastatin is effectively superior to other statins in LDL receptor expression and minimize serum LDL cholesterol level through boosting liver uptake from circulation\(^7\).

**Pharmacokinetics of pitavastatin:** Pitavastatin has been pretended to have elevated bioavailability reaching of 80% at a dose of 1 mg/kg\(^8\) where it is selectively dispersed and metabolized by liver cytochrome P450\(^9\).

**Adverse Effect of Pitavastatin:** Muscle, back and joint pain, diarrhea, constipation, skin rash, headache, flu symptoms\(^10\).

**Toxicity of Pitavastatin:** Temporary and little increase in serum aminotransferase without symptoms in about 1% of patients is seen in pitavastatin treatment, although results exceeding three times upper normal values are rare and absence of case reporting of obvious clinical hepatitis\(^11\) although manufacturers has extradited records of hepatic failure, hepatitis and jaundice compromising lethal conditions\(^12\), otherwise obvious acute hepatic insult appear after using other statins for one to six months with rise of serum liver enzymes in hepatocellular or cholestatic manner\(^13\). Allergic signs that have not confirmed yet in pitavastatin like eosinophilia, rash and fever are rare, hence autoimmune picture appear in few conditions comprising chronic hepatitis and production of autoantibodies proved in hepatic histopathology and clinical improvement after treatment with corticosteroids\(^14\).

**Rosuvastatin:** Rosuvastatin is another drug of statins having antilipemic and active antineoplastic effects. Rosuvastatin is blocked and bound to liver hydroxymethyl-glutaryl coenzyme A reductase in as selective and competitive manner causing distribution of LDL cholesterol into liver after decreased liver cholesterol values. Moreover, rosuvastatin, similar to else statins, shows varied actions on neoplasms as growth inhibition, pro_apoptotic, and pro_differentiation bounce\(^15\).

Rosuvastatin presented lipid mitigation impacts in both in vivo and in vitro researches via rise the number of liver cell surface of LDL receptors promoting raise in uptake and catabolism of LDL\(^16\).

**Pharmacokinetic of Rosuvastatin:** In man clinical researches peak serum, summit plasma concentrates of rosuvastatin were extended to three to five hours pursuing parenteral dosing. The ultimate rosuvastatin bioavailability is nearly twenty percent\(^16\).

Rosuvastatin is mainly bound to plasma albumin reaching eighty-eight percent that is not permanent and unconditional to its plasma level\(^16\).

**Metabolism:** The metabolism of rosuvastatin is restricted as nearly ten percent of dose is get metabolite. N-desmethyl rosuvastatin is the main metabolite that is emerged chiefly via cytochrome P450 2C9 that is about one sixth to half the blocking effect of HMG-CoA reductase of founder component, meaning more than ninety percent of efficacious plasma HMG-CoA reductase inhibitory activity is expounded by original compound\(^16\).

Rosuvastatin and related metabolites are taken out mainly in feces about ninety percent after oral dosing at a nineteen hours half life, next to parenteral potion about twenty eight percent of whole body clearance through kidney and seventy tow percent via liver expel\(^16\).

**Materials and Method**

This study was conducted on 18 Sprague dawley rats of male sex weighting between 270-370 g. They were separated into three groups each group consist of six animals maintained in the animal house of pharmacy college of Karbala university with open assess to water and food ad libitum, as the following:

- **Control group:** drenched normal saline for thirty days.
- **Rosuvastatin group:** drenched fifteen mg per kg per day of rosuvastatin for thirty days.
- **Pitavastatin group:** drenched 0.8 mg per kg per day of pitavastatin for thirty days.

The study was conducted after obtaining approval from the ethics committee of college of pharmacy / University of Karbala.

Rosuvastatin is used orally at a dose of fifteen mg per kg per day, and pitavastatin is used orally at a dose
of 0.8 mg per kg per day. Monitoring of the animals in their cages was achieved to elucidate clinical signs each day. Termination of the work time is done by analyzing serum enzymes aspartate amino transferase (AST), alanine amino transferase (ALT), alkaline phosphates (ALP), total serum bilirubin (TSB), serum creatinine and blood urea, and liver and kidney histopathological slides were prepared.

**Statistical Analysis:** SPSS version twenty in one-way analysis of variances; ANOVA was used to experiment and check difference between drugs groups and control group and results were demonstrated as mean ± SE. (ANOVA). Differences were dealt to the level P < 0.05.

### Results

Impact of the antihyperlipidemic drugs on the blood level of liver enzymes in rats:

The output values reveal significantly raise (p<0.05) in serum level of ALP and ALT (except AST) in rosuvastatin group when compared with control groups, while for pitavastatin group the results revealed no significantly raise (p>0.05) in serum values of AST and ALT (except ALP) when matched with control group, also serum level pf ALP in pitavastatin group is significantly different (p <0.05) when matched with control group as in table (1).

Discussion

Statins are sort of medicine utilized to lower levels of lipid in circulation including whole cholesterol and especially<sup>22</sup>. HMG Co A reductase enzyme inhibition is controlling factor for cholesterol product and the prime function of statins. Hence decreasing the availability of cholesterol and in addition they rise the synthesis of the harmful LDL cholesterol receptors that facilitate to refine circulation from LDL cholesterol and assist hepatic cells to comprehend from circulation further LDL cholesterol as it cross in<sup>21</sup>. The evolving output is a decreasing whole cholesterol LDL cholesterol and triglycerides. On the other hand, the advantageous high density lipoprotein C, HDL C, is raised<sup>24</sup>. Serum levels of ALT and ALP except AST reveal significant increment that p < 0.05 in rosvastatin group when they were compared with control group, furthermore ALT is significantly raised in rosvastatin group when they were compared with pitavastatin group. these are due to rosvastatin that is taken up by hepatocyte more selectively and more efficiently than other statin therefore it is considered a prime variable associated with the hepatotoxic potential of rosvastatin<sup>24</sup>.

Functional and structural modulations in liver are assessed by efficacy of ALP, ALT and AST in the circulation. The values of mentioned aminotransferases in blood are realized to raise in every hepatic illnesses and it is conspicuous that an extremely elevated level exceeding one thousand units could be detected in acute hepatitis<sup>25</sup>. We identified a clear temporal relationship
between initiation of rosuvastatin therapy and the elevation of liver enzymes.

While for pitavastatin group the results revealed no significantly increased p < 0.05 in serum levels of ALT and AST except ALP when they were compared with the group. So from all these consequences, pitavastatin is related to suave, non-symptomatic and temporal serum transaminase raises through management though it is comparatively recent evolved statin where it still has restricted use that could be related to the clear acute hepatic damage

**Conclusion**

People are vastly using statins for hypercholesterolaemia, that is a distinctive part of growing risk of clusters of diseased related to cardiovascular system, so that the chronic use of these drugs made the patients exposed to adverse and toxic effects of it, and by making comparison of both rosuvastatin and pitavastatin to evaluate their toxic effects by measuring biochemical and histological alterations which showed significant findings for liver and kidney.

Knowledge and Attitude for Sterile Women Regarding Infertility in Thi-Qar Fertility Centers

Sarah Talib Kadhim1, Oday Faris Washeel2, Doaa Samia Rashash1

1Instructor, Thi-Qar University, College of Nursing, Maternity and New Nate Department,
2Instructor Dr. Al Muthanna University, College of Nursing, Pediatrics Nursing Department

Abstract

Objective of Study: To explore knowledge and attitudes about Infertility for sterile women.

Methodology: A descriptive cross-sectional study of (100) sterile women selected randomly who visited in thi-Qar fertility center for the period from 3rd October 2019 to 15th January 2020. Validity and reliability of questionnaire are determined through pilot study. Used descriptive statistical procedures deductive data analysis, and data was collected from couples through predesigned interview questionnaire and attitude scale, data was analyzed by SPSS version (20). Descriptive and inferential statistic was used.

Results: The result showed in the age series (25-30 years) was for the elevated proportion from the pattern. General knowledge of sterile women was (44.34 per cent), knowledge of sterile women’s risk factors was (30%). The sterile women’s attitude to infertility was negative (28.6 percent).Women’s strategies in this study were weak (26.3 percent).Women’s age and duration of infertility were significantly correlated (PV=0.01).

Recommendation: Promote education programs to raise knowledge rates and improve infertility behaviors, and promote improving infertility coping strategies.

Keywords: Knowledge, attitude, Sterile Women, Infertility.

Introduction

Infertility is a global phenomenon affecting between 60 million people worldwide and 168 million people. This affects between 13 and 15 percent of the world’s couples5. Infertility is the inability to conceive after a year of unhealthy sexual relationships2. The cause is known in 90 percent of cases and successful treatment in 50 percent of cases may result in pregnancy. Infertility is a reproductive disease that affects both men and women at nearly equal rates1. The World Health Organization (WHO) describes infertility as: a major health problem that has resulted in 15% of couples worldwide suffering emotional, social and financial implications. While infertility as a source of stress that threaten infertile mental health, the severity of its effects depends on personal coping behavior’s. (WHO, 2013) WHO has labeled infertility as a global public health issue which deserves no attention, Reports suggest that infertility in the developed world in 1990 and 2010 is equivalent to 1.9% of women seeking children aged 20-44 years who reported primary infertility and 10.5% secondary infertility, but in developing countries, including the Middle East, the prevalence of infertility was maximum4. In many parts of the world awareness about infertility is insufficient. A global survey of approximately 17,500 women (mostly of childbearing age) from ten countries showed poor knowledge of fertility and reproductive biology. Most women have little knowledge about the time of the month they are most fertile and when to seek treatment. Apart from the low level of knowledge, there are a variety of myths around the world concerning infertility.5

Coping is the cognitive and behavioral effort to control and handle stressful life experiences and most of the time will mitigate the negative impacts of stressful situations. The stress level is correlated with coping strategies for infertility. Psychological treatment of infertile people, depression, and anxiety and rehabilitation services to deal with the infertility crisis may improve the quality of life. But we need to
identify predictor factors to manage the agitations and stresses caused by infertility and plan to promote coping strategies in infertile couples. Couples’ beliefs and attitude towards infertility, which are based on social and cultural factors and their inner desires, that affect the ability of the couple to deal with the crisis of infertility.

But these valuations and their impact on the adaptability of individuals to the issue of infertility would grow in the cultural, social and religious spheres.

Infertility is a stressor that often taxes a couple of personal and social capital so that coping strategies are a natural outcome of the experience. When men and women are in an unfamiliar situation, they consider other ways of coping with infertility. 6

Infertility epidemiology in the Gezira District, Central Sudan, consisting of 200 infertile pairs identified with infertility to the primary health care units. The results were that 79.5 percent had primary infertility and 20.5 percent had secondary infertility. Infertility due to husbands was only 20 percent, which was 37.5 percent due to wives alone and 31 percent due to both couples, while those with unknown etiology were 11 percent. Sexually transmitted diseases (STDs) were not imposed as an etiological factor for infertility 7

Methodology

Design of the Study: A descriptive cross-sectional study of (100) sterile women selected randomly who visited in Thi-Qar fertility center for the period from 3rd October 2019 to 15th January 2020.

Settings of the Study: The present study is conducted in Thi-Qar Governorate; Thi-Qar fertility center

Sample of the study: which include:

1. Inclusion Criteria are: A purposive” Non-probability” sample of (100) sterile women had referred to the infertility center seeking treatment for infertility

Instrument that Used for Data Collection: Data was collected from sterile women by a questionnaire which had been collected by direct interview; A questionnaire was designed for the purpose of the study which included the following:

Socio-demographic data:

1. Knowledge about infertility
2. Coping regarding infertility
3. Attitude toward infertility.

In this study we conceded the score of knowledge:

1. Less than 50% was poor or limited
2. 50% to less than 74% was fair
3. 75% and more was good.

Attitude score: Less than 50% conceded as negative attitude and more than 50% was positive attitude.

For coping score: Less than 50% conceded as weak coping and more than 50% was strong coping

Results

As for the level of education, the highest percentage (47 percent) of the study sample was secondary, and the lowest percentage (22 percent) of the study sample was primary.

In terms of employment, the highest percentage (65 percent) of the study sample is housewives, whereas the lowest percentage (35 percent) is employee The highest percentage (26 percent) of the study sample is resident in urban areas, whereas (74 percent) is resident in rural areas.

With regard to the socio-economic status, the highest percentage (74%) of the study sample is of sufficient socio-economic status and (26%) is of the view that they are not sufficient.

Discussion

This research showed that the majority of sterile women are between (25-30) years of age, who are more likely to be pregnant and seek medical help along the study in Kuwait that showed the age of dominant women (20-29) (Human Fertilization and Embryology Authority, 2013).

Many sterile women have an abnormal period (68%) that is vulnerable to infertility because of erratic hormones. In this sample, primary infertility in sterile women was (96%), which was almost the same with the study in Gezira, central Sudan, which found (79.5%) primary infertility couples.7

Menarche among study population occurs at less than 15 years of age between (10-13) years, this result is similar to the study they reported, most study samples have menarche (about 15 years of age).8

In this report, the causes of infertility caused more by sterile women and both couples followed by women (42 percent) (25 percent) respectively, which is conflict with the Gezira study, which found infertility caused more by wives followed by couples (37.5 percent and 31 percent). (American Urological Association, 2012).

A global study of 17,500 women (mostly of childbearing age) from 10 countries found that knowledge of fertility and reproductive biology was low (44.34 percent), respectively, (WHO, 2013) and Saudi Arabia Research aimed at evaluating awareness, behaviors and infertility practices. Reveals the awareness is usually poor (59 per cent) 1

In this sample, the sterile women’s attitude to infertility was negative among sterile women (28.6 percent) respectively, disagreeing with other studies that found positive attitude (76 percent) to infertility among Saudi Arabia couples.1

In this report, coping strategies in sterile women were poor (26.3 per cent) with no significant differences, which are inconsistent with the study that found men and women with significant differences in coping strategies (Caren & Tracey, 2016).

Conclusion

Awareness of infertility sterile

womnnwas limited; infertility attitude was Negative and infertility coping

Strategies were poor

Commendation: Media can play a role in
enhancing awareness about infertility. Encourage education programs to increase knowledge levels and change attitudes with respect to infertility. Encourage sterile women’s health promotion guides and education programmes. Encouraging information online offers ways to disseminate pair infertility information of good quality. Encourage improved infertility coping strategies.

Cross Sectional Study of the Correlation between ESR, RBCS and WBCs with Disease Duration in Iraqi Patients with Systemic Lupus Erythematosus Disease (SLE)

Ahmed Tawfeq¹, Abeer Fauzi Al-Rubaye², Manar Mohammad Hasan AL-Murshidi²

¹M.Sc. Student, ²Assist. Prof. Dr., College of Science for Women, University of Babylon, Iraq

Abstract

Systemic lupus Erythrematosus disease (SLE), is an autoimmune multisystemic disease, and is associated with the considerable morbidity. The hematological abnormalities might be the initial indicator. Disease duration may have an impact on the hematological parameters.

Method: This research has been conducted in the Renal Transplant Center, Medical City, Baghdad/Iraq. Total of 50 female patients, aged 31.15±9.11 years and 40 females aged 35.10±10.92 as controls. Total counts of RBCs, WBCs, and ESR has been valued by automated hematology analyzer.

Results: Results of ESR has been shown a significant increase (p<0.001) in patients with SLE as compared with the control group. And a significant decrease in RBCs, WBCs counts (p<0.001) in SLE patients when compared with those of control. Correlation analysis for RBCs and WBCs has been shown a significant negative correlation with the duration of disease in patients with SLE, and positive correlation has been found between ESR and the duration of disease.

Conclusion: RBCs and WBCs has been changed in SLE patients, and they were related to the duration of disease.

Keywords: ESR, RBCS, WBCs, Systemic lupus Erythematosus disease.

Introduction

Systemic lupus erythrematosus (SLE), is an autoimmune disease where cells and organs undergoing damages and initially mediated by a tissue-binding autoantibodies. These antibodies were form an immune complexes that might contributed to the formation of all the clinical and laboratory signs(1).

All tissues and cells in the body were could be involved in SLE. Involved systems were muscular, hematological, cutaneous, skeletal, renal, vascular, nervous, gastrointestinal, pulmonary and ocular. The hematological manifestations were more frequent once because blood and the blood vessels together were contain a various numbers of antigens than any other organs in the body(2). These principal hematological abnormalities were include leukopenia and anemia. The causes of these abnormalities in SLE patients may be due to the presence of chronic inflammation(6), autoantibodies(3), immunosuppressive drugs and the marrow suppression(4).

The majority of patients were present with hematological abnormalities as an initial manifestation. The duration of disease may have an impact on their hematological parameters. White blood cells and
red blood corpuscles counts parameters are an ideal biomarkers which were easily measured and they were sensitive to changes during disease activity.

The previous studies were reported an association among leucopenia and anemia, with the duration of disease\(^{(4-8)}\) but facts was not adequate in Iraq to establish that association. Therefore, the current study has been designed to discern the relationship between WBCs, RBCs and ESR with the duration of disease in patients with SLE\(^{(5)}\).

**Method**

This research has been conducted in the Renal Transplant Center, Medical City, Baghdad/Iraq. Total of 50 female patients who fulfilled the American College of Rheumatology (ACR) criteria\(^{(9)}\), aged 31.15±9.11 years and were selected from the same center, and 40 age matched females (35.10±10.92) as controls. Total counts of RBCs, WBCs, and ESR has been valued by automated hematology analyzer. the duration of disease>5 years were considered in this study.

Patients having history of renal diseases, liver diseases (other than SLE), ankylosing spondylitis, rheumatoid arthritis, psoriasis and malignant disease inflammatory bowel disease, history of taking anticoagulant, biological or chemotherapy and recent history of blood transfusions were excluded from this study. 3.6 ml of blood was collected from all subjects. Total count of RBCs, WBCs and ESR were estimated by using an Automated Hematology Analyzer, (Sysmex XT-2000). Data were expressed as mean and standard error (mean ± SE). Unpaired Student’s ‘t’ test, and Pearson’s correlation coefficient, (r) test were performed as an applicable. \(p\) value <0.05, was accepted as level of significance. The statistical analyses has been performed by using the computer based statistical program SPSS.

**Results**

Age, BMI and blood pressure (Systolic and Diastolic BP) of all subjects in study and control groups. They were almost similar and statistically has no significant differences among them (Table 1).

**Table 1: General characteristics of the Controls and SLE patients (N=90)**

</tbody>
</table>

Data were displayed as mean ± SE. Statistical analysis was done by Unpaired Student’s ‘t’ test. SLE= Systemic lupus erythematosus, RBCs, red blood corpuscles, WBCs, white blood cells, ESR, erythrocyte sedimentation rate.

Correlation analysis has been shown a positive correlation among, RBCs, WBCs and ESR with the duration of disease among patients with SLE, and these were statistically significant except that of ESR (Figures 1, 2, 3).
Figure 1: Correlation between ESR and the disease duration in SLE patients presenting the positive correlation. ESR, Erythrocyte sedimentation rate.

Figure 2: Correlation between RBCs count (x 106/μl) with the disease duration in SLE patients presenting the negative correlation. RBCs, Red blood cells.
Figure 3: Correlation between WBCs count (×103/μl) with the disease duration in SLE patients presenting the negative correlation. WBCs, White blood cells.

Discussion

In the present study, the ESR level was significantly higher, and RBCs, WBCs counts were significantly lower in patients with SLE patients if compared with controls. These findings were matched with the observations of some groups of authors(6-7).

Quite the reverse, Kanfir et al. and Hassan has been found no significant changes in WBCs counts in SLE patients(8). This disagreement might have occurred due to the demographic variations and the different methodology that were used in those studies. Correlation analysis of RBCs and WBCs with the disease duration in patients with SLE has been shown a significant negative correlation. Some researchers were found the same significant negative correlation between the RBCs count with the duration of disease, but there was no association found with the other hematological factors(9-15). Though the explanation of these changes in RBCs and WBCs counts and ESR levels of SLE patients was not known, but the literature reviews suggests that the increased ESR level maybe due to the chronic inflammatory response with the polyclonal increase in immunoglobulins(10). Some studies were reported that the genetic and the environmental factors results in an abnormal activation of the immune cells, T and B lymphocytes, and the ineffective regulatory CD4+ and CD8+ T cells(11). Therefore, the sustained auto antibodies were formed in SLE(13). These excess productions of the auto antibodies were cause an activation of the natural killers (NK) cells. These cells were binded with the antibody coated target cells and origins alysis of the target cells. Hematopoietic system is a very much vulnerable target to these effects. Thus the autoantibodies might causes a destruction of the circulating bloods cells and resulting incytopenia(7-19-20).

Evaluation of the Cleaning Efficiency of 2 Shape, Hyflex EDM and Pro Taper GOLD Systems Using Digital Image Morphometric Analysis (An in Vitro Study)

Safa S. Alobaidy¹, Biland M.S. Shukri²

¹M.Sc. Student, ²Asist. Prof. (Conservative Dentistry Department, College of Dentistry/Mustansiriyah University, Iraq)

Abstract

Aim of the Study: To measure and compare the cleaning efficiency of 2 Shape, Hyflex EDM and Protaper GOLD rotary systems in removing debris and compare the percentage of remaining debris at three different levels of root canal by using digital image morphometric analysis.

Material and Method: Total 60 freshly extracted human maxillary first molar with single straight palatal roots were selected were disinfected in a solution of 1% Thymol for 1 day then the palatal roots were sectioned at a length of 12 mm from the apex and randomly divided into three groups of twenty teeth: Group A: Was prepared by 2 Shape file system (Full rotary technique). Group B: Was prepared by Hyflex EDM file system (Full rotary technique). Group C: Was prepared by Protaper GOLD system (Full rotary technique). All systems were used according to the manufacture instructions and roots prepared to an apical preparation corresponding to size 40 K-file. Sodium hypochlorite (3%) was used as an irrigant for all groups.

Conclusions: 2 Shape system was significantly less effective than Hyflex EDM and Protaper GOLD systems in eliminating debris from root canals at all levels. There were no differences in the cleaning efficiency between Hyflex EDM and Protaper GOLD systems at all levels of root canals.

Keywords: 2Shape, Hyflex EDM, ProTaper GOLD, cleaning efficiency, Digital image morphometric analysis.

Introduction

The Successful endodontic treatment that depends on sufficient biomechanical preparation of the root canal space. The goals are consists of cleaning of root canal and removing most of debris and shaping of canal. The cutting efficiency is one of the basic properties of nickel–titanium (NiTi) endodontic instruments. Instrument design may be a factor that affects the efficacy of remnant debris removal and for smear layer production. The revolution in the manufacturing of root canal instruments leads to a great variety of these endodontic instruments. The cleaning capabilities of different NiTi rotary systems varies because of the different cross-sections and blade designs of each system. That’s include variable tapering along of the cutting blades, modifying the instrument’s design of cross-section, and the manufacturing process or by the use of new alloys that produce better mechanical properties. Recently introduced 2Shape file system that consist of TS1 (25/.04) and TS2 (25/.06) files at 300 rpm and 1.2 Ncm The 2Shape system (Micro-Mega) in continuous rotation and two finishing files, F35 size (35, .06) and F40 size(40, .04). The 2Shape system has undergone a thermomechanical proprietary process not disclosed by the manufacturer. The files have a special cross-section with a modified triple helix blade. One of the three blades is off-centred and is 0.06 mm shorter than the two others. Hyflex EDM is made by a thermo-mechanically treated alloy (CM-Wire), and it has three different horizontal cross-sections: quadratic in the apical third, trapezoidal in the middle and triangular in the coronal. The file has a 10.10 mm tip diameter and 5% constant taper. The ProTaper Gold system was manufactured by (M-wire) treated to gold wire with a triangular cross-section.
section with variable progressive taper. This design of file with progressively tapered that improve cutting efficiency and safety and more durability for ProTaper Gold system.\textsuperscript{11,12}

**Material and Method**

Sixty freshly extracted human maxillary first molar teeth. Immediately after extraction, bone, calculus and soft tissue on the tooth surface were removed manually with cumine scaler. Teeth was disinfected in 3\% of (NaOCl) for 30 minutes then wash and maintained with distilled water at room temperature with 0.1\% thymol crystal until use and in saline solution during the experiment.

The palatal root length was standardized for all samples (12 mm). The length was determined from anatomical apex to bifurcation area by using digital caliper and marked on the root using permanent marker.

The crown of the tooth was grasped with metal vice and a double-faced diamond disc mounted on a straight handpiece and water as coolant. The sectioning of the palatal root was perpendicular to the long axis of the root to facilitate straight line access during root canal procedure, and to establish a flat coronal surface that served as a stable reference position to facilitate length measurement of the canal, instrumentation, and penetration of irrigation needle.

The Pulp tissue was extirpated by using barbed broach followed by irrigation with 5ml distilled water. The k-file #15 was inserted in the canal until it appear from apical foramen to check the patency of the canals\textsuperscript{13}. The correct WL was established by subtracting 1mm from root length.

Only roots with initial file size 20 K-file were included in the study. Each sample was embedded in silicone rubber base impression material (putty consistency) that placed inside a mold To facilitate handling of the sample during instrumentation procedure.

The specimens Will be randomly divided into three groups (n=20) according to the type of instrumentation systems used. The canal was irrigated with 2 ml of 3\% freshly prepared NaOCl, and the final irrigation was done with 3mL of normal saline after root canal instrumentation.

In this study The gradation of root canal preparation used were performed according to the manufacturer’s instructions of the file system by electrical motor endomate used for each group. First, the silicon stopper was set on the instrument at full of W.L for all types of files and all root canals were instrumented to master apical file to size 40. For standardization all samples were fixed by a small bench vice during instrumentation.

**2Shape:**

Teeth (n = 20) were prepared with 2Shape system. All canals were prepared by:

1. TS1 (25/.04), at speed 350 rpm and 1.2 Ncm torque until a resistance can be felt.
2. TS2 (25/.06), at speed 350 rpm and 1.2 Ncm torque until a resistance can be felt
3. F40 (40/.04), at speed 350 rpm and 1.2 Ncm torque until a resistance can be felt

Each file use movement in three waves (3 up-and-down movements) with upward circumferential filing movement.

Each new instrument was used to prepare only two canals (Staffoli., et al, 2018). Remove the file from the root canal, clean the flutes and irrigate the root canal until reach to file size (40/0.04).

**Hyflex EDM:** Teeth (n = 20) were prepared with Hyflex EDM was used until reach to finishing file size (40/0.04). Each file was discarded after being used in two canals\textsuperscript{14}.

**ProTaper GOLD:** Teeth (n = 20) were prepared with ProTaper GOLD files.. The instrumentation was started with shaping files (S1 & S2) were use with a brushing action on the withdrawal stroke: S1 (18/.02) was used to 3/4 of W.L then, to full WL (speed: 300 Rpm and torque: 3.0 Ncm). S2 (20/.04) (shaping file # 2) was used to 3/4 of W.L then, to full WL (speed: 300 Rpm and torque: 1.0 Ncm).

while the finishing files were used with non-brushing motions (pecking motions) until reaching the full WL: F1 (20/.07), (speed: 300 Rpm and torque 1.5 Ncm). F2 (25/.08), (speed: 300 Rpm and torque 2.0 Ncm). F3 (30/.09), (speed: 300 Rpm and torque 2.0). F4 (40/.06) (speed: 300 Rpm and torque 2.0 Ncm).the canal was completed in crown down manner by gentle in and out motion. The canal was instrumented to MAF # F4/.06. One set of instruments was used for the preparation of two canals\textsuperscript{15}. 
Finally after final irrigation the canal was dried with absorbent paper points and the access opening was sealed with moist cotton pellet and temporary filling to block the entry of debris during sectioning and prevent contamination of the root canal space\textsuperscript{16,17}.

After removed the teeth from the impression material and before sectioning, a permanent blue marker was used to draw guiding line longitudinally on the tooth surface parallel to the long axis of the roots. A metal saw was used to make longitudinal groove along root, a short blast of air was used to remove any remaining dust then the root was splinted by placing a surgical chisel on the grooves and with small mallet applied with slight pressure. The longitudinal section root with most visible part <180 degree was selected for the study (because >180 degree possibly interfere with visualization during photography\textsuperscript{18-21}. (Fig. 1).

![Figure 1: Split root](image)

All images of split roots were taken by using a Nikon D5300 professional digital camera with macro lens(105) at 1:1 setting with electronic macro flash. The images was saved at computer with maximum resolution of 6000×4000 pixels. The camera position selected according to the optimum focusing without blurred vision. Sectioned root was placed over a gridding paper under lens for measurement.\textsuperscript{16}

All Images were saved and opened into Adobe Photoshop CC 2018 and magnified 100 times with the digital zoom tool. The root canal area was divided into three equal thirds (Apical, Middle and Coronal) by superimposed lines above canals after discarded 2mm coronally avoidance any remnant of temporary filling at 1, 4, 7 and 10 mm from the measured working length (1 mm shorter from the apical foramen).

by using special software tool (magnetic lasso tool) that allow traced The remaining debris in canal and the total number of pixels occupied by the debris was reported by using the histogram function in the software program.

Percentage of remaining debris will be calculated for the 1-4 mm (apical), 4-7 mm (middle) and 7-10 mm (coronal) areas for each canal

\[
\text{Percentage of Dentine Debris at each third} = \frac{\text{The Pixels of Dentine Debris at each third}}{\text{Total Pixels of entire canal area of third}} \times 100
\]
Figure 2: Digital image analysis magnified at (X 33.33) of one root section that instrumented by 2SHAPE system with using Adobe Photoshop CC 2018. pink arrows referred to some of dentin debris.

Figure 3: Digital image analysis magnified at (X 33.33) of one root section that instrumented by Hyfex EDM system with using Adobe Photoshop CC 2018. blue arrows referred to some of dentin debris.
Results

Data were tested for normality using the Shapiro-Wilk test. Kruskal-Wallis test showed a significant difference (P ≤ 0.05) between groups for the remnant of dentin debris at all levels (Apical, Middle, and Coronal).

The median values of the remnant of dentin debris for different groups and different levels. At the apical level, group A showed the highest remnant (2.79%) followed by a group B (0.40%) while the lowest remnant was found at group C (0.35%).

At the middle level, the highest remnant was found at the group A (1.32%) followed by group C (0.42%), and the lowest remnant was found at group B (0.39%). At the coronal level, the highest remnant was found in group A (0.95%) followed by group B (0.5553%), and the lowest remnant was found at group C (0.35%). (Figure 5).

For all groups and thirds, the highest remnant was found at the apical level of group A and the lowest remnant was found at middle of group B and coronal thirds of group C. (Figure 6)

Figure 4: Digital image analysis magnified at (X 33.33) of one root section that instrumented Protaper GOLD system with using Adobe Photoshop CC 2018. Yellow arrows referred to some of dentin

Figure 5: Median of percentages of remnant of dentin debris at different levels and groups.
Mannwhitney with bonferroni correction test showed a significant difference at apical and middle levels between group A and group C and also found significant difference at apical and middle levels between group A and group B.

Discussion

The most important objective of root canal therapy is to decrease the number of microorganisms and pathologic debris in root canal systems to prevent or treated apical periodontitis. Grossman (1976) described mechanical cleaning as the most important part of root canal therapy.

The result shows significant difference between (2Shape at all levels with no significant difference between Hyflex EDM and ProTaper Gold). The cause of a significant difference between groups and levels may be related to two reasons: the first one the instruments design and second one metallurgical properties (alloy processing). Endodontic instruments vary in their debris removal efficacy and their smear layer production.

In this study the 2Shape file produced the highest amount of debries among the tested file system. Also the 2 Shape file has a significant difference between levels (apical - middle) and (apical-coronal) most of remnant diagnosed apically.

Manufacture done by applied the thermal treatment which as the (T.wire) 2Shape files are exposed to multiple thermal cycles to transition the crystalline phase of nickel-titanium. The Hyflex EDM file system shows second least amount of debris. Hyflex EDM is the first endodontic instrument that is manufactured an electrical discharge machining (EDM) process creates a ‘rough spark-machined’ That creates a hard and rough surface of the file, resulting in superior fracture resistance and improved cutting efficiency.

Conclusions

Within the limitation of this in vitro study, None of the experimental instrumentation systems used were able to achieve completely clean canal from debris; 2 Shape system was significantly less effective than Hyflex EDM and Protaper GOLD systems in eliminating debris from root canals at all levels and There were no differences in the cleaning efficiency between Hyflex EDM and Protaper GOLD systems at all levels of root canals.

Abstract

Study the effects of different concentration of Zingiber officinale or called ginger (GG) on productive performance, blood biochemistry as White blood cells (WBC), Red blood cells (RBC), Packed cell volume (PCV), haemoglobin (Hb) and immune status against Newcastle disease (ND) virus of broilers. These experiment used (180) broilers chicks of one day age type Hubbard. All chickens vaccinated against ND on day 7 the chicks, which divided randomly into (4) groups and each group of (45) chicks. The study showed the effects of different concentration of (GG) given in 2g/kg, 4g/kg and 6g/kg with feed Groups of T0, T1, T2, T3, T0 as control and T1, T2, T3, as treatment. Parameters of body weight, weight gain, feed consumption and feed conversion. Statistical significant (P < 0.05) increased value of body weight, weight gain, feed consumption and feed conversion was observed in T3, then T2. A non-significant value was observed in T1 (2g/kg of GG) as compared to T0 (control). Significant (P < 0.05) increases in the WBC, RBC, PCV and Hb. The ginger additives groups showed significant (P < 0.05) increases in hemagglutination inhibition (HI) titer against ND virus. In conclusion, 4 - 6 g/kg of GG additives to broiler chicks feed, enhanced growth performance, enhance WBC, RBC, PCV, Hb and showed significant (P < 0.05) increases in hemagglutination inhibition (HI) titers against ND virus, while group T1 had less significant effects compared to the other groups.

Keywords: Zingiber officinale, Newcastle virus, Feed Additives, broilers.

Introduction

The growth and laying performances of birds are frequently improved by using growth promoters or feed additives that have a positive impact on the growth and immune responses. Among these substances antibiotics are no longer used as feed additives, because they are associated with residues in eggs and meat products, and their use has been restricted in many countries1. The beneficial effects of natural products are greater than those observed with antibiotics2, including a lower cost of production and reduced toxicity hazards3. Pseudofowl pest or Newcastle disease (ND), a devastating disease of poultry seen in chickens and turkeys, caused by Newcastle disease virus (NDV). The signs of disease are high mortality, hemorrhagic intestinal lesions, severe respiratory distress, decrease of egg production, and nervous disorders4. The NCV injected in embryonated eggs could grow in cells lining the allantoic cavity.

The virus grows in these cells, destructs them and is then released in the allantoic fluid reaching high titers in approximately 24 hours. If virulent NDV strains are inoculated, most of the embryos die two days after inoculation. Injected NCV causes remarkable histopathological changes in dead or alive embryos4. Vaccination programs can provide protection against NDV outbreaks, but they are not sufficient because infections by NC virus have remained frequent around the world in the recent years5. There is no known specific treatment for NDV, like other viral diseases. Several antiviral drugs are known to treat mammalian viruses, however their use in avian disease are limited because these agents may be toxic for the host cells. Although there is little documentation, there has been experimental evidence regarding the ability of several plants to treat numerous diseases6. Zingiber officinale Roscoe, belonging to the Zingiberaceae family,
popularly known as ginger, is a monocotyledonous herbaceous plant and one of the most common food-flavoring spices used worldwide. In recent years, several pharmacological properties of ginger, such as an inflammatory, analgesic, gastrointestinal regulating agent, antioxidant and antimicrobial properties have been identified. Live microbial feed preparations such as probiotics, prebiotics, or symbiotic play an important role in increasing the resistance to disease by improved immune response, thereby reducing the use of antibiotics. Some probiotic microorganisms have been reported to produce different types of bacteriocins, organic acids and reuterin which act by preventing pathogen growth. Furthermore, probiotics supplements can affect the intestinal environment by increasing desirable microbial growth. In parallel, there are few studies evaluating the performance and health-related traits of broilers receiving either ginger (Z. officinale) or particular mixtures of probiotics cultures to verify the possible beneficial effects of natural feed additives as substitutes of probiotics.

Materials and Method

Plant material and preparation: GG (Zingiber officinale) rhizomes were purchased from a local market in, Babylon, Iraq to be used in dietary treatment.

Experimental Animals: This study was conducted at the period for (42) days started from February-June 2019 in physiology department of veterinary medicine of AL-Qassim green university. One hundred eighty broilers chicks one day old age type Hubbard chicks, were divided randomly into (4) groups, (45 chicks per group) treatment had three replicates (15 birds) and received various treatments during the experimental period (6) weeks. Chicks were given starter diet (7-21) days and a finisher diet (22-42) days, GG was purchased from a local market, sundried, ground to a fine powder, and stored in an airtight polyethylene bag until required for use, as shown in Table (1). The additives were mixed with basic feedings to form the following parameters:

- **T0**: Control group chicks fed the standard diet.
- **T1**: Chicks fed standard diet plus 2g/kg GG.
- **T2**: Chicks fed standard diet plus 4g/kg GG.
- **T3**: Chicks fed standard diet plus 6g/kg GG.

A room was used inside the field controlling its thermal conditions at (32-35)°C. It was washed with soap and water, then fumigation with formalin and potassium permanganate. It was sprayed with wood sawdust and supplied with a number of feeders and fountains. The chicks and feed were weighed by one-sided balance. Body weight, weight gain, feed intake and feed conversion ratio were included within the experiment period. Hemagglutination inhibition (HI) six blood samples were collected from each group at 21, 28, 35 and 42 days old. The blood samples were centrifuged to separate the serum and estimate the antibody titer against the NC using a hemagglutination inhibition test, according to.

Haemotological Assay: On the 43th day of study, blood samples were randomly collected from groups of treatment. The blood samples were collected via the wing veins using sterile needles and syringes. The blood samples for hematological parameters were collected into well-labeled and sterilized bottles containing ethylene diamine tetra acetic acid (EDTA), as anticoagulant. The samples were investigated for the following hematological parameters as white blood cell (WBC), red blood cell count (RBC), haemoglobin (Hb) and packed cell volume (PCV).

Vaccination of chicks: The birds were vaccinated against infectious bronchitis day 1 and 14 day, ND day 1 and day 7, avian influenza day 1 and infectious bursal disease day 21.

Statistical Analysis: The statistical analysis was carried by using the mean differences between the averages of the studied traits were determined at the probability level of (0.05) using the Duncan test. Statistical data were analyzed using the (SAS, 2010).

**Result and Discussion**

The parameters of growth performance, were examined in the current study, these parameters are good indicators of the improvement effect of ginger supplementation at different levels on broiler performance. In the present study, final body weight, body gain, feed intake and feed conversion ratio improved after supplementation of ginger at levels of 4 g/kg - 6 g/kg, while diet. The GG had significant effects (P < 0.05) on total body weight, feed intake, weight gain and feed conversion ratio. There were significant differences in all performance traits (Table 3, 4). Chickens on T2 and T3 better than those in T1 and T0 groups. The results showed significant effects (P < 0.05) on the growth performance of broilers, the advanced may be due to stimulatory effect of ginger extract on digestive juices, microflora and nutrient absorption in digestive tract. The present results are in agreement with the findings of who observed that active compounds of ginger (shogaols, gingerdione, gingerol, phenolic and gingerdiol). Similar results were observed by who observed that ginger acts as stimulant for feed digestion and conversion which increase body weight gain. Its active compounds which improves feed digestion and stimulates enzymes thus enhancing feed conversion ratio which lead to an increase body weight. Ginger contains volatile oils like borneol, camphene, citral, eucalyptol, linalool, phenllandrene, zingibaine, zingiberol, gingerol, zingironand, shogaol and resin. Ginger’s have medicinal properties are chemicals responsible for the taste, the most noteworthy being gingerol and shogaol. Ginger speeds digestion, and enhances by a protein digesting enzyme, zingibaine found in ginger. It has antibacterial and anti-inflammatory actions. This observation however, disagree with the reports of who reported that the inclusion of ginger did not improve the weight gain of broilers, also reported that no significant difference among birds fed on 0.5%, 1% and 1.5% ginger powder on feed conversion ratio examined the effect of processed ginger with different size on growth performance and showed that the ginger additive had no significant effect on the feed efficiency. There was significant increase (P < 0.05) in the WBC, RBC, PCV and Hb, of birds on the ginger T2 and T3 than T0. reported that the number of erythrocytes (RBC) in chicken is influenced by the conditions of the animal. The increase in PCV, Hb, and RBC contents of the blood of birds fed the test ingredients is an indication of improved oxygen carrying capacity of the cells which translated to a better availability of nutrients to the birds consequently affecting their well-being. stated that The inclusion of ginger in broiler diets in the current study did not affect the haematological parameters of the chickens except for the total WBC and percentage of neutrophils. There was a significant increase in the total WBC as the ginger level increased in the diet reported that there are significance increase was found among the groups but 2% ginger treated birds show relatively high PCV with least standard deviation and other hematological parameters are almost similar as positive control.

**Conclusion**

Conclusion Based on the current findings, dietary supplementation of different levels of ginger powder at level up to 6 g/kg diet plays a role in enhance broiler growth performance and improving of WBC, RBC, PCV and Hb. Moreover, inclusion of ginger up to level 6 g/kg diet contributed to improvements of the immune response. This improvement on growth and health may be due to the biological activities of this plant to improve growth or that may be due to its role as enhanced digestibility, anti-oxidant, and anti-microbial, activities and properties and the prevention of gastric toxicity.

Violence Towards Nurses Staff at Teaching Hospitals in Mosul City

Mahmoud M. Ahmed1, Nasir M. Younis2, Ahmed A. Hussein3

1Lecturer, Faculty of Nursing, University of Mosul, 2Assist. Prof., Faculty of Nursing, University of Mosul, 3M.Sc. N/CHN, Faculty of Nursing, University of Mosul

Abstract

Background: Defining violence is one of the most common types of abuse at work in health care systems. The U.S. The Emergency Nurses Association found that workplace violence in the health service (3.8) is greater than privacy abuse, and also that the emergency room was especially susceptible.

Objectives: To determine the violence against nurses in (ED) at teaching hospital in Mosul city/Iraq

Method: To accomplish the study a retrospective research approach (2 years) was used. Sample study (218) nurse, (100) female, while male (118). The instrument developed by (Brislin, 1970) The questionnaire consist of (3) parts: part I includes demographic characteristics (6) variable such as (age, sex, qualification, working place, experience years and experience of ED). Part II: includes the main causes of the physical violence (eight items). Part III: include nonphysical violence (eight items).

Results: The study found more than one-third of nurses was subject to physical abuse almost (37.61%), most of them exposure to nonphysical violence (73.3%). That mean the assault direction nurses in ED are widespread.

Conclusion: The researcher concluded that the assault direction nurses who work in ED are widespread epically nonphysical violence, the most of the perpetrators of the assault direction the nurses in the EU are the relatives.

Keywords: Violence, Nurses staff, emergency department.

Introduction

Violence is one of the most popular types of violence at work in healthcare systems. The U.S. The Emergency Nurses Association found that workplace violence in the health service (3.8) is greater than privacy abuse, and also that the emergency room was especially susceptible. The CDC as an organization stated that abuse has long been known as an occupational hazard for many patients as the front door to the hospital, particularly, the assault experience frequently occurs in the emergency room due to urgent patients’ needs. Throughout recent decades, aggression in all its manifestations has risen significantly across the globe. Concerns about workplace abuse against health workers are now common. The problem in health care violence is not new it was possible always part of nursing. The emergency department is open 24 hours a day, and the nurse is at the front of the patient’s service delivery. As a result, the high incidence of attack among nurses was not reduced, which was the main reason for the job loss. Nurses work in emergency departments are at high risk of workplace violence as nurses meet and communicate with patients or families, thus offering more treatment than most other treatment professions. Patients and their families may use violence against nursing staff in response to stress caused by injuries or illness, and a range

of official studies, newspapers, stories and international initiatives have focused attention on the problem around the world (5). Violence in healthcare, from illness or relatives of the patient in the form of verbal abuse or beatings has increased significantly in recent times (6). In particular, this violence presents a significant challenge to healthcare workers in the delivery of services to patients or related individuals and adversely affects the delivery of healthcare services (7). Workplace violence incidents have become a growing problem for various professions, but nursing is known as one profession where the violent incidents rise e.g. beating nurses and insulted him verbally has become a big trouble that affects nurses everywhere (8). The health sector in Iraq suffered abuse, especially after the invasion of Iraq by the US due to the lack of protective means and the absence of legal legislation to prevent infringement on health care providers. And there is no clear database for determining the prevalence of violence toward nurses in Iraq’s emergency services, especially the city of Mosul. The study aimed to identify the prevalence of violence towards nurses staff at teaching hospitals in Mosul City.

Methodology

A retrospective study design for two years was used to achieve the study. The study carry out from emergency departments in the following teaching hospitals in Mosul city includes Al-Slam Teaching hospital, Al-Zahraoe Teaching hospital, Al-Kanssa teaching hospital and Ibn-Alatheer teaching hospital). The period of this study was extend from 1/1/2017 end to the 1/1/2019 (retrospective) and the data were collected from 1/1/2020 to 29/1/2020. Random sample use involved (218) nurse (100) female, and (118) male who working in emergency departments in deferent Mosul teaching hospital minted before. The instrument developed by (Brislin, 1970) consist of closed ended items to assess the abuse at work against nurses working in ED. Questionnaire consist (3) parts: part one includes demographic characteristics (6) variable such as (age, sex, qualification, working setting, experience years in health sector and experience of ED). Part two: includes the main causes of the physical violence (8 items) multiple choose question. Part Three include nonphysical violence (7 items) multiple choose question. The data of the study were collected by interview technique and all items in questionnaire was quickly explained with all participants. Data were collected for each nurse was transferred into code sheet and data entry was done using computer. Descriptive statistics e.g. number, %, mean of score and SD were calculated for nominal level data such as demographics date and individual items within the questionnaire.

Discussion

Important findings relating to physical and non-physical abuse are discussed in the Mosul TH, with regard to the study questions. Table (1) indicates that there are the most nurses working in Al-Salam teaching hospitals (35%), and the highest of them aged between (20-25 years), (32.3) with Diploma (37.3%). The high number of them with experience as a nurse (5-10 years), (42.7%), and their most of them (6-12) months experience in emergency department. The expertise and experience of nurses play an significant role in the prevention of violence; thus, less experience and inexperience nurses do not have enough knowledge to deal with the aggressor or to meet the disease’s needs quickly, and they are more vulnerable to abuse (10, 11).

Table (2) indicated that more than one-third of nurses was subject to physical abuse almost (37.61%), most of them exposure to nonphysical violence (73.3%). That mean the assaults against nurses in ED are widespread. Research contrasts with research (Darawadet.al., 2015) in Jordan nearly (91.4%) in this study exposure to work place violence among nurses in government hospitals (12). Although exposure to workplace violence was lower among those younger than older respondents, reversal trend seen in other studies (13). Table (3) revealed that the most of the perpetrators of the assault towards the nurses staff in the EU are the relatives, physical violence (80.6%) and Non-physical violence (74.2%). Hence in this study, patient families were the primary source of abuse. Research agreement with the Chinese research by (Jiao, 2015) which reported that nurses were subjected to violence from relative clients approximately (93.5%) and comparable to that in Iran (15). This table (4) indicated that most of those affected by the incidents of violence did not require interference to treat their condition. Physical (57.3%), and nonphysical (72.9%). The present study suggested that the key reason for not
disclosing the incident of violence was that they found it to be unimportant (74.3%), higher than the studies published in Iran\textsuperscript{(15)}. Table (5) indicated that the most causes of the physical violence are mental health and psychiatric health (45.1%) while the main causes of nonphysical violence are waiting to receive services, (27.6%). The popular forms of physical violence are pushing, punching, kicking and slapping, whereas verbal violence was the kind of non-physical abuse has been impact nurses (Fuadad,2016). Another risk factor listed by 28.6 per cent of respondents as significant in precipitating violence towards them was the lack of resources required to avoid harassment or violence against healthcare workers. Reinforced by\textsuperscript{(11)}, which found less of violence reduction approaches and resources to be a contributing factor in cases of harassment.

**Conclusion**

Based on the study finding the researcher concluded that the assault against nurses who work in ED are widespread epically nonphysical violence, the most of the perpetrators of the assault against the nurses in the EU are the relatives. While that most incidents of violence occurred in the treatment room.

**Recommendations:** The researcher suggested that the advanced practice nurse help define evidence-based treatment practices that can be integrated into healthcare systems to minimize the level of assaults in the workplace, improve safety, Provide guidance and preparation for advanced-practice nurses to serve as educators and advocates for staff members and provide them with critical strategies to better prepare them to deal with abuse at work.

Effectiveness of an Educational Program on Nurses’ Knowledge and Practices Concerning Nursing Management of patients’ with Vascular Access in Dialysis Centers at Baghdad Teaching Hospitals

Worood A. Mahmood¹, Khalida M. Khudur²

¹M.Sc., Academic Nurse, ²Assistant Professor, Adults Nursing Department, College of Nursing, University of Baghdad, Iraq

Abstract

Objective(s): The aim of a present study is to determination the effect of an Educational Program on Nurses’ Knowledge and Practices Concerning Nursing Management of patients’ with Vascular Access in Dialysis Centers.

Method: A quasi-experimental (two –group pre-post -test) design was conducted at Baghdad teaching hospitals, at 14th October 2018 to 25 December 2019. Non-probability “purposive” sample of (80) staff nurse who have been working at hemodialysis units were selected from Baghdad teaching hospitals which include Al-Yarmook teaching hospital, Baghdad Teaching Hospital, and Al-Kindy Teaching hospital, Al-Karama Teaching Hospitals, Imamein-kadhimein Teaching Hospital, Surgical Specialties Hospitals. Nurses were divided into two groups, study groups consist of (40) nurses exposed to the nursing education program, and control group consist of (40) nurses.

Results: The results of the study indicated that The majority of staff nurses are female, and they graduated from high school nursing within the age group (23-27) years. The study indicates the nurse knowledge and practices Concerning Nursing Management of patients with Vascular Access in Dialysis was poor level. While posttest results showed that the nurse knowledge and practices was improved to high level which as the positive effect of program.

Keywords: Nurses’ knowledge and practices, Vascular Access, Complication of VA and management for patient with vascular access in hemodialysis.

Introduction

The kidney disease at the end of stage of global health concerns. In 2013, it was nearly 3.2 million people receiving treatment worldwide. Bringing the number of people who develop ESRD Pal by an estimated 6% each year ¹. Dialysis is the treatment of chronic maintenance for the life of the savior of patients with kidney disease at the end of the stage. Renal disease final depends on the availability of efficient access hemangioma, and requires the establishment and use of the arrival of the blood vessels arterial successful access coordinator and educated multi-disciplinary team to ensure optimal blood vessels for each patient.² The nurses play an important role in the therapeutic success and outcome of the patients because they minimize the patients risk factors for infections through maintaining strict aseptic technique, changing the (HD) Catheter dressing, inspecting the solution for signs of contamination. Monitoring the patients closely before, during, and after an exchange and recording his vital signs.

Methodology

A quasi-experimental (two–group pre-post-test) design, at 14th October 2018 to 4th July, 2020 to find the effect of an Educational Program on Nurses’ Knowledge and Practices Concerning Nursing
Management of patients’ with Vascular Access in Dialysis Centers at Baghdad Teaching Hospitals. Non-probability “purposive” sample of (80) staff nurse who have been working at hemodialysis units were selected from Baghdad teaching hospitals which include Al-Yarmook teaching hospital, Baghdad Teaching Hospital, and Al-Kindy Teaching hospital, Al-Karama Teaching Hospitals, Imamene-kadhimein Teaching Hospital, Surgical Specialties Hospitals. The researcher constructed a questionnaire format based on a program in order to reach the objectives of the study, the questionnaire is composed of three main parts (demographic characteristics of the staff nurses It consists of (7) items which included: age, gender, marital status, level of education, Number of years in employment, Number of years in the hemodialysis units, number of training sessions, and the second part include knowledge of nurses’ concerning Management of patients with Vascular Access (35) items, and the third part include observational check list for nurses’ practices concerning Management of patients with Vascular Access (25) items. the researcher used SPSS version 23 to analyze the data. A pilot study was carried out between the periods it was conducted at Baghdad Teaching Hospitals during the period from 3th March to 1 March 17th 2018 on (10) nurses who work at hemodialysis units in Baghdad Teaching Hospital to determine the reliability of the questionnaire and content validity was carried out through the 26 experts. Reliability of the observational checklist was determined through the use of the inter-rater reliability method. Descriptive statistical analysis procedures (frequency, percentage, mean of score) and inferential statistical analysis procedures (Chi-square and t-test) were used for the data analysis.

df: Degree of freedom, P: Probability value Sig: Significance, N.S: Not significant, S: Significant, H.S: High significant
This table (4) indicates that there is no significant association between nurses’ knowledge and practices with regard to their level of education among the study group at p-value ≤ 0.05.

The findings among the control group show that there is significant association between nurses’ Knowledge with their level of education at p-value=0.019, while there is no significant association between nurses’ practices with their educational level.

Discussion

Table (1) demonstrates the total mean of score for Nurses’ knowledge which assigned that there is high level knowledge (1.98) good, for Nurses’ after implementing the educational program to the study group while no alteration is found of Nurses’ knowledge in the control group from pre to the post-test with consideration to the total mean of scores.

This outcome supported by 6 suggested that the majority of nurses surveyed had satisfactory knowledge of hemodialysis description, and more than half had satisfactory knowledge about pre-dialysis assessment of patient condition.

This outcome confirmed by 7 showed that most nurses do not have adequate information about early detection of AKI, so there is a need to establish and implement training programs with the goal of developing skills and competencies to prevent and detect early AKI.

This study supported by 8 that stated the knowledge of nurses about renal failure and hemodialysis, it was found that the majority of nurses (83.3 per cent) had a high level of awareness relevant to child care undergoing hemodialysis. This can be explained by the many years of experience that most nurses have had. These agree with 9 who reported the nurses who studied were better in their overall information percentage ratings.

Table (2) Demonstrates the total mean of scores for Nurses’ practices which indicate that there are high level practices (2.00) for Nurses’ after implementing the educational program in the study group while no change is found concerning Nurses’ practices in the control group in the pre and post tests with respect to the total mean of scores.

This result supported by 3 who show in their study that the majority of nurses reflect a fair knowledge about of nurses’ knowledge toward providing care to patients with Vascular Access Hemodialysis and These finding show that the nurses who were working in HD units need to develop their knowledge to be up-to-date of any knowledge related to vascular access.

This finding was reinforced by 10 who found in their experiment that by contrasting the degree of awareness between staff nurses and nursing students, staff nurses had an acceptable level of knowledge relative to nursing students about hemodialysis patient treatment.

This table (3) indicates that there is no significant association between nurses’ knowledge with their age group among the study and control group. But the findings show that there is significant association between nurses’ practices and their age group among both groups at p-value 0.024 and 0.008.

This research coincides with 8 It indicates that the finding in this study indicated that there is a significance of statistical between the age of nurses surveyed and the standard of practice at p-value (0.001). This research conflicts with (Mahmood, 2016). 3 It indicates that there is a substantial association between the expertise of nurses and their age at p ≤ (0.01) level.

This table (4) indicates that there is no significant association between nurses’ knowledge and practices with regard to their level of education among the study group at p-value ≤ 0.05.

The findings among the control group show that there is significant association between nurses’ Knowledge with their level of education at p-value=0.019, while there is no significant association between nurses’ practices with their educational level.

This result is supported by 3 It shows that there is was a significant relationship at p ≤ (0.05) level between nurse’s knowledge and their level of education. This finding coincides with Bakey’s (2008) study, which reported that there was a strong association between the expertise of nurses and their level of education.

Conclusion

There is a modification in nurses’ means before and after the appliance the educational program. The educational program has special effects on all age groups in both genders, and all learning levels, and all groups in marital status and all years in experience groups.
Recommendation:
1. Continuous nursing educational and work-related to training programs of dialysis unit concerning vascular access must be well organized within Baghdad teaching hospitals and prepared with the essential educational facilities and resources necessary to promotion the knowledge and skills of practicing nurses, which will be revealed on better result and service for the patients.

2. The multidisciplinary approaches will be used in the care of patients needing dialysis in the long term. Patients, the families of patients, the nurse and other dialysis workers, the renal dietitian, the nephrologists, the social worker and the psychologist should be included.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the Adults Nursing Department and all experiments were carried out in accordance with approved guidelines.

Study Effects of Nigella Sativa Seeds Oil in Some Physiological Parameters in Experimental Heart Failure Induced by Ivabradine in Male Rats

Heba A. Abd-Alsalam Alsalame

Assist. Prof., College of Education for Pure Science, Kerbala University, Iraq

Abstract

Aim of this study was to investigate the effects of Nigella Sativa Seeds oil in some physiological parameters against heart failure induced by Ivabradine in rats. A total of 60 male rats were used in this experiment, the rats were divided into three groups: control rats (n = 20); IBD (n = 20); IBD+ N. sativa oil (n = 20). The first group (G1) was a control group. The second group (G2) was given 10 mg/kg of IBD, while the third group (G3) was injected with 10 mg/kg IBD + oral dosage of 2.5 mg/kg N. sativa oil for three months. After three months, the blood was withdrawn from the heart to measure the concentration of ANP, BNP, NE, A-II, ALDO, ACE, MDA, SOD, TNF-α and IL-6. The results revealed that levels of BNP, NE, MDA, IL-6 and TNF-α were significantly increased in G2 rats, with no significant difference observed in ANP in rats in G2 compared to G1 rats. The level of ACE, A-II, SOD and ALDO in G2 rats had significantly decreased compared to that observed in G1 rats, oral administration of Nigella Sativa seeds oil (G3) showed no significant difference in ANP, BNP, NE, A-II, ALDO, ACE, MDA, SOD, TNF-α and IL-6 compared with G1 group.

Keywords: Nigella Sativa, heart failure, Ivabradine, male, rats.

Introduction

Ivabradine (IBD) is a commonly used medication lately used to alleviate the pain and treatment of patients with chronic angina pectoris, chiefly applied to the Patients who suffer from sinus rhythm who cannot treated with beta blockers. Many of studies have proved that treatment with ivabradine can enhance the function of global left ventricular and decrease accumulation of cardiac collagen in congestive heart failure in rats. Other studies have been reported that IBD can acts under the control of autonomic nervous system, thus it can reduce unsuitable sinus tachycardia. Moreover, IBD has been found used as cardioprotective drug that used in regulating myocardial ischemic injury. IBD has been utilized for lowering risk of hospitalization and cardiovascular death rate in chronic heart failure patients. In spite of there are little data about the mechanisms that make IBD used as benefit drug for chronic heart failure there was many studies demonstrated that many drugs like IBD, ranolazine can decrease the sodium influx in heart muscle, decrease the size of myocardial muscle, increases the function of left ventricular, decreases arrhythmias and thereby improves myocardial ischemic injury. Nigella sativa (N. sativa) belong to Ranunculaceae Family. This plant is vastly used over the world as herbal medicines. N. sativa is considered as one of the most widely used plants for treatment or preventing of many diseases. The seeds and oils of this plant are also used in diverse of traditional systems of herbal medicine. The seeds and oils of N. sativa are also used as a good food components in many of systems such as food preservative and spice. Many studies revealed that, both seeds and oils have several biological effects such as anti-inflammatory, anticancer, antioxidant, antimicrobial, diuretics, antihypertensive, analgesics, anti-diarrheal and appetite stimulant, thus the N. sativa seeds can be used as effective food components. Therefore, in this study, our first focus was to investigate the effects of IBD on cardiac system and study the effects of N. sativa seeds oil against heart failure that induced by IBD.
Materials and Method

Experiment Design: A total of 60 male rats were used in this research, the rats were equally divided into three groups: control (n = 20); IBD (n = 20); IBD+N. sativa seeds oil (n = 20). The first group (G1) was given normal saline and considered as a control group. The second group (G2) was given intraperitonealy with 10 mg/kg of IBD as described by 1 while the third group (G3) was injected inerperitonially with 10 mg/kgIBD+ oral dosage of 2.5 mg/kg N. sativa seeds oil for three months. After three months, 5 ml of blood was withdrawn from the heart. to measure the following parameters: concentration of atrial natriuretic peptide (ANP), brain natriuretic peptide (BNP), Noradrenaline (NE), angiotensin- II (A-II), aldosterone (ALDO), angiotensin converting enzyme (ACE), malondialdehyde (MDA), Superoxide dismutases (SOD), tumour necrosis factor-alpha (TNF-α) and interleukin-6 (IL-6) Plasma concentration of ANP, BNP, NE, A-II, ALDO, ACE, SOD, TNF-α and IL-6were measured by ELISA using commercially available kits. The concentration of MDA was measured according to thiobarbituric acid (TBA) reaction by Muslih et al (2001) 12

Plant material and extractions: The Nigella sativa seeds utilized in this study were obtained from the local market of kerbala, Iraq. The seeds were manually checked up to eliminate bad ones. The oil from N sativa seeds was extracted by Soxhlet apparatus for 12 h and petroleum ether (60-80°C boiling range) was used as a solvent according to the method described by AOCS 13. Later that the solvent was evaporated and finally the oil was obtained and stored -4°C.

Statistical Analysis: SPSS program was used to analysis the results and we tested the correlation coefficient by means of the analysis of variance by complete randomized design (CRD). We used the least significant difference (L.S.D.) to show the significance of the results 14.

Results and Discussion

Effects of Ivabradine and N. sativa seeds oil on level of ANP, BNP, NE, ACE, A-II and ALDO: Levels of BNP and NE were significantly higher among rats in G2, While no significant difference was observed in ANP in G2 compared to that observed in G1 rats (table 1). The level of ACE, A-II, and ALDO in G2 rats had significantly reduced compared to that observed in G1 rats, the rats in G3 showed no significant difference in all above parameters (table 1).

Our data prove IB caused chronic heart failure (CHF) and amplifies the concentration of BNP and NE in plasma. This results suggest the Malfunction in left ventricle may stimulate elevation of plasma concentration of BNP and NE.

The plasma concentration of BNP and NE have been investigate as a marker for diagnosis, prognosis, screening, and monitoring treatment of CHF patients the secretion of both of these parameters(NE and BNP) which under the control of sympathetic nerves was elevated with the development of CHF 15. Many of studies demonstrated that BNP level in patients with HF are associated with alters of its plasma level 16. Thus, in this study, we measured the plasma level of BNP and NE in rats that administrated with IBD.

In this study we also observed that the ivabradine therapy caused a reduction in sympathetic overdrive in rats showed by reduction inplasma levels of renin–angiotensin–aldosterone system (RAAS) components, proved by reduction inplasma levels of ACE, A-II, and ALDO. The continuation of sympathetic overdrive and long activation of RAAShave been accounted amain mediators of developing HF by developingnecrotic, fluid retention, apoptotic cell death and vasoconstriction.
This may be proved by increased uptake of Ca$^{2+}$ with ivabradine administration could have also participated to improve the diastolic function of ivabradine.

N. Sativa have many effects on cardiac system including cardiac depressant effect, diuretic effect and calcium channels blocking effects. As well as, N. Sativa was improving the inflammatory effects in many organs and protect many organs from any lesion, and we have been found that the daily use of NS with diet can protect the body from exposure to the sepsis. Thymoquinone(TQ), the active components of Nigella sativa found in its seeds, is the active quinone used in pharmacology, which play a vital role chiefly as anti-inflammatory and analgesic factor. Many studies has been reported that thymoquinonealso act as a powerful antioxidant which protects many of body organs from oxidative injury in various studies in rats and protects cell membrane from lipid peroxidation in many tissues. In addition, N. Sativa seed has a many of actions such as antioxidant, calcium channel blocker effects, anti-eicosanoid and a regulate the level of intracellular calcium in mast cells. NS have also myocardial protective effect which could be due to its protective activity of its components such as thymoquinone, thymohydro-quinone, thymol, dithymoquinone, 4-terpineol, carvacrol and tanethole.

Effects of Ivabradine and N. sativa seeds oil on Myocardial Cytokines and Oxidative Stress: The results of Table 2 showed a significant increase ($P < 0.05$) in the level of serum MDA and significant decrease in SOD in the rats injected with ivabradine (G2) the level of IL-6 and TNF-α. Were significantly increased in G2 compared with control group (G1), oral administration of 2.5 mg/kg of Nigella Sativa seeds oil lead to enhance the level of SOD, with no significant difference was observed in level of MDA, IL-6 and TNF-α in G3 compared with G1 group.

Several studies have indicated that there was many effects of ivabradine on cardic system especially inflammation. Lately, some of studies proved that IBDean reduce the level of inflammatory cytokines in mice. And can modify the gene expression of inflammatory cytokine while elevate the activity of endothelial nitric oxide synthase (eNOS) in rats. Other studies suggested that, treatment with ivabradine can promote the function of left ventricle, with modifying in cytokines expression mainly TNF-α and IL-6. This cytokines are responsible for any defect in cardiac system. Especially TNF-α and IL-6 which stimulate cardiac dysfunction. In this research, we found that ivabradine caused cardiac inflammation by increased levels of IL-6 and TNF-α.

Relation of Endometrial Hyaluronic Acid with Female Infertility in Women Undergoing Ovarian Stimulation Protocol

Sarab Khalaf Al-Juboory¹, Mufeda Ali Jwad², Muayad Sraibet Abood³

¹M.B.Ch. B. HD Ob & Gyn, Kirkuk Health Directorate, Kirkuk, Iraq, ²Lecturer Dr, Clinical Infertility, Reproductive Technologies, Baghdad, Iraq, ³Assistant Prof, Pharmacology, Al-Nahrain University, High Institute of Infertility Diagnosis and Assisted Reproductive Technologies Baghdad, Iraq

Abstract

A comparative prospective study was conducted in the High Institute of Infertility Diagnosis and Assisted Reproductive Technologies, Al-Nahrain University, from September 2019 to March 2020. The aim of the study was to evaluate the level of hyaluronic acid (HA) in endometrial fluid at day of trigger in infertile women whom undergoing ovarian stimulation protocol. The study included a total of 60 women who were selected from those attended the High Institute of Infertility Diagnosis and Assisted Reproductive Technologies. All couples subjected to a full history taking, complete general examination, complete gynecologic examination and infertility workup including: husband’s semen analysis, hormonal analysis, uterine cavity and tubal patency was performed. Different ovulation induction programs were used evaluation of endometrial thickness, pattern, size and number of mature follicles was performed by transvaginal sonography in the 2nd of menstrual cycle and cycle day 11-14 before HCG injection. In this study basal hormonal analysis were performed to the female in the 2nd or 3rd day of the menstrual cycle and study included aspiration of endometrial fluid for determination of hyaluronic acid level by ELISA technique. The study showed that mean of hyaluronic acid was elevated significantly in women received letrozole plus FSH (158.7±19.7 pg/ml) followed by women received Clomid plus FSH (160.8±13.5 pg/ml) and the lowest mean was recorded in the control group (146.1±26.2 pg/ml). The study showed positive correlation between hyaluronic acid and LH at day of triggering of ovulation in women received Clomid plus FSH (group B). The study showed positive correlation between hyaluronic acid and progesterone at day of triggering of ovulation in women received letrozole plus FSH. The study showed positive correlation between hyaluronic acid and number of follicles in women after receiving letrozole plus FSH. The study revealed that HA mean was elevated significantly (P< 0.05) in women who became pregnant after stimulation protocol compared with women who failed to be pregnant (164.2 vs. 152.1 pg/ml) as shown in Figure 4). The study also revealed that HA was significantly elevated in women who became pregnant after receiving letrozole + FSH (164.2 pg/ml) as compared with non pregnant women (152.1 pg/ml) while HA level was non significantly related with pregnancy occurrence after administration of Clomid+FSH. It was concluded that, hyaluronic acid was elevated significantly in women received ovulation simulation drugs and letrozole was superior to clomiphene as a treatment for anovulatory infertility in women

Keywords: Hyaluronic acid; Female infertility; Letrozole; Endometrial.

Introduction

Infertility is a disease of the reproductive system, defined by the failure to achieve a pregnancy after at least one year of regular unprotected sexual intercourse in women < 35 years not using contraception and after six months in women > 35 years. The causes of infertility can be generally classified into four groups: male, female, combined (both male and female) and unexplained. Some additional factors that may contribute to female infertility are behavioural factors such as diet, exercise, smoking, alcohol and drug use(1,2). Combined infertility arises from the combination of male and female causes and it may be that each partner is independently fertile but the couple cannot conceive together without assistance. Nowadays,
progress in assisted reproductive technology (ART) has enabled the clinicians to treat many types of infertility\(^3\). Endometrial receptivity is defined as a temporary unique sequence of factors that make the endometrium receptive to the embryonic implantation\(^4\). It is the window of time when the uterine environment is conducive to blastocyst acceptance and subsequent implantation\(^5\). Hyaluronic acid (HA) has also a significant role in establishing the cellular microenvironment conducive to the development of proliferative processes\(^6\). The lack of HAS regulation genes causes abnormal production of HA and promotion of abnormal biological processes such as metastasis and pregnancy loss. An increasing number of reports suggests a role of hyaluronan (HA) in female reproduction and interest in its application in assisted reproduction is rising. However, there are contrasting data about the effectiveness of adding HA to the embryo-transfer medium on improving pregnancy rates\(^4\). The aim of the study was to evaluate the level of hyaluronic acid (HA) in endometrial fluid at day of trigger in infertile women whom undergoing ovarian stimulation protocol.

**Patients and Method**

A comparative prospective study was conducted in the High Institute of Infertility Diagnosis and Assisted Reproductive Technologies, Al-Nahrain University, from September 2019 to March 2020. The study included a total of 60 women who were selected from those attended the High Institute of Infertility Diagnosis and Assisted Reproductive Technologies. All couples subjected to a full history taking, complete general examination, complete gynecologic examination and infertility workup including: husband’s semen analysis, hormonal analysis, uterine cavity and tubal patency was performed. Different ovulation induction programs were used evaluation of endometrial thickness, pattern, size and number of mature follicles was performed by transvaginal sonography in the 2\(^{nd}\) of menstrual cycle and cycle day 11-14 before HCG injection. Pregnancy outcome was used as a main comparative parameter between selected groups. 40 patients undergone with one of two of ovulation stimulation programs [clomid + gonadotropin and letrozole + gonadotropin] had been chosen for each patient according to her age, history and hormonal assay. In this study basal hormonal analysis were performed to the female in the 2\(^{nd}\) or 3\(^{rd}\) day of the menstrual cycle and study included aspiration of endometrial fluid for determination of hyaluronic acid level by ELISA technique.

**Results**

In this study, majority of women enrolled in this study were belonged to rural area and below 30 years, parity below 1 and infertile between 2-4 years, as shown in Table 1.

**Discussion**

In this study, majority of women enrolled in this study were belonged to rural area and below 30 years, parity below 1 and infertile between 2-4 years. These findings were close to that reported Ahmeid(7), who found that mean age of women under IVF was 30.36 year, his study also found that the mean of BMI was 25.9 (kg/m²). Hameed and Ahmeid(8) in recent study included 45 women who enrolled in ART programs in infertility center for in-vitro fertilization (IVF) and
found that the mean age of infertile women was (31.80 ± 5.38 years), his study also found that the mean of BMI was 25.36 ± 1.99 (kg/m²). Al-Dujaily et al(9) also found that the mean age of infertile women (31.0 year) and BMI 25.3 (kg/m²) Due to body mass index (BMI) has an adverse effect on reproduction, overweight women have a higher incidence of menstrual dysfunction and anovulation, possibly because of altered secretion of gonadotropin releasing hormone, sex hormone binding globulin, ovarian and adrenal androgen, and luteinizing hormone and also because of altered insulin resistance (10). The study showed that mean of hyaluronic acid was elevated significantly in women received letrozole plus FSH (158.7±19.7 pg/ml) followed by women received Clomid plus FSH (160.8±13.5 pg/ml) and the lowest mean was recorded in the control group (146.1±26.2 pg/ml).Thus, studies on the distribution of HA are important to understand the histophysiological and pathological mechanisms underlying events of the female reproductive tract, such as endometriosis, tumors, and infertility (11). There was very little declared studies regarding the relation of hyaluronic acid with infertility and no previous studies done about the levels of HA in women who received letrozole plus FSH and who received Clomid plus FSH. A study done by Santos Simões et al(12) indicated that there was an elevated concentration of hyaluronic acid in women endometrium in proliferative phase and higher HAS1 and HAS2 reactivity when compared with normal women. In addition, Nagyova (13) indicated that HA levels were increased in the endometrial stroma during the secretory phase of the menstrual cycle and fall to very low levels at menstruation, suggestive of a role in implantation.

In different study, Gomes et al(14) in study the immunoexpression of hyaluronic acid (HA) in the uterine horns of the mouse throughout the estrous cycle phases, their data showed that the highest concentration of HA in uterine horns occurred during diestrus compared with other phases. Moreover, Fouladi-Nashta and coworkers reported spatiotemporal expression of RHAMM protein in mouse endometrium during the oestrus cycle and peri-implantation period, suggesting its possible role in endometrial receptivity (15). HA has also been shown to improve the cryotolerance of blastocysts, which then leads to increased birth rates in cows (13). Moreover HA was detected in oviductal fluids collected by catheterisation during the oestrus cycle in heifers and cows and was shown to be highest at ovulation (16). In addition, Transcripts for HAS2 and HAS3 have been found in the oviducts of several animal species (17). Synthesis of HA is increased significantly in the uterus of mice on the day of implantation (18), and HA differential expression in the human endometrium during the menstrual cycle implies its involvement in implantation. In the human uterus, peak expression of HAS and CD44 is in the mid-secretory stage (19). There is a plethora of data suggesting the beneficial roles for HA in human embryo implantation (20). Artificially, Franik et al.,(21) in previous study indicated that the supplementation of Whitten’s medium with hyaluronic acid improves the development of 1- and 2-cell porcine embryos to the blastocyst stage

Conclusions

It was concluded that, hyaluronic acid was elevated significantly in women received ovulation simulation drugs and letrozole was superior to clomiphene as a treatment for anovulatory infertility in women.

Abstract

The scientific development that was brought by modern civilization has left its clear imprints in the field of biology, which is directly reflected on the living cell and its relationship to genetics and formation. That it has recorded many scientific discoveries in the field that provided a wide opportunity to reveal some of the secrets of the human cell. The science of cell study (cytology) is no longer limited to a purely descriptive study, but rather extended to the experimental study with the help of experimental embryology and analytical studies of the fertilization process, until the development of the scientific increases in the awareness of the major fundamental issues that are related to cytological genetics which are the nature of the human gene and self-reproduction and how to perform his work in a report about these attributes, also this development has extended to include the treatment of some genetic diseases, as this science has extended to the field of legal evidence (criminal and civil), this is because the traditional means which are used in evidence and improving may not achieve the justice or be insufficient to achieve them.

Keywords: Improving, murder crime, DNA fingerprinting.

Introduction

Dr. (Alec Jeffrey) is considered the first who addressed the term of the human fingerprint of the human being in 1985 as he continued to conduct his research until he was able to reach that the DNA is the characteristic of each individual and there can be no similarity between two people except in the case of identical twins and of the same gender.

In order to know the scientific meaning of the genetic fingerprint, it is necessary to know the genetics and the genetic guidance because it is the two specialized sciences1 in it, as Genetics is defined as: A branch of biology that studies the similarities and heterogeneities in successive generations of all living things, that is, it is interested in studying that similarity and the difference between children on the one hand and parents and relatives on the other hand2. The science of human genetics is a container of information of an individual and social nature at the same time, which affects the human race due to its ability to amend, change and transfer.3 The DNA is found in the nucleus of the cell, with the exception of red blood cells that do not have cell chromosomes, that the human body in general contains trillions of cells, each of these cells embraces a nucleus which is responsible for the life and function of the cell, each nucleus embraces the genetic material starting from the common characteristics to all human beings or between closely related strains and ending with the specifics of a particular individual and distinguishing it by itself, so that it does not match another individual of the people, as the genetic material that is found in the nucleus of the cell forms strings or tapes in a tight spiral form and is called ((chromosomes)) and they number (46) chromosomes as these chromosomes mate so that twenty three pairs appear from the father and the other is from the mother4. The genetic fingerprint was known from a practical point of view as (it is a genetic pattern formed by repeated sequences during the unknown function of the DNA, these sequences are what distinguishes each person from the other, as the reason for this is some enzymes that break down the
DNA in limited, unchanging and fixed places, as DNA is of two types: non-functional DNA (Non-Fontionnelle) and functional DNA (Founctionnelle) important here is DNA non-functional because it can be used as a scientific evidence, as for the enzymes, they are proteins, but not all proteins are enzymes, that every step of the biological reactions requires a specific enzyme which stimulates them. The proteins are either synthetic or functional that include enzymes and protein hormones. The genetic fingerprint was also defined: as two-pronged chemical units carried from the genes distributed in a way that accurately distinguishes each individual from the other and the reason for this specificity is due to the nature of the formation of the genetic fingerprint itself, as it is made up of two parts of the genes, one is that inherits from his father while the other one inherits from his mother to form a new formula, hence, the map of the presence of genes on the DNA strip is described as a fingerprint, as it carries characteristics that would reflect the personal and subjective elements that a person is unique to and from other people of his own race.

The legal meaning of the DNA: Despite the regulation of some criminal laws for the genetic fingerprint, such as the French Penal Code, where these laws have been permitted to be applied in the courts as evidence of proof and denial in civil and criminal fields, as they have not set a specific definition for them, or define a concept, leaving the matter in this regard to the legal jurisprudence in carrying out that task, which is also not the fingerprint of it has a full and comprehensive definition of it which has been defined by one of them as (pure information pertaining to a person that distinguishes him from others in a biological means to determine the personality and to identity the individual).

Another one is defined it as (it is a fixed original identity for every human being, which is required by genetic analysis and allows the identifications of individuals with almost complete certainty) It is also known as (the material that carries the genetic factors and genes in living organisms)

Second: Genetic fingerprint properties and ways of showing them: The genetic fingerprint is characterized by a set of characteristics that make it distinct in comparison with other forensic evidence, as this is proven by medical experiments. Each person has a genetic fingerprint that differs from the other person, as there are no two people who are similar to them except for identical twins from one egg, as more than half of the nitrogenous chemical bases present in chromosomes. The living cell is not suitable for the use in the genetic fingerprint technology, given its similarity among all people of the same type, while the rest of these rules and what they contain of DNA, they differ from one generation to another and from one person to another, which is used in the analysis of the genetic fingerprint. The genetic fingerprint is also distinguished by the diversity of its sources, as the genetic fingerprint can be obtained from any of the biological sources, whether the samples are liquid such as blood, saliva, semen, mucus or tissues such as flesh, bone, skin and hair. This characteristic of the genetic fingerprint may obviate the fingerprint in the case that there are no traces of fingerprints of criminals at the crime scene.

Also, the genetic fingerprint appears in the form of wide lines, which makes it an easy to read, save and store as it is saved on the computer until needed, one of the most important characteristics of the genetic fingerprint is that it is present in all cells of the human body except red blood cells, moreover, they are identical in all cells of the body as they do not change and do not substitute over time over them as the DNA remains constant until after the death of the human.

Crime is often committed in secret and surrounded by some ambiguity, this prompted the investigation men to pay attention to the remnant material, which is considered to be on the scene of the crime in order to benefit from it by following the criminals and identifying the characteristics that distinguish them from others by taking the remnant and transferring it to the laboratory and conducting the analysis and obtaining information that helps them in identifying the criminals or contributing significantly to show the innocence of the accused that the biological samples found differ with the variables committed crime, as we mentioned above and whatever its type, taking it requires the presence of a criminal photographer who is filming at the scene of the accident with the DNA fingerprint expert. By using a video camera to explain the crime scene as well as the relative dimensions of the crime scene and how the samples are located in that place. That there are several method for analyzing the genetic fingerprint, but there are two method that are considered one of the most common method in this field, which are the genetic packages method and the Polymerase Chain Reaction (PCR) method.

The second method: The serial polymerization
method (PCR), which means enlarging and copying the small part in the blood of the DNA that was found at the crime scene to give new copies until the number of generations that produce thirty generations of DNA which was presented in a drop of blood at the head of a needle more than a billion times during those three hours by raising the temperatures as this rise in temperatures will lead to an increase in the absorbed rays, instead of separating the orders that relate the nitrogenous bases, as if the temperature is preserved, these commands return to correlation with what it completes of the sequences (23). It is clear from the above that taking one of these two methods depends on the amount of the sample which presented at the accident scene, so if the quantity is big, using the genetic beams method and if the quantity is few it uses the method of polymerase chain reaction (PCR). It is worth noting in the field of biological resources that are necessary to conduct the DNA analysis. There are steps that must be taken into consideration when finding the sample, which are: calling the photographer to conduct video photography and make a sketch of the sample in order to determines its relative dimensions to each other before it is raised by the DNA fingerprint expert. The scattered samples must also be kept separately as an independent sample. When the sample is sent to the criminal laboratory, it must be sent, sealed with the stamp of the forensic medicine department, guarded by a police officer without mentioning any information which are related to the name of the sample, its type, size and date on a tube and it must be mention in special records in order to preserve its biography.

Third: Conditions for accepting the DNA as a proof:

The DNA analysis is described as a scientific guide in forensic evidence. It requires two conditions:

The first condition: Ensure the reliability of the DNA result

The certainty of the value of the DNA analysis depends entirely on the quality of the research method and the accuracy in interpreting the results of this analysis, which requires a highly efficient laboratory (24) because this test is described as a complex process as it requires an advanced laboratories and scientific devices as well as many chemical compounds also it requires extensive experience and accurate specialization.

It can be concluded from the above that the condition to verify the reliability of the result of the DNA analysis and its dependence as a scientific evidence in forensic evidence must be ensured that the value of the DNA test depends entirely on the quality of the research method and the accuracy in interpreting the results that resulted from it, so this quality and accuracy in the analysis requires extensive experience, a high-level specialization, a high-efficiency laboratory, as well as a laboratory that performs genetic testing. That the rules must be established to preserve samples and the information that results from this analysis as the strength of the fingerprint in the evidence depends on the method of sample collection, condition, quantity, laboratory efficiency and quality of tests.

Fourth: The authority of the forensic judge to take evidence of the DNA: The DNA analysis is presented by the people of expertise, whether it is laboratories or specialized departments in that, Especially if the matter related to the criminal case which is pending before the court is related to some of the issues that require knowledge and science to enter, given that it needs special knowledge that is not available to the forensic judge, so he seeks the assistance of an expert in order to provide advice that helps him to settle the case, as it is not permissible for a judge to replace himself with the expert in a specific matter that requires the use of specialists, as he can not reach the truth in the case except by resorting to the people of experience. However, the procedural law gave the judge the freedom to decide for himself the truth that he is convinced with it.

Fifth: The role of the DNA in proving the crime of murder: The word jurisprudence differed on the possibility of relying on the genetic fingerprint of the crime of murder to judge a conviction, so a side of the criminal jurisprudence sees that it is not permissible to rely on these clues to judge conviction and to accomplish and reinforce the evidence thereof because it is evidence that is suspected of suspicion, therefore, it is not suitable for itself to be the basis for the sole provisions that it should be based on certainty, He drew suspicion that the conclusion is not similar, but may be interpreted in more than one way that benefits more than one possibility, therefore it is not sufficient alone for conviction, if it is sufficient to take some measures of inception and preliminary investigation, it is permissible to rely on the judicial presumption in ruling the conviction if it is reinforced by other evidence, also it is not permissible to rely on it alone, so this is because of this presumption, regardless of its significance, is incomplete because it is indirect in the proof.
Conclusion

After we finished our humble research (the DNA and its role in proving the crime of murder), it became clear to us that every person has a unique genetic pattern in the genetic structure within every cell in his body that no person in the world shares in it. This pattern is called the genetic fingerprint, as it is a detailed structure that indicates the identity of each individual with a sample. The genetic fingerprint is characterized by a set of characteristics as it is numerous and varied its sources, which makes it possible to make this fingerprint from any liquid human waste such as blood, saliva, semen or tissues such as bone, flesh, skin and hair, as this feature obviates the absence of traces of fingerprints of the criminals at the crime scene as it resists decomposition, rot and other climatic factors from heat, cold and drought for long periods, so that the genetic fingerprint can be obtained from both ancient and modern relics, so the genetic fingerprint is considered to be one of the scientific physical evidence that has an effective role in forensic evidence for murder or other crimes for which the fingerprint has a role in proving it.

Abstract

OM is the most popular side effects of chemotherapy and it’s commonly caused by 5-Fluorouracil (5-FU). This study was aimed to assess the impact of glycine as a new option of treatment on experimentally induced oral mucositis in adult male rats.

Thirty two male rats (Rattus novergicus) were divided at random in to control group (8 rats), 5-FU untreated group and 5-FU-glycine treated group (12 animals each). OM model induced by chemotherapy was instituted by intraperitoneal injection of 5-FU (60 mg/kg body weight) on days 0, 5, 10, 15 and the dorsal tongue was scratched (days 3, 4) by needle with gauge 18 to induce mucositis. The rats in treated group were received a 2mg/g intraperitoneal injection of 5% glycine daily (day 0-20). All rats were scarificed at day 21, dorsal tongue mucosa sample was removed, prepared and examine by using histological and immunohistochemical (PCNA and BCL-2 immunostining) analysis. Glycine can protect the dorsal tongue mucosa from 5-FU induced cytotoxicity and alleviated the associated damage. In 5-FU/glycine group, both of the PCNA and BCL-2 immune expression was significantly increased (p≤0.05) in comparison with 5-FU untreated group.

Glycine provides protection toward 5-Fluorouracil induced tongue mucositis. It show fast epithelial propagation and wound healing through its antioxidant, anti-inflammatory and cytoprotective features.

Keywords: Glycine, 5-FU, Oral mucositis, PCNA, BCL-2.

Introduction

Oral mucositis (OM) is describe as mucosal barrier damage as result of desolation of its mucosal epithelium or suppression of its growth leading to change of the safety and function of oral cavity. It may become visible anyplace within the mouth but are regularly determine on cheeks, interior of lower lip or on the sides or base of the tongue. It can induce many complexity via extremely painful for the patients and limiting their ability to eat, drink, talk and swallow problems to sever pain of ulcer more than infection. Lastly menacing to life style of patients because of lower their dietary status with elevated their financial burden and exacting to their hospitalization. Several factors can induce OM like 5 fluorouracil (5-FU) is one of the most debilitating side effects of chemotherapy remedy as well as, radiotherapy and various forms of shock as chemical and mechanical incitation of mucosa. 5-Flourouracil (5-FU) is an anti-metabolite cytotoxic drug labor by blocking fundamental biosynthetic processes or by way being integrated in to macromolecules, including RNA and DNA. The mechanism action of its cytotoxicity has been attributed to the misincorporation of fluoronucleotides in to RNA and DNA and to the suppression of thymidylate synthase enzyme, a critical enzyme in nucleotide metabolism.

5-FU is broadly indicated for remedy of malignant tumors, particularly of the breast, colon, hepatic, pancreatic, gastric, ovarian and bladder carcinomas. The employ of 5-FU is one of the most popular causes of oral mucositis. Glycine, a simple amino acid, is providing a new selection in the treatment of mucositis. It has been demonstrated to have anti-inflammatory, immunomodulatory and cytoprotective effects in various experimental models. Protective effect of glycine on inflammatory lesions has been shown in different trial models. For instance, glycine is a potent restraint of resident liver macrophages and acts through a glycine-gated chloride channel. Furthermore, administration of glycine in a rat model of ischemic-reperfusion damage resulted in down regulation of cell apoptosis and the expression of pro-apoptotic genes. So, glycine has shown to have affirmative impacts on numerous of the paths concerned in the pathogenesis of OM. for this reason, the present study was designed to evaluate the impacts of glycine on experimentally induced oral mucositis in rats model. Histopathological and immunohistochemical fulfillments were used to elucidate its effect on cellular proliferation and cell apoptosis.

**Materials and Method**

Thirty two adult male rats (Rattus norvegicus) with weight about 200-250 g were provided and care in the animal house of college of Science, Basra University, Iraq. The animals were kept below a typical laboratory conditions, pallat common nutrition and water ad libitum with a 12/12 hrs light \dark cycle.

Induction of OM: Oral mucositis was induced according to protocol suggested by Sonis et al. In brief, 60 mg/kg of chemotherapy drug 5-FU (Sigma-Aldric, UK) was injected intraperitoneal (IP) to each animal study on days 0, 5, 10 and 15. The tongue mucosa was irritated by external superficial scratches with tip of an 18-mesure needle on days 3, 4.

**Group B: (5-FU group):** Untreated group extradited normal saline intraperitoneally.

**Group C: (5-FU treated with glycine):** The animals were received a 2 mg/g of body weight IP injection of glycine (BDH, England), diluted in saline 5%. Treated with glycine was started on day 0, with usage once time\day in the morning until the end of experiment on day 20. All rats were sacrificed at day 21; cross section of dorsal surface of tongue mucosa was removed and designed for histological examination and immunohistochemical analysis by PCNA and BCL-2 immunolabeling.

**Light microscopic method:** Dorsal surface of rats tongue mucosa samples fixed in 10% formalin for 24 hours, and then the specimens were regularly processed for embedding in paraffin by typical paraffin embedding method. Sections were cut at 5 μm, processed and then stained with Hematoxylin and eosin staining (H & E). Another sections positioned on top of positively charged slides for immunohistochemical revealing of anti-proliferating cell nuclear antigen (PCNA) and BCL-2.

**Immunohistochemical studies:** Immunohistochemical staining for revealing anti-proliferating cell nuclear antigen (PCNA), which was achieved by a monoclonal Mouse anti-PCNA clone pc 10, Dako, Denmark, and a monoclonal Mouse anti-Human BCL-2 Oncoprotein Clone 124 Code No. 1587 prepared to use N-series primary antibody, for employ with Dako EnVision TM, EnVision TM double staining and LASAB TM 2 systems. The staining method sections follow the directives included with all detection system used. Negative and positive controls were used through the study and run concurrently with all biopsy samples. PCNA positive cells expressing were recognized by brown nuclei, whereas BCL-2 positive cells expressing were showed brown cytoplasmic staining.

For analysis, 5 sections were randomly selected for each animal. About 1000 cells from cell population were counted by two watchers to make certain the topicality of analysis at a magnification of 400 X (Olympus, Japan). Finally, the percentages of PCNA and BCL-2 positive cells were calculated. The level expression of PCNA and BCL-2 was estimated depending to the scoring system of Seleit et al (16). The appliance of this system gives a score ranging from 0-3 for each degree of positivity.
stained cells as (negative: < 1%, mild: 1-10%, moderate > 10-50%, strong: > 50%). For statistical analysis Anova one way test was employed to compare the results, P value less than or equal to 0.05 (P≤0.05) was considered statistically significant.

Results

Histological Results: Microscopic observation of dorsal tongue of the control rats (group A) showed normal form and organization. The dorsal surface of tongue displayed conical, slender filiform papillae cornified with tapers tips, normal connective tissue within papillae and smooth keratinized epithelial covering, the section revealed to well define fungi form papillae with test bud. The tongue composed mainly from interlacing bundles of striated muscle fibers that run in different directions and cross one another (fig. 1). In 5-FU untreated group (group B), the dorsal surface of tongue revealed hyperkeratosis, sever atrophied of most filiform papillae with degenerated fungiform papillae, beneath few shallow epithelial rete ridges that invaginated deeply within the mucosa, sever inflammatory cells in the lamina propria, basal layer and supra basal with vacuolated cells specially that surrounded the papillae with shown no clear boundaries and atrophied of most muscle fibers (fig. 2). In 5-FU group treated with glycine (group C), the epithelial layer revealed to an increase in the thickness with re-epithelization of stratified squamous epithelium and vacuolated keratinocytes observed. Also, some of filiform papillae restored the normal shape with tapers tips and cornified, well developed fungi form and circumvallate papillae observed with test buds. Restoration of most normal rete ridges and inflammatory characteristics were still notable in the lamina propria (fig. 3).

![Figure 1](image-url)
Figure (2): Section of dorsal tongue of rats from (group B) showing hyperkeratosis ( ), sever damage in filiform papillae ( ), shallow rete ridges ( ), sever inflammatory cells (head arrow) and atrophied muscle fibers ( ) (H & E x10).

Figure (3): Section of dorsal tongue mucosa of rats from group C showing re-epithelization ( ), some of filiform papillae restored the normal shape ( ), well developed fungiform ( ) and circumvallate papillae ( ), still mild inflammatory cells ( ) with strand of irregular striated muscle fibers ( ) H & E, x100
Immunohistochemical detections: The photograph of dorsal surface of rats tongue in group A (control group) showed strong positive immune expression to PCNA was observer in the nuclei of basal and supra basal layers within tongue mucosa (fig.4). While, the immunoexpression of PCNA in group B was revealed mild immune reactivity reserved at the basal cells within nucleus and some of keratinocytes at surface layer (fig. 5). As for group C, it was recognized that PCNA immunostaining was moderate immune reactivity comprising the whole basal layer cells of tongue epithelium; also few positive cells of connective tissue were noticed (fig. 6). Furthermore, the immunoexpression of BCL-2 protein in normal rat tongue mucosae (group A) showed mild cytoplasmic reactions of some epithelial cells at surface of epithelium. In group B, the immunoexpression of BCL-2 revealed negative immunoreactions in the whole of epithelial cells. Also, the cells of lamina propria showed negative BCL-2 immunolabeling. The immunoexpression of BCL-2 of group C showed that positive immunostaining of BCL-2 was greatly than the control limited to keratinocytes of epithelial surface layer and also some cells of basal and Para basal layer.

Figure (4): Section of dorsal tongue mucosa of rats from group A showing strong brown PCNA positive nuclei in the basal and suprabasal layers of the tongue epithelium (arrow) (immunohistochemistry. X400).
Figure (5): Section of dorsal tongue mucosa of rats from group B showing mild staining to PCNA at basal cells with missing the positive cells in some basal layer cells (arrows) (immunohistochemistry X400).

figure (6): Section of dorsal tongue mucosa of rats from group C showing positive staining cells of basal layer (arrows) (immunohistochemistry X400).
Regarding to Statistical analysis, the immune expression of PCNA in the control group was showed 16.32±0.16 while BCL-2 in the same group 7.27±0.10. ANOVA test was showed a significant decrease (P=0.000) of mean immune expression in the 5-FU treated group in both of PCNA and BCL-2 were 4.71±0.08 and 0.07±0.05 respectively, in comparison with control group. The treatment with glycine causes a significant increase in the number of PCNA and BCL-2 positive cells 10.85±0.08 and 3.21±0.07 respectively, in comparison with the 5-FU treated group (p≤0.05).

**Discussion**

Oral mucositis is a complex process started through damage to cells in the basal epithelium and fundamental tissue of oral mucosa and has recurrent painful obstacles related with mucosal damage 17. As well, this complex process comprising not only direct cell damage happened by chemotherapy or radiotherapy, but also a complex cascade of biological proceedings 18. Administration of 5-FU has been accomplished like a technique to trigger oral mucositis in rats and the initiation of lesion appeared through five to seven days of their administration, so the mouth becomes prepared for entry of microbes. Therefore, the oral mucosa becomes vulnerable to an increased risk of infection and ulceration 19,20. Different histological changes as hyperkeratosis, flattening of rete ridges, sever inflammatory cells in lamina propria and severe atrophied in papillae were seen associated with use of 5-FU, perhaps because of the mechanism of suppression of epithelial proliferation by cytotoxic effect of 5-FU. Also, administration of 5-FU was joined by a significant reduction in PCNA and BCL-2 positive cells. Reactive oxygen species is generated by chemotherapy which is harmful to the DNA of epithelial cells and reduce the metabolism in progenitor cells and give rise to inhibition of mitosis and raise of apoptosis 21. These results were clarified and supported the findings of some investigators 22, were reported that nutritional supplementation with 5% glycine has accelerated the process of wand healing, recover the weight gain, antioxidant ability and immunity. The anti-inflammatory impacts of glycine are supposed to be mediated, because of its method of action in the cell membrane where it stimulates the chloride channel that stabilizes the membrane possible 23. Furthermore, glycine prevents the raise of intracellular calcium which stimulates the forming of the cytokines by suppressing cells that activate the inflammatory method through preventing stimulation of TNF-α and NF-κB and therefore reducing the production of free radicals and additional toxic mediators 24. PCNA is localized in the nucleus and is related with cell proliferation 25.

Fracture Resistance of New Fiber Post System (Rebilda GT)

Emad Farhan Alkhalidi
BDS, MSc, PhD [Assist Professor], University of Mosul, College of Dentistry, Department of Conservative Dentistry

Abstract

Background and Aims: Evaluate and compare the fracture resistance of endodontically treated teeth restored with bundle glass fiber post and tapered glass fiber post, at 45 degree oblique load.

Materials and Method: Thirty newly extracted single rooted mandibular first premolars were chosen, and after root canal preparation and obturation, post spaces were prepared. Then the samples were separated into three groups (n = 10) dependent on the type of restorative method used: group A restored with Rebilda fiber post [tapered glass fiber post], group B restored with Rebilda post GT post system (bundle glass fiber post), and group C restored with direct composite resin restoration without a post (control). Using a universal testing machine with speed of 0.5 mm/minute at 45 degree sloping load which was applied to the restored teeth, fracture resistance was recorded in Newton.

Results: The results showed that the fracture resistance significantly affected by different post systems (p < 0.05). The bundle glass fiber post (rebilda Gt) showed highest fracture resistance than the other groups.

Conclusion: Rebilda GT post (bundle glass fiber system) showed higher fracture resistance than the Rebilda fiber post (tapered glass fiber post) and control group respectively.

Keywords: Fracture resistance, Rebilda GT post, Rebilda fiber post.

Introduction

The restoration of root canal treated teeth is difficult to clinicians particularly when there is moderate to sever tooth loss, in such cases, the final restoration can be well retained only by means of a post and core system. The preference of suitable restoration for these teeth is affected by strength and esthetics.[1,2]

Prefabricated posts have become prevalent because of the wide assortment systems are available like: tapered, parallel sided, smooth or serrated, cemented, threaded or combination of these, the prefabricated metal posts have been used for many years to restoring endodontically treated teeth; However, the roots restored with metal posts are subjected to fracture because of the high elastic modulus of metals which is very high compared with that of dentin so any force specially lateral force will cause concentrated stress on the root and fracture. [3]

Fiber reinforced composite post was used as a substitute to metal cast post and cores and metal post, the first fiber post was introduced in the late of 1989 to restore endodontically treated teeth with an excessive loss of tooth structure, the priority of these posts can be basically attributed to that these posts has modulus of elasticity closer to that of dentin with good esthetic specially when all ceramic crowns are done, other advantages of fiber posts was decrease the hazard of root fracture because it enabling soft cementation without friction with root canal walls. [4-7]

Glass fiber posts have an elastic modulus comparable to that of dentin and can be bonded to the tooth structure which allows more homogeneous stress absorption and force distribution on the residual root consequently reinforcing the tooth structure, this property has been reported to reduce catastrophic fracture of the root and offer better distributions of the stress; Glass fiber post provides excellent esthetic and light transmission results, it require less dentin removal, and can be bonded to dentin. [8-11]
Furthermore the glass fiber posts are unaffected by corrosion; also these posts have tensile strength comparable to dentine; they are high retentive because of their matching and bonded to tooth structure also have revealed appropriate results comparative to root fracture and more convenient fracture modes.[8,9]

Other advantages of glass fiber posts are that they allow preparing the intra canal post preparation and fulfilling post cementation in a single clinical visit, because these procedures don’t required laboratory work, so that decreasing the working time, cost effective and decrease the risk of root canal contamination.[8,9]

A new glass fiber post developed by German company this post is basically a bundled post this post is radiopaque, translucent and exhibits dentine like elasticity. Each post composed of many of fine individual posts (0.3 mm in diameter) in varying numbers fixed together with color coded sleeve. In this system once remove the sleeve the bundles spread and are spread into the entire root canal, which can be adapted to any root canal anatomy. In contrast to conventional root posts, this provides uniform strengthening of the entire core buildup.

The purpose of this in vitro study was to estimate the fracture resistance of endodontically treated teeth restored with a bundle glass fiber post (rebilda GT) and tapered glass fiber post (Rebilda fiber post) at 45 degree oblique load.

The null hypothesis test was that the bundle fiber post will show superior fracture resistance than the tapered post.

**Materials and Method**

Thirty freshly extracted human single rooted lower first premolar teeth extracted for orthodontic reasons were selected for this study the teeth collected from young patient’s age between 18-25 years old.

The selected teeth with absence of cracks or caries, no posts or crowns, no external resorption, with anatomically similar roots were selected. Radiographs for all teeth were taken and examined to exclude any teeth with canal calcifications, abnormalities, and/or signs of internal resorption.

The extracted teeth stored in 0.1% thymol solution at room temperature.

During preparation of the specimen, the root surfaces were cleaned from soft tissue with a periodontal curette (LM- Ergomax, Finland). Before preparation of the root canal, the crowns of all teeth were sectioned at the level of the cement-enamel junction (CEJ) using diamond disc (Komet, Germany) adjusted to a slow-speed hand piece, with continuous water coolant, the roots were adjusted to 12 mm in length, any root that not 12mm length after section was excluded, and the working length was measured 1 mm shorter from the apex.[11]

All the root canals were instrumented by using pro-taper next rotary files driven at 250 rpm with 2N/cm torque (x smart pluse, Dentsply, Maillefer).

Each instrument was used for five canals up to size X3 (30/0.07) during preparation EDTA cream (SURE-PREP, SURE ENDO, korea) used inside canal to enhance instrumentation and 2ml of distilled water and 2ml of 5.25% sodium hypochlorite (NaOCl) irrigation were used between each file size, there after each canal received a final irrigation of 3 ml EDTA solution to remove the smear layer then 3 ml of NaOCl after washing the EDTA with 2ml of distilled water, then the canals flushed with 10 ml distilled water to remove any remnant of irrigation materials.[12]

After drying with paper points the canals were obturated with single cone using size X3 guttapercha cone which was fitted at the working length with slight resistance [tug back] effect, in conjunction with endodontic sealer (AD SEAL) (META BIOMED CO.LTD, Korea).

Then access gutta-percha was removed and condensed vertically with hand plugger after the ending of the endodontic treatment, temporary filling material MD Temp (META BIOMED, Korea) used to close the opening of the canals. Then the teeth stored inside incubator at 37°C with 100% humidity for one week.

**Fiber Post Procedure:** After one week of incubation the temporary filling removed and peeso reamer size 3 was used to remove the gutta-percha to a depth of 8 mm leaving 4mm of endodontic filling at the apex to ensure a clinically acceptable apical seal. As manufacturer instructions the Rebilda GT post system come without drills and this post well-matched with all drill systems.

Ultimately the canals flushed with 2ml NaOcl 5.25% and 2ml distilled water respectively to remove the debris then dried with paper points.
Then the roots were arbitrarily divided into three groups with regard to the post type:

**Group A:** 10 roots filled with Rebilda fiber post (1.2 mm in diameter tapered posts) (Voco Cuxhaven, Germany) (Figure 1).

**Group B:** 10 roots filled with Rebilda GT bundle fiber post (1.2 mm in diameter bundle posts) (Voco Cuxhaven, Germany) (Figure 2,3).

**Group C:** 10 roots restored with direct composite resin restoration without a post (control).

Before cementation, as manufacturer’s instructions all posts were disinfected with alcohol, then silane coupling agent was applied to the post and allowed to dry for 1 minute as manufacturer instructions, after that bonding agent (Futurabond U Voco Cuxhaven, Germany) which is self-etching and dual cure were applied inside the root canals and dried with gentle air without light cure as manufacture instructions then the core-built-up composite (Rebilda DC, VOCO Germany) inserted in the canal using special application tip for the groups: Rebilda post and Rebilda GT post. Following placement of the posts with slight finger pressure, the excess resin was removed after light curing for 3 seconds with the probe. Then the resin was light-cured with light curing device with 1600mW/mm² intensity for 40 seconds (Da-lux, Dia Dent Korea) in the occlusal direction; the intensity of light cure had been checked before using with a radiometer and rechecked after each curing. [12, 13]

The core build-ups with composite resin which were standardized using the same size of a cellulite core-forming matrices to ensure the uniformity of the specimens. Then all the specimens were maintained in 100% humidity, for 24 hours, at 37°C.

Fracture Resistance test was done by applying the load using the Instron Universal Testing Machine (TERCO, MT 3037, Sweden).

A 45-degree oblique load was applied at speed of 0.5 mm/minute until fracture occur, and the fracture loads were registered and the fracture was observed by visual inspection with the aid of transillumination and by return-back de-bonded force score to zero, as shown on a computer screen.

Statistical analysis was done using Statistical Package for the Social Science software, version 17.

Descriptive statistics were expressed as means and standard deviation (SD) for each group (Tables 1). The effect of different posts types on the fracture resistance of the tooth was assessed by comparison of groups using ANOVA test and post hoc Tukey HSD test (Tables 2 and 3). In the above tests, p ≤ 0.05 was taken to be statistically significant.

**Results**

The mean and standard deviation of fracture resistance for each experimental condition are presented in table 1.

Statistical analysis of data by using the analysis of variance ANOVA test and post hoc Tukey HSD test (Tables 2 and 3). The tables showed, that group B (Rebilda GT post) had the highest average fracture resistance, compared to group A (Rebilda fiber post) and group C (control group) respectively. Consistent with the finding, the null hypothesis was accepted as the bundle post restorations show higher fracture resistance than other groups.

**Discussion**

Restoration of endodontically treated teeth is a pivotal subject in restorative and prosthetic dentistry. Intra-radicular posts are used extensively to restore root canal treated teeth with an enormous loss of coronal structure. Glass fiber posts have elastic modulus similar, near to that of dentin which allows for the harmonized stress distribution, force absorption inside root structure. This posts are capable to bond to dentin so that it restores the function, esthetic and strengthening the remaining dental structure. Fiber-reinforced composite resin posts differ in conditions of design, shape and properties, the bonding of fiber reinforced composite resin posts to dentin is affected by many factors such as the post material, the shape of post tapered or parallel, and the luting material; the thickness of the luting materials around the post play an important role in the bonding strength. The posts absorb the applied stresses and dispense this force along the entire post channel. Rebilda GT is a new type of glass fiber dental posts, which is composed of a bundled of glass fiber-reinforced composite post, this post different from conventional posts because once open the sleeve it will occupied the canal space and adapted well to the canal walls also the thickness of cement will be less there for it show higher resistance to fracture than the single post. Rebilda GT can diffuse in the fine individual posts that are dispense in the entire root canal, this post fitted optimally to any root canal configuration; consequently, this oncoming can be used in conditions where strongly curved root canals or oval and pearl shape root cross sections and marked conicity occur. An 45 degree oblique load to the long axis of the tooth was applied to the tested specimens which appear to be the worst condition in terms of the fracture resistance this correspond to a worst occlusal loading for teeth. The results of this study revealed that the
Rebilda GT post (group B) system showed significantly higher resistance against oblique load than the Rebilda post (group A), and the control group (group C) showed the least fracture resistance, this could be attributed to a better chemical bond between the glass fiber and the resin matrix, however increase in the number of fibers in the coronal aspect leads to better adaptation and bonding to the walls of the canal and to the core respectively and thus better stress distribution than of the single post this bundle posts can be used to strengthening of the weak tooth specially the large canals because it can occupy the canal space with least amount of cement thickness which give more strength to the canal walls. This result agrees with Maceri et al. showed that a multi-post system may lead to superior adaptation to the tooth.[19]

**Conclusion**

Rebilda GT post (bundle glass fiber system) showed higher fracture resistance than the Rebilda fiber post (tapered glass fiber post) and control group respectively so that this post (rebilda GT) can be strengthen the weak tooth structure better than tapered post.

Relation of Endothelin-1 and Malondialdehyde with Pre-eclampsia in Pregnant Women

Rhama Hamid Kassar1, Baedaa Abdulaziz Salman2, Fatehiya Majeed Noori2
1M. Sc. Medical Biochemistry, Kirkuk Health Directorate, Kirkuk, Iraq, 2M.B.Ch.B, HD in Obstetric and Gynecology Kirkuk Health Directorate, Kirkuk, Iraq

Abstract
A case-control study was conducted in Kirkuk city in Kirkuk general hospital from first of March 2018 and to end of September 2018 to evaluate the role of endothelin-1 and malondialdehyde in pathogenesis of preeclampsia in pregnant women. The study included 30 pregnant women with preeclampsia, patients were defined and divided according to the National High Blood Pressure Education Program Working Group on High Blood Pressure in Pregnancy. A control group of 30 healthy normotensive pregnant females was also included. All comparison groups were matched for mother’s age, parity, and gestational age at the time of enrollment and blood collection. Three ml of blood was collected by vein puncture, blood samples were placed into sterile test tubes and left for 30 minutes at 37 °C then were centrifuged at 3000 rpm for 15 minutes then the clot was removed and the obtained sera were then aspirated using automatic micropipette and transferred into clean test tubes and stored in deep freeze at -20°C for determination of endothelin-1 and malondialdehyde by usingELISA technique. The study showed that the highest mean level of endothelin-1 was found in pregnant women with pre-eclampsia(13.15±2.81 pg/ml) and the lowest mean was in the control group (0.41±0.31 pg/ml). The result was highly significant (P<0.01). The study showed that the highest mean level of MDA was found in pregnant women with pre-eclampsia (6.75±2.94 nmol/ml) and the lowest mean was recorded in the control group (3.85±1.29 nmol/ml). The result was highly significant (P<0.01). The current study showed that the mean age of patients enrolled in the study was 33.5 years, the highest mean of endothelin-1 in HD patients was recorded within the age group 20-29 year of pregnant women with pre-eclampsia. Although the results was non-significant. The study showed positive correlation between endothelin-1 and MDA levels pregnant women with pre-eclampsia. It was concluded that serum endothelin-1 and MDA levels were highly correlated with pregnant women with pre-eclampsia.

Keywords: Endothelin-1; MDA; pre-eclampsia; Pregnancy.

Introduction
One of the most common complications of pregnancy is preeclampsia. Preeclampsia occurs in ~8% of all pregnancies, and is significantly more prevalent in specific ethnic subpopulations(1). Despite an increasing awareness of the condition, and aggressive therapeutic intervention, preeclampsia remains a leading cause of both fetal and maternal perinatal morbidity and mortality, with ~15% of all preterm pregnancies attributable to preeclampsia(2). The disease is primarily seen in nulliparous women, with a significantly decreased incidence in succeeding pregnancies. Traditionally, the disorder has been defined by hypertension (systolic >140 mm Hg), proteinuria (300 mg/24 h), and edema(3). However, current guidelines omit edema as a necessary symptom for diagnosis, and there is increasing discussion as to whether the absolute values of proteinuria are the correct metrics by which to guide treatment, or whether the protein/creatine ratio would be a more diagnostic measurement (1). The molecular structure of this endothelium-derived constricting factor which produces powerful, very long-lasting constrictions of a range of mammalian blood vessels in vitro including human arteries and veins. It also causes long-lasting elevation of blood pressure when injected into rodents(4). Because of these observation, scientists at this time were of the opinion that this peptide - nowadays called endothelin-1 (ET-1) plays an important role in the pathogenesis of
arterial hypertension as well as pregnancy induced hypertension/preclampsia\(^{(5)}\). Nowadays, role of oxidative stress in PIH etiology is being researched, and acquired results show that oxidative stress could have a significant role in generation of preeclampsia since it starts damage of endothelium of placenta vascularization and immune response\(^{(6,7)}\). Normal pregnancy is considered to be a state where oxidative stress increases a bit, but there is no increase in, so called, free radicals\(^{(8)}\). Recently, a great attention is being paid to lipid peroxidation, which actually is oxidative damage of lipids and increased creation of lipid peroxides, whose final product is malondialdehyde (MDA). Nowadays, malondialdehyde (MDA) is used in many expert researches as oxidative stress marker, i.e. for assessment of lipid peroxidation\(^{(9,10)}\). The aim of this study was to evaluate the role of endothelin-1 and malondialdehyde in pathogenesis of pre-eclampsia in pregnant women.

**Materials and Method**

A case-control study was conducted in Kirkuk city in Kirkuk general hospital from first of March 2018 and to end of September 2018. The study included 30 pregnant women with preeclampsia, patients were defined and divided according to the National High Blood Pressure Education Program Working Group on High Blood Pressure in Pregnancy. A control group of 30 healthy normotensive pregnant females was also included. All comparison groups were matched for mother’s age, parity, and gestational age at the time of enrollment and blood collection.

**Exclusion Criteria:**

1. Multiple gestations.
2. Fetal structural/genetic anomalies.
5. Inflammatory disease.
6. Autoimmune disease, and other comorbidities associated with endothelial damage.

Hypertensive disorders were defined according to classification of The National High Blood pressure Education program Working group on High Blood pressure in pregnancy. Twenty-four-hour automatic blood pressure monitoring was performed. Blood pressure readings were taken at 30-minute intervals. For patients who was admitted to the hospital, and two readings of blood pressure was taken for patients who was not admitted to the hospital and diagnosed as hypertensive disorders depend on history and examination and blood pressure readings that record on antenatal card in each antenatal visit. Measurement of Bp done by sphygmomanometer in sitting position, with cuff size appropriate to patients arm circumference was used, and to eliminate a possible stressor for the patients, the visual preview of blood pressure measurement was removed. Three ml of blood was collected by vein puncture, blood samples were placed into sterile test tubes and left for 30 minutes at 37 °C then were centrifuged at 3000 rpm for 15 minutes then the clot was removed and the obtained sera were then aspirated using automatic micropipette and transferred into clean test tubes and stored in deep freeze at −20°C for determination of endothelin-1 and malondialdehyde by using ELISA technique.

**Finding:** As shown in Table 1. There was no significant difference between studied cases and the control group regarding patient age and gestational age at sampling and parity (P>0.05) while there was a significant difference between studied cases and the control group regarding systolic and diastolic blood pressure (P<0.05).

(P.value 0.08)

The study showed positive correlation between endothelin-1 and MDA levels pregnant women with pre-eclampsia (Figure 1).

Figure 1: Correlation between endothelin-1 and MDA levels pregnant women with pre-eclampsia

Discussion

The result of the current study was in consistence with past study, showed that, plasma ET-1 concentrations are markedly increased in pregnant women with pre-eclampsia as compared with healthy individuals(11). Xu, et al(12) also found that ET-1 was more likely to be elevated in pregnant women with pre-eclampsia. Li, et al(13) indicated that ET-1 was activated in several diseases, including renal failure and arterial hypertension. Additionally, Cin, et al(14) found that level
of ET-1 was significantly higher in pregnant women with pre-eclampsia compared to the controls (P < 0.001).

Similar results were also achieved by Hocher, et al (15) who found that MDA concentrations were significantly higher in pregnant women with pre-eclampsia than in controls. An other study demonstrated that Plasma level of MDA was significantly elevated in pregnant women with pre-eclampsia group than in healthy controls (16). Additional reports demonstrated mean serum MDA levels was significantly elevated in pregnant women with pre-eclampsia compared with normal level in healthy control group (17,18). Former report also showed that MDA was elevated in pregnant women with pre-eclampsia in comparison to the control groups. Several other studies also agreed with our findings, they found high serum MDA levels in pregnant women with pre-eclampsia compared with healthy individuals (19,20).

Former researches dealing with problem of MDA indicate that pregnancy is a state of physiological, slightly increased oxidative stress in comparison to healthy non-pregnant women. Oxidative stress could have a significant role in generation of pregnancy induced hypertension (PIH), since it starts damage of endothelium of placenta vascularization and immune response (21,22). Others also concluded in their study that pregnancy induced hypertension (PIH) is a state of extreme increase of oxidative stress and lipid peroxidation (22). In our study, we proved the increased MDA level as oxidative stress marker in pregnant women with PIH, too. Based on our acquired results, that means that pregnant women of test group had extremely increased MDA values in comparison to control group. Our results in this research show that pregnancy induced hypertension is a state of extremely increased oxidative stress which corresponds to the other studies, too (23-25).

**Conclusion**

Serum endothelin-1 and MDA levels were highly correlated with pregnant women with pre-eclampsia.

**Financial Disclosure:** There is no financial disclosure.

Relation of Elevated Serum AFP Levels with Preterm Labor in Kirkuk City-Iraq

Noorjan Qasim Ahmed1, Maysaa Abdalhussein Mohammed2, Shaimaa Mohammed Sulaiman3

1M.B.Ch.B. D.G.O., Kirkuk Health Directorate, Kirkuk, Iraq

Abstract

In this study conducted in Kirkuk city in the period from February 2017 to the end of December 2017, which included 100 pregnant women who had regular contractions and/or short cervical cervices between 24 to 32 weeks of pregnancy and 100 healthy controls who did not suffer from complications Pregnancy and they were delivered on time. For the purpose of comparing the two groups with respect to the level of AFP. The study included collecting blood samples from both groups prior to birth to investigate and measure the level of the protein AFP in their blood. The study demonstrated that the lowest mean of cervical length and birth Wight were found in group with preterm labor as compared with the control group. The study revealed that the mean of AFP was elevated significantly in women with preterm delivery (17.7±2.11 pg/ml) as compared with the control group (8.23 ±1.67 pg/ml) at P. value <0.05. In this study, 40 of 100 of study cases delivered preterm (< 34 weeks). The study found positive correlation of serum AFP with birth weight, birth head during 1st and 5th weeks of delivery (p< 0.01).

Keywords: AFP, Preterm labour, Term Labour.

Introduction

Virtually every publication about preterm birth (PTB) cites the profound impact PTB has on the babies, families and the healthcare system(1). In Practice Bulletin 127 (June 2012), The American College of Obstetrician and Gynecologists (ACOG) states: “Preterm birth is the leading cause of neonatal mortality and the most common reason for antenatal hospitalization(2). In the United States approximately 12% of all live births occur before term, and preterm labor (PTL) preceded approximately 50% of these preterm births preterm births account for approximately 70% of neonatal deaths and 36% of infant deaths as well as 25–50% of cases of long-term neurologic impairment in children”. These statistics magnify the importance of PTL contributing to 50% of PTB’s(3). When a patient presents to the hospital with regular uterine contractions and cervical change between 20 0/7 weeks and 36 6/7 weeks gestation with intact membranes, a diagnosis of PTL is made. Some factor or factors have caused a response of the myometrium (contractions) creating the risk of PTB(4). Maternal serum alpha-fetoprotein (MS-AFP) is a second-trimester biochemical marker for prenatal screening. High or low MS-AFP suggests high risk of fetal open neural tube defects (ONTDs) or chromosomal aneuploidy, respectively(5). Based on the decades’ experience of prenatal screening, it has been reported in numerous studies that after excluding fetal ONTDs, women with elevated second-trimester MS-AFP have higher risk of APOs(6-8). Therefore, it has been well known that second-trimester MS-AFP can be a biomarker for the predictions of APOs(9). The aim of the study was to evaluate the role of maternal AFP levels with preterm and term delivery.

Material and Method

In this study conducted in Kirkuk city in the period from February 2019 to the end of December 2019, which included 100 pregnant women who had regular contractions and/or short cervical cervices between 24 to 32 weeks of pregnancy and 100 healthy controls who did not suffer from complications Pregnancy and they were delivered on time. The gestational age were determined by crown-rump length measured by ultrasound scan. In order to promote the first-trimester one-stop screening, we performed MS-AFP test additionally combining with ultrasonic measurement of intracranial translucency (IT) and detection of fetal structural abnormalities to study
the first-trimester screening of fetal ONTDs. The study included collecting blood samples from both groups prior to birth to investigate and measure the level of the protein AFP in their blood serum using immunofluorescence (i-chroma Korea). Through the study, patients were also monitored in terms of the consequences of early birth in terms of complications as well as birth weight.

**Statistical Analysis:** Computerized statistically analysis was performed using Mintabver 18.0 statistic program for determination of the $P$ value ($P<0.05$: significant).

**Findings:** The study showed no significant difference between preterm group (Cases) and term group regarding maternal age ($P$ value $>0.05$). The study also showed that the rate of regular contractions was 40% in patients group compared while no one of the control group was with regular contractions ($P<0.01$). The study demonstrated that the lowest mean of cervical length and birth weight were found in group with preterm labor as compared with the control group (Table 1).

In this study, 40 of 100 of study cases delivered preterm (< 34 weeks). In this subgroup, 12 mothers had histologically proven evidence of chorioamnionitis, and 10 of these patients additionally tested positive for funisitis. It is interesting to note that the levels of AFP in these 5 patients who tested positive for both Chorioamnionitis and funisitis were significantly reduced; (Table 3).

Discussion
The study showed no significant difference between preterm group (Cases) and term group regarding maternal age (P. value >0.05). The study also showed that the rate of regular contractions was 40% in patients group compared while no one of the control group was with regular contractions (P<0.01). The study demonstrated that the lowest mean of cervical length and birth weight were found in group with preterm labor as compared with the control group. The study showed minor differences between the two groups in relation to the ricin protein, as it was relatively low in patients with early birth. Other studies also found that the levels of the AFP are positively related to the child’s weight, height, and head circumference in the delivery period, and also found that there was a correlation with the child’s weight and head circumference after a month of birth. It was concluded in other studies that the high level of acrines was positively correlated with the weight of fetuses before birth (6-8). Moreover, the level of the iris in the blood correlates positively with the total weight of the fetus and its circular circumference as concluded by ultrasound (7). The results of our study are very similar to the results mentioned in the above-mentioned masses and his support for him, as it concerns the Moawad in the first month of their birth. Where previous studies confirmed that newborns represent low levels of serum ezine levels compared to infants during the first month of life (9), there is a significant difference between the first and second evaluation. Other studies conducted in different regions of the world indicate that the level of the iris of the eye was somewhat low compared to the control group in this research, previous studies on mature children showed that the levels of iris of the eye are generally higher compared to the results in our study (10). We assume that we have detected low levels of the iris as our blood samples are collected directly from children, unlike previous studies in which bloodstream analyzes of the iris were likely to be affected by the maternal iris. In our study of serum iris levels during the fifth week of life were positively associated with the degree of birth weight, the score increased in 5 weeks, the head circumference Z score in 5 weeks unlike some previous studies (11). Many researchers believe that AFP in serum levels in new children may be inherited (from parents) (12-14). According to earlier studies conducted earlier, the rates and concentrations of serum protein iris in new children, especially in the first month of their life, may be inherited from the mother through energy-regulating genes and in particular, the lipid protein linked to high-density cholesterol (15-18). Although this protein has not been taken as a differentiating factor in these radomas, which may be a hindrance to this research. However, we found that iris levels were positively related to the child’s weight, height, and head circumference in the delivery period, Park et al. found in recent study that newborn mother in preterm labour have elevated AFP level especially who have significant child outcomes like chorioamninitis and fusinitis(19).

**Conclusion**

Serum level of AFP decreased significantly women with preterm labour as compared with term ones

Genetic and Hybrid Gray Wolf Optimization Algorithm

Noor Muhammed Noori¹, Omar Saber Qasim²

¹M.Sc. Student, ²Assist. Prof., Department of Mathematics, University of Mosul, Mosul, Iraq

Abstract

Much of the data in the classification issue contains a number of additional attributes that do not affect the accuracy of the classification. There are many evolutionary algorithms that are used to define the feature and reduce dimensional patterns such as the gray wolf algorithm (GWO) after converting it from a continuous space to a discrete space. In this research, a method of feature selection was proposed through two consecutive stages in the first stage, the mutual information (MI) method is used to determine the most important feature selection. In the second stage, the binary gray wolf optimization (BGWO) algorithm is used to lessen and determine a specific number of features affecting the process of classification, which came from the first stage. The proposed algorithm MI_BGWO is efficient and effective by obtaining higher classification accuracy and a small number of specific features compared to other competing algorithms.

Keywords: Gray wolf optimization; classification; feature selection; mutual information.

Introduction

Gray wolf optimization (GWO) is a swarm intelligent technique developed by Mirjalili et al., 2014¹. The hunting techniques and the social hierarchy of wolves are mathematically modeled in order to develop GWO and perform optimization. The GWO algorithm is tested with the standard test functions that indicate that it has superior exploration and exploitation characteristics than other swarm intelligence techniques ². Scientists have developed the basic algorithm GWO by converting the search algorithm from a continuous search space to a discrete search space. This modified algorithm is called a binary gray wolf optimization (BGWO) algorithm, which works in binary search areas and uses binary values equal to 0 or 1³. Mutual information (MI) is one of the filtering method, which is calculated between two random variables using entropy. Entropy measures an average random variable the amount of information required to describe the random variable⁷. In this study, a new MI_BGWO algorithm is suggested to determine the best-feature selection. Our proposed algorithm can efficiently achievement the powerful points of both MI and BGWO algorithms in finding the most important feature. The experimental results show the excellent performance of the proposed algorithm when the number of feature is high, and the sample size is low. The GWO is presented in Section 2. In Sections 3 and 4, a brief description of feature selection and MI respectively. In Section 5, the proposed algorithm is explained. Section 6 covers the obtained results and their discussion. Finally, the most important general conclusions are mentioned, in section 7.

Grey wolf optimization (GWO): The gray wolf (Canis lupus) is part of the Canidae family. Gray wolves are types with a very rigorous social dominant hierarchy of leadership. Males and females in the pack are leaders, and they are called alpha¹. Alpha wolf is also known as the dominant wolf because all its orders must be followed by all wolves in the pack. Only alpha wolves are allowed to mate in the pack. This means that the order of the pack and its regularity is more important than its strength. Beta is the second level in the hierarchy of gray wolves. Beta are wolves that help alpha wolves make decisions or other things about the pack. The wolf beta is the best
candidate to be alpha in the case if one of the wolves of alpha becomes too big or in the case of the death of someone in command. Omega is less gray wolves. The omega wolf always offers all the other dominant wolves on it. Omega acts as a scapegoat. The last wolves allowed to eat are omega. We may apparently notice that omega is not an important member of the group, but in fact, if omega is lost, the entire pack will face problems and internal fighting. Delta is the fourth class in the pack. Delta wolves control omega, but they must undergo alpha and beta orders. Delta shall be responsible for guards, scouts, hunters, elders, and patients and each has its own specific responsibility\textsuperscript{8}.

**Mathematical Modelling:** The first best solution in GWO is alpha (\(\alpha\)), the second-best solution is beta (\(\beta\)), and the third-best solution is Delta (\(\delta\)). While the rest of the solutions are Omega (\(\omega\)), which follows the rest of the first three solutions.

**Encircling Prey:** Gray wolves surrounded prey while hunting. The following equations will represent a mathematical model about the surrounding behavior:

\[
\begin{align*}
\bar{D} &= |\bar{c} \cdot \bar{x}_p(t) - \bar{x}(t)| \quad (1) \\
\bar{x}(t+1) &= \bar{x}_p(t) - \bar{A} \cdot \bar{D} \\
& \text{where } t \text{ is the iteration, } \bar{x}_p \text{ is the prey position, } \bar{x} \text{ is the gray wolf position, the operator indicates vector entry wise multiplication.}
\end{align*}
\]

where \(\bar{A}\) and \(\bar{C}\) are coefficient vectors calculated as follows:

\[
\begin{align*}
\bar{A} &= 2\bar{d} \cdot r_1 - \alpha \\
\bar{C} &= 2 \cdot r_2 \quad (3)
\end{align*}
\]

where components of \(\bar{d}\) are linearly decreased from 2 to 0 over the course of iterations and \(r_1, r_2\) are random vectors in [0,1].

**Hunting:** Gray wolves have the ability to encircle prey and locate them. Hunting is performed by a complete pack based on, Information from the alpha, beta and delta wolves, So the updating for the wolves positions is as in the following equations:

\[
\begin{align*}
\bar{D}_{\alpha} &= |\bar{c}_1 \cdot \bar{x}_{\alpha} - \bar{x}|, \quad \bar{D}_{\beta} = |\bar{c}_2 \cdot \bar{x}_{\beta} - \bar{x}|, \quad \bar{D}_{\delta} = |\bar{c}_3 \cdot \bar{x}_{\delta} - \bar{x}| \\
\bar{x}_1 &= |\bar{x}_{\alpha} - \bar{A}_1 \cdot \bar{D}_{\alpha}|, \quad \bar{x}_2 = |\bar{x}_{\beta} - \bar{A}_2 \cdot \bar{D}_{\beta}|, \quad \bar{x}_3 = |\bar{x}_{\delta} - \bar{A}_3 \cdot \bar{D}_{\delta}|
\end{align*}
\]

\[
\bar{x}(t+1) = \frac{\bar{x}_1 + \bar{x}_2 + \bar{x}_3}{3} \\
\text{The updating of the parameter } \bar{d} \text{ through the following equation:}
\]

\[
\bar{d} = 2 - t \cdot \frac{2}{Max_{iter}} \\
\text{where } t \text{ is the iteration number and } Max_{iter} \text{ is the total number of iteration allowed for the optimization}.\text{9 The pseudo code of the GWO algorithm is displayed in Figure 1.}
Start
Generate an initial population of the gray wolf $X_i$ (i=1.....n)
Generate an initial value $A$, $a$, and $c$
Find the fitness function of each search agent
$x_a$ = the first best search agent
$x_b$ = the second-best search agent
$x_d$ = the third best search agent
while ($t < \text{Maxiter}$ of iterations).
for each search agent
Update the position of the current search agent by equation (7)
end for
Update $A$, $a$, and $c$
Find the fitness function of each search agent
Update $x_a$, $x_b$ and $x_d$
set $t = t + 1$
end while
return $x_a$
End

Figure 1: The pseudo code of the GWO algorithm.

Binary gray wolf optimization (BGWO): The positions of gray wolves constantly change in space to any point. Solutions are limited to binary values such as 0 or 1 in some special problems such as feature selection. In our research, we suggested feature selection through a binary GWO algorithm. Updating the equations of wolves are a function of the positions of three vectors is $X_a$, $X_b$ and $X_d$, which represents the best three solutions and which attracts each wolf towards it. At any given time, all solutions are at a corner of a hypercube and the solutions are grouped in binary form. Based on the basic GWO algorithm, the given wolf positions are updated, a binary restriction must be maintained according to equation (9).

The main update equation in the GWO algorithm is written as:

$$X_i^{t+1} = \text{Crossover}(X_1, X_2, X_3)$$  \hspace{1cm} (9)

where $(X_1, X_2, X_3)$ they are binary vectors representing wolves in bGWO and $\text{crossover}(a, b, c)$ are an appropriate intersection between solutions $(a, b, c)$ and $(X_1, X_2, X_3)$, and the wolves calculate alpha, beta and delta in order using equations (10), (13) and (16).

$$X_i^d = \begin{cases} 1 & \text{if } (X_a^d + b\text{step}_a^d) \geq 1 \\ 0 & \text{otherwise} \end{cases}$$ \hspace{1cm} (10)

where $b\text{step}_a^d$ is a binary step in dimension d, $X_a^d$ is a vector representing the position of the alpha wolf in dimension d. $b\text{step}_a^d$ is calculated by the following equation:

$$b\text{step}_a^d = \begin{cases} 1 & \text{if } c\text{step}_a^d \geq \text{rand} \\ 0 & \text{otherwise} \end{cases}$$ \hspace{1cm} (11)

where $c\text{step}_a^d$ is the continuous-valued step size for dimension d, $\text{rand}$ is a random number in the closed period $[0,1]$ derived from the uniform distribution. $c\text{step}_a^d$ can be calculated using the sigmoidal function by the following equation:
where $A_d^d$ and $D_d^d$ are calculated using equations (3), and (5) in the dimension $d$.

$X_2^d$ and $X_3^d$ Can be found by the following equations:

$$X_2^d = \begin{cases} 1 & \text{if } (X_2^d + bstep_2^d) \geq 1 \\ 0 & \text{otherwise} \end{cases}$$

$$bstep_2^d = \begin{cases} 1 & \text{if } cstep_2^d \geq \text{rand} \\ 0 & \text{otherwise} \end{cases}$$

$$cstep_2^d = \frac{1}{1 + e^{-10(A_d^d D_d^d - 0.5)}}$$

$$X_3^d = \begin{cases} 1 & \text{if } (X_3^d + bstep_3^d) \geq 1 \\ 0 & \text{otherwise} \end{cases}$$

$$bstep_3^d = \begin{cases} 1 & \text{if } cstep_3^d \geq \text{rand} \\ 0 & \text{otherwise} \end{cases}$$

$$cstep_3^d = \frac{1}{1 + e^{-10(A_d^d D_d^d - 0.5)}}$$

In the following equations, we will apply the intersection to each of the solutions $a$, $b$, $c$:

$$X_d = \begin{cases} a_d & \text{if } \text{rand} < 1/3 \\ b_d & \text{if } 1/3 \leq \text{rand} < 2/3 \\ c_d & \text{otherwise} \end{cases}$$

where $\text{rand}$ is a random number derived from the uniform distribution in the closed period $[0,1]$, and $a_d$, $b_d$ and $c_d$ represents the binary values of the first, second and third parameters of the dimension $d$, $X_d$ is the result of the exchange in dimension $d$. The pseudo code of the BGWO algorithm is displayed in Figure 2:

**Feature Selection:** The feature selection method improves the performance of the algorithm by reducing the number of attributes used to describe a data set. The purpose of features selecting in an algorithm is to reduce the number of genes used to improve classification and increase classification accuracy. The feature identification algorithms consist of three parts:

1. **Search algorithm:** A subset of properties (features), which are part of the original features.
2. **Fitness function:** These input and digital assessment modes. The goal of the search algorithm is to draw attention to this function.
3. **Classifier:** It represents the required algorithm that uses the latest subset of genes (i.e., an algorithm that selects the most important features required).

---

**Figure 3: Filter control strategy**

One of the ways to select a feature on the predictive performance of a predefined algorithm is the wrapper method, which evaluates the quality and efficiency of certain features. This is based on two-steps, based on a specific algorithm: (1) Searching for a subset of properties and features (2) Evaluate these specific features and attributes. In order to obtain learning performance or to reach some stop criteria we repeat (1) and (2).

1. **Mutual information (MI):** You can get some information about the variable Y that is included in the mutual information \( I(X, Y) \) which is considered to be in the information shared by two random variables.

   \[
   I(X,Y) = \frac{H(X)}{H(Y)}
   \]  
   \[ (23) \]

   If there is a close association between the two variables X and Y, the mutual information \( I(X, Y) \) will be large. If the variables X and Y are not completely associated, then \( (X, Y) = 0 \). The mutual information was applied to filter the feature set to see the relationship between certain features and category classifications. In the theory of information, there is a classic use of many measures of feature classification. Note that these statistics work to build a relationship with the classroom and feature in \( F \). In the theory of information, one of the most important contributions to the research is the selection of the feature where it works to use the information exchanged in the evaluation of the feature and in the following formula \( F \) will be indicated by a set of features is referred to and the class naming.

   \[
   I(F,C) = \iint P(F,C) \log \frac{P(F,C)}{P(F) \times P(C)} \, df \, dc
   \]  
   \[ (24) \]

   The evaluation of mutual information (MI) is in some method between class naming and one feature. The problem is not in this measure. When evaluating entire feature sets will have difficulties arise. Possible interactions between features are the reason for evaluating entire feature sets in a multivariate way. The combination of two features may in some cases provide important information, because in some cases two individual features may not provide sufficient information about the chapter. Between the variable Y and N variables X1, X2, ..., XN, the chain rule is

   \[
   I(X_1, X_2, ..., X_N; Y) = \sum_{j=1}^{N} I(X_j; Y | X_1, X_2, ..., X_{j-1})
   \]  
   \[ (25) \]

   \[
   \text{fitness}(X_i) = I(X_i; C)
   \]  
   \[ (26) \]
In the measurement of entropy, there is a way to calculate and replace mutual information in the form of mutual information. There is an appropriate criterion for selecting items through information exchange. It is possible to define the information exchanged is a measure to reduce the uncertainty of category labels, because of knowledge of characteristics of the data set, where the fitness function is maximizing the mutual information value.12

Experimental results

The proposed algorithm MI_BGWO is evaluated, and its interest is compared with the other competitor algorithms.

**Data Sets:** We have selected (3) different classification problems from the literature to verify the effectiveness of the proposed algorithm for classification problems. From a repository UCI, a data set was obtained.21

The target variable is a binary variable that includes a set of data where the binary variable represents the condition of the sick person who has good = 1 and bad = 0.

**The following table shows the overall description of the data set:**

<table>
<thead>
<tr>
<th>Dataset</th>
<th># Samples</th>
<th># Features</th>
<th>Target class</th>
</tr>
</thead>
<tbody>
<tr>
<td>Prostate</td>
<td>102</td>
<td>12601</td>
<td>2</td>
</tr>
<tr>
<td>DLBCL</td>
<td>77</td>
<td>7130</td>
<td>2</td>
</tr>
<tr>
<td>Colon</td>
<td>62</td>
<td>2001</td>
<td>2</td>
</tr>
</tbody>
</table>

**Discussion**

To correctly evaluate the proposed algorithm MI-BGWO, the results were compared with the BGWO algorithm for feature selection. The training and testing dataset for the proposed algorithm, MI-BGWO, achieved the best results for the classification. For instance, in the prostate dataset, the CA of the testing dataset is 94% by the MI-BGWO which is higher than 65% by BGWO.

**Table 2: Classification performance on average of the algorithms used over 20 partitions (where the number in parentheses is the standard error).**

<table>
<thead>
<tr>
<th>Datasets</th>
<th>Method</th>
<th>Training dataset</th>
<th>Testing dataset</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>CA</td>
<td>SE</td>
</tr>
<tr>
<td>Prostate</td>
<td>MI-BGWO</td>
<td>0.9426</td>
<td>0.9663</td>
</tr>
<tr>
<td></td>
<td>BGWO</td>
<td>0.6529</td>
<td>0.7901</td>
</tr>
<tr>
<td>DLBCL</td>
<td>MI-BGWO</td>
<td>0.9192</td>
<td>0.9914</td>
</tr>
<tr>
<td></td>
<td>BGWO</td>
<td>0.9000</td>
<td>0.9009</td>
</tr>
<tr>
<td>Colon</td>
<td>MI-BGWO</td>
<td>0.8619</td>
<td>0.7692</td>
</tr>
<tr>
<td></td>
<td>BGWO</td>
<td>0.7429</td>
<td>0.5833</td>
</tr>
</tbody>
</table>

When comparing the BGWO algorithm with the proposed algorithm MI-BGWO we note that the proposed algorithm MI-BGWO has a clear advantage in terms of accuracy and classification capacity and BGWO worse than MI-BGWO through the three datasets.

**Conclusion**

In this study, the MI_BGWO method was proposed between the MI technique and the BGWO to improve the classification performance (when the datasets are big), relying on subsets of important features of the dataset. After the feature selection process, datasets were submitted to the Naïve Bayes classifier, and the results of the MI_BGWO method were compared with the BGWO method by the criteria shown in Table 2. Experimental results from the feature selection dataset indicate that the MI_BGWO method has a better classification performance than the BGWO method and has few features compared to the default method.

Prevalence Comparative Study of Infection with *Trichomonas* *spp* in The Three Types of Birds at The Holy City of Kerbala

Rana A. Jawad¹, Firas Al-Ali¹, Ibrahim F. Rashid¹, Juman Khaleel Al-Sabbagh¹, Ihsan M. Sulbi², Mustafa Ali Noor³, Wissam Abdulrasool Saber³

¹Lecturer, University of Kerbala/College of Veterinary Medicine, Iraq, ²Prof., University of Kerbala/College of Veterinary Medicine, Iraq, ³University of Kerbala/College of Veterinary Medicine, Iraq

**Abstract**

The avian Trichomonosis is a parasitic disease caused by *Trichomonas gallinae*. This parasite lived in the bird’s mouth and digestive tract, and can caused a granulomatous lesions in the lumen which lead to death of bird because of severe starvation. The results of the current study for the purpose of conducting a field survey and the extent of the spread of infection in the three types of birds (Bird toilet decorations, Bird pigeon, Broiler bath decorations). The field of study was in the holy city of Karbala, which is located in south-west Baghdad, and is 100 km long and has a moderate temperament. During the course of the study (345 birds were tested). This is the study of 170 decorative samples, 150 samples of the pigeon bath and 25 samples of after the samples were taken. 15-day-old bathroom bath with 25 samples of Broiler bath decorations. Use eye and laboratory examination to examine the symptoms. The results showed that 7, 10.3 & 12 respectively.

**Keywords:** Trichomonas, Birds, Holy Kerbala.

**Introduction**

The avian Trichomonosis is a parasitic disease caused by the protozoan called *Trichomonas gallinae*. This parasite lived mainly in the bird’s anterior digestive tract, so it can caused a granulomatous lesions include the lumen of esophagus and lead to death of bird because of severe starvation. However, it’s well known that virulence of this parasite is vary among strains, so it can reached to the parenchymatous organs causing a generate necrotic foci. Columbidae is known as a parasite’s main host, particularly the domestic pigeon (Columba livia), which has been considered the responsible to the worldwide spread of *T. gallinae*. Despite of the parasite preference for pigeons and doves, *T. gallinae* can affect a wide range of bird families, and infections in bustards, psittacine birds, fowl and passerine birds also have been reported. The preyed of birds (diurnal and nocturnal) are also recorded frequently to infected by these flagellated protozoans, especially those species that usually feed on doves or bird carcasses. Data on prevalence found in Columbidae with different authors throughout the world vary greatly, ranging from 5.6% cited by 12 in mourning doves to 95% detect. This parasite has been reported throughout the year, but most outbreaks occurring which seen in spring, summer and autumn. This study is aimed to detect rates of inflection with *Trichomonas spp* in three types of birds (Bird toilet decorations, pigeon and Broiler bath decorations) at Holy Kerbala City and compared between them according to the rates of inflection.

**Material and Method**

The samples of parasite cultures (oral swabs) were taken from the oral cavity of infected pigeon and putting in tryptone/yeast extract/maltose medium, then supplemented with 10% foetal calf serum (Sigma Chemical Co., St Louis, Missouri, USA) and incubated at 378 °C (16).

These cultures were observed over three consecutive days for checking the growth of these parasites. The positive samples were frozen in tryptoneyeast extract/maltose medium which containing about 5% dimethyl sulphoxide. Necropsies were executed on euthanized or dead birds to determine the macroscopic lesions.
grams were suspended in 1000 ml distill water, then heat to boiling to melt the medium completely. Sterilize by autoclaving at 15 lbs pressure (121°C) for 15 minutes finally mix well and pouring in sterile petri dish.

Fungi were the first microorganisms recognized because some of the fruiting structures such as the mushrooms are large enough to be seen without a microscope. Fungi can be grouped simply on the basic of morphology with yeasts or molds and it’s used for isolation and differentiation from yeast and molds.

Fetal Calf Serum (FCS or FBS) consider as a common supplement for animal cell media culture, it is has free database part (3Rs programme database) the assembly function for record allows researchers to discuss them\textsuperscript{13,16}.

![Image](image1.png)

**Figure 1:** Method for taking swap from oral cavity from infected bird.

**Results**

The results showed infected at about 20 birds from all types of birds (345) which used in this study. Table 1 show the results with a percentage of total rates 14.7%.

**Table 1:** The rates and severity of infection with Trichomonas spp in the three different types of birds

**Discussion**

A number of researchers studied the distribution of this disease in Iraq and show that the prevalence of this disease has increased in the areas of birds breeding in recent time due to the lack of frequent test for the pages and poor health care for the bite birds so this disease is endemic. In Iraq the disease found in the all field and agree with5-8

The results of the current study showed that the incidence rate of the *Trichomoniasis* about 0.17% from the total number of examined birds; this result that record in germane (2,3) where others pointed to that the percentages of infection ranged from 61.04%, 72.36% and 70.40%; as well as this result was differed with some other previous studies that recorded a higher rates of infection with this parasite 4.

A ratio of 2.08% of infection in different birds approaching from the previous results (2,3). As well as this result were differed from some previous studies that recoded a higher rates of infection with this parasite 1-4.

The differences in the infection rates return to several reasons, including the number of samples where the studied number give real representative results, as well as the period of study whenever the longest study period will reflect a comprehensive picture of the disease in the conducted region of study, moreover the geographical location of the area and the surrounding environmental conditions where temperature and humidity are considered important factors affecting the life cycle of the this parasites 13.

Also pollution disparity affect the growth and activity of parasite and the ways of spared of these parasite in the different areas 11. Besides lack of health control and prevention the condition to growth the parasite

Also the percentage of the infection in bird toiler decorations with *Trichomoniasis* recorded 4.11% and this approximated from that record by researcher 2.

The differs from the percentages referred to by others4.

Also the percentage of infection of bird pigeon with *Trichomoniasis* recorded 6.6 and this approximated from the other researcher 8. In Iraq the ratio differ from the percentages referred by Amin et al., (4) the differences in the infection rate was caused by environmental conditions and geographic location where the environmental condition of kerbala city characterized by high temperatures for most of the year, the occurrence of drought in the summer and the end of spring and the beginning of autumn, and this parasite cannot live outside the body of the body for a long period of time, because of conditions of heat, moisture and nutrients are not available and is consistent with the study 11,13.

The percentage of infection of broiler bath decorations total 12% it is agree with 9 and this percentage in fact use this result depend on the condition and out or free condition and this disease depend on the environmental and the geographic location and size.

The results of this field study were based on the pigeonhole of the pigeon decorations and the results were recorded at 12%. This corresponds with Amin et al., 4. This result differs from one location to other depending on environmental conditions,

In this way the spread of this disease is reduced to small by mothers or through fodder, where the studies prove that this parasitic disease was spread in UK and then spread to the rest of Europe and we can control this disease by depriving one of the factors of growth and spread, Fresh feed and non-exposure to contaminants this adjusts 9,11.

Molecular and Phylogenetic Study of The H PA I (High Pathogenic Avian Influenza) Virus Sub-type H5N8 in Iraq

Muhamed Abdul-Kadhim1, Hayder A. Muhammed2, Ali K. Aljarah2

1Lecturer, Pathology & Poultry Disease Branch, 2Assist. Prof., Microbiology Branch, College of Veterinary Medicine, University of Kerbala

Abstract

The Avian influenza (AI) is a widespread infection of the birds and humans affected by type A of influenza virus. Highly pathogenic avian influenza (HPAI) caused by the viruses subtype (H5N1) and (H5N8) is consider as a definite risk to the poultry industry and human health and it is started as the occasional revolutionize a satisfactory because of migratory bird which consider as a carrier of the disease. Twenty oropharyngeal swabs were collected from infected flock have suffer from sudden death with high mortality, all these samples were collected from (1-5) days after clinical signs appears and the results summarized by three farms infected with HPAI subtype (H5N8), three viral isolates strain out of 20 samples were identified by RT-PCR assay, two of them have layer origin while one have broiler origin, the three sequencing results in this study have been presented to the gene bank database under accession number MN689674.1 and MN658854.1, phylogenetic analysis of our sequences were used to relatedness of strain obtaining with other avian influenza viruses around the world, the a current sequences of avian H5N8 strains were found to be related as a common ancestor with Iranian registered strain.

Keywords: Avian influenza H5N8, RT-PCR, degenerate primer, phylogenetic tree.

Introduction

The Avian influenza disease is a word that used to define influenza viruses type A and it is separate from a wide-ranging of birds species all over the world and mammals(1). Recombination between AIV strains with mammalian derived influenza strains may be take place and that producing a new recombiant influenza viruses have the ability to initiating disease in humane and other species in the same time wild birds, waterfowl and shorebirds consider important source of infection by influenza A viruses and producing important risk for this disease(2–4). AIV can be divided according to inducing pathological lesion in the natural host in to two groups: high pathogenic avian influenza (HPAI) and low pathogenic avian influenza (LPAI), the infection with HPAI strains (H5N1, H5N8) categorized from slight to heavy sickness with high death rate may arrived to 100% in infected flocks (8).

AIV was multiplication in the respirational and gastric tract system of sick birds, so the suggesting of isolation of the infections (H5N8) from oropharyngeal swabs, tracheal swabs, cloacal swabs and feces(5).

In Egypt HPAI subtype H5N8 was diagnosed since 2016 in both commercial and backyard bird with high mortality and there are six genotypes have been detected in both wild and domestic birds(5–7).

During the 2015-2017 HPAI subtype H5N8 widely spread throughout Europe, Asia and Africa and seasonal migration of wild aquatic birds and water birds consider the important source for vector of disease, so that the infected birds were shed the viruses through the rivers, marshes and lakes, eventually reached the poultry flocks(9–11). Interestingly, the H5N8 remained as localized sporadic active infection during the spring, summer and autumn of 2017 in Iran and Italy While, HPAI infection become epidemics in winter and early spring (9).

The World Organization for the Animal Health (OIE) in 2018(22) was established the HPAI (H5N8) in Iraq infected poultry with high sickness and death rate, In the last years poultry industry in Iraq suffering from high morbidity and mortality with sudden death and that lead to high economic losses in addition, the risk
of this disease on human health, so there are doubts around this farm infected with HPAI subtype (H5N8), so that this study was designed to diagnosed HPAI subtype (H5N8) by using molecular technic test and phylogenetic analysis with other avian influenza virus sequences from different geographic area due to limited research has been conducted to determine HPAI subtype (H5N8) virus in Iraq.

**Materials and Method**

**Sample Collection:** The study was conducted by collection samples from chicken broilers and layers in different unorganized cities of Karbala province, the study was carry on just birds which have suspected clinical respiratory sings and have covered with mucosa congestion in un feathered regions and highly mortality. Within 24 to 48 hours after onset symptoms oropharyngeal swabs were collected from these chickens by sterile ice boxand recently sent to the lab as soon as possible. The course of this study was beginning from February 2018 to January 2019.

**RNA extraction procedure:** RNA pellet was extracted from oropharyngeal by using (QIAamp Viral RNA Mini Kit/QIAGEN) Germany. The RNA extraction of avian influenza was done by Qia tube connected automated purification system according to manufacture company. Interestingly, the extracted RNA was eluted in 50 µl of DEPEC water and calculated by Nano drop-spectrophotometer device, and immediately store in -30C at freezing for RT-PCR analysis (23-32).

**Reverse Transcriptase Polymerase chain reaction assays and Primer designing:** RT-PCR assays were done for diagnosis avian influenza virus, depended on Hemagglutinin glycoprotein gene by using specific degenerate primers. These primers were designed using influenza genomic sequences database available in gene bank, and retrieved by multiple alignment, these set of primers are made by (Bioneer/Korea) as following table (1).

<table>
<thead>
<tr>
<th>Primer Sequence</th>
<th>Amplicon size</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hemagglutinin glycoprotein gene</td>
<td>1132bp</td>
</tr>
</tbody>
</table>

A total of 5 µl of cDNAs were added to new twenty micro liter of Master mix contain Taq PCR Master Mix Qiagen/germany contains Taq DNA Polymerase, the exclusive QIAGEN PCR Buffer that reduces the necessity for optimizing process, and dNTPs, and 0.5 µm of degenerate primers, The reaction was done in a Thermal cycler system (Mygene Bioneer) using the following protocol: 95°C for 5 minutes followed by 35 cycles consisted of 94°C for 35 second, 57°C for 45 second and 72°C for 35°C second as well as final extension 72°C for 5 minutes, The products were examined by agarosegel electrophoresis on a 1.5% gel under UV illumination (23-32).

**DNA sequencing method and Data analysis:** Genetic sequencing of Haemagglutinin glycoprotein gene by using analysis of phylogenetic relationship and study level of alignment by mega multiple sequence software alignment programs a product was purified from the gel by using (QIA quick Gel Extraction/Qiagen). The purified PCR product was sent to Korea for high quality DNA Sequencing service by Macrogen providing techniques (https://dna.macrogen.com/eng/support/ces/guide/ces_sample_submission.jsp). The nucleotides’ Sequences were truncated and aligned at both ends using ApE software (A plasmid editor Version 2.0.51); therefore the sequences majority were started and ended at the homologous nucleotide positions. The sequences target was submitted to BLAST (http://www.blast.ncbi.nlm.nih.gov) (Zhang et al., 2000), the nucleotides with diversity index as well as the Euclidean distances calculated were uploaded to the UPGMA (clustering) tree and the Maximum Parsimony phylogenetic tree by using the software MEGA 6 (Molecular Evolutionary Genetics Analysis Version 6.0),
Results and Discussion

Avian influenza is a very contagious viral disease among poultry flocks; the results showed that chicken were infected with highly pathogenic avian influenza by note systemic disease with multiple organ failure, we found lesion of cyanosis and edema of the head, comb wattles (figure 1) and red discoloration of feet and shanks due to subcutaneous ecchymotic hemorrhagic (figure 2). In chicken, medical marks reveal the virus duplication and harm to numerous visceral structures and circulatory, nervous systems and integument. Precisemedical appearances hang on the level of injury and which structures or organ systems are affected. In the severe stage, the results found clear clinical signs other than listlessness, closer observation of 3 obtaining chicken has discovered a reduced activity, decrease sensitivity to stimuli, reduction in “in-house” noise, dehydration, and decreased feed and water intake that rapidly progressed to severe listlessness and death\(^{(12)}\) figure 1.

Figure 1: head of infected bird suffer from conjunctivitis with congested comb and wattles (cyanosis)

Figure 2: subcutaneous ecchymotic hemorrhagic of legs
The medical signs of disease are particularly flexible and depend on other aspects including host species, age, sex, concurrent infections, acquired immunity and environmental factors\(^8\). The prevalence of H5N8 virus were revealed as 15% (3 out of 20) suspected viral samples in oropharyngeal swabs in different unorganized chicken farm field by using RT-PCR assays through amplification and visualization on agarose gel electrophoresis 1132 bp in length of HA glycoprotein gene figure 3.

![Agarose gel under UV light showing RT-PCR product analysis of hemagglutinin gene in avian influenza virus H5N8 isolates.](image)

Figure (3): Agarose gel under UV light that shows the RT-PCR product analysis of hemagglutinin gene in avian influenza virus H5N8 isolates. M: marker (range between 100 to 2000bp), lane (1, 3 and 5) wells showed positive results of avian influenza virus strain.

The Iraqi viral isolates shared features characteristic for recent HPAI virus H5N8 isolates, the genomic sequences of 3 isolates avian influenza strains were verified by dual sets of degenerate primers, two of them have shared 100% no identity with linear genomic product 1130 bp in length figure 1, except one of strain have different in some nucleotides from two previous strain, the three sequencing results in this study have been transduced to the gene bank database under the accession number MN689674.1 and MN658854.1, a neighbor-joining phylogenetic tree based on alignment of the deduced amino acid sequences of the H5 Haemagglutinating showed that 3 isolates iniraq country has the same multiple basic amino acids at the connecting peptides of cleavage site between HA1 and HA2 (PLREKRRKR\(\uparrow\)GLF) with other some recent strain isolates of different geographical distribution cities in Asian, European and American group, on this basis, it was considered that those strain high pathogenic avian influenza virus\(^13\) figure 4. Interestingly, Phylogenetic analyses of HA gene fragments from three strain indicated that most of the sequences obtaining from distinct geographic regions of world were closely related and cluster in to distinct branches based on geographic origins, the current study noted that two sequence obtaining are separated by a distinct strain originated from Iran have accession number KY701529.1 figure (5)\(^14\), the current study was limited to used reverse transcriptase Real time PCR and sequences analysis of Avian Influenza virus, otherwise, there are many method should be consider to confirm this strain by epidemiologic, Immunological results by hemagglutination-inhibition (HI) test, where the amount of antibody titers can be detected by using inhibition activity over the agar gel immunodiffusion (AGID) and enzyme-linked immunosorbent assays (antibody detection ELISA tests)\(^15,16\). Otherwise, the
incidence of AI virus can also be definite by the use of reverse transcription polymerase chain reaction (RT – PCR) or by the examination of a commercially offered immunoassay kit particular for type A influenza, e.g. Directigen TM Flu A(17) or Flu Detect®18, 23.

The phylogenic of H5N8 has been making Homology sequence identity by userRNA gene according to NCBI-BLAST site show table (2) highly sensitivity to accuracy of molecular detection. Analysis of Phylogenetic tree has done depend on the clone Hemagglutinylglycoprotein, a that used for final detection of H5N8 draw a tree by Phylogenetic analysis of Hemagglutinin in glycoprotein gene sequences has become the principal method for knowing avian influenzaphylogeny. Ourresultshowthe phylogenetic tree has done according to these strains isolates figure (4), the evolution histories of H5 N8 were contingent using the Neighbor-Joining method (20).

Our results were found that Avian influenza H5 N8 in the polygenetic tree diagram with an accession number (MN658854.1), a species identified in layer, was the next-highest match at 100% homology with our sequence21, 23.

Finally, The host species; the geographical factors and environmental conditions are main causes to formed contract values pheromones. We also found Avian influenza H5 N8 genomic sequences showed identical with other species sequences that isolates according to the geographical regions, the present study was found identical nucleotides of Avian influenza H5(21).
Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the College of Veterinary Medicine and all experiments were carried out in accordance with approved guidelines.

Abstract

Objective of Study: To assessment of nurse-midwives’ knowledge and performance concerning with post-abortion Care.

Methodology: A cross sectional descriptive analysis of (50) nurse midwives of this category of maternity nurse midwives was conducted in separate units of the Bint Al-Huda hospital between 19 January 2020 and 30 April 2020. The questionnaire’s validity and reliability was calculated through a pilot test. Due to the condition in the nation and the governorate, the emergence of the Corona epidemic and the implementation of curfews, the questionnaire was submitted electronically and the questionnaire was completed by the nurses and midwives, data was processed using the SPSS edition (20).

Results: The test showed that 22% of the test sampler replied correctly to Encourage the client to clear the toilet, 44% replied correctly to isolation of infected patients, 20% of the study sample responded correctly to the importance of hand washing, 35% responded correctly to Assess vaginal bleeding, 25% of the research sample responded correctly in, In terms of emotional assistance, 30 percent responded correctly, 19 percent of the research sample replied with right Test vital signs. 38 percent of them correctly replied with regard to the patient’s medical profile, 40 percent of the test group correctly replied with regard to Perineum care.

Keywords: Assessment, Nurse, Midwives’, Knowledge, Performance, Post-abortion, Care.

Introduction

Miscarriage is a common pregnancy failure happening in a number of women around the world. According to the American College of Obstetricians and Gynecologists¹, the most frequent cause of pregnancy loss can be encountered by around one in four women in the United States. A miscarriage or spontaneous abortion is generally described in the United States as a spontaneous loss of a fetus before the 20th week of pregnancy, about half of all fertilized eggs are believed to be spontaneously lost before a woman knows that she is pregnant, approximately 15-20% of recorded pregnancies result in miscarriage, with 80 per cent of miscarriages usually occurring before the 12th week of pregnancy². For women of reproductive age, pregnancy can be the realization of a dream or an unexpected occurrence throughout the life of a mother, however for every individual, all pregnancy and eventual miscarriage are extremely emotional. When a woman prepares to becoming pregnant and is preparing for the physiological and emotional changes that come with pregnancy, the usual course of pregnancy ends abruptly with a miscarriage. The actual loss of pregnancy can impact women in many physiological and emotional ways, and miscarriage can often influence relationships with husbands, families and friends, which also increases emotional stress related to the woman’s condition; Many variables can induce early pregnancy miscarriage and it is impossible to say for certain what induces a particular miscarriage, one or more complications of the pregnancy may be reported³. Such unregulated diabetes or uterine fibroid in significant percentage of early miscarriage in mom’s medical condition in some cases. Sporadic miscarriage is the most common early-
pregnancy complication. A less frequent phenomenon are two to three consecutive pregnancy deaths. Sporadic miscarriages are considered mainly to be a failure of faulty embryos to reach viability; repeated miscarriages are suspected of having multiple etiologies, including paternal chromosomal abnormalities, maternal thrombophilia disorders, and numerous endocrine disorders, but none of these conditions are unique to frequent miscarriages or are often associated with recurring early loss of pregnancy. Miscarriage is one of the major complications of pregnancy, causing a substantial incidence of world morbidity and mortality, estimated at 5-15 per cent of births. Slava et al. (2015), reported by the World Health Organization (WHO) at 21.6 million unwanted abortions worldwide in 2010. The rate of miscarriages is approximately 10% to 20%, while rates for all births are approximately 30% to 50%. About 5% of women have two miscarriages in a row (WHO 2010), up to 20% of pregnancies end in accidental miscarriages before 20 weeks of gestation, 80% of these arise before 12 weeks of gestation. Around 20% of abortions in the United States result in pregnancy which may result in persistent pain, grief, anxiety which signs of difficult life towards the end of pregnancy and require psychosocial assistance. WHO estimates that miscarriage happens in developed countries up to 20 per cent of surgical births, which is equal to around 14,000 miscarriages a year in Ireland. Traditionally, the majority of women who have undergone routine uterine surgery. The prevalence of miscarriage increases markedly with the parents age. Female pregnancies less than twenty-five years are 40 percent less likely than female pregnancies 25-29 years of age to result in miscarriage, 75 percent of pregnancy will end in miscarriage. Around 10% of miscarriages happen in developing countries, 35.5 percent of developed countries ‘miscarriages and 26.8 percent of Asian countries’ miscarriages, child miscarriages “(WHO 2015).

Methodology

Design of the Study: A cross sectional descriptive study of (50) nurse midwives’ such maternity nurse midwives were distributed between 19 January 2020 and 30 April 2020 in separate units of the Bint Al-Huda hospital.

Settings of the Study: The present study is conducted in Thi-Qar Governorate; Bint Al-Huda Teaching Hospital in three departments which includes: maternal words, emergency words, neonate words and labor room during morning, evening and night shift.

Sample of the Study: Which Include:

Inclusion Criteria are: A purposive” Non-probability” sample of (35) nurse-midwives’. These nurse-midwives’, who work in maternity, were distributed in different unit of Bint AlHuda hospital units.

Instrument that Used for Data Collection:
The aim of the electronic structure questionnaire was to collect the data required for this analysis, first the sociodemographic data of the nurse midwives, such as age, employment, experience, second part awareness of post-abortion treatment and third part performance of nurse midwives on post-abortion treatment. An observational check list was created to test the efficiency of the participant.

Data Collection: Collected data by using electronic instrument because of the situation in the country and the governorate, due to the outbreak of the Corona epidemic and the imposition of curfews, the form was sent electronically and the form was filled in by the nurses and midwives, was analyzed using the Statistical Package of Social Sciences (SPSS) program version22 simple. They constitute the available sample during the study period frequencies and percentage tables were used to presents the results.
Results

Figure (1): Nurse-Midwives Age

Figure (1) revealed that the higher percentage (43%) of study sample were at age group 20-25-years with mean and SD (2.14±7.969), while the lowest percentage for those who age 41-45-years were (n = 3; 6.0%).

Figure (2): Nurses -midwives Social status

Figure (2) shows that more than a half (n = 26; 52.0%) are married of study sample, while the lowest percentage is (n = 1; 2.0%) who is separated

Table findings (4) explicitly demonstrate that, during data collection times, services are available in the health center and all selected hospitals. All services have been shown to be accessible at more than three-fourth of the health facilities surveyed. For eg, place for hand washing in health facilities (46 percent), soap in (44 percent), antiseptic solutions in (40 percent), recovery room in (35 percent), masks in (33 percent), thermometers in (48 percent), sphygmanometers in (70 percent) and disposable gloves in health facilities (69 percent).

### Discussion

Miscarriage is: one of the common complications of pregnancy is a major problem in developing world as an important public health problem in the world endangers women’s lives by exposing them to complications which may have an impact on their health in a bio-psychosocial context. By living this situation, the woman experiences beyond the physical pain, manifested by signs and symptoms presented an existential pain for the loss of pregnancy. And led to increased mortality and morbidity death. The all findings of this study revealed the higher percentage (43%) of study sample were at age group 20-25-years with mean and SD (2.14±7.969), while the lowest percentage for those who age 41-45-years were (n = 3; 6.0%), more than a half (n = 26; 52.0%) are married of study sample, while the lowest percentage is (n = 1; 2.0%) who is separated, more than a one third (n = 18; 36.0%) of study sample had 10 years or more, while the lowest percentage (n = 7; 14.0%) had one years of experiences.). Fifty per cent said they did not undergo any post-miscarriage support program. This means that most of them did not receive the training needed to care for women after miscarriage. Results of the current study revealed that reflect that in this study the nurse-midwives performance in post-miscarriage care is done well in isolation of infected patients (44 percent), perineum care (40 percent), bimanual pelvic examination (40 percent), and hemoglobin checking (39 percent), as done by more than two-thirds of nurse-midwives. In other things, the post-miscarriage performance of nurses was not well performed as it is evident in emotional assistance (30 percent) evaluating vaginal bleeding (35 percent), monitoring vital signs (19 percent), instructing clients to clean the bladders (22 percent), handling performance (25 percent), explanation of the patient’s procedure by (38%), and hand washing by (20%). It is clear that the nurses in this sample perform well just three out of ten things of the performance needed for women’s treatment after miscarriage, thus the overall experience is poor in this regard. Gavino (2013) in Canada sought to broaden the perception of nurses’ experience when caring for women undergoing emergency department (ED) miscarriage, analyzed using a concise methodological approach. Also the study revealed explicitly demonstrate that, during data collection times, services are available in the health center and all selected hospitals. All services have been shown to be accessible at more than three-fourth of the health facilities surveyed. For eg, place for hand washing in health facilities (46 percent), soap in (44 percent), antiseptic solutions in (40 percent), recovery room in (35 percent), masks in (33 percent), thermometers in (48 percent), sphygmanometers in (70 percent) and disposable gloves in health facilities (69 percent). According to Neugebauer and Ritsher (2012), miscarriage should be considered a “form of deprivation and not merely an obstetric occurrence.” Nurses identified a deficit in knowledge and training on how to support women’s emotional needs and providing bereavement care, making them inadequately equipped to deal with this challenge.

Abstract

Objective of Study: To determine the causes of low amniotic fluid for pregnant women

Methodology: A descriptive study was carried out on (100) pregnant and post pregnant women had diagnosis with low amniotic fluid in Bint Al-Huda Hospital for the period from (3 March to 11 April 2019). Validity and reliability of questionnaire are determined through pilot study. Descriptive and inferential statistical procedures were used to analyze the data, and the data were collected by using interview technique, constructed questionnaire designed and developed for the purpose of the study.

Results: Results of the study showed that the highest percentage of the study sample were within the age group (20-25 years). And (44%) of the study sample were graduated from secondary school and more than half of the study sample were housewife, and residents in urban areas. 41% of the study sample of the current pregnancy duration were (32-36), the interval between the last pregnancy and current one year to two years, (76%) of the study sample have multigravida and have no history of previous abortion. And that the cause of low amniotic fluid from a medical point is the (35%) due to pregnancy induced hypertension, (25%) of the study sample due to Premature rupture of membranes (PROM) and (20%) of the study sample due to placental problems.

Keywords: Determine, Causes, Low Amniotic Fluid, Pregnant Women.

Introduction

The fluid that collects within the amniotic cavity surrounding the embryo is called amniotic fluid. Hippocrates was the first person to attribute the development of amniotic fluid to fetal urine. Fetal urination is the major source of amniotic fluid, once the fetal kidney function begins at 10 -12 weeks¹. Fetal lung fluid is a minor contributor of amniotic fluid¹. Amniotic fluid volume rises progressively until 32 weeks of gestation. From 32 weeks to term the mean amniotic fluid volume is relatively constant about 600-800 ml. After 40 weeks, there was a gradual decrease in the amount of amniotic fluid volume by about 400 mL in 42 weeks. Amniotic fluid is removed by fetal swallowing. Normal amniotic fluid volume is critical for normal fetal growth and development.¹ Amniotic fluid (AF) is marvelously dynamic milieu constantly in a transformation as pregnancy progresses. A number of nutrients and growth factors present in AF assist growth of fetus, acts as a cushion and antimicrobial properties allow fetal protection.² Low in amniotic fluid amount has been associated with increased risk of intrauterine growth retardation, meconium aspiration syndrome, severe birth asphyxia, low APGAR scores and congenital abnormalities. Low amniotic fluid is also associated with maternal morbidity in the form of increased rates of induction and/or operative interference.³ Low Amniotic fluid is defined as AFI ≤5 cm or less than the 5th percentile. It can occur at any time during pregnancy but is more common during the last trimester. Whenever there is continuation of pregnancy beyond 2 weeks of expected date of delivery, she may be at risk for low amniotic fluid levels since fluid can decrease by half once she reaches 42 weeks gestation Low Amniotic fluid can complicate 12% of pregnancies that continue beyond 41 weeks⁴. It is defined as a single pocket of
amniotic fluid measuring < 2 cm in both vertical and horizontal planes in ultrasound and amniotic fluid index (AFI)\textsuperscript{12} Sometimes it’s difficult to rule out the cause of low Amniotic fluid giving it idiopathic nature\textsuperscript{13} Amniotic fluid forms from the fetal urine so, obstruction in fetal urinary tract can lead to oligohydramnios. Low amniotic fluid levels during the first or second trimester may associates with some fetal abnormalities\textsuperscript{20} Several factors like leaky or ruptured amniotic membranes, fetal abnormalities, genetic factors, maternal illness, nutrition status, carrying twins, NSAIDs like indomethacin and certain ACE (angiotensin converting enzyme) inhibitors may play a crucial role. Early detection of oligohydramnios and its management may help in reduction of perinatal morbidity and mortality one side and decreased caesarean deliveries on the other side.\textsuperscript{3} Low Amniotic fluid may inhibit these processes and can lead to fetal deformation, umbilical cord compression and death.\textsuperscript{10} In contrast, a study conducted at University of Milano-Bicocca, Monza, Italy among 3050 women who underwent sonographic assessments of AFI after 40.0 weeks showed low Amniotic fluid of 11.18%.

Methodology

Design of the Study: A descriptive study was carried out on (100) pregnant and post pregnant women had diagnosis with low amniotic fluid in Bint Al-Huda Hospital for the period from (3 March to 11 April 2019).

Settings of the Study: The present study is conducted in Thi-Qar Governorate; Bint Al-Huda Teaching Hospital.

Sample of the study: which include:

1. Inclusion Criteria are: A purposive” Non-probability” sample of (100) pregnant women and post pregnant women had diagnosis with low amniotic fluid, were distributed in different unit of Bint AL Huda hospital units certain criteria are included for choosing the, and they are:

Pregnant women hospitalized and hadlow amniotic fluid (27- 40) wk, for treatment and monitoring baby (prenatal care).

a. Delivered woman who receiving care both for mother and neonatal postnatal care).

2. Exclusion Criteria are: The pregnant women without diagnosis with low amniotic fluid.

Instrument that Used for Data Collection:

The study instrument from consisted three parts according to the study’s objectives which were distributed through the following:

Part I: Sociodemographic data: Which include the following variables (age, Wife Education level, and Wife Employment, Residency and Socioeconomic status from family point of view?).

Part II: Reproductive characteristics: Which are related to(Current pregnancy duration (weeks), Interval between last pregnancy and current pregnancy(months), Gravidity, Number of live birth, Number of abortion).

Part III: Questions Related low amniotic fluid Causes:

1. Medical diagnosis of current low amniotic fluid

*F = Frequency, % percentage
Table (1) shows that highest percentage 41% of the study sample of the current pregnancy duration were (32-36) weeks while the 10% lowest percentages of them were, (28-29) weeks. Regarding the interval between last pregnancy and current pregnancy the highest percentage (40%) of the study sample have interval period between last and current pregnancy for one year to two years, while the lowest percentage (4%) of them have (>=36) month. Regarding the gravidity the highest percentages (76%) of the study sample have multigravida, while the lowest percentages (24%) of them have primigravida. Concerning the number of live birth the highest percentage (88%) of the study sample were more than one, while the lowest percentages (12%) of them were one. Regarding the number of Abortion, the highest percentage (69%) of the study sample have no history of previous abortion, while the lowest percentage (4%) of them have three and more time abortion.

*F = Frequency, % percentage

Table (2) shows that the highest percentage (35%) of the study sample had low amniotic fluid due to pregnancy induced hypertension, (25%) of the study sample due to Premature rupture of membranes (PROM) and (20%) of the study sample due to placental problems, while the lowest percentage (2%) of them were due to birth defects such as a kidney or urinary tract problem and (8%) of them were due to diabetes.

**Discussion**

**Age of the study sample:** Table (1) shows the highest percentage (56%) of the study sample is within age group (20-25) years, while the lowest percentages (10%) of them is less than >30 years. This result agrees with Radha (2017). Who reports that 45.9% of the respondents were in the age group of 21-25 years and 6.8% were above 30 years the maternal age over 30 years. Comparable with the finding of Nazlima et al., (2015) where 46.15% of pregnant women were between 21-25 years age group. Our findings are also in accordance with Vidyadhar et al., (2016) where 78% cases were in the age group of 20-29 years. This result agrees with Sayeda & Hajira (2015). Who reports that67% of patients were in 20-25 years age group and 23% patients were in 26-30 years age group. Thus, maximum patients were in 20-30 years age group.

**Education Level:** The wife education at level. The highest percentages (44%) of the study sample were graduated from secondary school, and the lower percentages (10%) of them were graduated from Intermediate school.

**Employment:** The study results reveal that the wife employment highest percentage (67%) of the study sample are housewives, while the lowest percentage (33%) of them are Government employee as show in table (1). These findings are is consistent with Grote, et al., (2017), who stated that women’s work during pregnancy may have an impact on their health and on the validity of the fetus, especially the risk of low birth weight (LBW) and preterm labor.

**Residency:** The highest percentages (75%) of the study sample are resident of was urban area, while (25%) of them live in rural area. as shown in table (1). These findings disagree with Kambala, et al., (2015), who reported that (60.4%) of pregnant women with low amniotic fluid live in rural areas, because the higher parity is more often encountered in the rural population.

**Current pregnancy duration (weeks):** The study result revealed that highest percentage 41% of the study sample of the current pregnancy duration were (32-36) weeks while the 10% lowest percentages of them were, (28-29) weeks.

**Interval between last pregnancy and current pregnancy:** The study result reveals that the pregnancy interval between last pregnancy and current pregnancy the highest percentage (40%) of the study sample have interval period between last and current pregnancy for one year to two years, while the lowest percentage (4%) of them have (>=36) month, as shown in table (2). This finding is in accordance with the study of Madhavi & Rao, (2015) where incidence of low amniotic fluid was 40% high among post term pregnancies (40->42 weeks). Mohamad, (2015) revealed...
that women in the low amniotic fluid group were significantly (p<0.002), less likely to have lower mean weeks of gestation compared to those in the control group (38.9±1.3 vs. 39.4 ±0.9 respectively)

**Gravidity:** The study finds that the highest percentages (76%) of the study sample have multigravida, while the lowest percentages (24%) of them have primigravida, as shown in table (2). This result disagrees with Petrozella et al., (2016), the incidence of oligohydramnios was 60% in primigravida.

**Number of live birth:** The study finds that the highest percentages (88%) of the study sample were more than one, while the lowest percentages (12%) of them were one as shown in table (2). Bahar, et al. (2017) reported that women with parity greater than four and nearly nine times have more chance of low amniotic fluid than those with of less parity.

**Number of abortion:** The highest percentage (69%) of the study sample have no history of previous abortion, while the lowest percentage (4%) of them have three and more time abortion, as shown in table (2). It is estimated that each year, worldwide 40- 70 per 1000 women of reproductive age have an abortion and that between one- fifth and one – third of all pregnancies are terminated (Royston and Armstrong, 2015).

**Medical causes of Low amniotic fluid:** The highest percentage (35%) of the study sample had low amniotic fluid due to pregnancy induced hypertension, (25%) of the study sample due to Premature rupture of membranes (PROM) and (20%) of the study sample due to placental problems, while the lowest percentage (2%) of them were due to birth defects such as a kidney or urinary tract problem and (8%) of them were due to diabetes. Jagatia, et al., (2015) reported that most common cause of low amniotic fluid is idiopathic (52%). Second commonest cause is PIH (25%). Operative morbidity is highest in PIH (60%). Sharma et al., (2016) reported 71% of oligohydramnios cases were associated with antenatal complications such as PIH 39%, IU GR 29%, PROM 15%, Abruptio placenta 15%, compared to 36% in control group. Bansa et al., (2017) reported 21% PIH, 55% anemia. Reddy et al., (2018) reported Anemia in 42.67%, PIH in 25.33%. Vidyasagar, et al., (2017) reported PIH in 17.07%, IU GR in 46.34% in study group. Bhat et al., (2015) reported PIH in 33.3%, post-datism in 50%.

Level of Some Biomarkers of Bone Remodeling in Treated Multiple Myeloma Patients and Compared with New Diagnostic Multiple Myeloma Patients

Shaymaa Obaid Abdullah¹, Hussein Jasim Al-Harbi²

¹Assist. Prof., Department of Biology, College of Science for women, University of Babylon, Iraq,
²Prof. Dr., Department of Biology, College of Science, University of Babylon, Iraq

Abstract

This study was conducted to evaluate the role of some biomarkers of bone remodeling and osteoclast activation/function in treated myeloma patients and to compare results with new diagnostic multiple myeloma (MM) patients who did not receive any treatment during the period from March (2019) to end November (2019). The study involved measuring serum level of RANKL, Osteoprotegerin (OPG), RANKL/OPG ratio, Interleukin 6 (IL-6), C-terminal cross-linking telopeptide of type I collagen (CTX type –I), tartrate-resistant acid phosphatase isoform-5b (TRACP-5b) as markers of bone resorption in 47 treated myeloma patients and the results of these parameters comparing with 13 new diagnosed patients and (30) age- and sex-matched healthy controls groups. The statistical analysis of results showed that the serum level of (RANKL, RANKL/OPG ratio, IL-6, CTX type –I and TRACP-5b) decreased in the treated myeloma patients compared to the new diagnosis patients and the level OPG increased in treated myeloma patients.

The results also showed a significant rise (p≤0.05) serum level of (RANKL, RANKL/OPG ratio, IL-6, CTX type –I and TRACP-5b) and reduce level OPG in myeloma patients (treated and new diagnosis) in general compared to healthy control individuals. In conclusion, RANKL, OPG and IL-6 play significant roles in MM pathophysiology, as regulators of bone turnover The study showed that an increase leads to an increase in bone resorption, and it appears that chemotherapy reduces resorption.

Keywords: Multiple Myeloma, Bone Remodeling, Biomarkers.

Introduction

Multiple myeloma is a type of malignant cancer of plasma cells that normally develops and found in the bone marrow and this disease is part of a group of disorders known as “plasma cell dyscrasias”. Plasma cell are playing important roles in immune system through produce humoral factors which is called antibodies.

A hallmark feature of Multiple myeloma is Myeloma bone disease (MBD); up to 80% of patients present with osteolytic bone lesions (bone disease) at diagnosis and leading to pathophysiological features referred to as skeletal-related events (SREs), which contribute to a reduced quality of life and associated with rise mortality and morbidity.

MBD occurs due to the interactions between malignant plasma cells (MPCs) and cells in the bone marrow microenvironment (BMME), leading to accelerated overall bone loss and the formation of focal osteolytic lesions.

Although the mechanisms responsible for the development of a myeloma bone disease still not clear, several studies have begun highlights on cytokines and growth factors produced by myeloma cells or by the stromal cells of bone. As a result of the interaction between them, leads to an increase in the formation and activity of the osteoclast and adherence of myeloma cells to bone marrow stromal cells hence an increase production of cytokines, Among these cytokine is (RANKL), a member of the tumor necrosis factor (TNF) gene family produce by stromal cells causes activation of the cellular receptor RANK on osteoclasts by its ligand, RANKL, differentiation, proliferation, and survival of osteoclasts is enhanced, osteoclast fusion
and activation is promoted, and osteoclastic apoptosis is suppressed, leading to a dramatic increase of the number and activity of osteoclasts. In addition, production of osteoprotegerin (OPG), a soluble decoy receptor of RANKL produced by marrow stromal cells, is suppressed through the above interactions and has been found to be reduced in patients with MM. Studies in vitro show that IL-6 trans-signaling promotes osteoclastogenesis by increasing RANKL expression in osteoblasts and T cells (Wong et al., 2006) this effect is dependent on the JAK/STAT-3 signaling pathway (Duplomb et al., 2008). IL-6 transsignaling also increases RANKL expression by synovial fibroblasts to support osteoclastogenesis in the inflamed joint., however, under some circumstances IL-6 can actually inhibit osteoclastogenesis from human CD14+ precursors in vitro.

Bio markers of bone turnover, C-terminal cross-linking telopeptide of type I collagen CTX type –I tartrate resistant acid phosphatase isoform 5b (TRACP-5b), provide information on bone dynamics that in turn may reflect myeloma disease activity in bone. Several studies have shown bone markers to be elevated in myeloma patients and reflect the extent of bone disease, while in some of them bone resorption markers correlate with survival. These markers may also be helpful in knowledge respond to bisphosphonate treatment, and monitoring the effectiveness of bisphosphonate therapy in the management of myeloma bone disease.

The purpose of this study was to evaluate serum levels of OPG, RANKL, the ratio sRANKL/OPG, CTX type –I, and (TRACP-5b) at diagnosis and to estimate the effect of treatment on their circulating levels in patients with MM.

**Subjects and Method**

**1. Patients and healthy:** The study subjects comprised of 60 patients suffering from multiple myeloma, 47 patients received drugs of multiple myeloma (28 male and 19 female) and 13 new diagnosis (7 male and 6 female), age (mean ± SD) = 63.28 ±6.68 (ranging from 45 to 80 years). All patients were suffered from MM and were referred to the Hematology Consultation Clinic in each of the teaching hospitals at Baghdad governorate (medical city), Babil governorate (Marjan city) for diagnosis and/or treatment Those MM cases then have been diagnosed by a specialized haematologist. Diagnosis was based on bone marrow aspiration, biopsies reports and other diagnostic criteria included complete blood counts (CBC), serum protein electrophoresis and renal function (urea and creatinine) treated patients received first-line bortezomib- or lenalidomide-based chemotherapy. The healthy group included 30 individual (15 male, 15 female) age (mean± S.D) = (55.96 ± 4.7) (range 45 to 62), not suffering from any disease, served as a control group and this group matched with patient group. All subjects in this study were taken consent before participation in this study.

**2. Biomarkers analysis:** Venous blood samples were drawn from patients and control subjects by using disposable syringes. Five ml of blood was obtained from each subject, pushed slowly into disposable gel containing tubes, allowed to clot at room temperature for 15 minutes and then centrifuged at 3000 rpm for approximately 10-15. minutes, after that sera was obtained and stored at -20˚C until used. Quantitative detection of RANKL, OPG,CTX type-I and IL-6 in serum was done according to the industrial company (Bioassay Technology Laboratory (China), that depended on the technique of the quantitative sandwich enzyme immunoassay (ELISA) and (TRAP – 5b) was assayed in serum according to the industrial company Express Biotech International (USA).that also depended on the technique (ELISA).

**3. Statistical Analysis:** Analysis of data was made by using Statistical Package for Social Science (SPSS) system/version 23 Results expressed as mean ± Standard division S.D . The analysis of variance (ANOVA),the independent sample T- test, and correlate bivariate were used for this purpose.

**Results**

General features and clinical characteristics of patients and healthy controls are reported in Table 1. In a figure(1) shows the results of the statistical analysis of the biomarkers that were included in this work, it was found that there was a significant increase (p≤0.05) in the level RANKL, RANKL/OPG ratio, IL-6 and enzymatic markers (TRACP-5b and CTX- type I) of myeloma patients groups when compared with healthy control individuals. Also the study showed the presence of a significant decrease (p≥0.05) in the level of (OPG) when compared with healthy people. As The results showed the presence difference with statistically indication of the level (enzymatic marker (TRACP-5b) in treated patients when compared with new diagnosed patients While the difference was not significant in, RANKL, RANKL/OPG and CTX type –I.

Discussion

The microenvironment of the bone is the primary facilitator of the myeloma where MM plasma cells (PCs) typically reside in and spread through the hematopoietic bone marrow. As result accumulation of myeloma cells in the bone marrow is increased osteoclast activity resulting in lytic bone disease in 80% of patients (Yaccoby et al., 2016). In normal physiological conditions, osteoblasts perform essential role in recruitment of osteoclast precursors and induction of osteoclast formation via production of osteoclastogenic cytokines and chemokines (Kohli and Kohli, 2016). Myeloma bone disease patients is characterized by reduced number of osteoblasts on bone surfaces adjacent to myeloma cells (Terpos et al., 2019), this explain that myeloma cells may play a direct role in increasing osteoclast activity through production of key osteoclastogenic factors. While recent studies shown that myeloma plasma cell stimulate indirectly the formation of osteoclast through disruption of the balance of osteoprotegerin and the receptor activator of nuclear factor-B ligand (RANKL) in the bone marrow (Raji et al., 2019), other studies suggested that myeloma cells express RANKL or macrophage inflammatory protein-1 and can directly induce differentiation of OC osteoclast progenitors into osteoclast 7. This may explain how myeloma cells induce osteoclastogenesis in bone areas highly infiltrated by myeloma cells with reduced number of osteogenic cells. However, in our work we test level of RANKL, OPG, TRACP-5b and CTX type –I as markers of bone resorption To study the relationship between myeloma cells and osteoclast in myeloma patients and knowledge effect the treatment on these biomarkers, we established that levels of RANKL rise significantly in myeloma patient when compared with healthy control groups as result of binding RANKL its signaling receptor RANK - a tumor necrosis factor receptor (TNFR) family member - on the surface of osteoclast precursor cells, leading to the fusion of these cells into multinucleated cells which then differentiate into mature osteoclasts So it plays an important role in skeletal-related events in patients multiple myeloma 8. Many Previous studies have demonstrated that the (IL-6)/signal transducer and activator of transcription 3 (STAT3) plays a central role in osseous metabolism and remodeling by signaling pathway in osteoclasts and osteoblasts 9, our results shown elevated in IL-6 concentration in MM patients this perhaps this cytokine implicated in bone metabolism and is principally secreted by myeloid precursor cells and myeloma cell as inflammatory factors in addition IL-6 enhances osteoclast differentiation, whereas it sustains MM cell survival.

On the other hand, the results of the current study showed a clear decrease in the level of OPG in myeloma patients compared with the healthy group, this finding, agreeing with its mention Seidel and his colleagues 2013, that OPG binds to heparan sulfate chains of syndecan-1 expressed on the surface of myeloma cells. Syndecan-1 is shown to be involved in internalization of heparan sulfate-binding molecules, but whether OPG is eliminated by this route is unknown. In later stages
of the disease, bone formation and osteoblast function are impaired, (Bataille et al, 1989) which gives an explanation to the reduced OPG levels in patients with overt bone destruction. While there was an insignificant increase in the treated myeloma patients group compared with the new diagnosed myeloma patients This is due to the role bisphosphonates impair osteoclastogenesis and disrupt osteoclast activity.

To have a better picture of bone formation and bone destruction in MM patients, we checked the levels of serum CTX-I and TRACP-5b a marker of bone resorption that has been demonstrated useful to evaluate osteoclast activity in MM patients 5 In our work level of serum CTX –I and TRACP-5b of MM patients are significantly elevated compared with healthy control groups, despite the reduction of serum CTX levels after bortezomib treatment when compared with new diagnosis myeloma patients. This observation correspond into Giuliani et al (2007) 12 indicate that bortezomib increases osteoblast differentiation in human mesenchymal cells without affecting the number of osteoblast progenitors and the viability of mature osteoblasts. In vivo and in vitro observations support the hypothesis that both direct and indirect effects on bone formation process could occur during bortezomib treatment.

Antibacterial Efficacy of Biosynthetic Zinc Oxide Nanoparticles by Lactobacillus Plantarum Combined with Poly-β-hydroxybutyrate Against Pathogenic Bacteria

Ali Shannan Atewy Abood Alaredhey¹, Qasim Najim Thewaini², Wejdan Ridha Taj-Aldeen³

¹M.Sc., Student, Biotechnology Department-College of Biotechnology/University of Al-Qasim Green, ²Prof. Dr., Biotechnology Department-College of Biotechnology/University of Al-Qasim Green, ³Prof. Dr., Biology Dep.-College of Science/University of Babylon

Abstract

The good capability of zinc-tolerant probiotic of Lactobacillus plantarum tolerating high concentrations of Zinc +2 and producing Zinc Oxide Nanoparticles highlights the unique characteristics of these bacteria as a natural microbial cell nano-factory for a more efficient and environmentally friendly process of biosynthesis of these nanoparticles. The morphological and structural properties of Zinc Oxide Nanoparticles were determined by X-ray diffraction, Atomic Force Microscope and Field Emission Scanning Electron Microscope showed that the synthesized nanoparticles were crystalline, moderately stable, roughly spherical, hexonal in shape and pure.

We examined the antibacterial activity of the Zinc Oxide Nanoparticles and Zinc Oxide Nanoparticles/Poly-β-hydroxybutyrate bionanocomposite on some pathogenic bacteria. It is clear in this study that Zinc Oxide Nanoparticles/Poly-β-hydroxybutyrate bionanocomposite has stronger inhibitory effect on pathogenic bacteria compared with Zinc Oxide Nanoparticles only because the bionanocomposites exhibited reduced water uptake and superior gas as well as vapour barrier properties and causes increasing damage of the pathogenic bacteria.

Keywords: ZnONPs, Lactobacillus plantarum, PHB, antibacterial efficacy and bionanocomposite.

Introduction

Zinc oxide nanoparticles have gained worldwide interest as multifunctional nanoparticles because of their distinctive features of being versatile semi-conductors and piezoelectric properties¹. Microbial metal nanoparticles synthesis has recently been widely used due to their low cost, biocompatibility and eco-friendliness². ZnO has many important features like chemical and physical stability, high catalysis and efficient antibacterial activity³. Symbiotic microorganisms may use NPs as safe source. Microbial nanoparticles synthesis has more benefits than other chemical and physical method. Nanoparticles have many applications in medicine¹. In addition, the bacterial nanoparticles may also be used for controlling human bacterial pathogens⁴. Among the micro-organisms, lactic acid bacteria (LAB) receive substantial attention because of their safe handling and food-grade status, which are “generally recognized as safe” (GRAS) in the production and preservation of food⁵. A low-cost, unreported and easy method for the biosynthesis of ZnONPs by using reproducible bacteria, Lactobacillus plantarum as an eco-friendly reduction and capping agent is described in our current study. Lactobacillus plantarum is a non-pathogenic, gram-positive, facultative anaerobic bacteria and is the largest of all lactic acid bacteria in its genome. Lactobacillus plantarum has a negative electrokinetic potential; which attracts cations easily and this step works as a trigger for the ZnONPs biosynthesis⁶. Poly-β-hydroxybutyrate is a biodegradable thermoplastic polyester that can be used in medicine, agriculture, etc.. Because of its non-toxic, biodegradable and biocompatible nature, poly-3-hydroxybutyrate (PHB) is considered as an ideal drug carriers⁷. Using solution casting technique,
bionanocomposites based on PHB incorporating different content of ZnONPs were prepared. The nanoparticles are distributed without the need for surfactants or binding agents within the biopolymer⁸.

**Methodology**

**Bacterial Isolate:** *Lactobacillus Plantarum* was selected as a biological model for the synthesis of ZnONPs because it is more efficient for biosynthesis of ZnONPs. We have obtained this isolate from the dairy products which is stored in the advanced Microbiology Lab./University of Babylon. We did culture to the isolate for 24hr. on MRS agar at 38°C, as well as it is diagnosed by Vitek2 system.

**Zinc Oxide Nanoparticles’ Biosynthesis by *Lactobacillus plantarum***: The pure culture of *Lactobacillus plantarum* was inoculated in the flask containing MRS broth that sterilized by autoclave and incubated at 37° C for 24hr. at 100rpm. After the incubation period, we did Centrifuge 5000 rpm. for 25 min. then we took the supernatant. The pH of the supernatant was regulated by 0.4 M NaOH to delay the transformation process (the pH of the supernatant is acidic 4.7 to be neutral we added the NaOH to reach pH 7 to eliminate the influence of organic acids). 28.8 g. 0.1 M ZnSO₄·7H₂O dissolved in 1000 ml of distilled water, was added to 250 ml of the supernatant and then heated by a water bath of up to 85 ° C for 5-10 min. A white precipitate appears at the bottom of the flask indicates the process of transformation. Then the flask was Incubate at 37 ° C for 12 hr., all the particles are accumulated at the bottom of the flask. In order to separate the white precipitate, the product was Centrifuged at 6000 rpm for 20 min. and washed with D.W. then the process was repeated 3 times to get pure products followed by drying at 60 ° C in a hot air oven for 4 hr⁹.

The instruments that used in determining the properties of ZnO nanoparticles biosynthetic by *lactobacillus plantarum* :-

- X-ray diffraction analysis (XRD).
- Atomic Force Microscope (AFM).

**Preparation of Zinc Oxide Nanoparticles**

**Reinforced Poly-β-hydroxybutyrate Films:** 0.3gm. Poly-β hydroxybutyrate (manufactured by SIGMA-ALDRICH company/Germany) was put into the ZnONPs mixed solution 0.18 gram of ZnONPs after that putting them into scuttle bottle containing 30 ml. chloroform then stirring by ultrasonic bath device for 30 min. continuing the process until achieving the homogeneous solution and verified the homogeneity by physical observation. Then the films were poured into glass petri dish at room temperature 30 °C and left for 48 hrs. for evaporation of chloroform [10]. In this study we use different weights of PHB (0.1, 0.2, 0.3 and 0.03gm.) while using 0.18 and 0.3 gm. of ZnONPs in the preparation of ZnONPs reinforced P(βHB) Films.

**Antibacterial efficacy of ZnONP and PHB-ZnONPs bionanocomposite.**

**Disc Diffusion Method.**

This method was accomplish on Muller Hinton media as follows:

1. Concentrations were taken from each bacterial isolates and compared to McFarland solution to get the right concentration for each of them.
2. The appropriate concentration 0.1 ml of each bacterial isolates were added to dishes containing Muller Hinton agar is spread on the surface of the dish-by spreader and left the dishes for an hour.
3. PHB-ZnONPs bionanocomposites were made (3.2.11) in cork borers each 6 mm diameter. it was equal distance between the film and well. Table 1 shows the concentrations of ZnONPs and ZnONPs/PHB used in the present study.

4. The nanoparticles were dissolved in distal water to get a final concentrations, and dunk ZnO NPs with filter paper.
5. After incubation at 37°C for 24 hrs., the PHB-ZnO nanocomposite film and nanoparticles inhibition zones were measured by a ruler.

Results and Discussion

Zinc Oxide Nanoparticles biosynthesis by Lactobacillus plantarum: The biosynthesis of nanoparticles from Lactobacillus plantarum has been confirmed by observing a change in solution color during the synthesis of ZnONPs that explains the reduction of ZnO into ZnONPs during exposure to bacterial extract followed by a change in color from brown to yellow during 24hr., this result was compatible with the study done by 12.

The deposition of the white color at the bottom of the flask by combining Lactobacillus plantarum with ZnSO₄·7H₂O, is agreed with the results reported through 13-15. Lactobacillus plantarum has a major role in the production of Zn-ONPs. It is possibly because this bacteria possesses negative electro-kinetic potential which attracts the cations readily and triggers the synthesis of nanoparticles. Furthermore, Lactobacillus has the capacity to grow even in the presence of oxygen allowing more capability of metabolic growth. In addition, the presence of glucose in the MRS media used for Zn-ONPs synthesis tends to lower the potential for oxidation-reduction. Energy producing glucose (which regulates the value of rH₂), medium pH ionic status and complete oxidation reduction potential (rH2) partially controlled by sodium hydroxide, all of these factors cumulatively negotiate ZnONPs synthesis in the presence of Lactobacillus 9, the final stage of ZnONPs biosynthesis by Lactobacillus plantarum after the process of drying these nanoparticles in the oven.

Morphological & Structural properties of ZnONPs biosynthesized by Lactobacillus plantarum: Moderately stable ZnONPs have been synthesized using Lactobacillus plantarum. The effect of reaction time plays a vital role in the morphology of nanoparticles. The Field Emission Scanning Electron Microscopy image of the ZnONPs have shown spherical clusters of the nanoparticles as in figure 1 shows the diameters of ZnONPs (21.75 nm, 24.13 nm, 25.77 nm), indicating the diameters of NPs were accurate and appropriate as ZnONPs.

X-Ray diffraction analysis (hexagonal phase) shows that the synthesized nanoparticles were crystalline and pure in nature. The peaks at 2θ = 32.01, 45.28, 56.41, 66.12 and 75.03 were respectation lines of spherical Zn-ONPs respectively, figure 1. The average particle size of ZnONP was determined by applying the Scherrer equation. The maximum diameter measured for particles is 5.5 nm., this result was agreed with the results reported through 16,17.

Atomic Force Microscope analysis of synthesized ZnONPs was carried out to assess their morphology and size range. The 2-D and 3-D images of AFM, figure 3, showed that most of the nanoparticles are spherical in shape and some of the agglomerations were present in the background of the nanoparticles. AFM analyses revealed that obtained nanoparticles were in a hexagonal, polydispersed, nearly spherical in shape, these results were compatible with the study of 18.

Figure 1. X-Ray diffraction (XRD) Microscopy (FESEM)
The antimicrobial efficacy was due to cell membrane damage, leading to cell contents leakage and cell death. While the exact mechanism of action is still unclear, the generation of H$_2$O$_2$ (a potent oxidizing agent harmful to the cells of living organisms) from the surface of Zinc Oxide has been considered as the main factor of Zn-O reinforced nanocomposites ‘antibacterial efficacy’$^{19}$. Zn NPs or ZnONPs of extremely low concentrations can’t cause toxicity in human systems$^{20}$. The antibacterial efficacy of Zn-ONPs and bionanocomposites Zn-ONPs/PHB were tested using the method of disc diffusion agar, Tables 3 and 4. The existence of an inhibition zone clearly
indicated that ZnONPs had an antibacterial effect. As indicated in the study of 21 it was also observed in this study that the growth inhibition was also increased by increasing the concentration of ZnONPs or Zn-ONPs/PHB in the disc. Depending on the type of pathogenic bacteria and concentrations of ZnONPs or ZnONPs/PHB bionanocomposites the inhibition zone was different. In this study, four concentrations of ZnONPs and Zn-ONPs/PHB bionanocomposites were used as in tables 3 and 4 indicate that increasing concentrations of ZnONPs and ZnONPs/PHB bionanocomposites leads to increase growth inhibition of the pathogenic bacteria, but ZnONPs/PHB bionanocomposites has more activity in the inhibitory effect for these pathogenic bacteria, this analysis agreement with previous study 22.

Also figure 2 explains the difference in the efficiency of the types of inhibitors for pathogenic bacteria is indicating that the efficiency of ZnONPs/PHB has stronger inhibition because the bionanocomposites exhibited reduced water uptake and superior gas as well as vapour barrier properties compared to ZnONPs and causes increasing damage to Staph. aureus.

**Conclusion**

Our current study for ZnONPS biosynthetic by Lactobacillus Plantarum and ZnONPs/PHB bionanocomposite, and using these them as antibiotics give us wonderful results, low complications, very low cost and low resistance in comparison with ordinary antibiotics. This means that ZnONPS and ZnONPS/PHB have high antibacterial efficacy but PHB/ZnONPs bionano-composites were more effective than ZnONPs in inhibition the growth of pathogenic bacteria. The results represent a great potential benefit for a wide numbers of medical applications in the battle against antibiotic-resistant bacterial pathogens.

Abstract

There is no doubt that Mercury is considered one of the significant pollutants to the environment. It have been noticed that exists in three forms. The previously mentioned forms are elemental or metallic (mercury), organic and inorganic mercury. Inorganic mercury can be converted microbiologically into organic form. The present paper has been focused on the genotoxicity and histopathological effect of mercuric chloride on *Ctenopharyngodonidella* (Grass carp). Basically, *Ctenopharyngodonidella* is one of the most important fish species according to FAO reports. Moreover, *C. idella* fry have been divided into four groups. The first Group was exposed to sublethal concentrations of 5 ppb, Second Group was exposed to 10 ppb of mercuric chloride and the third one was exposed to 15 ppb, on the other hand, the fourth Group was kept as unexposed control. Furthermore, A blood smear was done for micronuclei examination and gills and liver of the tested fish were obtained for histopathological study. A significant increase of micronucleus notched erythrocytes in fish exposure with HgCl₂ than in the controls. The microscopic examination has shown different histological changes in the organs of the examined fish which has been exposed to mercuric chloride in comparison with control organs.

Keywords: Mercuric chloride, Ctenopharyngodonidella, Micronucleus, Histopathological changes.

Introduction

Generally speaking, Mercury is classified as one of the most harmful pollutants because of its high toxicity and persistence in the environment. To put it in other way, it exists in three forms: elemental (metallic) mercury, organic mercury (methylmercury) and inorganic mercury (Mercuric Chloride).¹,² No one can deny that the fact that it is a naturally occurring element, but it has been directly mobilized into ecosystems through mining. Moreover, it has been used in products on (paint, electronic devices) and industry.³,⁴

To that end, Mercury pollution in aquatic ecosystems has received a great deal of attention since the discovery of mercury as the cause of Minamata disease in Japan in the 1950s⁵. Having said that most mercury is released into the environment as an inorganic form, which is primarily bound to particulates and organic substances and might not be available for direct uptake by aquatic organisms. Then, part of the inorganic mercury can be microbiologically converted into methyl-mercury and taken up by the aquatic organisms⁶,⁷.

However, once Hg exists in aquatic systems, it can be accumulated in different organisms, leading to its biomagnification through the food chain. Studies examining Mercury accumulation in fish tissues are significant because these organisms represent the main human contamination pathway⁸,⁹,¹⁰.

Furthermore, *Ctenopharyngodonidella* (Grass carp), a species of the family Cyprinidae, is a subtropical to temperate fish species, native in eastern Asia with a native range from northern Vietnam to the Amur River on the Siberia-China border. It is considered one
of the most important species, according to FAO, the value of farmed *C. idella* is about 6.46 billion USD for a production of 5.03 billion tons in 2012\(^{11,12,13}\).

Additionally, this species is characterized by a wide, sacaleless head, terminal or subterminal mouth with simple lips and very short snout\(^{13}\). That is to say, the body is slender and fairly compressed with a rounded belly and the lateral line is complete, slightly decurved and extending along the middle of the depth of the tail\(^{14,15}\). As well as, adult *C. Idella* has a dark greycolour while the dorsal surface sides have a slightly golden shine. Colour fins are clear to gray-brown\(^{16}\).

*C. idella* is consumed as food in Iraq and many other countries in the world. It is also being widely introduced to control of submersed aquatic weed because of their strong preference for aquatic vegetation\(^{17,18}\).

Although many studies had been estimate the pollution of aquatic environments in Iraq, There is a need to investigate the effect of this pollution on aquatic biomass. So this study was performed to examine the effect of mercuric chloride on the histology of some organs of *C.idella* fish.

**Materials and Method**

**Fish and experiments:** *C.idella*fry with an average length of 15 -20 cm and weight of 100g were purchased from a commercial aquaculture facility in Al Rifaiacity (Thi-Qar, Iraq) and adapted to experimental conditions (running dechlorinated tap water at 25°C (with a 12 h-D,12 h-L photoperiod)for a minimum period of 15 days. During the adaptation period, fish were fed dry commercial pellets, and water was renewed daily. Later 15 fish were transferred to each one of four aquaria; of 200 L capacity. Different test doses were prepared making dilution of the stock concentration. Three of aquaria containing 5,10 and 15 ppb HgCl\(_2\), respectively. Control fish were added to the fourth aquarium which containing uncontaminated water. The fish were sacrificed after14days. Micronuclei Examination,Gills and liver was pulled out for histopathological study.

**Cytogenetic Examinations:**

**Micronuclei:** Determine the number of Micronuclei by\(^{19}\). A blood smear was made on a glass slide to dry, then fixed for 10 minutes with methanol and dye with gmsa stain for 30 minutes. The prepared slides were examined under the (40X), the number of Micronuclei was calculated in 1000 cells.\(^{20}\).

**Histopathological study:** Tissue specimens from used fish (Gills, liver and muscles) were taken and fixed in 10 % formalin. They were processed into the routine histological procedure to obtain five micron thick paraffin sections then they were stained with hematoxylin and eosin and were examined under light microscope\(^{21}\).

**Results and Discussion**

**Cytogenetic study:** It is noticed from Table (1) the rates of the number of micronuclei in (1000) red blood cell of the three groups and the control group fish, in the third HgCl\(_2\) groups a significant increase (P≤0.05) in micronuclei rates during the time of the experiment was (3.400 ± 0.910), (7.133 ± 1.355) And (10.333 ± 3.145), respectively, compared to the control group (0.666 ± 0.487), (Fig. Micronuclei). The results indicated a significant increase in micronuclei of mercury chloride exposure group compared with control groups. These results agreed with the previous\(^{22-24}\).

The micronucleus test, one of the most popular and promising tests of environmental genotoxicity, has served as an index of cytogenetic damage for over 30 years.\(^{25}\). The increase in micronuclei of red blood cells in the present study of (*ctenopharyngodonidella*) due to mercury chloride toxicity was identified as a good biological indicator of genetic toxins to monitor the influence of such elements. Mechanisms of erythrocyte nuclei deformity have not yet been explained and there is no consensus about the causes of these changes\(^{26}\).
Recently, it has been proposed that severe nuclear deformations can also originate from physical forces, such as the compression of the nucleus during migration through confined spaces that can lead to nuclear envelope rupture.27.

Histopathological study: There is no sign of mortality was noticed at the study period in all fish groups. However different histopathological changes were noticed through microscopic examination the studied organs. Moreover, the gill sections of C.idella have shown that the all fish groups which have been treated with the three concentration of mercuric chloride (5, 10 and 15 ppb) have a loss of epithelial tissue (Fig. 1,2). Additionally, the other microscopic histopathological changes in fish group which have been treated with 10 ppb mercuric chloride are the congestion of small blood vessels (Fig. 2), whats more, it has been noticed that there is presence of inflammatory cells in the secondary lamina in the gills of C.idella treated with 15 ppb of experimental toxic element that has been used in this investigation (Fig. 3). The normal histology of gills is presented in (Fig. 4).

---

![Fig 1. Gills section of C. idella treated with 5 ppb mercury chloride 10X](image1)

![Fig 2. Sever loss of epithelial lining, Gill sections, Fish treated with 10 ppb mercuric chloride 10X](image2)

![Fig 4. Presence of inflammatory cells in the secondary lamina in the gills of C. idella treated with 15 ppb mercuric chloride 40X](image3)

![Fig 5. Normal set of gills 40X](image4)
Furthermore, figures (5) pointed to the Presence of inflammatory cells in the liver section of the fish treated with 5 ppb mercuric chloride.

Fish gills are particularly sensitive to the chemical and physical modifications of surrounding water. Not only but also, morph functional alterations of the gills have been widely documented after exposure to water pollutants. However, many authors suggest that gill damages are largely non-specific and can be induced by a wide range of toxicants\(^{(28,29)}\).

Several studies have been focused on the effects of mercury on gill tissues. Most of the available data have been focused on methyl mercury, while the effects of inorganic mercury are less investigated. However, gill damages and structural changes caused by water-borne inorganic mercury have been reported for relatively few species, from both marine and freshwater ecosystems\(^{(30-34)}\). Mercury caused a wide variety of morphological changes in *Danio rerio* gills and modifications of both Na+/K+-ATPase and metallothioneins expression\(^{35}\).

It has been noticed that the appearances of lysed areas were found in zebrafish liver after exposure to copper sulphate. As well as, considering the copper’s ability to induce membrane disruption, the authors suggested that the lysed distribution may reflect a heterogeneous distribution of Copper in the parenchyma. Interestingly, Observation of lysed area after exposure to inorganic mercury; whereas similar adverse effects have not been reported in liver after exposure to methyl mercury; These results further support the hypothesis that inorganic mercury, affect membrane whereas methyl mercury does not appear to act directly at plasma membrane\(^{36}\).

Wu et al\(^{37}\) provided strong evidence for liver toxicity following exposure of adult guppies (*Poeciliareticulata*) to methylmercury (1–10 µg/L for 1 and 3 months). Additionally, alterations have involved hepatocytes (cell swelling and nuclear pyknosis) and hyperplastic biliary epithelium of the intrahepatic bile duct.

It have been concluded that fish exposure to inorganic mercury causes different histopathological changes. However, further study is warranted to study the molecular effect of mercuric chloride of *C. idella*, or to know the toxic effect of mercury on the other important types of fish \(^{(38-40)}\).

Psychoactive Substance Use among Medical and Pharmacy Students, University of Kufa 2019

Karrar Mohammed Hasan Al-Gburi1, Ali Mohammed Abd Alridha1, Roaa Khalid Mohsin Al-Murshedi2, Abulfadhel Jaber Neamah AL-Shaibani3

1Assist. Lecturer, Department of Clinical Pharmacy, Faculty of Pharmacy, University of Kufa, Najaf, Iraq, 2Lecturer, Department of Clinical Pharmacy, Faculty of Pharmacy, University of Kufa, Najaf, Iraq, 3Senior, Dr., Ministry of Health–Al-Asatetha Primary Healthcare Center, Babil, Iraq, 4Assist. Lecturer, Department of Clinical Pharmaceutics, Faculty of Pharmacy, University of Kufa, Najaf, Iraq

Abstract

Background: Medical and pharmacy students are at greater risk of using psychoactive substances. Iraqi medical and health science students are at great danger of using these psychoactive substances and this may be attributed to different reasons, e.g. stressful life.

Objectives: Hence, this study was designed to identify the pattern and to investigate the triggering factors associated with psychoactive substance use among medical and pharmacy students, University of Kufa.

Subjects and Method: A descriptive cross-sectional institutional-based study was conducted from the period of March to June 2019 at the University of Kufa, in which students were recruited in multistage fashion. Randomly selected students were asked to fill in an online questionnaire prepared based on different standard questionnaires and previous studies. Pearson’s chi-square test (X²) and Fisher-Exact test were used to find the association between categorical variables. A p-value of ≤ 0.05 was considered significant.

Results: Overall, 129 students participated in this study. The mean age of the students was (21.89 ± 2.76). Overall, seven percent of the participants have confessed that they are tobacco smokers. In terms of waterpipe tobacco smoking, 10 out of 129 (7.8%) of the students were hookah smoker and only 2 students (1.6%) were e-cigarette smokers. Most of the students stated that multiple reasons behind their tobacco smoking. Nearly one-third of participants had quarrels or arguments. While no one had trouble with the police or made something who regretted later. In general, most of the students acknowledged that the use of psychoactive substances carries a risk. In terms of the triggering factors, all factors studied in this study were associated insignificantly with tobacco smoking among the target population (p-value > 0.05), except gender, if they have a family member who smokes or friends who drink alcohol and the age at initiation (p-value < 0.05). No pattern of alcohol consumption and prescription drug among the participants have been identified.

Keywords: Medical Students, Psychoactive substance use, e-cigarette, hookah, Pharmacy students.

Introduction

Psychoactive substances are a group of drugs, which has the capability of changing both internal perceived mental states, e.g. mood, and external observable activities, such as behaviors. Using these psychoactive substances is of major public health issue as it can affect both the health and well-being of millions of people. It has been estimated that more than 275 million people in 2016 had used psychoactive drugs at least once in the previous year, which represents 5.6 percent of the whole people aged between 15-64 years in the world1. Psychoactive substance use is associated with an increase in the risk of morbidity and mortality, psychological and interpersonal issues, school performance difficulties, difficulties in establishing a satisfactory relationship, engaging in unwanted and unprotected sex, crime, accidents, and injuries2,3.

Several consequences have been reported to be
attributed to psychoactive substance use. For instance, studies have linked poor academic performances with substance use or misuse. It has been found that substance use (current smoking, chewing khat at least weekly, drinking alcohol daily, and having an intimate friend who uses substance) was significantly and negatively associated with students’ academic performance. Furthermore, Olivier Marie and Ulf Zölitz have demonstrated that academic performance was increased among students who were restricted to buy cannabis. More significantly, psychoactive substances use is one of the modifiable and important risk factors for suicide attempts. It was reported that psychoactive substance use was responsible for one in five suicide attempts in 2012 (175000 out of 800 000). Furthermore, in one meta-analysis study, which identified a total of 12,413 references and included 43 studies with 870,967 participants, there was a significant association between substance use disorder and suicidal ideation: OR 2.04 (95% CI: 1.59, 2.50; I² = 88.8%, 16 studies); suicide attempt OR 2.49 (95% CI: 2.00, 2.98; I² = 94.3%, 24 studies) and suicide death OR 1.49 (95% CI: 0.97, 2.00; I² = 82.7%, 7 studies). Iraqi medical and pharmacy students are undoubtedly at greater risk of using psychoactive substances. This may be attributed to different reasons, for example many conflicts Iraq has faced in recent years and availability of psychoactive substances in the shops, markets, and drug dealers. Despite that, only a few studies have been conducted to address this rising issue in the general population and more specifically among students. Hence, this study was designed to identify the pattern of psychoactive substance use among medical and pharmacy students, University of Kufa and to investigate the triggering factors associated with psychoactive substance use among medical and pharmacy students.

Subjects and Method

Study design and settings: A descriptive cross-sectional institutional-based study was conducted from the period of March to June 2019 at the University of Kufa, in which students were recruited in multistage fashion. In the first steps, colleges were considered strata (stratified sampling). While in the second step, students were selected randomly and were fully surveyed. To make students trust the investigators before distributing the questionnaires, an illustration was given to the participants about the purpose of the current study, anonymity of the questionnaires, and the voluntary nature of participation in the survey. Furthermore, students were told not to disclose or fill in any personal information in the questionnaire.

Data collection tool: Randomly selected students were asked to fill in an online questionnaire, which was prepared and test before conducting this study. This questionnaire had been prepared based on a different standard questionnaire and previous studies, such as The Global Assessment Program on Drug Abuse Toolkit Module 3: Conducting School Surveys on Drug Abuse. The questionnaire was started asking the students if they are given consent to participate in the current study. The following sections were the demographic data including, age, gender, marital status, residency, mother’s educations, father’s education, relationship to parents and family, and the department of study.

Data analysis: Statistical analysis was carried out using Statistical Package for Social Sciences version 24. Categorical variables were presented as frequencies and percentages. Continuous variables were presented as (Means ± SD). Pearson’s chi-square test (X²) and Fisher-Exact test were used to find the association between categorical variables. A p-value of ≤ 0.05 was considered significant.

Perception of participants about psychoactive substance use: In general, most of the students acknowledged that the use of psychoactive substances carries risks. For instance, students believe that smoking occasionally or regularly has an impact on their lives and they think this risk raise with regular smoking (table 3). Similarly, students consider have one or two drinks nearly every day or have four or five drinks in a row per weekend carry moderate to great risk (31.8% and 37.2% and 26.4 and 46.5 respectively), yet the majority (55.0%) of them acknowledged that have four or five drinks in a row per every day carry a great risk. Regarding misusing marijuana or hashish, most of the students consider using these substances once or twice or using it regularly carry a moderate to great risk.

Triggering factors associated with exposure to smoking: In terms of the triggering factors, all of these factors are associated insignificantly with tobacco smoking among the target population (p-value > 0.05), except gender, if they have a family member who smokes or a friend who drinks alcohol and the age at initiation of this tobacco smoking (p-value < 0.05). Association between triggering factors and illicit drug use are illustrated in table 4.

Discussion

The objectives of this study were to identify the pattern and the triggering factors of psychoactive substance use among medicine and pharmacy students at the University of Kufa. The prevalence of current tobacco cigarette smoking was 7.0%, where all of the smokers were female. This prevalence of cigarette smoking is lower than found in Hawler University, Kurdistan region, which was 12.3% and lower among the University of Karbala students in 2005, which was
Furthermore, this current smoking prevalence among medical and pharmacy students when compared to Arabic and adjacent countries is lower than that found in Sudan (The National Ribat University, 10%), Lebanon (7 different universities, 25.8%), Egypt (Tanta University, 12%) and Saudi Arabia (King Fahad Medical City in Riyadh, 17.6%) (21–24). The difference in the prevalence may be attributed to different universities, hence different regulations and policies, and different ways of data collection (online versus handwritten questionnaire).

Moreover, the current study has investigated the ongoing rise issue among the Iraqi community, which is the water pipe (hookah) and e-cigarette tobacco smoking. The prevalence of hookah smoking was 7.8%, while e-cigarette prevalence was 1.6%. This hookah smoking is lower than found among medical students in Saudi Arabia (12.6%), Syria (23.5%), London (11%), and Turkey (28.6%) (23, 25, 26). This finding highlights the rise of hookah smoking among medical students, and this may be attributed to the wrong belief that hookah is less harming than tobacco cigarette smoking and the cheap cost of this sort of tobacco smoking. Another rising issue among Iraqi medical and medical students is the use of the e-cigarette. The prevalence of e-cigarette tobacco smoking was 1.6%, which is quite low percent and this could be attributed to the newer introduction of this type of smoking to the Iraqi markets and the high cost of these cigarettes. The use of e-cigarette is believed to be a route to cease cigarette smoking, yet studies have identified that using this form of tobacco smoking is a strong risk factor for current tobacco cigarette smoking among young adults.

Conclusion

Some pattern of tobacco smoking was identified and several factors play an essential role in this pattern. A larger study is warranted to address this highly risky issue.

Therapeutic Exercises for Spine Aberrations, According to the Kinematic Analysis, in Improving the Motor Capabilities of Children (6-9 Years)

Haider Fayyadh Hamad Alamiri¹, Basim Najiabdull Hussein¹, Maher JafarAmeenShlash²

¹Assist Prof. Dr. University of Kufa, Physical Education of Sport and Science,
²University of Kufa, Physical Education of Sport and Science, Maher

Abstract

Physical deviations that are closely related to technological development helped to the emergence of diseases resulting from inactivity and lack of movement, So therapeutic exercise is one of the means to help improve the strength of pupils by using the means of assistance as a means of treating deviations of the spine such as (rubber ropes, medical balls, stick and various sponge pieces). The purpose of therapeutic exercises is to help the child return to activity and life as quickly as possible, reduce pain and increase the flexibility of joints and muscle elasticity. Therefore, the researcher used the one-group experimental curriculum (tribal-after test), and the research community was identified from the 150 students and students of the 2018-2019 school year, and 22 students were identified. Their age of (6-9) years in the deliberate way, as the therapeutic program was implemented which includes therapeutic exercises for (6) weeks by (12) therapeutic units and the time of the therapeutic unit (35) minutes, and concluded the researcher that the therapeutic units followed by the researcher to reduce deviations in the column.

Keyworld: Biomechanic of sport, Therapeutic exercises, motor capabilities of children.

Introduction

Good texture sits as the outward appearance through which we define the human pause and the beautiful shape of it. Due to the increased prevalence of physical deviations that may be closely linked to technological development, the emergence of diseases resulting from inactivity and lack of mobility, therapeutic exercise is one of the means to help improve the strength of pupils by using assistance as a means of treating spinal deviations¹. The purpose of therapeutic exercises is to help the child return to activity and life as quickly as possible and reduce pain and increase the flexibility of joints and muscle rubber². The process of describing the movement must be attributed to the axes and imaginary bodies in the human body where the point of prevention these bodies represent the point of the center of the weight of the body and there are three axes and three flats and when the representation of movement is said to be around the axis and this movement is located in the flat and this helps in the mechanical analysis of movement which is one of the method of research in the field of biomechanics which is looking for the effect of internal laws³. The human spine is the most complex part of the musculoskeletal system, the basic functions of the spine are to protect the spinal cord, support the head, neck and upper limbs, transfer loads from the head of the trunk to the pelvis and allow various movements. The use of kinematic analysis³ and x-ray to identify spinal deviations in pupils and pupils of the sample by comparing it with the correct anatomical position, Hence the importance of research in the use of therapeutic exercises and aids such as (physical ball, rubber ropes, some sponge pieces, wooden stick and other tools) that help in the treatment of spinal deviations in pupils by strengthening tendons and ligaments and increasing the flexibility of joints and muscle rubber where Taking care of strength helps to reduce these deviations, And through the researcher’s observation of the problems suffered by schoolchildren from carrying bags more than the required weight or study seats not suitable for the age of the students as well as sitting long imam TV or electronic devices make the child low movement and activity and may be due to
a genetic factor, as well as excess weight these factors lead to real problems suffered by society⁴, so the study aimed to prepare therapeutic exercises using the means of assistance, and to identify the effect of therapeutic exercises for some spinal deviations according to analysis Kinematic in improving the motor abilities of children.

**Material and Method**

The researcher used the one-group experimental curriculum (tribal-after test), the research community was identified from the 150 students and pupils of the Amirat Primary School for Boys/Girls in Najaf. The treatment program, which includes (6) weeks of therapeutic exercises with (12) therapeutic units and the time of the treatment unit (35) minutes, was determined by the method of treatment.

Community photography and presentation of video photography to a committee of doctors specializing in orthopedic surgery:

1. Preparing a special form on which the members of the committee indicate cases of deviations of the spine.
2. After that, the sample was determined by those who had deviations in the spine and in the intentional manner and numbered (22) pupils.
3. X-ray image of the spine was taken from the back and from the side to determine the degree of deviations.
4. The degree of deviations was determined by the introduction of the x-ray image in the calculator and within the program of dynamic analysis kinovea 8,26).

**Devices used in the search:** Digital electronic stopwatch (1/60) of a second to measure time and calculate for tests that need time (German industry) number 1 and hand-made Sony cameras with its cushions quickly (100 images/s) number 2 and rubber ropes number (2) Chinese industry and medical ball number (3) Chinese industry weighing (1kg), (2kg) and stick number (2) and various sponge pieces number (6) and physical balls number (3) weighing (1,5).

After looking at many scientific sources and conducting interviews to determine the most important the motor capabilities of children (6-9 years), namely (agility - flexibility - balance - compatibility).

**Kinematic Measurements:**

**First:** Horizontal deviation: a deviation of the axis of the shoulders from the horizontal axis, as this variable is measured from the method of x-ray imaging of the sample, and then the introduction of imaging in the program of kinetic analysis kinovea 8,26) inside the computer to determine the angle of the horizontal axis (the first side) and the second side draws between two points or two fixed on the top of each side of the body so that the point of the intersection of the two rectum represents the top of the rectum represents the axis of the two corners representing the axis of the two sides.

**Second:** Vertical deviation: which is the deviation of the spine from the vertical axis, where this variable is measured from the method of x-ray of the sample, and then the introduction of imaging in the program of kinematic analysis kinovea 8,26) inside the computer to determine the angle of the vertical axis (the first rib) and the second rib straight draws along the longitudinal axis of the spine, and the intersection of the rectum represents the head of the vertical angle.

**Third:** Gibbosity: How to measure the angle of thoracic kyphosis: By using the x-ray image of the bones of the spine (dorsal area), then the upper and lower arch is determined as the level at which the vertebrae begin to arch, and the degree of curvature is measured by drawing straight on x-ray rays), the first on the upper limits of the upper vertebrae of the arch, the second straight drawing spout from the lower boundary of the lower vertebrae of the arch, and the angle formed by the point of the intersection of the two rectum represents the angle of the curvature (cup). Through the side view the use of the horizontal axis that is perpendicular to the arrow level on which the curvature occurs, and the natural degree of curvature from the side up to (40 degrees), and the higher degree of (60) need surgical interference, but the degree of curvature between (41-60) can be treated using physical therapy programs⁵, as shown in figure 1.

The results of the tribal tests after the following tests showed that all the tests conducted on the students have a statistical difference of moral because the moral value is below the level of significance of (0.05).

The statistical results showed a difference between tribal and dimensional tests and in favor of dimensional tests, the researcher attributes the reason for the difference to the applications of the period between the two tests and the various exercises included with the use of several means, and those exercises targeted a large group of skeletal muscles, that the continuous work of the muscles according to the improvement of the topical, some muscles require flexibility i.e. focus on them with exercises flexibility, especially the chest and abdominal muscles to reduce their stiffness and shortness. Because the shortness of those muscles works to pull the vertebrae inward, which leads to increased stupor of the dorsal area and this is the result of the continuation of the wrong habits of sitting or standing, or as a result of the lack of movement and activation of those muscles or focus on a muscle group in certain movements such as carrying heavy school bags for long distances, forcing the front muscles of the trunk to contract for a long time in order to generate a tightening force of the spine to the imam, resulting in obtaining vertical weight gain on the center of gravity resulting in the result of the weight of the weight. The result is bag weight and body weight. The overall improvement in the strength and elasticity of some muscles of the trunk area has helped a lot in reducing deviations of the spine, because deviations greatly affect the compatibility and movement of the pupil with the rapid change of direction during running, and the development of muscle function.
and increased capacity while reducing the deviations of the spine helped the sample members achieve a better time when applying the running test in form (8) 9,10. Physical and motor improvement has to do with the physical corrections that give balance in movement and stability. The use of auxiliary means such as rubber ropes, physiological balls, sponge pieces, stick and flexibility exercises that correct the wrong conditions taken by the body in the performance of its work and restore the body to its proper position 11. Lateral spine flexibility exercises help elongat the short muscles, which reduce the tilt of the torso to its side, either flexible exercises of the back spine help straighten the spine and stretch the short muscles in the pectoral and abdominal area, including the torso on the physical ball, and the braces on the sponge pieces 12. The continuation of the application of fixed and moving flexibility exercises during the period of therapeutic exercises has a clear effect on reducing deviations of the spine from the horizontal axis and vertical axis and stiffness, because most of these cases are caused by stiffness in more than one muscle due to not being exposed to stretching and elongation as a result of wrong social habits in terms of sitting and standing13. The diversification of the physical effort helped in involving the largest number of muscle groups, and as a result the activation of inactive and weak muscles with treatment cases of short muscles on one side of the trunk and weak muscles on the opposite side, and these steps were carried out by involving a group of method such as rubber ropes, and the wooden stick in the twisting and pulling exercises For the side with resistance to rubber cords, with applications of exercises to tighten the abdominal muscles and their flexibility on flat, inclined terraces and arched terraces. All these applications aim to reduce the deviations of the spine resulting from physical and behavioral imbalance, because the presence of these deviations will generate rotational attribution in the parts of the body hindering the constant and motor balance, i.e. the body is tilted to one side, which requires greater effort from the muscles of the opposite side to work to maintain its balance.

Conclusions

The program of therapeutic units followed by the researcher was able to reduce deviations in the spine of the sample, and the use of kinematic analysis helped the researcher in determining the degrees of deviations of the spine, in addition to the use of auxiliary means with the implementation of therapeutic exercises helped to achieve the goals of those exercises in terms of time and effort and improve the motor abilities of the sample, as working with deviations in the spine early gives better results and delay increases the difficulty of treatment.

Posttraumatic Stress Disorders among Adolescent Post the (Islamic State of Iraq and al-Sham) (ISIS) War in Kirkuk City

Iman Hussein Alwan¹, Abid Salih Kumait², Hassan A. Hussein³

¹Lecturer, Ph.D. Psychiatric, University of Baghdad, College of Nursing, ²Ph.D. Adult nursing, Lecture, University of Kirkuk, College of Nursing, ³Assist. Professor, Department of Psych. Nursing, Collage of Nursing, University of Baghdad, Baghdad City, Iraq

Abstract

Background: The gathering of Islamic assembling in Iraq and the Levant was known as the Islamic State in Iraq and the Levant, known as the ISIS, a furnished affiliation that follows the way of thinking of jihadi Salafi social occasions, and whose people point - according to their conviction - to restore “the Islamic caliphate and the utilization of Sharia”, and its people exist and spread its effect is generally in Iraq and Syria with refreshes on its embodiment in the zones various countries are southern Yemen, Libya, Sinai, Azawad, Somalia, northeastern Nigeria and Pakistan. Additionally, the pioneer of this affiliation is Abu Bakr Al-Baghdadi

Objective(s): To assess post-traumatic stress disorders among adolescents after (the Islamic State of Iraq and the Levant War) (ISIS) in the city of Kirkuk.

Methodology: A non experimental approach using descriptive design was applied in the present study from 1st October 2019 to the 20th of February 2020. The study was conducted at rural area which was under ISIS at Alhawija district in Kirkuk Governorate. the study involve many village at alhawija district includes (Musaanaa village, Shamlan village Aleaoa village, Alhalawa village, Alkhan village). A Purposive sample consisted of (100) from both (male and female) the sample was collected from five village at alhiwija district, these village was occupied by ISIS groups approximately for 3 years from June, 2014 until October 2018. In order to gather the study data, a questionnaire was building depending on the criteria of WHO scale (formate and modify by researcher) and related literature according to their study Data were analyzed by Statistical Package for Social Science (SPSS) version (24) is used for data analysis at.

Results: The study revealed the sample size was consist of (57.0%) male and (43.0%) female also the result shows the participants are suffering from moderate to severe level of psychological distress which indicates having low level of psychological wellbeing and general health.

Recommendation: National and international interventions are required for them especially for the victims of sexual violence, physical, social and psychological supports are needed. Further studies and researches also required to assess their suffering and other possible psychological disorders.

Keywords: Post-traumatic stress disorder, adolescent, Islamic State of Iraq and al-Sham (ISIS).

Introduction

Life for many kids and youths in Iraq was flipped around in 2014 as the Islamic State in Iraq and Syria (ISIS) started a fast development that saw rushes of viciousness heighten across a significant part of the nation. In the assault that followed, more than 5 million individuals – half of them kids – were displaced. Psychiatric side effects and mental issue among evacuees are perceived as a pressing issue, particularly in the Yazidi populace, after the extreme assaults by the
alleged “Islamic State of Iraq and Syria” (ISIS) in July 2014\(^1\). Through the long stretches of cruel ISIS rule, Iraqi youngsters and teenagers were exposed to probably the most awful infringement of their privileges possible. For some residents the later battle to another control bring all the more torment. Homes and entire networks were decimated or proceed onward in the battling and innumerable kids and their families were harmed. A two year after inviting;ISIS was removed from Nenwa and Kirkuk, the injury of war lives on. Youngsters are ceaselessly helped to remember the past revulsions they encountered and still face unending threat from mines and unexploded arms, which keep on slaughtering, mangle and psychological warfare all the time. Many are battling to come back to class after years without instruction\(^2\).

A large extent of ladies than male experienced Post Traumatic SD and MD, and ladies with PTSD or gloom were more probable than their man partners to record having encountered or seen the demise of a mate or youngster. Ladies with PTSD announced the center indications of PTSD (flaShbacks, hypervIgilance, and exceptional mental misery because of tokens of injury) more much of the time than their male partners, and ladies would in general show undermodulation of feelings and low confidence in light of horrendous pressure. Discouraged ladies were almost certain than their male partners to report sentiments of blame or uselessness. Seriousness of posttraumatic side effects is by all accounts the most grounded indicator of disabled wellbeing related personal satisfaction in PTSD outpatients\(^3\). Iraq’s populace is contained generally of kids and youngsters, with about 60 percent under the period of 25.2 And it is this gathering who are frequently the most exceedingly awful influenced mentally by the battling. Just by supporting their strength and defending their psychological wellness and psychosocial prosperity can networks really push ahead, making sure about an increasingly positive future for their nation\(^5\).

Aims of the study :- to assess post-traumatic stress disorders among adolescents after (ISIS) in the city of Kirkuk

**Recommendations**: national and international interventions are required for them especially for the victims of sexual violence, physical, social and psychological supports are needed. Further studies and researches also required to assess their suffering and other possible psychological disorders.

**Methodology**

A non experimental approach using the type of design is a descriptive from 1\(^{st}\) october 2019 to the 20th of February 2020. The study was conducted at rual area which was under ISIS at Alhawija district in Kirkuk Gvernorate. the study involve many village at alhawija district includes(Musaanaa village, Shamlan village Aleaoa village, Alhalawa village, Alkhan village). A Purposive sample consisted of (100) from both gender, the sample was collected from five village at alhiwija district,these village was occcupied by ISIS groups approximately for 3 years from june,2014 untill october 2018, the sample chosen according to the following criteria: Males and females from five fillage at ahiwija district. Ranges of age was between (10 -19 years for children). Agreed to attendance in the study. The inform consent obtained from all victimes befor starting in take information. In order to gather information, a questionnaire was constructed depending on the criteria of WHO scale (formate and modify by researcher) and related literature according to their study. It is composed of many parts parts:

- **Part I**: Demographic characteristic of sample includes (age,marital status and types of event)
- **Part II**: Scale of post trauma stress which consist of 22 questions,two liker scale 2 for Yes and 1 for No
- **Part III**: Physical and psychological health assessment consist of from 28 question, four liker scale
- **Part IV**: Psychometric distress measure which consist of from 10 questions, three liker scale
Part V: Psychological reactions which consist of from 20 questions, five liker scale. Data collected by questionnaire via interview technique throughout as a means of such collection. The data was collected between 10 th october 2019 to the 10th of January 2020. Analyz data in several steps. First, descriptive statistics, which include frequency and percentages. The second step, which includes inferential statistics (Chi-Square test and ANOAV), the statistical done by SPSS version (24) is at (P.value ≤ 0.05).

*Statically Significant (P<0.05), OR=odd ratio

Table (3) shows a significant differences between participants at (P<0.05).

The findings presented in table 3 indicate that the participants are suffering from moderate to severe level of psychological distress which indicates having low level of psychological wellbeing and general health.

Figure (4): Psychological distress measure/Chi Square ($X^2$) = 30.93, Degree of Freedom (DF)=27, P=0.0022*)
Discussion of the Results

Part I: The present results revealed that 100% of participant of the study sample at age of 10-18 years old. Explanation of this result refers to all study sample from same age and sample region also the research focus on this sample at study findings of the present study supportive evidence is available in the study that showed (the high percentage of their sample were adolescent and shows 65%) from total sample.

Table 2 included survey about post-traumatic stress disorder. Participants answers significantly different (p<0.05) on survey options except on Q10(P<0.444). However, most participant not exposure to condition of present survey when most of them answer by no on all question except options on this survey where $X^2$ is 30.08 and p value equal to 0.001. Explanation of this result refers to most of victim was under ISIS suffering from traumatic disorder.

Our results is agreement with other study conduct by McCarthy and Semmache (2018) and report that numerous young ladies and young men keep on feeling is probably going to be fuelling their powerlessness to recuperate and is a key main impetus for their concerns. More than 80 percent of young people matured 13 to 17 said that they didn’t have a mood of security strolling alone and right around 50 percent didn’t have a sense of security away from their folks. Almost 33% of teenagers detailed failing to feel safe site at school, and just one-quarter think about school as a protected space (6).

Also the result shows the majority of Participants with PTSD were (57%) were male, the study conducted by Alison (2017) reported that in her study we are concentrated on male child soldiers that constituted the largest group of children within the ISIS fighting-related structures and have lacked institutionalized support. It is, of course, important to systematically take into account female child soldiers as well that are certainly in equal need of attention, protection, and support (7).

Also the result shows in Figure (2) included describe post-traumatic stress disorder, the result of study indicate that there is a high significant differences between the overall sample at (p<0.05). except Q10 represent (P<0.444).

Bobic and others (2015) Studies assessing mental clutters in war exiles show heterogeneity in commonness paces of sadness (run 2.3%–80%), PTSD (4.4%–86%), and undefined uneasiness issue (20.3%–88%), for the most part because of clinical and methodological variables (8).

With regard to psychological problems the findings presented in table 3 indicate that the participants are suffering from moderate to severe level of psychological distress which indicates having low level of psychological wellbeing and general health. This result is agreement with study conduct by Ceri and others (2018) (9).

Figure (4): Psychological distress measure (Chi Square ($X^2$) = 30.93, Degree Of Freedom (DF)=27, P=0.0022)

This figure shows most of respondents suffer from mild and severe psychological problems. The most generally detailed mental outcome of horrible accidents and war clashes specifically is the post-horrendous pressure issue (PTSD). Then again, examines have increase the issue of substance use issue (SUD) among evacuees and populaces presented to war clashes. Be that as it may, enslavement in dislodged populaces is as yet an understudied point (10).

Recommendations: National and international interventions are required for them especially for the victims of sexual violence, physical, social and psychological supports are needed. Further studies and researches also required to assess their suffering and other possible psychological disorders.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved and all experiments were carried out in accordance with approved guidelines.

Effectiveness of Educational Program on Nurse-midwives’ Knowledge about Pregnancy Induced Hypertension at Bint Al-Huda Hospital in Al-Nasiriya City

Sarah Talb Kadhim1, Suhad H. Khairi2

1M.Sc. Instructor, Maternal and Neonate Nursing Department of College of Nursing, Thi-Qar University,
2Assistant Prof., Maternal and Neonatal Health Nursing Department of College of Nursing, University of Baghdad

Abstract

Background: Pregnancy induced hypertension, is common throughout the world but more frequent in developing countries and cause of maternal and infant mortality and morbidity.

Objectives: To the effectiveness of educational program about PIH on nurse-midwives’ knowledge

Subjects and Method: A quasi-experimental design, non-probability (purposive) sample of (50) nurse-midwives’ who are working in Bint Al-Huda hospital in Al-Nasiriya City during February 13th through April 2nd 2019.

Results: The results of the study show that more than a one third of the study sample are within age group (20-25) years, and had more than a half were married, one third were nursing school graduates and had experiences for 10 years or more. In pretest the nurse’s knowledge show poor and fair level, after intervention of the program and through two posttest in different timing the score show a progress in result to very good level. (84.9%) for knowledge during posttest I and to (100%) for posttest II to knowledge.

Conclusion: The study concludes there were significant of educational program on nurse-midwives’ knowledge.

Keywords: Effectiveness, Educational Program, Nurse-midwives’, Knowledge, Pregnancy Induced Hypertension.

Introduction

Pregnancy induced hypertension is defined as BP ≥ 140/90 mmHg, taken after a period of rest on two occasions or ≥160/110 mmHg on one occasion in a previously normotensive woman1. Or as systolic blood pressure (SBP) >140 mmHg and diastolic blood pressure (DBP) >90 mmHg. It is classified as mild (SBP 140-149 and DBP 90-99 mmHg), moderate (SBP 150-159 and DBP 100-109 mmHg) and severe (SBP ≥160 and DBP ≥110 mmHg)2 According to the Canadian Hypertension Society, PIH refers to one of four conditions: a) pre-existing hypertension, b) gestational hypertension, and preeclampsia, eclampsia and HELLP syndrome) pre-existing hypertension plus superimposed gestational hypertension with proteinuria and unclassifiable hypertension3 Worldwide, (10%) of all pregnancies are complicated by hypertension, with pre-eclampsia and eclampsia being the major causes of maternal and prenatal morbidity and mortality 28 It is also estimated that pregnancy induced hypertension (PIH), one of the hypertensive disorders of pregnancy, affects about (5 – 8%) of all pregnant women worldwide Muti, (2015). Incidence of hypertensive disease associated with pregnancy varies widely in epidemiological studies due to variations in definitions, and the differences in data collection Schoenaker, (2014)Pregnancy induced hypertension is one of the causes of maternal deaths in Iraq (30) deaths per year according to the 2014 census. According to the WHO, 2011 PIH is one of the main causes of maternal, fetal and neonatal mortality and morbidity, it is the most common cause of maternal
death in Europe. It is a major pregnancy complication associated with premature delivery, intra-uterine growth retardation (IUGR), abruptio placentae, and intra-uterine death, as well as maternal morbidity and mortality. It is estimated that (9.1%) of maternal deaths in Africa are due to hypertensive disorders of pregnancy. Other maternal short-term complications include central nervous system dysfunction, hepatocellular injury, thrombocytopenia, acute disseminated intravascular coagulation (DIC), oliguria, pulmonary edema, cerebrovascular events and placental abruption. Interventions during pregnancy, may improve maternal outcomes. In this regard, the intervention includes primary prevention, detection of increased risk and early detection of any stage of PIH by antenatal adequate care. Secondary prevention of progression is by treatment at primary level or referral for expert care. It is understood that care guided by findings generated from rigorous scientific method consists of gold standard in health care.

Methodology

Subjects and Method: Non-probability (purposive) sample of fifty (50) nurse-midwives’ who are working in Bint Al-Huda hospital during study intervention regardless of their age, social status and educational level on nurse-midwives’ who worked in obstetrics and gynecology department (emergency words, labor room, maternal ward, operation room and maternity intensive care unit).

Data collection has been performed throughout the use of the study instrument and the application of educational program on nurse-midwives’ knowledge about pregnancy induced hypertension, from February 13th through April 2nd 2019.

The questionnaire consists of three part: Part I included sociodemographic data related to the respondents characteristics such as age, level of education, social status, years of experience, Current site of work, previous site of work, did you know before about pregnancy induce hypertension, did you previously participation in any course about pregnancy induces hypertension and Have you ever nurse pregnant woman with pregnancy induce hypertension during work.

Part II this part is assessing with (65 items) related to the nurse-midwives’ performance, the items are rated according to a (2) points rating scale, scoring, which are as (2) for agree and (1) for dis-agree. The questions items include items of PIH performance during antenatal, during convulsion, during Labor and during postpartum.

Part III check list for evaluation the nurse-midwife performance, the items are rated to a (2) points rating scale, the level of the scale are scored as (2) for done and (1) for Not done. The questions items include items of PIH performance during emergency, convulsion, labor and Postpartum.

The data of present study were analyzed through the application of descriptive and inferential statistic.

Results

Nurses-Midwives Age (years)

![Figure (1): Nurses -midwives Age](image-url)
Figure (1) revealed that the higher percentage (43%) of study sample were at age group 20-25-years with mean and SD (2.14±7.969), while the lowest percentage for those who age 41-45-years were (n = 3; 6.0%).

![Nurse-midwife Social status](image)

Figure (2): Nurses -midwives Social status

Figure (2) shows that more than a half (n = 26; 52.0%) are married of study sample, while the lowest percentage is (n = 1; 2.0%) who is separated.

![Figure (3): The Actual Effectiveness of Program on Nurses-Midwives Knowledge during Three Periods (Pre, Post I And Post II-Test) Related To Pregnancy Induced Hypertension](image)

This finding shows that the results consistency with research hypothesis which mean the overall percentage at posttest-I and II is higher than the mean at pretest, at conclude that the program is effectively improve nurse-midwives knowledge.

**Discussion**

Assess nurse-midwives’ knowledge about pregnancy induced hypertension: The tables displays the distribution of the nurse-midwives’ knowledge about pregnancy induced hypertension that was assessed in pretest. It indicates improvement of nurses’ knowledge in the all items in post-test-I and post-test-II from poor to good. These improvements were statistically significant in the all items. Except magnesium sulphate drug application change from poor to fair in post-test-I and preeclampsia superimposed on chronic hypertension and HELLP syndrome definition item (7&8) were change from poor to fair. Nonetheless, the levels were still significantly higher in compare with pre-program levels. This is finding is consistent with Emam (2018) who stated that there was statistically significant difference before and after regarding all items of the knowledge with increased knowledge of nurses after program.
Mohamed, et al., (2013) supported this result based on the onset of hypertension in relation to the Chronic hypertension and PIH, with the distinction two basic types of hypertension during pregnancy. Disorder with pregnancy (HDP). Clinically, there are outlines current accepted terminology of hypertension for health care providers. The Watanabe et al., (2019) pregnancy induced hypertension is causing confusion (2016) mentioned that, it is important to provide care, the nurse should have a comprehensive knowledge of PIH, to detect deviations from normal and provide early treatment and supportive nursing care.

The mean value of the knowledge of nurses regarding definition of PIH at pretest measurement was (1.26±0.443), and at posttest-I was (1.86±0.351); and at posttest-II was (1.74±0.443) indicates high significant differences between (pre and posttest-I) (pre and post II-test) from poor level to good level in both posttest-I and posttest-II measurements regarding knowledge of the nurses about definition of PIH (P < 0.05).

The mean value of the knowledge of nurses regarding the classification of PIH at pretest measurement was, (1.18±0.388) and at posttest-I was,(1.88±0.328) and posttest-II was,(1.76±0.431)With comparison shows there are high significant between (pre and posttest-I) (pre and post II-test) from poor level to good level in both posttest-I and posttest-II measurements regarding knowledge of the nurses about classification of PIH (P < 0.05). Comparing with similar study was conducted in port Said University reached (100.%) in the immediate posttest and there was improvement in study sample knowledge in both study (Muti, et al., 2015) the nurse and nurse midwives should know the definition of pregnancy induced hypertension that increase blood pressure 140/90 mm/Hg or above after 20 gestation. Berhan (2016) mentioned that terminology used to describe the pregnancy induced hypertension is causing confusion for health care providers. The Watanabe et al., (2019) outlines current accepted terminology of hypertension disorder with pregnancy (HDP). Clinically, there are two basic types of hypertension during pregnancy. Chronic hypertension and PIH, with the distinction based on the onset of hypertension in relation to the pregnancy. Mohamed, et al., (2013) supported this result by reported a improvement of nurses’ knowledge in the all items of knowledge of PIH. These improvements were statistically significant in the all items. Regarding causes of PIH the meanvalue at pretest measurement was (1.18±0.388), and at posttest-I was (1.84±0.370); and at posttest-II was (1.76±0.431); indicates high significant differences between (pre and posttest -I) (pre and post II-test) from poor level to good level in both posttest-I and posttest-II measurements regarding knowledge of the nurses about causes of PIH (P < 0.05). The mean value of the knowledge of nurses regarding risk factors of PIH at pretest measurement was (1.12±0.328), and at posttest-I was (1.84±0.370), and at posttest-II was (1.80±0.404); indicates high significant differences between (pre and posttest -I) (pre and post II-test) from poor level to good level in both posttest-I and posttest-II measurements regarding knowledge of the nurses about risk factor of PIH (P < 0.05).

Conclusion

In conclusion the nurse could identify the risk group of pregnancy induce hypertension such as nulliparity and hypertension increased the risk of preeclampsia, High pre- pregnancy weight was related to a higher risk of mild and moderate preeclampsia, whereas previous preeclampsia strongly increased the risk of early onset preeclampsia. Regarding clinical picture of PIH the mean value at pretest measurement was (1.18±0.388), and at posttest-I was (2.00±0.000), and at posttest-II was (2.00±0.000); indicates high significant differences between (pre and posttest -I) (pre and post II-test) from poor level to good level in both posttest-I and posttest-II measurements regarding knowledge of the nurses about clinical picture of PIH (P < 0.05).The nurse’s knowledge about clinical picture of pregnancy induced hypertension assessed overtime. It indicates improvement of nurses’ Knowledge in the all items. These improvements were statistically significant in the all items. The most prominent improvements were related to clinical picture needed for the infants and complications of hypertension for the pregnant women, which reached 100.0% in the immediate posttest-I and remained at the level at the follow-up posttest-II.Nonetheless, the levels were still significantly higher than the pre-program levels. ELfakki, (2017) supported this result by reported the nursing knowledge in two study was better than pretest. The nurse should be aware about the weight gain during pregnancy and when the patient developed pathological edema and should know that when patient complain from severe symptoms of preeclampsia such as right hypochondrial pain, epigastric pain. This finding supported
by the result of (Magee et al., 2005), who reported that the maternity nurses mentioned some signs and symptoms. In respect to investigations related to pregnant women of PIH the mean at pretest measurement was (1.34±0.479), and at posttest-I was (1.94±0.240), and at posttest-II was (1.94±0.240); indicates high significant differences between (pre and posttest-I) (pre and post II-test) from fair level to good level in both posttest-I and posttest-II measurements regarding knowledge of the nurses about Investigations of PIH (P < 0.05). Williams et al., (2013) stated that diagnosis of hypertensive disorders in early pregnancy and preeclampsia in late pregnancy need through investigations. These investigations will differ slightly depending upon the diagnostic priorities. In early pregnancy identifying any underlying causes of hypertension is important, whereas after 20 weeks of gestation the investigations will be tailored to making the diagnosis and determining the severity of pre-eclampsia. There will, however, be a great deal of overlap between the two situations and their investigations will be considered in tandem. Légaré & Witteman (2013)24, reported that the nurses are responsible for explaining screening and diagnostic procedures and for clarifying options, so that women can make informed decisions about care.

Conclusion

The study concludes there were significant of educational program on nurse-midwives’ knowledge.

Financial Disclosure: There is no financial disclosure.

Serum Glucose Level According to Menstrual Cycle Phases in Young Students at the College of Science for Women

Ghadeer Hamid AL-Ardhi1, Noran Jameel Ibraheem2

1Assist. Lecturer, Department of Biology, DNA Research center, University of Babylon, Al-Hila, Iraq,
2Prof., Dr. Department of Biology, College of Science for Women, University of Babylon

Abstract

Objective: This study was carried out to present data on serum fasting glucose level in healthy young women with regular menstrual cycle who have moderate active state across their three different stages of the menstrual cycle (menstruation, proliferation and secretory) phases.

Subjects and Method: A total of 50 non-diabetes women with normal regular menstrual cycle were involved in this study, the subjects ages ranged from 20-24 years, fasting venous blood (3ml) was collected at early morning during menstruation phase (days 1-5), proliferation phase (6-14 days) and the secretory phase (15-28days) for each subject, serum glucose measurement were conducted by colorimetric technique.

Results: The present study shows non-significant (p<0.05) increase in the mean of glucose level during menstruation and proliferative phase (92.8±12.7, 92.6±10.2 mg/dl) respectively in the same subject comparison with secretory phase (90.48±8.3mg/dl) in the same subject.

Conclusion: This study revealed that serum glucose level does not change along stages of normal and regular menstrual at rest or moderate active young women.

Keywords: Menstrual cycle phases, Serum glucose, level, young students.

Introduction

Determining how the menstrual cycle phase affect varies aspects of metabolism is necessary to provide a comprehensive understanding of normal physiology in women1, many women notice blood glucose fluctuation at certain times in their monthly cycle, these occur to change in hormones (estrogen and progesterone), at the same time, these hormones affect another important hormone, insulin which may in turn cause variation in blood glucose level2, previous study showed relation between fluctuation of hormone and level of glucose during menstrual cycle, as well, that variation in insulin sensitivity during menstrual cycle was found by other researchers3,4 menstruation describe the female period5. Women begin menstruation at an average age of 13 years till age 51, this period involves highly complex hormonal interactions estrogen and progesterone the key hormones were involved6.

Material and Method

This study was conducted at college of science for women/university of Babylon. A total of 50 non-diabetes women with normal regular menstrual cycle were involved in this study, the subjects ages ranged from 20-24 years with BMI mean (23.67±4.37Kg/m2). Fasting venous blood (3ml) was collected at early morning during menstruation phase (days 1-5), proliferation phase (6-14 days) and the secretory phase (15-28days) for each subject, no subject was excessively sedentary or participate in heavy physical activity. Colorimetric technique was used for glucose measurement by use the Bio Merieux (France) Company kit.

Statistical Analysis: Repeated measures a nova– pair-wise comparisons test was used in studying the glucose level differences across the three menstrual phases using (spss) system. P value less or equal to 0.05 was taken as significant.
Results and Discussion

Our data revealed that rise in the mean serum glucose level in healthy women during their menstruation (92.68±12.68mg/dl) and proliferative stages (92.64±10.22mg/dl) were non-significant compared to secretory phase (90.08±8.49mg/dl), as well its non-significant different found in glucose level between the menstruation and proliferation stage as showed in table 1.

NS: P value >0.05

Concerning with the result of glucose during menstruation phase it is agreement with studies which suggested that possible change in eating pattern in few days before and during menstrual cycle may affect glucose level, where many women experience craving for high-carbohydrate food during the days leading up to menstruation. Other study suggested that possibility of pre-menstrual hyperinsulinism to account for their findings of a lower premenstrual blood sugar compared to the midcycle values this association with premenstrual tension syndrome, while other study suggested that glycolysis peak rate just occurs prior to ovulation that may reason to that glucose level increase in proliferative stage in our population study.

Other studies performed on glucose utilization and carbohydrate metabolism have shown no significant difference in moderate active or at rest women across the menstrual cycle, moreover, change in estrogen and progesterone across the normal menstrual cycle do not appear to be of sufficient magnitude to significantly affect resting glucose flux, this may be the same responses in our study population was observed.

Additionally, the effect of menstrual cycle on fuel metabolism may be more apparent during exercise however contrary to what was originally hypothesized however, variables such as age, body weight and parity may be contributed in the result of the present study.

Conclusion

This study revealed that serum glucose level does not change along three stages of normal and regular menstrual cycle at rest or moderate active young women.

Blood Pressure, Blood Sugar, Smokers and their Relationship with Physiological Variables of Some Risk Factors

Nada Saad Naji Al-Taee

Department of Environmental Pollution, Faculty of Environmental Sciences, AL-Qasium Green University, Iraq

Abstract

This study deals with the physiological measurements of fasting blood sugar (FBG), clinical blood pressure (CBP) and smokers and their association with risk factors (obesity, gender and age) among university students. A total of 257 students (77 females and 180 males) were registered. Including 41 healthy and 42 students who were FBG; 33 were healthy and 69 were suffering from CBP; 39 non smokers and 33 students who were smokers; aged 19-26 years. A statistically not-significant connection was found between FBG, CBP and smoking with obesity rates; but a significant difference between smoking and CBP with age and gender, respectively. These findings highlight the prevalence of FBG and CBP also smoking in students and its relation to certain risk factors such as obesity, sex and age among selected student groups.

Keywords: Blood glucose, blood pressure, smoking, risk factors.

Introduction

It is important to prove now that many factors such as obesity, sex and age are linked to BG, BP and smoking. The obesity is a hazard factor to many diseases, as diabetes and hypertension1. In 2030, around 438 million people worldwide (7.8%) in adult population are suffering from diabetes. This global rise in the propagation of diabetes is attributed to urbanization, population growth, aging and obesity2. According to there is a significant impact of diabetes with gender, and women are more probability to develop diabetes than men. A study in Iraq found that the diabetes prevalence was 15.2% in female compared with 11.8% in males4. Despite the increasing burden of obesity and HBP in growing countries, there was limited information about BMI contribution in BP in these populations, especially among students. BMI is independently and positively connected with mortality and morbidity due to HBP, cardiovascular disease CVD and diabetes II5. For all BMI categories in study6, age was higher with HBP and HBP in men than in women. The systolic-BP and diastolic-BP increased with age, both for men and women7. Smoking is one of the leading causes of death as well as the main challenge to public health all over the world8. Smoking is connected with low weight9. Lack of smoking propagation has been proposed as one of the agents connected with a high in obesity10. There may be a causal impact of smoking on weight because nicotine is a metabolic stimulant as well as appetite suppressant11. The difference in CVD risk among smokers and non-smokers is significant in middle age, particularly for men12.

Materials and Method

Criteria of participants: A sample of 257 students was selected randomly among students. About 83 participants of FBG with mean(X)±standard deviation (SD) of age were divided to: health (<100 mg/100cm³; 21.97±1.49), pre-diabetes (100-125 mg/100cm³; 21.83±1.59), diabetes (≥126 mg/100cm³; 21.77±1.09), and hypoglycemia (≤70 mg/100cm³; 21.66±2.30). In addition, 102 participants of a CBP-level with X±SD of age were divided: normotensive (<120/<80; 21.38±1.706, 110.87±5.129, 72.16±6.126, 86.29±11.07), EPB,
elevated blood pressure (120-129/<80 mmHg; 21.96±2.007, 124.78±2.848, 75.71±4.767, 86.40±11.09), hypertension (130-139/80-89 or ≥140/90 mmHg; 22.00±1.647, 144.68±10.90, 90.41±6.873, 84.82±9.26), and hypotension (<90/60 mmHg; 20.28±1.603, 84.57±6.160, 56.57±3.101, 84.28±8.76). In addition, only 72 men were employed for smoking and the periods of cigarette smoking of 2-3 year with X±SD of age were divided into 39 non-smokers (control; 22.25±1.91), 9 light-smokers (≤10 cigarette daily; 22.11±1.96), 16 moderate-smokers (11-20 cigarette daily; 22.06±1.80), and 8 heavy-smokers (≥ 20 cigarette daily; 22.25±1.90).

Collection of data and measurement: The data were gathered utilizing a self-administered questionnaire. It is built on several axes such as: age, smoking case, duration of smoking, the number of cigarettes smoked per day, the family history of diabetes and physical activities. The criteria for selecting students were that no one should suffer any medical complication such as heart disease, stroke or any other disorder. BG was measured in the morning after fasting for at least 8-10 hours, using the active glucose Accu-chek meter. BP was measured by the electronic pressure device by taking the pressure reading after 5 minutes of inactivity. CW was measured by placing the measurement meter tightly on the waist (cm) and the WC/risk level are classified as follows: Low (Women <80 and Men <90), high (Women 80-88 and men 94-102), and very high >102. The waist circumference, (WC), is measured by placing the measurement meter on the active glucose Accu-chek meter. BP was measured in the morning after fasting for at least 8-10 hours, using the active glucose Accu-chek meter. BP was measured by the electronic pressure device by taking the pressure reading after 5 minutes of inactivity. CW was measured by placing the measurement meter tightly on the waist (cm) and the WC/risk level are classified as follows: Low (Women <80 and Men <90), high (Women 80-88 and men 94-102), and very high >102 for smokers men.

Measurement of obesity: The obesity was estimated using body mass (BMI) index, measured by weight in kilograms (kg) divided by a height in the meters squared [kg/m²]; BMI classification was based on WHO as: normal weight, 18.5-24.9; underweight, less than 18.5; and overweight 25-29.9. The waist circumference, (WC), is measured by placing the measurement meter tightly on the waist (cm) and the WC/risk level are classified as follows: Low (Women <80 and Men <90), high (Women 80-88 and men 94-102), and very high >102 for smokers men.

Statistical analysis: The descriptive analysis was also used to show the X±SD of the results. Gender, age and obesity were statistically tested by Chi-square ($\chi^2$) test at $p<0.05$.

Results And Discussion

Fasting blood glucose and obesity, sex and age: In Table 1: A statistically insignificant in BMI between FBG classes and healthy, although the highest percentage of pre-diabetes was obese compared with healthy. The statistically insignificant in WC of FBG levels compared with control, although the highest percentage was observed in diabetes from Low of WC and hypoglycemia from a high of WC risk level. The prevalence of diabetes (77.77) in males, and pre-diabetes (66.66) also hypoglycemia (66.66) in females. Statistically insignificant in age in FBG categories, although the highest rate of pre-diabetes and diabetes was found in both gender in the 21-22 age group, and a higher proportion of hypoglycemia in the 23-24 age group compared to health.

Clinical blood pressure level and obesity, gender and age: In Table 2: No-significant relationship between the level of CBP and obesity measured by BMI and WC, although the highest rate of EBP and hypertension was overweight and obese compared to normotensive, respectively. Hypertension and EBP are the highest in low and high of WC risk level compared with normotensive, respectively. The male had a high percentage of hypertension (82.76) and a high percentage of hypotension (85.71) in female compared with normotensive. EBP and hypertension appeared 21-22 and 23-24 years of age, compared to normotensive, respectively.

Smoking status with obesity (BMI and WC) and age: In Table 3: A statistically not-significant in obesity with BMI $\chi^2=5.652$ among smoking status. A statistically not-significant in CW risk level of smokers compared to non-smokers. And a significant in age in which the high percentage was appeared at age (21-22) years of light-smokers followed by low percentage appeared at age (23-24) years of moderate-smoker compared to non-smokers. In addition to high percentage that noted at age (21-22) years of light-smokers, moderate-smokers, and heavy-smokers compared to control, and heavy-smokers has been shown in age 25-26 years compared with non-smokers of a same age. Obesity is connected with poorer control of BP-levels and BG-levels making people with diabetes more susceptible to micro-vascular and cardiovascular diseases. Other studies have shown a strong epidemiological link between the development of diabetes and obesity. When the study trends were studied by BMI groups, disease increased only among those who have obese (18.0% to 20.1%), indicating that much of the rise in the prevalence of diabetes is due to the growing prevalence of obesity, and diabetes was less prevalent in males than in females in Iraq community.

In Turkey, there was a statistically non-significant relation between BP and sex. Although this study was statistically insignificant in age with FBG, the results were favorable with the prevalence of disease and hazard factors among people aged 15 Years and older in...
Ethiopia. A significant connection was also found in college students between age, overweight, and sex, as well as between BGelevation with gender. Many people own a classification of BP without knowing it. The results of the current study were consistent with, where a positive relationship was absorbed between obesity and hypertension, also which observed a positive connection between hypertension and BMI. The current study shows that male students had a high percentage of hypertension compared with a healthy and female students, and is close to. It is also appropriate with that there is a positive connection with BP and increasing age. The low prevalence of smoking has little impact, often less than 1%, on increasing the prevalence of obesity and reducing the healthy weight of the population.

The BMI of smokers appeared a diminishing trend compared with nonsmokers. No-significant variation in the physical mean parameters such as obesity are found when calculating X±SD in smokers and passive-smoker; but my results do not identical the results of, it was observed that both cigarette consumption and smoking frequency had positive effects with weight loss in adolescents. There has been a significant elevate over the past decade in the numbers of smokers of college age. Various studies have reported that the spread of smoking raises between the first to last year among college students, confirming the fact that the early years of the university are important to target anti-smoking activities. The University of Karbala, smokers (45.7%) smoked before the age of 18 years, and were positively correlated with male sex and growing age.

Detect of Phylogenetic Relationships by RAPD_PCR among *Staphylococcus aureus* Isolated from Different Sources in Hilla City

Amal Raqib Shamran¹, Zainab A. Tolaifeh²

¹University of Babylon/Collage of Science for Women, Iraq, ²University of Babylon/Collage of Science for Women, Iraq

**Abstract**

*Staphylococcus aureus* (brilliant staphylococcus) is a Gram-positive, cocci – shape, it is an individual from the typical verdure of the body, oftentimes found in the nose, respiratory tract, and on the skin. Usually positive for catalase and nitrate decrease. We can portrayed *S. aureus* strains that are across the board in hospital in Hilla city, 60 clinical and condition tests were gathered from numerous parts of patients like injuries, skin, nails and urinary tract disease taken from general doctor’s facilities of Hilla city. Strategies for segregation and distinguishing *S. aureus* dependent on culture strategies with biochemical tests, A sum of 17 enhanced DNA sections from 250 to 1K base match) were watched utilizing the 2 groundworks, and every one of preliminary that fruitful giving intensification groups uncovered distinctive hereditary example. End: RAPD-Polymerase Chain Reaction investigation it used to discover an incentive in structuring an assortment of sub-atomic DNA unique finger impression dependent on epidemiological examinations that centers around the recognizable proof and portrayal of *S.aureus*.

**Keywords:** Phylogenetic, RAPD_PCR, Staphylococcus aureus

**Introduction**

*Staphylococcus aureus* is an opportunistic pathogen that causes a nosocomial infections ranging from self-limiting to lifethreatening in both developing and developed countries¹³,¹⁴. It is critical in the study of disease transmission and nature to have the capacity to distinguish bacterial species and strains precisely. Fast distinguishing proof and order of microscopic organisms is ordinarily completed by morphology, healthful prerequisites, anti-microbial obstruction, isoenzyme examinations, phage affectability³,⁴,²,⁵ Meanwhile, a few strains of *S. aureus* have mecA quality which presents protection from methicillin and the greater part of the regularly utilized antimicrobial operators including b-lactams and cephalosporins. These strains are called methicillin-safe Staphylococcus aureus (MRSA) and they thought to be more destructive than methicillin-powerless Staphylococcus aureus (MSSA) strains¹⁶. The expanding rates of nosocomial and network related MRSA diseases and their capacity to exchange between people, ox-like, and nourishment of creature birthplaces have turned into a worldwide hazard¹⁵. Recognition and distinguishing proof techniques utilizing the PCR to enhance DNA have been utilized for different creatures⁹, yet these require sequence information for particular preliminaries. In any case, PCR utilizing discretionary groundworks (AP-PCR) requiring no earlier arrangement data has uncovered DNA polymorphisms that might be valuable for fingerprint (Welsh and McClelland, 1990; Williams et al., 1990). Haphazardly Amplified Polymorphic DNA (RAPD), a straightforward PCR based procedure, has been broadly utilized for epidemiological examination. In addition, RAPD preliminaries can successfully examines the entire chromosomal DNA for the nearness of little reversed rehashes and intensifies the

interceding DNA portions of variable length that can be utilized for distinguishing hereditary variety and setting up strain PARTICULAR fingerprints. Likewise the test can be performed with low convergence of DNA utilizing short engineered oligonucleotide groundworks long.

**Methodology**

**Sampling:** Sixty samples were collected from clinical and environmental cases. Samples were taken from out and inpatients who admitted to AL-Hilla General Teaching Hospital and Babylon Hospital for Maternity and Pediatric Hospital. Between October 2016 and May 2017.

**Bacterial Isolation:** Around 250 ml S. aureus detach was enraptured into a 100 ml of supplement soup (pH seven.5) and command underneath consistent shaking at thirty seven C for twenty-four h. The microorganism cell was expelled o by action, washed with zero.1mM Tris EDTA and unbroken at - 20oC for DNA extraction.

**Genotypic identification:**

**DNA Extraction:** DNA of staphylococcus aureus isolates was extracted and purified using Extraction and purification Kit from Geneaid company (UK).

**Primers:** Two arbitrary or random primers (OPB-10,OPX-01) obtained from Bioneer, IDTDNA (USA). Bacterial isolates were tested for single primers for RAPD-PCR technique (table 1).

**RAPD-PCR amplification:** Final product of 30μl reaction volumes containing ten ul of single primer,12.5 ul of inexperienced Master combine, 5 ul of Genomic DNA and therefore the volume of reaction was completed up to thirty ul by adding a pair of 5 ul of enzyme free water Amplification was applied during a thermo-cycler (Eppendorf) programmed for 2 minutes at 94°C; for 45cycles one minute at 94°C, one minute at 35°C and 2 minutes at 72°C; and a final extension of 5 minutes at 72°C. Amplification product were electrophoresed in one.8% agarose gels so pictured by staining with ethidium bromide commonplace molecular markers were conjointly enclosed in every action run. Ultraviolet trans-illuminated gels were photographed.

**Phylogenetic Analysis::** Positions of unequivocally scorable RAPD bands were transformed into a binary characters matrix (“1” for the presence and “0” for the absence of a band at a particular position). Phylogenetic tree was created by the unweighted pair-group method arithmetic (UPGMA) average cluster analysis.

**Results and Discussion**

**RAPD analysis of staphylococcus aureus:** Polymorphism assay for staphylococcus aureus isolates was carried out using two primers. Random amplification of the DNA of S. areus isolates reveals the efficacy of these selected nucleotides sequences in determination the similarity or variations among all isolates.

**S.aureus isolates by RAPD:** A total of 9 amplified DNA fragments ranging in size from 250 to 1 Kpb were observed using two random amplified polymorphic DNA (RAPD) primers (opX-10,opB-01) where as17 polymorphic amplified fragments were commonly detected among the 9 S.aureus isolates (table 1) and each of primer give different genetic profiles. UPGMA analysis for the dendrogram made based on the RAPD data generated by primer OPX-10 were performed and shown in figure 3. Analysis showed that the 9 s. aureus strains were grouped into two and clustered into three classes. The large cluster comprised the Stap4, Stap5, Stap9,Stap7, and Stap8; a second cluster included strains of the S2, S8 and S9; and the third remaining clusters corresponded to the Stap1, Stap3,Stap2 and Stap6. While primer OPX-01 were performed and shown in figure 4. Analysis showed that the 9 S. aureus strains were grouped into two and clustered into three classes also. Genetic fingerprint and process diversity between Staphylococcus aureus isolates were determined by ever-changing RAPD data into a Jaccard similarity analysed by UPGMA to produce a organic process tree. The compound band pattern obtained is equivalent to a Universal Product Code, allowing the identification of each individual as Associate in Nursing example, isolate Sa1 presents distinctive bands once its compound amplified with most of the primers tested (Figure 1. It’s well documented that RAPD-PCR is one of the most widely used method to investigate the genetic variability of any given nosocomial pathogen, moreover in RAPD the power of designated and discriminatory primers can be been easily assessed. phenotypes consist of isolates that less related and such identification isolates using cultural and morphological techniques often lack consistency and precision. In the current examination, we have discovered that distinguishing proof of hereditary assorted variety in S. aureus relies upon wellsprings of segregates, diverse host cells and event of freaks. RAPD markers uncovered conceivable
association between host start line, amendment and hereditary selection among S. aureus separates, and this shown its process and symptomatic potential. Clearly, for these deoxyribonucleic acid teams examples to possess a helpful significance within the zones of prescription, people science and also the study of illness transmission, explicit deoxyribonucleic acid teams should be known with host beginning points, transformation and quality qualities, Rapd-pcr is important to possess fast and solid epidemiologic composing method to screen the bury or intra-spread of multidrug safe MRSA strains, this might be practiced by a organized correlation of deoxyribonucleic acid band styles among microorganisms differentiating for the varied host birthplaces, transformation and quality qualities gift. Comparative methodology has been utilised to separate forceful from non-forceful disengages of the seed assault microorganism Phoma symbol[12]. The DNA mark characterized for each race of S. aureus ought to be valuable for epidemiological reviews, medicinal analyses, and in the distinguishing proof of new destructive strains and detaches and their birthplace.

Lipsticks Elemental Analysis by Energy Dispersive X-Ray Used as Criminal Evidence

Wedad Al-Dahhan¹, Hassan Hashim², Emad Yousif¹, Ayad F. Alkaim³

¹Prof. Department of Chemistry, College of Science, Al-Nahrain University, Baghdad-Iraq, ²Prof. Department of Physics, College of Science, Al-Nahrain University, Baghdad-Iraq, ³Prof. Department of Chemistry, College of Sciences for Women, Babylon University, Hilla, Iraq

Abstract

Since ancient times, man has been interested in showing his appearance in the best shape and has used make-up materials including lipstick for this purpose. Four lipstick samples were selected for one brand with different colors (Lipstick-03, Lipstick-23, Lipstick-29 and Lipstick-51) as well as two different colors for the so-called magic lipstick (Luxe orang and Luxe yellow). Energy-dispersive X-ray spectroscopy (EDX) is an analytical technique was used for the elemental analysis for the selected six samples. These tests aims to explain that there are clear elemental differences for the selected samples which can be used to define the identity of each sample. Lipstick-51 has been selected to contaminate some substances that can be commonly used in homes, offices and others. The selected substances were (Plastic bottle, Plastic cup, Glass, Cigarette filter and Tissue paper). The elemental results indicate a partial match for the types of elements in lipstick contaminated with substances taken from the crime scene compared to the original Lipstick-51. Results could be more accurate when identifying the contaminated material and select the most concentrated positions for samples taken from the crime scene and for conducting tests.

Keywords: Lipstick, EDX, Crime scene, Element.

Introduction

Since the dawn of civilization cosmetics have constituted a part of routine body care not only by the upper strata of the society but also by middle and low class people(1).

A cosmetic product is any substance or preparation intended to be placed in contact with the various external parts of the human body (epidermis, hair system, nails, lips and external genital organs) or applied to the teeth and the mucous membranes of the oral cavity with a view exclusively or mainly for the purpose of cleaning, perfuming, protection, changing their appearance, correcting body odors’ and keeping the surfaces in good condition(2,3). The demand for cosmetic products has increased recently, resulting in massive production by the cosmetic industry. Different products are marketed under the name of cosmetics, such as creams, beauty soaps, talcum and facial powder, lotions, shampoos, hair products such as haircolors, baby products, bath oils, personal hygiene products, perfumes, lipsticks, skin care products, makeup products, shaving creams, body lotions, fingernail polish and polish removal(4-8).

In addition, the use of herbal medicinal preparations is common in most developing countries due to poverty and disillusionment with conventional medical care(9,10).

Heavy metals are found naturally in the environment in rocks, soil and water, and therefore exist in the manufacture of pigments and other raw materials in all industries including the cosmetics industry. Some of these metals have been used as cosmetic ingredients in the past. Examples include the preservative thimerosal (mercury), the progressive hair dye lead acetate and a
number of tattoo pigments such as red cinnabar (mercuric sulfide), Cadmium is a deep yellow to orange pigment and mostly present in lipsticks and face powders. The use of cadmium in cosmetics products are due to its color property as it has been used as a color pigment in many industries\(^{(11)}\).

For more than two thousand years humankind has been attempting to solve crimes through the application of scientific knowledge. Physical evidence often plays a pivotal role in reconstructing the series of events surrounding a crime, and may be used to prove or disprove a point in question based upon its discernible characteristics.\(^{(12)}\) In addition, trace physical evidence can be instrumental in providing evidence of association. This value stems from the exchange principle developed by Edmond Locard, who posited that physical contact between two surfaces will likely result in a cross-transfer of matter between them\(^{(13,14)}\). Zadora and Brozek-Mucha applied cluster analysis with scanning electron microscopy (SEM)-EDX to differentiate glass samples into use-type groups based on their elemental content\(^{(15)}\). An emerging area of interest in forensics is the examination of cosmetic products. Kulikov \textit{et al.} employed wavelength-dispersive X-ray fluorescence spectrometry for the elemental analysis of 39 cosmetic powders\(^{(16)}\). Cluster analysis and PCA were able to clearly discriminate between samples possessing traditional ingredient or mineral-based formulations, and also distinguish specific manufacturers of the latter.

Salahioglu \textit{et al.} later demonstrated the use of Raman spectroscopy to discriminate lipstick samples deposited on textile fibers, cigarette butts and paper tissues. The combined SEM/EDX techniques indispensable for fast, nondestructive, physicochemical analysis of trace evidence and solid objects of any size. The SEM/EDX is not ideal for quantitative analysis of elements present at traces. The ability of the SEM/EDX to detect an element below a minimum detection limit (MDL) (0.1–0.3% w/w)\(^{(17)}\).

**Experimental Part: Sampling:** Four lipstick samples were selected for one brand with different colors (Lipstick-03, Lipstick-23, Lipstick-29 and Lipstick-51) as well as two different colors for the so-called magic lipstick (Luxe orang and Luxe yellow).

**Elemental Analysis:** Energy-dispersive X-ray spectroscopy (EDS, EDX, or XEDS) Bruker model XFlash6110, is an analytical technique we used for the elemental analysis for the selected six samples (Lipstick-03, Lipstick-23, Lipstick-29, Lipstick-51, Luxe orang and Luxe yellow).

**Simulation of samples taken from the crime scene:** One type of lipstick (Lipstick-51) has been selected to contaminate some substances that can be commonly used in homes, offices and others. The selected substances were (Plastic bottle, Plastic cup, Glass, Cigarette filter and Tissue paper) as shown in figure 1 (pictures 1-5).

**Result and Discussion**

**EDX Analysis for the selected samples:** EDX analysis was carried out for the four lipstick samples (Lipstick-03, Lipstick-23, Lipstick-29 and Lipstick-51) as well as for the two different colors for the so-called magic lipstick (Luxe orang and Luxe yellow). These tests aims to explain that there are clear elemental differences for the selected samples which can be used to define the identity of each sample. Figures 2, shows EDX analysis for the selected sample Lipstick-03.
Samples withdrawn from crime scene as criminal evidence: Criminal evidence inspectors are keen to select samples that may be of benefit from the crime scene. Contaminants with personal belongings, such as lipstick, will certainly be of interest to the relationship of someone to the crime scene. The prepared samples which explained in sec. 2.3 were examined for elemental composition using EDX instrument. Results for the five samples stated in figures: 3 and 4.
In order to identify the elements in the samples taken from the crime site that belong to the contaminant (Lipstick-51), these samples must be examined using the same instrument (EDX), but without contaminants. Therefore, the elements of the contaminant will be known. Table 1 shows the elemental analysis for the contaminant and uncontaminated samples.

Table 1: The elemental analysis for the contaminant and uncontaminated samples

</table>

From table 1 it was found that the elements belongs to the lipstick-51 in the plastic bottle (Mg, Al, Si), Plastic cup (Fe, Si), Glass bottle (Fe), Cigarette filter (Ca, Si) and for Tissue paper (Al, Si, Mg). These elements are part of the elements in the lipstick-51 (C, Ba, Mg, Se, Al, Si, Hg, Ru, K, Ba, Ca). On the basis of these results, it takes two things to focus on:
1. Accuracy in taking the sample from the crime scene so that it contains the most contaminated material.

2. The EDX operator must examine and select the most concentrated places of the contaminated sample, as well as a precise focus of the radiation (X-ray) on the site of the contamination, making the results more accurate.

**Conclusion**

The crime scene contains many elements and observations through which forensic inspectors can access the facts and analyze the components of the crime. The use of EDX technology could be a guide to identify the nature of existing elements as contaminants for samples taken from the crime scene. It was recommended to be more accurate in identifying the contaminated material and select the most concentrated positions when taking samples from the crime scene and conducting tests.

Abstract

The present study investigate the hepatoprotective and antioxidant effect of crude extract of *Arctium lappa* stem (E-ALS) and isolated total flavonoids (ITF) from the stem, With qualitative and quantitative determination of flavonoids by HPLC. Twenty four local adult male rabbits were used in this study which divided into four groups (6 animal in each group), Control-1 (C1) as control group, Control-2 (C2): treated with 300mg/kg *paracetamol* administrated for one week, Group 1 (G1): 300mg/kg *paracetamol* administrated for one week +Orally 250mg/kg of E-ALS administrated daily for 4 weeks, Group 2 (G2): Orally 300mg/kg *paracetamol* administrated for one week +Orally 50mg/kg of ITF administrated daily for 4 weeks.

The results identified five types of flavonoids for the first time in plant stem (Rutin, Myricetin, Quercetin, Apigenin, Kaempferol) with quantified determination for the concentration of each type of flavonoids in E-ALS and also in ITF which identified the same five flavonoids. The hepatoprotective effect of E-ALS and ITF were observed by monitoring the antioxidant parameters and activity of liver enzymes.

The results obtained from this study showed that the levels of glutathione-GSH, Glutathione peroxidase-GPX and Glutathione-S-Transferase-GST were significantly (P ≤ 0.05) decreased in C2 treated with *paracetamol* as comparing with C1, with significant (P ≤ 0.05) elevation of alanine aminotransferase-ALT activity and non-significant effect on Aspartate aminotransferase-AST, while the level of GSH and GPX were significantly (P ≤ 0.05) elevated in G1 and G2 treated with E-ALS and ITF respectively as compared with C2, in which the levels of GSH and GPX are less than the levels in C1 and G1. Otherwise the levels of GST, ALT and AST significantly (P ≤ 0.05) decreased in G1 and G2 as compared with C2. These findings show the hepatoprotective properties of E-ALS and IFT against liver injury induced by paracetmol and also the protective role of anti-oxidative defense system of flavonoids in the two extracts.

Keywords: *Arctium lappa*, flavonoids, acetaminophen, Glutathione, Glutathion-S-transferase, liver enzymes.

Introduction

The flavonoids are a category of natural substances belonging to the family of polyphenols, they are one of the important types of plant secondary metabolites, widely distributed in foods and Medicinal Plants (1,2). More than thirty years ago, the research studies focusing on flavonoids from medicinal plant species have increased considerably, because of their versatile benefits for human health (3). These includes: antioxidants, anti-inflammatory, anticancer, antibacterial, antiviral, anti-allergic, immune system promoting and also as detoxifying and pro-survival agents (4,5,6). So that the many researcher use different method of isolation and identification of flavonoids from different medicinal plants and evaluate the pharmacological effect of the isolated flavonoids, such as; Al-Salihi et al, study the Hypolipidemic effect of isolated flavonoids from date palm pollen (7), while AlSamarraieta (8), isolated the flavonoids from Bay leaf *Laurus nobilis* L. and also study the hypolipidemic effect.

*Arctium lappa* (also known as burdock), one of the important plant in traditional medicine worldwide medicine,
many studies have evaluated the biological activities of the different parts of plant, roots, seeds and leaves\(^{(9,10)}\), including antioxidant activities\(^{(11)}\), anti-inflammatory\(^{(12)}\), anti-cancer\(^{(13)}\) and anti-hepatotoxicity\(^{(14)}\). Many researchers identified many secondary metabolites in different parts of the plant, which include: phenolic compounds, lignans, saponins, tannin, sterols, alkaloids and Flavonoids\(^{(15-17)}\). The types of flavonoids which were identified in \textit{Arctium lappa} leaves include, luteolin, rutin, quercetin and quercetinrhamnoside. On the other hand Rajasekharan et al\(^{(18)}\) identified quercetin 3-vicianoside and quercetin 3-O-glucuronide in the root of the plants, with no flavonoids in seeds. The present study aims to isolate and identify the flavonoids from \textit{Arctium lappa} stems and study the protective effect of it against the liver damage induced by paracetamol (acetaminophen).

**Material and Method**

**Plant Materials:** The dried stems of \textit{Arctium lappa} were obtained from a local market in Samarra city, Salah Al-Din, Iraq. The stems were separated from other parts of the plant, kept in a dark container until used.

**Method**

**I. Preparation of extracts:**

- Crude extract from \textit{Arctium lappa} stems E-ALS: 45g of \textit{Arctium lappa} powder was suspend in 180ml normal saline solution.

- Isolation of total flavonoids from \textit{Arctium lappa} stems: This isolation was done according to (Chen et al, method) with some modification\(^{(19)}\), the first step before extraction was remove fatty contents, 250g plant stems powder were extracted with 750ml diethyl ether, soxhlet apparatus for 3 hours, dried the defatted plant material at 35 C° in an air oven, the second step extracted flavonoids twice with 500ml (70%) ethanol solution at 90C° for 2h. The solution was filtered and centrifugation at 3000 rpm for 15 min. The clear supernatant was subjected to charcoal treatment to remove pigments prior to evaporation under vacuum (BuchiRotavapor Re Type). Dried samples were re-suspended in 1.0 ml HPLC grade methanol by vortexing, the mixture were passed through 2,5um disposable filter and stored at 4° C for further analysis, then 20 μl of the sample injected into HPLC system according the optimum condition. Five standard solutions (25μg/ml) were used (Rutin, Myricetin, Quercetin, Apigenin and Kaempferol).

The concentration of identified flavonoids was done according to the following equation:

\[
\text{Area of sample} = \left( \frac{\text{Conc. of Flavonoids(μg/ml)/ Area of standard}}{C} \right) \times C \times D
\]

\[C = \text{Conc. of Standard solution}\]

\[D = \text{Dilution factor}\]

**III. Animals:** twenty-four local adult male rabbits (1200-1550 g weight) were used in this study. Groups of rabbits were housed at room temperature with a lighting schedule of 12 hours light and 12 h dark. Animals had free access to a standard pellet diet. All animals were divided into four groups (6 animals in each group) described as follow:

- **Control 1(C1):** Orally 1ml/kg/day administrated daily dose normal saline only.

- **Control 2(C2):** Orally 1ml/kg/day of paracetamol (300mg/kg- normal saline was used as solvent) administrated daily for 7 days.

- **Group 1(G1):** Orally 1ml/kg/day of paracetamol (300mg/kg- normal saline was used as solvent) administrated for 7 days + Orally 1ml/kg/day of \textit{Arctium lappa} stems extract (250mg/kg- normal saline was used as solvent) administrated daily for 4 weeks.

- **Group 2(G2):** Orally 1ml/kg/day of paracetamol (300mg/kg-normal saline was used as solvent) administrated daily for 7 days + Orally 1ml/kg/day of flavonoids isolated from \textit{Arctium lappa} stems (50mg/kg-normal saline was used as solvent) administrated daily for 4 weeks.
IV. Collection of blood samples: After 4 weeks, serum samples were collected by heart puncture from fasting rabbits for 12 hours. Determination of serum levels of Glutathione-GSH\(^{21,22}\), Glutathioneperoxidase-GPX\(^{23}\), Glutathione-Transferase-GST\(^{24}\), alanine aminotransferase-ALT and Aspartate aminotransferase-AST\(^{25}\) by using standard method.

V. Statistical Analysis: Results were analyzed statistically by using (analysis of variance test-ANOVA the statistical program Minitab). Averages were compared to calculations of the characteristics of the application Duncan’s Multiple Range Test by probability level \(P \leq 0.05\).

Results and Discussion

Part I: Phytochemical study: The HPLC analysis of flavonoids were done firstly by using five standard flavonoids, Table 1 showed the Retention Times and Area Under Curves for Standard Flavonoids.

The HPLC analysis of the crude *Arctium lappa* stem extract showed seven peaks with different Rt (1.987, 2.51, 3.807, 4.883, 5.763, 6.038, 6.823) min [Fig. 1], while the area under curve were (186616, 406614, 387611, 58062, 404152) µvolt [Table 2].

![Fig. 1: HPLC analyses of flavonoids in Arctium lappastems](image-url)

The types of flavonoids in *Arctium lappastems* were identified by comparing the \(R_t\) obtained from chromatograms of crude stems extract with \(R_t\) in chromatogram of standard flavonoids, and then the concentration of the identified flavonoids was done by using the values of the area under curve for stem extract and for each standard. The results indicate that the crude plants contain 793.56 µg/g of rutin, 741.33 µg/g of Myricetin, 866.31 µg/g of Quercetin, 44.80 µg/g Apigenin and 810.76 µg/g Kaempferol with two unknown peaks [Table 2].

Part II: Biochemical study: The hepatoprotective effect of crude extract and isolated flavonoids from *Arctium lappastems* as an antioxidant on liver damage induced by acetaminophen were investigate in the present study, the results indicate that the levels of GSH, GPX and GST were significantly (P ≤ 0.05) decreased in control-2 treated with paracetamol as comparing with control-1 group with significant (P ≤ 0.05) elevation of ALT activity and non-significant effect on AST, while the level of GSH and GPX were significantly (P ≤ 0.05) elevated in G1 and G2 treated with crude stem extract and isolated flavonoids respectively compared with C2, in which the levels of GSH and GPX are less than the levels in C1 and G1. Otherwise the levels of GST, ALT and AST significantly (P ≤ 0.05) decreased in G1 and G2 as compared with C2.

The result indicate that the types of flavonoids in isolated flavonoids fraction from the plant stem indicate 607.73 µg/g of rutin, 363.35 µg/g of Myrecetin, 720.26 µg/g Quercetin, 502.44 µg/g Apigenin and 637.96 µg/g Kaempferol, with two unknown pecks [table 3].

Discussion

*Arctium lappa* one of the common medicinal plant in china. The fresh or dried roots, ripe seed and leaf were used medicinally(26), with no information related to use of plantstem in traditional medicine, in spite of the *Arctium lappa* stem may be eaten stewed or raw as a snack(27). Kim etal(28), indicate that the methanolic extract from leaves and stem of *Arctium lappa* have anti-inflammatory effect. In recent years, the drug derived from natural sources have been given much attentions more than the chemical drugs, in addition to study the chemical composition and biochemical effect. The *Arctium lappa* contain lignin especially arctin (lower concentration than other part of the plant)(29), no more information were available about the chemical composition of the *Arctium lappa* stem or about the
protective effect of it against the liver damage induced by paracetamol.

The results of the present study identified five types of flavonoids for the first time in plant stem (Rutin, Myricetin, Quercetin, Apigenin, Kaempferol) with quantified determination for the concentration of each type of flavonoids by HPLC, isolated the stem flavonoids and identified the same five flavonoids and then study the hepatoprotective and antioxidant effect of the crude stem and its isolated flavonoids.

Barros et al.\(^{(30)}\) provides invaluable insights into the therapeutic efficacy of quercetin in acetaminophen induced toxic liver damage, which suggest that the reduction in serum ALT and AST levels due to the treatment with quercetin, which is useful for prevention of liver damage caused by paracetamol, this results agree with the result of the present study, whereas the treatment with crude extract of stem and isolated flavonoids significantly (P ≤ 0.05) reduced the activity of AST and ALT in serum of rabbit in G1 and G2, on the other hand Wang et al.\(^{(31)}\) indicate that treatment with different doses of kaempferol decrease the oxidative stress, lipid peroxidation and increase the antioxidant defense activity, So this findings show the protective effect of kaempferol against liver injury.

The treatment with high dose of paracetamol in C1 cause significant high (P ≤ 0.05) elevation in serum liver enzymes (AST and ALT) and reduction of antioxidant parameters levels (GSH, GPX, GST), this depression in the level of GSH may be due to the effect of toxic metabolite N-acetyl-p-benzoquinone imine–NAPQI, which produced by hepatic cytochrome p450- CYP450 system which oxidize the excess paracetamol, and the normal detoxification of the toxic metabolite (NAPQI) by the thiol group in GSH cause consume it\(^{(32)}\), resulting in accumulation of NAPQI which then binds covalently -SH groups of proteins in hepatocytes forming NAPQI-protein adducts

**Conclusion**

1. *Arctium lappa* stem (E-ALS) and isolated total flavonoids (ITF) have hepatoprotective properties against liver injury induced by paracetamol.

2. *Arctium lappa* stem (E-ALS) and isolated total flavonoids (ITF) have the protective role of antioxidant defense system.

Studying Some of Immunological Parameters of doges that Toxocara Infections in Saladin province

Alaa Mohammed Awwad

Assistant Lecturer M.Sc. Educational Department of Sammara, Ministry of Education, Sammarra, Iraq

Abstract

The study examined 60 stray dogs from both sexes and aged 3 months - 3 years old, included 30 stray dogs and 30 dogs clinically normal, served as a control group. Toxocara infection has detected in the College of veterinary medicine Health Center in Tikrit city. Clinical signs were observed, the study groups divided to two groups one of these groups infected by the parasites of the study and other group was control the result appear immunological changes for protein levels in study groups, represented with significant differences was reported between toxocariasis group and healthy control in terms of Complement 3 proteins (33.21 ±14.18726, 35.57±15.56254), Complement 4 proteins (268.5±14.34, 146.06±17.83) although increased complement 3 level in toxocariasis group compared with healthy control, While the Complement 4 reported no significant differences increased between toxocariasis group and healthy control group. The immunoglobulins was reported highly significant differences in IgM (297.4±14.18726)in toxocariasis group compared with healthy control group (159 ±15.56), While revealed no significant decrease levels of IgG of toxocariasis group (760 ±14.34) compared with healthy control group (843±17.83). Toxocara Canis induces an early immunological response that detected by presence of these antibodies and immunological markers against T.canis infection.

Keywords: Complement 3, Complement 4, Immunoglobulin G, Immunoglobulin M, Toxocara Cainis.

Introduction

Dogs and cats are the most important animal hosts for toxocariasis, especially in developing countries where most cats and dogs have access to public parks and playgrounds, serving as the main source of soil contamination, and posing a huge risk of human exposure to infective eggs 17. Toxocariasis is a highly prevalent parasitic disease in the tropical regions of the world, with its impact on public health being typically underestimated[1–2]. Toxocariasis is a zoonotic disease usually caused by dog and cat roundworms, Toxocaracanis and T. cati. Detection and diagnosis is difficult in paratenic and accidental hosts. The roundworm Toxocara is a perfect example of a parasite moving from wild canids to their domestic counterparts and to humans[3,4]. Dogs or cats, especially in low-income and rural regions, play important roles in the transmission of Toxocara spp. through environmental contamination, which spreads the infection to humans[3]. Toxocara parasite has a notorious tendency to cause extraintestinal pathologies[5,6]. Indeed, toxocariasis includes four clinical forms, which can lead to serious health consequences[5,7,8]. The newly sequenced genome of T. canis along with transcriptomic analysis has allowed an in-depth characterization of this organism’s molecular characteristics[9]. Also, knowledge of the parasite’s genetic diversity has been improved and new diagnostic markers have been discovered [10, 9–11]. Indeed, evidence from recent investigations suggests that human toxocariasis is seriously neglected because limited attention has been paid to its prevention, treatment, and surveillance and because it is a non-notifiable disease[12–13]. The clinical symptoms of toxocariasis may vary from asymptomatic infection to localized symptoms (ocular and neurological) or severe systemic infection (visceral larva migrans), which is commonly complicated by blood eosinophilia[17] preposition many infections are asymptomatic and thus can be misdiagnosed[14]. Phylogenetic analyses based on the sequences of the nuclear ribosomal DNA(rDNA),
showed that Toxocara spp. form a distinct clade, in relation to their definitive hosts, which is separate from Ascaris spp.\[15\]. This syndrome relates to the migration of \textit{T. canis} larvae in CNS and subsequent induction of meningitis, encephalitis, cerebral vasculitis, or myelitis, usually associated with relatively non-specific clinical symptoms (eg, fever and headache)[16].

The aim of this study is to investigate the prevalence of toxocara parasite in study dogs insalahdin prevalence province with its immunological effects.

**Materials And Method**

**Specimen Collection and Preparation:** Serum preparation: Peripheral blood samples from cases and controls were collected by venipuncture using vacuum tubes (Vacutainer). Whole blood and plasma aliquots were obtained and stored at 4°C and -20°C, respectively until analyzed, and we use deep frozen or fresh serum samples. The specimens was obtained by Lode, The specimen after centrifugation was overstocked for up to 48 hours at 2-8°C before assay and for along storage period,. The samples thawing and repeated freezing must be impossible.

Detection of C3 and C4 concentration: The radioimmuno diffusion microplates were embosomed for 24 to 72 h at room temperature. These technique essentially of[22]. Calibrating viewer was used to gauged the distance of the ring, this technique is called Mancini method. In this reaction Ag-Ab spread on in semisolid phase, where antigen aspur will form into these phase. The reactants spread toward each other on the semi solid phase even they concurs, The distance of the ring is a calculated of antigen amount, the ring diameter microplates are read after of incubation 24-72 hrs[13].

Detection of IgG and IgM concentration: The examined protein, diffusing in agarose gel containing aspecific antibody will form an immune-complex, visible as aring around the well. The ring diameter is direct proportional to concentration of the analysed protein. The proportion corresponds to the diffusion time, in fact, at the end (72h), the square of diameter will be in linear proportion to the concentration of the sample. fill the wells with 5μl of sample and wait it has been completely adsorbing before handling the plate. close the plate and place it in amoist chamber for (72h)[13].

Statistical Analysis: The data analyzed by SPSS program (statistical package for social science) version[15]. Quantitative variables were represented as mean ±SD. P-value less than 0.05 (< 0.05) consider statistically significant. The relationship between studied variables was assessed by using Spearman correlation.

**Results**

The present study was designed to estimate some immunological biomarkers (C3, C4) in studied groups; 30 Toxocariasis patients and 10 healthy controls. The association between circulating levels of these biomarkers were investigated.

The complement protein calculated by using method encompass radially diffusing of antigen that found in well through agarose gel including monoclonal Ab. Intricate of Ag-Ab are configured under the circumstances proportioned to these reactions will constitutes ring that configured made of reactions. The Diameter of ring will proportion suited ejective between the diameter and concentration in accordance with data sheet that provided with the kit. The Diameter of ring will proportion. (Table, 2) display demographic characteristics of the patients with toxocara infection, as well as relationship between disease and different variables.

HC: Healthy control; IgG: immunoglobulin gamma; IgM: immunoglobulin moderate p<0.05(t test); Highly significant; P<0.05: Significant; P≥ 0.05; No-significant.

Characteristics of patients with Toxocarasis and healthy control are detailed in (Table 3). Showed Significant increase in IgG concentration compared with healthy control which non significant level (P>0.05), While IgM showed Significant increase in concentration compared with healthy control in significant level (P>0.05).

### Discussion

The present Study was designed to correlation between some of immunological biomarkers (C3, C4, IgG, IgM). In studied groups infected stray cats showed a number of clinical signs include diarrhea, loss of appetite and wasting, and due to the diagnosis of infection with *Toxocaracanis* parasite. The infection rate appeared in this parasite high in stray dogs, which may be the reason for stray dogs spread in different regions and lack of attention with unhealthy culture conditions, which increases the chances of exposure to parasitic infection and other diseases. The presence of anti-T. canis antibodies from T. canis-infected sera were showed Significant decreased in IgG concentration compared with healthy control which non-significant level this level exhibited detectable amounts of IgG in sera at 14 days post-infection, While IgM showed Significant increase in concentration compared with healthy control in in significant level(P>0.05). The levels of circulating antigen were highest during the first week of infection, The production of specific anti-*T. canis* antibodies was increased with significance the lowest detectable levels were observed at 3 months post-infection T. canis infection exhibited detectable amounts of IgG in sera at 14 days post-infection this results aggregated with the same study[1]. No significant differences was reported between Toxocarasis group and healthy control in terms of Complement 4 proteins, Complement 3 proteins although increased complement level in Toxocarasis group compared with healthy control in in significant level(P>0.05), differences were significant and highly significant in terms of C3, and run up serum echelons of complement 3 are combination with acute phase of inflammatory interactions, Whereas C3 and C4 are completely inactivated by removal of the C-terminal arginine, C5a retains approximately 10% of its chemotactic activity, which may explain the partial inactivation of chemotaxisin this infection.
Complements and some serological markers levels were elevated in Toxocariasis group with healthy control. But some of these decline. Compared with healthy control, however, the above results revealed that in the variations observed in the time of detection and the concentration of antibodies in sera may have been due to factors such as the species of the experimental host, strain used, age of the experimental host, sex of the animal.

The Effect of Research Project Course on Nursing Students’ Attitudes toward Research Process

Selman Hussain Faris1, Fatma Makee Mahmood2, Ali Kareem Khudhair3

1Community Health Nursing Department/College of Nursing/University of Kerbala, Iraq, 2Adult Department/College of Nursing/University of Kerbala, Iraq, 3Psychiatric and Mental Health Nursing Department/College of Nursing/University of Kerbala, Iraq

Abstract

Objective: Investigate the effect of research project course on nursing students’ attitude toward research at a college of nursing in Kerbala University and identify the relationship between nursing student’ attitude and demographic variables. A pre-experimental design (One-group Pretest-Posttest design) was utilized to determine the effect of research project course on nursing students’ attitude toward research at a college of nursing in Kerbala University. All participants were exposed to assess of attitudes regarding research before and after the implementation of the research project course in order to detect the effect of the course. The current study results revealed that; the majority (74.2%) of nursing students were within age groups (20-22) years old the mean age of the all students was (22.27) years. 82.3% of total students were female the majority (82.3%) of subjects were single, most of sample (80.6%) were urban resident, the mean of score of the positive attitude of respondents in posttest of the research project course was significantly higher than the pretest of the research project course in all aspects of attitude regarding research project course, and no significant difference between the nursing students’ demographic variables and attitude responses in the posttest of research project course.

Keywords: Nursing students, Attitudes, research project course, research.

Introduction

Nursing research is characterized as the integrating, and dispersing procedure to have effect on the current nursing practice by utilizing research produced information. Additionally, nursing research application has been connected with enhance nature of nursing practice1. According to Chien, et., al. (2013) and Nieswiadomy (2011), Applying research prove amid day by day clinical practice help to upgrade the; nature of nursing care, medical attendants’ close to home and expert execution and additionally to enhance the responsibility for training, and documentation of the cost-adequacy of nursing care2,3. So, the nursing research acts to give a base to confirm base practice by approve and refine existing information (science) and growing new learning that is connected to nursing practice4,5. What’s more, when you are connected the nursing research finding in nursing practice prompt abatement expenses of medicinal services, expands individual profitability, long more advantageous lives for patients, and lessening torment and enduring of patients6. The act of nursing care needs particular information and clinical aptitudes to take care of real or potential issues that influence wellbeing of people7. Therefore, the enthusiasm for nursing research is considered as a need for medical attendants instructors and school of nursing, in light of the fact that the utilization of research is of extraordinary significance to the up and coming age of nursing staff in aptitudes, for example, leading examination, settling on free clinical choices perusing logical articles, and critical thinking approaches8. Baccalaureate programs get ready understudies for section level nursing positions.

The center is to nurture all people through the human life expectancy. Information is procured from course books, classroom and Web-based direction, recreation, and clinical encounters. The objective of all projects is for understudies to graduate as protected, section level experts, have gotten a balanced introduction to the nursing field. Understudies are presented to prove based nursing practice all through their educational programs; nonetheless, the apportioned time for nursing research is frequently constrained. Nursing research is significance of its incorporation amid undergrad guideline can’t be overemphasized. Just with introduction and experience students would be able to start to comprehend the idea and significance of nursing research. Hence, a basic research course wound up obligatory in most baccalaureate nursing programs the world over to build understudies’ interest in research and usage of research discoveries practically speaking. Working on nursing understudies, is tested to stay up with the latest via searching for recovering and scrutinizing research articles that apply to hone issues that are encountered in their clinical setting. Also, it is essential to outfit understudies with a solid establishment in research to enable them to assess inquire about judge explore discoveries for conceivable application to clinical settings and to take an interest in investigate purports. Undergraduate research project program aims to facilitate quality undergraduate research between students and mentors and to bring students into a community of scholars within their field. They urge medical caretakers to use and be effectively engaged with investigate. Undergraduate education positively affects understudies to gain an essential perspective about research and encourage them to undertake research. The initial step into compelling use of research, which makes incredible commitments to change of nursing, is preparing for look into amid undergrad training. The exploration course ought to be joined into all undergrad training projects and educational program. With the goal that undergrad medical attendants can turn into a compelling exploration peruser and set research discoveries in motion, they ought to have the capacity to comprehend look into reports, reprimand them and comprehend phases of research. Among investigate exercises anticipated from nursing understudies are; perusing research articles fundamentally, gathering and announcing solid and legitimate information, going to nursing meetings, utilizing library assets, and plan theoretical or paper introduction. A nursing research course is viable in expanding learning about strides of research and getting the capacity to assess after effects of research and in addition having a positive attitude towards research. Students’ attitudes are connected with their inclusion in inquire about as future nurses. Positive students’ attitudes toward research encourages students to contribute in research, and increases effective application of research findings as well as improving healthcare outcomes.

Methodology

A pre-experimental design (One-group Pretest-Posttest design) was conducted on nursing students’ attitudes toward research in nursing college. During the period from October 25th 2017 to April 15th, 2018 a non-probability (purposive) sample of (62) nursing students in nursing college was participated in the research project course which are selected after taking their consent. All of the students in the fourth undergraduate academic year 2017-2018, were invited to participate in this study. The aims of the study was clarified before achievement the participants’ consents. Only 62 students were participated and returned the questionnaires. All subjects participated in the research project course at the same time, place, and environment; All participants nursing students exposed to posttest assessment of attitudes regarding research after the implementation of the research project in order to detect the effect of the research project. The tool of this study was adapted from a study by Larson (1989), Halabi and Hamdan (2010) and Halabi, (2016). Several statements of this questionnaire were modified and developed to increase the validity of this instrument and to be more appropriate for achieving the aims of the present study. After reviewing the related literatures and relevant studies, and prior to implementation of the research project, the researchers constructed the attitudes test questionnaire to assess the nursing students attitudes respondents pre and post the implementation of the research project, in order to identify the difference in attitudes of the respondents toward research. The study instrument consisted of 2 parts as the following: Demographic data (which include nursing students’ gender, age, marital status, and residence) and nursing students’ attitudes which is comprised of (22 items): section one is related to usefulness of research (4 items), section two is related personal interest in research (4 items), section three is related to research abilities (7 items), and section four is related to using research in clinical practice (7 items). Likert Scale was used to assess the level of student’s attitude towards research pre/post research project. It was adopted from Likert Scale (2006) and modified.
by the researchers according to the aims of the study. The overall number of the items included in the nursing students’ attitudes were measured in a three levels scale; Agree, uncertain and disagree, and rated as 3, 2, and 1, respectively with a cut-off point = 2. Assessment of nursing students’ attitudes was based on: Mean score for attitudes items equal to 2 or more is considered as a positive. While Mean score for attitudes items below (2) is considered as an negative. The researchers calculated the score percentages of attitudes response for each nursing student in the two related period of the course, and then calculated the difference between the posttest and pretest for each study sample to achieve the attitudes improvement effect for each nursing student.

**Data Analysis:** SPSS version 20 was used to analyze of the data. Statistical analysis was made using Chi-square and paired T-test, have been used to identify the significant change in attitudes before and after research project. The level of significance was set at $P \leq 0.05$.

**Ethical Considerations:** The study was approved by the research department of the participating college of nursing. Students were assured anonymity and confidentiality as well as the right to refuse participation and to withdraw from the study without penalty.

**Results and Discussion**

Table 1 reveals that the majority ($n=46$) 74.2% of nursing students participant in study sample were (20-22) years old with mean age of the all students was 22.27 (20-41) years. 82.3% ($n=51$) of total students were female and 17.7% ($n=11$) were male. Regarding to the nursing students marital status, the majority ($n=51$) 82.3% of the subjects were single. Also, this table shows most of sample ($n=50$) 80.6% of the residents were urban. Results related to attitude respondents regarding to research project, were presented in this table, indicate that the mean of score of the attitude respondents in posttest of the research project course was higher than the pretest of the research project course in all aspects of attitude regarding research project course (positive attitude respondents in comparison between pretest and posttest of the research project course). This table also indicates that a significant difference between pretest and posttest of the attitude of respondents at p-value (0.001). The study results reveal that there is a high significant difference between the nursing students’ attitude responses in the two tests (pretest and posttest) of research project course. Table 4 shows that there is no significant difference between the nursing students’ demographic variables and attitude responses in the posttest of research project course. Nursing research is fundamental to the practice of nursing staff, and the significance of its incorporation during undergraduate direction can’t be overemphasized. Just with presentation what’s more experience nursing students can be able to start to comprehend the concept and significance of nursing research. After the analysis of demographic characteristics as shown in table (Table 1) it was revealed that the majority of subjects (74.2%) were at age 20-22 years old with mean age of the all students was 22.27. Regarding to the nursing students gender the findings indicate that slightly more than three quarters of the students (82.3%) were females and the other (17.7%) were males. According to marital status of nursing students, the study results reveal that more than half (51%) of samples were single and 49% were married. Concerning resident place, the study findings indicate that more than three quarters (80.6%) of the sample were urban. This finding is consistent with Erkin et al. (2017) who revealed that the mean age of the nursing students was 20.72 years. 86.3% of nursing students were females and 13.7% were males (17).While, other study which was done by Hasan (2016), to assess students’ attitudes towards research at mazandaran university of medical sciences shows that approximately half (61%) of students were females and (39%) were males, this result was inconsistent with the findings of the present study. After participating the nursing students in the graduation research project course the results of analysis indicate a significant improvement in nursing students’ positive attitudes regarding research in comparison with the two periods (pretest and posttest), when the results of current study revealed that the nursing students’ attitudes about research; Usefulness of research in pretest 11.145 while in posttest 11.467 ; Personal interest in research is pretest 10.129 while in posttest 10.612; Research abilities in pretest 14.919 while in posttest 16.871; and Using research in clinical practice in pretest 13.919 while in posttest 17.112.

Conclusion

According to the findings of this study, the nursing students’ attitudes toward research were increasing significantly after exposing to the research project course and the demographic variables (gender, age, marital status and resident) of the nursing students had no significant effect on their attitudes toward research.

Association of Serum Myeloperoxidase Level with Risk of Coronary Artery Disease in Patients with Type 2 Diabetes

Huda S. Abdulghani1, Sura A. Abdulsattar2, Essam N. Salman3

1M.Sc. Student, Department of Chemistry and Biochemistry, College of Medicine, Mustansiriyah University, Iraq, 2Prof., 3Assist. Prof., National Diabetes Center for Research and Treatment/Mustansiriyah University, Iraq

Abstract

Aim: This study aimed to investigate if the change of serum myeloperoxidase (MPO) level would be associated with the incidence of coronary artery disease (CAD) in the type 2 diabetic patients. Method: Eighty-eight (88) Iraqi subjects were grouped into three categories:(29) Type 2 diabetes mellitus patients and (29) diabetic patients with CAD compared with (30) healthy person. Serum Myeloperoxidase was performed by using ELISA kit. Fasting blood sugar and lipid profile were done by Roche/Hitachi cobas c311 device. Atherogenic index (AI) and Coronary risk index (CRI) were estimated.

Results: The results of myeloperoxidase (ng/mL) indicate highly significant increase (p<0.01) in the sera of type 2 diabetic (54.18±22.62) and diabetic with CAD (70.79±35.90) patients groups in comparison to that level in control group (29.94±11.11). Meanwhile indicate highly significant differences between T2DM group and diabetic with CAD group. The results of FBS, HDL, triglyceride, VLDL, CRI and AI indicate a significant (p< 0.05) differences between all studied groups. While the results of Cholesterol and LDL indicate no significant (p≥0.05) differences between control, T2DM and diabetic with CAD groups.

Conclusion: Elevated level of MPO are association with the presence of Coronary Artery Disease in type 2 diabetic patients. These findings support a potential role of MPO as an inflammatory marker.

Keywords: Type 2 Diabetes Mellitus, Lipid profile, Myeloperoxidase, coronary artery disease.

Introduction

Diabetes is a major global health concern, it is a metabolic syndrome that manifests a grade of systemic inflammation, leads to an increase in all-cause mortality and contributes to the development of number of cardiovascular complications3,4. Cardiovascular diseases remain the leading cause of deaths in many countries globally, including coronary heart disease, stroke, high blood pressure, and arterial diseases. Notably, death rates among adults with both heart disease and diabetes mellitus are 2–4 times higher than those with heart disease alone, and the mortality rate of patients with heart disease >65 years of age is ~68% in conjunction with diabetes3,4. Clearly, diabetes very negatively impacts the progression and outcome of heart disease, thus understanding the interplay between the two is an important endeavor for advancing treatment strategies of patients with diabetic cardiac complication.

Oxidative stress and inflammation play important roles in the pathogenesis of destabilization of coronary artery disease (CAD) leading to acute coronary syndromes (ACS). Previously, there has been a renewed interest in MPO, a pro-inflammatory enzyme that is abundant in ruptured plaque5. Numerous clinical studies have assessed the utility of inflammatory biomarkers for characterization cardiovascular disease (CVD) severity and thus the risk of plaque rupture. Previous research has focused on an inflammatory markers of which myeloperoxidase (MPO), released systemically and locally by activated leukocytes, has shown great promise6. Prior study hypothesized that MPO can be used as a diagnostic aid and risk stratification tool in patients who present to the emergency department with ACS7. Myeloperoxidase (MPO) (EC 1.11.1.7) is a mammalian enzyme localized in granules of polymorphuclear granulocytes and macrophages, MPO is a homodimeric
protein with a mass of 146 kDa, consisting of two 73 kDa identical and functionally independent monomers joined by a single disulfide bond at cysteine residue 153. Each monomer has 2 polypeptide chains: a glycosylated heavy chain consisting of 467 amino acid residues and a mass of 58.5 kDa and a light chain with 106 amino acid residues and a mass of 14.5 kDa\(^{(8,5)}\). Myeloperoxidase produces reactive oxidants and other free radicals either through its peroxidase cycle or through a halogenation cycle, depending up on the substrate availability. However, any excessive or unregulated production oftheses oxidants can lead to damage of host cells and result in several diseases\(^9\).

Therefore, in this study, the relationship between MPO levels and the incidence of CAD in patients with type 2 diabetes was determined.

**Method**

The study included 88 Iraqi subjects were grouped into three categories: (29) Type 2 diabetes mellitus patients and (29) diabetic patients with CAD compared with (30) healthy person in term of non-diabetic, non-hypertensive and have no ischemic heart disease. Patients with Type 1 diabetes, gestational diabetes, chronic diabetic complication (nephropathy, retinopathy and neuropathy), type 2 diabetes taking insulin injection, malignancies were excluded. This study was designed as case–control study and done at National Diabetes Center for Research and Treatment/Mustansiriya-University.

Serum of Myeloperoxidase was performed using ELISA kit an enzyme immunoassay for quantitative in vitro diagnostic measurement, kit manufactured by Mybiosource. Fasting blood sugar and lipid profile were done by Roche/Hitachi cobas c 311 device. Atherogenic index (AI) was estimated by AI = log TG \ HDL and Coronary risk index (CRI) estimated by CRI = TG \ HDL.

**Results**

The results of myeloperoxidase (ng/mL) indicate highly significant increase (p<0.01) in the sera of type 2 diabetic (54.18±22.62) and diabetic with CAD (70.79±35.90) patients groups in comparison to that level in control group (29.94±11.11). Meanwhile indicate highly significant differences between (T2DM) and (diabetic with CAD) groups. Table (1) showed the results of FBS, lipid profile, CRI and AI that demonstrated a highly significant (P<0.01) differences of FBS, HDL, triglyceride, CRI and AI, meanwhile the VLDL result indicate a significant (p< 0.05) differences of studied groups. While the results of Cholesterol and LDL indicate no significant (p≥0.05) differences between control, T2DM and diabetic with CAD groups.

Figure 1: The correlation between serum MPO with HDL in T2DM.
Figure 2: The correlation between serum MPO with HDL in all studied groups.

Figure 3: The correlation between serum MPO with Triglyceride in all studied groups.
Discussion

In this study, the results of myeloperoxidase indicate a highly significant increase in the sera of T2DM group and diabetic with CAD group in comparison to that level in control group. This finding was agreement with Song P, et al. study, which indicate that plasma MPO level was positively correlated with the degree of coronary artery stenosis in type 2
diabetic patients\textsuperscript{10}. Also agree with I. V. Gorudko, et al., study which reported that myeloperoxidase is increased activity in the blood can be an additional marker of oxidative stress and cardiovascular risk in patients with diabetes mellitus\textsuperscript{11}. Diabetic patients are prone to atherosclerosis, which is the major cause of cardiovascular diseases (CVD), neutrophils and monocytes play a key role in atherosclerosis, leading to chronic inflammatory problems. Different events and sequences occur during CVD, which include endothelial dysfunction besides the formation and rupture of atherosclerotic plaque. In the arterial wall sub endothelial region, all of these stages occur during inflammation, which ultimately leads to the accumulation and deposition of altered lipids \textsuperscript{12}. Atherosclerosis leads to the accumulation of cholesterol and cholesteryl esters on arterial walls, which derived from LDL. In addition to this, LDL retention on these walls triggers an immune response, resulting in a cascade of production of oxidants and inflammation\textsuperscript{13}. Plasma LDL interacts with circulating MPO, which has been reported to be higher in patients suffering from atherosclerosis. HOCl reacts with LDL, which promotes atherogenesis\textsuperscript{14}. High glucose stimulates the production of hydrogen peroxide. This hydrogen peroxide which is a physiological substrate for Myeloperoxidase is converted to hypochlorous acid. Thus, high glucose results in increase in Myeloperoxidase activity\textsuperscript{15}.

The results of cholesterol and LDL indicate no significant increase between studied groups. This finding disagreement with Rothangpui, et al., who shows LDL cholesterol level are higher among the diabetics with cardiomyopathy compared with those without cardiomyopathy\textsuperscript{16}. Also, disagree with Po-Chung Cheng, et al., who observed an inverse correlation between plasma LDL-cholesterol and heart function in individuals with T2DM. Patients with higher levels of plasma LDL cholesterol had worse left ventricular function\textsuperscript{17}. Plasma LDL-cholesterol may be a modifiable risk factor of heart failure in diabetes. P. R. Lawler, et al, study that showed cardiovascular disease events prevalent among individuals with low or normal LDL, both pretreatment and during statin therapy\textsuperscript{18} and Kenneth R Feingold & Carl Githey were reported that in Type 2 diabetes, poor glycemic control increases triglyceride levels and decreases HDL cholesterol levels with only modest effects on LDL cholesterol levels \textsuperscript{19}. The results of Triglyceride and VLDL in the sera of T2DM group and diabetic with CAD group indicate a significant increase in comparison to that level in the control group. These finding agreements with Adam Shaver, et al., who’s indicated that triglycerides are elevated in diabetic patients due to an increased dependence on fatty acid metabolism, and demonstrated that diabetic patients with CVD patients had significantly elevated triglyceride levels\textsuperscript{20}. Triglyceride are negatively associated with atheroprotective HDL-cholesterol. The most obvious lipid defect in uncontrolled diabetes is the elevated level of triglycerides \textsuperscript{21}. Increasing TG in fasting status could be marker for increased level of remnant lipoprotein particles, which could be directly atherogenic, and they could penetrate into the vessel wall and cause inflammation \textsuperscript{22}.

Results of HDL demonstrated a highly significant decrease in T2DM group and diabetic with CAD group in comparison to that level in control group. This result was in agreement with Rothangpui, et al., who indicated that serum HDL-cholesterol was lower among the diabetics with cardiomyopathy compared with those without cardiomyopathy\textsuperscript{16}. In addition, HDL decreased in many CVD patients, blood level of HDL < 40 mg\textper dl may be an effective warning sign for atherosclerotic development \textsuperscript{23}. High-density lipoprotein cholesterol is inversely associated with risk of coronary heart disease\textsuperscript{24}, associated to the anti-inflammatory, anti-thrombotic and anti-oxidant properties as well as to the ability to support endothelial physiology \textsuperscript{25}. Raising plasma HDL-cholesterol through weight loss and a healthy diet, by an increased physical activity and, if required, by proper pharmacotherapy is therefore a legitimate therapeutic target for the optimal prevention of CHD in a large proportion of high-risk patients\textsuperscript{26}.

The results of Coronary risk and atherogenic index of the studied groups indicated a highly significant increase of levels in sera of T2DM group and diabetic with CAD group in comparison to that in (control) group. The result was in agreement with Domingo O Beltran, et al., who reported that high level of CRI and AI were associated with all-cause mortality and risk of hospitalization due to coronary heart disease\textsuperscript{27}, also agree with Harini D Nimmanapalli, et al., study that demonstrated atherogenic
indices were found to be significantly different and the ratios contribute significantly to the estimation of CVD risk in type 2 diabetes mellitus. Diabetic dyslipidemia that characterized by an increased TG level and also decreased HDL-C value, a main feature of lipoproteins abnormalities in diabetic patients and in turn affects the results of CRI and AI, which lead to increase risk factors for developing CVD. There is correlation between AI and lipoprotein particle size, therefore AI could be considered as an indicator of atherogenic lipoprotein status and used as a diagnostic indicator when other atherogenic parameters appear normal.

Conclusion
Elevated level of MPO are association with the presence of Coronary Artery Disease in type 2 diabetic patients. These findings support a potential role of MPO as an inflammatory marker.

Call for Papers / Article Submission

Indian Journal of Forensic Medicine & Toxicology has commenced publication since 2007. IJFMT will be published two times in a year.

Purpose & Scope: Indian Journal of Forensic Medicine & Toxicology is a peer reviewed six monthly Journal. It deals with Forensic Medicine, Forensic Science, Toxicology, DNA fingerprinting, sexual medicine and environmental medicine. It has been assigned International standard serial No. p-0973-9122 and e-0973-9130 website: www.ijfmt.com. This journal is also indexed with Index Copernicus (Poland).

The journal encourages research from theoretical perspectives, research reports of evidence based practice as well as praxis research work that focuses on the interface between theory and practice and how each can support the other. In addition, the journal strongly encourages reports of research carried out within or involving countries in the Asia-Pacific region.

Invitation to submit papers:
A general invitation is extended to authors to submit journal papers for publication in IJFMT.

The following guidelines should be noted:
1. The article must be send by E-mail in word only as attachment. Hard copy need not be send.
2. The article should be accompanied by a declaration from all authors that it is an original work and has not been sent to any other journal for publication.
3. References should be in Vancouver style.
4. As a policy matter, journal encourages articles regarding new concepts and new information.

Please submit paper in following format as far as applicable
1. Title
2. Names of authors
3. Your Affiliation (designations with college address), email id
4. Corresponding author- name, designations, address, email id
5. Abstract with key words
6. Introduction or background
7. Material and Methods
8. Findings
9. Discussion / Conclusion
10. Conflict of Interest
11. Source of Support
12. Ethical Clearance
13. References in Vancouver style.
14. Word limit 2500-3000 words, MSWORD Format, single file
15. Please quote references in text by superscripting
