Indian Journal of Forensic Medicine & Toxicology

EDITOR in Chief
Prof. R K Sharma

Formerly at All India Institute of Medical Sciences, New Delhi, E-mail: editor.ijfmt@gmail.com

EDITOR
Prof. Dr. Adarsh Kumar
Forensic Medicine & Toxicology, AIIMS, New Delhi

INTERNATIONAL EDITORIAL ADVISORY BOARD

1. Prof Mete Gulmen Cukurova University, TURKEY
2. Prof. Leandro Duarte De Carvalho, Minas Gerais, Belo Horizonte, Brazil
3. Prof. Donata Favretto (Full Professor) Forensic Toxicology at University of Padova, Italy
4. Prof. Babak Mostafazadeh Department of Forensic Medicine & Toxicology, Shahid Beheshti University of Medical Sciences, Tehran, Iran
5. Prof Halis Dokgoz, Mersin University, TURKEY
6. Prof Jozef Sidlo, Comenius University, Bratislava, SLOVAKIA
7. Dr. Rahul Pathak (Lecturer) Forensic Science, Dept of Life Sciences Anglia Ruskin University, Cambridge, United Kingdom
8. Dr. Hareesh (Professor & Head) Forensic Medicine, Ayder Referral Hospital, College of Health Sciences, Mekelle University, Mekelle Ethiopia East Africa
9. Dr. Mokhtar Ahmed Alhrami (Specialist) Forensic Medicine & Clinical Toxicology, Director of Forensic Medicine Unit, Attorney General’s Office, Sana’a, Yemen
10. Dr. Sarathchandra Kodikara (Senior Lecturer) Forensic Medicine, Department of Forensic Medicine, Faculty of Medicine, University of Peradeniya, Sri Lanka
11. Dr. Noha A. Magdie El Rafie, Forensic Toxicology, Ain Shams University, Cairo, EGYPT

SCIENTIFIC COMMITTEE

1. Prof Udai Pratap Singh, Department of Anthropology Lucknow University Lucknow
2. Dr Anil Rahule (Associate Professor) Dept of Anatomy, Govt Medical College Nagpur
3. Dr Shankar Baikkanwar (Associate Professor) Forensic Medicine, Kasturba Medical College, Manipal, Karnataka
4. Dr K. Ravikumar Raksha Shakti University, Ahmedabad, Gujarat
5. Dr. Pragnesh Parmar (Associate Professor) Forensic Medicine, Valsad, Gujarat
6. Dr Vandana Mudda (Awati) (Associate Prof) Dept of FMT, M.R. Medical College, Gulgarga, Karnataka,
7. Dr. Asha Srivastava (Senior Scientific Officer) Forensic Psychology, Central Forensic Science Laboratory, CBI, Delhi
8. Dr. Lav Kesharwani (Asst.Prof.) School of Forensic Science, Sam Higginbottom Institute of Agriculture Technology & Sciences, Allahabad U.P.
9. Dr. Anu Sharma (Associate Prof) Dept of Anatomy, DMCH, Ludhiana (PB)
10. Dr. Shalini Gupta (Prof ) Oral Pathology and Microbiology, Dental Sciences King George Medical University, Lucknow, UP
11. Dr Rituja Sharma, Associate Prof, Law Banasthali Vidyaapeeth Jaipur

NATIONAL EDITORIAL ADVISORY BOARD

Chairman
Prof Sudhir K Gupta - Head, Department of Forensic Medicine
All India Institute of Medical Sciences, New Delhi

Members
1. Prof. SK Dhattarwal, Forensic Medicine, PGIMS, Rohtak, Haryana
2. Prof. N K Aggrawal Forensic Medicine, UCMS, Delhi
3. Prof Ajay Ghangale Forensic Medicine Dr DY Patil Medical College, Pune, Maharashtra
4. Dr. Amar Jyoti Pathwory Professor, Forensic Medicine NEIGRIHMS, Shillong
5. Dr. S. Venkata Raghava Professor, Forensic Medicine, Banglore Medical College, Bengaluru
6. Prof Praveen Arora, Professor Department of Forensic Medicine & Toxicology, SAIMS, Indore
7. Dr. Pankaj Datta (Principal & Head) Department of Prosthodontics, Indraprastha Dental College & Hospital, Ghaziabad
8. Dr. Mahindra Nagar (Head) Department of Anatomy, UCMS & GTB Hospital, Delhi
9. Dr. Virender Kumar Chhoker Professor Forensic Medicine and Toxicology, Santosh Medical College, Ghaziabad, UP
10. Dr. Dayanand G Gannur (Professor) Department of Forensic Medicine & Toxicology, Shri BM Patil Medical College, Hospital & Research centre, Bijapur, Karnataka
11. Dr. Alok Kumar Professor Department of Forensic Medicine & Toxicology, UP Rural Institute of Medical Sciences and Research, Saffal, Etawah, U.P.

Institute of Medico-legal Publications
Logix Office Tower, Unit No. 1704, Logix City Centre Mall, Sector-32, Noida - 201 301 (Uttar Pradesh)
1. Determination of Sex by Osteometry of Third Metatarsal .......................................................... 1
   Arthy, Rohit Goel, Sreenivas M

2. Incidence of Tuberculosis in Unidentified Dead Bodies amongst Autopsy Conducted at Government
   Stanley Medical College and Hospital, Chennai ........................................................................... 7
   A.Gokulakrishnan, S.Praveen

3. Study of Lip Print Pattern among Young Individuals in Bangalore City .......................................... 12
   Chandru K, Naveena Preethi

4. Effectiveness of Educational Intervention on Knowledge & Attitude about MTP Act 1971 among
   Apparently Healthy Reproductive Age Group Population Visiting A Tertiary Care Centre, Puducherry...... 16
   Fathima S, James Rajesh J, Jothi Marie Feula, Siva Reddy

5. Study of Profile of Motor Vehicle Accidents in Thiruvanmiyur Traffic Police Station ...................... 22
   G.Shivani, V.Dekal

6. Demographic Profile of Poisoning Cases in a Tertiary Care Center in South India – An Observational
   Study ................................................................................................................................................ 27
   James Rajesh J, Sampath Kumar P, Priyadarshee Pradhan, Jothi Marie Feula A, Siva Reddy B

7. Estimation of Age through Elbow Joint in children of Karnataka .................................................... 33
   Manjunatha A

8. Identification of Sex of Sacrum in Karnataka Population .................................................................. 36
   Manjunatha A

9. Demographic Profile and Pattern of Presentation of Organophosphorus Poisoning at Tertiary Care
   Hospital Agra ....................................................................................................................................... 39
   Mustaria Pankaj Kumar Shusil, Ajay Agarwal

10. Green Pitch- Be the Part of Solution ............................................................................................ 45
    Nandhini V, Gayathri S, Sumathi H Rao, .P. B.Anand, T. Geetha,

11. A Four Years’ Retrospective Study of Poisoning Cases in Southern India .................................... 49
    P.C. Sahoo, Karma Mingur Diki Bhutia, Ashim Mishra

12. Effect of Audio Assisted Relaxation Therapy on Level of Blood Pressure among Mothers with
    Pregnancy Induced Hypertension ................................................................................................. 56
    Shasi Bala, Lekha Viswanath

13. A Demographic Study on Cases of Drowning with Special Reference to Histopathological Changes
    of Lung and Other Tissues in a Tertiary Centre ............................................................................. 63
    Somnath Maity, Soumeek Chowdhuri, Satik Das, Sovan Kumar Das, Rupam Karmakar
14. Fixing the Deepest Point on Greater Sciatic Notch for Measuring or Calculating Maximum Depth of Greater Sciatic Notch

Uday Pal Singh, D Vijaya Raghavendra

15. Enrofloxacin poisoning in Humans – A Rare Case Report

Vipul Khandelwal, Namrta Pradhan, Priya Mathu, Shailesh Jhawa, Ajay Pal Singh

16. Serotonin Syndrome Precipitated by Escitalopram

Deshna H. Lad, Harsha Makwana, Vidhi Shah, Supriya D. Malhotra, Pankaj Patel

17. Pattern and Profile of Injuries Sustained During Assault by Sharp Weapon: A Prospective Study During Year 2015-16 at Sms Medical College-Jaipur

N.L. Disania, Rajesh Kumar Verma, R.K. Punia, Vinod Kumari Jat

18. A Study of Awareness on Artificial Insemination among Medical College Students

Shifa Shahina Nijamudeen, Dekal V

19. A Cross-Sectional Study of The Pattern of Cases of Deliberate Self-Harm in a Tertiary Care Hospital

Shinto Devassy, Varghese P.S

20. Study of Profile on Juvenile criminals in Chennai

Siddharth R, V Dekal

Zakharova A.N., Malev A.L., Kaliberdenko V.B., Shanmugaraj K, Keerthanaa B

22. Effectiveness of Ocular Muscle Exercises on Myopic Individuals with Forward Head Posture

Shradha Patel, Trupti Yadav, Amrutkuvar Pawar, Radhika Chintamani

23. An Autopsy Based Study of Sexual Dimorphism of Adult Human Sterna

Bhumesh Darade, Pawan Sabale, Shailesh Mohite

24. Effect of Jack Knife Stretching Versus Proprioceptive Neuromuscular Facilitation (Hold Relax) Stretching Technique in Asymptomatic Individuals with Hamstring Tightness: A Randomized Clinical Trial

Amruta Kabra, Kajal Salekar, Tanvi K Alanekar, Kajal Salekar

25. Comparative Effectiveness of Kinesio Taping and Ift in Upper Cross Syndrome- A Randomized Clinical Trial

Amrutkuvar Rayjade, Trupti Yadav, Radhika Chintamani, Nisha Joshi

26. Proportion of Diagonal Ear Lobe Crease and its Association With Sudden Death Due to Coronary Artery Disease- An Autopsy Study

Anwar Abdul Rahman, Renju Raveendran

27. Peek (Polyether Ether Ketone) – A Review Article

Arunmozhi Kannan, Praveen P, Sanjna Nayar

28. Effectiveness of Strengthening Vs Strengthening with Stretching in Individuals with Nonspecific Low Back Pain

Brity Alex, G Varadharajulu
29. Effectiveness of Guided Imagery on Stress and Coping among Wives of Alcoholics: A Systematic Review

Aarti, Srinivasan P

30. Assessment of Epidemiological Causes, Occurrence and Allocation Resulting to Fatality in Two Wheeler Fortuitous Accidents in Uttar Pradesh

Abhishak Kumar Varshney, Qaiser Rasool Panzoo, Anuj Gupta, Vinod Kumar

31. Effect of Core Strengthening and Conditioning Programme on Badminton Beginners

Aditi B. Churi, G. Varadharajulu

32. Effect of Postural Ergonomics and Static Gluteus Exercise Along with Bridging on Quality of Life in Individual with Mechanical Low Back Pain

Aishwarya Vedpathak, Poonam H. Patil

33. Leukopenia, Hypomagnesemia in 2,4-D Poisoning-A Rare Presentation

Ajita Kumar Bhoi, Prafulla Kumar Bariha, Khetra Mohan Tudu, Manoj Kumar Mohapatra

34. Factors that Correlation to Occupational Contact Dermatitis Among Tobacco Farmers in Jember District, East Java Province, Indonesia

Anita Dewi Prahastuti Sujoso, Tri Martiana, Santi Martini Firman Suryadi Rahman

35. Improve Awareness of the Forensic Odontology among Medical Graduates: Need of the Hour?

Anushtha Jain, Nandita K.P, Srikant N

36. Spectrum of Hepatic Pathologies in Medicolegal Autopsies

Apoorva Nigam, Navneet Kaur, Ramesh Kumar Kundal, Akashdeep Aggrawal, Kanwardeep Kaur

37. Epidemiological Profile of Fatal Abdominal Injuries Secondary to Blunt Force Impact: Autopsy based Study Conducted At A. J. Institute of Medical Sciences & Research Centre, Mangaluru

Arun Pinchu Xavier, Karen Prajwal Castelino, Francis N.P. Monteiro, Bharath Shetty, M. Deepak

38. Antimicrobial and Biofilm Inhibitory Activity of Nanoparticles Against Clinical Isolates from Urinary Tract Infection

Ashwak Jasim Kzar

39. Ulnar length – A Tool for Stature Estimation

Atul S Keche, Harsha A Keche

40. Occlusal Morphology of Primary Molars in Anganwadi Children, Faridabad

Brinda Khanna, Archika Singh, Nisha Rani Yadav, Meena Jain, Ankur Sharma, Vishal Jain, Akansha Monga

41. Health Status of Children in Assam

Chayanika Goswami

42. Knowledge, Attitude and Behavior of Undergraduate Dental Students towards Cardiopulmonary Resuscitation: A Descriptive Study

Deesha Kumari, Thara Chandran, Bless Annie Philip, Mithun K, Shilpa M

43. Effect of Therapeutic Shoulder Sling And Proximal Control Exercises on Shoulder Subluxation in Stroke Survivors

Devayani Mukund Moghe, Suraj Bhirrao Kanase
44. Assessment of the Prevalence of Refractive Error among School Children (6-16 Years) of Rural Field Practice Area of Kims, Malkapur, Karad ................................................................. 228
   Ankitkumar Bhopalka, B.S. Joshi, V.H. Karambelkar

45. An Autopsy Study of Fatal Thermal Burns in Married Women: A Prospective Study ...................... 233
   Bandenawaz, Viswakanth B

46. Analysis of Homicidal Deaths among Medicolegal Autopsies Conducted at a Tertiary care Hospital in Karnataka: A Prospective Study ................................................................. 238
   Bandenawaz, Viswakanth B

47. Effectiveness of Abdominal Drawing in Maneuver with Lumbar Pelvic Exercises on Swiss Ball for Spinal Flexibility Among Patients with Low Back Pain ................................................................. 242
   Faldu Liza Jitendra, S Anandh

48. Saliva in identification of ABO Blood Grouping & Rhesus Factor ......................................................... 247
   Harshada R

49. Pattern of Injuries in Road Traffic Accidents – An Autopsy Study ........................................................ 252
   K H Thippeswamy, Ravindra Kumar C N, H C Govinda Raju

50. Chromatographic Analysis of General Otc Anti-Allergic Drug: Cetirizine ........................................... 258
   Kaur Loveleen, Kaur Ridamjeet, Sharma Tina

51. Pattern of Injuries Observed in Drivers Involved in Fatal Road Traffic Accidents in Tirupati ......... 264
   B. Venkatesulu, Vishnu Vardhan Poluru, M. Abdul Khalid

52. Profile of Medicolegal Autopsy Cases Conducted at Tertiary Care Centre, Kalaburagi, Karnataka ...... 269
   Manish K, KhajaAzizuddin Junaidi, Deepak S, Umesh SR

53. Liver Pathology in Autopsy Cases: A Retrospective Study in A Tertiary Care Center .. 275
   Ekta Rani, Sarita Nibhoria, Sanjay Kumar,

54. Histopathological Study of the Freshwater Fish Ctenopharyngodon Idella Exposed to Λ-Cyhalothrin 5% EC ................................................................................................................ 279
   G. Rajeswari., Lalitha Vinnakota, V.Venkata Rathnamma

55. Vocal Nodule and Polyp by Microlaryngoscopy and Cold Instruments ............................................. 285
   Ganesh M. Vihapure, Abhay D. Havle, Mannuru Khaleel Basha, Naman Pincha, Tripti, Sanket C Prabhune

56. Knowledge Among Parents about Importance of Primary Dentition .................................................. 289

57. Clinical Profile of Amblyopia in Young Adults ................................................................................... 293
   Girish Gadre, Surabhi Khandelwal, V.H. Karambelkar

58. Psychometric Properties of Hindi Version of Physical Activity Recall Assessment for People with Spinal Cord Injury ........................................................................................................ 299
   Heeral Joshi, Shambhovi Mitra, Rajeev Aggrawal
59. Comparative Study on Different Modified Techniques Used For DNA Isolation From Teeth Samples for Obtaining Optimized Output.................................................................................................................... 305
   Indresh Kumar Mishra, Amarnath Mishra, Amit C Kharkwal, Braja Kishore Mohapatra, Chittaranjan Behera, Bhoopendra Singh

60. Maternal age ≥ 35 years, Nulliparity, High Blood COHb Levels, and Low Serum Nitric Oxide Levels Increased Risk of Preeclampsia ..................................................................................................................... 311
   Ita Rahmawati, Anies, Mateus Sakundarno Adi, Cahyono Hadi

61. Effect of Unilateral and Bilateral Shoulder Rehabilitation Exercise Protocol in Patients Secondary to Radical Mastectomy ...................................................................................................................................... 318
   Jasleen Kaur Sohal, Poonam H. Patil

62. Effectiveness of Oropharyngeal Exercises on Daytimesleepiness, Snoring and Risk of Obstructive Sleep Apnea Amongadults: Review ........................................................................................................................................ 325
   Jaspreet Kaur, Kanika Rai, Vinay Kumari, Jyoti Sarin

63. Effects of Aerobic Exercises for General Anxiety Disorders in Adolscents .......................................................................................................................... 330
   Jhaveri Nikita H, Malawade Mandar

64. Gender Wise Difference in Presenting Signs and Symptoms of Stroke: Observational Study ............ 335
   Jhaveri Nikita H., Kanase Suraj B.

65. Pattern and Distribution of Scalp Injuries in Fatal Road Traffic Accidents in Rohtak Region of Haryana - An Autopsy based Study ...................................................................................................................................... 340
   Jitender Kumar Jakhar, Naveen Yadav, Taitiksh Jakhar, Sunil Dahiya, Kunal Gaba, S.K. Dhattarwal

66. Comparative Analysis of Associated Risk Factors Amongst Young and Old Stroke Survivors ............... 345
   Joshi Madhura S., Kanase Suraj B.

67. Knowledge and Practice of Bio Medical Waste Management in a Mortuary and Casualty of Tertiary Care Hospital ................................................................................................................................................ 350
   K Srinivasulu, T Leela Manasa, Dedipya, Summaya begum

68. Profile of Fatal Cases of Organophosphorus Poisoning at a Tertiary Care Centre, Mandya ............... 354
   K. Ashwini Narayan, K. Ashwini Narayan

69. Study of Pattern & Distribution of Injuries in Fatal Road Traffic Accident Cases Autopsied at MIMS, Mandya ........................................................................................................................................ 357
   K. Ashwini Narayan

70. Variations of Dermatoglyphic Patterns among Smoking and Smokeless Forms of Tobacco in Oral Potentially Malignant Disorders and Oral Cancer- A Review of Literature ........................................ 361
   K.V.Swathi, G.Maragathavalli

71. Polymorphism in Superoxide Dismutase, Catalase Genes and Their Role in Cervical Cancer Susceptibility among Rural Population of Maharashtra: Findings from A Hospital based Case Control Study ........................................................................................................................................ 366
   Kailas D. Datkhile, Anand Gudur, Rashmi A. Gudur, Madhavi N. Patil, Pratik P. Durgawale, Vinit N. Deshmukh, Nilam J. Jagdale
72. Prevalence of de Quervain’s Tenosynovitis in Buffalo Milkers ......................................................... 372
   Kajal Vijay Kale, Pragati Salunkhe

73. Study of the Closure of Sagittal Suture in Relation with Age of the Individuals in Native of Gujarat.. 376
   Kamesh Modi, Uttamkumar Solanki, Kavita Banker, Rajni Bhagora, Jagdeep Jadav

74. Effect of Blended Learning on Academic Achievements and Attitude of Nursing Students: A Systematic Review ................................................................. 383
   Kanika, Harmeet Kaur

75. Development of Submerged Latent Fingerprints on Non-Porous Substrates with Activated Charcoal based Small Particle Reagent ......................................................... 388
   Kavleen Kaur, Tina Sharma, Ridamjeet Kaur

76. GC-MS Analysis of Methanol Extracts of Five Toxic Plant Seed For Detection of Bioactive Compounds 395
   Kiran Kumari, Saurabh Bhargava, Rajvinder Singh

77. Psycho Social Factors in Adolescent Suicides- A Psychological Autopsy based Study....................... 402
   Krishna Kumar Siva Sankara Narayanan, Muthukumar Duraiappa, Prajith Thekke Madathil

78. Awareness of Most Commonly Used Drugs in Dentistry Inducing Teratogenic Effects among Dental Practitioners ................................................................................................. 407

79. Awareness of Oral Hygiene Aids among General Population .............................................................. 411
   J. Manju, C. Krithika, P.R.Koteshwari, G. Manoj Kumar

80. An Experimental Study to Assess the Effect of Disinfectants on the Shade Tab........................................ 416
   Manoj Shetty, Isha Singh, Anmol Chandhok, Chethan Hegde

81. Radiological Study of Fusion of Tri-radiate Cartilage in hip bone in Bikaner Region in 14-22 Years Age Group ........................................................................................................ 421
   Mathur Indubala, Sajjad Hussain, Agrawal Anjali, Sharma Yogesh

82. Effects of Circuit Training Program on Quality of Life of Children with Hemophilia............................. 426
   Mandar Malawade, Amrutkumar Rayjade, G. Varadharajulu

83. Study of Pedestrian Injuries and Fatalities in Maharashtra Population .................................................... 432
   Mohammed Abdul Mateen

84. Stress, Anger and Coping among Dental Students .................................................................................. 438
   Nor Masitah Mohamed Shukri, Dhanraj.

85. Assessment of Salivary Flow Rate in Edentulous Patient ....................................................................... 444
   Nurul Afiqah Amani Binti Zaaba, Dhanraj

86. Assessment of Pattern of Suicidal, Accidental and Homicidal Cases Along with the Sort of Poisoning in North Indian Population ................................................................. 449
   Qaiser Rasool Panzoo, Abhishak Kumar Varshney, Anuj Gupta, R.N. Tandon

87. Importance of Forensic Odontology ........................................................................................................ 454
   Mutum Sangeeta Devi, Manju J, Rahul Rajpurohit
88. Study of Otoacoustic Emissions and Brainstem Evoked Response Audiometry in Infants

Naman Pincha, Vikas S Kulkarni, Abhay D. Havle, Disha Jain, Ganesh M. Vihapure, Swapna A Shedge

89. Role of Hand and Foot Print Dimensions in Stature Identification among Indian Population

Nandita K.P, Srikant N, Shweta Yellapurkar, Srishty Pundir, Akriti Kaul

90. A Profile Study of Sudden Natural Death Cases in Vadodara Region of Central Gujarat

Neerav M. Rana, Anil R. Pandey

91. Effectiveness of Progressive Resistance Drills and Dynamic Balance Training on Functional Performance among the Patients with Osteoarthritis of Knee

Nikhil Jitendra Desale, Shrinivasan Anandh

92. Evaluate the Effectiveness of Calisthenics on self-esteem among Elderly Residing in Selected Old Age Homes of Haryana, India

Nilu Moirangthem, Srinivasan P, Dhanesh Garg, Jyoti Sarin

93. Observational Study on Sexual Dimorphism of Carrying Angle among Natives of Ajmer region

Nirjhar Mathur, Anupam Johry

94. Quasi Experimental Study to Evaluate the Impact of Psychoeducational Intervention on Level of Anxiety among Hospitalized Children

Niyati R. Patel, Vipin Vageriya

95. A Study on Sociodemographic Profile and Pattern of Injuries in Road Traffic Accidents amongst Pillion Riders in Chennai

P. Shruthi, S. Varsha

96. A Retrospective study on Non Fatal Motor Vehicle Accident cases in the Emergency Department, Saveetha Medical College, Chennai

P. Tejesh Thanigavel, Magendran. J

97. Comparative Evaluation of Cention with Glass Ionomer Cement, Composite Resins and Silver Amalgam with Respect to Mechanical Strength: An in-Vitro Study

P. Laxmish Mallya, Ravindra Kotian, Prashanthi M, Srikant N

98. Correlation between Stature and Length of Clavicle in Female Population of Central India

Pande Varsha Patond Swapnil Patil Bharat

99. Forensic Investigation and Comparison of Blood Sample Referring to Thalassemia

Pankila Khanna, Surender Sehrawat, KS Rana

100. Perspective of Maternal Deaths: A Retrospective Autopsy Study

Patekar M B., Jagtap N.S., Pawale D.A.

101. Effect of Nordic and Normal walking on coronary risk factors among middle aged obese population: Comparative Study

Pradnya P. Ghadage, T. Poovishanu Devi

102. Awareness among Intern Doctors Regarding Privacy and Confidentiality in Medical Practice

Pragnesh Parmar, Swapnil Patond, Gunvanti Rathod, Sudhir Ninave

134. Effect of Ankle Dorsiflexors Facilitation on Gait in Cerebral Palsy ............................................................. 730
   Supriya S. Jadhav, Mandar Malawade

135. A Study of Histochemical Characteristics of Mucosubstances in Normal Endocervical Glands ............... 735
   Swapna Shedge A, Padmaja A Havle, Megha A. Doshi, Priya Roy

136. Significance of Cheiloscopy and Dermatoglyphics in Sex Determination .................................................... 741
   V.Anu, P.Lokeswari, S.Madhumitra, S.Lavanya, C.Lavanya, K.Madhumitha

137. Effectiveness of a Dynamic Ergonomic Chair in Individuals with Postural Dysfunction ............................ 745
   Vaishnavi J Chavan, S. Anand

138. Prevalence of Piriformis Tightness with Relevance of Sitting Duration in Bankers ........................................ 749
   Vaishnavi S Desai, S. Anand

139. Assessment of Effective Oral Health Status among Diabetic population by Modified Special Tooth
   Brush with Beat Sound- An observational study ................................................................. 755

140. Age Estimation by Dental Eruption in Schoolchildren of 14-16 Years Age Group ........................................ 761
   Vijay Kumar AG, Suresh J

141. A Retrospective Study of Fatal Road Traffic Accidents on Autopsies done at Madurai Medical College
   and Hospital .................................................................................................................... 764
   T. Selvaraj, R. Uthayakumar

142. Identification of Sex from Facial Index in Western Maharashtra Population ................................................. 768
   Umang P. Patel, Makandar UK, Karkhyle Md layeeque, Kailash Balkund

143. A Cross Sectional Study of Correlation of ATD Angle with Body Fat Distribution in North Indian
   Population ......................................................................................................................... 772
   Zeenat Akhtar, Vishal Verma, Farida Khanam, Bhamini Sharma

144. A Vignette on the Trend of Medicolegal Cases in a Tertiary Care Hospital in South India ....................... 779
   Yogesh C, Amirthvarshan, Paranthaman, Priyanka

145. An Exploration into the Biography of Road Traffic Accident Cases in a Tertiary Care Hospital in
   South India ...................................................................................................................... 784
   Yogesh C, Paranthaman, Amirthvarshan, Priyanka

146. Prevalence of Non-Strabismic Binocular Vision Dysfunction in A Hospital based Population ..................... 790
   Rajib Mandal, Rajesh Kamath

147. Determination of Stature From Index and Ring Finger Lengths in South Indian Population ........................ 795
   Jayanth SH, Basappa S Hugar, S Praveen

148. Determination of Sex From Adult Clavicle – An Autopsy based Regional Study ....................................... 800
   Levis Vaseem Moorkhan, Prajith Thekke Madathil

149. Profile of Medico-legal Cases at JSS Hospital, Mysuru – a Two Year Prospective Study .............................. 805
   S.Prasanth Kumaran, H.V.Chandrakanth, Arun.M, Smita Rani
150. A Qualitative Exploration of Substance Abuse among the Nursing Students of Coastal Karnataka........... 813
  Dharnappa Poojary, Madhumitha Muruganandam, Avinash Kumar, Ganaraja B, Sneha Shetty Bhoja,
  Trupti Bodhare, Rashmi K S

151. Assessment of Oral Health Related Quality of Life and Patient Satisfaction after Complete Denture
    Therapy- An Observational Study........................................................................................................................................... 820
  MR Athira, Shenoy VK, Mehendale A, Kamath M, Zaheer A, Rodrigues S

152. Study of Death among Children Below Five Years of Age and Its Correlation with Health Care
    Utilization and Place of Residence. Using Verbal Autopsy as a Tool in Deharadun...................... 827
  Sushil Dalal, Kiran Pande, Neetu Pippet, Vishal Modgil

153. Study of Death among Children below five Years of Age and Its Relationship with Person Conducting
    Delivery and Place of Residence. Using Verbal Autopsy as a Tool in Deharadun...................... 832
  Sushil Dalal, Kiran Pande, Neetu Pippet

154. Profile of Pediatric Deaths in Bellary District.......................................................................................... 836
  Gururaj Biradar, Pavanchand Shetty H, B Suresh Kumar Shetty, Haneil Larson Dsouza, V
  Yogiraj, Charan Kishor Shetty

155. Prevalence of Knee Dysfunction in Mallakhamb Players in Karad .............................................................. 839
  Arundhati V. Nimbalkar, S. Anandh

156. Bipolar Disorder: A Major Setback in Substance Abuse ........................................................................ 844
  Jeetendra Kumar Gupta

157. Tunica Vaginalis Flap Versus Inner Preputial Dartos Flap as Waterproof Layer for Proximal Staged
    Hypospadias Repair: A Comparative Study......................................................................................... 849
  Zakaryia Yahya Moosa, Yousuf Mohammed AL-hallak

158. Association of HLA-DRB1 Gene Polymorphism in Rheumatoid Arthritis Patients in Babylon
    Province, Iraq........................................................................................................................................................................... 855
  Bariaa A. Aljoboury, Abdulsamie H. Alta’ee, Sabah J. Alrubaie

159. Parents’ Perception of Rehabilitation Services for their Children with Special Healthcare Needs in
    Helena Center in Erbil City ......................................................................................................................................................... 861
  Zainab Abdurrahman Abdullah, Kareem Fatah Aziz

160. Assessment of Patient’s Knowledge Regarding Hemodialysis Therapy at Imam Hussein Medical City
    in Holly Karbala Governorate ...................................................................................................................................................... 868
  Hussam Abbas Dawood

161. Nurses Competence with Regard Congenital Heart Diseases in Cardiac Care Unit of Pediatric Hospital
    in Sulaimani City ........................................................................................................................................................................... 876
  Banw Azad mohammed, Aso Faeq Salih

162. Assessment of Mother’s Practice among Using Oral Rehydration Solution for their Children with
    Diarrhea in Babylon City.............................................................................................................................................................. 884
  Abdulmahdi A. Hasan
163. Isolation and Identification Bacteria Species and Study Epidemiological Features to Burns Patients in Al- Yarmook Teaching Hospital ................................................................. 889
   Faraj, H. Johni, Abdulla L. Jiad

164. Critical Care Nurses’ Knowledge about Pulmonary embolism in Respiratory Care Unit in Baghdad Teaching Hospitals ................................................................. 895
   Massara Abdullah Najm, Ageel H. Jassim, Tahseen R. Mohammed

165. Assessment of Calprotectin Protein in H. Pylori Positive Persons................................................. 902
   Salim Hussein Hassan, Balqees Sadoon Jasim, Maytham Salim AL-Nasrawii

166. Knowledge and Awareness among Mothers Regarding Exclusive Breastfeeding in Holy Karbala City / Iraq........................................................................................................... 906

167. Effectiveness of an educational program on Nurses’ Knowledge towards Nursing Management of Patients with Transurethral Resection of the Bladder Tumor at Hilla Teaching Hospitals........................................... 913
   Basim Hasson Hussein, Halima Yusuf Al-Rubaiyee

168. The Children with Attention-Deficit/Hyperactivity Disorder (ADHD) More Likely Creates to Irritable Bowel Syndrome ........................................................................... 919
   Abdul AL-Kareem Hamza

169. Estimation of Parameters (Serum Glucose, Urea, Creatinine And C-Peptide) in Diabetic Nephropathy..... 925
   Rukia A. Jassim, Zeena A. Alsaady

170. A Chronic Toxicity Study of Oral Administration of Collagen-α® Supplement using Pregnant Rabbits..... 930
   Alia M. Kudayer, Nawras A. Alwan, Alaa A. Sawad

171. Nurses’ Knowledge Concerning the Management of Bleeding in Patients with Leukemia .................. 936
   Safad R. Isam

172. The Histological Alteration of Proximal Part of Aorta Exposed to (MSG) and Protective Effect of an a Lipoic Acid (ALA) in Male Rabbits.......................................................... 942
   Eman.M.Heil, Wefak Al-Bazi, Muna.Hussain AL-Aameli

173. Effect of Pioneer Aeromedical Evacuation Program on Flight Medics’ Practices toward Emergency Casualties at Army Aviation Bases in Iraq............................................ 949
   Ammar Kadhim Gaeed, Huda Baker Hassan

174. Anatomical, Histological and Histochemical Investigation of Soft Palate in Cat (Felis Catus Domesticus.L)........................................................................................................ 957
   Abbas Lafi Batah, Hussein Bashar Mahmood, Walaa F Obead

175. Molecular Detection blaOXA50 gene of P. aerginosae Isolated from Otitis Media................................... 962
   Ahmed Maki N. Al-Muaala, Noor A.Neama, Thulfikar H. al-kefaei

176. Effects of Alcoholic Extracts of Cinnamomum zeylanicum and Origanum Majorana on Expression of Hly Gene in Escherichia coli ............................................................................ 966
   Luma Saeed Mohammed, Enass Ghassan Sweedan May Talib Flayiyih
177. Assessment of Systemic Lupus Erythematosus in Term of Serum Anti-nucleosome and Interleukin 12 Markers in Relation to Epstein–Barr virus and Cytomegalovirus
Saif S. Ibrahem, Ahmed Sahib Abdulamir

178. Study of Immunological Parameters, Hematologic Outcomes And Epidemiology Features of Renal Dysfunction Frequently in Karbala Province, Iraq
Alyaa Aziz Gubiar Al-Nasrallah

179. Study on Correlation between IL-33 serum level, IL-33 Gene Single Nucleotide Polymorphism and Rheumatoid Arthritis Susceptibility
Hind Fouaad alhammami, Mahdi H. AL-Ammar

180. Association between IL12A Gene of G/A genotype Polymorphism and Pulmonary Tuberculosis Risk in Baghdad Population
Anwar Abed Nasser Dhabaan and Mayes Abdul-Hadi Mahdi

181. Evaluation of Oxidative Stress and Antioxidants in Iraqi Patients with Hydatid Disease
Ahmed A. Mohammed

182. Pharmacological Effects of Dexamethasone in Rats
Safa Azhar Razzag, Israa Jawad Jaber, Shahd Abdulamer Kadhim, Ahmed Adnan Abbas

183. Association of soluble HLA-G and HLA-G 14bp ins /del Polymorphism in some Iraqi patients with Breast Cancer
Hanaa N. Abdulllah, Alia Gh. Abdulwahid

184. Detection of Acute Childhood Meningitis using PCR in a group of Children at Childs Central Teaching Hospital/Baghdad
Rana Fahmi Shitran, Warqaa Y. Khudur, Mohammed E. Atallah

185. Molecular Physical Properties of Cryogloblin in Patients with Hepatitis B Virus in Al-Najaf Province
Ahmed Aleiwi Al Hassani, Adil Ibadi AL-Luhaiby, Mohammed Jasim Al-Shamarti

186. Hospital Door Knobs as a Source of Bacterial Contamination: A Study in Iraqi Hospitals
Zainab Salim Jaafar

187. Estimation the Level of Metals (Lead, Cadmium, Copper and Zinc) In Multiple Sclerosis Patients in Basra\ Iraq
Ali Diame Nashmi, Ali Faris Hassan, Mazin Mohamed Hammady

188. The Differences of Individual Characteristics and Working Environment That Influence Job Stress on Female and Male Workers at Pt. X Sidoarjo (Using Gender Prespective)
Adli Prasetyo, Tri Martiana, Rr. Soenarnatalina Melaniani, Firman Suryadi Rahman

189. Estimation of Pitch and Fundamental Frequency Variation Between Normal Males, Females and Intersex Population
Akashlina Basu, Pooja Ahuja, M. S. Dahiya

190. Dating of Long Bone Fracture Healing among Egyptian Pediatrics by Radiography (X-Ray)
Amal Salama Mahmoud, Amany Mohamed Fahmy, Alaa Mohamed Mahmoud, Amani Abdelfattah Bayomi, Ahmed Yosri El- Amir
191. Risk of Nutritional Status and Blood Sugar on Type 2 Diabetes Mellitus with Pulmonary Tuberculosis in Sawahan Subdistrict, Surabaya, Indonesia

Ana Mala Fitri, Muhammad Atoillah Isfandiari

1053

192. Risk Factors of Green Tobacco Sickness on Tobacco Farmers in Jember Indonesia

Anita Dewi Prahastuti Sujoso, Tri Martiana, Santi Martini

1058

193. Identification of the Direction and Strength of Relationship between Complaints of Musculoskeletal Disorders (MSDs) to Smoking Habits and Repetitive Movements of Informal Workers in Surabaya, Indonesia Using Spearman Correlation Test Methods

Annisa Dwinda Shafira, Genduk Lintang Rusmawarda

1064

194. Influence of Vitafort and Lactobifadol Probiotics on Excremental Microbiocenoses of Turkey Poults

Ayrat Khabirov, Fail Khaziakhmetov, Yaroslav Rebezov, Olga Gorelik, Marina Derkho, Valeriy Kozlov, Anna Vasyukova

1070

195. Analysis Of Work Climate And The Increase Of Blood Pressure Of Construction Workers In Pamekasan Regency

Dzul Fahmi Afriyanto, Noeroel Widajati

1076

196. Relationship between Temperature and Behavior with Pulmonary TB Incidence in Women in the Banyu Urip Health Center Surabaya, Indonesia

Fenti Nur Aini Amallia, Retno Adriyani

1081

197. Correlation of Standing Work Position and Musculoskeletal Disorders (MSDs) Complaints on Rack Frame Bending Section Workers in Informal Industry of Rack Making in Surabaya, Indonesia

Genduk Lintang Rusmawarda, Endang Dwiyanti

1087

198. Genetic variation analysis and kinship relationship between Dayak Ngaju tribe and Dayak Bukit tribe through examination of core DNA of Bukit CODIS STR Locus (combine DNA index system) 13 for the purpose of Forensic Identification

Iwan Aflanie, Wening Prastowo, Roselina Panghiyangani, Ahmad Yudianto, Toetik Koesbardiati

1094

199. Occurrence of Emerging Pollutants in Skudai River in Johor Bahru Region of Malaysia

Juhaizah Talib, Azmi Aris, Jafariah Jaafar, Zaiton Abd Majid, Ainul Syarmimi

1098

200. Relationship of Individual Factors, and Social Factors with Mother’s Intention to Continue Early Marriage Tradition in Indonesia

Nurma Fuji Astutik, Ira Nurmala

1104

201. Knowledge, Attitude and Practice of Menstrual Hygiene among Primary School Adolescents in Surabaya, Indonesia

Pinesa Rachma Andani

1109

202. The Effect of Chromium Exposure on Creatinine and Bun Level of Tanners in Leather Industry in Magetan

Siti Asiah, Abdul Rohim Tualeka, Y. Denny Ardyanto W

1115

203. The Relationship Between Husband Support and Health Workers Support with Exclusive Breastfeeding Behavior in Sidotopo Village, Surabaya, Indonesia

Yurike Dian Pangesti, Shrimarti Rukmini Devy

1122
204. Human Rights Based Law Protection Model for the Mental, Spiritual and the Healing Victims of Child Trafficking In Indonesia
Sulistya Eviningrum, Hartwiningsih Hartwiningsih, Mohamad Jamin

205. Potential of Hospital Fraud in the Indonesia National Health Insurance Era (A Descriptive Phenomenological Research)
Abu Khoiri, Widi Hidayat, Djazuly Chalidyanto, Fendy Suahriadi

206. Breast Feeding Practice Prevention for Nutritional Stunting of Children In Buginese Ethnicity
Agustian Ipa, Rudy Hartono, Sirajuddin, Aswita Amir, Sharifah Intan Zainun Sharif Ishak

207. Assessment of Undergraduate Critical Care Nursing Students’ Knowledge and Attitudes toward Caring of Dying Patients In Colleges of Nursing at Baghdad University
Ahmed F. Hassan, Haider M. Majeed, Aqeel H Jasim

208. Toxopathological and Cytogenetic Effects of Commercial Sweetener Aspartame after Chronic Oral Administration in Rat Pups
Ali, I. Al-ameedi, Zahraa M. Ayad, Falah Mousa Kadhim AL-Rekabi

209. Examining The Forensic Toxicity of Ricin Using Lc/Ms Techniques
Bandr Siraj Fakiha

210. Nurses knowledge about Management Extravasation Intravenous Cytotoxic Medication At Amal National Hospital in Baghdad City
Batool Kadham Hussin, Wrood Abdul Razaq Ahmed

211. Correlation between BMI and Thyroid Hormones in Infertile Groups
Etab Abdul-Ameer Al-ogla, Manar Saad Hussain, Suad Torki Abd-AL abbas

212. Effectiveness of an Educational Program on Primary School Teachers’ Knowledge about Attention-Deficit/Hyperactivity Disorders
Hassam M. Al-Amarei, Saja H. Mohamed

213. Anatomical and Immunohistochemical Variations Regarding the Epidermal Stem Cell among Different Traumatic Fingers of Hands in Iraqi Male Workers
Hatem A Hatem, Ahmed S. Mazyon, Hala Mohammed Majeed

214. Gene Expression and Levels of Plasma Protein Tyrosine Phosphatase Non-Receptor Type 22 (PTPN22) in Pulmonary Tuberculosis Patients and Their Household Contacts in Makassar, Indonesia

215. Quantitative and Histological Study of the Effect of Cadmium Oxide on Both Body and Kidney of Mice
Khalid H. Gathwan, Ahmed Anwar Albir

216. Clove (Syzygium aromaticum) Effect on Growth Malassezia Furfur and Aspergillus sp on Media
Leka Lutpiatina, Pebri Fitria Lestari, Dwi Intan Purnama Sari, Haitami, Rifqoh, Nurlailah

217. Assessment of Aggression among High Schools Students
Mansour Abdullah Falah Al-Zorfi, Hussein Jassim Muhammad Al-Ibrahimi.
218. Correlation of Anthropometry Characteristics and Six-Minute Walking Test Distance In Children Aged 7-8
Martha Kurnia Kusumawardhani, Ratna Darmanti, Andriati

219. Ultrasound Characterization of Abdominal Wall Endometriosis
Mohammed Bader Hassan, Omar Muayad Sultan, Adnan Mohammed Brayyich

220. Gene Polymorphism Vitamin D receptor BsmI in Thalassemia Children in Al-Muthanna Province
Mohammed Qasim Waheeb, Yasar Adil Jabbar Alabdali, Hanaa Ali Azez

221. Role of Interleukin-36 in Response to Pseudomonas Aeruginosa Infection
Muslim Idan Mohsin, Mohammed Jasim Al-Shamarti, Rusul Idan Mohsin, Sarmad Al-Sahaf

222. Study of Mean Platelet Volum When Exposed to Ultrasound Waves for Hypertension Patients
Mustafa Abdulkareem Salman, Asmaa Najm Abd

223. Oral Candidiasis in Chronic Kidney Disease
Mustafa Naeem N. Al-Sarray, Abdul Basit A. Sammed Abdulla, Mohamed Ali Al Kabe

224. The Effect of Boiling Time on the Concentration of Nitrite in Sausages
Nurlailah, Dinna Rakhmina, Badar Ruddin, Anny Thuraidah

225. Platelet Counts Analysis of Platelet-Poor Plasma (PPP) Produced by Several Centrifugation Techniques
Pande Putu Rangga Raditya, Yetti Hernaningsih

226. Feeding Style for Children Aged 0-59 Months of Buginese Ethnicity
Rudy Hartono, Agustian Ipa, Sirajuddin, Aswita Amir, Sharifah Intan Zainun Sharif Ishak

227. Renal Protective Effects of Gamma-Mangostin in Streptozotocin-Induced Diabetic Mice
Saikhu Akhmad Husen, Salamun, Arif Nur Muhammad Ansori, Suhailah Hayaza, Raden Joko

228. Complementary Feeding Practices Influences of Stunting Children in Buginese Ethnicity
Sirajuddin, Saifuddin Sirajuddin, Veny Hadju, Toto Sudargo, Rudy Hartono, Agustian Ipa, Sharifah Intan Zainun Sharif Ishak

229. Effect of Purified prodigiosin from Serratia Marcescens on the Inhibition of Breast Cancer (MCF-7 and CAL-51 Cell Line)
Taif H. Hassan, Sawsan H. Authaman, Khawlah J. Khalaf

230. The Incidence of Hepatitis C Virus Infections among People Screened in Governmental Health Care Facilities in 2018 in Iraq

231. Study of Gastroesophageal Reflex Disease in adult Type II Diabetes Mellitus Patients with Upper Gastrointestinal Symptoms
Maysam Riyadh Mohammed Hussein, Sadiq Jabar Almohana, Hayder Nadhum Muhsen

232. Molecular and Phylogenetic Study of Sarcocystis Gigantia from Different Slaughterhouse Regions in Karbala province
Kawther A.M. Al-Mussawi, Hayder A. Muhammed, Saja A. M. Al-Saadi
233. An in Vitro Study to Evaluate Antibacterial Effect Thymus Vulgaris Essential Oil Against Porphyromonas Gingivalis in Kurdistan– Iraq

Hama Rash A, Kareem S, Hamaamin H, Qadr K, Salih S, Azees S, Sha A

234. Salivary and Serum Aspartate Aminotransferase and Alanine Aminotransferase in An Uncontrolled Diabetic Patients

Dunya malhan henweet, Amina Ryhan Diajal

235. Effectiveness of an Educational Program Regarding Postpartum Care on Women’s Practices in Primary Health Care Centers at Amara City /Iraq

Rasha Leteef Neamah, Ezedeen F. Bahaaldeen, Iqbal Majeed Abbas

236. The changes in Blood Pressure in Patients Undergoing Spinal Anesthesia According to the Size of Spinal Needle (G22 versus G24): Case Reference Study

Ahmed Matrood Kadhim, Salman Abbas Badi, Watheq Maeh Naji

237. Nurses’ Knowledge based on Evidence Based Practice toward Eye Care for Intensive Care Units Patients

Sabah Abdullah Jaafir, Mohammed Baiqer Al-Jubouri Derham Majeed Alfatlawee

238. Prevalence of Musculoskeletal Pain among Iraqi Dentists

Alia Tabour Thijeel

239. The Evaluation of Ochratoxin A in Patients Suffer from Renal Failure

Haider Abbas Hadi Al-Mhanna, Atheer B. Al-Obaidi

240. Estimation of Radiation Exposure to Some Iraqi Patients with Hyperthyroidism treated with Radioactive Iodine-131 as an Outpatient Basis

Nafal NazarBahjat, Zahraa Neamah Abbas

241. Evaluation of Some Minerals Content of Drinking and River Water in Iraq by AAS Method

Mustafa A. Kadhim, Abd-alussain Sh. Naji, Luay S. Khaleefah, Hayder N. Salman

242. Impact of Social Media upon Juvenile Delinquency in Basra Central Prison and AL- Maqal Police Station

Haider Falih Jabbar, Ali Kareem Al-Juboori

243. Assessment of Referral System Quality from Clients’ Perspectives at Outpatient Consultancy Clinics in Al-Hilla City Hospitals

Mahdi Hamzah Manthoor Al-Taee, Mahasin Talib Al-Harbawi

244. The Effect of Adding Different Concentration of Vitamin E to Frying Oil on the Peroxide Value

Abd-alussain Sh. Naji, Luay S. Khaleefah, Hayder N. Salman

245. Correlation between Hormonal and Biochemical Changes with Kidney Function in Newly and Previously Diagnosed Women Diseased with Polycystic Ovary Syndrome

Zahraa Abed al-kareem, Jinan Hussein Multag, Ban Hoshi Khalaf, Amal Umran Mosa

246. The Effect of the use of E-Learning Teaching Physiology in the Academic Achievement of Students of the Technical Medical Institute

Mayad Nazim Rashid

Determination of Sex by Osteometry of Third Metatarsal

Arthy1, Rohit Goel2, Sreenivas M3

1Resident, 2Senior Resident, 3Professor, Department of Forensic Medicine, Maulana Azad Medical College, New Delhi

Abstract

In forensic anthropology and bio archaeology, sex determination is considered to be a primary step, as accurate identification of one sex eliminates half of the population of other sex. Though pelvis, cranium and long bones are considered more accurate indicators for sex determination, they are often not available or fragmented. The aim of this study is to specify the relation between prediction of sex of an individual and osteometry (length and mid shaft diameter) of third metatarsal and to assess the reliability of these morphometric traits in predicting the sex of the individual. Sample used in the study were 100 cases (50 males and 50 females) presenting for post mortem examination in the mortuary of Lok Nayak Hospital and Maulana Azad Medical College. The present study found sex determination accuracy of third metatarsal to be 67% to 72%, which rose to 75% on combination of variables from both sides. The results suggest that metatarsal bones can be used for sex determination when remains are fragmented or incomplete.

Key words: Metatarsal, Sex determination, Morphometric traits.

Introduction

Forensic anthropology in 1979 was defined by Stewart as “the branch of physical anthropology, which for forensic purposes, deals with the identification of more-or-less skeletonized remains known to be, or suspected of being human”. Modern anthropology is not restricted to skeletonized remains but includes identification of alive humans too. An anthropologist faces challenges with respect to identification of race, age, sex and stature in cases where the complete remains are not available.

Sex determination is the first and important step before age, ancestry and stature estimations as sex of the individual influences all these attributes. Examination methods include visual assessment (i.e. identification of special characters on skeleton) and metric analyses (i.e. measurement of bone trait). Metric based analysis is superior being examiner independent and relies largely upon statistical analysis. The most accurate sex indicators are pelvis and cranium followed by long bones. But when these bones are not available, fragmented or have been rendered unexaminable, then the small bones like metatarsals come to play a significant role.

The shafts of long bones often survive exhumation but the epiphysis bear a thin layer of compact bone on fragile cancellous bone, which is prone to damage. The smaller long bones of the hands and feet often remain intact/complete. Metatarsals being resistant to post-mortem changes and external trauma, are usually intact in comparison to long bones in mass disasters particularly explosions, aircraft and railway accidents. Shoe/boot protects the foot to some extent preserving the bones even in severely mutilated bodies. Though size variation due to activity or stress related robusticity is documented for the upper limbs, but this cannot be considered a factor to the same extent for metatarsals.

To the best of our knowledge, metatarsals remain unstudied in Asian population and studies on sex determination using cadaver metatarsals was not found even after extensive search.

The aims of this study were:

1. To specify the relation between prediction of sex of an individual and osteometry (length and mid shaft diameter) of third metatarsal.

2. To assess the reliability of these morphometric traits in predicting the sex of the individual.

MATERIALS AND METHODS

The study was conducted on autopsy cases
coming for medico-legal postmortem examination to the Department of Forensic medicine, Maulana Azad Medical College and Associated Hospitals, New Delhi. We studied a sample of 100 cases (50 males; 50 females) above 18 years of age as the data for the purpose of sample calculation was deficient.

Metatarsals with fractures, disease, deformity, surgical repairs were excluded from the study. Also cases with conditions affecting the stature were excluded.

**Method**

After explaining the study to the next of kin of deceased and consent was taken to participate in study, the case was included in the study. Autopsy was performed using standard autopsy techniques. Rigor mortis, if present, was released and the length was taken. The cadaver length (vertex of head to the base of heel) was measured with a measuring tape (in centimetres). After making an incision on right and left foot in midline over the dorsal aspect, soft tissue attachments were released and third metatarsal was dissected out. The metatarsal was prepared by placing it in boiling water, cleaned and washed for taking measurements. The following measurements from metatarsal were taken:

- The length of both (left and right) third metatarsal bone was taken from the highest point to the lowest point.
- The mid-shaft diameter (cranio-caudal) was measured from the middle of metatarsal taking the thickness of cortex into consideration.

Each linear measurement was taken three times, in anatomical position using vernier calipers (in centimetres to the nearest millimetre) and their average was recorded. The metatarsal after its measurement was put back in its place in the body before handing over the body to the relatives of deceased.

The data obtained was entered in excel spreadsheet and appropriate statistical analysis were done using SPSS 20 software.

**Observations and Results**

Of the 100 individuals used in this study, 50 are male (50%) and 50 are female (50%). The data belonged to north Indian Population.

The Kolmogorov-Smirnov and Shapiro-Wilk test revealed that the data was normally distributed. The Wilcoxon signed ranks test for bilateral asymmetry found no statistically significant difference between the right and left metatarsals.

**Determination of Sex**

Table 1 shows the descriptive statistics of measured values of metatarsal grouped by sex and side. All measurements were higher in males.

</table>
Demarking point analysis finds a point at which the one sex is excluded. In the study population, the demarking point for metatarsal length was 7.6 cm for females and 6.2 cm for males. That is, metatarsal length > 7.6 cm definitively excludes the female sex and indicates a male and metatarsal length being < 6.2 cm definitively excluded the male sex and indicates a female. The demarking point for mid-shaft diameter was 0.8 cm for females and 0.9 cm for males. Meaning that metatarsal with mid-shaft diameter of < 0.8 cm cannot be a male and hence will be female and > 0.9 cm cannot be a female and hence will be male.

Wilcoxon signed rank test and Wilk’s Lambda test showed that there was a statistically significant difference between the values obtained from male and female populations. Spearman’s rho correlation for the total population showed significant correlation with all metric parameters for sex determination with p-value being < 0.001. Mid-shaft diameter (Right- 0.497, Left -0.500) showed better correlation than the metatarsal length (Right- 0.398, Left -0.376). Sexual Dimorphism Index \[SDI = (X_m - X_f/X_m)*100\] where \(X\) represents the sample mean for each measurement. The mid-shaft diameter (pooled SDI 17.30) has better SDI as compared to metatarsal length (pooled SDI 11.62) as shown in table 2.

**Table 2: Sexual Dimorphism Index**

Receiver operator curve showed that area under the curve was higher for mid-shaft diameter than for metatarsal length indicating higher accuracy of mid-shaft diameter in predicting the sex of the individual. The co-ordinate of the curve showed that when metatarsal length is \(\leq 6.05\) cm the sensitivity will be 98 % and specificity will be 100% in assuming the sex to be female. Whereas, if metatarsal length is \(\geq 7.7\) cm, sensitivity will be 84 % and specificity will be 100% in assuming the male sex. For mid-shaft diameter, the co-ordinate of the curve showed that when the diameter is \(\leq 0.75\) cm the sensitivity will be 98 % and specificity will be 100% in for female sex. At the upper end when mid-shaft diameter is \(\geq 0.95\) cm, sensitivity will be 28% and specificity will be 100% in assuming the male sex.

Predicted percentage for sex determination using univariate logistic linear regression showed that mid-shaft diameter is better predictor than metatarsal length. Multivariate logistic analysis considering all the variables of both sides increased the prediction to 74%. With females (76%) having a higher sex prediction than males (72%).

However, the rise in the prediction using multivariate regression was not significant \((p > 0.05)\). Thereby indicating that the measurements taken from the metatarsals are individually significant in identifying the sex of an individual; though the prediction accuracy increased by combining these parameters, it was not a significant rise.

**Discussion**

**Side symmetry:**

The metatarsal measurements of right and left side did not show any significant difference indicating the uniform distribution of physical stress between the lower limbs unlike in upper limbs where the difference is expected. Researchers suggest that the dimorphism in foot bones are most likely due to the difference in body size between males and females indicating that the intrinsic factors of sexual dimorphism by gonadal and pituitary hormones plays a major role.

**Measurements from metatarsal:**

On comparing metatarsals measurements reported by different researchers, mean values obtained in this study are consistent with the reports of Mountrakis but mean metatarsal length was higher and mean shaft diameter was lower than values reported by Abdel. The population studied by C. Mountrakis and Abdel are expected to have a taller stature and bigger metatarsals than the Indian population. As the present study examines freshly dissected metatarsals where intact articulation capsule the measurement are likely to be higher. Also in radiological study by Abdel, the angulation of the bone appears to make a difference.

**Determination of Sex**

Sexual dimorphic index calculated for metatarsal length and mid shaft diameter were 11.62 % and 17.30% respectively. It confirms the sexual dimorphic property
of 3rd metatarsal morphometry. SDI obtained in our study was indeed higher than calculated by C. Mountrakis as 7.92 % and 9.08 % for metatarsal length and mid-shaft diameter respectively.\(^5\)

The present study found sex determination accuracy of third metatarsal to be 67% to 72%, which rose to 75 % on combination of variables from both sides. This accuracy is consistent with report of Alicia K Wilbur but lower than the reports of Roblin, Smith, Abdel and C. Mountrakis.\(^5, 7-10\) This variation in accuracy can be attributed to different ancestry of the study population, sample collection techniques and processing. For example, Abdel studied the radiological measurements of metatarsal from the highest point to the lowest point with the bones in angulated state. Although his study gave 100 % accuracy in predicting original study samples of 160, but when tested on a sample of 80, the accuracy fell to 96.25 %. Mountrakis obtained accuracy ranging 80.7% - 90.1% after measuring the maximum length of archaeological metatarsals along with other measurements as medio-lateral and dorso-plantar width of base, mid-shaft and head.\(^5\) He noted that metatarsal length may change slightly at proximal and distal ends due to activity and remodelling related changes, but with limited effect. Case and Ross obtained correct classification rates exceeding 80% with a stepwise analysis model based on phalangeal and metatarsal measurements.\(^11\) Kautilya observed that foot breadth correlates best with sex of the person instead of foot length that is consistent with our findings on studying the metatarsal bone.\(^12\)

### Comparison of sex prediction of metatarsal with other bones

Different studies give different prediction percentage for the same variable observed, as shown in table 4. This variability can be due to population ancestry, experience of the author, variation in techniques employed by them and special circumstances peculiar to study. For example, Krogman’s samples were from a medical school where the ratio of male to female cadaver was 15:1.\(^2\) Thus, Krogman with his experience while predicting the sex, in cases of dilemma had to roll the dice towards male where he had 15 to 1 chance of being correct. The prediction variability due to ancestry is appreciated by Flanders. He studied 200 sacri and reported the accuracy varying from 84% in whites to 91% in blacks in absence of bias arising out of observer and technical differences.\(^13\) Pelvis is the best bone for sex prediction, the accuracy of correct classification as per Krogman is 95%.\(^2\) Abdel’s testing of metatarsals gave a prediction of 96.25%, which has been as high as that of the studies done on pelvis.\(^7\) Indeed, it was higher than the prediction value obtained from skull (Krogman 92% and Stewart 80%).\(^1, 2\) Though the prediction percentage obtained in present study are significantly lower than pelvis and skull
but importance of metatarsal needs emphasis in situations where fragments of long bones or destroyed axial skeleton are available for examination. When fragments are available like the lower end of the humerus, the prediction with those fragmented bones has been equal to that of the metatarsals.\textsuperscript{14,15}

The data suggest that metatarsals cannot substitute a primary bone for sex determination but it can be used to determine sex where skeletal remains are fragmented or incomplete, which is a frequent occurrence in medicolegal cases. The accuracy of prediction is expected to increases further when metatarsal is combined with other bones. However, further studies are needed for the testing the applicability of this model to archaeological remains, an effort that presents a range of theoretical and methodological challenges, primarily in terms of population continuity, secular and behavioural changes.

**Conclusion**

This study demonstrates that third metatarsal showed correlation with sex determination. Mid-shaft diameter proves to be a better pointer to the sex of individual rather than the length of metatarsal. The maximum prediction accuracy obtained for sex determination was 75% after combination of length and mid-shaft diameter of one side which was almost equivalent to those obtained by examination of long fragmented bones. The specificity was high when the bones of extremes of measurements were encountered where mid-shaft diameter of <0.75cm has a specificity of 100% for females and a diameter of >0.95 cm is 100% specific for being a male.

We recommend that this study be carried out more extensively on larger samples in different populations (as in different regions of our own country) separately and in combination with other bones to arrive at a final conclusion regarding the validity of this method in prediction of sex and stature of the individual. The standards of the study should not be applied to archeological samples and skeletonized dried remains where shrinkage is a known phenomenon.

Incidence of Tuberculosis in Unidentified Dead Bodies amongst Autopsy Conducted at Government Stanley Medical College and Hospital, Chennai

A.Gokulakrishnan¹, S.Praveen¹

¹Assistant Professor, Department of Forensic Medicine, Government Stanley Medical College and Hospital, Chennai-01, Tamil Nadu, ²Professor, Department of forensic medicine, M.S.Ramaiah medical college and hospital, Bangalore, Karnataka

Abstract

A autopsy based prospective study on incidence of tuberculosis was conducted at government Stanley medical college for two year from June 2016 –June 2018 in that 425 cases of unidentified bodies were subjected for postmortem in that 376 cases were taken for the present study these based on exclusion criteria during autopsy in that 201 cases were male and 175 cases were female, in all the cases sterile swabs were taken from intra bronchial region and directly from caseous necrosed sites and lung tissues from pathological sites are subjected for histopathological examination during autopsy and sterile swabs were subjected for acid fast staining and culture by lowenstein Jensen medium medium among the376 cases studied 52 cases had pulmonary tuberculosis and 2 cases had milliary and intestinal tuberculosis respectively.

Key words – unidentified bodies, pulmonary tuberculosis, Milliary tuberculosis and intestinal tuberculosis.

Introduction

“Unidentified body” refers to a person who dies in a public place or hospital, which has not been claimed by any near relatives or personal friends within such time period as may be prescribed¹.

Tamil nadu is India’s third most populous state and Chennai stands for fifth-most populous urban agglomeration. With a huge migrant population who came down in search of job opportunities or take up any menial works to eke out a living and 10% of chennai population lives in slums further the migrants who are illiterates and do not possess any identification proofs and upon death either natural or unnatural, establishing their identity or even informing their relatives becomes very difficult.

At least 10 bodies are recovered every day in Tamil Nadu, most of which remain unidentified and unclaimed². The latest National Crime Records Bureau statistics show the state has the second highest number of unidentified bodies at 3,739, after Maharashtra with 6,185 corpses. As per the same report, 2,795 bodies were recovered around the State in 2010, thus showing a more-than-significant rise in body count of 60 per cent. Ironically³.

India is the country with the highest burden of TB. The World Health Organisation (WHO) TB statistics for India for 2016 give an estimated incidence figure of 2.79 million cases of TB for India. The TB incidence is the number of new cases of active TB disease during a certain time period¹. 

Tuberculosis (TB) remains a major respiratory cause of morbidity and mortality worldwide and has been identified as a ‘global emergency’ by the WHO. One third of the world’s current population has been infected with M.tuberculosis, and new infections occur at a rate of one per second⁴. Latent infection is however, most common and about 10% of it eventually progresses to active disease, which, if left untreated, kills more than half of its victims⁵.

It is estimated that about 40% of the Indian population is infected with TB bacteria, the vast majority of whom have latent TB rather than TB disease.

In 2004, mortality and morbidity statistics included 14.6 million chronic active cases, 8.9 million new
cases, and 1.6 million deaths, mostly in developing countries. The national average of tuberculosis per 100,000 populations in India was 168 in the year 2006. Worldwide problem status is presented in Table 17. India has the largest number of infections, with over 1.8 million reported cases. In March 2017 the Government of India (GoI) announced that the new aim with regard to TB in India was the elimination of TB by 2025 by National Strategic Plan 2017 – 2025.

India also has more than a million “missing” cases every year that are not notified and most remain either undiagnosed or unaccountably and inadequately diagnosed and treated in the private sector.

Reasons for increasing incidence of this treatable disease in unidentified cases were due to lack of access to health care, ineffective preventive and control programmes and comorbid condition like HIV infection, drug abuse and alcoholism, etc.

Tuberculous elimination program was started by the government of India, the present study was taken up to highlight the missed population in the community who are suffering from severe form of this disease and left untreated and cause death due to complication of tuberculosis.

**Materials and Method**

**Source of Data**

Unidentified cases subjected for medico legal autopsy at Department of Forensic Medicine, government stanley Medical College and Hospital, chennai.

**Method of Collection of samples**

A two year prospective study on unidentified dead bodies were started from June 2016 in that unidentified cases without any external or internal injury were taken up for study in all cases two sterile swabs were taken from intra bronchial region from both the lungs (image 1a and 1b) in certain cases directly from the caseous necrosed sites (image 2a and b) for acid fast staining and culture by Lowenstein Jensen medium and lung tissues from pathological sites were subjected for histopathological examination.

**Exclusion Criteria**

Unidentified bodies with external and internal injuries due to road traffic accident, railway injuries, assaults, poisoning cases, decomposed dead bodies and abandoned new born babies were excluded from the study group.

**Results and Discussion**

**Table No. 1: Total Number of unidentified cases during study period.**

<table>
<thead>
<tr>
<th>Total No of Autopsies during study period</th>
<th>No of Unidentified bodies studied</th>
<th>Percentage</th>
</tr>
</thead>
<tbody>
<tr>
<td>3516</td>
<td>376</td>
<td>10.08%</td>
</tr>
</tbody>
</table>

Of the 3516 cases subjected for medico legal autopsy, 376 were unidentified (10.08%). This increased number of unidentified cases is because the department of forensic medicine caters to the population of north chennai, which has its fair share of slums and as well as migrant population working in market places, also the proximity of railway station with constant influx of passengers.

In a similar study conducted by Lucinda et al in Pretoria (South Africa), unidentified bodies constituted for about 7-10% of total autopsies.

In another study conducted by Kumar S et al in Lucknow, unidentified bodies constituted for about 15% of total autopsies.

**Table No. 2: Sex distribution among unidentified cases.**

<table>
<thead>
<tr>
<th>Sex</th>
<th>Total no. of cases</th>
</tr>
</thead>
<tbody>
<tr>
<td>Male</td>
<td>201 (53.45%)</td>
</tr>
<tr>
<td>Female</td>
<td>175 (46.54%)</td>
</tr>
<tr>
<td>Total</td>
<td>376 (100%)</td>
</tr>
</tbody>
</table>

Among 140 unidentified cases, 201 (53.45%) were males and 175 (46.54%) were females. Males being more as commonly the males constitute the crux of migrant population who came in search of job opportunities.
In a study conducted by Kumar S et al in Lucknow on unidentified bodies, majority of cases were males (2218, 69.99%) as compared to females (951, 30.01%).

Table No. 3: Age group in cases studied for incidence of tuberculosis.

<table>
<thead>
<tr>
<th>Age group</th>
<th>No of unidentified cases</th>
<th>percentage</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 – 20 yr</td>
<td>4</td>

<tr>
<td>21 – 40 yr</td>
<td>92</td>
<td>24.4%</td>
</tr>
<tr>
<td>41 – 60 yr</td>
<td>159</td>
<td>42.2%</td>
</tr>
<tr>
<td>61 – 80 yr</td>
<td>121</td>
<td>32.1%</td>
</tr>
</tbody>
</table>

In our study, most of the unidentified cases (42.2%) were in the age group of 41 to 60 years, 32.1% were in the age group of 61-80yrs, 24.4% were in the age group of 21 – 40yrs and 1.06% were in the age group of 0 – 20yrs.

Due to the diminished family ties, abandoning of parents by their children in the modern society, illiteracy, and low socio economic status were the most common reasons for higher incidence in the age group 41 to 60 years.

In a similar study conducted by Kumar S et al in Lucknow on unidentified bodies, 47.24% were in the age group of 41-60 years. 8.36% were in the age group of 0 – 20yrs. Observations were similar to those in our study.

Table no 4: Types of tuberculosis in unidentified cases.

<table>
<thead>
<tr>
<th>Type of tuberculosis</th>
<th>No of cases</th>
<th>Percentage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pulmonary tuberculosis</td>
<td>52</td>
<td>96.2%</td>
</tr>
<tr>
<td>Milliary tuberculosis</td>
<td>01</td>
<td>1.8%</td>
</tr>
<tr>
<td>Intestinal tuberculosis</td>
<td>01</td>
<td>1.8%</td>
</tr>
</tbody>
</table>

Among 376 unidentified cases in that 52 cases showed presence of mycobacterium tuberculosis through culture and by acid fast staining and 2 cases showed extra pulmonary tuberculosis by histopathological examination.

Of 54 cases of tuberculosis, most (n=52, 96.2%) cases were presented as pulmonary tuberculosis(image 3). 1 ( 1.8%) cases were presented as Milliary tuberculosis and 1( 1.8%) case were presented as Intestinal tuberculosis(image 4a and 4b).

And the pulmonary tuberculosis were further classified based on number of acid fast bacilli seen per field. In 34 cases 4+ (>9 bacilli /field) is seen due to lack of access to health care, ineffective preventive and control programmes and comorbid condition like HIV infection, drug abuse and alcoholism, 13 cases 3+ (1-9 bacilli /field) seen, 02 cases 2+ (1-9 bacilli /10 fields) seen, 02 cases 1+ (1-9 bacilli /100 fields) seen, 01 case +/- (1-2 bacilli /300 fields) is seen (image 5a and 5b).

In a retrospective study conducted by Buyuk Y et al in Istanbul on unidentified bodies, (n=138, 60.2%) cases were died naturally. Remaining (n=91, 39.4%) cases were died unnaturally. Approximately 1/3 of natural
death cases were revealed evidence of pulmonary tuberculosis, but only in 32 cases tuberculosis was primary cause of death\textsuperscript{10}.

**Conclusion**

“Study of incidence of tuberculosis in unidentified dead bodies amongst Autopsies” conducted at Government Stanley Medical College and hospital, Chennai, between Jun 2016 to Jun 2018, the results of the study have been concluded as follows.

- Of the 3516 cases subjected for medico legal autopsy, 376 unidentified cases were full filled the criteria (10.98%).
  - 201 (53.4%) were males, 175 (46.5%) were females.
  - 159 (42.2%) of the cases were in the age group of 41 to 60 years.
- Of 376 cases 52 cases had pulmonary tuberculosis.
and 2 cases had miliary and intestinal tuberculosis respectively.

- Pulmonary tuberculosis was most commonly seen and showed (4+ / > 9 bacilli per field) smear classification in most of the cases due to lack of treatment.
- In 13 cases 3+ (1-9 bacilli /field) seen, 02 cases 2+ (1-9 bacilli /10 fields) seen, 02 cases 1+ (1-9 bacilli /100 fields) seen, 01 case +/- (1-2 bacilli /300 fields) is seen.
- Based on the above results it indicates
  - the present study highlights the missed population in the community who are suffering from severe form of this disease and remains latent reservoir for constant source of infection in the community.
- Most of the cases were left untreated and cause death due to complication of tuberculosis.
- Identifying and treating these community will only leads to eradication of tuberculosis in India by 2020.

Study of Lip Print Pattern among Young Individuals in Bangalore City

Chandru K1, Naveena Preethi2

1Professor and Head, Department of Forensic Medicine and Toxicology, Sri Siddhartha Medical College, Tumkur; 2Assistant Professor, Department of Pedodontics, Rajarajeshwari Dental College, Bangalore

Abstract

Chieloscopy or study of pattern of lip print is one of the easiest tools available for the identification of an individual in a medico legal investigation. The present study involves evaluating the pattern of lip prints among hundred individuals with 50 male and 50 female subjects. Lip prints are obtained on a white bond paper and studied involving all four quadrants. It was observed that Type I pattern was commonest lip print pattern among all the individuals and in female subjects, whereas Type II pattern was common among males. No two individuals had the same lip print pattern.

Key words: Chieloscopy, quadrant, reticular, lip print.

Introduction

Chieloscopy is one of the most emerging methods of human identification that deals with study of lip prints. Lip prints are formed by the pattern of grooves present on the labial mucosa. Lip prints are unique to particular individual and do not change during life of a person. They were first studied by anthropologist; R Fisher in 1902. In 1950, two Japanese scientists Kazuo Suzuki, Yasuo Tsuchihashi reported the arrangement of furrows on lip is unique and proposed a classification.1

Lip prints are classified into following types:

Type I: Clear cut grooves running vertically over the length of lip.

Type II: Grooves running vertically over partial length of the lip.

Type II: Grooves branch in their course.

Type III: Intersected grooves.

Type IV: Reticular grooves.

Type V: Irregular nonclassified pattern.

The dissimilarity among individuals is influenced by hereditary factors, seasonal effects and age. This could be a hurdle in lip print being used as lifelong constant identification feature2. Lip prints are similar to finger prints and foot prints in that individual characteristics are used for identification. They recover after undergoing alterations like trauma, inflammation and disease3. Lip prints of parents, children and siblings show some similarities which can establish relationships to limited extent. Variations in pattern among males and females could help in sex determination. Apart from standard types, 24 individual characteristics are distinguished. To simplify the study lip prints are classified into 4 quadrants and each quadrant is studied separately. Establishing 7 to 9 characteristics leads to positive identification. Substance forming print saliva and cosmetics can be identified which act as corroborative evidence4.

Identification of person and a suspect in crime is becoming more difficult for investigators as criminals are using sophisticated techniques while committing crime. Lip prints though a less recognized forensic investigating technique can be silent important evidence in a scene of crime to nail the culprit. The significance of Chieloscopy is linked to the fact that lip prints are inherent, develops at 6th month of intrauterine life. They are permanent, unalterable even after death unique to each person except for monozygotic twins5.

Aim

To study the pattern of lip prints among fifty young males and fifty young females.
Material and Method

Materials required are white bond papers, transparent foil of adhesive tape or cello tape, red lip stick and magnifying lens. Lip prints are collected from young individuals between 18 to 22 years of age. A total of 100 individuals are studied among which 50 are males and 50 females. Lips are first cleaned with tissue paper, red lip stick is applied over cleaned lips. Lip print is obtained by applying cello tape over the lips and pasting the same over white bond paper. Lip prints thus obtained are studied manually using magnifying lens.

Exclusive criteria: Persons with lip lesions, scars, and fissures.

Results

Lip prints are classified into 4 quadrants namely I\textsuperscript{st} quadrant which is right upper quadrant, II\textsuperscript{nd} quadrant is left upper quadrant, III\textsuperscript{rd} quadrant is left lower quadrant and right lower quadrant being the IV\textsuperscript{th} quadrant. Lip print pattern are studied in all four quadrants. A total of 50 male lip prints and 50 female lip prints were obtained. Type I lip print was commonest among all individuals and among females, whereas type II pattern was common among males. No two individual had the same pattern of lip print. Results are tabulated as follows:

Discussion

The study of lip prints among 100 individuals revealed that no two individuals had same pattern of lip print which enhances the effectiveness of lip print as a tool for identification of an individual. In this study Type I was the commonest pattern occurring among individuals in contrast to the study done by Umesh Babu\(^6\) where type IV was most commonly occurring lip print pattern. The study showed the least common type of lip print was type IV and type V in contrast to the other study\(^6\) where type II was least occurring pattern. In the present study, type II pattern was the commonest occurring lip print in males followed by type I, while in females type I was commonest followed by type II. Our study result was in contrast to study done at Wardha\(^7\) where type III pattern was more common in males and type II was commonest in females. The present study is in agreement with previous study\(^8\) where type I was common in females.

In males there were five subjects with all four quadrants having similar pattern. There were fifteen female subjects having similar pattern in all four quadrants which is in agreement with study at Wardha\(^7\) where more females had similar pattern in all four quadrants than males. In our study majority of them had two quadrants with similar lip print i.e, 15 in males and 20 in females. Least occurring pattern in males was type III and in females was type IV. The study is in contrast to results obtained by Sivapathasundaram\(^9\) study which showed type III as the commonest pattern where as type I pattern is more common in our study.

Conclusion

Chieloscopy remains a credible, non invasive and economically viable tool for identification of an individual. The study concludes that no two individuals have same lip print pattern. Type I is the commonest lip print pattern among all individuals. Type II in males and type I in females are the commonest pattern observed respectively. The result obtained varies with other studies done in similar field as various factors have a role in deciding the pattern of lip print in an individual. Hence a particular pattern of lip print cannot be attributed to a particular gender or region. The present study involving 100 subjects is a small sample size for generalizing the results. This study should be helpful in initiating further studies with larger amount of subjects providing enhanced results.

Effectiveness of Educational Intervention on Knowledge & Attitude about MTP Act 1971 among Apparently Healthy Reproductive Age Group Population Visiting A Tertiary Care Centre, Puducherry

Fathima S1, James Rajesh J2, Jothi Marie Feula3, Siva Reddy4
1Undergraduate Student, Sri Venkateshvaraa Medical College, Hospital and Research centre, Puducherry, 2Assistant Professor, Department of Forensic medicine, Sri Venkateshvaraa Medical College, Hospital and Research centre, Puducherry, 3Senior Resident, Department of Physiology, Jawaharlal Institute of Postgraduate Medical Education & Research, Puducherry, 4Professor and Head, Department of Forensic medicine, Sri Venkateshvaraa medical college, hospital and research centre, Puducherry.

Abstract
Medical termination of Pregnancy Act is one such Act which was brought by the Indian Government to streamline the process of abortions conducted in India. Its rules were framed for the first time in 1972, amended in 1975, 1977, 2003, and 2009 and recently in October 2014. The main motive of passing such bills was to decrease the female foeticide rate, decrease the maternal mortality rate, improve the health of the mother and the newborn and to avoid unwanted and illegal abortion practises. In spite of these measures from the government, more than 5000 deaths due to unsafe abortions take place every year in our country. The main cause of such death related to abortion is mainly due to the ignorance of the general public towards abortion. Majority of the women, not only in the rural parts, but also in the urban regions does not know about the mere existence of the MTP law. Hence this study was aimed to estimate the level of awareness about the MTP Act among the apparently healthy reproductive age group public, visiting the hospital and apart from it, we also educate them regarding the MTP Act and its uses. Among our participants the minimum age reported was 20 and the maximum age was 45. Out of total 220, female accounted to 63.2% and male 36.8%. Among them married people accounted for 69.5%, unmarried 28.2% and others were 2.3%. 42.3% of people had history of abortion their family but 64% of people doesn’t know whether the conducted abortion was a legal or a illegal one. Eleven questions were asked to the participants and an initial assessment of their knowledge was done with the help of a questionnaire. After this immediately, educational intervention was carried out about the law and after a gap period of one month the participants were asked the same questions as before using telecommunication device and their knowledge was tested.

Key Words: MTP Act, Abortion, Educational intervention, Knowledge & Attitude.

Introduction
Many acts & bills are constantly passed and amended respectively for the welfare of the people of India, but the real question is whether these acts and laws reach the people concerned? Medical termination of Pregnancy Act is one such Act which was brought by the Indian Government to streamline the process of abortions conducted in India. Its rules were framed for the first time in 1972, amended in 1975, 1977, 2003, and 2009 and recently in October 2014(1). The main motive of passing such bills is to decrease the female foeticide rate, to decrease the maternal mortality rate, improve the health of the mother and the newborn and to avoid unwanted and illegal abortion practises.

In spite of these measures from the government to reduce the maternal mortality rates, female foeticide and other illegal abortion deaths, more than 5000 deaths due to unsafe abortions take place every year in our country(2). Unsafe abortions are killing one woman every two hours in India. A lancet paper in 2007 reported
that there were 6.4 million abortions, out of which 3.6 million (56%) were unsafe. According to census 2011 abortions taking place in institutions varies from 32.0% in Chhattisgarh to 73.9% in Assam\textsuperscript{(3,4,5)}.

The main causes of such deaths related to abortions are mainly due to the ignorance of the general public towards the Abortion procedures carried out in India. Majority of the women not only in the rural parts, but also in the urban regions does not know about the mere existence of the law. This ignorance related to abortion like, when it has to be conducted, the indications, the place, who has to conduct the procedure etc..remain unknown to them. Hence this study is aimed to estimate the level of awareness about the MTP Act among the apparently healthy public visiting the hospital and apart from it, we also educate them regarding the MTP Act and its uses.

**Materials and Method**

This is a quasi experimental study / Before-after intervention study, carried out in the medicine Out Patient Department (OPD) of Sri Venkateshwara Medical College Hospital and Research Center, where on an average of 75 patients visit OPD per day. The sample size was 220. Sampling Procedure followed was that all the eligible participants available during the study period were included in the study.

**Inclusion Criteria:**

- The study subjects are those who are apparently healthy people who accompany the patients to the Medicine OPD.
- They may be a relative/friend/guardian, irrespective of the sex.
- Age group of 15 – 45yrs, of either gender.
- Who own/ use telecommunication devices

**Exclusion Criteria:**

- Persons less than 15 years and more than 45 years will not be included in the study.
- Persons who don’t have telecommunication devices or who don’t know to use one will not be included in the study.

We assumed that 20 eligible participants will be available at the OPD, each day during the visit of the investigator.

**Phase I:** The investigator visited Medicine OPD on all days from Monday-Friday. A pre-tested self-designed questionnaire was used for data collection after obtaining informed written consent. Contact numbers of the study participants was collected. The study participants were given educational intervention on MTP Act, 1971. In this educational intervention, all the details like the latest updates, the merits and usefulness of the MTP Act was explained to them. Informative charts, attractive and thought provoking PPTs presentations were used as a tool to educate them.

**Phase II:** One month after the intervention period, the study participants were contacted through phone and post intervention assessment was done. Pre and Post test results were analysed using SPSS 23.0

**Study tool and study variables:** A pre-tested self-designed questionnaire comprising two parts will be used for data collection. **Part A-** Socio demographic details (Age, gender, education, occupation, income, marital status, religion, number of children, use of contraceptives, obstetric index.) **Part B-** The Investigator will assess the knowledge and attitude by using structured questionnaire regarding MTP Act 1971.

**Observation and Results**

Distribution of the study population based on age is shown in table 1. The minimum age reported was 20 and the maximum age was 45. Distribution of study population based on gender and education is shown in table 2. In this study female participants accounted for 63.2% and male 36.8%. Among the total participants, 77.4% of people have completed high school and have graduated and 8.6% of people have never attended even primary school. Distribution of study population based on socio – economic status is shown in table 3. Modified Kuppusamy scale was used to assess the socio-economic status and based on this 64% of people are middle and above middle class with maximum number of people fall under upper middle class 37.7%. Out of 220, 93 participants reported past history of abortion and among them 67 doesn’t know whether it was a legal or an illegal abortion (Table 4). While analysing the pre and post test results, majority of the persons have answered many of the post intervention questions correctly and overall it was statistically significant for all the questions. Pre and post test results and analysis is shown in table 5.

P – Post test questions  NA – Not Applicable  * - Statistically Significant

Discussion

This study was conducted among reproductive age group individuals of either sex in a tertiary medical college in Puducherry. The total numbers of participants were 220. Among the participants, the minimum age reported was 20 and the maximum age was 45. Mean age group participated 33. In this study female participants accounted for 63.2% and male 36.8%. Among the total participants, 77.4% of people have completed high school and have graduated and 8.6% of people have never attended even primary school. The basic demographic details were collected to avoid the bias in the study subjects. Equivalent to females, males also play a major role in decision making with relation to conduct of abortion. This was the reason both male and female were included in this study were as in the study conducted in Kerala(6) as well as in South Africa(7), only females were included but the awareness study...
conducted in New Delhi\(^{(8)}\), both male and female were included. In this study both rural and urban people were included and more than 75% of people have completed their schooling and also some under graduate courses. All the other studies also included both rural and urban population.

When compared to all the three studies which have evaluated the knowledge aspect alone of the people, in this study we have evaluated about their self experience about the abortion and their knowledge in it. Among the participants, 127 people had no personal history or family history of abortion. 93 participants reported either personal history or a family history of abortion. Among the 93, 67 participants don’t know the type (legal or illegal) of abortion conducted. 10 persons reported as legal, done in a hospital set up and 16 reported as illegal, done in home.

Regarding the awareness of MTP Act, the pre intervention answers denote that the public are totally unaware of the mere existence of such an act in India. The same conclusion was driven from the studies conducted in Kerala \(^{(6)}\), South Africa \(^{(7)}\) & New Delhi \(^{(8)}\). All the three studies conducted only a survey regarding the awareness of the act among them, but we also conducted an educational intervention. We also evaluated the knowledge of the public by contacting them through phone after a period of one month and re evaluated them with the set of same questionnaire. Each question was evaluated for pre and post intervention and for all the questions, they have mostly answered correctly and upon analysing statistically, all the 11 post intervention answers were statistically significant.

The first question was about the knowledge of mere existence of the MTP Act in which 26.4% gave correct answer in the initial test, while 98.2% gave correct answers after the educational intervention. The second question was about the awareness on MTP Act in which initially 28.2% gave the correct answer, while after 93.1% gave the correct answers. The third to sixth questions were regarding the termination of a pregnancy with respect to mother, baby, rape and contraception failure. In these the initial percentage of correct answers were 9.1%, 5.9%, 54.1 & 19.1% respectively, while the post intervention answers were 80.5%, 65%, 87.7% & 91.9% respectively. The seventh question was on husbands’ consent, the eighth & ninth was on doctors qualification, the tenth was on gestation week for termination and the eleventh was regarding hospitals for MTP. Initially the percentage of correct answers were 0%, 0%, 10%, 15.5% & 10% respectively, while after educational intervention it was 70.5%, 82.7%, 76.4%, 90.5% and 86.8% respectively.

**Conclusion**

A study to assess the effectiveness of educational intervention on knowledge & attitude about MTP Act 1971 among apparently healthy reproductive age group population visiting a tertiary care centre, Puducherry was carried out, in which the following observation was made:

- The minimum age of participant reported was 20 and the maximum age was 45 with a mean age of 33.
- Female participants accounted for 63.2% and male 36.8%. Among the total participants, 77.4% of people have completed high school and have graduated and 8.6% of people have never attended even primary school.
- Analysing the socio economic status, 64% of people are middle and above middle class with maximum number of people fall under upper middle class 37.7%.
- 93 participants reported past history of abortion and among them 67 doesn’t know whether it was a legal or an illegal abortion.
- Analysing the pre and post test results, majority of the persons have answered many of the post intervention questions correctly and overall it was statistically significant for all the eleven questions.
- The results were that, there is a need to expand awareness about when, where and under what circumstances legal abortion can be availed. This awareness was poor not only among women but also among the gatekeepers of the decision making process in the family as well. Women also need to know their rights and study concluded that they should also know, what are safe quality services, in order to ask for information or question poor quality care Providers
- From this study we like to expose to the government about the lack of knowledge of the general public about the MTP Act.
- We believe the knowledge which we feed them about the MPT Act1972 will help them know the correct methods and indications and provide them overall
knowledge about illegal abortions.

Study of Profile of Motor Vehicle Accidents in Thiruvanmiyur Traffic Police Station

G.Shivani1, V.Dekal2

12nd M.B.B.S Student, Saveetha Medical College & Hospital, SIMATS, Chennai, 2Professor and Head of the Department, Department of Forensic Medicine, Saveetha Medical College & Hospital, SIMATS, Chennai,

Abstract

Accidents are an intentional act which is not a voluntary act done by the people. Accidents, tragically, are not often due to ignorance, but are due to carelessness, thoughtlessness and over confidence [1]. Human, vehicle and environmental factors play roles before, during and after a trauma event. Accidents, therefore, can be studied in terms of agent, host and environmental factors and epidemiologically classified into time, place and nature of injury.

Keywords: Accidents, Ignorance, Carelessness, Environmental factors

Introduction

We all know how difficult it is to cope up with a sudden loss of life of a near and dear one; moreover, if the person who died was the bread earner, then the lives of the dependents turn topsy-turvy. One of the major reasons for sudden or unexpected deaths in India is road accidents. The irony is that, most of the road accidents could have easily been avoided. A Motor Vehicle Accident can be defined as an event that occurs on a way or street open to public traffic; resulting in one or more persons being injured or killed, where at least one moving vehicle is involved [1]. Thus it can be due to collision between vehicles, between vehicles and pedestrians, between vehicle and animal or between vehicle and geographical or architectural obstacles.

Road traffic accidents are a human tragedy. They involve high human suffering and socioeconomic costs in terms of premature deaths, injuries, loss of productivity and so on. The situation that leads to improper interactions could be the result of the complex interplay of a number of factors such as pavement characteristics, geometric features, traffic characteristics, road user’s behaviour, vehicle design, driver’s characteristics and environmental aspects. Thus, the whole system of accident occurrence is a complex phenomenon. The problem of deaths and injuries as a result of road accidents is now acknowledged to be a global phenomenon. The authorities in all countries of the world feel concerned about the growth in the number of people killed and seriously injured on their roads.

The major human factors that contribute to the potency of road accidents causation include drunken drivers, indecisiveness, fatigue, distraction, and confusion. In addition most of the drunken drivers are found to be inexperienced, risk takers, impulsive, aggressive, casual and unaware of the road signals. In India, the motor vehicle population is growing at a faster rate than the economic and population growth. According to WHO, motor vehicle injuries are the sixth leading cause of accidents in our country [2].

Materials and Method

The study on the profile of Motor vehicle accidents for the year January 2017 - December 2017 at Thiruvanmiyur Police Station which comes under South Chennai division, Taramani subdivision, Adyar Traffic Police Station and Thiruvanmiyur police Station covers the areas starting from Indira nagar, Kamarajar nagar, Radhakrishnan nagar, Thiruvalluvar salai,
my study was analyzed in accordance to the data given by the Thiruvanmiyur Police Station for J6 limit control areas and on the basis of Sex of the victim and accused ; Type of injury either fatal/ non-fatal ; Date of occurrence ; Time of occurrence ; Type of area whether it was nearby a recreational area, nearby hospital , an office , market , bazaar ; Total number of vehicles involved either one or two or three ; Accused vehicle ; Victim involved either a vehicle or pedestrian ; Accused wearing helmet or not ; Nature of injury / death ; Nature of accident due to over speed , rash driving, bad overtaking , sudden breaks , close following , inattentive turn and others[3].

Thus the nature and severity of the problem though vary to a great extent in the different parts of the world but has posed a serious menace for every society in the recent years. Therefore it needs an in-depth study so as to suggest the preventive and curative measures. In this descriptive work, efforts have been made to study and analyse the problem of motor vehicle accidents with special focus on the time, months and place of occurrence and so on. The design structured for this study is descriptive. This purpose of this research design is to provide description of the individuals, nature and causes of the problem under investigation.

**Result and Discussions**

**According to the type of injury**

Whenever a road accident occurs on the road, mainly two types of accidents i.e. fatal injury and non-fatal injury are said to happen, depending upon the severity of injury.

Out of total 39 motor vehicle accidents that occurred under the limit of Thiruvanmiyur Traffic Police Station [fig1], 34 where non-fatal (87%) and 5 where fatal (13%). It is observed that maximum injuries where non-fatal which can be serious, severe or minor injuries.

In the similar studies made during the year 2008, nearly 1.3 million people died every year in Indian roads and 20 to 50 million people suffered from non-fatal injuries [4]. When we compare this data with the study made, there is huge reduction in the rate of fatal injuries during 2017 in a particular area.

**Figure 1: Type of Injury**

According to the type of vehicles involved in accident

The severity of accident depends upon the type of vehicle involved in the accident. There are more chances of fatal accident taking place in case of van, car, motor cycle, auto rickshaw, MTC bus, jeep and other vehicles.

Out of total 39 cases that was registered, 16 accidents was due to car (41%), 11 by Motor Cycle (28%),4 due to van (10%), 2 was due to auto and MTC bus each(5%) and 1 due to jeep (3%) [fig2].

Previous studies showed that cars contributes to about 46% of the total accidents occurred followed by truck, bus, tempo up to 38% and the least 6% by auto[4]. Hence there is a reduction in rate of car accidents in this study of a small area.

**Figure 2: Vehicles Involved**
According to time of accident

Mainly, we divide road accidents according to 24hrs time period in the interval of three hours i.e., 00:00 - 03:00, 03:00 - 06:00 and 06:00 - 09:00 and so on.

From the total of 39 cases about 9 accidents took place during 09:00 - 12:00 (23.07%) then followed by 7 during 21:00 - 24:00 (17.9%). It is also clear that there was no accident occurred during 03:00 - 06:00 (0%) and the least 2 accidents during 00:00 - 03:00 (5.1%). It is also evident that during 06:00 - 09:00 and 18:00 - 21:00 there were equal percentage of accidents (15%) occurred [Table1].

According to the similar studies we can observe that in 2012, 16.7% of the cases of road accidents were reported to have occurred between 1500 and 1800 hours followed by 16.6% between 1800 and 2100 hours [4]. But in this study the maximum number of accidents occurred during 0900 and 1200 hours which is working hour’s daytime.

According to the nature of accident

The nature of road accidents that occur on the road can be due to vehicle overtaking, head on/rear end collision, rash driving, sudden turn without collision, inattentive turn, wrong turn, close following and sudden break, over speed, negligent and careless driving.

From the study, out of 39 road traffic accidents, 12 were due to over speed (30%), 8 due to inattentive turn (20.5%) and rash driving (15%) whereas careless driving (2.5%) and wrong turn (2.5%) [Table3].

According to the month of occurrence

The number of accidents differs in each month due to change in climatic conditions and other physiological conditions.

From the study of 39 accidents [Table2], maximum of 8 accidents occurred during the month of April (20.5%), 7 during the month of September (18%) and the least about 1 occurred in the month of February (2.5%), June (2.5%), October (2.5%) and December (2.5%). There was no evidence of accident during the month of August.

When we compare with previous study done in Tamilnadu during the year 2012, the month wise distribution of road accidents has also shown more accidents during the month of May (8.8%) followed by the month of April (8.74%) and January (8.72%) while the least number of accidents were reported in the month of September [4]. Hence my study shows maximum occurrence of accidents during the month of April (20.5%) and the minimum during February, June, October and December (2.5%) each.

Table 2: Month of Occurrence

<table>
<thead>
<tr>
<th>Month</th>
<th>Accidents</th>

</tr>
<tr>
<td>October</td>
<td>3</td>
</tr>
<tr>
<td>November</td>
<td>1</td>
</tr>
<tr>
<td>December</td>
<td>1</td>
</tr>
</tbody>
</table>

According to the similar studies made showed that the major reason was rash driving (30%), over speeding (28%) and rear end collision (5%) being the least reason for occurrence of accidents [5]. When we compare this with the present study made maximum number of accidents was due to over speeding and there is decrease in the number of accidents due to rash driving.
Table 3: Nature of Accident

</tr>
<tr>
<td>Total</td>
<td>39</td>
</tr>
</tbody>
</table>

According to the nature of Injury / Death

There are certain sites where injury is more common like the legs, hand, face etc.

According to the road traffic accident data, out of 39 cases [fig3], 13 injuries was on the head (33%), 15 were on legs (38%), 2 was on the hip (5%) and 1 injury on face (3%).

A similar study showed the commonest site of injury was the head (23%) and the least common site was the hip (8%) [6]. But in this study the more common site is the leg and head injury is relatively lower when compared.

Nature of Injury

Conclusion

When we were young, we were taught “precaution is better than cure”, and so many other things like “one should help a person in need”, etc. but as we grow old we almost forget these things and seldom follow them and by the time we realize that what was taught to us is really true and worthwhile, it gets too late. People need to be convinced that following rules and being in discipline is also cool and it is in their interest to follow traffic rules. Some of the rules to be followed in order to prevent motor vehicle accidents:

Overspeeding- Excess speeding is always unsafe, and excess speed means running vehicle more than the safe limit. Excess and inappropriate speed can result in crash, injuries to occupants and pedestrians, and damage to others as well.

Drunk or Driving under Influence of Drugs - Driving under the effect of alcohol or drugs is one of the causes of RTAs and mortality associated with it. Hence proper measures have to be taken in order to prevent accidents.

Teenage Driving- Teens as drivers are known for rash driving impulsively and also to get away reasons. They cause accidents due to inexperience and speed.

Night Driving- Night driving is a potential risk for travelers. Lack of street lights results in glare of the incoming vehicles especially on high beam. The speed must be under control. Night driving should be avoided on long routes as far as possible.

Overtaking and Wrong Driving- It is common in our country to drive on the wrong lane or driving in wrong opposite direction, not keeping to left, which may result in head-on collision.

Poor Construction of Roads and Bad Planning- About 400 people die on our roads daily. The roads we plan and make are substandard, constructed without due attention, and with disregard to mandatory super-vision.

Demographic Profile of Poisoning Cases in a Tertiary Care Center in South India – An Observational Study

James Rajesh J1, Sampath Kumar P2, Priyadarshree Pradhan3, Jothi Marie Feula A4, Siva Reddy B5

1Assistant Professor, Department of Forensic Medicine, Sri Venkateshwara Medical College Hospital and Research Centre, Puducherry, 2Professor and Head, 3Professor, Department of Forensic Medicine, Sri Ramachandra Medical College and Research Institute, Chennai, 4Senior Resident, Department of Physiology, Jawaharlal Institute of Postgraduate Medical Education & Research, Puducherry, 5Professor and Head, Department of Forensic Medicine, Sri Venkateshwara Medical College Hospital and Research Centre, Puducherry

Abstract

The word ‘poison’ has been evolved from the Latin word ‘potion’ i.e. ‘to drink for health’, but in the due course of time the definition of ‘poison’ has changed reversibly to its present form i.e. any substance which when administered, inhaled or ingested is capable of acting deleteriously on the human body. In the current study we have aimed at determining the demographic profile of poison cases reporting to our institute. This prospective study was carried out involving 353 cases of poisoning admitted in Sri Ramachandra Medical College & Research Institute, Sri Ramachandra University, Porur, Chennai, during the period of June 2014-June 2015. Age-wise distribution of poisoning cases revealed that the maximum cases are in the age group of 20-29 years and the incidence decreased as the age increases. It is evident that the incidence of poisoning is more in case of females when compared to males. Occupation-wise distribution revealed poisoning is more common among people who are skilled workers contributing 167 cases. Socio economic status wise distribution revealed poisoning is more common among the people who belong to Upper middle (52%), followed by 33% of cases belong to Middle class. Poisoning is more common among married people when compared to unmarried people. Out of 353 cases, 203 cases were married, which accounts for 58%, 150 cases were unmarried, which accounts for 48%. Distribution of the study population based on the type of family revealed that out of total 353 cases, 299 cases belonged to nuclear family. Persons who belong to joint family were 46 in number.

Key Words: Poisoning in South India, demographic profile, age-wise distribution, marital status.

Introduction

The word ‘poison’ has been evolved from the Latin word ‘potion’ i.e. ‘to drink for health’, but in the due course of time the definition of ‘poison’ has changed reversibly to its present form i.e. any substance which when administered, inhaled or ingested is capable of acting deleteriously on the human body. Thus, almost anything is poisonous and there is really no boundary between medicine and poison.1 The way a poison is controlled depends on its potential for harm, its usefulness and the reasons for its use. The law has a right and a duty pursuant to the police power of a state to control substances that can do great harm.1

Poisoning as a mode of death is known from antiquity. Poisoning among all age groups and both sexes is seen everywhere and the incidence of poisoning with reference to insecticides, pesticides, hair dye, cleaning acids and rodenticides has become more common than the others in the recent times because...
of increased availability and indiscriminate use of the various pesticides in agricultural areas.\textsuperscript{2}

The incidence of poisoning in India is among the highest in the world, it is estimated that more than 50,000 people die every year from toxic exposure. Among children the common culprits include kerosene, household chemicals, drugs, and garden plants.\textsuperscript{3}

The trend in poisoning show a change due to introduction of newer pesticides under different classes. At one point historically arsenic was the most popular besides Copper Sulphate, and Barbiturates. In the recent past DDT, Benzene Hexa Chloride, Endrin, Organochlorines and Organophosphorous compounds took the toll. Of late Aluminum Phosphide, Alcohol, hair dye and Carbamates are in vogue. Interestingly, incidences of snake strike deaths are still prevalent and not receding.\textsuperscript{2}

Arising out of a growing concern over the burgeoning incidence of poisoning worldwide, coupled with a lack of public awareness about its seriousness, Poisons Information Services made their first appearance in the Netherlands in 1949, there are 75 such certified centers in the USA alone, providing almost any information within a matter of seconds through the use of an intricate, computer information resource system (POISINDEX) on more than 800,000 poisonous products. India made a belated foray with the establishment of the National Poisons Information Centre at the All India Institute of Medical Sciences, New Delhi in December, 1994.\textsuperscript{2} The World Health Organization has released its Computer Software on Poisons (INTOX) for use by the centre.\textsuperscript{2} In this study we have aimed at determining the demographic profile of poison cases reporting to our institute.

Materials and Method

This prospective study was carried out involving 353 cases of poisoning admitted in Sri Ramachandra Medical College & Research Institute, Sri Ramachandra University, Porur, Chennai, during the period of June 2014- June 2015. The study was approved by scientific and ethics committee of the institute.

Inclusion Criteria

- All cases of Poisoning either suicidal or accidental, both directly admitted and referral cases during the period of June 2014 – June 2015.
- Snake Strike and Scorpion stings.
- Domestic as well as Commercial Poisoning.

Exclusion Criteria

- Cases without proper diagnosis (undetermined).
- Outside body brought to SRMC mortuary with history of poisoning.

Methodology

The demographic details like age, socioeconomic status by modified Kuppusamy scale (Annexure 1), marital status, time of the day during which poisoning has occurred, type of family were acquired from the patient, relatives, friends or the investigating officer and by going through the medical records and the inquest report. Among the admitted cases, if some turn out to be fatal, in those cases post mortem examination is done. All the data collected in the Performa were complied and analyzed statistically using SPSS software version 15.

Observation and Results

Distribution of the study population based on age, gender, marital status and type of family is shown in table 1. The minimum age affected was 1 year old and maximum age affected was 80 years. Mean age of the study population was 28 years. Incidence of poisoning was also reported to be more in case of females when compared to males. The incidence of poisoning was also reported to be more in number among married individuals and in nuclear families. Modified Kuppusamy scale (Annexure 1) was used to assess the socio-economic status and based on this distribution of the poisoning cases bases on occupation, education status and socio economic status are mentioned in Table 2, 3 and 4 respectively. And based on the above observation it is also evident that the incidence of poisoning is more in upper middle class group.

Discussion

The total number of cases admitted in Sri Ramachandra Medical College and Research Institute from June 2014 to June 2015 was 26,190 cases, out of which 4,498 cases were Medico-Legal Cases (MLC). Among the MLC, poisoning accounts for 353 cases. As the institute is a tertiary care centre, the numbers of cases are more when compared to most of the other studies to which this research work is compared. When compared to the studies done by mani et al which was a retrospective study for a period of three years, the total number of poisoning cases was 365 and other studies done by Bharath K Guntheti Udaypal Singh, Unnikrishnan B, Singh B, Rajeev A, Ansam F Sawalha., Waleed M Sweilah., Maysoon T Tufaha. and Dua Y Al-jabi, the number of cases were considerably more in our study.

In the current study age-wise distribution of poisoning cases revealed that the maximum cases are in the age group of 20-29 years and the incidence decreased as the age increases (Table 1). Young adults are affected more as they are more exposed to stressors.
like job, marital issues, financial problems etc. The results of the studies conducted by, Bharath K Guntheti Udaypal Singh 4, Shreemanta Kumar Dash, Manoj Kumar Mohanthy, Kiran Kumar Patnaik, Sachidananda Mohanthy 8, Ramanath K.V. Naveen Kumar H.D 8, Shoaib Zaheer.M, Aslam.M, Vibanshu Gupta, Vibhor Sharma and Shadab Ahmad Khan 10, Dr. Gargi.J, Dr. Hakumat Rai, Dr. Ashok Chhana, Dr. Gurmanjit Rai et al 9, Tejas Prajapati, Kartik Prajapati, Rakesh Tandon, Saumil Merchant 11.

Sex-wise distribution of poisoning cases in our study revealed that out of the total 353 cases, 160 cases i.e (45.3%) were males and 193 cases i.e (54.7%) were females and it is evident that the incidence of poisoning is more in case of females when compared to males (Table 1). Similar findings were also noted in the study conducted by Deepak Pokhrel, Sirjana pant, Anupama Pradhan, Saffar Mansoor 7. However, male dominance is noted in the studies conducted by Shreemanta Kumar Dash, Manoj Kumar Mohanthy, Kiran Kumar Patnaik, Sachidananda Mohanthy 6, Ramanath K.V. Naveen Kumar H.D.8 Shoaib Zaheer.M, Aslam.M, Vibanshu Gupta, Vibhor Sharma and Shadab Ahmad Khan 10, Dr. Gargi.J, Dr. Hakumat Rai, Dr. Ashok Chhana, Dr. Gurmanjit Rai et al.14 Unnikrishnan B, Singh B, Rajeev A 5 Ansam F Sawalha., Waleed M Sweileh., Maysoon T Tufaha. and Dua Y Al-jabi 7.

In the present study occupation-wise distribution showed that poisoning is more common among people who are skilled workers contributing 167 cases, followed by Semi – Skilled workers 94 and 58 Unemployed. The second least was Semi – Profession with 3 people. This is due to the fact that middle class people are subjected to more stress from the developing world (Table 2). In the study conducted by mani et al showed similar results with farmers (29.86%) followed by housewives (23.38%) and least common among businessmen (0.54%). Study conducted by Ramanath K.V. Naveen Kumar H.D 9 also showed similar results i.e. commonly involved groups are farmers (38.4%), followed by housewives (21.9%). Study conducted by Shreemanta Kumar Dash, Manoj Kumar Mohanthy, Kiran Kumar Patnaik, Sachidananda Mohanthy 8 Vinay B shetty, Gurudatta S Pawar., Inamadar 13 also reveals that, skilled workers topped the list. However, in their studies housewives occupied 3rd position.

In the current study among the 353 cases, people who have graduated till Post High School/ Diploma/ College (Intermediate) are the common victims in poisoning, amounting to 172 cases which indirectly denotes the people who are skilled workers, followed by 118 high school people, who are semi – skilled workers and Non – literate and graduates are very less, together counting 11. These findings of the study go in hand with other studies.

In our study, socio economic status wise distribution revealed poisoning is more common among the people who belong to Upper middle (52%), followed by 33% of cases belong to Middle class. As per the Monthly Income distribution, people who earn between Rs. 16,020 – Rs. 32,049 are most commonly affected with the maximum count of 176, followed by people who earn between Rs12,020 – Rs16,019, which includes 110 poisoning .People earning above Rs. 32,050 and below Rs. 4,810 are least affected. The system used in calculating the socio-economic status was modified Kuppuswamys classification (Table 4). The inference which other studies have obtained is almost the same, as middle class people are the most commonly affected ones and the variation in the upper middle and lower middle may be due to the status of the hospital and the affordability. Similar studies with similar classification of economic strata was done by Shoaib Zaheer.M, Aslam.M, Vibanshu Gupta, Vibhor Sharma and Shadab Ahmad Khan 10 reveals that majority of cases belongs to Class iii and Class iv, followed by class v and vi and least among class i and ii. (57.69%, 32.69% and 9.61%), which is similar to our study (79.44%, 14.78% and 5.74%).

Marital status wise distribution of our study population revealed that poisoning is more among married people when compared to unmarried people. Out of 353 cases, 203 cases were married, which accounts for 58%, 150 cases were unmarried, which accounts for 48% (Table 1). In the study conducted by Mani et al yielded the same type of results that Married males (41.36%) are more affected, followed by married females (22.19%). Unmarried males (20.00%) and unmarried females (16.43%) are the least. Study conducted by Bharath K Guntheti Udaypal Singh 4 also yielded the same kind of results that poisoning was more common in married men (67.92%), followed by unmarried males (17.92%), married females (12.74%) and unmarried females forms only (1.39%) of poisoning cases.

In the current study distribution of the study population based on the type of family revealed that out
of total 353 cases, 299 cases belonged to nuclear family. Persons who belong to joint family were 46 in number and only 8 persons who live in extended families were affected (Table 1). Except four studies, many of the studies did not use this family pattern as a parameter in their study. This is one of the important parameter to consider as in the current developing and busy life many forget the elementary aspects and basic morals of life and the advantages of being in a joint family are missed in the current era. The studies of Unnikrishnan B, Singh B, Rajeev 5, Dr. Gargi J, Dr. Hakumat Rai, Dr. Ashok Chanana, Dr. Gurmanjit Rai et al14 also revealed the same kind of results to help the physician in the treatment aspect and I also like to state the public awareness on producing the proof of poisoning is amazing. As the substances consumed were produced it was easy and confident to proceed with the treatment aspect for the physician and it would have been as an important reason for the overall less mortality rate.

Conclusion

A study of the demographic profile of poisoning cases admitted in the casualty was carried out in the department of Forensic Medicine & Toxicology of Sri Ramachandra Medical College and Research Institute, Porur, Chennai. The following observation was made:

- Poisoning is more common among the adult (20 to 29 years) age group, with a mean of 28 years.
- 70 Children (20%) are also affected, which are mainly accidental in nature.
- Poisoning was more common among females (54.7%) when compared to males (45.3%).
- Profession wise skilled workers are affected the most (167 cases). They form the major part of the middle class. Semi skilled and unemployed are also affected more.
- Education wise people who have graduated from college with a diploma and other post high school courses are affected more as these people usually form the middle class society.
- Married persons (58%) are more affected more when compared to unmarried persons (42%).
- Family pattern wise, people who live in nuclear families are affected more (299 cases) when compared to people who live as joint families (46 cases).

Estimation of Age through Elbow Joint in children of Karnataka

Manjunatha A

1Assistant Professor, Department of Forensic Medicine And Toxicology, Subbaiah Institute of Medical Sciences & Research centre, Shivamogga –(Karnataka)

Abstract

70(35 male and 35 females) children aged between 11 to 18 years were studied for ossification of elbow joint radiologically, 4(11.4%) were 11 years 5(14.2%) were 12 years, 7 (20%) were 13 years of age, 5(14.2%) were 14 years, 3(8.57%) were 15 years were 16 years, 3 (8.57%) were 17 years and 4 (11.4%) were 18 years old. The radiological study of elbow joint was Appearance of trochlea was observed only in female at 11 year. Fusion of trochlea was in males at 14 to 15 years of age and in 12 to 14 years in females. Appearance of lateral Epicondyle in male was 11 to 12 years but in females at 11 years only. Fusion of lat epicondyle in males was between 13 to 16 years and in females 13 to 14 years. Fusion of medial epicondyle in males was between 14 to 16 years but in females between 11 to 15 years. Fusion of head of Radius in males between 14 to 16 years of age but in females between 11 to 13 years only. Appearance of olecranon process in males between 11 to 13 years and in females between at 11 years only. Fusion of olecranon process in males was between 17 to 18 years of age in females between 15 to 16 years only.

This study of elbow appearance and joint in which early appearance and ossification of females bones will be helpful to medico-legal expert, orthopedician, radiologist, anthropologist and anatomist. Moreover this study has ethnic and regional importance because morphometric values of mesodermal derivatives are uncertain

Key words: Olecranon process, epicondyle, trochlea, Karnataka

Introduction

There are many criteria for estimation age required for medico-legal export in day today legal practice like eruption of teeth. Closure of cranial sutures, symphysis of menti of mandible, graying of hair in temporal region, despite of the facts that, the birth and death are registered by the government officials globally. Ossification centre are seen earlier in the tropical countries and females, variations in the appearance and union of ossification centers mainly attributed to various factors like climate, hereditary, race nutrition, dietary habits of gender and socio-economic status (2)(3)(4) . Hence attempt was made to study the age in the children of Karnataka as the habit and habitat of Karnataka differs from other states of country and abroad as well.

Material and Method

35 boys and 35 girls aged between 11 to 18 years were visiting to Subbaiah medical college hospital along with patients as attendant or visitors were selected for study. Whoever volunteers came forward. Their elbow joint ossification was studied radiologically A P and lat view of elbow joint was studied.

A P view was taken by placing the upper limb in full extension and supine position to visualize medial, lateral epicondyle and radio- capitular joint. Lateral view was taken by flexing the elbow at 90° degree and forearm in semi-pronated poison to visualize olecranon process and Humero-ulnar joint.

The mal- nutritious, previous fractured of elbow joints and having chronic illness like osteoporosis or Rickets were excluded from the study.

The duration of study was about 2 years.
Observation and Results

Table-1 – Boys and girls were classified 4 (11.4%) were 11 years 5 (14.2%) were 12 years 7 (20%) were 13 years 5 (14.2%) were 14 years, 3 (8.57%) were 15 years, 4 (11.4%) 16 years, 3 (8.57%) were 17 years, 4 (11.4%) were 18 years in both sexes.

Table-2- Radiological study of elbow joint in sex-

1. Appearance of Trochlea - (a) Not observed in males (b) observed in females at 11 years.

2. Fusion of Trochlea – (a) observed in females in 12 to 14 years and at 14 to 15 years in males show process of fusion (b) observed in females at 12 year but process of fusion completes at 14 years only

3. Appearance of Lateral Epicondyle in males it appeared at 11 to 12 and in females at 11 years only

4. Fusion of lateral epicondyle In males between 13 to 16 years but in females 13 to 14 years only

5. Fusion of medial epicondyle fusion occurs at 14 to 16 years but in females 11 to 15 years only

6. Fusion of Head of Radius – In males fusion completed between 14 to 16 years but in females 11 to 13 years only

7. Appearance of olecranon process In males between 11 to 13 but in females at 11 years only

8. Fusion of olecranon process In males fusion occurred between 17 to 18 years of age but in females between 15 to 16 years only.

Discussion

In the present study of estimation of age from elbow joint in children of Karnataka, 4 (11.4%) boys and 4 (11.4%) girls of 11 years old, 5 (14.2%) boys and 5 (14.2%) girls of 12 years old, 7 (20%) boys and 7 (20%) girls 13 years old, 5 (14.2%) boys and 5 (14.2%) girls of 14 years old. 3 (8.57%) boys 3 (8.57%) girls of 15 years old 4 (11.4%) boys and 4 (11.4%) girls of 16 years old 3 (8.57%) boys and 3 (8.57%) girls belonged of 17 years old (Table-1). In the Radiological study. Appearance of trochlea was at 11 years of females only. Fusion of trochlea was observed 14 to 15 years of male and 11 to 12 years of females. Appearance of lat epicondyle was at 11 to 12 years in males, at 11 years in females, fusion of lat epicondyle was observed at 13 to 16 years in males and 13 to 14 years of age in females, Fusion of medial epicondyle was 14 to 16 years of age in males and 11 to 15 years in females, fusion of head of Radius was 14 to 16 years of age in males, 11 to 13 years in females Appearance of Olecranon process was observed at 11 to 13 years in males and years in females fusion of olecranon process was at 17 to 18 years at males and 15 to 16 years in females (Table-2). These findings were more less in agreement with previous studies (5)(6)(7)

These findings of ossification varies in the study of western population (8)(9). However in both studies of India and abroad females bones have earlier Ossification than males. It could be due to higher secretion of endocrine glands, nutritional status un doubtfully there are racial, geographical and hereditary difference play vital role for earlier ossification in females bones (10). Apart from the secretion of local enzyme called phosphatase is largely influenced by degree of ossification (11). Moreover biochemical phenomenon includes deposition of calcium salts, metabolism of cellular elements also decide the duration of ossification

Summary and Conclusion

The present radiological study to estimate the age by elbow joint in Karnataka children will be useful to medico-legal expert, orthopedician, radiologist, anthropologist and anatomist But this study further demands genetic, embryological, hormonal, nutrition studies because the factors which determine the ossification is still obscure

This research paper was approved by Ethical committee of Subbaiah Medical college Shivamogga- (Karnataka)

Identification of Sex of Sacrum in Karnataka Population

Manjunatha A

Abstract

35 male and 35 females adult, non pathological dried sacra were studied. The height and width was measured with vernier caliper. In comparison of height of sacrum, the mean value of male was 106.4 (SD±0.30) and female 90.1 (SD±0.16) ‘t’ test was 395, and P value was highly significant (P<0.01). In the comparative study of width of the sacrum mean value of males was 99.3 (SD±0.44) and female was 112 (SD±0.08) ‘t’ test was 122.65 and P value was highly significant (P<0.01). The sacral Index of male was 93.3 and female was 124.27. This significant value to differentiate the male and female genders will be quite useful to medico-legal expert anthropologist and anatomist because these obtained value represent the regional or ethnic study of sacra. Moreover morphometric values of mesodermal derivatives are un-certain.

Key words: Sacral Index, vernire caliper, gender, Karnataka

Introduction

Sacrum or sacra is constituent of hipbone form sacra-iliac joint. It takes parts in locomotion and child bearing. Sacrum name derived as sacred bone because it is considered as last bone to get decay when buried. Identification of sex, from sacra is on well established factor (1). But the regional or ethnic environmental, socio-economic status, genetic makes up different dietary, habits play vital role in the morphometric values (2). Moreover degrees of locomotion, stress during parturition also have contributory role in the variation of length and breadth of sacra. Apart from this the hormones secreted by anterior pituitary hormone will also decide the morphometric values in both sexes at different ethnicity and regions. Nevertheless Ossification centers of bone may express their morphological individuality may create variations in the morpho-metric values in bones of sexes. Hence attempt was made to study the sacra in both sexes.

Material and Method

35 Male and 35 Female sacrum were selected for study. These sacral bones were collected from Anatomy and Forensic medicine department of Subbaiah medical college Shivamogga-577002 (Karnataka)

Each sacrum was put in a Anatomical position. The length and breadth of sacrum was measured by vernire caliper. The obtained value were studied statistically by SPSS 2007 software. The sacral Index of both male and females were studied and compared.

Pathological and broken sacrum was excluded from the study.

The duration of study was about two years.

Observation and Results

Table-1-Comparison of length of sacrum in male and females mean value of male sacrum was 106.4mm (SD±0.30) and females was 90.19mm (SD±0.16) ‘t’ test was 395. (P<0.01) and P value was highly significant.

Table-2-Comparison of width of sacrum in both male and females. The mean value of male was 99.36mm (SD±0.44) and females was 112.09mm (SD±0.08) ‘t’ test value was 122.65 (P<0.01) P value

Table-3-(a) Sacral index of male was 93.37 (b) Sacral Index of female was 124.27 (SD±0.44)

Discussion

In the present study of identification of sex from sacrum in Karnataka population. In the comparative study of height of sacra. The mean value of male was 106.4 (SD±0.30) and females was 90.1(SD±0.16) ‘t’ test was 395 and P value was highly significant (P<0.01).
sexes. The mean value of male was 99.3 (SD±0.44) and females was 112 (SD±0.08) ‘t’ was 122.65 and P value was highly significant (P<0.01) (Table-2). The sacral Index of male was 93.37 and female was 124.27 (Table-3). This study was more or less in agreement with previous studies(3)(4)(5).

In the present study the sacrum index of male was 93.3 which falls under dolichoieric group (narrow sacrum) and females sacral index was 124.27 falls under platyehric group. The present finding of male sacred index 93.3 (dolichoieric) was more or less in agreement with previous studies of west Bengal(6) and Jammu region(7) sacral Index of female was 124.27 of present study was more less in agreement with previous North Indian studied(8). These similar parameters of present studies with other region indicate that, there is a migration of population and intermixing races in India and abroad. However sexual dimorphism of sacra is highly significant in present study, as it was observed in previous studies in abroad population also(9)(10).

These gender differences of sacra was quite natural because bone is a plastic tissue next to blood whenever exposed to any stress and strain. (11). It is but natural that, the stress and strain differs from male to female. Moreover before quadrupeds adopted the erect posture of bipedalism the vertebral column was like cantilever bridge, which modified into pillar to transmit the body weight of erect posture, hence there is a re-orientation of sacrum occurred(12). Which may lead to obstetrical problem which was un-known to quadrupeds. Hence due to adaptation of erect posture against antigravity stress sacra have adopted as per their functional and bio-mechanical status.

**Summary and Conclusion**

The present study of Identification of sex from sacrum will be useful to medico legal expert anatomist and anthropologist because apart- from sexual dimorphism, it indicates regional and ethnic significance but this study further demands embryological, genetic nutrition and hormonal study because the factors which decide the ossification of sacral vertebrae is still un-clear.

This research paper was approved by Ethical committee of Subbaiah Institute of Medical science Purle, Shivamogga(Karnataka).

Demographic Profile and Pattern of Presentation of Organophosphorus Poisoning at Tertiary Care Hospital Agra

Mustaria Pankaj Kumar Shusil¹, Ajay Agarwal²

¹Assistant Professor, Forensic Medicine & Toxicology Department, MLB Medical College, Jhansi (UP),
²Prof & HOD, Forensic Medicine & Toxicology Department, S. N. Medical college, Agra (UP)

Abstract
India is agriculture dominant country and organophosphorus commonly used by former in agriculture field. Therefore, Organophosphorus poisoning is common India. Study done at emergency department to know the pattern of sign and symptoms presentation at the time of admission. Total number of cases was 160, out of them 102 (64%) were males and only 58 (36%) were females. Male to female ratio was 1.75:1. farmers 61 (38%) were commonly affected, followed by 35 (22%) of patients were housewives and 26 (16%) of patients were students. symptoms presented were vomiting 150 (93.75%) and salivation 150 (93.75%), followed by sweating 147 (91.88%), lacrimation 102 (63.75%) and blurring of vision 80 (50%), breathlessness (40%), faecal incontinence (31.88%), urinary incontinence (18.13%), headache (18.13%) and convulsion (10%). commonest signs were smell of poison 150 (93.75%), followed by tachypnoea 134 (83.75%), altered consciousness 115 (71.88%), miosis 86 (53.75%), fasciculation 70 (43.75%), tachycardia (36.25%), bradycardia (28.13) and pulmonary oedema (06.25%). Increased body secretions were the commonest presentation then other symptoms followed were blurring vision, tachypnoea altered consciousness, and respiratory symptoms. It can be helpful to make diagnosis and take awareness, preventive measures about organophosphorus poisoning.

Key words: Organophosphorus, Lacrimation, Tachycardia, Convulsion, Altered Consciousness, Respiratory symptoms.

Introduction
Organophosphorus compounds poisoning is not only the Indian problem but it’s a global problem seen high number cases reported in other country died due to organophosphorus poisoning. Agricultural pesticide poisoning is a major public health problem in the developing world, killing at least 250,000-370,000 people each year.¹ Hospital-based studies from five major hospitals across the country in 1999-2000 showed OP compounds were the most common form of poisoning comprising 52% of total cases in Nepal.² Organophosphate poisoning is a major public health problem in South Africa. Individuals get exposed to organophosphate in both the domestic and industrial spheres.³ Organophosphorus poisoning is a familiar medical emergency which is associated with high rate of mortality if not diagnosed and treated in time. Acute organophosphate (OP) poisoning can be deadlier than any other type of chemical poisoning.⁴ Organophosphorus compounds are used extensively in India to control insects so as to increase production of agricultural commodities. In addition to the accidental exposure from use of these compounds as agricultural insecticides these agents are frequently used for suicidal and homicidal purposes because of their low cost and easy availability.

Organophosphorus (OP) compounds are used as pesticides, herbicides, and chemical warfare agents in the form of new gases. Some have also been used in the medical treatment of myasthenia gravis’s and glaucoma. ⁵ An estimated 3 million or more people worldwide are exposed to organophosphates each year, accounting for about 300,000 deaths. In the United States, there
are around 8000 exposures per year with very few deaths. While most often the exposure occurs from an agricultural pesticide, there are household items, such as ant and roach spray, that also contain organophosphate compounds. Commonly used organophosphates have included monocrotophos, dimethoate, parathion, malathion, diazinon, etc. Organophosphorus pesticides can be absorbed by all routes, including inhalation, ingestion, and dermal absorption. Their toxicity is not limited to the acute phase, however, and chronic effects have been noted. Organophosphorus insecticides inhibit the enzyme acetyl cholinesterase leading to accumulation of acetylcholine, which binds to muscarinic and nicotinic receptors throughout nervous system. Signs and symptoms of poisoning are due to persistent acetylcholine hyperstimulation at muscarinic and nicotinic receptors sites. Signs of organophosphate poisoning include salivation, lacrimation, urinary incontinence, defecation, GI-upset / diarrhoea, emesis and miosis.

Material and Method

The study was conducted at S.N. Medical College & Hospital, Agra from February 2011 to July 2012. There were 240 patients of OP Compound poisoning admitting to the Department of Medicine during the study period. After applying inclusion and exclusion criteria, 160 patients were chosen as study subjects. It was Hospital based prospective study. All organophosphorus poisoning patient coming to SN Medical College Agra were considered as working unit and information collected from their Close relatives of victim, victim himself and police records. Following Inclusion criteria were taken in consideration were

1. A known case of organophosphorus poisoning
2. Patient with clinical signs and symptoms suggestive of organophosphorus poisoning
3. Patient showing evidence of organophosphorus poisoning after being investigated

And following Exclusion Criteria: were taken in consideration

1. Patient brought dead in emergency department of S.N.M.C. Agra
2. Cases in which causes of poisoning is not known
3. Patient on Ventilator.
4. Patient with double insecticidal/ multiple poisoning with other drug such as opioids, diazepam, barbiturates etc.
5. Patients who received partial treatment outside and referred later to our hospital were excluded.
6. Patients who absconded or referred to higher centre.

Data collected by Thorough history and clinical examination was carried out with reference to vital parameters, pupil size, assessment of central nervous system, respiratory system, cardiovascular system as per prescribed proforma. This examination took place during initial resuscitation and treatment of the patient. Data processing and analysis: Required information is collected on open ended semi-structural scheduled and compiled analysis with the help of MS Excel software.

Observation and Discussion

Study done at Sarojini Naidu medical college and tertiary hospital Agra, in our study majority 62 (38.75%) of patients was in the age group of 21-30 years, followed 39 (24.37%) by the age group of 31-40 years. In the present study, youngest patient was 10 years old and oldest patient is 64 years old. (Table No.02) commonly affected age group was middle age 21-50 years of age affected other study done by other researcher they also reported middle age group was commonly affected age group. study done in Tshwane district south Africa researcher reported same age group profile as our study maximum number of cases 21-30 years age group 23.7% cases and 31-40 year age group 16.9 %, significant almost equal number cases as age group 21-30 years which was 23.2 % . in our study only 02 case reported in this age group. (3) study done at Turkeyo The most affected age group was 15-24 years (40.5%), in both sexes. (7) organophosphorus and carbamates poisoning patient admitted to a North Jordan Teaching Hospital over a five-year period were reviewed and found that The most cases occurred in the 15-19 year-old age group which is not correctly associated with our study our study reported maximum patient seen in age group 21-30 years(8) max number
case seen in age group 16-30 years were 66.15% south India. (9)

Sex wise distribution we observe that exposure of organophosphorus poisoning male predominant male affected 102 (64%) and female patient contributed 58 (36%). (Table no.03) Sex wise distribution compare with other studies and seen that almost all the study reported male predominantly affected than the female. There were 131 (59.5%) female and 89 (40.5%) male patients (7) out of the 25 patients, 14 (56%) were male and 11 (44%) were female with a mean age of 34.8 + 17.66 years (Range: 14-77 years). (10) The proportion of OPPs was 15.1% among 564 poisonings. Other study male female ratio seen that the female to male ratio was 1.1:1 .Our study differ study done at Emergency Department of Yu¨ zu¨ ncu¨ Yil University Medical Faculty Hospital in Turkey there was Fifty-seven (67.1%) patients were female, 28 (32.9%) were male. (11)

In our study 61 (38.13%) of patients were farmer, followed by 35 (21.88%) of patients were housewives and 26 (16.25%) of patients were students, labour contributed 19 (11.88%), private employee 13 (08.13%), unemployed/others (03.37%). (Table No.04) study done by other author in India distribution of patients did in respect to occupation maximum number seen in agriculture occupation 48% and housewife also contributed same numbers 48%, student contributed only 04%. In our study student contribution was 16.25%. (10) study done at Manipal majority of patients admitted, due to OP poisoning were agriculturists. Out of 100 patients, 51 patients were (45.1%) agriculture workers. (12) A study into OP poisoning were agriculturists. study conducted in Sri Lanka in 2006 by Hoek and Flemming showed that majority of acute poisoning occurs in Agriculture worker. (13)

In our study symptoms presented were vomiting 150 (93.75%) , salivation 150 (93.75%), followed by sweating 147 (91.88%), lacrimation 102 (63.75%) and blurring of vision 80 (50%), breathlessness (40%), faecal incontinence (31.88%), urinary incontinence (18.13%), headache (18.13%) and convulsion (10%). (Table 05)

Study done in Manipal they found symptoms Sweating 69% cases, fasciculations 69% cases, miosis in 78% cases, Respiratory system findings 22%, Tachycardia 34% cases, Loss of consciousness 28% cases, Hypertension 12% cases, Seizure 01% cases, Hypotension 02% cases. (14) comparative pattern of clinical presentation given in (Table No. 01) with other researcher.

In our study commonest signs were smell of poison 150 (93.75%), followed by tachypnoea 134 (83.75%), altered consciousness 115 (71.88%), miosis 86 (53.75%), fasciculation 70 (43.75%), tachycardia (36.25%), bradycardia (28.13) and pulmonary oedema (06.25%). (Table No 06) increased body secretions were the commonest presentation then other symptoms followed were blurring vision, tachypnoea altered consciousness, and respiratory symptoms. Miosis was the most frequent symptom and was seen in 80.66% of the patients. (16)

Table No. 06: Distribution of Study Subjects According to their Clinical Signs.

### Conclusion

Demographic profile and pattern of sign and symptoms presentation of organophosphorus poisoning can be helpful to make the diagnosis of the poisoning. Demographic profile of the poisoned person can be used to take preventive measure as organophosphorus poisoning is a common poisoning in our country because in India most of the people's livelihood base on agriculture. This information may be useful in future for preventing the incidence of poisoning by educating the target population and restricting the availability of the organophosphorus.

Green Pitch- Be the Part of Solution

Nandhini V1, Gayathri S1, Sumathi H Rao2, P. B.Anand3, T. Geetha4
1Reader, 2Professor, 3Professor & H.O.D, 4Tutor, Sathyabama Dental College and Hospital

Abstract:
Pursuing “Green” has become the new drive for organisations on the quest towards growth, competitiveness and global excellence. Environmental issues have gained importance in business as well as in public life throughout the world. Green dentistry is a part of strategy to promote our practice by employing environmental credibility. In growing concern of global warming, switching our practice over to green is the need of hour as it involves abundant utilization of natural energy and also produces large amount of biomedical waste at the same time, creating a huge environmental impact. We cannot deny the fact intelligence is the ability to adapt to change. This article speaks about the various concepts of how to go for eco-friendly dental practice.

Key-words: sustainability, Renewable energy, Biomedical waste.

Introduction
Modern health care facilities are highly resource intensive. Unsustainable and inefficient buildings, unsafe disposal of hospital waste and untreated sewage, heavy reliance on processed foods and a fleet of fuel guzzling vehicles are just a few factors that increase the health sector’s carbon footprint, thus making the environment sick. According to the annual report of Central Pollution Control Board (CPCB) in 2016 the quantity of Bio Medical waste generated is approximately 517 tonnes per day and it increased to 550 TPD in 2018 and is proposed to increase to 775 TPD in 2022.1 Dentistry as profession has got a major role toward the health care waste. On exploring the possibilities to counter these issues, we arrived at the idea of “Green hospitals”. Indian Green Building Council approved by US Green Building Council defined Green Hospital as “The hospital which enhances patient wellbeing, aids the curative process, while utilizing natural resources in an efficient, environment-friendly manner”.2 The concept of green hospital comprises of factors such as building design that focuses on providing the proper lighting, improvising the indoor air quality, minimising the unfriendly waste generated either by reducing or recycling, reducing the pollution and conserving the natural energy resources.3 Research team from IGBC propose that by implementing these green strategies in dental clinics/ Hospitals buildings can have positive impact on patients and staff by eliminating the “Sick Building Syndrome” and also provide economic co benefits by reducing the finance required to maintain the practise over a period of time.

Importance of Green Dentistry:
Eco-friendly dentistry is relatively a new concept in dental practice, where as in hospitals it has started its way in 2010. India’s first green hospital was built in Ahmadabad in 2010 and in a more appreciable way, by 2018 with the help of Health and Environment Leadership Programme around 5600 Hospitals and health systems in and around country showed their interest in fulfilling the Global Green Health Hospital agenda.4 Green Dentistry is a part of a bigger picture of the ecologically-sustainable healthcare system. It provides

- Positive impact on the environment & promote environmental awareness & sustainability to the patients.
- It helps prevent the world’s biggest problem – “GLOBAL WARMING”.
- It forms the vital step in maintaining a balanced

What is Green Dentistry??

Green Dentistry includes the following categories of green practice, providing a comprehensive, eco-friendly model for the dental office. Green dentistry can be simply concised to 4 Rs.

- Rethink
- Reduce and replace.
- Recycle
- Reuse.

Let us discuss how we can approach these 4 Rs in our dental practice

Architectural design of Dental clinic

The architectural planning and designing of the dental clinic takes care of the major deal in switching to ecological side. The prime concern factors in designing are lighting, indoor air quality, construction and maintenance of the building with ecologically accepted material. The construction involves efficient floor plated design, glazing facades to improvise lighting, permanent entry way system with HEC, indoor environmental air quality improvised by zero Volatile organic compound materials and some indoor plants which absorbs the VOC material from air.

Energy management

Good energy management structure not only helps us in bringing the energy efficient culture but also reduces the cost of energy expenses. Major electricity consumers in hospitals are air conditions, waterpumps, aircompressors, lighting and autoclave. The eco model of hospital should maximize the day lighting and optimize the artificial lighting. According to ASHRAE 90.1-2007 ideal lighting power density in a patient waiting room and treatment room should be 0.4- 2.2 respectively. IGBC suggested few design aspects to increase light efficacy such as using Low energy LED lights rather than halogen bulbs, use of task lights in the consultation room and occupancy sensor in passageways and maximizing the day.

Solar-powered medical autoclaves can be an appropriate alternate for off-grid sterilization of medical and dental instruments. Using nanofluid Ni- Gly-water as a base in the solar autoclave setup, ideal autoclaving temperature and pressure can be attained rapidly attributing to its thermophysical properties.

Water management:

Dental clinics utilise water for both core and noncore functions. Speaking on water resource management we need to focus on two factors,

- minimizing the water consumption and
- Dental clinic waste water management.

Dental vacuum systems can use as much as 360 gallons of water per day. Conventional wet suction in dental practice utilizes fresh clean ½ gallons of water per minute per horse power also the oil in suction contaminates the immediate environment. Dry vacuum system eliminates the need of use water for suction purpose and the carbon fibervanes replaces the use of oil thereby making it more environmentally sustainable. It is a known fact that medical grade autoclaves are water consumptive. We can overcome this by installing ejectors in autoclave. It creates vacuum inside the pressure vessel allowing thorough penetration of vapour during the sterilization cycle and speed up steam evacuation system. Scaling and cavity preparations by conventional scalers and aerotors take up 20- 40 ml of water per minute. Embracing the use of ER: YAG LASER for scaling, cavity preparation and crown cutting produces desirable clinical effect with water conservation. The other ways of reducing the water waste is to install a low flow faucets, dual flush system and recycled water which can be used for potable purposes.

Water Waste management

Dental clinic waterlines constitutes hazardous waste such as mercury, lead and silver containing particles and non-hazardous waste such as hand wash, sterilents etc. They enter the sewer system through the chairside and the suction trap. Mercury from dental offices contributes significantly to the overall mercury contamination in wastewater. Amalgam separators are devices designed to remove amalgam particles from dental office wastewater through sedimentation, filtration, centrifugation, chemical removal by ion exchange or a combination of these mechanisms. According to the effluent guidelines of waste management amalgam separator should be installed in all the dental office
by December 2019. The collected amalgam from the separator can be collected and recycled.\textsuperscript{15}

The unused chemical wastes differ in their degree of risk. P-listed chemicals are acutely toxic cause irreversible damage and death at low dose whereas U-listed chemicals are relatively less toxic, but are still considered hazardous. Though we don’t use P-listed chemicals in dental practise, mercury comes under U category. Tree oil or thyme can be can viable alternative to the surface disinfectant.

**Radiographic waste**

Radiation exposure associated with dentistry represents a minor contribution to the total exposure from all sources, including natural and man-made. Threat not only involves the radiation exposure but also the materials and the components used for the conventional radiographs such as lead, silver and silver thiosulfate complex in the developer solution. These materials pose various environmental and human health damages. It can be best managed by electrolyte recovery and metallic replacement treatment and more wisely it could be dealt by switching over to digital radiography.\textsuperscript{16}

**Recycling biomedical waste:**

Biomedical waste is a lethal highly polluting and cannot be disposed through land filling and incineration. Though proper waste management reduces pollution to a larger extent, it still have a major impact on the environment through eutrophication and dioxin gas.\textsuperscript{17} Atmospheric concentration of carbon dioxide, sulphur dioxide and nitrous oxide is increased by incineration which in turn causes global warming. Methane is mostly released from landfills and can absorb 23 times as much infrared radiation as carbon dioxide, warming the earth’s surface.

More that reducing waste, sustainable development requires recycling it or, even better, assessing it as an energy resource Bio waste when anaerobically digested with the poultry yields high quality biogas. Biological fuel cells have increased its importance in recent years due to its implacability in implantable medical devices. The glucose components in the blood and saliva will be oxidised quickly and henceforth been considered as primary energy source of electrical energy among the dental waste.\textsuperscript{18}

**Going Green with the treatment**

Dental diseases are among the major public health problems in the global level affecting man kind. The need for alternative prevention and treatment options and products for oral diseases that are safe, effective and economical comes from the rise in disease incidence, increased resistance of pathogenic bacteria to currently used antibiotics and chemotherapeutics, opportunistic infections in immune compromised individuals and financial considerations in developing countries. The herbal medicine has an edge over conventional antibiotic treatment with high benefit to low-risk ratio.

Aloe Vera, Bloodroot, Caraway, Chamomile, Clove, Cranberry, Evening Primrose, Garlic, Zingiber officinalis, Syzygium aromaticum gel, Eucalyptus globules, ethyl acetate extracts of Piper betle plants, Mimusops elengi L. and Punica granarum L. seed Green Tea, Haritaki, Liquorice, Myrrh, Neem, Peppermint, Propolis, Purple Coneflower, Rosemary, Sage, Thyme, Turmeric, Tulsi, Triphala, represent summary of herbs used in treatment of oral diseases.

**Challenges in implementation of Green Dentistry!**

The most painful barrier in the implementing the concept is unawareness among our professionals about the over exploitation of the resources. The important prerequisite is the green building design which demands financial affair. Lack of incentives from the government demotivates the dentist to adapt to the change. Cost of initial equipment installation will be high. But green dentistry cannot be an option anymore. Challenges have always been faced with every technology revolution. Green marketing is gaining importance in India for various issues concerning sustainable development. Some of the concepts of green dentistry have been made mandatory by ‘Clinical Establishment Act 2018’. This presents us with window of opportunity to make our practise more reliable and efficient with environmental credibility.

**Conclusion**

After years of warnings from scientists, environmental groups and the ecologically conscious people, the ramifications of not caring for the health of the planet finally seem to have crept into our awareness. With increasing eco consciousness we are now driven to the trend of ‘green’. In order to be environmentally-friendly, health sector can deploy some basic measures.
like: improvement of hospital design, introduction of sustainable waste-reduction and management strategies, sustainable use of natural resources such as water and energy, and utilization and purchase of such products and chemicals, which have a minimal impact on the environment.

A Four Years’ Retrospective Study of Poisoning Cases in Southern India

P.C. Sahoo1, Karma Mingur Diki Bhutia2, Ashim Mishra3

1Professor & HOD, 2Assistant Professor, 3Associate Professor, SMIMS, Sikkim Manipal University

Abstract

Objective: To study the pattern of poisoning in Visakhapatnam and its demographic correlates.

Materials & method: The study was retrospectively conducted in all poisoning cases admitted in Casualty department of Anil Neerukonda Hospital, Visakhapatnam and carried out during the period of 1st Jan 2014 to 31st Dec 2017.

Results: Majority (47.37%) of the subjects were between the ages of 20-29 years with slight preponderance towards female (52.63%) as compared to male (47.37%). Most of the cases belonged to lower socioeconomic status (94.74%). Place of occurrence was most commonly within the house (85.97%) & it was predominantly observed during winter season. Aluminum phosphide (21.05%) was the most commonly abused substance followed by Organophosphate compounds (14.04%).

Conclusion: The government should take legislative steps to curb down the menace of poison in the hands of the vulnerable people in the society primarily focusing on developing the poisons with less toxicity or non-toxic to humans.

Keywords: Poisoning, demographic profile, pattern, Aluminum phosphide, Organophosphate compound.

Introduction

According to WHO, poisoning occurs when people drink, eat, breathe, inject, or touch enough of a hazardous substance (poison) to cause illness or death. 1

As per the records of National Poisons Information Center, New Delhi the highest incidence of poisoning was due to household agents (44.1%) followed by drugs (18.8%), agricultural pesticides (12.8%), industrial chemicals (8.9%), animal bites & stings (4.7%), plants (1.7%), unknown (2.9%) & miscellaneous groups (5.6%). The commonest case of poisoning in developing countries is pesticides which include organophosphates, carbamates, chlorinated hydrocarbons, Pyrethroids & aluminum or Zinc phosphide.2

Even National Poison Data System showed that in 2017, 2,607,413 closed encounters were logged by NDPS: 2,115,186 human exposures, 51,164 animal exposures, 435,540 information contacts, 5,424 human confirmed non-exposures, and 99 animal confirmed non-exposures. Analgesics were the most frequently involved substance with more serious outcome. NPDS documented 3,208 human exposures resulting in death.3

Pesticide poisoning is a common cause of suicidal & rarely accidental death in India. The distribution pattern of death due to poisoning in a region depends on its easy accessibility, low cost, effectiveness, socio-economic condition, education, health care facilities, transportation facilities, social stigma etc.

Hence, a detailed study of poisoning in a particular area can help in inoculating primordial & primary preventive measures, early diagnosis, prompt evaluation & treatment of the patient.

Objectives

To study the pattern of poisoning in Visakhapatnam
and its demographic correlates.

**Material & Method**

A retrospective study of all poisoning cases admitted in casualty department of Anil Neerukonda Hospital, Visakhapatnam was carried out during the time period of 1st Jan 2014 to 31st Dec 2017. All the information for the present study was collected from the medical record section of the hospital after obtaining the due permission. A pre-designed pro forma was used to collect the detailed information and categorically tabled followed by statistical analysis using SPSS20.0. Patients discharged against medical advice were not included in our present study.

**Results**

In the present study, 73 poisoning cases between the time periods of 2014-2017 were reported in the hospital. Among those 73 cases only 57 cases were taken into account. The rampantly rising trend of poisoning cases is observed in our study. All the poisons were consumed orally except for 1 snake bite case.

The female proportions were 52.63% followed by 47.37% of male cases. Majority of cases reported were in the age group of 20-29years (47.37%) followed by (17.54%) 10-19years & 30-39years age group. The mean age of entire 57 cases were 26.53±10.75 and the median age is 23years, which indicates the preponderance of suicides in females & young adults as described in Table 1. Statistically, $x^2$ value= 6.876, p= 0.14250. Hence, no significant difference is observed in the age group & sex.

The marital status was not stated in 63.16% while 26.31% were married & 10.53% were single. Similarly, occupation was also not stated in 92.98% while 5.26% were housewife & 1.75% was student. As the data is inconclusive, it cannot be used for study.

94.74% belonged to the low socioeconomic strata while 5.26% were from middle socioeconomic strata (Table 2). On computing, it was observed that $x^2$ value= 45.62, d.f. =1 & p<0.0001. Statistically, the data is significant. Maximum number of patients 31.58% was admitted only for 1 day followed by 21.05% for three days. With the increasing number of days, the patient number decreased as they were discharged after full recovery or loss on follow up or referred to higher center for further evaluation & management or expired. On evaluation it was observed that $x^2$ value= 6.05, d.f. =4, p=0.1954. Therefore, it is not significant.

In this study, only one (1.75%) patient had history of suicidal tendency in the past & only 2 (3.50%) patients were alcoholic. 55(96.49%) of them had committed suicide in their own/rented house, 01(1.75%) of them in college hostel & 01(1.75%) of them in field.

Failure on personal level like marital discord, familial dispute, unemployment, quarrel etc was the most common reason for suicide with 84.21%, followed by 3.5% of accidental, depression & financial reasons (Table 3). The observed proportions are significant as $x^2$ value=227, d.f. =$6$ & p<0.0001 (p<0.001). The mean time of poisoning was 1:25pm & the median time of poisoning was 2pm. The highest number of cases was reported in the last quarter of the year with 35.09% followed by the second quarter of the year i.e. April – June with 29.83% (Table 4). Statistically, $x^2$ value= 5.94, d.f.= 3 & p=0.05.

Almost 86% of cases consumed poison which was available in house followed by 12.28% who bought the poison from shop. The median of time lapse between places of occurrence to hospital was 2hrs & the mean lapse time was 3.37hrs.No. of patients survived after admission into hospital was 52 i.e. 91.24% of the total no. of case while 5 of them expired i.e. 8.77%

Aluminum phosphide (21.05%) accounts for maximum number of poisoning cases followed by organophosphorus poisoning (14.04%) in our study (Table 5). The findings are statistically significant as $x^2$ =58.79; d.f. =15; p<0.001.

Most of the patients came with complaints of vomiting, nausea, drowsiness, respiratory distress, dysphagia, altered sensorium etc. While only 8.77% of patients were asymptomatic on examination (Table 6). Statistically, it is significant as $x^2$ value= 57; d.f. =19; p<0.0.

Gastric lavage was done in 53 cases (92.98%) & not conducted in 4 cases (7.02%). 96.49% of the cases were suicidal while only 3.51% were accidental in manner of poisoning.

**Discussion**

In the present study, we aim to assess the pattern of poisoning & outcome. It was observed that there has been an increasing trend in poisoning among low socio-economic community with greater preponderance of female at 20-29 years among others. The approximate findings were also observed by other workers.

In majority of the cases, place of observance was the patient’s residence which is in concurrence with other studies. The most common reason for suicide was failure at personal level in our study which is concurred by other study. Similar seasonal variations was also observed in other study. In contradiction to our observation summer season recorded the maximum incidences in few studies.
Suicide was the most common intention for consumption of poison & it was also observed by many other workers in India, Nepal & Bangladesh. While a study done by Liu Q, et al suggest that accidental poisoning (64.7%) is the most frequent manner of death in China. Aluminum phosphide is the most commonly used poison followed by organophosphorus poisoning in Visakhapatnam (our study). The similar kind of findings was also observed by other workers in the same field in Haryana & Amritsar. In contrast to our study organophosphorus compound & insecticides was observed as the highly abused poison in different studies done in Nepal & India. While organochlorine compounds was found to be increasing abused in Bangladesh.

**Conclusion**

Poisoning with an intention to cause self-harm has been an increasing trend in the recent past. Suicidal tendencies among young adults belonging to low socio-economic background are alarming. The millennial these days are living in a digital world with tremendous exposure & influences from internet isolating them from other social being. Disappointment, failure, bankruptcy, sickness, fear etc. can frustrate an individual very easily & with the cheap & easy availability of poisons like Aluminum phosphide, organophosphorus compound, Zinc sulphide etc. it paves their way to suicide as an easy means to end all the problems.

Hence, with an attempt to reflect the psychology of a person who commits suicide we have come to an understanding that mental wellbeing of an individual should be acknowledged & primordial prevention at grass root levels should be prioritized. Health services department, employment agencies, education institute, etc. can play a pivotal role in shaping the young minds. The government should also strengthen the legislature by introducing awareness programme, educating people about poison & its harmful effects, introduction of poison information center in every state if not in all the districts, control on availability of poison along with development of new & less toxic insecticide, herbicide, rodenticide, pesticide etc. which over a long run can drop down the number of suicidal cases using poison.

**Acknowledgement:** We wish to thank Dr. G. Krishna Murthy, Principal, NRI Institute of Medical Sciences for letting us collect, compile & publish the hospital’s data.

We sincerely thank Sikkim Manipal University for its resources.

Effect of Audio Assisted Relaxation Therapy on Level of Blood Pressure among Mothers with Pregnancy Induced Hypertension

Shasi Bala1, Lekha Viswanath2
1Postgraduate student, Akal College of Nursing, Eternal University, Baru Sahib, Dist.Sirmour; Himachal Pradesh India, 2 Professor, Himalayan College of Nursing, Swami Rama Himalayan University, Dehradun. (Professor cum Vice-Principal, Akal College of Nursing, Eternal University, Baru Sahib, Dist.Sirmour; Himachal Pradesh, India at the time of doing the study)

Abstract

Introduction: The incidence of PIH is about 8-10% of pregnancies. Hypertensive disorder of pregnancy if unchecked will result in eclampsia with generalized convulsions, HELLP syndrome etc. It is usually managed with medicines. There are various non-pharmacological treatment like muscle relaxation, meditation, breathing etc. which are used to control of hypertension. Present study was aimed to assess the effectiveness of audio assisted relaxation therapy on level of blood pressure among mother with pregnancy induced hypertension.

Method: Experimental approach with one group pretest- posttest design was used for the study. Study was conducted among 30 antenatal mothers diagnosed with PIH admitted in Kamla Nehru Hospital, Shimla H.P, selected by using convenience sampling technique. Semi structured interview schedule is used to collect background information and sphygmomanometer was used to measure the level of blood pressure. The blood pressure (BP) was monitored three times a day for two days to obtain a baseline data and average of it was considered as pre-test. Audio assisted relaxation therapy was then administered for 20 minutes per sessions, two times a day for three days. The blood pressure (BP) was monitored before and after each session of relaxation therapy

Results: The mean posttest systolic is BP, 139.81 mm of Hg was significantly lower than the mean pretest systolic BP, 146.45 mm of Hg. The mean posttest diastolic BP, 87.63 mm of Hg was also lower than the mean pretest diastolic BP, 92.06 mm. Both differences were significant at the level of <0.001.

Discussion: The result of present study shows there is a significant difference in BP before and after intervention. So audio assisted relaxation therapy can be used as an effective add on intervention for the management of with women hypertension during pregnancy.

Key words: Pregnancy induced hypertension, Audio Assisted relaxation Therapy, Pregnant Mothers, blood pressure.

Introduction

Pregnancy-induced hypertension (PIH) is a condition which present with high blood pressure with or without proteinuria and edema, with other clinical manifestation usually occurring late in pregnancy and regressing after delivery of the conceptus1.

According to American College of Obstetricians and Gynecologists (ACOG) 2013 guidelines, the criteria for PIH is systolic blood pressure of 140 mm Hg or higher, or diastolic blood pressure of 90 mm Hg or higher occurring after 20 weeks of gestation in a pregnant mother whose blood pressure (BP) has previously been normal. Preeclampsia is diagnosed by persistent high BP that develops during pregnancy or during the postpartum period that is associated with a lot of protein in the urine or visual disturbances2,3. Indian scenario the incidence of PIH ranges from 5-15% in the
primi gravid mothers, whereas it is 16% in multigravida mothers[^4]. Several epidemiological studies have been performed to determine the prevalence and risk factors of hypertensive disorder of pregnancy (HDP) as well as its subtypes. It was found in a study that prevalence of HDP is 5.2–8.2%, gestational hypertension 1.8–4.4%, and preeclampsia is 0.2–9.2%, respectively[^5]. WHO estimates that out of 5,29,000 maternal deaths reported globally each year, 1,36,000 (25.7%) was contributed by India. Among these 16% are due to pregnancy-related complications. According to WHO census 2010 the risk of a woman dying from a pregnancy-related cause is about 36 times higher during her lifetime in a developing country as compared to a woman living in a developed country[^6]. According to WHO census 2013 every year nearly 76,000 women die globally due to preeclampsia[^7]. Global scenario incidence of PIH is range from 1 to 35%. WHO estimates the incidence of preeclampsia to be seven times higher in developing countries[^8]. Incidence rate of PIH is 8-10% in India[^9].

According to WHO expert committee and Joint National Committee recommends non-pharmacological treatment like muscle relaxation, meditation, breathing therapy as the first measure used to control of hypertension. Relaxation therapy is beneficial as it counteracts the physiological effects of stress and fight or flight response[^10, ^11, ^12]. Present study was aimed to assess the effectiveness of audio assisted relaxation therapy on level of blood pressure among mother with pregnancy induced hypertension.

**Materials and Method**

The aim of the study was to find out the effectiveness of audio assisted relaxation therapy on level of blood pressure. So an experimental approach was appropriate for the study. One group pretest-posttest design with multiple observations is used for this study. As BP is a variable which is subject to variations due to the effect of many external and internal factors, average of three observations per day for two days was obtained to get the baseline blood pressure. The average of baseline measures is considered as pretest. Average of three observations on the last day was considered as the posttest. Intervention included the administration of audio assisted relaxation for 20 minutes two times a day for three days. In order to find the immediate effect of each session of audio assisted relaxation, the blood pressure level before and after intervention was measured.

The setting of the study was Kamala Nehru Hospital, Shimla, Himachal Pradesh (KNH). A sample of 30 antenatal mothers diagnosed with PIH admitted in Kamala Nehru Hospital District Shimla, Himachal Pradesh was recruited for the study by using convenience sampling technique. The study included mothers who are willing to take part in the study, diagnosed with PIH and admitted in KNH and understand Hindi or English. The study excluded the mothers whose medication or dose changed in the past three days, variability in BP more than ten mm hg between mean of first and second day, having complications like eclampsia, HELLP syndrome, and having mental illness.

A detailed explanation was given to participants about the purpose of the study and intervention and it was informed that intervention does not cause any harm to them. Participation was based on their willingness and written informed consent was obtained from each participant prior to data collection and they were allowed to withdraw from the study at any point. On recruitment Semi-structured interview schedule was used to collect Background information. Sphygmomanometer was used to measure the Level of blood pressure at the specified intervals and and blood pressure was recorded in a flow sheet.

Audio assisted relaxation therapy (AART) was given to antenatal mothers along with routine medication and care. AART included sessions of guided relaxation of 20 minutes duration administered to mothers with PIH, with the help of prerecorded instructions by using headset for three continuous. It was developed and validated by experts in relaxation therapy. The intervention was administered in a separate quite room and was guided by prerecorded instructions. The mother was allowed to assume a sitting or side lying position as per her comfort and preference. The technique used for relaxation is focused attention. It is a prerequisite for meditation as a person is required to channelize all his attention to a specific sound and his breath. Focused attention helps in keeping the mind free from any distractions and channelizing thoughts in one direction towards slow breathing.

The data was analyzed using frequency and percentage for distribution of background information. Mean and standard deviation and Paired t test to compare pretest and posttest level of blood pressure.
Results

Background information:

Based on demographic variables majority 73.3% of mothers were in age between 19-30 years, 43.3% of them having diploma or degree and 76.6% of mothers were homemaker. Majority 53.3% of women’s were belongs to joint family. Majority 30% of mothers were having monthly income of 10001-20000 monthly family income. About 66.6% of mothers were primigravidae and 46.6% of them were in gestational week between 36-40 weeks. None of them from any coexisting complications during pregnancy.

Based on PIH related data 40% of mothers were diagnosed with pregnancy induced hypertension at 31-35 weeks of pregnancy. Majority 60% of mothers were taking Labetalol for the treatment of PIH and also among them 51% of mothers used 50 mg dose for once a day. Majority, 87% of mothers were not received any teaching regarding relaxation therapy. About 20% of mothers reported to receive some informal teaching regarding management of PIH by restriction in diet like salt and oil free diet, avoid stress, positioning, fluid intake etc. None of them were not using any Non Pharmacological method.

Discussion

The present study was aimed to assess an effect of Audio assisted relaxation therapy on level of blood pressure among mothers with pregnancy induced hypertension. Findings of the study showed that AART was a safe method and helps to reduce systolic and diastolic BP and there was a positive strong correlation between AART and level of BP. So there is need to focus on use of non-pharmacological methods to manage PIH and it can be implemented throughout the pregnancy.

Research studies conducted on effectiveness of interventions focusing on level of BP has shown to improve BP among mothers with PIH. A quasi experimental study was conducted at Government hospital and A.J Hospital, Mangalore in India in 2012 to evaluate the effectiveness of relaxation therapy on Mild Pregnancy Induced Hypertension. The results showed that the mean of pre-relaxation score (17.40) was significantly higher than the mean of post relaxation score (7.17). Since the difference in mean post therapy score is evident. A study was conducted to assess the effectiveness of guided imagery on level of blood pressure among PIH mothers in selected hospital in Pankajam Sitharam hospital at Trichy District, Tamilnadu 2015. A quantitative approach using quasi experimental pre-test post-test design with control group. Study sample is 60 PIH mothers were selected using Non-probability purposive sampling technique was used. Guided imagery was given to the mothers in experimental group for 10 minutes duration twice a day for 3 days. Sphygmomanometer was used to assess the level of blood pressure. Analysis using paired ‘t’ test was obtained for level of blood pressure in control group was 0.84 which is not significant at p<0.05 level. The findings of the study revealed that Guided Imagery helps in reducing blood pressure among PIH mothers. In present study there was a significant difference in level of systolic and diastolic BP in pretest and posttest at level of 0.001.

So Audio assisted relaxation therapy can be used as an add on therapy for the management of mothers with pregnancy induced hypertension.

Conflict of Interest: The investigator has no conflict of interest.

Source of Funding: The study is funded by self.

Ethical Clearance: Ethical clearance was obtained from the institutional Ethics committee of Akal College of Nursing. Participation was based on willingness and written informed consent was obtained from all participants.

A Demographic Study on Cases of Drowning with Special Reference to Histopathological Changes of Lung and Other Tissues in a Tertiary Centre

Somnath Maity¹, Soumeek Chowdhuri², Saikat Das, Sovan Kumar Das⁴, Rupam Karmakar⁵

¹Assistant Professor, Department of Forensic and State Medicine, Midnapore Medical College, ²Tutor, Department of Forensic and State Medicine, Calcutta National Medical College, ³Final Professional MBBS, Calcutta National Medical College, ⁴HOD, Dept. of Forensic and State Medicine, R. G. Kar Medical College, Kolkata, ⁵Professor, Dept. of Pathology, Burdwan Medical College

Abstract

Introduction: Drowning is the 3rd leading cause of unintentional injury deaths. As drowning is a preventable cause of mortality, our aims for the benefit of society at large is to minimize the events as far as possible. Objective: A clear knowledge about factors which play a major role behind such incidences is important. It has equal forensic importance as determination of cause and manner of death require thorough investigation. Methodology: We conducted one-year study of demographic variables and the histopathological changes in relation to lung and splenic tissues in cases of drowning deaths, in the hot and humid climatic region of Eastern India. Results: The demographic findings were presented in graphs and charts. However, none of the commonly known autopsy findings (histopathological) are found to be individually confirmatory of drowning. Conclusion: Several factors inclusive of autopsy findings, biochemical examination, radiological and molecular technique, are needed to be taken together as complementary methods to conclude drowning as the cause of death when bodies are recovered from water.

Keywords: Drowning, Forensic, Demography, Histopathology

Introduction

Mortality due to drowning is a major global public health concern.¹ A study on Global Burden of Disease (GBD) revealed that drowning constitutes 7% of all injury-related deaths (WHO, 2010). It is the 3rd leading cause of unintentional injury deaths. In 2012, an estimated 372,000 people died from drowning, making drowning a major public health problem worldwide. The WHO Global report on drowning: preventing a leading killer, published in 2014, highlights that 372,000 people drown worldwide each year. Drowning is among the ten leading causes of death for children and young people in every region of the world.² Approximately 90% of drowning take place in freshwater (rivers, lakes and swimming pools) and 10% in seawater.² As with other south East Asian countries, fatalities due to drowning are common in India. Drowning as a method of choice in suicides is also responsible for a substantial proportion of unnatural deaths. According to the National Crime Records Bureau, MHA Govt. of India NCRB (2014), 29,903 deaths (6.6% of total accidental deaths) were reported due to drowning in 2014.³ In developing country like India formulation of health care planning is very much dependent on incidence, prevalence, frequency and distribution of a particular disease or accident.⁴ As drowning is a preventable cause of mortality, our aims for the benefit of society at large is to minimize the events as far as possible. A clear knowledge about factors which play a major role behind such incidences is important. Modell et al.⁵ stated that to ascribe drowning as a cause of death to a body found in water without some evidence of the effect of having aspirated water is risky and concluded that ‘in this situation, it...
may be more accurate to list a differential diagnosis rather than a specific cause of death’. In this study we attempted to analyze the demographic variables and the histopathological changes in relation to lung and splenic tissues in cases of drowning deaths, in the hot and humid climatic region of Eastern India.

**Materials and Method**

A cross sectional study was conducted at the R.G.Kar Medical College & Hospital Police Morgue attached to the Department of Forensic Medicine and Toxicology and Department of Pathology, R.G.Kar Medical College. It was conducted on the dead bodies on which medico legal autopsy performed in the morgue for a one-year period i.e., 1st April, 2012 to 31st March, 2013.

Cases of unnatural deaths (on whom Medico legal Autopsy was performed during the stipulated period) where cause of death was clearly identified as drowning were included in the study.

Cases presenting as drowning but actual cause of death found after autopsy to be something else e.g. head injury, any natural disease etc. were excluded.

**Results & Analysis**

16 cases of drowning were found in age group 11 to 20 years, 13 cases among 31 to 40 years, 10 cases among first 10 years whereas only 2 cases found in 61 to 70 years but no cases in 61 to 70 years age group. Eighty percent of study population was male while twenty percent were female. Maximum cases (46) were found to be accidental in nature, 6 cases were suicidal, only 2 cases were homicidal and 6 were unknown or undetermined. 21 cases of drowning were found in pond, 17 in river, 13 in lake, 6 in canal whereas 2 cases from well and only 1 in sewage pipeline water. Most of the cases (10) found in the month of June whereas least cases (3) in July and December (Fig 1).

Scatter diagram shows age distribution in cases with known manner of death (Fig 2). 70% of all cases were happened during bathing among people with no swimming lesson; different disease conditions including depression comprised 5% of all cases as risk factor; in 3% cases alcohol intake was possible risk factor whereas in 15% cases no significant risk factor was found (Fig 3). 78% of all cases showed dilatation of alveoli and thinning of alveolar septa as microscopic changes in lungs whereas in 14% cases alveolar oedema was found and only 8% cases showed interstitial oedema.

All of the cases showed reactive changes as microscopic feature of spleen. Histopathological examination was performed on all the organs of non-putrefied bodies with the aim to differentiate between death due to drowning and other causes of death. Hematoxylin and eosin (H & E) staining often gives excellent results to determine the cause of death in bodies recovered from water. Pulmonary changes in drowning are distributed heterogeneously in the lung parenchyma (Fig 4, 5). In this study, other organs like spleen showed nonspecific changes like generalized congestion and swelling of the capillary endothelia (Fig 6).

![Fig. 1: Showing distribution of cases in different months](image-url)
Fig. 2: Scatter diagram showing age distribution in cases with known manner of death

Fig. 3: Pie diagram showing possible risk factors among all cases

Fig. 4: Microscopic picture showing bronchopneumonia of lung indicating interstitial oedema (H& E, 100X) in a case of Secondary drowning (Near-drowning).
Discussion

The results of observations have been analyzed in form of graphs & charts and compared with available studies to bring out similarities and dissimilarity in different aspects.

Our study population were distributed from newborn to 80 years of age and it is seen that most of the cases (16) of drowning was in the age group 11 to 20 years. Palimar V, Manjunath S (2010) in their study in Manipal, found that age group commonly involved in drowning was 11-20 years. Davoudi- Kiakalayeh A et al (2008) in their study in Northern Iran also found that more than one-third of all victims of drowning were under the age of 20. Results of both the study corroborated with the findings of our study. On the other hand, Singh A, Gorea R K, Dalal J S, Thind A S, Walia D (2003) showed that most commonly involved age group was 31-40 years. Shetty M conducted a study regarding the profile of drowning deaths in coastal Karnataka (1999-2004) and found that maximum number of drowning victims were of age group 31 – 40 years. Therefore, findings of both the study were nearly similar to findings of our study as second highest no. of cases were found in age group 31-40 years in our study.

Incidence of drowning deaths were much higher in male with a male: female ratio 4:1, as found in our study. Male predominance in drowning deaths was shown in
many other studies done by Kanchan T et al\textsuperscript{10}, Chaudhary B L et al\textsuperscript{11}, Byard R W et al\textsuperscript{12}, Davoudi-Kiakalayeh A et al\textsuperscript{7} and many more. ArdeshirSheikhazadi et al (2009)\textsuperscript{13} found in their study in Iran that male: female ratio was 6.5:1 among drowning deaths whereas Somers GR et al (2005)\textsuperscript{14} found male: female ratio as 2.5 in paediatric drowning cases.

Accidental submersion is the most common manner of deaths by drowning and we found the same result. According to our study, accidental drowning cases comprised of 77% of all cases. Gomiak J M et al (2005) in a 10-years long study\textsuperscript{17} in Ohio, USA found that the majority (78%) of drowning deaths were accidents. This finding was consistent with our findings. Palimar V, Manjunath S (2010) in a 12-year long study\textsuperscript{6} in Manipal, also found that accidental drowning was most common form of drowning. ArdeshirSheikhazadi, Mohammad Hasan Ghadyani (2009) studied about epidemiology of drowning in a province of Iran and found somewhat higher rate of accidental drowning (85.1\%)\textsuperscript{13}.

Data analyses showed that 10% of all cases were suicidal submersion, i.e. 6 out of 60 cases. According to Gomiak J M et al (2005)\textsuperscript{17} 14% cases were suicidal which is close to our findings. On the other hand, Stemberga V et al (2010) studied\textsuperscript{18} about suicidal drowning in Croatia and found that it accounted for 31% of all drowning deaths. A study done by Avis SP (1993)\textsuperscript{19} in Canada also found higher rate (25%) of suicidal drowning.

It is stated that homicidal submersion is really rare because of difficulties it involves when the victim is adult, unless the victim is first weakened by something like alcohol or drugs. Only 2 homicidal cases of drowning were found in our study, both were unknown cases and newborn, one was male and other female, found in lake and sewage pipeline water respectively. It represented 3% of all deaths due to submersion [Table 5, Fig.6&7] which was consistent with findings of Gomiak J.M. et al\textsuperscript{17}. Although ArdeshirSheikhazadi et al\textsuperscript{13} found only 0.3% homicidal cases in Iran. On the other hand, Auer A\textsuperscript{20} found 2.3% homicidal cases in Finland.

When the manner of death could not be recognized, the case is considered undetermined or unknown which comprised 10\%, i.e. 6 cases of total deaths caused due to drowning in our study.

Natural freshwater settings were the sites of all drownings except a newborn which was found in sewage pipeline water. It highlights the risk of going in such water whether deliberately or not. The absence of salt-water drowning case in our area is not surprising, because of geography of the region and jurisdiction of our area.

In our study pond was the location with highest number of drowning victims. Patetta M J, Biddinger P W in a study\textsuperscript{21} in North Carolina, USA showed that most death occurred in freshwater settings, notably lakes and ponds, 39 percent, and rivers and creeks, 29 percent. Chaudhary B L, Singh D et al in their study\textsuperscript{11} in Sevagram, Wardha found that most of drowning deaths were seen as a result of fall in well which was inconsistent to our study and may be due to geographical variation. On the other hand, Stemberga V et al\textsuperscript{18} found 57% incidents occurred in the sea, 34% in water wells, 6% in rivers, and 3% in bathtubs in a study done in Croatia.

We tried to highlight over some risk factors which possibly contributed to the fatal outcome. In our study 70% cases of death occurred during bathing among people with no swimming lesson. Chaudhary B L et al in their study\textsuperscript{11} found that maximum cases of suicidal drowning were seen in person with history of some kind of mental illness or some chronic disease. Byard R W et al in a study\textsuperscript{12} in South Australia showed that alcohol use was not usual and there was often a significant history of mental illness. Copeland AR in a study\textsuperscript{22} in Florida found that the reason for the act was depression concerning poor health, death of a loved one, financial problems, chronic pain, or being “tired of life”.

The increase or decrease of drowning death in a year is closely related to seasons, climatic factors and geographic zone. Our study showed that the majority of deaths took place during the summer followed by the end of the spring, when the weather is warm. This correlates to the results of studies done by ArdeshirSheikhazadi et al in Iran\textsuperscript{13} and also in some western countries. Shetty M.\textsuperscript{9} and Palimar V et al\textsuperscript{6} in their study found different result and concluded that incidence of drowning death increased during rainy season.

We have studied macroscopic and microscopic changes of lung of the drowning victims. In our study 78% cases showed dilatation of alveoli and thinning of alveolar septa as microscopic changes in lungs whereas in 14% cases alveolar oedema was found and only 8% cases showed interstitial oedema. These findings were
consistent with the opinion of Farrugia A and Ludes B. Somers GR et al. highlighted the need for thorough clinicopathologic correlation in cases of drowning to accurately interpret the pathologic findings like frothy exudate, pleural effusion and increased lung weight.

We have studied microscopic changes of spleen of the drowning cases during our study period. In all of the cases no specific finding characteristic of drowning was found; only some reactive changes were found. Kotani H et al. found a significant relationship between red splenic arteriolar hyaline and drowning deaths; moreover, the presence of the red pattern had high specificity for the detection of rapidly fatal cases. These findings were inconsistent with our study findings.

**Conclusion**

Death due to drowning has forensic importance as determination of cause and manner of death require thorough investigation. The forensic pathologists often confront cases wherein the findings are not definite enough to clinch the diagnosis as death due to drowning though the body might have been recovered from water. Moreover, in the majority of the cases, autolytic and putrefactive changes would preclude a scientifically sounded diagnosis of drowning. None of the commonly known autopsy findings are individually confirmatory of drowning. Several factors inclusive of autopsy, biochemical examination, radiological and molecular technique are taken together as complementary methods to conclude drowning as the cause of death when bodies are recovered from water. Unfortunately, the cost–benefit analysis in current practice could be hard to defend. The roles of chloride, magnesium, strontium, silicon is promising. Molecular tools like expression of aquaporins are useful for differentiating salt water from freshwater drowning. This mandates ongoing research to further fine-tune the various modalities of confirming drowning and applying them in real forensic casework.

Fixing the Deepest Point on Greater Sciatic Notch for Measuring or Calculating Maximum Depth of Greater Sciatic Notch

Uday Pal Singh¹, D Vijaya Raghavendra².
¹ Professor and Head, ² Assistant Professor, Dept of Forensic Medicine, Mamata Medical College, Khammam

Abstract

Background: Aim of the present study is to fix the deepest point in the curvature of greater sciatic notch for measuring or calculating maximum depth.

Material and Method: Hip bones of each sex (30 male and 30 female) were divided in two groups consisting of 15 bones in each group. For first group the farthest point from the maximum width of greater sciatic notch was taken as the deepest point. For the second group the point of first touch from arcuate line onto the greater sciatic notch curvature was taken as the deepest point. Maximum depth of greater sciatic notch was calculated from that point for both groups. The maximum depth of greater sciatic notch for each sex were checked for any statistical difference between the two groups by using two tailed t-test to calculate the p-value.

Result: p-value, for maximum depth of greater sciatic notch between group 1 and 2 was found to be 0.149 for male hip bones and 0.8883 for female hip bones. Statistically there was no significant difference in the maximum depth of greater sciatic notch calculated by fixing the deepest point either from maximum width of greater sciatic notch or from arcuate line.

Conclusion: We can use the point of first touch from arcuate line to greater sciatic notch as the point of maximum depth of greater sciatic notch.

Key words: Hip bone, gender, maximum depth of greater sciatic notch, Arcuate line.

Introduction

Determination of gender of unknown skeleton is a routine work for those who are involved in medico-legal work. Sexing of unknown skeletal material depends on the relative completeness of the skeleton. Percentage of accuracy for adult material is 100 percent from entire skeleton; 95 percent from pelvis alone; 90 percent from skull alone; 98 percent from pelvis plus skull; 80 -90 percent from long bones alone; 90-95 percent from long bones plus skull; 95 percent or more from long bones plus pelvis. The female pelvis, on account of its development for child bearing, has always been the principal and most reliable indicator of sex. The bone which is most important in determining the gender of skeletal remains is hip bone. As a single criterion to determine the sex greater sciatic notch has an accuracy of 75% (Washburn). Different parameters used in determining the gender are maximum width of the greater sciatic notch, maximum depth of greater sciatic notch, greater sciatic notch index, index I of greater sciatic notch, index II of greater sciatic notch and Genovos index. But for the maximum width of greater sciatic notch all the remaining parameters need the maximum depth of greater sciatic notch for calculations. In other words, the value of maximum

depth of greater sciatic notch is a must when we study the greater sciatic notch. Various scholars used different methods to measure the maximum depth of the greater sciatic notch. In all the studies, the deepest point on the curvature of greater sciatic notch was assessed and then measured the perpendicular distance from that point to the maximum width of the greater sciatic notch.\textsuperscript{10,11,12} But the exact location of deepest point on the greater sciatic notch curvature is not found in texts. It is true that the perpendicular maximum distance from the width of the greater sciatic notch to the notch curvature is to be considered as the maximum depth, hence technically if we keep on drawing parallel lines from the maximum width of greater sciatic notch the point of last touch on greater sciatic notch is to be considered as the point farthest from the width (photograph 1) and hence the deepest point on the curvature of greater sciatic notch. The problem with this method is the deepest point on greater sciatic notch depends on the points taken for measurement of maximum width of greater sciatic notch. Keeping that in mind fixation of the point of maximum depth of greater sciatic notch is attempted independent of the points taken for measuring width of greater sciatic notch. If we draw parallel lines from arcuate line towards greater sciatic notch the point of first touch on greater sciatic notch can be the deepest point (Photograph 2,3). The current study is taken with the aim to check whether the point of first touch from arcuate line is the deepest point on the greater sciatic notch or not.

**Aims and Objectives**

The present study is done on 30 male and 30 female dried adult hip bones to fix the deepest point in greater sciatic notch curvature. Hypothetically it is assumed that point of first touch of the line parallel to the arcuate line of hip bone and the curvature of greater sciatic notch is the point of maximum depth of greater sciatic notch. The hypothetically assumed point is checked statistically whether it corresponds to the point of maximum depth of greater sciatic notch or not.

**Materials and Method**

Materials used for the present study were: Dried adult hip bones of known sex (30 male and 30 female), Vernier calliper, CD marker, OHP sheet with printed parallel lines on it and series of parallel lined paper. Statistical analysis is done using Micro soft office excel 2016.

Inclusion criteria: Morphologically intact dry adult hip bones of known sex.

Exclusion criteria: Broken, incomplete, unossified hip bone and the hip bones of unknown sex.

Sixty morphologically intact dried adult hip bones of known sex (30 male and 30 female) were collected from department of forensic medicine and anatomy of Mamata medical college, Khammam. The hip bones were divided in 2 groups consisting of 15 male hip bones and 15 female hip bones in each group. Two points were marked on each hip bone

1. Point A: Posterior inferior iliac spine,
2. Point B: Tip of ischial spine.

The maximum depth of greater sciatic notch was marked as point “C”. For group 1 the point of last touch from width of greater sciatic notch on the curvature of greater sciatic notch is considered as the deepest point. This was done by using a paper with parallel lines and keeping the hip bone over the paper and then marking the point of last touch as point “C” (photograph 4). In the second group the point of first touch on the curvature of greater sciatic notch from the arcuate line is marked as the point of maximum depth (the nearest point on the curvature of greater sciatic notch from arcuate line), using the OHP sheet with printed parallel lines (photograph 5).

Using Vernier callipers following measurements were taken:

AB (the width of greater sciatic notch), BC and AC (as shown in photographs 6,7 and 8). The perpendicular distance from point C to AB touches the line AB at point “O”. The distance OB is the maximum depth of greater sciatic notch which is calculated as $OC = \frac{2\text{(area of triangle ABC)}}{AB}$.

The maximum depth of greater sciatic notch of group 1 is compared with that of group 2 for the same gender using p-value.
**Observation and result**

Table 1 is showing the depth of greater sciatic notch in males. The mean depth of greater sciatic notch was found to be 33.28 millimetres with standard deviation of 2.35 and a range of 7.36 in group 1. The mean depth of greater sciatic notch was 34.46 with standard deviation of 1.98 and a range of 6.8 in group 2. The $p$-value of 0.149 (as calculated by 2 tailed t test) suggested that the difference between the depth of greater sciatic notch of males of the two groups were statistically insignificant.

Table 2 is showing the depth of greater sciatic notch in females. The mean depth of greater sciatic notch was found to be 31.14 with standard deviation of 2.71 and range of 9.6 in group 1. The mean depth of greater sciatic notch was 31.27 with standard deviation of 2.16 and range of 7.63 in group 2. The $p$-value of 0.8883 (as calculated by 2 tailed t test) suggested that the difference between the depth of greater sciatic notch of females of the two groups were statistically insignificant.

Photograph 1. Showing the deepest point on greater sciatic notch ie Point of last touch from the width of Greater sciatic notch; 2. Showing point of first touch on greater sciatic notch curvature from arcuate line and 3. Showing that both these points may be the same.

Photograph 4. Showing marking of deepest point using point of last touch from width; 5. Showing way to get point of first touch from arcuate line.

Photograph 6. Showing measurement of width of greater sciatic notch; 7. Showing measurement of the distance between B(tip of ischial spine) and C(deepest point in greater sciatic notch); 8. Showing measurement of AC (distance between posterior inferior iliac spine and deepest point in greater sciatic notch).
Discussion

The maximum depth of greater sciatic notch depends on the points taken for the measurement of width of greater sciatic notch. The width of greater sciatic notch is measured as the distance between posterior inferior iliac spine to tip of ischial spine which seems to be correct by seeing the morphology of the bone. The width of greater sciatic notch is measured from pyriformis tubercle to ischial spine, Pyriformis tubercle to tip of ischial spine; Posterior inferior iliac spine to base of ischial spine. This makes the deepest point on greater sciatic notch to be marked differently for the same hip bone, as the deepest point on the greater sciatic notch varies with the variation in selection of points for measurement of width of the greater sciatic notch. We must be in a position to mark the maximum depth on the curvature of greater sciatic notch independent of the points taken for width of the greater sciatic notch. The structure of the hip bone that is less damaged is the mid part of the hip bone. The arcuate line, which is near to the greater sciatic notch curvature and a fixed bony landmark, found in all hip bone was taken into consideration to fix the deepest point of greater sciatic notch. The calculated depth of greater sciatic notch of the two groups of same sex in our study has not shown any statistically significant differences. Hence we can use either point of first touch from arcuate line or point of last touch from the width of greater sciatic notch as the deepest point on the curvature of greater sciatic notch.

Conclusion

Determination of deepest point on the curvature of the greater sciatic notch makes the measurement of maximum depth of the greater sciatic notch easier, more convenient and objective. As forensic experts most of the time we do receive broken hip bones, in such situation point of maximum depth of the greater sciatic notch can be fixed from arcuate line with ease.

²Consultant Critical Care, Apex Hospital, ³Consultant Nephrologist, Apex Hospital, Jaipur (Rajasthan)

Abstract

Enrofloxacin flouroquinolone - Veterinary Medicine. It has the general effect of the class of flouroquinolone. This poison is rarely reported in human. We present a case of Enro poisoning. Patient ingested Enrofloxacin. Which was followed by seizures and altered sensorium. Patient was taken on mechanical ventilator. He was managed symptomatically. He developed ST-T changes in ECG. But coronary angio was normal. We also tried doing plasmapheresis. But patient expired even after all efforts. The best of our knowledge, we did not find any such reported case of enro poison in Human. Hence we present this case report.

Key Words: Enrofloxacin, Poisoning, Flouroquinolone

Introduction

Enrofloxacin is a synthetic chemotherapeutic agent from the class of the flouroquinolone carboxylic acid derivatives, acting against a variety of Gram Negative and Gram Positive Bacilli, in veterinary medicine. It is generally administered by subcutaneous injection and intramuscular injection to Pigs, and Chickens for the treatment of infection of the respiratory and alimentary tract(1). We present a case report of its use in human, which is a rare presentation.
Case Report

A 30 year old male, was brought to the Emergency Department in an unconscious, gasping state. The history was given by the attendant who revealed that the patient developed headache, vomiting and frothing from the mouth around 8-10 hours back. It was followed by generalized seizures which lasted for around two minutes. However there was no history of fever. Patient developed seizures and was taken to a local hospital. He was given primary care there and was referred to a private medical college hospital, There the patient was revived a loading dose of Inj. Epsolin. A CT scan of the Head was done, which was normal. Subsequently the attendant shifted the patient to our hospital. There was no significant past history.

The vitals in the ER were as follows:

**Pulse:** 95/min,

**BP:** Systolic 70, Diastolic not recordable.

**GCS:** E, M, V (3/15).

**Deep tender reflexes:** Normal

**Chest:** Bilaterally clear and heart sounds normal, Shallow Breathing

**CVS:** S1, S2

Looking at the gasping state, Patient was immediately intubated and taken on mechanical ventilation. IV fluids were administered and vasopressor support in the form of INJ. Nor Adrenaline was started.

ABG was done which showed metabolic acidosis with a PH: 7.02, HCO3: 7 Lactate: 12.8,

PCO2: 27, Po2: 82.

ECG was normal (fig 1)

Total Leukocyte Count was 13,000. Liver and Renal functions were normal. A provisional diagnosis of Cerebrovascular accident was made.

However the hypotension remained unexplained. Another differential diagnosis was septic shock. But the G.C.S of 3/5 remained unexplained with this looking at the age of the patient, frothing and hypotension a detailed history was again taken from the relatives.

On deep questioning, it was revealed that he had consumed a bottle of Enrofloxacin, an empty bottle of
which was found at home by family members. However
the exact quantity consumed, could not be concluded.

Immediately symptomatic treatment was started
in the form of gastric levage, IV fluid and vasopressor.
Soda bicarbonate was administered for the correction
of metabolic acidosis, demonstrated on ABG. This
gradually improved.

None of our team member had an experience of
managing Enrofloxacin poisoning’s, we searched the
internet for this poisoning, but to our surprise, we did
not find much literature about human exposure. All the
evidence was in animal use.

A single session of plasmapharesis was also done in
hope to eliminate the poison. But matter did not seem to
improve.

MRI BRAIN was done, the very same day which
came out to be normal and hence our provisional
diagnosis was eventually ruled out.

On second day, patient developed significant ST
elevation in ECG in multiple leads including inferior
and lateral leads. (Fig 1). An urgent cardiology reference
was taken.

Echocardiography showed a regional wall motion
abnormality with EF 40%. An urgent Coronary
angiogram was done which ruled out coronary blockage.
But any significant lesion in coronaries was ruled out.

There was only 30% lesion in ostial part of left
circumflex artery. This lesion was insufficient to explain
the clinical findings.

Symptomatic treatment was continued. Patient
developed further hypotension which becomes refractory
to vasopressor. Urine Output started declining gradually.

Partially ultimately developed cardiac arrest and could
not be revived.

**Discussion**

Enrofloxacin (CASRN: 93106-60-6) is a synthetic
fluoroquinolone antibiotic for animal use only. Like
other fluoroquinolone side effects include dizziness,
drowsiness, disorientation, seizures, nausea, vomiting
and tremors. Cardiovascular effect may include QT
prolongation, Polymorphic Ventricular Tachycardia.
Elevated liver enzymes and liver dysfunction have been
reported following therapeutic use of fluoroquinolone.
Other side effects may include joint or cartilage
tenderness, photosensitivity and epidermal necrolysis. (2)

We were unable to find any reported human
ingestion and toxicity.

Serotonin Syndrome Precipitated by Escitalopram

Deshna H. Lad¹, Harsha Makwana², Vidhi Shah³, Supriya D. Malhotra⁴, Pankaj Patel⁵

¹Post Graduate Student, Department of Pharmacology, ²Associate Professor, Department of Emergency Medicine, ³Post graduate Student, Department of Emergency Medicine, ⁴Professor and Head, Department of Pharmacology, ⁵Dean, Smt. NHL Medical College, Ahmedabad, India

Abstract

Depression is characterized by symptoms like sad mood, loss of interest and pleasure, low energy, worthlessness, guilt, psychomotor retardation or agitation, change in appetite and/or sleep and suicidal thoughts, etc. It may be a unipolar or a bipolar cyclic disorder in which cycles of mood swings from mania to depression occur over time. Fluoxetine, Fluvoxamine, Paroxetine, Sertraline, Citalopram and Escitalopram are the various SSRIs(Selective Serotonin Reuptake Inhibitors) preferred as first line of drug in such conditions. Among the SSRIs, Escitalopram exerts a highly selective, potent, and dose-dependent inhibitory effect on the human serotonin transport. By inhibiting the reuptake of serotonin into presynaptic nerve endings, this drug enhances the activity of serotonin in the central nervous system. Herein we report a case of a 82 year old male who presented with altered sensorium, tachycardia, hypertension and restlessness to emergency department of our hospital. Patient was known case of Adjustment disorder with Depressed mood and was on treatment with Tablet Escitalopram 10 mg OD and Tablet Zolpidem 10 mg OD since 1 month. Patient overdosed himself with 4 Escitalopram tablets of 10 mg. He presented with features similar to serotonin syndrome.

Keywords – Depression , Adverse drug reaction(ADR) , Escitalopram , Pharmacovigilance , Serotonin Syndrome

Introduction

Depression is a disorder of mood and it is characterized by persisting feeling of sadness and loss of interest. SSRIs are the first line drugs for the treatment of depression and anxiety disorders(1). TCAs(Tricyclic Antidepressants) are also frequently prescribed for the Depression. The advantage of SSRIs among the Tricyclic antidepressants is that they are relatively safe in overdose. The majority of SSRI overdose cause minor side effects. Central nervous system depression is the most common side effect after SSRI overdose, although in large doses it can cause serotonin syndrome, seizure and cardiac abnormalities.(1) However, QT-interval prolongation and tachycardia have been reported mainly with Citalopram and more recently in case report of Escitalopram toxicity(1). Escitalopram is the S–enantiomer of Citalopram and has been marketed because it is more potent inhibitor of the serotonin transporter and likely accounts for the majority of the inhibitory effects in racemic citalopram. During the last 10 years, there has been an increase in the prescription of Escitalopram and an associated increase in overdose. Serotonin toxicity is more common with escitalopram than with citalopram or other SSRIs because of its increase serotonergic potency. The most common clinical effects with escitalopram overdose are tachycardia, hypertension, drowsiness, nausea, and vomiting. With citalopram, in addition to above, the most common clinical side effects are tremor and seizure. Nausea, vomiting, and hypertension were more common with escitalopram. Escitalopram is comparatively safer than Citalopram(2). Therapeutic dose of Escitalopram is 10 mg /day and maximum dose 20 mg/day(3).Herein we report a case of suspected Serotonin Syndrome as an ADR to high doses of Escitalopram.
Case Details

An 82-year-old Diabetic, Hypertensive male patient brought by relative to the emergency medicine department of our hospital with altered sensorium. On examination, Temperature: normal, Pulse: 116/min regular, BP: 160/90, respiratory rate – 14/min, SpO2-98% on room air, RBS: 273 mg%, CVS: S1S2+, RS: Clear, CNS: In delirium state; planter: right flexor and left extensor. Patient was having Tachycardia, Hypertension, Restlessness and Agitation. He was kept under observation with suspicion of Hyponatremia or CNS problem. His ECG was showing heart rate more than 110/min but rhythm was normal. In emergency room, ABG was done showing normal with Na⁺:141 mEq/L. After 1 hour patient didn’t regain consciousness so CT brain was done which did not reveal any significant finding. IV line started with Normal Saline pint at the rate of 60 ml/hour and patient shifted to ER ICU for further management. On detailed history Patient’s relative told that patient was alright in the evening on previous day and did not wake up in the morning. On arousal he was not following verbal command so he was brought to the hospital.

Patient is a known case of Psychiatric illness diagnosed as Adjustment disorder with Depressed mood since 1 month. He was on treatment with Tablet Escitalopram 10 mg OD and Tablet Zolpidem 10 mg OD, taking regularly. Patient is also known case of Diabetes Mellitus and Hypertension since 15 years so he was on treatment with tablet Voglibose SR 0.3 mg TDS and Tablet Amlodipine 5 mg BD. After 3 hours of admission patient was having persistent tachycardia and hypertension so overdose/toxicity of SSRI was suspected so Tablet Escitalopram and Zolpidem were withheld. Ryle’s tube was inserted and gastric sample collected and stomach wash done with normal saline. Inj Furosemide 20 mg IV was given. Urinary catheter was inserted and Urine drug abuse assay was done to exclude other drug overdose. In ICU patient was treated by Inj Ceftriaxone 1 gm IV BD, Inj Pantoprazole 40 mg IV BD, Inj Ondansetron 4 mg TDS, Inj Optineuron 2ml IV BID, Tab Voglibose SR 0.3 mg BD, Tab. Amlodipine 10 mg OD. 2D Echo was done and normal. His investigations including CBC, Serum electrolytes, LFT, RFT and X ray chest were normal. Patient subsequently improved and regained consciousness on 2nd day with pulse rate of 92/min regular and blood pressure of 120/70 mmHg.

On detailed inquiry Patient had given history of deliberate ingestion of 4 tablets of Escitalopram of 10 mg yesterday night. Psychiatric refer was done and advised to continue Tablet Escitalopram 10 mg OD and Tablet Zolpidem 10 mg OD. Patient was conscious and psychologically stable so discharged on 4th day. This case illustrates an example of toxic overdose with escitalopram that resulted in features suggestive of Serotonin syndrome. This case was reported via Vigiflow at WHO-UMC with Id-2019-38323.

Discussion

Serotonin syndrome is often described as a clinical triad of autonomic hyperactivity, mental status changes and neuromuscular hyperexcitability. Although clinically, serotonin syndrome has a broad range of presentations that often result in under diagnosis. Mild cases may result from therapeutic doses, and the patient may or may not be symptomatic. Moderate cases present with more autonomic and neurological dysfunction. Severe cases generally presents with worsening vital signs, rigidity, hyperthermia and the potential for multiorgan failure(4). There are a number of drugs from different classes that can cause serotonin syndrome either alone at high doses or when combined but the most commonly prescribed class of antidepressant, which work by increasing serotonin, are the serotonin reuptake inhibitors. Escitalopram is a well-tolerated medication, with a side-effect profile comparable to the other SSRIs. A number of side effects have been seen during escitalopram therapy, such as insomnia, nausea, and increased sweating, agitation, restlessness, weakness etc. Cases of serotonin syndrome with escitalopram are reported, but quite a few(5). Previously cases of Serotonin syndrome induced by the readministration of escitalopram after a short-term interruption in an elderly woman with depression by Sato Y et al(6) and Serotonin Syndrome Induced by Combined Use of Tramadol and Escitalopram by Caamano A. et al(7) are reported. Escitalopram works by increasing intra-synaptic levels of the neurotransmitter serotonin by blocking the reuptake of the neurotransmitter into the presynaptic neuron. The use and prevalence of serotonergic drugs for various psychiatric issues is on the rise. As a result, physicians should carefully consider and rule out the clinical diagnosis of serotonin syndrome when presented with an agitated or confused patient with signs and symptoms of serotonin syndrome who is taking serotonergic drugs. One should be hypervigilant when serotonergic drugs are used. Previous studies have reported that 10% to 14% of patients who overdose with
SSRIs experience serotonin toxicity many of whom with only mild presentations(8). Although escitalopram has been reported to show less serotonin toxicity compared with other SSRIs, its effect was best described by one previous study in which 15% of 46 patients exposed to escitalopram alone exhibited significant serotonin toxicity, while isolated serotonergic neuromuscular findings developed in as many as 46% of the patients at a mean ingested dose of 140 mg. Another study reported that the most common clinical effects after an overdose with escitalopram with a mean dose of 130 mg were tachycardia (19.5%), drowsiness (15.0%) and hypertension (9.0%) (8). Serotonin syndrome has long been known, and it is clearly an iatrogenic effect of modern medications.

Here we report a case of elderly male patient who developed this ADR. Age-related physiological changes affect drug pharmacokinetics (absorption, distribution, metabolism and excretion) and pharmacodynamics (the study of effects of a drug on the body) (9). Of the four traditional components of pharmacokinetics—absorption, distribution, metabolism, and excretion—only absorption appears to be substantially independent of age. The distribution of a particular drug can differ importantly in the elderly. An increase in the volume of distribution combined with a reduction in clearance will prolong elimination half-life, which might prolong the duration of action of a single dose of drug. With chronic dosing, reduced clearance without a change in the dosing interval leads to an increased steady-state concentration of medication (10). The higher frequency of ADRs in the elderly, rather than being a consequence of senescence alone, may be attributable in part to the fact that older patients consume more medications and are likely to have more baseline illness than younger patients (11).

**Conclusion**

This case shows a rare incidence of serotonin syndrome with Escitalopram use. It is very important that physicians are familiar with the signs and symptoms of Serotonin syndrome and should suspect it in anyone with altered mental status who is taking serotonin-modifying drugs. In our patient, the diagnosis was made early due to autonomic and neurological signs and suspicion of SSRI overdose which was confirmed when patient regained consciousness. Cessation of serotonergic medication and supportive care remain the mainstay of therapy.

**Acknowledgment:** We are thankful to Dr S. T. Malhan sir, Superintendent of our hospital and our institute for allowing to collect and publish this case report.

**Conflict of Interest:** Nil

**Source of Funding:** Nil

**Ethical Clearance:** Since it is a Case Report which was reported as an Adverse Drug Reaction (ADR) to our centre under Pharmacovigilance Programme of India, Ethical Clearance is not needed. However, the author has taken consent of patient to publish the data for scientific purpose, patient confidentiality is insured.

Pattern and Profile of Injuries Sustained During Assault by Sharp Weapon: A Prospective Study During Year 2015-16 at Sms Medical College-Jaipur

N.L. Disania 1, Rajesh Kumar Verma2, R.K. Punia3, Vinod Kumari Jat4

1Associate Professor, 2Associate Professor, 3Senior Professor, Forensic Medicine S.M.S Medical College, Jaipur Rajasthan, 4Medial Officer, Forensic Medicine Mahatma Gandhi Medical College, Jaipur Rajasthan

Abstract

Introduction: Death and injuries by sharp weapons needs proper attention as regards to their pattern and manner of infliction. This study was thus undertaken to obtain statistical data of the injuries caused by sharp force in fatal and non-fatal medico-legal cases at SMS Hospital, Jaipur to evaluate their pattern and medico-legal profile for of intentional injuries inflicted by others.

Material and method: This study consisted of all the Medico-legal cases of sharp force trauma inflicted by others during assault, including fatal and non-fatal cases comes in department of Forensic Medicine of S.M.S. Medical college Jaipur during the period extending from April, 2015 to March, 2016. A total no. of 93 cases of sharp weapon injuries were studied.

Observations: Males predominated in the present study with 86.02% of cases. Injury inflicted by others was more common in urban population (90.32%). In this study majority of cases of injuries inflicted by others were incised with 62 cases (60.78%) In 24 cases single edged weapon was used to inflict stab wound. Out of all the cases only 5 succumbed to death and was most commonly resulted from by hemorrhagic shock (4 cases).

Key words: Assault, Sharp, Incised, Stab, Shock.

Introduction

Injuries by sharp weapon have been a universal issue since antiquity to human kind. From mass warfare since ancient times to personal feuds of modern times has witnessed the use of sharp weapons leading to serious injuries and sometimes even loss of precious human lives. In modern times the medico-legal diagnosis of the injuries is considered an important aspect in serving the justice to the needful which cannot be overlooked. The medico-legal diagnosis of sharp injuries at post-mortem is handled by autopsy surgeons who are experts in the concerned field. But an individual in casualty suffering the sharp weapon injury requires multi-dimensional treatment ranging from primary treatment and medico-legal diagnosis of the said injury. These doctors might have a significant experience of treatment of the injured but the medico-legal diagnosis of the injuries is also expected from them as this is also of utmost importance in serving the justice.

The most common manner of injuries associated with sharp force trauma is homicide, followed by suicide. Fatalities by accidental sharp injuries do occur but are relatively rare. Fatal sharp injuries are usually indicative of extreme violence; and leads our attention towards the developing sense of frustration and lack of tolerance, indicative of mental disturbances in individuals. Death and injuries by sharp weapons is an underrated issue which needs proper attention as regards to their pattern and manner of infliction, which remains controversial at some times. Study of the profile and pattern of any type of Medico-legal cases is a fundamental aspect for...
the prevention of causalities in forthcoming times. This study was thus undertaken to assess the injuries caused by sharp force in fatal and non-fatal medico-legal cases at SMS Hospital, Jaipur to evaluate their pattern and medico-legal profile for accurate medico-legal diagnosis of intentional injuries inflicted by others and help the Autopsy surgeons and the causality medical officers to anticipate the types of injuries and their probable outcomes and help in aiding justice.

Material and Method

This study consist of all the Medico-legal cases of sharp force trauma inflicted by others, including fatal and non-fatal cases except those cases of alleged history of injury by sharp weapons but found to be resulting from blunt trauma which were brought for medico-legal examination or for autopsy in department of Forensic Medicine of S.M.S. Medical college, Jaipur during the period extending from April, 2015 to March, 2016. A total no. of 93 cases of sharp weapon injury inflicted by others were studied to find medico-legal profile of sharp weapon injuries in both Fatal and non-fatal cases.

Observation

A total of 22,740 medico-legal cases were catered to in the out-patient and in-patient department of SMS Hospital, Jaipur. Amongst them 179 cases were of sharp force trauma (0.78%) out of which 86 cases were excluded from the study. During the study period 4838 medico-legal autopsies were performed among which there were five cases of deaths due to sharp force injuries inflicted by others. Thus, a total of 93 cases comprised the study population in the present study.

Males predominated in the present study with majority of cases. In this study the injuries inflicted by others was most common in age group between 21 to 30 years with 40.86% cases followed by 31 to 40 years group with 27.96% cases. (Table I)

Injury inflicted by others was more common in urban population (90.32%). Sharp injuries sustained during assault were most common during evening and night hours (82.42%). Most of the injuries sustained were outside home (51.61%) followed by incidence at home (25.80%). Alcohol ingestion was associated in 14 cases (15.05%). Only 5 cases were fatal out of 93 cases. Single injuries were noted in 37 cases (39.78%) followed by multiple injuries were noted in 33 cases (35.48%) (TABLE II)
In this study majority of cases of injuries inflicted by others were incised with 62 cases (60.78%) followed by stab injury with 16 cases (15.69%). (TABLE III)

In 60 cases, light sharp weapon was used and in rest 33 cases, moderately heavy weapon was used. In 24 cases single edged weapon was used to inflict stab wound and in rest of 7 cases stab wounds were inflicted using double edged weapons. Defense wounds were seen in 36 cases (38.70%). In this study it was observed that limbs were the most common part of the body that was injured followed by thorax and abdomen.(Table IV)

</table>
Out of all the cases only 5 succumbed to death and was most commonly resulted from by hemorrhagic shock (4 cases) while 1 person succumbed to septicemic shock. In 2 cases of those who succumbed to death the preferred area for assault was thorax injuring heart in both the cases. It was followed by assault to neck injuring common carotid and other major blood vessels of neck.

**Discussion**

This study was undertaken with the aim to study the medico-legal profile of fatal and non-fatal injuries inflicted with sharp force trauma at SMS Hospital, Jaipur during 2015-16 as regards pattern, manner of infliction and sharp weapons used for infliction of sharp injuries.

The load of cases of sharp injuries during this one year period was 0.78% out of which 0.001% cases proved fatal.

In the present study males were predominant (86.02%) and 13.98% females. The results of the present study are slightly variable to those of Bhullar DS and Aggarwal KK (2007) who reported use of 92% light and 7% heavy sharp weapons. However, their study did not classify heavy sharp weapons into moderate and heavier categories. Our findings were contrary to those of Kokatanur CM et al. (2015) who reported 64.6% of sharp injuries were caused by light sharp weapons in this study .Heavy sharp weapons were used in two cases although chop wounds were not caused. The gravity of those wounds could not manifest as accepted from the type weapon used most likely because of the difference in the area of the weapon used. The results of the present study are similar to those of Bhullar DS and Aggarwal KK (2007) who reported use of 92% light and 7% heavy sharp weapons. However, their study did not classify heavy sharp weapons into moderate and heavier categories. Our findings were contrary to those of Kokatanur CM et al. (2015) who reported 64.6% of sharp injuries were caused by light sharp weapons in this study and 28% by moderate sharp weapons.
where maximum victims 31.5% died of shock and hemorrhage followed by 28.5% died due to injury to brain, 17% died due to asphyxia, 15% died due to injury to vital organs. Similarly Dasgupta and Tripathi (1983) had observed that 56.72% died due to hemorrhage and shock. Dikshit PC et al (1986) had observed that cause of death in 51.28% victims was shock, 41.42% was coma due to brain injury and 4.28% was asphyxia. Though there is difference in number of cases, but the sequence of causes of death is similar to study of Dasgupta and Tripathi (1983) i.e. shock and hemorrhage is the main cause of death which outnumbers the other causes.

Present Study is consisted and correlated with simultaneous study Socio-demographic profile of fatal and non-fatal cases of sharp weapon Trauma at SMS medical College & Hospital, Jaipur During the 2015-16, Medico-legal Update:Vol 18:Number 1 January –June 2018; 20-249.

Conclusion

1. A forensic medicine specialist being an expert witness should be able to diagnose the medico legal injuries in their right perspective to help the investigating authorities and the courts of law for their logical conclusions. Apart from playing the role of an expert witness, he must also maintain the comprehensive data pertaining to the injured and the injuries for epidemiological records to assist in the surveys pertaining to the crimes on humanity for behavioral treatment of the criminals and the assault victims. Injuries caused by or sustained from sharp edged weapons may be suicidal, homicidal, self-suffered, self-sustained or accidental but certain medico legal parameters definitely help to diagnose the nature or mode of these injuries. It is worth taking a closer look at patterns of sharp injuries to assess their nature and manner for legal assistance

Conflict of Interest: None Declared.

Ethical Clearance: not required

Source of Funding: Self.

A Study of Awareness on Artificial Insemination among Medical College Students

Shifa Shahina Nijamudeen¹, Dekal V²
¹Shifa Shahina Nijamudeen IInd MBBS Student, Saveetha Medical College; ²Dekal V. Professor and HOD of Forensic Medicine of Saveetha Medical College

Abstract

Introduction: Artificial Insemination (AI) is the deliberate introduction of sperm into a female’s cervix or uterine cavity for the purpose of achieving a pregnancy through in vivo fertilization by means other than sexual intercourse. This is one among the methods of assisted reproductive technique. This study aims to find out the level of awareness about Artificial Insemination among medical students

Materials and Method: This is a questionnaire-based study. A self-administered questionnaire in multiple-choice format distributed among the medical students of Saveetha medical college. Total of 120 students, Forty students from each batch from second to final year were randomly chosen to participate in the the survey.

Results: 120 medical students participated in the survey out of which 76.67% of students had adequate awareness on artificial insemination. 85% of students knew the correct definition of AI while 86.74% were able to correctly identify the techniques used for artificial insemination. Final years medical students had more awareness on artificial insemination than their junior colleagues, and 2nd years medical students had least awareness. Students have inadequate knowledge on the technical aspect of artificial insemination like storage of semen (21%, n=25) and the time duration of sperm viability (54%, n=65) etc. Students also having inadequate knowledge on the legal, social and psychological issues like donor selection, consent of the spouse and the importance of understanding between the partners on artificial insemination.

Discussion: Most of the respondents knew about the basics of Artificial insemination with less awareness on its technical aspect, legal and ethical implications. Medical education have been a good source of information and the inclusion of Artificial Insemination as a form of infertility management in the curriculum of medical students could help in increasing awareness among students.

Keywords: Artificial insemination, Assisted reproductive technique, Awareness, medical students

Introduction

Artificial Insemination is a method of assisted reproductive technique, by which healthy semen is deposited into the vagina, cervix or uterus by instruments to bring about pregnancy.

There are three types of Artificial insemination: Artificial Insemination Homologues (AIH), Artificial Insemination Donor (AID), Artificial Insemination Homologues Donor (AIHD).¹²

A wealth of information about Artificial insemination exists on the internet but current public perceptions and awareness on Artificial insemination among Indian citizens are still unknown because attitude surveys have not conducted. Furthermore, to the best of our knowledge, this is the first survey of its kind in India.

Infertility is nowadays a common medical condition with social, emotional and psychological implications, displaying increasing rates in India and worldwide.

Artificial Insemination is the first line of treatment for infertility. According to PUTOWSKI L et al.³:

‘Popularity of the Artificial Insemination is due to the relatively simple procedure and the lower cost of
treatment compared with In vitro fertilization. In the case of Artificial Insemination, the time of stimulation is shorter and therefore the stimulation itself is cheaper. In countries where the access to IVF/ICSI is significantly limited by e.g. the lack of even partial coverage of costs, insemination treatment remains an important therapeutic step that can be offered to a couple who is unsuccessfully trying to have a child.’

The term Artificial Insemination (AI) includes techniques like intravaginal, intracervical, intrafallopian, intraperitoneal. In clinical practice the Intrauterine Insemination is most often performed. Its effectiveness in the form of live births outnumbers other methods of insemination⁴.

The effectiveness of Artificial Insemination is influenced by many factors, appropriate choice of the treated couple, the duration of infertility, woman’s age, semen quality, semen preparation, the number of inseminations in a cycle, mild ovarian hyper stimulation, the number of inseminations that a couple has already undergone.⁵

**Materials and Method**

This cross-sectional study was carried out from January 2019 to April 2019 at the Saveetha Medical University, Chennai, Tamil nadu. The convenience sampling technique was used to select students for the purpose of enrollment into the study.

This is a questionnaire-based study. A semi structured questionnaire in multiple-choice format was used to collect information in relation to the awareness of the participants about various domains of artificial insemination process.

The questionnaire was handed out to the Students of Saveetha Medical University from second year to final year with various background.

The study was conducted after taking the permission from Institutional ethics committee of the Saveetha Medical University.

On an average forty to fifty students from each batch from second to final year were randomly chosen. 140 Medical students were included. Students who were willing to participate were included in the study. Those who were not willing to participate were excluded from study.

After taking their informed consent the participants were asked to fill out the questionnaire and hand it back. 120 students returned the questionnaire with the response rate of 85.71%.

Questioners returned with incomplete response were excluded from the study.

The questionnaire was pretested before the data collection and necessary modifications were made in terms of content and language.

**Data analysis and presentation**

The responses from returned and properly completed questionnaires were collated, entered into an Excel spread sheet in a laptop and coded accordingly. The analysis was performed in terms of descriptive statistics proportions and means.

**Results**

This study included 120 medical students (Females: 80.833% n=97 and Males: 19.16% n=23) from second to final year with 40 students from each year.

When asked if the students had any prior knowledge of artificial insemination, 115 students said yes while only five said no.

Students had mostly acquired information on artificial insemination from lectures and books while internet, media and CME only played a minor role. (Fig.1)
A total of 15 questions (table I) were analysed using a scoring system where each right answer was coded as 1 and any wrong answer as 0.

</tbody>
</table>

Among 40 students from each year, 38 students from final year had more than 50% knowledge on artificial insemination while only 28 from third year had more than 50% knowledge and 26 students from second year had more than 50% knowledge on artificial insemination. In total 76.67% of students had adequate awareness on artificial insemination among all the years.

85% (102) of students knew the correct definition (Fig-2) of AI while 86.74% were able to correctly identify the techniques used for artificial insemination.

**Figure 2 Definition Known correctly**

Comparatively only 17% (n=20) knew that the overall success rate of AI is 30-40
72% (n=86) of the students knows correct timing for Artificial insemination while remaining 28 (n=34) are not known the timing for AI.

When asked whose semen can be used 82%(n=97) answered that either the husbands or donors semen can be used while 7% answered only husbands semen can be used and 9% answered that only donors semen can be used while 2% answered not sure. (Fig-3)

Students seemed to have very little knowledge on the technical aspects of AI only 21% (n=25) knew that the semen is stored at -196 degree C while 48% (n=58) believed the storage temperature to be -4 degree C.

Almost half the participants 54% (n=65) knew that the sperms retain their power to fertilize the ovum after leaving the genital tract for 48 hours. While 31%(n=37) answered that they retain their power only for 24 hours while 8% (n=10) thought it was upto 7 days and 7% (n=8) thought it was less than four hours.

Most of the participants were aware of the legal issues pertaining to AI while some of them were mostly unsure.

73%(N=87) of students were aware that AIH is legal while 3% answering that it is illegal, 25% (n=30) were unsure about it. 68%(n=82) agreed that AID is legal while 7% thought it was illegal.

54% (n=65) agreed that the donor cannot be a relative of the couple while 35% (n=42) weren’t sure .62% (n=75) believed that donor cannot be held guilty of adultery while again 28% (n=33) weren’t sure.

Can the donor be a relative of the couple?

- 54% Yes
- 35% No
- 11% Not sure
- 2% Not sure

49% knew that unmarried or widowed woman could avail artificial insemination while 25% weren’t aware that unmarried woman can avail artificial insemination.

However most of the students (n=104) agreed that artificial insemination cannot be used for gender selection while only 3 thought that it could be used for gender segregation with 13 not sure.

Discussion

Overall awareness on Artificial Insemination among the students was good. This shows the impact of lectures held by professors and specialists in the field impact step-wise education in the process of solving fertility problems through Artificial Insemination. The inclusion of Artificial Insemination in medical books is also an important factor in students knowledge of the subject. This may also be why a large proportion of respondents agreed that Artificial Insemination should be socially acceptable.

According to Howkin and Bourne⁶:

The semen used for Artificial Insemination is first washed, concentrated and its quality improved by
the ‘swim-up’ technique or by use of Percoll gradient. The semen with normal sperms with good motility thus obtained is then inseminated into the female genital tract. Obviously, Artificial Insemination is done around ovulation. About 1/2 mL of concentrated semen is injected 36 h after hCG injection when the ovarian follicle reaches 20 mm. Semen washing removes the abnormal sperms, seminal plasma containing antibodies and other debris, as well as prostaglandins’ (p.247)

They also state that:

‘Intrauterine insemination is normally done once around ovulation, some prefer to do twice in each cycle. Intrauterine insemination (IUI) is repeated up to 3–6 cycles. One moves to IVF or intracytoplasmic insemination if conception fails. The IUI should be done within 90 min of collection of semen, for optimal results. Prophylactic progesterone is recommended to the woman in the luteal phase An Artificial Insemination with husband’s semen for 4 cycles has yielded 30% overall success with 10% success per cycle.’ (p.247)

In this study only 17% of respondents knew the overall success rate of Artificial Insemination

According to ESHRE experts7 IUI combined with the ovulation stimulation before the IVF treatment trial can be offered to the infertile couples because of low cost of procedure and potential success in the form of pregnancies in numerous couples qualified for such a treatment.

According to the study conducted by Ashrafi M et al8:

‘The rate of achieved pregnancies per cycle with IUI is the highest among couples with unexplained infertility and the lowest among couples in whom there is a number of factors limiting fertility determined.’

Artificial Insemination can be done with the husbands or donor semen. Unsuccessful attempts with the use of the husband’s semen in IVF or ICSI and couples in whom the IVF procedure cannot be proposed (e.g. financial barrier) and the presence of severe oligoasthenotatozoospermia or obstructive or non-obstructive azoospermia which do not give chance for pregnancy are factors that qualify to IUI with the donor’s semen.9-10

Majority of students (87%) agree that Artificial Insemination must not be used for gender selection.

Most of the students were unsure about the legal aspects of Artificial Insemination. This problem is also compounded by the absence of a statutory law on Artificial Insemination in India. The status of a child born after Artificial Insemination still remains unclear. A study conducted by Sita Kumari11, looked into the legal issues and current existing laws on Artificial Insemination in India and in other countries around the world. The study concludes that the current legal position of India on Artificial Insemination is inadequate and warrants suitable amendments to all existing laws which are related directly and indirectly related to the status of an AID child

On studying the laws of other countries the study concluded that legitimacy will be conferred on an AID child if the husband consents for the same11

Another ethical issue related to semen donation is the right to disclosure. There is an increasing tendency to disclose the identity of donors to the resulting offspring. A Swedish study12 on disclosure behavior and intention suggested that majority of the infertile couples were willing to disclose the donor identity to their offspring. Seventy-eight percent (78%) of the study population were planning to tell their offspring about the donation. However in a study conducted by Ezugwu et al13 in low resource settings in Nigeria, approximately nine out of ten infertility couples indicated that the identity of the sperm donor should not be disclosed to donor-conceived children. This shows the disparity among infertile couples in different countries. In our study, most (44%) were unsure if the child born after Artificial Insemination should be informed after growing up with only 38% agreeing that the child should be informed. Majority (89%,n=107) agreed that donor identity should remain anonymous while only 11% disagreed

This preference may be as a result of the absence of legislation in both Nigeria and India addressing the legal issues involved in gamete (sperm) donation. In countries where donor nonanonymity is practiced, there are usually regulatory bodies and legislations guiding gamete donation and its use in ART. In the UK, sperm donors do not have any legal claim to the child and are also protected from any legal responsibility to the child14

Hence this study shows an overall good level of knowledge, awareness as well as perception of Artificial Insemination among medical students. Medical lectures have been a good source of information and the inclusion
of Artificial Insemination as a form of infertility
management in the curriculum of medical students has
helped in increasing awareness among students

Study limitations

This study has some limitations. First it was a
convenient sampling of all medical students from a
particular geopolitical area of the country and does not
necessarily represent the views, opinions and awareness
level of medical students from other parts of Tamil Nadu.
Also, a control group of non-medical students could
probably have strengthened the study.

Acknowledgement: The authors are very grateful
to the students who participated in the study and helped
collect the data.

A Cross-Sectional Study of The Pattern of Cases of Deliberate Self-Harm in a Tertiary Care Hospital

Shinto Devassy1, Varghese P.S1
1Senior Resident, Dept of Forensic Medicine, AIIMS, New Delhi,
2HOD, Dept of Forensic Medicine, St John’s Medical College, Bengaluru

Abstract

Objective of the Study: To study the different methods used for DSH and precipitating factors

Materials and Method: The present study was conducted in the department of emergency medicine in St John’s Hospital, Bengaluru. 337 individuals who were brought to the emergency department with an alleged history of DSH and were stable after medical management were selected for the study. Subjects were assessed using the structured questionnaire and a thorough history. Group differences for categorical variables were examined with fissure exact test.

Results: Analysis revealed that 60.5% of DSH cases were in the age group of 18-30 years, 54.3% were females, 37.7% of family problems, 42.1% preferred drug over dosage, 10.7% in February and17.8% on Mondays.

Interpretation & Conclusion: Young adults were the most vulnerable group. Singles outnumbered all others. Nuclear family and urbanization proved to be risk factors. Most of them attempted DSH because of family problems and most attempted at home. Drug overdose was the most preferred method.

Keywords: Deliberate self-harm, Suicide attempt, Suicide prevention

Introduction

Deliberate self-harm, both fatal and non-fatal, has become a serious challenge to the public and private health sector of India. Known in many other terms like attempted suicide, deliberate self-injury and Para suicide, an act of self-infliction is well defined by the word ‘Deliberate Self Harm’, which covers all dimensions of self-poisoning and injury – the purposes behind be any1. DSH also forms one of the most common causes for acute medical admissions for both men and women. Most of the developing countries including India don’t maintain an active register of self-harm. England is the first nation to introduce one such, in 2002. Health service planning requires frequently updated information in the dynamic trends of self-harm, to assess the effectiveness of management and preventive measures, as well as to maintain an optimal provision of services to the victims.

This study considers all non-fatal self-harm cases as parts of deliberate self-harm and also carries references to intentional self-inflicted poisoning, injuries and self-harms which may or may not have fatal intents or outcomes. Some of the survivors of self-harm commit it again with a strong intention to die, but they fail. Presently no specific nomenclature exists to denote these two groups. Suicides have been studied and theorised extensively but a very few of those studies consider self-harm, which is a main reason why very less amount of data exists in the national level regarding DSH. Though the National Crime Bureau keeps the statistics of committed suicides, there is no credible source at national level for data regarding the number of deliberate self-harm cases. Most of the suicide cases were under reported in this regard.

Materials and Method

This study was conducted in the Emergency Medicine Department of St John’s Medical College Hospital, a tertiary care hospital with a yearly Emergency OPD cases of around 50000. This hospital is located in Koramangala, situated in the south-eastern part of Bangalore. It is a cross-sectional study and data
collection was done from January 2014 to December 2014. All those individuals who came to/brought to the emergency department of the hospital with a known history of DSH and stable after medical management were selected. An average of 25-30 cases each month accounted to a total of 337 cases of DSH in the year 2014. All cases with history of accidental over dosage of therapeutic agents, alcohol or other poisons and fatal cases of deliberate self-harm were excluded.

A structured questionnaire was given to the subject after taking written informed consent by explaining them the pros and consequences of the study under taken at emergency department of St John’s Hospital, Bangalore. An informed consent to participate in the study was taken from each one of the patients. Strict confidentiality was assured to the patients and their families regarding their identity and details collected during the interview. They were interviewed once they gained physical stability after resuscitation, recovery and a short period of observation in the emergency medicine intensive care unit.

This study has been granted ethical clearance by the Institutional Ethical Review Board (IERB), St. John’s National Academy of Health Sciences. A pilot study was undertaken at St John’s Hospital, Bangalore in December 2013 with individuals who came with history of deliberate self-harm. The purpose of this pilot study was to assess the feasibility of the study, ease with which individuals could answer the self-administered questionnaire and time taken per subject interview. A total of 10 subjects were interviewed in the pilot study. The pilot study helped in scheduling data collection for this study and incorporating changes in questionnaire where required.

Statistical examination and data treatment were carried out by standard statistical methods using SPSS 20 version software. All study variables were described by appropriate descriptive statistics methods like frequency and percentages were done by using Fisher’s exact test since the expected counts in some cells were considerably small. The p value of <0.5 was considered to be statistically significant.

Discussion

Table No. 1 depicts that the maximum number of DSH patients were in the age group of 18-30 years (60.5%) and least in the age group <14 yrs.(0.9%). The probable reason for young adults being the most important group of DSH patients is- they are the most vulnerable group and as they grow older, there is a chance of their traditionalist households becoming less supportive. They are more prone to job anxiety, higher expectations at home and work place. The modern day youth lives in a fast paced and highly competitive environment with an additional burden of peer pressure and familial pressure. It is a time of emotional turmoil and they are unable to cope with rejection or the other challenges faced in love. Most of the women in this age group are newly married and find it difficult to adjust and coexist in peace and harmony with their spouse and his family. One of the study determined the mean age of attempters as 25.3

Another study shown that people belonging to the age group of 16 – 40 are found with more suicidal ideation in a study of suicidal ideators in a general hospital setting. So almost all studies are consistent with these findings.

Table No. 2 depicts that deliberate self harm is more prevalent in females. Although attempted suicide was 1.2 times higher in women relative to men in some studies, other studies showed a male predominance of Male: Female ratio ranging from 1.13: 1² to 1.63: 1⁶. These differences may be reconciled by an appreciation of social changes in India, with a shift toward nuclear families and the cultural emphasis on the male stereotype which the individual tries to fulfill in vain. In our study the Male: Female ratio was 1: 1.19.

Majority of them were due to marital discord (20.2%) with other family problems (17.5%) coming a close second as depicted in table no 3. Most of the cases in other family problem were due to argument with one of the family member other than the spouse. So in total family problems formed a group of 37.7%. Love affairs formed 14.5% and illness 17.8 % (including insanity/ mental illness (12.5%). Studies on attempted suicide concluded most of the cases with interpersonal conflict, financial stressors, and educational burden as the most common triggers. Chronic pain and illness is featured as a common reason in some studies.

Self-inflicted injuries constituted 6.8% of the cases as depicted in table no 4, of which most of them were due to love failures and was probably motivated by what they had seen on the media when encountered with a similar situation. The common injuries noted were cut injuries near the wrist joint by a sharp object, injuries sustained while punching a mirror or a window and while banging their head on the wall. Other means of attempting DSH constituted around 6.5% and included cases such as consuming bangles, rings and injecting air. Only 4.2% of cases were due to hanging as it was done more with
a definite suicidal intention and most of them succeeded and hence excluded from the study. Those who survived this method were those who did it in front of or in the presence of others and was rescued immediately or due to an improper or failed technique such as a broken fan or ligature material. There was also one case of a person who attempted hanging because her mother had hung herself. 1.8% cases were attributed to alcoholism with most triggering factors being academic failure or the loss of a dear one. Next group was self-immolation (0.9%) and the least attempted method in our study was drowning (0.3%). As these are lethal methods and as DSH are non-fatal in nature only very few are in this group. An Indian study of suicide attempters classified motivation into ‘the wish for change’ and ‘the wish to die’ groups and found that the former had low lethality, lack of planning for their attempt, more likelihood of rescue and were not intoxicated during the attempt. The latter group utilized more drastic measures, such as hanging and was more likely to have a psychiatric disorder with co morbid alcoholism. 

Most of them opted for drug over dosage. Among them, many were impulsive responses to acute psychosocial stressors. So most of the cases were unplanned type and used whatever accessible tool at that particular time. In drug over dosage cases, almost all of the drugs used were already available in their households. Analgesics, vitamins, cough syrups and psychiatric drugs were on the top of the list. The second highest numbers of cases were from poisons other than insecticides like herbal cockroach powder, phenol, goodnight solution, nail removers and rat poisons. The next groups were those who had insecticide.

Table 5 shows more cases were reported in the month of February forming 9.8% and then January and august with 9.8% each and least in the month of December around 5.9%. When analysed with the seasonal pattern of Bangalore, it was noted that the maximum incidence occurred in winter, followed by monsoon and summer. Table 6 shows more cases were attempted on Mondays at about 17.8% and it was followed by Sundays(15.1%). Thus Sunday and Monday constituted about 32.9% and these similarity can be seen in almost all of the yearly reports of NSRF.

In summary our study had identified as 18-30 years as the most stressful time period in one person’s life as more prone to job anxiety, higher expectations at home and work place. Family problems were the first precipitating factor followed by love affairs. Most of them preferred drug overdose because of its easy availability followed by poisons. The month with more number of cases was February and in the winter season and among days it was Monday.

Study of Profile on Juvenile criminals in Chennai

Siddharth.R¹, V.Dekal²

¹ 2nd Year M.B.B.S student, ² Professor & Head of the department, Department of Forensic Medicine, Saveetha Medical College & Hospital, SIMATS, Chennai, India

Abstract

Juvenile delinquency is a serious offence and it is detrimental for the social order in any country. There is a trend of increase in juvenile crimes world-over, with more and more involvement of the youth in violent crimes. Chennai shows similar trends of increasing rate of violent crimes committed by the juveniles. It is a very serious concern for the district and solutions to end the problem need to be sought very carefully. Indian legal system and judiciary has responded to these trends and has brought some amendments in the laws pertaining to juvenile justice in India [1]. This paper aims at looking at the causes of juvenile delinquency and explanations in Chennai for the year 2016. The analysis of statistical data available at the CBCID office crime branch indicates increasing involvement of the juveniles in heinous crimes. Observation homes, Shelter homes have been started by the government for the sake of such offenders then also the rate is continuously increasing day by day. For delinquent juvenile we can say that Prevention is better than cure juveniles should be protected from going to the wrong path.

Keywords: Juvenile criminals, Educational status, Economic status, Nature of crime, Family background, Recidivism, Juvenile delinquency.

Introduction

A child is born with innocence and if nurtured with tender care and attention, then they grow in positive way. Physical, mental, moral and spiritual development of the children makes them capable of realizing their fullest potential. On the opposite side, harmful surroundings, negligence of basic needs, wrong company and other abuses may turn a child to a delinquent i.e. a juvenile delinquent [2].

Juvenile Delinquency means participation of minors or young people in illegal activities. Various legal systems in the world have adopted specific procedures to deal with juvenile offenders such as Juvenile Justice Courts, Observation Homes etc. A juvenile delinquent in India is a person below the age of 18 and has committed act prohibited under the Indian Penal Code, 1860.

This paper aims at looking at the causes of juvenile delinquency and explanations given by scholars from various fields to explain the problem.

Objective

1. To identify the insights about the personal and family background of the juveniles in under the conflict with the law in Tamil Nadu.

2. To explore the nature of offences and charges committed by juveniles such as offence against person, property, etc.,

3. To analyze the role of family and other agencies for the cause of juveniles who are charged committing the offence.

Materials and Method

In case of juvenile criminals the nature and severity of the problem though vary to a great extent in the different part of the world but has posed a serious menace for every society in recent years. Therefore, it needs an in-depth study so as to suggest suitable preventive and curative measures [3]. In this descriptive work, efforts have been made to study and analyze the problem of juvenile in conflict with the law with special focus on the factors responsible for prevalence of the problem which include the educational status, age limits, economical status, family background and recidivism of the juveniles. The design structured for this study is descriptive because the aim of descriptive research design is to interpret and explain the problem on the basis of collected facts. The purpose of this research design is to provide description
of the individuals, nature and causes of the problem under investigation, i.e. juvenile in conflict with the law. This study describes the profile of the juveniles to be in conflict with the law.

The secondary data were collected from different sources such as books, journals, documents and newspapers to substantiate the primary data and to add validity to the analysis. Information was also collected from the records of the District Crime Records Bureau, Chennai.

**Result**

**Educational status**

As we know education plays an important role in the formation of behaviour pattern particularly among the children at the earlier stages. From our data it is clear that out of 485 juvenile offenders the majority of the juvenile offenders i.e. 208(42.8%) belong to above primary but below matric education. But no one had the opportunity to study matric or higher secondary. About 19.7% of the juvenile criminals are illiterate and 181(37.3%) juvenile criminals attended primary school.

![Figure 1: Education of juvenile criminals](image)

**Age**

The age group starts from below 12 years and till 18 years. These age limitation was also amended by Juvenile Justice Act 2000. It is seen from the collected data that major age group was found to be between 16 to 18 years and out of 485 juvenile criminals the number of juvenile criminals who belong to this category are around 339(69.8%), as the age increases anti-social activities also increases. The minimal juvenile delinquents belong to below 12 years of age that is about 8.1%. The juvenile criminals between 12 years to 16 years are 107(22.06%)

It is found out from the above analysis that overwhelming majority of the juvenile delinquents belong to the age group 16 -18 years of age.
Our collected data indicates that out of 485 criminals a large majority i.e. 243 (50.1%) of the juvenile criminals had annual income of Rs. 50,001 - 1,00,000 and the remaining 50% have a varied annual income. Juvenile criminals with annual income of Rs. 25,001 to Rs. 50,000 are 40 (8.2%) and criminals with middle income of Rs. 1,00,001 - 2,00,000 are 191 (39.38%). There were no criminals with annual income more than Rs. 3,00,000 and very little criminals belong to the upper middle class. Findings summary indicated that most of the criminals were belonging to poor families which were resource poor or were earning limited income. It can be said that poverty and wishes for better life were leading these young children towards crime.
Nature of the crime

Table 1: Nature of crime of juvenile criminals

<td>100</td>
</tr>
</tbody>
</table>

The table 1 depicts the crime committed by the juvenile criminals. About more than 3/4 of the criminals have committed theft. 3.9% of the criminals are involved in criminal trespass or burglary. The remaining criminals have committed varied crimes like robbery, murder, dacoity, culpable homicide not amounting to murder and other IPC crimes.

It can be said that theft and criminal trespass or burglary are the majority of the crimes committed by juvenile criminals. So it can be inferred that the juveniles have committed these crimes mostly for their income generation.

Family background

Our data reveals that the majority of the criminals which is 283 (58.3%) live with their parents and 70(14.4%) criminals are living with their guardians. On the other hand, 132(27.3%) criminals are homeless. The criminals who are with their parents should have committed crimes in order to satisfy their daily and family requirements.

![Figure 4: Family background of juvenile criminals]
Recidivism

In Chennai majority of the juvenile criminals (93.1%) have been apprehended for the first time. Minority of the juvenile criminals (6.9%) have been apprehended in the past. Most of the juvenile criminals who have committed crime for the first time have not reoffended the crimes for the second time.

**Figure 5: Recidivism of juvenile criminals**

Discussion

Education

From our study it is found that majority of the juvenile offenders in Chennai belong to above primary but below matric education category. But no one had the opportunity to study matric or higher secondary. And about 19.7% of the juvenile criminals are illiterate. According to times of India, out of the 7,870 juveniles apprehended in 2015, 3,088 have only been educated up to a primary level, 902 were illiterate and 3,261 had an educational background till higher secondary. For many young offenders, education has long been a struggle. Peter Leone, a professor of behavior disorders at the university of Maryland who specializes in youth incarceration, said that kids who do poorly in school early on are more likely to be truant, or to participate in the sorts of low-level criminal activity that send many kids to detention facilities. The evidence is clear that poor school performance, truancy, and leaving school at a young age are connected to juvenile delinquency.

Age

In our study it is found out that over whelming majority of the juvenile delinquents belong to the age group 16 -18 years of age and minimal juvenile criminals are below the age of 12 years. As per the statistics released by the National Crime Bureau (NCRB), juvenile criminals between 16 and 18 years accounted for more than 60% of the crimes registered against minors in India in 2013. So it is evident that most of the juvenile offenders belong to the age group 16-18 years of age. However, when the latest trends in juvenile delinquency in India are analyzed, in respect of the age pattern and nature of offences committed, it appears that we need to review and amend our juvenile justice policy (Shivani Goswami and Neelu Mehra, 2014). The same kind of trends appeared in US and UK, with peaking of heinous crimes committed by the juveniles in the age group of 16 to 18 years (McDowell, L. Gary, Smith, Jinney, 1999). So there should be strict laws for such juveniles. So that a person cannot be remained unpunished in the cover of a juvenile. Studies of criminal activity by age consistently find that rates of offending begin to rise in preadolescence or early adolescence, reach a peak in the adolescence, and fall through young adult.

Economic status

On analysis of our data it indicates that a large majority i.e. 50.1% of the juvenile criminals had a...
income of Rs.50,001 -1,00,000 and the remaining 50% have a varied annual income and very little criminals belong to the upper middle class. There were no criminals with annual income more than Rs.3,00,000.similarly in a research conducted in Madurai kamaraj university on a study of the causal factors leading juveniles to be in conflict with the law in Tamilnadu indicates that nearly 42 percent of the children come from poor economic condition of their parents (or) family. Around 47 percent of the children belong to normal economic condition of their parents (or) family and only 5.4 percent come from rich back ground [3].One of the important reason for juvenile delinquency is poor economic status. Low income is not, as we have seen, often a single direct cause of juvenile delinquency. It is a complex of factors associated with low income: bad housing, slum neighborhood, prevalence of gangs and lack of community organization. From the above discussion it is understood that people with low economic status tend to commit crimes more than people with moderate economy in order to improve their economy.

Nature of crime

In our study about more than 3/4 of the criminals have committed theft 3.9% of the criminals are involved in criminal trespass or burglary. In similar studies conducted in Maharashtra and Rajasthan in 2015, the highest share of cases registered against juveniles were reported under the crime head “theft” (19.2%), “rape” (5.4%), and kidnapping and abduction (5.2%) [6]. The most involved criminal activity is theft. These crimes are almost always likely to rise with poverty. Thus, both poverty and income inequality are considered to be reasonable proxies of resource deprivation. But, some other types of crimes are different in their relationship with poverty.

Family background

The data in our study reveals that the majority of the criminals (58.3%) live with their parents and 14.4% of the criminals are living with their guardians. On the other hand, 27.3% of the criminals are homeless. Another study done by the child line, India in 2004 reveals that children living with parents/guardians accounted for 76.6% of the total juvenile arrested. The number of homeless children arrested for various crimes was only 7.5% [7]. As a child’s emotional attachment to his parents ensures a well- adjusted adult, so parental rejection of the child has powerful opposite effects. Rejection by the family, which is the child’s first and fundamental “community,” sets the stage for another social tragedy. Rejected children tend gradually to drop out of normal community life. Bonding between children and parents is critical to helping protect against youth violence.

Recidivism

On analysis of the data it is seen that majority of the juvenile criminals (93.1%) have been apprehended for the first time. Minority of the juvenile criminals that is 6.9% have been apprehended in the past. In an identical study too, among the 211 juveniles interviewed, 174 juveniles (82%) indicated that they were the first time offenders whereas only 37 juveniles (18%) mentioned that they were repeat offenders [6]. While researchers have not yet been able to establish a direct causal relation between these two variables, it has been demonstrated that poor academic outcomes can adversely affect a child’s behavior, and early behavioral problems can lead to poor academic outcomes. Studies have also shown that rates of recidivism are highly correlated with low levels of academic performance. Lastly, research has demonstrated that the implementation of sound academic interventions, particularly in reading, can effectively reduce rates of both delinquency and recidivism.

Conclusion

Juveniles involved in crimes are not criminals, in fact, they are victims of society. Juvenile delinquency can be stopped at an early stage, provided special care is taken both at home and in school. Parents and teachers play a significant role in nurturing the mind of a child. Instead of labeling them as criminals or delinquents- steps need to be taken to give them a scope of rectification and it would be better if the errors in their lives (involving social and psychological) are brought to their notices. Juvenile delinquent needs the sympathy and understanding of our society and not the heavy hand of the law. In India, it is indicated from the crime trends that existing laws (prior to 2016) were not proving to be a deterrent. The constant exposure of children to violence and lack of understanding about the consequences of crime committed makes them quite prone to delinquent tendencies. The problem gets worsened in absence of some adults in role of responsible guardians to give them and help them in filtering the information that comes to them through various sources. The primary socialization that functioned through groups such as family, peer groups, traditional neighborhood ties, close kin circles.
is fast becoming ineffective in Indian society. All this has lead to present trends in juvenile delinquency. It is hoped that the study findings will be useful for increasing greater awareness about the profile juvenile criminals, enhancing sensitivity towards the vulnerability of juveniles in conflict with law and planning for systematic rehabilitation.

**Recommendation**

1. Training should be given to the parents who are not able to adjust with their children’s behavior, by the family consellors’

2. Create the awareness about the moral education and behavioral changes among the school children by the school teachers, NGO’s, counsellors

3. Creating and inspiring team work of private and public agencies to prevent the increasing delinquency

4. Giving preparatory training to the members and staff of all organizations concerned with delinquency control.

5. Establishing child guidance clinics to give appropriate treatment to the disturbed and mal adjusted children in schools and all local areas especially rural and slum areas.

6. Counselling centre in every school should be established for early detection and care of the problematic children in the school

7. General awareness programmes should be launched for educating the family to motivate the children in developmental activities.

8. Proper healthy recreational facilities should be provided in rural areas and slums so that the children may channelize their energies in the right directions and neutralize the criminal tendencies.

9. Giving proper assistance to under privileged children to build them with good character.

10. Improving the social environment – slum areas, devoid of gambling centers to prevent children from getting polluted.

Abstract

At present, the question of the effectiveness of the use of bioflavonoids in the treatment of the alcoholic liver disease is of practical interest and attention from modern medicine. **Aim of our research** is to analyse the antioxidant properties of Enoant in alcoholic liver and to establish the ultra morphostructural changes in liver tissue. **Materials and methods** - assessment of changes in alcohol-impaired rat liver were studied before and after administration of Enoant bioflavonoid concentrate. **Results** - The positive effect of “Enoant” is explained by the antioxidant properties of bioflavonoids, their ability to reduce peroxidation of proteins, stimulate reparative processes, activate protein synthesis and enhance the system of antioxidant protection of hepatocytes. All this allows to attribute the concentrate of bioflavonoids “Enoant” to highly active hepatoprotectors and is of practical interest at all stages of treatment of patients with different stages of liver lesions.

**Keywords:** Alcoholic liver damage, Liver tissue morphology, Concentrate of bioflavonoids “Enoant”, Antioxidant properties of bioflavonoids, Toxicology, Liver pathology.

Introduction

At this time, according to WHO, there is an increase in the number of liver diseases. Alcohol is one of the etiological factors that cause these diseases. Depending on the dose and duration of its use, various forms of damage occurs from alcoholic fatty infiltration to alcoholic cirrhosis [1, 4, 6, 7]. The basis of liver damage by alcohol is the activation of free-radical processes [8, 9, 10]. Medicines used in the complex therapy of these diseases have more than 1000 names. Among them are drugs that increase the resistance of the liver to pathogenic factors and restore its functional activity [5, 11].

Biological activity of grape processing products which are rich in polyphenols as well as their benefits of the human health are well known and worth of studying. It was first shown in Toulouse, France, that cardiovascular mortality stayed the lowest in Europe despite the high level of dietary saturated fats. It was named “a French paradox” [12]. It was proved later that the paradox is caused by the cardioprotective action of polyphenols in red wines that are the traditional beverages of an average Frenchman. Polyphenols are supposed to act as antioxidants that neutralize free radicals, decrease oxidative enzymes’ activity and reduce peroxide lipids’ levels in blood serum [13]. One of the richest sources of polyphenols is *Vitis vinifera*, and products of its processing, including flavonoids and other polyphenols of grape, wine, and grape seeds, are of a great interest due to their antioxidant properties and the ability to scavenge free radicals [14].

Substances of plant origin, in particular, concentrate of polyphenols of grapes “Enoant”, are quite promising for clinical hepatology. Monomeric grape polyphenols have a pronounced antioxidant activity. In the concentrate of “Enoant”, it mainly consists of components of flavonoids. Their therapeutic effect is due to the ability to bind with free radicals, that stimulate the synthesis of proteins and macro-energies, which facilitates the course of biochemical reactions.

Evaluation of hepatoprotective efficacy and experimental justification for the use of bioflavonoids concentrate “Enoant” for the treatment of liver diseases is a very important issue to be discussed.

**Purpose of the Study**

Aim of our research is to analyse the antioxidant properties of Enoant in alcoholic liver and to establish the ultra-morphostructural changes in liver tissue.

**Material and Method**

The model of alcoholic liver damage in rats was used in the research. The nature and extent of alcoholic damage to the liver was studied morphologically, including electron and light microscopy.

The experiments were performed on 60 non-linear white rats (mean weight 200-230 g), divided into 3 series of 20 animals each. 1st series - intact animals (control). Animals of the 2nd series were injected into the stomach with 40% ethanol for a period of 90 days at a rate of 0.016 ml of 40% ethanol per 1 g of body weight [2]. To the animals of the 3rd series, after a 90-day alcohol intoxication, the probe was injected for 21 days with a concentrate of bioflavonoids “Enoant” at a dose of 0.25 ml per kilogram of weight [3].

**Results and Discussion**

As a result of morphological examination, by the method of light microscopy, the characteristic signs of alcoholic injuries were revealed:

- dyscirculatory (hyperemia of sinusoids and central venules);

- alternative, in the form of fatty and hydropic dystrophy of hepatocytes;

- Mononuclear infiltrates of portal tracts and periportal area.

Electron microscopy of hepatocytes, endothelial cells and stellate reticuloendotheliocytes in animals treated with ethanol for 90 days revealed a number of dystrophic changes.

The nuclear membrane of hepatocytes had foci of loosening and invagination, causing the contours to lose clarity. In places, the nuclear membrane was destroyed. Chromatin is condensed unevenly and dispersed as fragments throughout the nucleus area. The perinuclear space is greatly enlarged. Tanks of the granular endoplasmic reticulum were expanded and had the appearance of electron-transparent vacuoles. Hepatocyte mitochondria had edema and a rounded shape, with an electron-transparent matrix. The destruction centers of the outer membrane of the mitochondria and their cross were determined (Fig. 1). The number of ribosomes on the membranes of the granular endoplasmic reticulum was significantly reduced compared to the control group.

**Fig. 1. Round-shaped mitochondria with swollen and clarified matrix, cells of destruction of the cross and outer membrane of the mitochondria. Electronic micrograph. Magnification x 50,000.**

In most of the hepatocytes there was a pronounced loosening of the cytosol due to the disappearance of glycogen granules and intracellular edema, which was accompanied by a pronounced decrease in the electron-optical density of the cytoplasm (Fig. 2). In the cytoplasm, many transparent vacuoles were noted.

The cytoplasm of endothelial cells was electron-transparent, with frequent lipid inclusions. The nuclei of the endothelial cells became elongated, with deep invaginations of the nuclear membrane. Karyorrhexis was observed.

The cytoplasmic membrane, facing the sinusoid lumen, was partially destroyed and loosened. The lumen of the sinusoids revealed destructively altered
fragments of cell membranes and a structured substance of uneven electron density. There was a sharp swelling of mitochondria, some mitochondria had ruptured membranes and crosses. The cytoplasmic processes of the endothelial cells contained virtually no micropinocytosis vacuoles.

Fig. 2. Cytosol loosening in the cytoplasm of hepatocytes. Perinuclear edema. Electronic micrograph. Magnification x 2000.

Dystrophic changes in organelles were in the cytoplasm of stellar reticuloendothelial cells. The mitochondria swelled, their matrix became electron-transparent, the number of crosses decreased. The endoplasmic reticulum looked like transparent vacuoles. The Golgi lamellar cytoplasmic complex was moderately reduced. In Electron microscope, the experiments of this series, marked sharply expressed plethora of sinusoids, erythrocyte sludge, enlargement of intra acinar bile ducts and ducts.

To study the therapeutic effect of concentrate bioflavonoids “Enoant”, after 90 days of alcohol intoxication, on the background of complete alcohol deprivation, the experimental animals were administered concentrate for 21 days (3 series). In this series of experiments it was found that the trabecular structure of the liver tissue was preserved. Sinusoids were occasionally enlarged only in single preparations, the boundaries of the sinusoids were clear, the phenomena of hyperemia were absent. The dyscirculatory changes consisted only of the plethora of the interosseous veins, but not of the sinusoids. Vacualization of hepatocytes was extremely rare (Fig. 3).

Fig. 3. Minimal dystrophic changes in the liver after the use of concentrate “Enoant” on the background of previous alcohol intoxication. Painting hem-eos. Mag. x 200.

There were no alterative changes in most micropreparations. Dystrophic changes were limited to separate centers of evacuation. Hepatocytes with large nuclei and fine-grained chromatin prevailed. Duplicate hepatocytes were encountered around large portal tracts, indicating an increase in liver regenerative potency. There were many hepatocytes with hyperchromic nuclei and homogeneous light eosinophilic cytoplasm (without evidence of hydropic dystrophy). A lively histioliymphocytic response was observed in the portal tracts and the proliferation of sinusoidal cells was well expressed (Fig. 4).

Fig. 4. Proliferation of sinusoidal cells. Hematoxylin-eosin staining. Magnification x 200. [vol. 20, approx. 10]

At the ultrastructural level, the state of the cell organelles did not differ from the control: the hepatocyte nuclei were rounded, centered or eccentric. The outer and inner membranes of the nuclei were clearly observed. Chromatin was evenly distributed in the nucleoplasm. The mitochondria had a typical structure, the crosses were tightly packed. Tanks of the granular endoplasmic reticulum were slightly expanded (Fig. 5).
In the cytoplasm of hepatocytes contained many membrane-bound and free ribosomes. Submicroscopic organization of endothelial cells was not different from the norm. Activation of intracellular metabolic processes was noted in stellar macrophages. This was manifested in the moderate expansion of the granular endoplasmic reticulum tanks and the Golgi hypertrophy.

**Conclusion**

The enteral use of concentrate of bioflavonoids “Enoant” immediately after the cessation of alcoholization, reduces the damage from alcohol. After the application of “Enoant” was observed complete restoration of trabecular structure of the liver. Around the large portal tracts, in some cases, double-core hepatocytes appeared, as well as hepatocytes with hyperchromic nuclei and homogeneous light eosinophilic cytoplasm, with no evidence of hydropic dystrophy. This indicates an increase in the reparative capacity of the liver tissue.

The positive effect of “Enoant” is explained by the antioxidant properties of bioflavonoids, their ability to reduce peroxidation of proteins, stimulate reparative processes, activate protein synthesis and enhance the system of antioxidant protection of hepatocytes. All this allows to attribute the concentrate of bioflavonoids “Enoant” to highly active hepatoprotectors and is of practical interest at all stages of treatment of patients with different stages of liver lesions.

Effectiveness of Ocular Muscle Exercises on Myopic Individuals with Forward Head Posture

Shradha Patel1, Trupti Yadav2, Amrutkuvar Pawar2, Radhika chintamani2

1Intern, Faculty of Physiotherapy, KIMS “Deemed to Be University” Karad, Maharashtra, India,
2Assistant professor of Department of Musculoskeletal Sciences, Faculty of Physiotherapy, KIMS “ Deemed To Be University” Karad, Maharashtra , India

Abstract

Background: The dependence of today’s younger generation on technology is increasing and the work hours spent by professionals in front of computer screens are also increasing. These are the leading causes of myopia. Task related postural adaptation may also cause myopia. However, very few if any people suffering from myopia are being referred to a physiotherapist. There is positive effect of ocular muscle exercises on increasing visual acuity and decreasing stress on the ocular muscles.

Objective: The objective of this study was to find out the effect of ocular muscle exercises on myopic individuals with forward head posture.

Method: There were total 46 subjects who were willing participants of this study. They were divided in two groups one excremental who received exercises while other was control. Pre intervention and post intervention postural assessment were taken and analysed.

Result: There was a significant effect of the ocular exercises on craniovertebral angle of these myopic individuals compared control group (p = 0.0219). Its effect on forward shoulder angle was not quite significant (p = 0.0619).

Conclusion: Ocular exercises are not quite effective in improving forward head posture.

Key Words: Ocular exercises, craniovertebral angle, forward shoulder angle .

Introduction

Myopia is a refractive defect of the eye in which collimated light produces image focus in front of retina when accommodation is relaxed. Myopia is commonly known as nearsightedness. Here, objects that are close appear clear but distant objects appear blurred.1

Myopia can be classified as low Myopia to high myopia with dioptres ranging from - 0D to -8.0D2 Incidence of myopia has increased from 0.4% (1993) to 34.2% (2016). In India, the incidence of myopia in individuals older than 40 years of age is 34.6% In children it is 4.7%, 7% and 10.8% in 5, 10 and 15 year olds. Prevalence of myopia in India is 45% (2012).4

Prevalence of forward head posture in myopic individuals (2019) is 58.95%.

Forward head posture is defined as excessive anterior positioning of the head in relation to a vertical reference line. The thoracic spine thus goes into kyphosis to compensate for this and the pelvis tilts anteriorly. A myopic individual may generally squint, tilt their head or lean forwards in an unnatural position to see clearly. This leads to problems of neck, upper and lower back causing muscle imbalance. It could manifest as tingling or numbness. Burning pain between shoulder blades is also

Treatments that alleviate the problem temporarily are used. Over time however, these problems worsen and may lead to more severe complications. Photogrammetry can be used to measure the angle by taking a picture of the patient’s head and neck from the lateral view or it can be measured manually. Angles can be measured using Web plot digitizer software. For measuring the angle three dots of an image are transformed onto Cartesian coordinate’s axis and the angles are auto calculated.

Symptoms of myopia are blurring of far objects, eye strain, squinting, excessive bending forwards, headaches, abnormal titling of head and excessive blinking.

Posture is rarely mentioned by researchers, although in a study it was found that head posture is correlated with myopia. Workers in textile industries who had to lean forwards to carry out the task of detecting and correcting flaws in the fabric in which correlation between myopia and duration of work was found. In another study of a group of clinical microbiologists who worked for a minimum 20 hours per week. A high prevalence of myopia of 71% was found in them. A study on analysis of head position used by myopes and emmetropes when performing a near-vision reading task proved that posture might play some role in myopia development. The effect of extraocular muscles on eye ball could cause myopia.

In a study ocular exercises were designed and were implemented on student population which showed improvement in the visual acuity. Therefore, focus needs to be put on studying effect of ocular muscle exercises on myopic individuals with forward head posture.

**Methodology**

An approval for the study was obtained from the Protocol committee and the Institutional Ethical Committee of KIMSDU. 80 individuals were approached and screened out of which 46 were selected according to the inclusion criteria of age 18-32 years, duration of myopia for 1 years and above and Myopia of -0.25 to -6.0D degree of. The procedure was explained and written informed consent was taken. Exercises were explained thoroughly which included palming exercises, swinging exercises, eye muscle exercises, cross crawl, tibetan eye chart. Exercises were given twice a week for six weeks. Pre and post intervention postural assessment was taken and analysed.

**Result**

**1. DISTRIBUTION OF FORWARD SHOULDER ANGLE:**

<table>
<thead>
<tr>
<th>2. Forward shoulder angle</th>
<th>Mean ± ± SD</th>
<th>Paired t-test</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Pre Intervention</td>
<td>Post Intervention</td>
</tr>

</table>

**Interpretation:** Table no 2 shows that the mean Craniovertebral angle in group A pre intervention was 44.39 ± 4.85 and post intervention was 54.39 ± 6.34. In group B it was 56.65 ± 5.16 pre intervention and 56.65 ± 7.35 post intervention. The paired t test for Group A angle had t-value 2.019 and p-value 0.0559 which is not quite significant. For Group B, angle had t-value 0.000 and p-value >0.9999. Intergroup post-test values according to unpaired t-test, t-value was 2.377 and p-value was 0.0219 which is significant.

**Discussion**

The aim of this study was to find out the effect of ocular muscle exercises on myopic individuals with forward head posture. The objectives of this study were to assess young adults with myopia for forward head posture. To assess the severity of the postural misalignment in relation to the degree of myopia. To assess the severity of the misalignment in relation to the duration of myopia and to observe the effect of ocular muscle exercises on forward head posture. An effort to find the association between the effects of the ocular muscle exercises with the effects of not administering any exercise program was made.

Total 80 myopic individuals were screened for forward head posture and 46 individuals fulfilling inclusion and exclusion criteria were selected. 46 subjects of both the genders of age group 18-32 and degree of myopia ranging -0.25 to -6.0 D were selected. They were divided into two groups, A and B respectively where group A was administered an exercise protocol and group B underwent no form of exercise protocol. Palming, cross crawl, swinging exercises, eye muscle exercises and Tibetan eye chart were included in the exercise protocol for group A. Exercises were given twice a week for six continuous weeks. Forward shoulder angle and craniovertebral angle were measured using Web Plot Digitizer and Pre and post measurement for posture was taken.

The mean Forward shoulder angle in group A pre intervention was 64.22 ± 12.82 and post intervention was 53 ± 8.23. In group B it was 56.87 ± 14.15 pre intervention and 58.26 ± 9.77 post intervention. Forward shoulder angles were measured pre-intervention and post-intervention, the effect of exercise was not quite significant as seen by p value of 0.0862 of group A and not significant p value of 0.6623 of group B. Intergroup post-test values according to unpaired t-test t-value was 1.916 and p-value was 0.0619 which is not quite significant.

The mean Craniovertebral angle in group A pre intervention was 44.39 ± 4.85 and post intervention was 54.39 ± 6.34. In group B it was 56.65 ± 5.16 pre intervention and 56.65 ± 7.35 post intervention. Effect of exercise on craniovertebral angle was also found to be not quite significant as seen by p value 0.0559 of group A and not significant p value >0.9999 of group
B. Intergroup post-test values according to unpaired t-test, t-value was 2.377 and p-value was 0.0219 which is significant.

Higher amount of near work load, head positions during performing tasks could also make these exercises insufficient even if the eye exercises are effective in bringing about a change, which could have been a possibility in present study. Stress on eyes, exposure to electronic devices, improper postural adaptations, head position while a near task was performed etc, may be the factors due to which the exercises may not be effective in improving visual acuity. Increasing the interventional period could help improve the effectiveness of ocular muscle exercises on posture.

Rahul Pandey et al. studied effect of eye exercise on myopia in children aged between 10-15 years and concluded that visual acuity and ocular health was improved with eye exercises in children with myopia.

The reason for this discrepancy in this study results may be due to various factors. The study included myopic children with a degree of myopia under -3D only whereas this study had a mean degree of -3.25D which is significantly more than their study. Also, the study was conducted in children in contrast to this present study which was on young adults. These young adults will comparatively have myopia for more duration compared to the children. Poor postural habits and stress over the neck and eyes have had a greater time to build in young adults compared to children and thus may be more difficult to treat.

Thus, the present study concluded that the ocular muscle exercises were not quite effective in improving the forward head posture or degree of myopia. There are multiple studies supporting the result but there are also considerable number of studies that contradict the present result. On the basis of this it is safe to say that more detailed and precise research must be conducted to find conclusive results. This can be done by increasing the frequency and duration of exercises, including individuals with uniform demographic data and using more efficient outcome measures. As a result, there is immense scope for further research in this topic.

CONCLUSION:

On the basis of the results of the study, there was some improvement in forward head posture however it was statistically not quite significant. There was a difference in alteration of both forward shoulder angle and craniovertebral angle measurements in Group A and Group B pre and post treatment but were not quite significant.

**Conflict of Interest:** There were no conflicts of interest in this study

Abstract

Creation of an individual’s biological profile is of extreme importance and depends on age, sex and stature. The cranial and pelvic bones are important in identifying the sex of an individual. However, loss of complete bones or bones getting destroyed renders it impossible to use them for such estimations. However, since such sex-specific bones are hard to find at each and every scene, forensic experts are left with no choice but to depend on less sexually dimorphic elements of the human skeleton such as the sternum.

This study was conducted in subjects that were subjected to medicolegal autopsy. The deceased aged 18 years and above, of either sex, were included in study. The deceased with evidence of trauma and surgery to the anterior chest wall, generalized bone diseases, observable deformities over the sternum were excluded. The analysis of 300 sterna was carried out to study sexual dimorphism in sternum using different parameters such as width of suprasternal notch, width of sternum at level of fourth rib, posterior curved length of sternum, manubrio-corpus index and length of sternum.

Key words – Sexual dimorphism, sternal measurements, sternum.

Introduction

In forensic medicine, characterization of the biological profile of a deceased includes investigating the individual’s age, sex, stature etc. Although pelvic and skull bones are known to be best identifiers of an individual’s sex, relying on only these two bones for sexual dimorphism is limiting, considering their fragile nature or instances of their unavailability. Therefore, intensive research work has been performed and confirmed the potential use of sternum to detect sexual dimorphism. Moreover, manubrium and sternum are reported to have a high recovery rate as it resists the effects of putrefaction and decomposition for a long period of time.

Sex estimation from sternal remains relies on factors of sexual dimorphisms, such as length and proportion differences of the manubrium, corpus sterni and combined length of manubrium and mesosternum between males and females.¹ Sexual dimorphism has been considered in sex estimation from sternum, specifically with the application of Hyrtl’s law which stipulates the length of a female’s manubrium to exceed half the length of the corpus sterni, while those of the male sterna are, at least double the manubrium length.² This study of sexual dimorphism in adult human sterna is also carried out to compare and analyse the sternal measurements among both genders.

Materials and Method

This autopsy study was conducted in the mortuary at the department of forensic medicine, Topiwala National Medical College, Mumbai after obtaining permission from the institutional ethics committee.

This study was conducted in subjects that were subjected to medicolegal autopsy. The deceased aged 18 years and above, of either sex, were included in study.
The deceased with evidence of trauma and surgery to the anterior chest wall, generalized bone diseases, observable deformities over the sternum were excluded. During the period of November 2014 to August 2016, 150 (50%) sterna of males and 150 (50%) of females were studied. The preliminary data, in each case, was collected from the inquest report and hospital indoor paper records in admitted cases.

During the autopsy ‘I’ shaped incision was taken from chin to pubis symphyses. The skin over the chest, subcutaneous tissue under the skin and pectoralis muscles on both the sides was separated carefully. The clavicle was disarticulated from sternum and sternum was removed by cutting ribs by their costal cartilage. After removing the sternum from the thoracic cage, the sternal margins that articulate with the cartilages of the first seven pairs of ribs were carefully dissected. The sternum was washed and soft tissue was scraped and direct measurements were taken using a calibrated vernier calliper and measuring tape. After noting the measurements the sternum was placed back in the body. The xiphoid process was not taken into consideration in the present metric study to measure the length of sternum because of the high variability of its length.

The following measurements were taken keeping the bone on a flat surface in anatomical positions:

1. Width of suprasternal notch (WS).
2. Width of sternum at level of 4th rib (WM4).
3. Posterior curved length of sternum (PCL).
4. Distance from suprasternal notch to manubrio-mesosternal junction in midline (M)
5. Distance from manubrio-mesosternal junction to mesosternal-xiphoid junction in midline (B)
6. Manubrio – corpus index (MCI) = M / B x 100
7. Length of sternum (in cm) = M + B

Baseline study participant characteristics were described using descriptive statistics like mean and standard deviations. The unpaired ‘t’ test was used to compare the mean values between males & females. Discriminant functional analysis was done to examine the sexual dimorphism in the sternum and how the variables correctly assigned the bones to the proper sex.

Findings

A mean WS in males (30.67 ± 4.96 mm) was more in comparison with that of females (28.61 ± 4.32 mm). In males, the largest WS noted was 45 mm while the smallest was 20 mm in length. In females, the largest observed WS was 43 mm and the smallest WS was 21 mm in length. Similar findings were reported by Mukhopadhyay, who studied 35 adult sterna in West Bengal, India, that WS was more in males than females. However he observed that the mean WS in males was 5.71 ± 0.39 cm and that of females was 4.79 ± 0.31 cm which was far greater than the mean WS observed in the present study. The ROC for WS was equal to 0.629 (95% confidence interval (CI) of 0.566-0.693) with 60% sensitivity and 64% specificity. Results of present study showed that, if WS is greater than 29.5 mm, the cadaver is that of a male whereas if WS is <29.5 mm it belongs to a female.

The mean WM4 in the present study was greater in males (33.25 ± 5.60 mm) than females (30.19 ± 4.56 mm). The largest WM4 in males, was found to be 48 mm as compared to that in females which was 40 mm; while the length of the smallest WM4 was observed to be 22 mm in both the genders. The mean WM4 of males and females studied by Mukhopadhyay were 5.3 ± 0.31 cm and 4.4 ± 0.33 cm respectively. Their findings were more than those found in present study. The ROC for WM4 was equal to 0.659 (95% CI of 0.596-0.722) with 62% sensitivity and 68% specificity. Results of present study showed that, if WM4 is greater than 31.5 mm, the cadaver belongs to a male and if WM4 is <31.5 mm it belongs to a female.

The mean PCL was greater in males (140.37 ± 12.90 mm) as compared to females (135.10 ± 11.09 mm). The maximum length of PCL observed in both the genders was same, i.e. 185 mm. However, the minimum length of PCL in males was noted to be 124 mm and that in females was 115 mm. However Mukhopadhyay noted the mean PCL in males as 22.4 ± 1.01 cm; females as 17.92 ± 0.98 cm which are more than that observed in present study this might be due to regional and ethnic variations in population. The ROC for PCL was equal to 0.628 (95% CI of 0.564-0.691) with 52% sensitivity and 67% specificity. Results of present study showed that, if PCL is greater than 137.5 mm, the cadaver belongs to a male whereas if PCL is <137.5 mm it belongs to a female.

The mean length of manubrium (M) was greater in females (46.06 ± 4.66 mm) as compared to males (42.58 ± 5.74 mm). The distance from suprasternal notch to manubrio-mesosternal junction in midline of sternum ranged from 65 mm (maximum) to 34 mm (minimum) in males and from 60 mm (maximum) to 35 mm in females.
However, the findings observed were in contrast to previous studies where the lengths of the manubrium were reported greater in males rather than females.1,5,6,7 This might be due to regional and ethnic variations in population. The ROC for length of manubrium was equal to 0.297 (95% CI of 0.238-0.356), hence it cannot be considered as a parameter for sexual dimorphism.

The mean mesosternum length (B) was greater in males (97.4 ± 10.79 mm) as compared to females (87.72 ± 8.4 mm). The distance from manubrio-mesosternal junction to mesosternal-xiphoid junction in midline of sternum ranged from 140 mm (maximum) to 83 mm (minimum) in males and from 120 mm (maximum) to 75 mm (in females). These results are in accordance with the studies of Gautam et al7 (95 mm males; 76 mm in females), Dahiphale et al5 (94.427 mm in males; 70.191 mm in females) Ankit et al6 (92.11 mm in males; 78.28 mm in females), Hunnargi et al1 (89.17 mm in males; 72.38 mm in females), Ramadan et al8 (100.7 mm in males; 85.1 mm in males) and Puttabanthi et al9 (92.36 mm in males; 88.95 in females). The ROC was equal to 0.773, with 95% confidence interval 0.721-0.825, showing mean mesosternum length can be considered as a good detective test with 63% sensitivity and 69% specificity. In agreement with previous studies and the results of present study, we agree that the length of mesosternum is a reliable parameter in determining the sex of a deceased.

A highest manubrio-corpus index of 61.91 in male cadavers and 70.51 in female cadavers; and the lowest observed manubrio-corpus index was 25 in male cadavers and 40 in female cadavers. The mean (SD) manubrio-corpus index in males was 43.91 (5.32) and that in females was 52.70 (4.98). Though the samples follow Hyrtl’s law and statistically significant gender differences are obvious, sternal indices among males and females shows considerable overlapping. Therefore, the manubrio-corpus index (MCI) is not helpful when applied to detect sexual dimorphism of an individual specimen. Similar conclusions were reported by various researchers, viz. Hunnargi et al1, Dahiphale et al5, Ankit et al6, Puttabanthi et al9. On similar grounds, Ashley10 and Jit et al11 also reported the index to be ‘unreliable’. Since the ROC for manubrio-corpus index was equal to 0.097 (95% CI of 0.012-0.10), hence it cannot be used as a detective test.

The mean combined length (M+B) observed in the present study was greater in males (139.98 ± 14.40 mm) than females (133.94 ± 11.78 mm). The maximum distance from suprasternal notch to mesosternal-xiphoid junction in midline of male cadavers was 188 mm and in female cadavers was 177 mm. The minimum distance from suprasternal notch to mesosternal-xiphoid junction in midline of male cadavers was 119 mm and in female cadavers was 110 mm. The results obtained in present study are in accordance with those reported by several previous studies.1,5,6,7,8,9 According to results of present study, the distance from suprasternal notch to mesosternal-xiphoid junction in midline can be considered as an excellent detective test since the ROC curve was equal to 0.935 with 95% confidence interval of 0.90-0.97, 99% sensitivity and 90% specificity.

**Conclusion**

Distance from suprasternal notch to mesosternal-xiphoid junction in midline i.e. sternum length can be considered as excellent detective test for sexual dimorphism from sternum. Parameters like width of suprasternal notch (WS), width of sternum at the level of 4th rib (WM4) and the posterior curved length of sternum (PCL) can be considered as average parameters for sexual dimorphism from sternum. Length of manubrium (M) and the manubrio-corpus index (MCI) are not helpful for sexual dimorphism.

It has been observed that detection of sexual dimorphism using sternum is subjected to population diversity. To obtain an excellent detective test to access sexual dimorphism of adult human sterna from different measurements of sternum, a detailed analysis in a larger sample size and closed Indian population is warranted.

**Abbreviations**

- WS - Width of suprasternal notch.
- WM4 - Width of sternum at level of 4th rib.
- PCL - Posterior curved length of sternum.
- M - Distance from suprasternal notch to manubrio-mesosternal junction in midline.
- B - Distance from manubrio-mesosternal junction to mesosternal-xiphoid junction in midline.
- MCI - Manubrio – corpus index = M / B x 100
- M+B - Length of sternum (in cm).

Effect of Jack Knife Stretching Versus Proprioceptive Neuromuscular Facilitation (Hold Relax) Stretching Technique in Asymptomatic Individuals with Hamstring Tightness: A Randomized Clinical Trial

Amruta Kabra¹, Kajal Salekar², Tanvi Kalanekar³, Kajal Salekar²

¹Second year MPTh student, Faculty of Physiotherapy, KIMSDU, Karad, Maharashtra, ²Second year MPTh Student, Faculty of Physiotherapy, DPU, Pune, Maharashtra, ³Second year MPTh student, Faculty of physiotherapy, GNDU, Amritsar, Punjab 143001

Abstract

Background: Study is to compare the effectiveness of Jack knife stretching and Proprioceptive Neuromuscular Facilitation (PNF) stretching Technique in asymptomatic individuals with hamstring tightness.

Aims and Objectives: 1. To study the effect of jack-knife stretching on the individuals with asymptomatic hamstring tightness in terms of Active knee extension test, finger to floor, passive SLR and LEFS Questionnaire. 2. To Study the effect of PNF stretching on individuals with asymptomatic hamstring tightness. 3. To compare the effect of Jack knife and PNF stretching in individuals with hamstring tightness.

Material and Method: Ethical approval was obtained. 56 healthy subjects were assigned into two groups. PNF (hold relax) stretching technique was given to the Group A and Group B received Jack Knife stretching. Active knee extension test, Finger to floor test, Passive single leg raise test and Lower extremity functional scale these parameters were measured.

Results: Intra-group comparison for all the outcome measures in both the groups showed statistical significance. Inter-group comparison for all the outcome measures for both the groups had differences but showed statistical significance. Group B Jack knife stretching was more effective than group A PNF (hold relax) stretching.

Conclusion: The present study results indicate that to increase hamstring flexibility both the treatment techniques i.e PNF stretching and jack knife stretching are effective in asymptomatic individuals with hamstring tightness. Thus, our study shows jack knife stretching gives immediate effect due to closed pack position of stretching compared to open pack position of PNF group.

Keywords: Hamstring Tightness; PNF Stretching, Jack Knife Stretching

Introduction

Almost everyone, regardless of age knows and values the ability to function as independently as possible during activities of daily life.¹ Humans have the capability to produce infinite variety of postures and movements that will need the structures of human body to both generate and respond to forces that produces and control movement at the body’s joints.² The movement occurring in the human body is caused by the musculature system.³ There are about 700 muscles, which are attached to the bones of the skeletal system that make up up-to half of the person’s body weight. Hamstring muscles is situated at the posterior part of the thigh. It includes 3 muscles – biceps femoris muscle, semitendinosus

muscle, semimembranosus muscle. These muscles share some common characters of which is its origin which is from ischial tuberosity and its insertion into one of the bones of the leg. Nerve supply to these group of muscles is from the tibial part of sciatic nerve. These muscles function together for the flexion of the knee (front bending of the knee) and helps in the extension of hip (moving the hip backwards). These muscles also help in rotating the knee. According to Darlene Hertling, the term muscle tightness refers to adaptive shortening of the contractile and non-contractile elements of muscle. Inability to achieve more than 160 degree of knee extension with hip at 90 degree of flexion is considered as hamstring tightness. Hamstring tightness can be treated successfully in many ways like with cryotherapy, thermotherapy, stretching and spray, ultrasound, soft tissue massage, shortwave diathermy, myofascial release, and muscle energy technique, bowen technique.

Jack knife stretch for improving the hamstring flexibility was tested by Michelle Hamilton. Benefits of these stretch include improvement of the blood flow to the lower extremities, relaxation of tight hamstring and many more. The stretch is to be held for 5 second’s and is to be repeated 5 times, 2 sets every day.

Hold relax PNF stretching facilitate muscle relaxation and increases the range of motion. This PNF stretching is facilitated by the Golgi tendon organ. The stretch is to be held for about 6 seconds and is to be repeated thrice and is then repeated on the other side. Outcome measures which are being used in study are lower extremity functional scale (LEFS), active knee extension test, popliteal angle, finger to floor test and passive SLR test.

Aims and Objectives

1. To study the effect of jack-knife stretching on the individuals with asymptomatic hamstring tightness in terms of Active knee extension test, finger to floor, passive SLR and LEFS Questionnaire.

2. To Study the effect of Proprioceptive neuromuscular facilitation stretching on individuals with asymptomatic hamstring tightness in terms of Active knee extension test, finger to floor, passive SLR and LEFS Questionnaire. 4

3. To compare the effect of Jack knife stretching and Proprioceptive neuromuscular facilitation stretching in individuals with asymptomatic hamstring tightness in terms of Active knee extension test, finger to floor, passive SLR and LEFS Questionnaire

Methods & Methodology

Ethical approval was obtained from the Institutional Ethical Committee and written consent was obtained from the participants of our study. The present randomized clinical trial was carried out among 56 normal healthy subjects which comprised of both male and female between the age of 18-24 years and were assigned into two groups. PNF (hold relax) stretching technique was given to the Group A and Group B received Jack Knife stretching technique. Six alternate sessions were given to both the Groups for two weeks. Active knee extension test, Finger to floor test, Passive single leg raise test and Lower extremity functional scale these parameters were measured pre intervention and post intervention.

Procedure

The purpose of this study was explained to all the subjects volunteered in the study. A written informed consent was also obtained from all the subjects. The subjects were then screened upon the basin of the inclusion and the exclusion criteria and were selected based on the inclusion criteria. Subjects were explained about: Pattern of study, Need of study, Information generated out of the study. Once the consent was taken detailed information was gathered and statistical analysis was done in order to derive conclusion. Subjects in both the group’s, PNF (hold-relax) group and the jack-knife group were assessed before starting the treatment. Demographic data was collected with the initial assessment of the pre-treatment measurements of finger to floor test for flexibility of the hamstring muscle, active knee extension test to measure the popliteal angle, passive SLR test to check the range of motion and the lower extremity functional scale to check the limitations of work due to tight hamstrings.

PNF(hold-relax) Group

1. The subject is told to lie down in a supine lying position.

2. The subject is then told to take a belt which he/she has to place it under the sole of the foot, the two ends of which will be held by the patient.

3. The other leg of the Subject is stabilized by the belt to the table.
4. The subject is now asked to raise his leg straight with knees in extension to the level where he cannot take his leg further and hold the position with the help of the cloth for 30 seconds and then relax repeating it 3 times.

5. Alternate day intervention will be given for 2 weeks.

Jack-knife Group

1. In this technique, subject is asked to squat completely and hold the ankles from behind and then instructed to extend the knees holding the ankle wherein the chest the subject is in complete contact with the thigh.

2. This position is held for 5 seconds and is repeated 5 times.

Jack knife Stretching

Result

Components of demographic data such as age, height, weight, BMI were analysed and compared between the two groups. Pre intervention measurements and post intervention measurements were compared between the groups (intergroup comparison) by using independent t-test. Probability values less than 0.05 were considered statistically significant. To find the significance of the study parameters between two groups paired t-test was used, and Kolmogorov smirnov test was used to find the pair wise significance of the outcome measures i.e active knee extension test, passive SLR, finger to floor test and LEFS.

The mean± SD before intervention is 34.86±9.28 and after intervention is 46.8±9.60 in PNF group and mean± SD pre intervention is 31.43±8.47 and post intervention after 2 weeks is 49.8±10.7 for active knee extension by independent t test in Jack knife group. For finger to floor test pre intervention mean± SD is 17.16±6.47 and post intervention 9.19±3.65 for Group PNF. Mean± SD for group Jack knife pre intervention is 17.96±6.49 and post intervention is 7.43±6.22. In passive SLR Baseline mean
receive passive mobilization. The subjects stretching increased their range of passive single leg raise to a higher degree and at a faster rate than the subjects receiving PNF hold relax mobilization on increasing hamstring muscle length. The conclusion of our study was that the subjects receiving the PNF hold relax stretching for 6 alternate sessions for two weeks, our study also showed improvement in the flexibility of hamstrings to a greater extent when measured for FTF test, PSLR test, AKET and LEFS. Hence our study came to a conclusion that, Jack-knife stretching technique and PNF(hold-relax) stretching technique when compared are equally effective in increasing the hamstring flexibility and ROM when administered for six sessions alternatively for 2 weeks. It also concluded that Jack-knife group showed significantly more improvement then PNF (hold-relax) group in terms of FTF, PSLR, LEFS and AKET. As per our knowledge, this is the first study comparing the effect of Jack-knife and PNF(hold-relax) on hamstring flexibility in healthy individuals with alternate 6 day sessions intervention. Hence jack knife stretching showed immediate effect on hamstring tightness as it is closed pack position, PNF stretching technique is in open pack position which again one of the impact factor for the result. Hence both the techniques can be used clinically to increase the flexibility and range of motion of the hamstring muscle.

Discussion

The present study was conducted to compare the effects of jack knife stretching and PNF (Hold relax) stretching on asymptomatic subjects with hamstring tightness. An alternate day intervention was done for two weeks (six sessions) to see which stretching technique is more effective in increasing hamstring muscle flexibility in terms of Active knee extension test, passive single leg raise test, finger to floor test and lower extremity functional scale.

Koichi Sairyo has done study on tight hamstring muscle for four week by using jack knife stretching. Pelvis forward inclination angle (PFIA) and finger to floor distance (FFD) were the parameters included in the study. FFD was 14.1 ± 6.1 cm before the intervention and decreased to -8.1 to 3.7 cm by the end of 4 week. Which indicated the gain of hamstring flexibility by 22cm. PFIA was 50.6± 8.2 before the experiment and 83.8± 5.8 degree after the intervention was given. Before and after the experiment difference of outcome measure were significant (p<0.05) which concluded that jack knife stretching is useful technique to improve flexibility of tight hamstring. After the application of jack knife stretching for 6 alternate sessions for two weeks, our study showed significant improvements in hamstring flexibility in terms of finger to floor test, lower extremity functional scale and increase in range of motion in terms of active knee extension test and passive single leg raise test. Scott G. Spernoga, Timothy et al conducted a study to see the duration of maintained hamstring flexibility after a one time modified hold relax PNF stretching protocol concluded that 5 min. of hold relax stretches produced significantly increased hamstring flexibility that lasted for 6 min after the stretching protocol was given. One study was done by Marvin C. Tanglawa in comparing the hold relax PNF stretching and passive mobilization on increasing hamstring muscle length concluded that the subjects receiving the PNF hold relax stretching increased their range of passive single leg raise to a higher degree and at a faster rate than the subjects receiving passive mobilization. A study carried out by Jill M Binkley et al to assess the reliability, validity and sensitivity of Lower Extremity Functional Scale (LEFS) concluded that the test retest reliability of LEFS scores were excellent (R= 0.94 with … interval = 0.89 ) and that LEFS is efficient to administer and is applicable for research purpose as well as for clinical practice. A study undertaken by Michelle Hamilton to compare if standing jack-knife stretch is better than seated for hamstrings included 17 youths aged between 8-18 years with back pain who performed 2 sets of stretch twice a day for 04 weeks. One set consisted of 5 repetitions of jack-knife stretch holding it for 5 seconds and FTF forward bend test was taken to establish a baseline of flexibility. This study concluded standing jack-knife stretch increases flexibility in hamstrings After the application of jack-knife stretching technique for six sessions alternatively for 2 weeks our study also showed improvement in the flexibility of hamstrings to a greater extent when measured for FTF test, PSLR test, AKET and LEFS. As per our knowledge, this is the first study comparing the effect of Jack-knife and PNF(hold-relax) on hamstring flexibility in healthy individuals with alternate 6 day sessions intervention. Hence jack knife stretching showed immediate effect on hamstring tightness as it is closed pack position, PNF stretching technique is in open pack position which again one of the impact factor for the result. Hence both the techniques can be used clinically to increase the flexibility and range of motion of the hamstring muscle.

Conclusion

The present study proves that both the stretching techniques that is Jack knife and Proprioceptive neuromuscular stretching are equally effective for increasing the flexibility of hamstring muscles in individuals with asymptomatic hamstring tightness. However, jack-knife stretching technique showed immediate effect on hamstring tightness compared to Proprioceptive neuromuscular facilitation stretching. Thus, both the stretching can be used in clinical practice for improving the flexibility of hamstring muscle.

Comparative Effectiveness of Kinesio Taping and Ift in Upper Cross Syndrome- A Randomized Clinical Trial

Amrutkuvar Rayjade¹, Trupti Yadav², Radhika Chintamani³, Nisha Joshi³

¹Associate Professor, ²Assistant Professor; Department of Musculoskeletal Sciences, Krishna College of Physiotherapy, Krishna Institute of Medical Sciences “Deemed to Be” University, Karad,
³MPT, Sports Physiotherapy

Abstract

Background: Upper cross syndrome refers to a particular configuration of overlapping overactive and underactive muscle groups in the neck, chest and shoulders. Typically, poor posture causes the syndrome, including the forward head posture, which occurs when people use electronic devices, read, and drive. The present study is intended to investigate the effect of kinesio taping on upper cross syndrome

Objectives: 1. To study the effectiveness of kinesio taping, Hot Moist Pack and exercises in upper cross syndrome, 2. To study the effectiveness of IFT, HMP and exercises in upper cross syndrome and 3. To compare the effectiveness of kinesio taping and IFT in upper cross syndrome.

Methodology: The study consisted of 2 groups. Group A was experimental group and Group B was conventional group. Both the groups received treatment protocol for 2 weeks. Sample size was 60 with 30 in each group.

Results: Visual analogue scale, cranio-vertebral angle and forward shoulder angle were used as outcome measures. Statistically significant results were found with VAS p=<0.0001, cranio-vertebral angle p=0.0632 and forward shoulder angle p=0.285

Conclusion: The study concluded that the use of kinesio taping is recommended in reducing pain and improving the neck angles in participants with upper cross syndrome as compared to conventional therapy.

Key Words: Conventional Physiotherapy, IFT, kinesiotaping, upper cross syndrome

Introduction

Crossed syndromes are characterized by alternating sides of inhibition and facilitation in the quadrants. The muscle imbalances are seen between the fronts and back of the body or sometimes in left and right side of body.

Upper cross syndrome (UCS) is also referred as proximal or shoulder crossed syndrome. According to Dr. Vladimir Janda, upper cross syndrome is characterized by tightness of the upper trapezius, levator scapulae on dorsal side crosses with tightness of pectoralis major and minor. Weakness of the deep cervical flexors ventrally crosses with weakness of middle and lower trapezius¹.

This pattern of imbalance creates joint dysfunction, particularly at the atlanto-occipital joint, C4-C5 segment, cervicothoracic joint, glenohumeral joint, and T4-T5 segment. Janda noted that these focal areas of stress within the spine correspond to transitional zones in which neighboring vertebrae change in morphology²,³,⁴.

Specific postural changes are seen in UCS, including forward head posture, increased cervical lordosis and thoracic kyphosis, elevated and protracted shoulders, and rotation or abduction and winging of the scapulae¹.

As these muscles help maintain spinal curvature in turn normal body posture. When these muscles undergo imbalance gives rise to altered posture and signs and symptoms related to it. These kind of postural alterations are seen in all aged population.

Because of increased work stress and sedentary lifestyle, the society is becoming more flexion-addicted attitude. In which people tend to frequently stoop forward. This is seen in office workers and students who tend to sit at a desk for prolonged periods, slouching forward to see the computer screen. Students carrying heavy backpacks also tend to lean forward. All these reasons in turn increase prevalence of UCS.

Poor posture leads to consequences such as, pain in the neck, mid-back muscle spasm/tightness, decreased range of motion, fatigue, arthritis due to uneven joint wear over time, increased risk for disc herniation, headaches, reduced performance which collectively reduces quality of life.

There are different treatment approaches available for UCS Out of which one of the successful treatment approach is physiotherapy.

Kinesio tex tape has been modified since its creation to mimic the qualities of skin. This tape has been designed to allow longitudinal stretch of 55-60 % of its resting length. This degree of stretch approximates the elastic qualities of human skin. The thickness of the kinesio tex tape is approximately the same as that of epidermis of the skin. This was intended to limit the body’s perception of weight and avoid sensory stimulus. The composition of kinesio tex tape is polymer elastic strand wrapped by 100 % cotton fibers which absorbs moisture from skin. These tapes are latex free. The adhesive is 100 % acrylic and heat activated. Kase et al have proposed several benefits, depending on the amount of stretch applied to the tape during application:

1) To provide a positional stimulus through the skin,
2) To align fascial tissues,
3) To create more space by lifting fascia and soft tissue above area of pain/inflammation,
4) To provide sensory stimulation to assist or limit motion, and
5) To assist in the removal of edema by directing exudates toward a lymph duct.

Various therapeutic currents have been used for modulating clinical pain. Interferential current (IFC) is a medium frequency (3000–5100 Hz) alternating current with a beat frequency ranging from 0 to 250 Hz.

Interferential current (about 100 Hz for TENS), IFC produces lower impedance on skin and subcutaneous tissue, therefore the theoretical penetration power should be deeper than that of TENS (6). Studies have demonstrated that IFC is effective in managing pain conditions such as migraine and muscle soreness.

The analgesic effect of interferential therapy can be explained in part by Wednesky inhibition of Type C nociceptive fibres, although other mechanisms are certainly involved. ‘Pain gate’ theory, proposed by Malzack and Wall and much modified subsequently remains central to this explanation.

Methodology

It was an comparative study in the physiotherapy department of Krishna institute of medical sciences. Ethical permission was obtained from institutional ethical committee, KIMSDU, Karad.60 subjects were equally divided into 2 groups using lottery method. Subjects were selected according to inclusion and exclusion criteria. The inclusion criteria was as follows 1) Both male and female participants with clinical diagnosis of upper cross syndrome. 2) Age group between 21 to 40 years. 3) Participants willing to participate in the study.

The exclusion criteria was as follows. 1) Degenerative condition of spine. 2) Cervical rib. 3) Thoracic outlet syndrome. 4) Tumors or malignancies. 5) Subjects with mental disorders. 6) History of spinal surgery. 7) Clinical conditions such as over sensitive skin, pregnancy, pacemakers etc. where IFT application is contraindicated. 8) Any shoulder pathology causing limitation of movement.

The exclusion criteria was as follows. 1) Degenerative condition of spine. 2) Cervical rib. 3) Thoracic outlet syndrome. 4) Tumors or malignancies. 5) Subjects with mental disorders. 6) History of spinal surgery. 7) Clinical conditions such as over sensitive skin, pregnancy, pacemakers etc. where IFT application is contraindicated. 8) Any shoulder pathology causing limitation of movement.

Written informed consent form was taken, and the whole study was explained to them. A detailed musculoskeletal evaluation was done to screen the subjects.

Study Design : Experimental study

Setting : Krishna Hospital, Physiotherapy Department
**Study population:** All participants were selected by Simple Random Sampling method. Participants were selected on the basis of inclusion and exclusion criteria. Selected participants were then randomly divided into 2 groups.

**Procedure:**

Both groups received respective training for 4 weeks.

**Group A:**
- Pectoralis major inhibitory technique: tonus-decreasing muscle application
- Middle and lower trapezius facilitation technique: tonus-increasing muscle application
- Deep neck flexors and serratus anterior strengthening
  - 10 rep* 3 sets
- Middle and lower trapezius strengthening
  - 10 rep* 3 sets
- Stretching of pectoralis major and minor muscles
  - 30 sec hold* 5 rep
- Hot Moist Pack for 15 mins

**Group B:**
- Hot moist pack 15 mins for upper back
- IFT 20 Mins for upper back
- Deep neck flexors and serratus anterior strengthening
- Middle and lower trapezius strengthening
  - 10 rep* 3 sets
- Stretching of pectoralis major and minor muscles
  - 30 sec hold* 5 rep

**Variables:**
1) Visual analogue scale
2) Cranio-vertebral angle
3) Forward shoulder angle

**Study size:**
The study size was 60
- Group A – 30
- Group B – 30

**Statistical analysis**

Statistical analysis of the study was done manually as well as using the instat software so as to verify the results. The data was entered into an excel spread sheet, tabulated and participated to statistical analysis. Various statistical measures such as mean, standard deviation and tests of significance such as paired ‘t’ test and unpaired ‘t’ test were utilized for all the available scores in all the participants. Nominal data from patient’s demographic data i.e. age, sex distribution were also analyzed. Intra group comparison of pre interventional and post interventional outcome measures was done using student paired ‘t’ test whereas Unpaired ‘t’ test was utilized to measure the difference between two groups (Intergroup comparison)

Discussion

The present clinical trial was conducted to compare the effectiveness of kinesio taping in Upper cross syndrome. Results of this study were focused on pain relief, improvement of cranio-vertebral angle and forward shoulder angle. It was noticed that there was improvement in all the above parameters in both groups.

A combination of pain assessment by visual analogue scale (VAS); cranio-vertebral angle and forward shoulder angle range of motion assessment outcome measures were used to assess the effectiveness of kinesio taping in Upper cross syndrome.

In this study, the age group of the participants was in between 21 to 40 years. Participants between this age group were prone for upper cross syndrome because of increased work stress and sedentary life style, the society is becoming more flexion-addicted attitude. In which people tend to frequently stoop forward. This is seen in office workers and students who tend to sit at a desk for prolonged periods, slouching forward to see the computer screen. Students carrying heavy backpacks also tend to lean forward. All these reasons in turn increase prevalence of UCS.

Sample size of present study consisted of 28 females and 32 males that are 46.66% females and 53.33% males. When the intragroup mean values of visual analogue scale (VAS) were analyzed it was found statistically significant in both groups pre to post intervention p=<0.0001. The adhesion of the K-Tape to the skin, and the resulting mechanical displacement caused by body movement, leads to stimulation of the mechanoreceptors in the skin. Like the nociceptive afferents, these proprioceptive afferents also run to the dorsal horn and inhibit the relaying of nociception. Additionally strengthening and stretching exercises for affected muscles along with electrotherapy modalities might have helped in reducing pain by improving balance of short and weak muscles.

The results of this study found that there was significant improvement in cranio-vertebral angle p=0.0632 and forward shoulder angle p=0.285 within groups pre and post intervention. There was significant difference was seen on comparing the pre session and post session values between the groups. Possible reasoning for improvement in these angles could be in a tonus-increasing muscle application; the elastic stretch tape exerts tension via the restoring force in the direction of origin to the fixed base, and thus displaces the skin in the same direction. This brings about support of the muscle contraction. In a tonus-decreasing muscle application, the elastic stretch tape exerts tension in the direction of insertion to the fixed base and likewise displaces the skin in the same direction. This causes a reduction in muscle contraction.

Limitations:

1. Small sample size
2. Participants could not be followed up after the study.
3. Duration of the study was short.

Recommendations:

1. Studies with longer duration are recommended with longer follow-up period to assess long term benefits.
2. Study can be conducted with larger sample size.
3. This was a heterogeneous group with both male and female population, future studies could be done taking up a homogenous sample with either male or female participants separately.
Conclusion

In conclusion, the present experimental study provided evidence to support the use kineio tape in relieving pain, improving range of motion and improving the cranio-vertebral angle and forward shoulder angle in participants with Upper cross syndrome.

Proportion of Diagonal Ear Lobe Crease and its Association With Sudden Death Due to Coronary Artery Disease- An Autopsy Study

Anwar Abdul Rahman1, Renju Raveendran2

1Senior Resident, 2Professor, Department of Forensic Medicine, Government Medical College, Kottayam.

Abstract

Coronary artery disease has been a number one killer worldwide and in India it has increased phenomenally as the most important cause of sudden natural death of cardiac aetiology in the last few decades. Changing lifestyles, stress, habits, presence of other predisposing pathologies etc have played direct as well as indirect roles in its causation. Conventionally the predictors for coronary artery disease have been predominantly risk factors. Notwithstanding this, of recently a number of extra cardiovascular physical parameters like ear lobe crease have shown a reasonably promising trend in predicting the presence of coronary artery disease thereby enabling prompt intervention which in turn can reduce cardiac mortality in the long run. The present study focuses on this aspect of detecting an association between diagonal ear lobe crease and sudden death due to coronary artery disease. A total of 188 cases brought for medicolegal autopsy was studied. It has been revealed that diagonal ear lobe crease detected at autopsy has a statistically significant association with both the presence of coronary artery disease as well as the severity of atheromatous occlusion in sudden deaths. Hence diagonal ear lobe crease can have a reasonable predictive value in detecting coronary artery disease that could be used for the early detection of individuals with coronary artery disease and thus pave the way for early interventional strategies.

Key words: diagonal ear lobe crease, coronary artery disease, sudden death, extra cardiovascular physical predictors.

Introduction

Atherosclerosis is a major source of disability and leading cause of mortality in India. Coronary artery atherosclerosis has resulted in millions of citizens suffering either a fatal myocardial infarction or stroke associated death 1. Premature mortality because of cardiovascular disease in India has showed a phenomenal rise especially during the last few decades2. Many of these catastrophic events were in individuals free of prodromal symptoms and often without classical risk factors such as hypertension, hyperlipidemia, diabetes, tobacco use, obesity, or sedentary lifestyle. This “detection gap” has spurred clinicians to attempt to find extravascular physical signs which might identify individuals at high risk of atherosclerosis and consequent cardiac fatalities. “Frank’s sign or diagonal ear-lobe crease” is found to be associated with the development of premature atherosclerosis of the coronary arteries.

It has been postulated that diagonal ear-lobe crease and coronary artery atherosclerosis originate simultaneously because the ear lobe and heart are supplied by “end arteries” without the possibility for collateral circulation.3 Still controversies exist regarding the association between them4. If there is such an association, an intervention at the right time could bring down the mortality rate due to cardiovascular disease. Several studies conducted abroad have demonstrated an association between ear lobe crease and sudden death5,6,7,8, 9. So, this study is scientifically challenging and socially relevant to these changing times as far as cardiovascular disease and sudden death is concerned.
Materials and Method

This was a cross sectional study conducted in the Department of Forensic Medicine, Government Medical College, Kottayam during the period from 1st March 2017 to 28th February 2018. All sudden death cases in the age group 15-60 years brought to the department for medico-legal autopsy were selected. A total of 188 such cases were studied. Relevant details of the deceased regarding the previous history of illness, details of the present illness, treatment history etc were obtained from the police and the available close relatives. All cases were studied for diagonal ear lobe crease and categorized as:

1. absent
2. unilateral
3. bilateral

Coronary arteries were examined for atheromatous thickening of the intima, calcification, any haemorrhage into the atheromatous plaque and thrombosis. Circumference of coronary artery, 5 cm distal to its origin was taken using twine and measured using Vernier callipers. Thickness of coronary artery wall was also measured using Vernier callipers. From these measurements, area of original lumen and residual lumen of coronary artery and the percentage of occlusion were calculated mathematically.

Results

Among the 188 cases studied, the greatest number of victims were in the age group of 40 to 60 years (48.94%). The youngest age to participate in the study was 18 years, whereas the eldest was 82 years. The mean age of the study sample was 50 years with a standard deviation of 14.

Of the 188 cases, 163 (86.7 %) were males and 25 (13.3 %) were females. The lowest age among the females was 32 years and the highest was 82 years. On the other hand, the lowest age among males was 18 and the highest was 82 years.

In the present study, the most common cause of death was cardiovascular disease (64.9%) and among this, coronary artery disease due to atherosclerosis accounted for 62.2%. Second commonest cause was respiratory system disorders (21.3%). Third commonest cause was central nervous system diseases (7.4%) followed by gastrointestinal system disorders (2.7%) and those related to the genito-urinary system (3.7%), which were by far the least common. Among coronary artery disease, males are mostly affected (92.3% and 96.4%) compared to female (7.7% and 3.6%) in younger and middle age groups respectively. But during old age, it was seen that the proportion of females with coronary artery disease rose to 25%. In male population incidence was more during middle age (51%) but in female population incidence was more during old age (69.2%).

The subjects were classified into three categories based on presence of ear lobe crease as: a. Absent. b. Unilateral ear lobe crease and c. Bilateral ear lobe crease.

Among the study group consisting of 188 cases, 53.2 % had bilateral earlobe crease, 5.3% had unilateral earlobe crease and absent ear lobe crease in 41.5 %.

Table 1: Table showing association of cause of death and diagonal earlobe crease

Diagonal Earlobe crease was present in 69.2 % cases of sudden death due to coronary artery disease and 26.4% cases of sudden death due to other causes. Statistically significant association (Chi-square – 14.666, p value = 0.000) was observed between the coronary artery disease and diagonal earlobe crease.
The subjects were further classified into four categories based on percentage of stenosis as follows:

1. <25% - minimal stenosis
2. 25-50% - mild stenosis
3. 50-75% - moderate stenosis
4. >75% - severe stenosis.

74.5% cases with ear lobe crease showed critical narrowing. Whereas only 25.5% of cases with ear lobe crease showed noncritical narrowing. Statistically significant association (Chi-square for trend – 26.350, *p value = 0.000*) was observed between the severity of occlusion and diagonal earlobe crease.

**Discussion**

Among the 188 cases studied, the greatest number of victims were in the age group 40 to 60 years (48.94%). Regarding coronary artery diseases, nearly half (47%) of cases, were present in the middle age category (40 to 60 years).
In an autopsy study conducted by Salini.R et al\textsuperscript{10} at Government Medical College Thiruvananthapuram, maximum incidence of sudden cardiac death was found to be in the age group of 40-50 years (28.3\%) followed by 27.7 \% in the age group 50-60 years. Therefore, an estimated 55.3\% were in the age group 40-60 years which is very close to our study. In another autopsy study by Deepu.T et al\textsuperscript{11} at Government Medical College, Kottayam, maximum number of Sudden natural deaths due to coronary artery disease were in the 36-50-year age group (42.2\%) and 33.3\% in the 51-65-year age group which is again in agreement with our findings. Among coronary artery diseases, nearly half (47\%) of cases were occurring in the middle-aged group. On increasing age, risk of coronary artery disease was also seen rising exponentially.

In a study by Mittal.G et al\textsuperscript{12} conducted at Kasturba Medical College Mangalore; a male to female predisposition ratio of 7:1 was observed, which is proximate to our findings. In the autopsy study by Salini.R et al\textsuperscript{10}, among coronary artery diseases, incidence was more in males (90\%), which is again consistent with findings of the present study. Incidence of coronary atherosclerosis is very high in males which may be due to high workload, stress, change in dietary habits and addictions like alcohol, drugs and smoking.

In the study group, irrespective of the cause of death 53.2 \% had bilateral earlobe crease, 5.3\% had unilateral earlobe crease and it was found absent in 41.5 \%. As regards coronary artery disease in particular, 69.2\% of them had diagonal earlobe crease. Statistically significant association (Chi-square – 14.666, \textit{p value} = 0.000) was observed between the coronary artery disease and diagonal earlobe crease.

In an autopsy study by Kaukola et al\textsuperscript{13}, ear lobe crease was present in 66.3\% of cases of occlusive coronary artery disease which is in compliance with our findings. As revealed in a British forensic necropsy study\textsuperscript{8}, proportion of diagonal earlobe crease in males and females was (72\%) and (67\%) which is also in agreement with our findings. In the study by Salini.R et al\textsuperscript{10}, ear lobe crease was present in 66.3\% of cases of occlusive coronary artery disease and hence is not inconsistent with the present study.

Statistically significant association was also observed between the severity of occlusion and diagonal earlobe crease with 74.5\% cases showing critical narrowing of the coronary arteries especially the anterior descending branch of the left coronary artery. In an autopsy study by Patel. V et al\textsuperscript{14}, sensitivity of well-defined bilateral diagonal earlobe crease for detecting severe coronary artery disease was 62.1\% for men and 69.2\% for women, which is in accordance with our findings. In an angiogram study by Evrengül H et al\textsuperscript{7}, there was a highly significant statistically greater prevalence of diagonal earlobe crease (51.4\%) in those patients with more than 70\% stenosis than in those whose angiogram was normal (15.1\%), which is evidently lesser than the findings of this study.

As per the present study, horizontal ear lobe crease can be considered as a predictor for the presence of coronary artery disease.

Conclusions

The present study “Proportion of Diagonal Ear Lobe Crease and its Association with Death due to Coronary Artery Disease – An Autopsy Study” was to assess the proportion of new risk factors in coronary artery disease and whether it can predict chances of coronary artery disease so that fatalities due to cardiovascular diseases may be reduced in the future. 1. Majority of victims were in the age group of 40 to 60 years (48.94\%). Among sudden deaths due to coronary artery disease, greater number of victims were present in the middle age group.

2. Males are predominantly affected in sudden death due to coronary artery disease (88.88\%).

3. The most common cause of death was cardiovascular diseases (64.9\%) and among this, coronary artery disease due to atherosclerosis accounted for 62.2\%. Second commonest cause was respiratory system disorders (21.3\%). Third commonest cause is central nervous system disorders (7.4\%) followed by gastrointestinal system diseases (2.7\%) and least commonly those of the genito-urinary system (3.7\%).

4 Among coronary artery disease, 69.2\% of them had diagonal earlobe crease. Statistically significant association (\textit{p value} = 0.000) was observed between coronary artery disease and diagonal earlobe crease. Diagonal ear lobe crease can be reasonably considered as a predictor for the presence of coronary artery disease.

5 74.5\% cases with ear lobe crease showed critical narrowing (more than 75\%). Statistically significant association (\textit{p value} = 0.000) was observed between
the severity of occlusion and the presence of diagonal earlobe crease.

6. Among the three coronary arteries, critical narrowing (more than 75%) was mostly seen in left anterior descending artery (46.3%), followed by right coronary artery (23.4%) and least commonly in the left circumflex artery (9%).

Peek (Polyether Ether Ketone) – A Review Article

Arunmozhi Kannan¹, Praveen P², Sanjna Nayar³
¹Professor, ²Post graduate, ³Professor & Head, Department of Prosthodontics, Sree Balaji Dental College & Hospital, BIHER

Abstract

This article is aimed to review the applications of Polyether Ether Ketone (PEEK) in dentistry. The evolving desire for functions and aesthetics, few drawbacks with existing materials and clinicians shifting their paradigms towards metal free restorations led space for the metal-free restorations in today’s restorative practice. PEEK is a polymer based innovative material, that can be used in either fixed or removable prosthetics. This literature review discusses various applications and uses of PEEK.

Keywords: PEEK, Polyether ether ketone, aesthetics, biocompatibility, restoration

Introduction

Advance in dentistry and development of technologies can be reached by improving materials. Biocompatibility, good oral hygiene, good aesthetics and characteristics close to dental structure are essential to modern materials used in advanced dentistry. It helps to rebuild the defects of the teeth and dentition and please demanding patients. Dental defects can be restored by using fixed or removable restorations. For better aesthetics and metal-free restorative treatment, we can prefer PEEK material which can be used in both fixed and removable prosthesis.

PEEK (-C₆H₄-OC₆H₄-O-C₆H₄-CO-)ₙ is a semi-crystalline linear polycyclic aromatic polymer. Later PEEK became an important high-potential thermoplastic material for alternating metal implant components, in vertebral surgery as a material of the interbody fusion cage. Ma R, Tang T et. Al in 2014 found that, With the introduction of carbon fibre reinforced PEEK (CF/PEEK), this new composite material was exploited for fracture fixation and femoral prosthesis in artificial hip joints¹.

Physical Properties of PEEK

PEEK is rigid, radiolucent material with great thermal stability up to 335.8° C. It is non allergic and has low plaque affinity². Density – 1300 kg/m³, Flexural modulus of PEEK is 140-170 MPa, thermal conductivity 0.29 W/Mk³-⁶. PEEK’s mechanical properties do not change during sterilization process, using steam, gamma and ethylene oxide³,⁵,⁶. Young’s (elastic) modulus of PEEK is 3-4 GPa⁷,⁸. Young’s modulus and tensile properties are close to human bone, enamel and dentin⁹. Polyether ether ketone is resistant to hydrolysis, non-toxic and has one of the best biocompatibility¹⁰,¹¹. PEEK shows stable physical and chemical properties: stability at high temperatures (like sterilization processes), resistance to most substances apart from concentrated sulfuric acid and wear-resistance¹. Lieberman et al.¹² in vitro research comparing PEEK, poly methyl methacrylate (PMMA) and composite resin showed that PEEK has the lowest solubility and water absorption values. As PEEK is quite new material in dentistry comparing to composite, ceramics or zirconia, it is important to find out and summarize its properties. The aim of this literature review is to understand PEEK polymer and its use in dentistry.

Discussion

PEEK is quite new material in prosthodontics. Comparing to the metals used in dentistry, PEEK is more aesthetic, stable, biocompatible, lighter and has reduced degree of discoloration¹³,¹⁴. This fulfills patient’s aesthetic requirements. However, due to its grayish-brown...
colour PEEK is not suitable for monolithic aesthetic restorations of anterior teeth\textsuperscript{15}. High aesthetic material like composite can be used as a layering to obtain desired aesthetics. Air abrasion with and without silica coating creates wettable surface, but etching with sulfuric acid makes rough and chemically processed surface\textsuperscript{3,16}. Low energy of PEEK surface creates resistance to chemical processing. Uhrenbacher et al.\textsuperscript{17} investigated the modification of the surface strength of PEEK crowns adhesively bonded to dentin abutments. The greatest values were found for the airborne-particle abrasion and sulfuric etched groups. The results of Hallmann et al. research show that abraded PEEK surface with 50 μm alumina particles followed by etching with piranha solution lead to the highest tensile bond strength when Heliobond was used as adhesive\textsuperscript{14}. Various research confirms that resin composites can be used as a layering material for the PEEK frames. However, it is hazardous to use concentrated sulfuric acid in dental practice.

Mechanical properties of the PEEK resembles dentin and enamel. Thus its advantageous over metal and ceramic restorations. The fracture resistance of CAD- CAM milled PEEK fixed prostheses 2354N. It has higher resistance than lithium disilicate ceramic (950N), aluminium (851N) or zirconia (981-1331N)\textsuperscript{18}. Mastication cyclically loads the teeth with a 400 N force. As PEEK has high fracture load resistance it is suitable for producing frames. High fracture resistance is also stated in Stawarczyk et al. publications. A mean fracture relative load was 1383 N of 3-unit PEEK frameworks without veneering\textsuperscript{15}.

Relatively weak mechanically in homogenic form. Tannous et al.\textsuperscript{13} in vitro research showed that clasps that are made of PEEK material have low resistance forces than those made of cobalt – chrome metal. Scientists have searched for combinations with other materials, to improve PEEK’s properties. Polyether Etherketonethat are modified containing 20% ceramic fillers known as BioHPP, is non allergic material and has high biocompatible. Possibility of corrections, excellent stability, great optimal polishable properties and aesthetic white shade of BioHPP help to produce high-quality prosthetic restorations\textsuperscript{3}. BioHPP has a great potential as framework material. This is a good alternative to Cr-Co frames for the patients with high aesthetic requirements. But in clinical situations the results might be different. Individual abutments on implants can be milled of PEEK. They are usually used for temporary restorations. Randomized controlled clinical trial showed, that there is no statistically significant difference between PEEK and titanium abutments, causing bone resorption or inflammation. Moreover, the attachment of oral microorganisms to PEEK abutments is comparable to those made of titanium, zirconia and poly methyl methacrylate. Therefore, PEEK is a promising alternative to titanium abutments\textsuperscript{3}. Comparing to titanium, the polymer could exhibit less stress shielding, but very limited inherent osteoconductive properties\textsuperscript{3}. Thus PEEK has better Osseo integrative property. Nowadays, there are many combinations of PEEK with other materials such as fibres, carbon or ceramics. Due to its chemical structure and poor wetting capability of PEEK it is difficulty to fabricate its surface to increase its bond strength and bonding with composites. For better functioning, the surface of PEEK restorations has to be layered by resin composites or lithium disilicate. The best surface processing option is still not found. Moreover, composite as a coating material of the PEEK may degrade with time. So if the polymer frame remains stable, it is necessary to renew the coating material. These are extra expenses to the patient. Unfortunately, there was not enough clinical research made to prove PEEK’s superiority over other materials. There is still not enough information stated about complications, biofilm formation on PEEK surface and its resistance to compression. Even so, PEEK is being used in manufacturing fixed restorations\textsuperscript{17}, dental implants, individual abutments, removable prostheses and their parts\textsuperscript{3} and even maxillary obturator prostheses\textsuperscript{19}.

**Conclusions**

PEEK is an innovative material to use in prosthodontics. Due to its excellent physical, mechanical and chemical properties it is used in fabricating fixed and removable prostheses. As most of the studies have been carried out in vitro, more clinical research is essential for its better applications.

Effectiveness of Strengthening Vs Strengthening with Stretching in Individuals with Nonspecific Low Back Pain

Brity Alex¹, G Varadharajulu²

¹Intern, Krishna college of Physiotherapy, ²Professor and Dean, Department of Neurosciences, Krishna college of Physiotherapy, KIMS “Deemed To Be University” Karad, Maharashtra, India.

Abstract

Objectives:- To assess and compare the effectiveness of strengthening and strengthening with stretching in patients with nonspecific low back pain

Methodology:- There were total 40 patients with low back pain in the study. This study was done to find and compare the effect of strengthening and strengthening with stretching in patients with nonspecific low back pain. The patients were assessed with Visual Analogue Scale for pain and Manual Muscle Testing for the strength before and after 12 weeks of treatment.

Result: Strengthening and stretching of the muscles has effect on the pain reduction as well as strength of the muscles in patients with nonspecific low back pain.

Conclusion: On the basis of the result of this study, it was concluded that the strengthening and stretching of the muscles has effect on the pain reduction as well as strength of the muscles in patients with nonspecific low back pain

Keywords: Nonspecific Low Back Pain, Visual Analogue Scale, Manual Muscle Testing, Strengthening, Stretching

Introduction

Low Back Pain is one of the most commonest musculoskeletal condition affecting the adult population with a prevalence of about 84%[1]. It affects both the genders, but most commonly seen in women than the men[2]. Low Back Pain is the pain which is localized between the 12th rib and the inferior gluteal folds, with or without any radiating pain to the legs[2]. Low Back Pain can be due to degeneration of the spine and discs, trunk stabilizers, jobs that requires repetitive heavy lifting, excessive mechanical stress on the intervertebral disc, along with psychological factors of the patients[2]. Patients complaining of low back pain for almost 3 months may present with decreased muscle strength. Impaired motor control, decreased Co-ordination and Postural Control that interferes with the functional activities of the patients[2].

Age: Children usually do not complain of low back pain, and if they complain that may be because of some Organic disease[12]. Traumatic back pain and postural back pain is the common cause in the adolescent age group[12]. In adults the pain may be due to various conditions such as Ankylosing Spondylitis, Disc Prolapse etc. Degenerative Arthritis or osteoporosis is the main cause of low back pain in elderly[12].

Sex: Women who had multiple pregnancies are mostly affected. Poor Muscle Tone due to Lack of Exercises are the contributory factors in these women. Obesity during the pregnancy can also lead to Mechanical Back Pain[12].

Occupation: Occupation gives us the clues of the risk factors which are responsible for the low back pain people with the sedentary jobs are most likely prone for the low back pain[12].

Physical activity to Increase the Muscle strength as well as the aerobic capacity of the lumbar extensors is an important factor of the patients with chronic low back pain in assisting the patients to complete the activities of daily living[3]. Abnormal habitual posture can lead
to tightness in the lumbo-pelvic Hip complex muscles that can cause abnormal stresses which can increase the shear or the compressive forces on the joints that can lead to excessive stress on the articular surface and further develops mechanical low back pain\[4\].

If the Tensor Fascia Lata which helps the hip joint in flexion, adduction and the internal rotation and helps the knee joint for extension shortens then the Hip joint will be internally rotated more which leads to rotation of the pelvis and that excessive rotation of the hip joint will cause an abnormal alignment of the lumbar spine and the hip joint further leading to pain in the lumbar region\[4\]. Shortening of the Tensor Fascia Lata can increase the iliotibial band tightness which leads to anterior inclination of the pelvis\[5\]. In addition due to shortening and muscle spasm of the hamstring muscle results in a posterior inclination of the pelvis\[5\]. Therefore simultaneous contraction of these two muscles can decrease the flexibility of the pelvis and increase the lumbar stress during the functional activities\[5\].

The related muscle involved are the trunk extensors which become tightened due to prolonged overstretching of the innervated soft tissue, but whereas the abdominal and the gluteal muscle undergo weakness and atrophy\[5\].

Some studies have found that passive and active stretching of the muscles help to improve the flexibility and also increases the Range of Motion in low back pain individuals. Weaker muscles often act as tight muscles, owing to the Neurological changes within the particular muscles which are weak\[6\]. If the muscles are not strong enough to perform the particular action, then it can seize up to protect itself which may further lead to a feeling of tightness\[6\].

The core muscles are the primary muscle group responsible for maintaining the spinal stability\[7,8\]. These muscle includes the transversus Abdominis, lumbar Multifidus, Internal Oblique muscle and the Quadratus Lumborum\[6,7,8\]. The lumbar Multifidus is the muscle which is directly connected to each lumbar vertebral segment and transversus Abdominis and the lumbar Multifidus activate a co-contraction mechanism\[4,5\]. These muscles provides a precise motor control and are thus primarily responsible for the spinal stability\[7,8\].

Most of the low back pain patients experiences fear of pain therefore they tends to avoid the physical activity which can result in tissue and structural changes. Ultimately continuous back pain persists during the lifetime and consequently this can cause secondary damage and followed by recurrence of back pain\[5,7,9\].

**Methodology**

Prior to the commencement of the study the ethical clearance was taken from the Institutional ethical committee. Individuals with Low Back Pain were selected as subjects. The subjects were selected as per the inclusion and exclusion criteria. They were given a detailed instruction about the study. The consent was taken from the subjects. The study was taken place in Satara District.

The duration of the study was 3 months. The sample size for this study was 40 irrespective of caste, religion and gender. After selecting the sample the subjects were divided into two groups randomly. The age group was between 20-40 and both the gender was selected.

The study was conducted in Karad. Demographic Data including name, age, gender, address was collected. Prior to the treatment the pre-treatment assessment was taken. Pain was assessed with the help of visual analogue scale and muscle strength with the help of manual muscle testing.

A detailed instructions were given to the participants about the treatment protocol. Group A was given only the Strengthening program, and Group B was given Strengthening and Stretching program. Group A was given strengthening program for the back muscles. Group B was given strengthening of the back muscles as well as stretching of three muscles.

All the subjects from both the group performed the exercises twice in a week for around 50min per session with the instructor for 12 weeks. Pain assessment and Muscle strength was taken before and after 12 weeks of the exercise program. The score were calculated and data was recorded. Later statistical analysis was done.

**Result**

The MMT post intervention was found to be 4.500 ± 0.5130 for Group A patients and 4.700 ± 0.4702 for Group B patients. A statistically significant increase in MMT score was found in Group B patients when compared to Group A patients where P value is (<0.0001).

Discussion

Low Back Pain is one of the most common musculoskeletal condition affecting the adult population with a prevalence of about 84%. It affects both the genders, but most commonly observed in women than the men. Low Back Pain is the pain which is localized between the 12th rib and the inferior gluteal folds, with or without any radiating pain to the legs. Low Back Pain can be due to degeneration of the spine and discs, trunk stabilizers, jobs that require repetitive heavy lifting, excessive mechanical stress on the intervertebral disc, along with psychological factors of the patients. Patients complaining of low back pain for almost 3 months may present with decreased muscle strength, Impaired motor control, decreased Co-ordination and Postural Control that interferes with the functional activities of the patients.

This research was undertaken with the aim to study and compare the Effect of Strengthening and Strengthening with Stretching in Nonspecific Low Back Pain patients.

A total of 40 Patients with nonspecific low back pain coming in the age group 20-40 years were included in the study out of which 25 were females and 15 were males. The patients were randomly divided into two Groups. The patients were assessed on the basis of Visual Analogue Scale for the pain and Manual Muscle Testing for Strength. Group A was given Strength training and Group B was given Strengthening as well as Stretching.

The pain intensity score of the patients belonging to Group A and Group B was assessed using Visual Analogue Scale (VAS). The scoring range of this scale is in the range of 0-10, where 0 indicates low intense pain and 10 indicates extremely intense pain. The pain score was assessed at rest and on activity pre and post treatment. The baseline mean VAS score pre treatment at rest was found to be 6.470 ± 1.055 for Group A patients and 6.400 ± 0.953 for Group B patients. The treatment Strengthening was given to Group A patients twice in a week and Group B patients Strengthening and Stretching was given for the same duration. The VAS score was reassessed after 3 months in both Group of patients. The mean VAS score post intervention at rest was found to be 5.375 ± 0.968 for Group A patients and 3.300 ± 0.935 for Group B patients. A statistically significant reduction in Mean VAS score at rest was found for Group B patients when compared to Group A patients where the P value is <0.0001. The study conducted by Khwairakpam proved stretching as an effective treatment intervention for patients with chronic mechanical lower back pain whereas this study proves that the combination treatment intervention is superior than single treatment intervention in patients with nonspecific chronic low back pain.

The baseline mean VAS score pre treatment on activity was found to be 8.385 ± 1.177 for Group A patients and 8.515 ± 1.075 for Group B patients. The treatment Strengthening was given to Group A patients twice in a week and Group B patients Strengthening and Stretching was given for the same duration. The VAS score was reassessed after 3 months in both Group of Patients. The mean VAS score post Intervention on activity was found to be 6.925 ± 0.8949 for Group A patients and 4.440 ± 0.8550 for Group B patients. A statistically significant reduction in Mean VAS score on activity was found for Group B patients when compared to Group A patients where P value is <0.0001. The study conduction by Khwairakpam proved stretching as an Effective treatment intervention for patients with chronic mechanical lower back pain whereas this study...
proves that the combination treatment intervention is superior than single treatment intervention in patients with nonspecific chronic low back pain.

The Muscle strength of the patients belonging to Group A and Group B was assessed using Manual Muscle Testing (MMT). The scoring range of this scale is in the range of 0-5, where 0 means no contraction and 5 means full range of motion against gravity with maximal resistance. The strength of the back extensors was assessed pre and post treatment. The baseline mean MMT score pre treatment was found to be 3.450 ± 0.5104 for Group A patients and 3.400 ± 0.5026 for Group B patients. The treatment Strengthening was given to Group A patients Twice in a week and Group B patients Strengthening and Stretching was given for the same duration. The MMT post Intervention was found to be 4.500 ± 0.5130 for Group A patients and 4.700 ± 0.4702 for Group B patients. A statistically significant increase in MMT score was found in Group B patients when compared to Group A patients where P value is (<0.0001) as the strength of the back extensors was found to be increased as Group B patients where given a combination treatment Strengthening and Stretching. This study proves that the combination treatment intervention is effective for the increase in the strength of the muscles.

Conclusion

On the basis of the result of this study, it was concluded that the strengthening and stretching of the muscles has effect on the pain reduction as well as strength of the muscles in patients with nonspecific low back pain.

Abstract

Background: Alcoholism is one of the major health as well as social problem all over the world today. Alcoholism is a family problem, it causes stress in the relationship and misuse affects couples’ relationship in a variety of negative ways. Purpose: To systematically review articles to evaluate the effectiveness of Guided Imagery on Stress and Coping among Wives of Alcoholics in selected De-addiction centre. Method: The search of significant articles including effectiveness of Guided Imagery on Stress and Coping among Wives of Alcoholics was carried out in PubMed/Medline, and Google Scholar. The included studies both qualitative and quantitative were evaluated according to predefined quality criteria. Medline and PubMed were searched to identify peer-reviewed English-language studies published between 1985 and March 2018 reporting on stress and coping among wives of alcoholics. Total 300 studies were selected for review, out of which only 32 were found appropriate to be included in the study. Results: Analysis was done 90 papers were retrieved by the search. Among them, 30 were evaluated to be of higher quality. Studies recruiting sample of wives of alcoholics and excluded wives of non-alcoholics. Conclusion: Based on the review it was concluded that Wives of alcoholics had more stress and social disabilities which were directly related to the severity of husband’s drinking pattern. Wives of alcoholics have highest rate of personality and emotional disturbance. Working women faced lesser stress as compared to non-working women. Wives of alcoholics had poor coping skills. They used maladaptive coping behavior to cope up with their husband’s drinking problem such as but not limited to discord, fearful withdrawal and avoidance were commonly used maladaptive coping behaviors. Relaxation therapies were found to be effective to reduce stress and in improving coping. Guided imagery was very effective in reducing stress and improving adaptive coping among wives of alcoholics.

Introduction

Alcohol poisoning kills six people every day. Three of every four people killed by alcohol poisoning are men.1

Corresponding Author:
Aarti
Nursing Tutor, Maharishi Markandeshwar Institute of Nursing, Maharishi Markandeshwar (Deemed To Be) University, Mullana- 133 207, Ambala, Haryana, India E-mail: aartisainimani@gmail.com

Alcohol addiction causes stress and family disruption. Usually the children and wives of alcoholics have low self-esteem, decreased trust and are less communicative. Alcoholism is the third leading psychiatric problem in the world today.2

Stress now a days is very common and one must learn how to deal with it and also about the stress reduction techniques. Relaxation therapies help to reduce stress and in improving one’s ability to cope with stress and stressful situations.2
Method

A systematic review was conducted by electronic search to identify articles in PubMed/ Medline, and Google Scholar. Inclusion criteria were the studies including stress and coping among wives of alcoholics. Descriptive, cross sectional, systematic review, quasi experimental studies and qualitative studies were included and studies on children and other family members of alcoholics, case reports/series, randomized clinical trials regarding other relaxation therapies except guided imagery were excluded. The search generated a total 92 articles. Out of 90 articles, the full texts of the 32 articles were retrieved and reviewed.

Results

Analysis was done. 92 papers were retrieved by the search. Among them, 30 were evaluated to be of higher quality. A systematic review was done to evaluate the effectiveness of guided imagery on stress and coping among wives of alcoholics.

The reviews were divided into three areas:

• related to the stress among the wives of alcoholics.
• related to the coping among wives of alcoholics.
• related to effect of psychological interventions on stress and coping among wives of alcoholics.

• Review related to the stress among the wives of alcoholics.

Out of 10 studies three studies (30%) were descriptive studies on stress among wives of alcoholics and revealed that wives of alcoholics had moderate to severe level of stress. (3, 4, 5) Another three studies (30%) were a comparative study which focused on comparison of stress level among alcoholic wives and non-alcoholic wives and they revealed that wives of alcoholics had more psychosocial stresses as compared to non-alcoholics spouses. (6,7,8) Two studies (20%) were non-experimental studies which revealed that the stressful life events are significantly higher among spouses of alcoholic in comparison to non-alcoholic’s spouse (9, 10) One cross sectional study to evaluate the quality of life and stress in wives of alcoholics revealed that 55.9% were mothers with a mean age of 47.66 years and 23.8% had depressive symptoms. Mean stress among caregivers was 2.24. There was significant correlation in quality of life, depression and stress of caregivers. (11) One more exploratory study to assess the role of work in lives of wives of alcoholics revealed that majority of working wives reported minimal negative impact of their husbands’ drinking on all areas of their work functioning. The working wives described work as a positive experience they faced the issues such as changing jobs, absenteeism and discussing husband’s drinking at work. None of the study revealed that the wives of alcoholics had no stress. (12)

Sample reviews:

A descriptive study was conducted to assess the level of stress among spouses of alcoholic men admitted at ranipokhri community, Dehradun. Fifty spouses of alcoholic were selected for study by using purposive sampling technique. Tool used for the study were: modified four point likert scale to assess the stress level among the wives of alcoholics.

A comparative study was conducted to assess the stress levels among wives of alcoholics and non-alcoholics at hanumanahalli village, Kolar district. A sample of sixty, 30 wives of alcoholics and 30 wives of non-alcoholics were selected by using purposive sampling technique. A tool used to measure stress level was Perceived Stress Scale (PSS) with the help of Interview Technique. The results of the study revealed that there was a significant difference (χ² = 21.418, df= 1, p<.05) between the stress level scores of the wives of alcoholics and the wives of non-alcoholics (χ² = 9.180, df = 1, p<.05). The study concluded that the research should need to focus on the impact of stress on health. (8)

• Reviews related to the coping among wives of alcoholics.

Out of 11, six studies (46.15%) were descriptive studies on coping strategies among wives of alcoholics and it was found that major coping style used by wives were Avoidance (53%), Discord (57.5%), Fearful Withdrawal (40.4%) and Sexual Withdrawal (25.8%) which were maladaptive strategies of coping. (13, 14,15,16,17,18) Two studies (15.38%) were exploratory studies on assessing the coping strategies among wives of alcoholics and there was difference in the coping strategies between the treatment and non treatment groups. (19,20) Another two studies (15.38%) were
non-experimental studies to assess the psychosocial problems and coping among wives of alcoholics and it was found that about 71.1% women had adaptive and 28.3% showed mal-adaptive coping. Majority of women had physiological problems [13.13%] followed by psychological problems [12.79%] and psycho-social problems [7.40%]. While 6.6% women had financial problems and only 3.92% had sexual problems. (21,22)

**Sample reviews:**

A descriptive study was conducted to assess the coping strategies among wives of alcoholics. Hundred wives of alcoholics were selected in the study by purposive sampling technique. The tool used was ‘Coping with Drinking Questionnaire’. Result of the study revealed that the avoidance was the most commonly endorsed coping behavior. Further the study revealed that there was a significant correlation between all the coping components and alcohol related problems. There was no correlation between neurotism scores and coping behavior. The study concluded that both personality and situational variables play a role in determining the coping behavior of the wives of alcoholics. (15)

A descriptive study was conducted to assess the ways of coping among the wives of alcoholics staying with their husbands. The objectives of the study were to delineate how wives in India cope with their alcoholic husbands and what motivates them to carry on in spite of the husband’s addiction. A total 200 wives of alcoholics were selected and data was collected by tool “Coping Questionnaires”. Results showed that the majority of wives of alcoholics used escape-avoidance as a coping strategy. Further the coping strategies were evaluated by substantial scores translated to relative scores to find out the highest proportion for each coping strategies mean score from 0.14 to 0.16. (17)

- Reviews related to effect of psychological interventions on stress and coping among wives of alcoholics.

Two out of nine studies (22.2%) assessed the effect of guided imagery along with other interventions on stress and coping among wives of alcoholics and it was found that guided imagery when combined with other interventions was effective enough to reduce stress among wives of alcoholics. (23,24) Further two more studies (22.2%) assessed the effectiveness of guided imagery alone on stress reduction among wives of alcoholics and it was found that guided imagery therapy was effective in reducing the level of stress among wives of alcoholics. (25,26) One randomized control study to assess effects of coping skills training, group support, and information for spouses of alcoholics and the study results revealed that changing of coping strategies in spouses of alcoholics can be successful with only one single information session, whereas the reduction of mental symptoms may need longer treatment. (27) One quasi experimental study to assess the effectiveness of coping strategies on stress and coping among the care givers of alcohol dependents revealed that the coping Strategies was significantly effective in improving the coping and reduction of stress among the caregivers of alcohol dependents. (28) One more experimental study to evaluate the effectiveness of three different interventional programmes i.e. Coping Skills Training, Group Support, and Information for spouses of alcoholics and it was found that all the three groups score similarly on 24 months on the four scales which showed long term retention of programme effectiveness is still questioned. (29) Further one more pre experimental study to assess the effectiveness of psycho-educational package on stress and coping among wives of alcoholics revealed that the wives of alcoholics experience more stress and the Psycho-educational package was highly effective in improving the coping level among wives of alcoholics. (30)

**Sample reviews:**

A quasi experimental study was conducted to assess the ways of coping among 200 wives of alcoholics who were staying with their husbands at residential substance abuse treatment facility in Charleston Centre Clinic. Samples were selected by using the convenient sampling technique and the tool used was DASS Stress Scale to assess the level of stress. Guided Imagery technique and intellectual life skill training was given to the spouses of alcoholics. The study revealed that there was significant relationship between Guided imagery and intellectual life skill training and the stress reduction (r(148) = .17, p = .07) among the spouse of alcoholics. (27)

A Pre-experimental one group pre-test post test study was conducted to evaluate the effectiveness of Guided imagery on stress among spouses of alcoholics at de-addiction ward in Government Rajaji hospital, Madurai. Purposive sampling technique was used to select the samples and the sample size was 40. The
data was collected by DASS Stress scale with interview technique before and after Guided imagery. Study subjects were given with Guided imagery technique once a day for 20 minutes for the period of 7 days. The results of the study revealed that there was a significant difference in the mean score of stress before and after Guided imagery as the calculated ‘t’ value was 19.613 at 0.05 level of significance. Further there was no any significant association between the stress score and selected demographic variables. The study concluded that the Guided imagery was cost effective, non invasive, non pharmacological complementary and alternative therapy to reduce the level of stress among spouse of alcoholics. (28)

**Conclusion**

Based on the above stated reviews it was found that: Wives of alcoholics had more stress and social disabilities which were directly related to the severity of husband’s drinking pattern. Wives of alcoholics have highest rate of personality and emotional disturbance. Working women faced lesser stress as compared to non-working women. Wives of alcoholics had poor coping skills. They used maladaptive coping behavior to cope up with their husband’s drinking problem such as but not limited to discord, fearful withdrawal and avoidance were commonly used maladaptive coping behaviors. Engaged and tolerant were commonly used adaptive coping styles by wives of alcoholics. The Psychological interventions such as Guided Imagery, Paced Auditory Serial Addition Test, Coping Skills Training, Group Support and Information, psycho-educational package and intellectual life skill training were effective enough in reducing stress and improving coping among wives of alcoholics.

**Ethical approval:** The ethical clearance was obtained from university research ethics committee of Maharishi Markandeshwar (Deemed To be University) Mullana, Ambala (MMDU/IEC/197) and the study was carried out in accordance with the guidelines laid by Indian Council of Medical Research ICMR(2006). The permission was taken to conduct the study in the De-addiction centre (from Chief Medical Officer of Civil Hospital Ambala city). The written consent from the wives of alcoholics was collected prior to the study. The purpose for carrying out research project was explained and assurance of confidentiality was given to the participants.

Assessment of Epidemiological Causes, Occurrence and Allocation Resulting to Fatality in Two Wheeler Fortuitous Accidents in Uttar Pradesh

Abhishak Kumar Varshney1, Qaiser Rasool Panzoo2, Anuj Gupta3, Vinod Kumar4
1Assistant Professor, Dept. of Forensic Medicine, TMMC & RC, Moradabad, 2Assistant Professor, Dept. of Forensic Medicine, Saraswathi Institute of Medical Sciences, Hapur, 3Associate Professor, 4Professor, Dept. of Forensic Medicine, TMMC & RC, Moradabad

Abstract

Introduction- This study is intended to construe epidemiological causes, occurrence and allocation resulting to fatality in two wheeler fortuitous deaths.

Materials and Method- This observational and cross section study, among the medico-legal autopsies conducted in the study Centre, includes motorized and non-motorized two wheeler associated accidental deaths. It was too assessed to identify the individual, automobile and road issues originating accidents. All findings pertaining to the bodies including wounds were thoroughly observed at autopsy and well interrelated with pat instances.

Results- Two wheeler fatalities in males were found to be considerably much elevated (91.66%) than females. The fatalities percentage in male were recorded as 91.66% whereas in females, it was only 8.33%. The entire victims were in the age group of 20 to 29 years (35%). The preponderance of the victims belonged to the city population which comprised of 48% of the total size. Working and business group individuals were 28%. National highways share maximum numbers of fatalities (37%) whereas roads in villages have comparatively less accidents (13%).

Conclusion- Road traffic accidents are very frequent in the riders of young age group which is also a huge loss to the nation.

Keywords- Epidemiological, occurrence, Road traffic accidents, medico-legal autopsies, two wheeler

Introduction

Road traffic accidents (RTA) are worldwide a great concern as about 3400 people die every day due to them. The predicted figures of such cases are even more devastating as they are expected to be around 1.9 million every year by the year 2020.1 The numbers of losses due to RTA are very high in low and middle income nations which almost covers 90% of worldwide fatalities. On the contrary, countries having 60% of world’s automobile assets have very less number of such cases.2 Developing countries comparatively have major numbers of causalities due to Road traffic accidents (RTA). Two wheelers motor vehicles are major responsible factors for road traffic. Consequently, two wheeler riders are more likely to fall prey to the road accidents. Other than motorcycle users, usual amblers and cyclists too are at risk of road traffic accidents as they are at the directly exposure of the impacting vehicle at the time of collision.

Worldwide increasing RTAs are very much disquieting for all. Despite massive progress and insinuation of advanced technology in medical sciences, the increasing causality and deformity rates occurring due to the road traffic accidents are yet to be controlled.

Rather incidences of R T A have been increasing at an alarming rate throughout the world. Road traffic accidents could be controlled with a strategic planning resulting from the outcomes of this study. Asia-Pacific region alone have almost half of the total road accident fatalities occurring in developing countries which ranges up to 85% of the total accidents recorded globally. India covers about 10% of it. RTAs happen due to certain responsible factors which involve increasing load of traffic and automobiles on roads, rash driving, public in general, over speeding, unskilled driving, poor traffic knowledge, exhaustion due to long driving, mechanical breakdown, pitiable road conditions, infringement on roads, road rule defiance etc. Poor weather conditions too could be responsible for road traffic accidents. In India, Bangalore is recorded to have an adverse rise in road traffic accidents ensuing from escalating populace and traffic on roads. Even RTA cases of two wheelers are very high in numbers in Uttar Pradesh Region. Apparently these accidents seem to be ignored by responsible bodies.

Therefore, this study is intended to construe epidemiological causes, occurrence and allocation resulting to fatality in two wheeled vehicle fortuitous demises.

**Materials and Method**

The practice was carried out at Teerthanker Mahaveer Medical College and hospital from 1st April to 31st March 2018, this observational and cross section study, amongst the medico-legal autopsies conducted in the study centre, includes motorized and non-motorized two wheeler associated accidental demises.

Despite the progression of technology and medical sciences, demises and deformities following road traffic accidents are yet to be controlled. Prevalence of RTAs is mounting at a frightening pace throughout the globe. At the very start of the study, the diverse features of RTA death victims autopsied in the department of Forensic Medicine, TMMC and RC Moradabad were taken into consideration for further findings and analysis. A premeditated arrangement could definitely be ensured to prevent road-traffic accidents with the findings of this study. Furthermore, it was too assessed to identify the individual, automobile and road issues originating accidents. All findings pertaining to the bodies including wounds were thoroughly observed at autopsy and well interrelated with pat instances. The study eliminates RTA deceases causing apart from two wheeled automobiles; accidents and gashes caused without vehicles, and unproven cases.

**Statistical Methodology**

Statistical Software Package SPSS version 20 was used for analysis in the study. Statistical study was exercised for occurrences, amounts, proportions and quotient. Outcomes were construed.

**Results**

On the whole, 610 medico-legal autopsies were performed in the study centre during the calendar year 2018. Out of the total numbers, 287 are RTA incidents and 120 are solely two wheeler associated RTA deaths.

However, this study involves 120 cases of road traffic accidents. The numbers of selected males for the study were 110 that are approx 91.66% of the total sample size and the rest 10 were of females comprising 8.33% of the cases selected. Subsequently, male/female ratio was about 6.91:1 [Table 1].

Discussion

Almost half of entire RTA deaths encompass two wheeler accidents. As a result, two wheeled vehicle users and pedestrian have the uppermost rates of terminal injuries.5,6 Two wheeler accidents are more likely to happen due to various responsible factors which include rapidly increasing numbers of vehicles on Indian roads, vehicle susceptibility, meager road conditions, and moreover unawareness and ignoring tendency of riders to road safety, rules and traffic regulations. In comparison to females, males share major numbers of causalities. The reasons behind such statistics may incorporate the spending of major portions of time in travelling and diverse outdoor engagements by men. Subsequently they are more prone to accidents and have adverse gender proportions.7 The most susceptible age group was identified as between 21–30 years mounting to the total numbers of 56 of total sample size (30.77%) and the slightest affected cluster was of those who were above 70 years of age as they were counted only 2 in numbers amounting to 1.10% of total size selected for the study.8,9 However, it is mentioned as 2% according to Gupta Setal10 & 1% by Menon A and NageshKR.9

One interesting point too was identified in the study. Literacy in general has been found to be playing no significant role in taking caution of accidents or casualties since a fine number of natives, who were recorded to have met with accidents which ultimately resulted in demise, were from educated backgrounds. As mentioned earlier, preponderance of accidents took place on National Highway 113 which mounts to the total percentage of 62.09%.11-13 Though, one possible reason for such big numbers could be the recently constructed main four lane National highway fleeting through Barpeta district which is in good quality condition and hence woos riders for overspeeding resulting in accidents. Highest number of cases were recorded to be in the winter months which reaches up to the numbers of 61 amounting to the total percentage of 33.52. These figures are in consensus with Dhillon Setal12 and Singh H and Dhatarwal SK.13

Timings of the accidents too were taken into consideration in the study. Maximum numbers of accidents were recorded between the peak period of 12 Noon to 6 PM. Total number of 88 cases which mounts to the percentage of 48.35% were followed by a number of 42 cases between the period of 6 AM to 12 noon figuring 23.08% of total fatalities. These findings indicate to the truth that Barpeta is under developing area and major operational hours of the natives are the day time. These finding are unafiling with the conclusion supplied by Kachre R V, Kachre VH and Asawa SS12. However, some dissimilarities too are observed by Biswas G, Verma S K, Sharma JJ and Aggarwal NK & Ghangale AL13 where culmination of prevalence of RTA were suggested between 6 PM to 12 Midnight.

The possible reasons for accidents on city roads, national and state highways account to the busy roads are, narrow passages in roads, heavy traffic during climax hours, inadequate or sometimes even no traffic signals at crossroads and negligence of firm implementation of road security rules. Sternness of mishap, transportation issues, scarcity of therapeutic
emergency services, inadequate and unqualified workforce and amenities in the hospitals too are some multifarious causes of incidents. Intoxicated driving too is a contributor to the accidents. Driving a vehicle under the influence of intoxication is against law as alcohol of any other intoxication weakens driving capacity of a person and echelon of mutilation is straight away related to blood alcohol assimilation. Tendency of using cell phones while driving too escalates possibility of accidents. Therefore traffic laws forbid the application of such devices by drivers while riding a vehicle. Many countries have made it binding constraint on permissible age for driving, over speeding, amplification in fine and abandonment of driver’s permit, graduate rider licensing, and speed control interference which have led to momentous decline in traffic accidents.

Conclusion

Accidents could be toned down with improved attentiveness, utilization of road safety and shielding procedures and tutoring to the general public and susceptible highway users to abide by traffic regulations. Road traffic accidents are very frequent in the riders of young age group which is also a huge loss to the nation. Therefore, incidents of these accidental deaths has to be discouraged by providing guidance to general populace about emergency and first aid services, founding suitably prepared treating centers, adopting apposite road safety measures and by creating appropriate roads to put up the weight of escalating traffic.

Effect of Core Strengthening and Conditioning Programme on Badminton Beginners

Aditi B. Churi¹, G. Varadharajulu²

¹Intern, ²Professor and Dean, Department of Neurosciences, Krishna College of Physiotherapy, KIMS “Deemed to be” University, Karad, 415110, Maharashtra, India

Abstract

Background: Badminton requires a specific physical conditioning in terms of motor and action controls; coordinative variables such as reaction time, foot stepping and static or dynamic balances, which are essential motor demands in this sport. Therefore, badminton players need enough core strength and a high level of dynamic balance during the rapid postural movements around the court.

Objectives: To study the effect of core strengthening and to study the effect of conditioning program on badminton beginners

Methodology: 25 players, aged between 12-19 years were given core strengthening and conditioning protocol for 4 weeks. Players were assessed at 0, 2nd and 4th week through 60 degree curl up test and modified Sorensen test.

Results: statistically significant difference was seen in pre and post treatment values of the 2 tests. In 60 degree curl up test at 0 week p=, 2nd week p= and 4th week p= and in modified Sorensen test at 0 week p=, 2nd week p= and 4th week p=

Conclusion: players showed improvement in their core strength after 4 weeks of core training.

Key words: badminton, core, conditioning, players, strength

Introduction

Badminton is a racquet sport played using racquets to hit a shuttlecock across a net. There is high level skill required to play badminton at the elite level, though to be a successful player they also need good reflexes and be quick and agile around the court. The important factors for badminton players are muscle strength, muscular endurance, power, speed, agility, flexibility, balance and coordination. Functional movements are highly dependent on this part of the body, and lack of core muscular development can result in predisposition of injury¹.

Core muscles includes transverse abdominal muscle, abdominal external oblique muscle, multifidus muscles, abdominal internal oblique, psoas major muscle. A core muscle is used to stabilize the thorax and the pelvis during dynamic movement and it also provides internal pressure to expel substances. Static core functionally is the ability of one’s core to align the skeleton to resist a force that does not change. The core strength training plays an important role in reducing and preventing lower and knee joint injuries².

It appears that repeated activation of core musculature along with extremity movements helps to improve postural control. During performance of sports skills, a stable core provides a foundation upon which the muscles of the upper and lower extremities can...
accelerate body segments and transfer force between distal and proximal body segments\(^3\).

Core stability is defined in athletic settings as the optimum production, which can transfer and control the force from the centre of the body to the limbs, through stabilization of the position and motion of torso\(^4\). Also described it as a central motor control of the lumbar-pelvic-thigh to maintain the stability of the core region against different postural and external forces.\(^5\)

Generally referred to as the core area, these overall and local muscles which constantly working to maintain posture and assist in changing postures and dynamic movements\(^10\). Described the role of core muscles as to, transfer force and doing a link between upper and lower extremities, help passive existence protect and support the spine. Previously, core stability exercises were widely used for reducing the injuries of the low back and lower extremities\(^5,6,7\). Recently, core stability training has been purported to improve player performance\(^7-11\), but the previous studies have not supported these claims in badminton sport.

The core muscle strengthening may help to improve dynamic balance and muscle coordination between lower and upper extremities, as well as reducing injury risk and muscle imbalance. Thus, the purpose of this study to find out the effect of core strengthening and conditioning programme on badminton beginners.

### Methodology

An approval for the study was obtained from the Protocol committee and the Institutional Ethical Committee of KIMSDU. An Experimental study was conducted for a duration of 6 months at Physiotherapy department of Krishna college of Physiotherapy. Individuals were approached and those fulfilling the inclusive criteria were selected.

**Study Design**: Experimental study

**Setting**: Krishna Hospital, Physiotherapy Department

**Study population**: All participants were selected by Simple Random Sampling method. Participants were selected on the basis of inclusion and exclusion criteria.

**Study size** – 25 subjects

**Procedure**: In general, the subjects performed 3 sessions badminton training per week for ~90 - 120 minutes every session; the (CSG) group performed the core stability training only 2 sessions per week over a period of 4 weeks. The core stability training programme of (CSG) group consisted of three progressive levels of exercises which focusing on the strengthening training of muscle abdominal, low back, and pelvic muscles through a variety of functional positions and different exercises.

### Exercise protocol

The group will receive respective training for 4 weeks:

Outcome Measures:

60 degree curl up test was done with subjects positioned on the plinth against a wedge supporting the back so that the hip was flexed to 60 degrees. Knees flexed to 90 degrees as measured with goniometer. In that stable arm is parallel to the ground and movable arm is at the supporting wedge. The test began when the wedge was removed and was terminated when the subject could no longer maintain the 60 degree angle independently. Subjects were asked to hold the position as much as possible. The duration on the stopwatch was noted for the individual subjects.

Modified Sorensen test subjects lay prone on an examination table with the trunk of the body extended off the edge of the table at the level of the anterior superior iliac spine of the pelvis. The buttocks and legs are fixed to the table with two straps. Subject were instructed to cross their arms in front of their chest and to lift their upper body until their trunk was parallel to the ground. Subjects were asked to hold the position as much as possible. The duration on stopwatch was noted for individual subjects.

Discussion

The present clinical trial was conducted to compare the effectiveness of core strengthening and conditioning program in badminton beginners. Results of this study were focused on improvement of core strength and endurance. It was noticed that there was improvement in all the above parameters in the experimental group.

A combination of 60 degree curl up test and modified Sorensen test were used as outcome measures were used to assess the effectiveness of core strengthening and conditioning program in badminton beginners.

In this study, the age group of the participants was in between 12 to 19 years. Subjects between this age group were considered as beginners of badminton and training them before hand could raise their level of performance in the game much early. The players of this age group could take up more advance training and more hours of play.

Sample size of present study consisted of 12 females and 13 males that are 48% females and 52% males.

From table number 3 we can see that in 60 degree curl up test the group showed statistically significant differences in pre and post treatment with p value, in 0-2 weeks p=1.393, 2 – 4 weeks p=2.241 and 0-4 weeks p=3.418. Similarly, a study showed statistically significant difference in 60 degree curl up test after incorporating core strengthening exercises with the help of swiss ball exercise for 4 weeks was found to be significant.

From table number 3 we can see that in modified Sorensen test the group showed statistically significant difference in pre and post treatment with p value within, 0-2 weeks p=2.154, 2-4 weeks p=1.669 and 0-4 weeks p=0.670.

The core muscles after four weeks of strengthening will respond like any other skeletal muscle, to training, thereby improving the ability of the neuromuscular system to perform dynamic, eccentric, isometric stabilization contractions in response to gravity and momentum. Higher core stability performance might lead to improved synchronization of motor units and lowering of neural inhibitory reflexes.

It is well known that position of the spine significantly determines the position of the body’s COG and compensatory muscle synergy/strategy to counteract the perturbations, to maintain the body’s equilibrium state and to regulate body’s postural control. Higher core stability performances allow optimal and long sustained contraction of the deeper spinal stabilizer muscles. These stabilizer muscles due to their close proximity with the spine are responsible for better control of the intersegment motion of the spine and thus a better control of the body’s COG. Study also indicated that core training not only improve the core muscle strength, but also improve the stability of the body movement during the LOS test which requires the well coordination of the upper and lower extremity limb, because a recent study also indicated that pilates training can enhances the control of trunk movement, and improves the neuromuscular coordination of movements.

An Article concludes that there is effect of core strengthening on dynamic balance and agility in badminton players.

The finding of this study showed significant improvement in the overall performance of 60 degree curl up test and modified Sorensen test.

Limitations:

1. Small sample size
2. Subjects could not be followed up after the study.
3. Duration of the study was short.

Recommendations:

1. Studies with longer duration are recommended with longer follow-up period to assess long term benefits.
2. Conduct the study with larger sample size.
3. This was a heterogenous group with both male and female population, future studies could be done taking up a homogenous sample with either male or female subjects separately.

Conclusion

This study concluded that there was an improvement in the core strength of the beginner badminton players after undergoing 4 weeks of core strengthening protocol. This indirectly improved their game by reducing injuries to lower limb and improving their dynamic balance.

Effect of Postural Ergonomics and Static Gluteus Exercise Along with Bridging on Quality of Life in Individual with Mechanical Low Back Pain

Aishwarya Vedpathak\textsuperscript{1}, Poonam H. Patil\textsuperscript{2}

\textsuperscript{1}Intern, Krishna College of Physiotherapy, KIMS ‘Deemed to be’ university, karad-415110, Maharashtra, India, \textsuperscript{2}Assistant professor, Department of Cardiopulmonary Sciences, Faculty of Physiotherapy, Krishna Institute of Medical Sciences, ‘Deemed to be’ university, karad-415110, Maharashtra, India

Abstract

Background: This study is to improve the posture of the patient to reduce the excessive stress on the joint and muscular structure It can reduce the mechanical low back pain in the patient .To enhance the performance and productivity of the job and prevent muscle fatigue .It can improve the posture and controls the health of the patient. So we need to study effect of static gluteus exercise along with bridging in patient with mechanical low back pain.

Objectives: To find out the effect of static gluteus exercise along with bridging in patient with mechanical low back pain. To find out the effect postural ergonomic who have low back pain.

Methodology: The study was carried out in karad area. The subjects were selected according to inclusion and exclusion criteria. Total 26 subjects were participated in this study. Prior consent and assent form was taken. Aim and procedure were explained to the subjects in their preferred language before data collection. The subjects were given static gluteal exercise along with pelvic bridging and postural ergonomic advise also given. Pre and post assessment was done before treatment and after 6 weeks of treatment respectively with the help of Visual analogue scale and the data was analysed with help of appropriate statistical analysis.

Result: In conducted study, Visual analogue scale showed statistically significant difference between pre and post treatment values. Pain decreases in individuals.

Conclusion: On the basis of the result of the study, it can be concluded that postural ergonomics and static glutes exercise along with pelvic bridging helps in reducing mechanical low back pain and improving quality of life.

Key words: static gluteus exercise along with pelvic bridging individual with low back pain.

Introduction

Low back pain is mostly nonspecific or mechanical. Mechanical low back pain arises from the spine, intervertebral disks and surrounding soft tissues. This comprises lumbosacral muscle strain, disk herniation, lumbar spondylosis, spondylolisthesis, spondylolysis, vertebral compression fractures, and acute or chronic traumatic injury.\textsuperscript{(1)} Common causes of chronic mechanical low back pain are repetitive trauma and overuse which is often secondary to workplace injury. Most patients who experience activity-limiting low back pain suffer from recurrent episodes. Chronic low back pain affects up to 23\% of the worldwide population, with 24\% to 80\% of patients having a recurrence at one year.\textsuperscript{(2)}
The low back pain in active workers is associated with occupational exposure. Individual in jobs which includes manual materials handling, repeated heavy lifting and lifting while twisting, are at risk of back pain leading to work absence. Exposure to job requirements for static postures are associated with back pain. The pelvic bridge pose helps to reduce excessive shortening of the hip flexors from prolonged sitting. It helps to stretch tight hips and also helps to strengthen the gluteus. In supine position keep hips and knees bent to 90 degrees with feet flat on the floor and arms palm down by sides. Take a deep breath in, and breathe out while lifting hips off the floor until shoulders, hips, and knees are in a straight line. Hold this position for 10 seconds and repeat 3-5 times.

Bend elbows to 90 degrees so that upper arm will be on the ground. Press lower back down into the ground which will create a posterior pelvic tilt. This will help to protect lower back and engage abdominals as well as your gluteus muscles. Then drive up through heels and upper back to lift your pelvis up off the ground. Lift hips up as high as possible. Focus on squeezing gluteus muscles.

Pelvic bridging can be recommended as an effective method to selectively facilitate gluteus muscle activity. Lumbar segmental stabilization exercise and exercise to strengthen the muscles of the gluteus resulted in a greater decrease in low back pain and increase in lumbar muscle strength.

Ergonomic interventions are used to prevent or reduce low back pain. There is high rates of low back pain in office workers, the association between low back pain and sitting posture in the occupational setting has been infrequently studied. There is association between prolonged sitting and an increased risk in low back pain.

Material and Methodology

This was a study to find the effect of postural ergonomics and static gluteus exercise along with pelvic bridging exercises on quality of life in individuals with mechanical low back pain. The exclusion criteria were subjects who had gone through Spinal operation, Patients with bone Fracture, Patient who had bone malignancies and spinal deformity. Demographic data of the subjects was taken. Prior consent and assent form was taken. Aim and procedure were explained to the subjects in their preferred language before data collection. The subjects undergone pelvic bridging along with static gluteus exercises and back isometric exercises for 6 weeks and postural ergonomics also taught. Pre and post assessment was done visual analogue scale (VAS). The experimental results were statistically analyzed.

Graph no: 1 (pre test)

Interpretation: In the present study pre interventional mean and standard deviation of VAS scale on rest of group A is 3.5 ±1.047 and group B is 2.707±1.098 and p value is 0.0104, whereas t value is 2.663 with 50 degree of freedom. It concluded that interference was considered extremely significant.

Graph no: 2 (post test)

Interpretation: In the present study pre interventional mean and standard deviation of VAS scale on rest of group A is 3.5 ±1.047 and group B is 2.707±1.098 and p value is 0.0104, whereas t value is 2.663 with 50 degree of freedom. It concluded that interference was considered extremely significant.
**Interpretation:** In the present study post interventional mean and standard deviation of VAS scale on activity of group A is 6.488±1.257 and group B 4.411±0.7612 is and p value is < 0.0001, whereas t value is 7.205 with 50 degree of freedom. It concluded that interference was considered extremely significant.

**Discussion**

This research was undertaken with the aim to study the effect of postural ergonomics and static gluteus exercise along with bridging individual with mechanical low back pain. The study was carried out and the result was drawn by postural ergonomic advice and static gluteus exercise along with bridging by using visual analogue scale. The study was carried out in karad area. Subjects with a sample of 50 were screened for inclusion and exclusion criteria. Subjects fulfilling inclusion criteria were recruited in the study with a sample of 26. Total 26 Prior consent and assent form was taken. Aim and procedure were explained to the subjects in their preferred language before data collection. Treatment started with warm up exercises. Pre and post assessment was done by using visual analogue scale to find whether the pain is reduced or not. Mean. Included participants started Exercise protocol will start with stretches and warm up exercise. Static gluteus exercise with bridging – 10 times repetition and 3 set Back isometric exercise – 5 times repetition . Participants will also receive postural ergonomic advice. For pre treatment mean is 3.5 on rest and on activity is 2.707. Standard deviation(SD) of pre treatment on rest is 1.047 and on activity is 1.098. P value of pre treatment is 0.0104. This is considered significant. Mean difference of pre treatment is -0.7923. t value of pre treatment is 2.663 with 50 degree of freedom. For post treatment mean is 6.488 on rest and on activity is 4.411. Standard deviation of post treatment on rest is 1.257 and on activity is 7612. The result shows p value of is <0.0001. It considered extremely significant. Mean difference post treatment is – 2.077. t value of post treatment is 7.205 with 50 degree of freedom. Included participants started Exercise protocol will start with stretches and warm up exercise. Static gluteus exercise with bridging – 10 times repetition and 3 set Back isometric exercise – 5 times repetition . Participants will also receive postural ergonomic advice.

**Conclusion**

On the basis of the result of the study, it can be concluded that postural ergonomics static gluteus exercises with pelvic bridging helps in reducing mechanical low back pain.

**Conflicts of Interest:** There is no conflict of interest in this study.

**Source of Funding:** The study was funded by Krishna institute of medical sciences deemed to be university, karad.

**Ethical Clearance:** This study is undergone ethical clearance through the university level ethical committee. Protocol number is 0104/2019-21.

Leukopenia, Hypomagnesemia in 2,4-D Poisoning-A Rare Presentation

Ajita Kumar Bhoi¹, Prafulla Kumar Bariha², Khetra Mohan Tudu², Manoj Kumar Mohapatra³

¹Post graduate Trainee, Dept.of General Medicine VSS Institute of Medical Sciences and Research (VIMSAR), Burla, Odisha, ²Asst. Prof. Dept of General Medicine, VIMSAR, Burla Odisha, ³Professor of Medicine, Dept.of General Medicine, VIMSAR, Burla, Odisha

Abstract

2,4-D (2,4-Dichlorophenoxyacetic acid) is a common herbicide in agriculture field. It has moderately toxic effect on mammals. 2,4-D is available either in salt or ester formulations for field level use. Although no specific antidote available for this herbicide, forced alkaline diuresis is one of the modalities of treatment to promote early excretion of toxin through kidney and minimize its complications. Other management are essentially supportive measure and prevention of possible complications like aspiration pneumonia. There are a numbers of complications that are reported in varying degree. It affects skeletal muscle, cardiovascular, gastrointestinal, renal, central and peripheral nervous system. Here we report a case who developed unusual complications like leukopenia, hypomagnesemia, proximal muscle weakness after consumption of 2,4-D after suicidal intent.

Keywords: 2,4-D formulations, leukopenia, hypomagnesemia.

Introduction

2,4-D is a selective broad-leaved weed killer. It is marketed as ester or salt compound in India. The ester formulation is commonly available in North India, whereas in Western part of Odisha state, which is an important agricultural belt of state, both forms are available. Here we report a case who consumed 58% salt formulation of 2,4-D (Weedmar-super58%SL™) for suicidal intent.

Case Report

A 24-year-old lactating mother after quarrel in the family consumed around 30 ml of 2,4-D, methylamine 58% salt and brought to emergency Department of VSS Institute of Medical Sciences and Research, Burla, Odisha. During admission she was anxious, confused and restless. General examination showed pulse rate-88/min; regular, blood pressure (BP) -100/70mm of Hg, respiration rate-22/min, without pallor, icterus, clubbing, cyanosis, and pedal edema. There was no engorgement of neck veins or thyromegaly. Examination of respiratory, cardiovascular, gastro-intestinal, and central nervous system did not show any abnormality. Investigations showed Hb-11.4gm/dl, differential leukocyte count (DLC)-N 79 L16 M5, total leukocyte count (TLC)-9100/cu.mm., total platelet count (TPC)-2.24L/ml, blood ura-50mg/dl, serum (s.) creatinine-1.1mg/dl, s. Na+-142meq/l, s. K+-3.7meq/l, s.Ca++-1.0meq/l, s.bilirubin (total)-0.39mg/dl, AST-32IU/L, ALT-23IU/L, ALP-87IU/L. Urine routine and microscopic examination, electrocardiogram were within normal limits. She was treated with gastric lavage, forced alkaline diuresis, iv fluids and inj. ceftriaxone 1 gm IV twice daily, Inj pantoprazole. She was put on nil per oral for next 48 hours. On 4th day she developed proximal muscle weakness. On examination she had lower motor neuron type of quadriplegia. On repeat investigations all investigations mentioned above were within normal limits except s.Mg++ which was low (1.3mg/dl; normal1.8-2.3mg/dl) and leukopenia (TLC: 2500/cmm). She was given magnesium 2 gm three times a day orally. After 24 hours, the power was improved to normal. On 8th day there was improvement of muscle power to normal, improvement of leukopenia and s.Mg++ to normal range.

Discussion

2,4-D compounds are available either as ester or salt
formulation for commercial use as weedicide for broad leaved weed in agriculture sector. Most case reports done have shown ester compound as culprit. Here in this case a lactating mother consumed salt compound (2,4-D-dimethylamine salt 58%). The lethal dose of 2,4-D lie between 447-826mg/l in plasma\(^4\). Nausea, vomiting, diarrhea, gastrointestinal hemorrhage are early effects of these compounds\(^3\). It affects skeletal muscle, kidney, heart, liver, central and peripheral nervous system. Hypokalemia, hypomagnesemia, hyperthermia, leukopenia, thrombocytopenia are rare complications reported\(^5\). There is no specific antidote available. Supportive measure included alkaline diuresis, assisting respiration, and prevention of aspiration and arrythmia\(^1\)\(^3\). The mechanism of injury by 2,4-D are cell membrane damage, uncoupling of oxidative phosphorylation and disruption of Acetyl coenzyme-A metabolism\(^6\). Hypomagnesemia usually mimics hypocalcemia, hypokalemia. The present patient developed hypomagnesemia leading to proximal muscle weakness and leukopenia. Although 2,4-D itself can cause myopathy leading to muscle weakness we attribute it to hypomagnesemia as the muscle weakness improved to normal with magnesium supplementation\(^5\). The transient leukopenia developed in first week (4\(^{th}\)day) returned to normal in second week (8\(^{th}\) day) prompting to search for such complications in patients of 2,4-D poisoning for proper management. This case highlights that muscular weakness may be due to hypomagnesemia which can be treated with magnesium replacement. Further this observation encourages to search whether the salt and ester formulations have a different clinical profile and whether they have different degree of affection to different systems in humans.

Factors that Correlation to Occupational Contact Dermatitis Among Tobacco Farmers in Jember District, East Java Province, Indonesia

Anita Dewi Prahastuti Sujoso1,2, Tri Martiana*3, Santi Martini4-Firman Suryadi Rahman1

1Doctoral Program of Public Health Faculty Universitas Airlangga, 2Faculty of Public Health University of Jember, 3 Occupational Safety and Health Department Faculty of Public Health, Universitas Airlangga. 4 Epidemiology Department Faculty of Public Health Universitas Airlangga

Abstract

Introduction. Contact dermatitis is positived by most agricultural sector workers. Tobacco farming is one of the places where chemicals are sourced from pesticides, fertilizers, and also nicotine derived from tobacco leaves. This study aims to analyze the factors associated with contact dermatitis in tobacco farmers in Jember, East Java Province, Indonesia. Method. The research design is case control with 155 tobacco farmers. The dependent variable of this study is Occupational Contact Dermatitis (OCD) as measured through the results of a doctor's examination. Independent variables are individual factors and occupational factors. Individual factors include age, sex, education, individual hygiene, use of personal protective equipment, and complaints of GTS. Occupational factors consist of the main job, additional work, types of tobacco leaves, work at risk, work period, length of work, length of rest. Data analysis used Chi-Square test with a significance value of p <0,05. Result and Discussion. The results revealed that factors related to OCD in tobacco farmers in Jember Regency were age (p = 0.037), education (0,013), GTS complaints (p = 0,030), type of tobacco leaf (p=0,005), working periode (p=0,042) and working hours (p=0,008). Conclusion Individual factors related to OCD in tobacco farmers are age, education, and GTS complaints. Occupational factors related to OCD are the type of tobacco leaves, working period and length of work. This study revealed that OCD through promotion and integrated occupational health education.

Keyword: occupational contact dermatitis, tobacco farmers, tobacco workers

Introduction

Contact dermatitis (CD) is the most widely known occupational disease in many countries, and occupational contact dermatitis (OCD) is not reported (1). Dermatitis is inflammation of the skin. The term dermatitis is synonymous with eczema. The skin becomes red, itchy, and can blister. Skin with dermatitis becomes hard, thickened and cracked (2). OCD is a skin disorder caused by contact with certain substances in the workplace. Research has shown that within 10 years after the condition first occurs the worker will still have some skin problems, like allergens and irritants (3). Tobacco farming shows that workers are exposed to or contact pesticides, fertilizers, and nicotine derived from tobacco leaves which can cause contact dermatitis (4). Exposure to chemicals in the workplace can increase risk (5). OCD is one of the occupational diseases that often occurs in agricultural workers such as tobacco farming. OCD accounts for a significant proportion of occupational diseases. Exposure to allergens and long-term or repeated irritation can cause dermatitis which can reduce quality of life (3), (6).

The agricultural sector is one of the workplaces that lacks health and safety protection. Farmers, vulnerable to occupational diseases. Meanwhile, in Indonesia data regarding work-related diseases are not recorded properly. This study aims to analyze OCD and the factors associated with dermatitis due.

The research findings are factors related to OCD cases beneficial for occupational health policy makers to be used as the basis for occupational health and safety policies so that the quality of life of farmers increases.
Materials and Method

Research Design

This type of research is observational analytic research. The study observes the variables, then analyzes the risk factors or causal factors for the event to be examined. The research design used is case-control.

Location and Time Schedule

The results of previous surveys indicate that there is exposure to substances that have the potential to cause OCD. The time of the research is starting in May 2018-November 2018. The population was chosen by considering the inclusion and exclusion criteria, ie respondents aged between 15-65 years old, not sick or pregnant, no history of skin disease.

Population and Sample

Samples are obtained through formula (7)

\[ P_2 = 0.31, \text{ Proportion of Exposure to the group that is not sick} \]
\[ P_1 = \text{Exposure proportion in the sick group} \]
\[ \text{Odds Ratio} = 2.31, \text{ Odds ratio in previous studies} \]
\[ Z_1-\alpha / 2 = \text{value in the standard normal distribution which is equal to the significance level} \]
\[ Z_1-\beta = \text{value in the standard normal distribution equal to power by 90%}, \text{ value 1.28.} \]

From the above calculation results obtained a sample of 129 (=130) people. In order to anticipate missing data, samples were added to become 155 tobacco farmers.

Research Variable.

The variables of this study are workers and occupational factors. Worker or individual factors are personal characteristics that exist in tobacco farmers which can be a risk of dermatitis. Individual factors consist of age, gender, education, individual hygiene, use of personal protective equipment, and complaints of GTS. Occupational factors consist of the main types of work, types of tobacco leave, risky activities, working periode and working hours per day.

Instrument

The dependent variable of observed dermatitis cases was measured through doctor’s examination Positive cases of dermatitis if the results of examination by a doctor found signs of dermatitis in one part of the body, legs, hands or arms. Negative cases of dermatitis if the results of a doctor’s examination found no signs of dermatitis. Data on independent variables were obtained through interviews and questionnaires.

Data Analysis

The collected data were analyzed using the Bivariate Chi-Square test with a significance p <0.05.

Finding

Result and Discussion

Table 1 shows the results of bivariate tests of individual factors and cases of dermatitis in tobacco farmers in Jember Regency. Among 155 tobacco farmers, 36 (23.22%) had dermatitis. The results showed that based on the age of the majority of tobacco farmers aged ≤ 45 years. In the group of farmers who positived dermatitis, it was more common in farmers aged> 45 years, as many as 24 people (66.7%), while in the group of farmers who negative dermatitis, they were dominated by age ≤45 years, as many as 64 people (58.8%). Table 1 indicates that age was associated with dermatitis cases with a significance value of p <0.05 (0.037). This means that young and old age have different risks for OCD.

Based on gender, Table 1 reveals that in the group of farmers who positived dermatitis cases, it was more positived by farmers with female sex. Table 1 provides an illustration that gender is not related to dermatitis cases, meaning that the sexes of men and women have the same probability for the occurrence of OCD p> 0.05 (0.280).

The next variable is the level of education. The majority of tobacco farmers in the both of group had primary school education. Based on education level, Table 1 displays data that educational status is associated with dermatitis cases with p-value <0.05 (0.013). Different levels of education will also be different probability for OCD.

Table 1 proves that the majority of farmers with dermatitis as many as 20 people (5.6%) had good individual hygiene. Individual hygiene is not associated with dermatitis cases with p value> 0.05 (0.482). Tobacco farmers who have good and bad hygiene have the same probability of OCD.
Table 1 shows the results that in the group of tobacco farmers who positive dermatitis as many as 19 people (52.8%) used good personal protection. The use of personal protective equipment is not related to the status of dermatitis with a significance value of $p > 0.05$ (0.273). Tobacco farmers who use or do not use personal protective equipment have the same chance of occurring OCD.

The next variable is Green Tobacco Sickness (GTS) complaints. GTS complaints are classified into two, there are GTS complaints and no GTS complaints. GTS was associated with dermatitis cases with a significance value of $p < 0.05$ (0.030). Farmers who positive GTS and negative GTS have different opportunities for OCD.

</table>
Table 2 shows the results of the bivariate test of occupational factors and cases of dermatitis in tobacco farmers in Jember Regency. The main occupation was not related to dermatitis cases $p > 0.05$ (0.773). Landowners and farm laborers have the same possibility of occurrence of dermatitis cases.

Table 2 reveals cases of dermatitis based on the type of tobacco leaf planted. There are four types of tobacco leaves that are planted by tobacco farmers in Jember Regency, namely Traditional Oogst Na, Kasturi, Lower Shade Tobacco and Choper Tobacco. The type of leaf will determine the need for pesticides. Tobacco leaf type is associated with dermatitis with $p$ value $< 0.05$ (0.005).

Table 2 shows cases of dermatitis based on risky activities. The majority of tobacco farmers in the all group have more than 5 risk activities. Farmers who have risk activities of more than five or less than five have the same chance for the occurrence of dermatitis $p > 0.05$ (0.083).

Table 2 shows the dermatitis cases based on working periode. Working periode was related to OCD cases with a significance value of $p < 0.05$ (0.042). Farmers who have a working period of $< 18$ years or $\geq 18$ years have different opportunities for the occurrence of dermatitis.

Table 2 informs dermatitis cases based on working hours. The working hours of tobacco farmers in the group with majority dermatitis is more than 8 hours / day as many as 27 people (75%). Tobacco farmers with less than 8 hours / day and more than 8 hours / day have a different chance of developing dermatitis with a significance value of $p < 0.005$ (0.008).

The results revealed that there were 36 people (23.22%) tobacco farmers positived OCD. Nicotine enters the body through the skin together with pesticides attached to the leaves (10). The leaf nicotine which exposed the peasant’s skin can be in the form of granules or liquid form. In the form of granules, nicotine is black and is sticky. Nicotine attached to the hand will cause a persistent eczeome reaction. This reaction extends along with worsening- spreading improvement off work (11). Figure 1 shows the farmer with a sign of contact dermatitis caused by contact with nicotine.

The main toxic compound found in tobacco farming is nicotine. Nicotine (C10H14N2) is released by fermentation and curing together with ammonium, carbon dioxide and furan aldehydes (11). Direct contact with tobacco has the potential to cause contact dermatitis (4). This will also increase with the working hours. The longer working hours, the greater the amount of exposure.

Another toxic ingredient found in tobacco farming is pesticides. Several studies state that tobacco farmers face the danger of pesticides and nicotine all at once (12), (13). Type of tobacco pesticides are generally organophosphates (14). Types of leaves planted will determine the need for pesticides. Among the four types of tobacco leaves planted, the leaves that need the most pesticides are Na Oogst. Agricultural chemicals present in pesticides can affect health (15), (16), (17).

Other results from this study mention that dermatitis is associated with cases of Green Tobacco Sickness (GTS). GTS is caused by the absorption of nicotine derived from wet sugarcane leaves. Nicotine is absorbed through the skin in direct contact with tobacco (18). GTS is a disease that is very common in tobacco farmers and occurs in the harvest season (19), (20). Farmers with dermatitis will be at greater risk for developing GTS.

Research conducted on tobacco farmers in Latino is different. Skin problems diagnosed with contact dermatitis and traumatic skin lesions did not have a significant relationship with GTS in bivariate or multivariate analyzes. Skin conditions do increase the possibility of GTS. However, this skin problem must have enough intensity to attract the attention of agricultural workers. Rash, which harms the surface of the skin and increases the potential for nicotine absorption, is the skin problem most strongly associated with GTS (9).

**Conclusion**

The findings in this study revealed that the factors associated with occupational contact dermititis among tobacco farmers in Jember Regency, East Java Province, Indonesia were age, GTS complaint, education, type of tobacco leaves, working periode and working hours. OCD can be prevented through promotive and preventive efforts that can be done by maintaining individual hygiene and the use of personal protection. More broadly, it is necessary to have integrated management of occupational health and prevention of occupational diseases by the parties involved, namely from farmers, doctors and agricultural landowners. Suggestions for further research is to conduct research by examining OCD with various examination methods and types of occupational contact dermatitis.

**Conflict of Interest:** There is no conflict of interest.

**Source of Funding:** This research was funded by the Indonesian Endowment Fund for Education (BUDI DN-LPDP) scholarship.

**Ethical Clearance:** Research ethics approval was proposed through the Health Research Ethics Commission of the Faculty of Public Health, Airlangga University, Surabaya. Research has passed the Ethics Review by the Health Research Ethics Commission of the Faculty of Public Health Universitas Airlangga Surabaya, No 472-KEPK August 3, 2018.

Improve Awareness of the Forensic Odontology among Medical Graduates: Need of the Hour?

Anushtha Jain1, Nandita K.P2, Srikant N3

1Principal Investigator, Intern, 2Associate Professor, Dept of Oral Pathology and Microbiology, 3Head of the Department, Dept of Oral Pathology and Microbiology, Manipal College of Dental Sciences, Mangalore, Manipal Academy of Higher Education, Manipal

Abstract

Introduction: Forensic odontology is a fastly growing field in both dental and forensic sciences. It involves the application of principles and expertise of dental sciences for criminal investigations. With increasing demand and use of dental evidence in forensic examinations, proper knowledge and awareness of the subject is more necessary than ever before.

Materials and Method: A survey was conducted in Medical and Dental colleges in and around Mangalore, Dakshina Kannada after approval from institutional ethics committee. It included MBBS and BDS students (III year to internship)

Result: The analysis of the data showed two fold results. Knowledge of tooth as a source of DNA, evidence for natural disasters in personal identification was equal among the graduates. Medical graduates had higher awareness of certain aspects like barr bodies and anthropometry whereas; Dental graduates were aware of the odontology aspects in identification of cases of rapes, child abuse, techniques like forensic radiology, bite mark analysis and sexual dimorphism in teeth.

Conclusion: The study highlighted the difference in knowledge of forensic odontology between medical and dental students. It emphasized on the need of increasing awareness of the subject among medical graduates and to help them understand the role of their peers from the dental fraternity in forensic sciences. The study also stressed on the need of a forensic odontologist in the State Forensic Team.

Keywords: Forensic odontology, teeth, dental records, questionnaire, graduates

Introduction

Forensic odontology has evolved as one of the most important tools of forensic sciences. It uses dental records, ante-mortem and post-mortem records, analysis of bite marks, oral photographs and radiographs in solving criminal cases and in identification of persons. It involves proper handling, examination and evaluation of dental-evidence, which could be presented in the court of justice.

Teeth tend to survive extreme conditions and is often resistant to decomposition, thus are sometimes the only source of information, the pulp contains DNA and enamel, dentin and cementum change with age. Every dentition is different, the rationale of forensic odontology depends on this uniqueness and recognizable marks of the teeth.1

Dentistry faction of forensic science plays important role in many scenarios like, solving cases of assaults, murders, rapes and domestic violences, identification of victims in natural disasters like fires, earthquakes, etc., and to examine and interpret archaeological findings.2 As time is passing, the number of criminal activities are also

email- nandita.kp@manipal.edu
increasing, the murder and rapes cases we hear about in the NEWS are getting horrific by the day. In most of these cases the body of the victims are left badly mutilated. Forensic Odontology plays a major role in getting to the root of these cases and finding the criminal.

It is important for Indian doctors and dentists to be educated and trained in the subject. More importantly, doctors must understand the role of a dentist in forensic related cases. Students should be exposed to forensic sciences during their undergraduate course to an extent where they truly understand the subject.

The objective of this study was to draw a comparison between the knowledge and awareness of forensic odontology between Medical and Dental graduates. It also aimed to recognize the need of a forensic odontologist in the state forensic team.

**Aims and Objectives**

The aim of this study is to compare the knowledge and awareness of forensic odontology among medical and dental graduates.

**Materials and Method**

A questionnaire study was conducted in medical and dental colleges of Mangalore, Dakshina Kannada after approval from Institutional ethical committee. It included students from IIIrd year to internship in both the groups.

A questionnaire validated by experts in forensics was prepared. It consisted of 23 questions with 6 divisions (TABLE B & C). First question has 18 subdivisions with Yes/No answers assessing the knowledge and need of forensic evidence. The next 5 questions have multiple choice answers, to evaluate subject specific knowledge of the participant have. Each consenting individual was given 10-15 minutes to answer the questionnaire. The collected data of both the groups was then entered in an excel sheet (Microsoft Inc.). Chi square test was done on the collected data and P Value was found calculated.

**Result**

Both medical and dental graduates (third year to internship) were given a survey on Forensic Odontology consisting of 23 questions, the questionnaire aimed to assess their knowledge and awareness on the subject. On analysis of the statistics many significant differences in the knowledge of the two groups were seen. (Table 1, 2 and 3)

It was observed that almost equal number of participants from both the groups knew that teeth can be used to recognize the dead and that the teeth contain DNA, they are aware that dental records can help during a forensic examination, most of them think that forensic examination requires a complete dental examination to be done when a case is brought to an expert. All the participants of both the groups are aware of bite marks being of importance in certain criminal offenses.

Chi square tests identified significant differences between the medical and dental graduates. Higher awareness and knowledge were observed among dental graduates in most of the questions about the subject. About 88.20% dental graduates knew that a tooth can be used to identify the gender of the dead compared to 64.90% medical graduates. Only 73.70% medical graduates know that enamel and dentin act as an aid for age identification, while this fact is known by 94.10% of dental graduates. 45.10% dental graduates know of institutions offering training in forensic odontology in contrast to only 6.10% medical graduates. The awareness among dental graduates was also high regarding the information of the cases being solved with the help of forensic odontology, accounting for 80.40% as compared to the medical graduates (42.10%). Approximately fifty seven percent (57.80%) dental graduates knew a forensic odontologist in the country compared to 4.40% of medical graduates. Although both medical and dental graduates agreed regarding the need for a forensic odontologist in the team of forensic expert, the need was emphasized more by the dental graduates (95.10%) compared to 79.80% by medical graduates.

While majority of participants agreed to the fact that dental forensic evidence can be presented as an expert witness in the court of law, the numbers were very high among dental graduates (89.20%) compared to the medical graduates group (69.30%). Around eighty eight percent (88.20%) dental graduates want their college to set up a forensic odontology department in contrast to 55.30% medical graduates agreeing for the same. Approximately, sixty two percent (61.80%) dental graduates feel forensic medicine is a good career option in comparison to only 43% medical students, also, 66.70% dental students have interest in forensic sciences, compared to 34.20% medical students.
Some of the attributes showed more positive response from the medical graduates. It was seen that more medical graduates (86.80%) knew that barr-bodies can be used to identify gender in comparison to 62.70% dental graduates. Though the number of participants who are confident in handling a forensic case is low in both the groups, the number is still higher in medical graduates (24.60%) than dental graduates (12.70%).

The participants were asked if forensic odontology was a recognized specialization in India, to our surprise, 47.10% dental graduates and 24.21% medical graduates agreed.

The participants were then asked, in what cases they believed dental evidence was of importance. Though not a significant difference was seen, but some options were considered more important by dental graduates than medical graduates. Dental graduates were more aware of the significance of dental evidence in solving cases of child assaults, rapes and domestic violence and murders. Around seventy three percent (73.5%) dental graduates and 61.4% medical graduates agreed on the importance of dental evidence in solving cases of child assaults, while 73.5% dental graduates knew about the role of dental records in solving rapes and domestic violence crimes compared to 61.4% medical graduates. 76.5% dental graduates said murder cases could also be solved with dental evidence whereas only 58.8% medical graduates agreed on the same.

The importance of archeological evidence was better understood by the medical graduates, with the percentages of medical graduates being 65.8% in comparison to 57.8% dental graduates.

When asked, what would they do if they recognized signs and symptoms of child abuse in a patient, more dental graduates (65.7%) thought that parents should be informed while more medical graduates thought (55.3%) NGO’s should be notified. Almost 80% people of both the groups agreed on involving the police.

Most dental graduates (72.5%) know that visual identification is the first step of identification in unclaimed bodies in comparison to 64% medical graduates. Around 35.1% and 14% medical graduates thought that analysis of physical features and dental examination are the first steps respectively. The number of dental graduates who believed the same were much lesser.

Various techniques are used in forensic odontology examination to identify the deceased. Almost equal number of participants from both the groups thought comparative dental identification, forensic anthropology, DNA methods like PCR, rugoscopy, cheiloscopy, occupational dental considerations and abnormalities of tooth formation and eruption. More medical graduates (52.6%) believed forensic anthropometry is used in many cases compared to only 39.2% dental graduates agreeing to the same.

Bite mark analysis was considered important by 71.6% dental graduates compared to 56.1% medical graduates answering the same. (p value=0.019) Forensic radiology was another method more popular among dental graduates compared to medical graduates. Also, dental students felt that the study of habits and dental variations can also be more helpful compared to medical students.

The participants were then asked about how did they gain the knowledge about forensic sciences. Teachers played the most important role in education participants of both the groups. Almost equal number of participants gained knowledge from the internet and television sitcoms, crime scene investigation shows. While seminars held in colleges and institutions was a source of information for many dental graduates (51%), only 21.9% medical students gained knowledge from seminars. More medical graduates (33.3%) gained awareness from NEWS than dental graduates (24.5%). Family was the last source of knowledge on the subject.

Discussion

Forensic odontology is one of the most progressing fields of forensics. Newer morphometric, histological metrics are employed to not only identify the deceased but also to solve civil and criminal cases.

Size, shape and color of teeth vary with age, gender and ethnicity, hence they can be very helpful in classifying the dead. In addition the pulp is potential a source of DNA even in adverse conditions. In the present study both the groups were equally aware of teeth as a source of DNA and they were aware of teeth being able to be used to identify the deceased. Previous dental records of a person ease the process of identification of a victim and even an offender (in cases of rapes, domestic violence, abuse, murder etc.), dentition, number of teeth, restorations, crowns etc., all count as valuable information in cases of identification. Dental post-mortem and ante-mortem records can also help in certain cases, this was known by participants of both the groups, hence, doing a complete dental examination during a forensic evaluation is also considered of importance. Importance of bite marks was known by all the participants from the two groups. Bite marks are of grave importance in cases of rapes, domestic violence and abuse, they are very helpful in identifying the culprit.

In our cohort the awareness of use of teeth as an identification of sex was more in dental graduates than in medical graduates. Sexual dimorphism is an inherent trait of the tooth. The sex chromosomes (X and Y chromosome) both code for the enamel formation and are responsible for the larger size of the teeth in males. Studies have shown minimal influence of hormones in regulating the tooth size. Dental graduates have better knowledge about using enamel and dentin in age estimation. Age changes in tooth can be in all structures of teeth. The enamel shows attrition, dentin formation is present throughout life leading to pulp recession, dentinal sclerosis is a part of the tooth aging process, cementum deposition occurs in increments. All these features can be grossly as well as radiological or histopathologically be estimated to assess age. Enamel, dentin and cementum change with age, while the amount of enamel decreases, dentin increases with age correlating with formation of reparative and
sclerotic dentin and cementum increases with age. Thus, as seen with various methods of age estimation (like Gustafson’s methods, Dermijian’s method etc.), enamel and dentin play an important role in identifying the age.

Use of teeth or the jaw to solve criminal cases since time immemorial. Awareness about cases solved with the help forensic sciences more in dental graduates. From the identification of Lollia Paulina to the identification of Abraham Lincoln’s assassin to the very recent Nirbhaya case, all were solved with the help of forensic odontology. A forensic odontologist’s presence, as agreed by most participants, is of importance in a state forensic team, as he/she is the most capable of doing a complete forensic dental examination as and when required. Dental forensic evidence, bite marks, oral radiographs, patient records, ante-mortem and post-mortem reports etc., can be used as evidence in a court of law.

Medical graduates are more aware of use of barr bodies in identification of gender in the dead. Barr bodies are gender markers, presence of Barr bodies marks genetic femaleness. It is an inactivated X Chromosome.

However, forensic odontology is not a recognized specialization yet in India. This showed more awareness among medical graduates. Some institutions provide a diploma fellowship and certificate courses and training for the same in the country.

The number of people agreeing to importance of forensic odontology in Fires and earthquakes is still low, as it is of utmost importance in mass disasters. Teeth tend to survive high temperatures and extreme conditions, hence, can be the only source of information in these cases. Differences in jaw and teeth morphology, number of crowns and restorations can help in unmasking the criminals.

There is no correct response for who should be informed first in cases of child abuse, while some might consider that informing parents, agreed response by dental graduates is must, a certain group of people, some dental graduates and most medical graduates, might think that informing the police can be more helpful as parents can also be the reason of abuse in certain cases.

Most of the participants agreed on visual identification being the first step of forensic examination. When an oral forensic examination is required to be done, firstly visual examination is done after a complete clean up of the deceased. Oral autopsy is done before any other body part is incisioned. Oral photographs must be taken before and after the autopsy procedure. Radiographs are taken by keeping the mouth open with clamps, impressions are made, and the dentition and oral conditions studied. These records are used to formulate a forensic report and find the criminal.

The awareness about the use of bitemarks in identification was more among the dental graduates. Bite mark analysis sure is on one of the most important tools of forensic dental sciences, however, rugoscopy and cheiloscopy can also be very helpful. Occupation considerations, habits and dental variation studies can also give fruitful results, like, notched incisors in tailors, attrited teeth in bruxers, etc. Even though DNA methods came out to be the most popular response, it is not usually done in most cases, as it is very expensive in comparison to the other methods and time consuming as well. Similarly, comparative dental identification, though answered by many participants, is not always done.

The evaluation of the results of the present study reflected on the gap of knowledge between the two groups of participants. It is evident that dental graduates are more aware and educated on the subject of forensic odontology, yet the subject is not given much importance. However, dental graduates also lack awareness in certain aspects, like the importance of barr bodies and the technique of forensic anthropomtry in identification, needed to be updated by more intensive lectures on the subject. Medical graduates need to be taught various parts of the subject like sexual dimorphism of teeth, use of teeth in cases of identification, natural disasters and rapes and murders, importance of bite mark analysis and forensic radiology and role of dental variation and habits in identification. (Table 1, 2 and 3).

Forensic investigations are a team effort, where the forensic experts, law makes and the police work together to solve mysteries around the death of a person.

**Conclusion**

Forensic odontology should be included on the curriculum of both dental and medical degrees. More seminar should be held for medical students to understand the importance of the role of their peers in forensic sciences. A forensic odontologist should be made an integral part of the state forensic teams. The law makers, the police officers and the forensic medicine experts should come together to accept the role of
this new key member who can help solve many more unsolved cases.

Abstract

Background: Silent liver disease is a major cause of morbidity and mortality in the population due to its silent progression to end stage liver disease without significant symptoms. We aim to study pattern of pathological findings and latent forms of diseases in the 100 liver autopsy specimen and to find clinicopathological correlation between clinical diagnosis and pathological diagnosis wherever possible.

Method: The present study was conducted on 100 liver autopsy specimens received in the department of Pathology, Govt. Medical College, Patiala. Sections from representative areas were submitted for processing, sectioned and stained with Hematoxylin & Eosin stain.

Results: Out of 100 specimens, 38 cases (38%) showed hepatic steatosis, followed by cirrhosis 14 cases (14%), chronic venous congestion 13 (13%) cases, portal triaditis 12 (12%) cases, normal 12 (12%) cases, hepatitis 8 (8%) cases, granulomatous/tuberculosis pathology 2 (2%) cases and 1(1%) metastatic deposits of carcinoid tumour. Maximum cases seen in age group of 41-50 years with mean age 39.92±12.68 years. Liver disease predominated in males with male:female ratio of 6:1.

Conclusion: Silent liver diseases are not uncommon. Autopsy examination of liver is very helpful to identify silent liver diseases like hepatic steatosis, cirrhosis, venous congestion and malignant tumours.

Keywords: Autopsy, Histopathology, Liver disease, Cirrhosis

Introduction

Liver is vulnerable to wide variety of metabolic, toxic, microbial and circulatory insults. In some instances, the disease is primary while in others the hepatic involvement is secondary to cardiac decompensation, alcoholism or 'extra hepatic infections. Quite rightly liver is, called as “The custodian of milieu interior”. Autopsy study is useful to monitor the cause of death and to plan medical strategy. [2]

Liver diseases have been known to have diverse etiologies. Broadly they are classified into various categories namely Infectious disorders of liver, Autoimmune disorders, Drug and toxic induced liver injury, Alcoholic liver diseases, metabolic liver diseases, cholestatic diseases, Autoimmune cholangiopathies, structural abnormalities of the biliary tree, circulatory disorders, Hepatic complications of organ or stem cell transplantation, Hepatic diseases associated with pregnancy and lastly tumors of different origins. [1]

Alcohol abuse generally leads to three pathologically distinct liver diseases; these are fatty liver, hepatitis and alcoholic cirrhosis. Any one or all the three can occur at the same time, in the same patient. [3] Fatty changes (steatosis) are very common finding both in biopsies and at postmortem examinations. Liver cell involvement may be focal, diffuse or zonal. [4]

Chronic hepatitis is usually due to hepatotropic viruses, or conditions like auto immune chronic hepatitis or chronic idiosyncratic drug-induced hepatitis. [4]
Material and Method

The present descriptive pattern of study was conducted on 100 liver autopsy specimens received in the department of Pathology, Govt. Medical College, Patiala over a period of 1 year 9 months. Liver specimens were received as a part of multiple viscera from mortuary for histopathological examination of medicolegal cases. In each case, important information regarding age, sex, clinical diagnosis (wherever possible) and postmortem findings were obtained from postmortem papers. Gross examination of the liver specimen was done as regards to the weight, surface, capsule, colour, consistency, etc. Formalin fixed liver tissues stained with Hematoxylin and Eosin were examined under microscope. The findings were recorded and analysed. Autolytic specimens were excluded from the study.

Observations

During the study, 100 cases were evaluated, out of which liver diseases predominated in males 86 cases (86%) as compared to females 14 cases (14%).

p value 0.223

In 100 liver autopsy cases included in the present study, 48 cases had ante-mortem clinical diagnosis and 52 cases had no clinical diagnosis.
From the above table, we can conclude that there is no significance difference between the clinical diagnosis and pathology diagnosis as there $p>0.05$ therefore both are showing correlation.

**Discussion**

A wide spectrum of liver pathologies has been observed in liver autopsies and has a significant role in mortality across the globe.

In the present study, clinical diagnosis was available in 48 cases. The age of the cases in the present study ranged from 12 years to 90 years; however, the predominant population was in the 4th decade with a mean age of 39.92±12.68 years. The results of the present study agree with the studies by Selvi et al[6] (2012), in which the mean age was 46.9 ±-5.28 years. The decline in the number of cases beyond the age of 80 years reflects the average life span of people in our country.
Liver diseases predominated in males in the present study (86%) compared to females (14%). These findings were in close concordance with the study done by Singal et al[5] (2017) where maximum cases predominated in males (82.8%). This may be attributed to the fact that men are more prone to alcohol consumption.

In the present study, hepatic steatosis (38%) was the most common silent liver disease. This finding is similar to studies conducted by Bal et al[2] (2004) showing 39% cases.

Alcoholic liver disease was the most common clinical diagnosis observed in 38 cases. Out of total 38 cases of hepatic steatosis, 26 (68.42%) cases had alcohol liver disease as a clinical diagnosis and 12 (23.08%) cases were incidental findings. This finding is similar to study conducted by Tuusov et al[10] (2014) where association of alcohol liver disease with hepatic steatosis was found to be 60.5%.

Maximum cases of hepatic steatosis in the present study belonged to the age group of 40-49 years comprising to be 52.63%. Similarly, study conducted by Bal et al[2] (2004) found maximum cases (53.85%) in the same age group.

In the present study, maximum cases of cirrhosis was seen in the age group of 40-49 years i.e. 6 (42.86%) cases which is comparable to the study conducted by Devi et al[7] (2013) with maximum cases in 40-49 years age group i.e. 10 (40 %) cases.

The frequency of cirrhosis in the present study was seen in 14 (14 %) cases which is comparable to the study conducted by Bal et al[2] (2004) showing 14% cases of cirrhosis. Whereas, Singal et al[5] (2017) and Konjengbam et al[8] (2017) found cirrhosis in 11.4% and 11.8% cases respectively. In the present study, cirrhosis was predominately seen in males i.e. 13 cases (13.51%) which is in concordance with study done by Singal et al[5] (2017) where males predominated i.e. 8 cases (13.7%). In the present study, 12 out of 14 cases (31.58%) had history of alcohol liver disease whereas other 2 cases (25%) had history of jaundice with viral etiology. In study conducted by Goncalves et al[11] (2014), association of alcohol liver disease and cirrhosis was found to be 40.5%. In a study conducted by Nandakumar et al[12] (2003), frequency of virus induced cirrhosis was found to 25% which is concordant with the present study (25%).

The present study shows the frequency of hepatitis in 8 (8%) cases which is in concordance to the study conducted by Singal et al[5] (2017) i.e. 6 (9%) cases. Similarly Konjengbam et al[8] (2017) had 6.2% cases. In the present study, hepatitis viral serology was not performed however, 5 out of 8 cases (62.5%) presented with clinical diagnosis of jaundice with viral etiology and 3 cases (5.77%) were incidental findings on histopathology.

The maximum cases of hepatitis is found in age group of 20-29 years i.e. 3 (37.5%) cases which is comparable to the study conducted by Devi et al[7] (2013) where maximum cases were in 20 -29 years age group i.e. 7 (32%) cases. This could be attributed to the intravenous drug usage in younger age group in these regions. No case of fulminant hepatitis was noted.

The frequency of chronic venous congestion in the present study is 13 (13%) cases. This finding is in accordance to studies conducted by Konjengbam et al[8] (2017) showing 11.5% cases.

In the present study, the incidence of portal triaditis is 12% which is similar to the studies conducted by Devi et al[7] (2013) and Konjengbam et al[8] (2017) with 15% and 10.9% cases respectively.

In the present study, the frequency of granulomatous/tuberculosis pathology is 2% which is similar to studies conducted by Konjengbam et al[8] (2017) and Singal et al[5] (2017) showing 2.1% and 1.5% cases respectively.

In one case of Granulomatous/Tuberculosis pathology, there was ante-mortem clinical diagnosis of tuberculosis (100%). Ziehl Neelseen stain was positive in one case of Granulomatous/tuberculosis pathology exhibiting acid fast bacilli.

In the present study, the frequency of metastatic deposits is 1% similar to the study conducted by Selvi et al[6] (2012) and Patel et al[9] (2017) showing 1.9% and 0.24% cases respectively. The age of the case in the present study was 47 years. The histopathological finding in this case correlated with the positive ante-mortem clinical diagnosis of cancer (100%).

The primary origin of the metastasis is unknown in the present study however, Patel et al[9] (2017) reported a case of metastatic carcinoma from lung adenocarcinoma in their study. In the present study, liver findings were normal in 12% cases which are comparable to studies.
conducted by Singal et al\textsuperscript{[5]} (2017) and Konjengbam et al\textsuperscript{[8]} (2017) showing 13\% and 14\% cases respectively.

**Conclusion**

From the present study, we conclude that autopsy specimens of liver helps to identify silent liver diseases. The incidence of hepatic pathology being more common in males as compared to females. Histopathological examination and clinical correlation are two most important tools for diagnosis of liver diseases.

Abstract

Background: Evaluating patients who have sustained blunt abdominal trauma remains one of the most challenging and resource-intensive aspects of acute trauma care. The objective of this dissertation is to analyse the pattern of fatal abdominal injuries secondary to blunt force impact.

Aim: The aim of this research is to analyze the pattern of fatal abdominal injuries secondary to blunt force impact

Materials and Method: Detailed observations for 38 autopsies with evidence of fatal abdominal trauma during the period October 2014 to July 2016 were carried out. Routine information like age, sex, occupation brief facts of the cases collected from the inquest report. Clinical history like time of admission, and deaths and other relevant data was collected from the hospital case sheets and death summaries.

Results: Analysis involves 38 autopsies with evidence of fatal abdominal trauma during the period October 2014 to July 2016. The most common age group involved was between 21-30 years of age comprising 26% of total 38 cases followed by the age group of 11-20 years comprising 21% of total cases. The most common cause of blunt fatal abdominal trauma was vehicular accident seen in 84% of cases. In 38 cases, it was found that 24 cases (63%) were dead on arrival. Amongst 32 vehicular accidents, a total of 21 pedestrians (66%) were killed in 38 fatal blunt abdominal trauma cases. Liver was the organ mainly affected in fatal blunt abdominal trauma followed by pelvic trauma and kidney. Haemorrhage accounted for the largest number of cases (94.74%).

Conclusion: The present study emphasizes the need for adopting measures to prevent morbidity and mortality resulting from blunt abdominal trauma.

Keywords: Abdominal Trauma; blunt force; Hemorrhage; Pelvic trauma.

Introduction

Trauma is one of the leading preventable causes of death in developing countries, and is a major health and social problem. Trauma affects generally the young people, and accounts for loss of more years of life,
than lost due to cancer and heart diseases put together. Accidents are considered as a modern day epidemic and counter product of modernization and hasty life. The statistical profile reflects a global estimate of 5.1 million deaths in 2000. Road Traffic Accident (RTA) accounted one of the top five causes of morbidity and 10% -25% of mortality in South-East Asian countries.1,2

RTA cause mechanical trauma, resulting in morbidity, disability and even mortality. India is one of the highest victimized by road traffic accidents in the world and reported to be 20 times more than that reported in developed countries.3

Abdominal trauma accounts for nearly 20% of all severe traffic injuries and can often result from intentional physical violence. Blunt liver injury is regarded as the most common type of injury following abdominal trauma, and is associated with a high mortality rate.4,5 Blunt abdominal trauma is a leading cause of morbidity and mortality among all age groups. Identification of serious intra-abdominal pathology is often challenging. Many injuries may not manifest during the initial assessment and treatment period. Missed intra-abdominal injuries and concealed hemorrhage are frequent causes of increased morbidity and mortality, especially in patients who survive the initial phase after an injury.

Blunt abdominal trauma usually results from motor vehicle collisions (MVCs), assaults, recreational accidents, or falls. The most commonly injured organs are the spleen, liver, retroperitoneum, small bowel, kidneys, bladder, colorectum, diaphragm, and pancreas. Men tend to be affected slightly more often than women.

Physical examination findings are notoriously unreliable. One reason is that mechanisms of injury often result in other associated injuries that may divert the physician’s attention from potentially life-threatening intra-abdominal pathology. Other common reasons are an altered mental state and drug and alcohol intoxication.

The care of the trauma patient is demanding and requires speed and efficiency. Evaluating patients who have sustained blunt abdominal trauma remains one of the most challenging and resource-intensive aspects of acute trauma care.6,7 The objective of this dissertation is to analyse the pattern of fatal abdominal injuries secondary to blunt force impact.

**Materials and Method**

Detailed observations for 38 autopsies with evidence of fatal abdominal trauma during the period October 2014 to July 2016 were carried out. Due permission was taken from Institutional Ethics Committee of A.J. institute of Medical Sciences & Research Centre, Mangalore for the conduct of the study.

Routine information like age, sex, occupation brief facts of the cases collected from the inquest report. Clinical history like time of admission, and deaths and other relevant data was collected from the hospital case sheets and death summaries. Pattern, nature of injuries, complications, cause of death and mechanism of death were obtained from a detailed follow up and study of the autopsy cases and reports.

**Results**

Detailed observations for 38 autopsies with evidence of fatal abdominal trauma during the period October 2014 to July 2016 were carried out and various statistical results were drawn from them. The most common age group involved was between 21-30 years of age comprising 26% of total 38 cases followed by the age group of 11-20 years comprising 21% of total cases. Children below 10 years constituted only 8% of total cases. Persons above 60 years constituted only three cases, i.e., 7.9% of total cases.

The most vulnerable age group involved among males was between 21-30 years of age followed by the age group of 11-20 years. The most vulnerable age group involved among females was between 21-30 and 31-40 years of age as depicted Figure 1. Among those 38 cases studied, males comprised 29 cases, i.e., 76.32% of cases, while females were only 9 in number, i.e., 23.68% of cases.
The most common cause of blunt fatal abdominal trauma was vehicular accident seen in 84% of cases followed by fall from height constituting 13% of cases.

In 38 cases, it was found that 24 cases (63%) (Were dead on arrival i.e., died at the scene/spot or were brought dead to the casualty as depicted in Figure 2. Those surviving for more than a day constituted only 8% of the cases.

Amongst 32 vehicular accidents, A total of 21 pedestrians (66%) were killed in 38 fatal blunt abdominal trauma cases. The next common category was two wheeler occupants which accounted for 10 cases (31%). Car occupants were not involved in any case as illustrated in Table 1.

In all the cases studied manner of death was accidental. Haemorrhage accounted for the largest number of cases (94.74%) followed by Speticemia (5.26%) as illustrated in Figure 3.
Discussion

In the present study it was observed that majority of cases were males in the age group of 21-30 years. The large number of cases in this age group can be attributed to the fact that this period of life is the most vulnerable to trauma because of a very high level of outdoor activities. Male dominance in this type of injury could likely be due to the fact the males are more exposed to trauma as they constitute working and earning member in majority of families and so move out of the house more often than females. Similar findings were also observed by Jha et al, Meera and Nabachandra, Rautji et al, Sharma et al, and Mansar et al.

In the present study, majority of fatal blunt abdominal injuries were due to vehicular accidents. There was no case of assault by blunt weapon. This finding is also in agreement with the work of Meera and Nabachandra who also observed that the commonest cause of blunt thoracoabdominal trauma was vehicular accidents (86.40%).

Liver was injured in maximum number of cases. This may be due to the fact that in maximum number of vehicular accidents causes primary impact injuries over the upper abdominal region. Another reason for the greater involvement of the liver could be due to fall on the ground after impact with offending vehicle leading to liver injury.

These findings are also in agreement with the findings of Bergqvist et al who studied patients with abdominal trauma and fatal outcome in an analysis of a 30-year series in a rural Swedish area. They found that Patients with blunt abdominal trauma with fatal outcome comprised of 127 patients and found that one fourth of these patients died from an abdominal injury alone.

A total of 21 (66%) pedestrians were killed in 38 fatal blunt abdominal trauma cases. Similar increased numbers of abdominal trauma among pedestrians have also been reported by Jha et al, Meera and Nabachandra, and Sharma et al (Table 18). The next common category was two wheeler occupants which accounted for 10 (31%) cases. Car occupants were not involved in any case. The pedestrians in most of the instances were knocked down by vehicles leading to fatal abdominal injuries. Encroachment of pavements making people walk on roads, little segregation between vehicular and pedestrian traffic, lack of awareness among pedestrian of road rules and lack of pedestrian crossings are some of the reasons for increased involvement of pedestrians. Poor maintenance of roads and lack of observance of traffic rules by vehicular traffic are some other reasons.

In the present study majority of cases were dead on arrival. Similar findings have also been reported by Meera.
and Nabachandra and Sharma et al. This emphasizes the fact that most of our vital organs are present in the chest and abdominal cavity and further the abdominal cavity lacks any protective bony cover. So trauma quickly leads to injuries to the vital organs and major blood vessels present in the thoracic and abdominal cavities. Inadequate infrastructure for early transport of victims and lack of proper management of trauma patients on the way to hospital because of traffic congestion on the highway leads to early deaths. These victims need on-spot emergency, medical care and rapid transportation from the incident site to the hospital which is lacking in this part of the world.9,10

**Conclusion**

Analysis involves 38 autopsies with evidence of fatal abdominal trauma during the period October 2014 to July 2016. The most common age group involved was between 21-30 years of age comprising 26% of total 38 cases followed by the age group of 11-20 years comprising 21% of total cases. The most vulnerable age group involved among males was between 21-30 years of age followed by the age group of 11-20 years. The most vulnerable age group involved among females was between 21-30 and 31-40 years of age. The most common cause of blunt fatal abdominal trauma was vehicular accident seen in 84% of cases. In 38 cases, it was found that 24 cases (63%) were dead on arrival i.e., died at the scene/spot or were brought dead to the casualty.

Amongst 32 vehicular accidents, a total of 21 pedestrians (66%) were killed in 38 fatal blunt abdominal trauma cases. Liver was the organ mainly affected in fatal blunt abdominal trauma followed by pelvic trauma and kidney. In all the cases studied manner of death was accidental. Haemorrhage accounted for the largest number of cases (94.74%).

Antimicrobial and Biofilm Inhibitory Activity of Nanoparticles Against Clinical Isolates from Urinary Tract Infection

Ashwak Jasim Kzar

Department of Medical Laboratory Technology, College of Health and Medical technique, Middle Technical University, Iraq.

Abstract

At these days nanoparticles (NPs) are used as antibacterial due to its have chemical-physical addition to biological effect. A big group of microbial cells adhering to a surface are called biofilm. Exposure to nanoparticles such as (Ag, Al$_2$O$_3$, Ni) may prevent colonization of new bacteria onto the biofilm. In the present research we have analyze whether the biofilm formation of some isolates of pathogenic bacteria could be influenced by NPs. Also we examined the susceptibility of the isolates to some antibiotics in combination with Ag, Al$_2$O$_3$ and Ni nanoparticles. (50) Strains of isolated K. pneumonia have been examine from patients with urinary tract infection were collected from Education of Baghdad hospitals in Iraq. Serial dilution of Tube method to determination of MIC and MBEC for Nanoparticles against isolates was done. Biofilm formation was evaluated by micro titer plates. Additionally, disc diffusion method was used to assay the various antibiotics and combinations for bactericidal activity against the isolates. The results showed that about 97% of the strains were capable to form of structure biofilms. More than 82% about of strains showed resistance to commonly used antibiotics. Antibiotics and antimicrobials from mixed nanoparticles were higher than compared to nanoparticles alone. Therefore, a synergistic effect was observed between silver - Nickel nanoparticles and silver - aluminum oxide nanoparticles in to inhibiting the growth of K. pneumonia strains. Furthermore, cytotoxicity activity of Ag NPs against Neuro-2a cells was higher than Al$_2$O$_3$ NPs. The results suggest that nanoparticles can be used as antimicrobial agents for therapeutic to treat urinary tract infections caused by K. pneumoniae.

Keywords: Antimicrobial activity, anti-biofilm, K. pneumoniae, Urinary Tract Infection, Nanoparticles.

Introduction

Urinary tract infections are one of the most common infectious diseases, mainly caused by gram negative bacteria it is estimated that klebsella species account for about 8% from all infectious diseases in the USA and Europe (1). Klebsella infection is mainly caused by K. pneumonia bacteria the most common infection of the urinary tract infection. K. Pneumonia is an opportunistic pathogen, rod form, negative gram and a member of the intestinal family (2), which is widely found in the intestines, mouth, and skin it can lead to pneumoniae, blood, surgical infections and urinary tract infections (3). The most important agents of pneumonia strains can be polysaccharide adhesives sideophore, lipid polysaccharides and the formation of biofilms (4). Biofilm is one of the key factors for the development of chronic diseases. Studies have shown that most K. pneumonia isolates from blood, wound and urine are able to produce biofilms. Bio membranes formed in vivo protect pathogens against antibiotic and host immune responses (5, 6).

Recent developments in nanotechnology, especially the ability to manufacture nanoparticles in different shapes and sizes, have caused a wide range of antimicrobial agents. The small size (<100 nm) and the ratio of the surface to the large size of the nanoparticles led to the unique chemical, thermal, mechanical and electrical properties of their massive materials and increased biological and chemical activity(7). To date,
many nanoparticles have been actively synthesized against antimicrobial agents, such as Ag, Ni, ZnO, Au, and Cu nanoparticles. Nanoparticles kill bacterial cells through various mechanisms, including cell wall binding and cell penetration, the release of metal ions, interaction with their groups in enzymes and proteins, the accumulation of nanoparticles in the cytoplasm, and the production of ROS(8).

Most bacteria are present in the form of biofilm, which often contains diverse types that interact with each other and their environment. Bio-membranes specifically microbial aggregates and extracellular products such as extracellular polymeric materials. (9). The bacteria growth inversely on the out surface but the expression of extracellular polymers the attachment irreversible. Once bacteria are stable bacterial whip is discouraged and the bacteria multiply rapidly, leading to the development of mature biofilm. From this step the bacteria are restrict together and form a barrier that can tolerate antibiotics and supply a source of chronic systemic infection. (10). The aim of this study was to investigate the potential antibacterial and antibiofilm activities of nanoparticles against K. pneumonia associated with urinary tract infection.

**Materials and Method**

Collection bacterial strains

50 strains of (K. pneumonia) were collected from urine sample of patients in Baghdad / Iraq hospitals. They were grown in nutrient broth, and nutrient agar. To isolate urinary tract strains loop full of urine samples was placed in nutrient agar blood agar and agar chocolate plates and incubated at 37 ° C for one day. Individual colonies were selected the following day and were determined based on morphological characteristics, gram staining and biochemical characters (11).

Biofilm formation assay

Measurement of biofilm formation among the (K. pneumoniae) strains was carried out by using the tube method and tissue culture plate assay. In this tissue culture method, 100 µl (0.5 McFarland) of an overnight culture of strains was inoculated into each well of a 96-well polystyrene plate, and incubated at 37 ° C for 48 days. After incubation period, the bacteria were stained with 150 µl of crystal violet (0.1 %) for 10 min. Finally, 100 µl of acetic acid (33 % v/v) was added to each of the wells and the optical density was measured at 545 nm.

Antibiofilm activity assay of nanoparticles

Antibiofilm activity of nanoparticles (Ag, Al₂O₃ and Ni) alone and in mix with each other, against biofilm producing strains was performed by micro titer plate method. Briefly, 100 µl of bacterial suspension (0.5 McFarland) was inoculated into 96 plate wells, with different concentrations of Ag (0.031 – 2 mg ml⁻¹), Al₂O₃ (0.031 – 1 mg ml⁻¹) and Ni (0.031 – 4 mg ml⁻¹) nanoparticles and incubated at 37 °C for 48h. And read on absorbance at 545 nm (12).

**Cytotoxicity test:**

Both Neuro 2a cells were cultured using DMEM containing 10% fetal bovine serum (fbs) and 1% antibiotics (100 mg/ml streptomycin and 100 U/ml penicillin) and were maintained at 37 °C in a humidified atmosphere with 5% CO₂ They were subculture every 2 days when they reached 90% confluence by digestion with trypsin/EDTA.

**MTT assay**

The MTT assay was performed on Neuro 2a cells. The eight concentrations of Ag NPs (0.78 – 100 µg ml⁻¹) and Al₂O₃ NPs (1.95 – 500 µg ml⁻¹) were prepared in water by two-fold serial dilution method. 50 µl of various concentrations of Ag and Al₂O₃ NPs were added to wells containing cells, separately. Untreated cells were taken as the control. Over time, 20 µl of MTT solution at a concentration of 5 mg ml⁻¹ were added to each well, and the plate was incubated for 4 hours. Afterward, the medium containing MTT was removed and 200 µl of DMSO solution was added to each well to dissolve the formazan crystals formed in living cells. Finally, after 15 min of incubation, the optical absorption of each well was read by ELISA reader at a wavelength of 570 nm. All tests were performed in triplicate and the results were reported as cell viability referred to control (Eq. 1).

**Statistical analysis**

All the experimental, data were expressed as means (means ± SD). The antimicrobial activity data were analyzed using the one-way ANOVA with IBM SPSS version 20.1.
Results

Out of 50 (K. pneumonia) isolate collected from the Urinary tract infection patients, were obtained. Initial identification of bacterial strains using biochemical tests, showed that 100% of the strains were negative for catalase, oxidase, and endol and positive for VP. 95% of cases were positive for urea’s and citrate and 90% were positive for H2S. As showed in Fig 1

Antibiotic susceptibility testing

The Antibiotic susceptibility testing cards used to determine antibiotic susceptibility and ESBLs producing strains. Based on the antibiotic resistance profile, 9 (17.6 %) from strains were sensitive (S) and 42 (82.3 %) from strains were resistant (R). The highest and lowest resistance among K. pneumoniae strains was observed for ampicillin (AMP) (100 %) and tigecycline (TGC) (0 %), respectively. The piperacillin/tazobactam (TMP-SMX), cefazolin (CFZ), cefoxin (FOX), ceftazidime (CAZ), ceftriaxone (CTR), cefepime (FEP), imipenem (IPM) and amikacin (AMK) antibiotics with 82 % resistance among the strains were ranked second. It was also found that none of the bacterial strains produces ESBLs. Yang and colleagues reported that among 137 K. pneumoniae strains isolated urine, more than 85 % of ESBLs-producing bacteria have the ability to produce biofilm, whereas our results showed that none of the strains were ESBLs producers.

The result in the Table 1. Observe the minimum biofilm eliminating concentration (MBEC) of the mixed nanoparticles also found that Ag - Al2O3 NPs has the highest inhibitory effect on biofilm formation of K. pneumoniae strains. Treatment of K. pneumoniae strains with 0.5 mg ml⁻¹ of Ag - Al2O3 NPs completely prevented the formation of biofilm in K-13 and K-36 strains. The checkerboard assay was used to evaluate the synergistic effects of mixed nanoparticles. Statistical analysis revealed that there was no significant difference in MBEC of nanoparticles against K. pneumoniae strains in the concentration range of 0.031 – 1 mg ml⁻¹ (p > 0.05).

The minimum inhibitory concentration (MIC) against bacterial strains were performed using broth microdilution assay. As you can see in the Table 2, the results of the statistical analysis shows that there is a significant difference between the GI % of Ag and Ni NPs, as well as Al2O3 and Ni NPs in the concentration range of 0.125 – 1 mg ml⁻¹ in K. pneumoniae strains. Significant (p > 0.05). The interaction between Ag – Ni and Ag – Al2O3 NPs was synergistic against all the K. pneumoniae strains. While an indifference effect was observed for Al2O3 - Ni NPs in K. pneumoniae strains.

The MTT assay was used to assess the cytotoxicity of NPs. The percentage of cell viability in the presence of Ag and Al2O3 NPs are shown in Fig. 2a, b, respectively. As it can be seen the cell survival is reduced, by increasing the concentration of (NP) nanoparticles in a concentration-dependent manner after 24 h. Ag NPs showed higher cytotoxicity toward Neuro-2a cells as compared to Al2O3 NPs, so that at a concentrations of 100 µg ml⁻¹ of Ag NPs and 500 µg ml⁻¹ of Al2O3 NPs decreased the Neuro-2a cells survival by 61 % and 36.7 %, respectively.

Fig. 2. Percentage of cell viability of Neuro-2a cells in presence of different concentrations of Ag NPs (a) and Al2O3 NPs (b)
This study was carried out on 50 *K. pneumonia* isolates was identification of bacterial strains by biochemical tests revealed that all strains it’s belong to *K. pneumonia* consistent. This is in accordance with results developed by (13). The results of biochemical tests showed that *K. pneumonia* strain is gram negative, rod-shaped, non-motile, negative gelatinase and indole, and positive catalase and urease. The strains are positive for the fermentation test of all carbohydrates Voges-Proskauer (14).

From Figure 1, it can be observed. antibiotic susceptibility cards was found a similar study by (15) reported that among 137 *K.pneumoniae* strains isolated from sputum and urine, more than 85 % of ESBLs-producing bacteria have the ability to produce biofilm, whereas our results showed that none of the strains were ESBLs producers.

Similar findings were observed the MIC and MBEC in the study conducted by (16). They evaluated the antibiofilm activity of silver nanoparticles against microorganisms using of Congo-red and tube methods, it was determined that biofilm formation in *C.neoformans* and *K.pneumoniae* bacteria was completely inhibited by tube method. Other study investigated the effects of AgNPs in different concentrations on *K.pneumoniae* biofilm; the findings demonstrated that biofilm growth was completely inhibited in 40 and 80 µg ml-1 of nanoparticles (17). The MIC results showed that the addition of thallium ions into ZnO significantly increased the bacteriostatic activity of ZnO nanoparticles against *E. coli*, *S. aureus* and *B. subtilis* strains by (18).

Many studies have also been conducted to evaluate the cytotoxic activity of Al₂O₃ NPs, but unlike other NPs, Al₂O₃ NPs have less effect for human cell lines. In one of these studies, the cytotoxicity effects of Al₂O₃ NPs on L926 and BJ cells were investigated and it was found that NPs had no significant cytotoxicity in the concentration range of 10 to 200 µg ml⁻¹, and at a concentration of 400 µg ml⁻¹, about 10% of the cell survival was reduced (19). Zhang et al. evaluated the impact of various NPs (ZnO, TiO₂, SiO₂ and Al₂O₃) on HFL1 cells. The findings showed that Al₂O₃ NPs had the least effect on cellular survival, and a reduction of about 10% of cell viability at a concentration of 250 µg ml⁻¹ was observed (20).

**Conclusions**

In this study we have investigated the antimicrobial activity of different nanoparticles against urinary tract infections caused by *K. pneumonia*. The nanoparticles could be used as an effective anti-microorganism agent for the treatment of urinary tract infections caused by *K. pneumonia*. However, Ag-Ni NPs revealed more efficacy than other mixed NPs. On the other hand, Ag NPs indicated higher cytotoxicity against Neuro-2a cells as compared to Al₂O₃ NPs. It seems that the mentioned NPs can be a good candidate for the treatment of bacterial infections and the removal of antibiotic-resistant strains.

Ulnar length – A Tool for Stature Estimation

Atul S Keche¹, Harsha A Keche²

¹Professor, Department of Forensic Medicine & Toxicology, JNMC, Sawangi, Wardha, Maharashtra, ²Professor, Department of Anatomy, JNMC, Sawangi, Wardha

Abstract

Stature is a important factor in identification of an unidentified dead body or any mutilated part of such body. In present study we made an attempt to estimate the stature from percutaneous length of ulna. Study consists of 94 adult males and 96 adult females between the age group of 18- 24 years, born and brought up in Maharashtra. The length of the of the right and left ulna was measured with a venier calliper from the apex of the olecranon to the styloid process and the height of the individual was measured with a calibrated standing meter rule. The measurements were noted in the proforma. The data was statistically analyzed and linear regression formulae were derived.

Key Words: Ulnar length, Stature, Linear regression.

Introduction

Stature is a important factor in identification of an unidentified dead body or any mutilated part of such body.¹ Anthropometry has an extensive application in forensic sciences, and it is receiving augmented use especially in the discipline of Forensic Medicine and Anatomy. Anthropometric data are believed to be objective.²

When intact bodies are to be examined, stature estimation does not pose any problem. However, in cases of dismembered human body parts, mutilated and decomposed bodies there is a greater challenge for the forensic experts. Several factors are taken into consideration for establishing the identity in these cases. Stature is considered as one of the important parameters for personal identification and stature reconstruction plays a vital role in identification of individuals.³ Assessment of height from different parts of body by anthropometry of skeleton is always an area of interest to anatomist, anthropologists and forensic experts.⁴

In calculating stature from bones, regression formulae based on long-bone measurements is the easiest and trustworthy method that yields the most accurate results. The ulna is a long bone that is often used for body height estimation. Once the ossification of all bones is complete, there is no further growth of a person. Ossification of upper limb bones is usually complete within 19-22 years of age. Hence, the present study was conducted on persons belonging to age group of 19 -24 years with an effort to establish a correlation between length of ulna and body stature.²

The equations that were derived by Trotter and Gleser in the early 1950s for Americans were being continuously revised using data from different sources. In 1961, Allbrook attempted to develop standards for the estimation of stature from a British sample using ulnar length.⁵ The most detailed description of stature estimation from skeletal remains was compiled by Krogman and Iscan. Pearson estimated the stature from long bones by formulating the regression equations. He also found that these formulae are population specific and should not be applied to individuals of different population groups.⁶

Material and Method

The present study comprised of a total 190 Medical college students belonging to different regions of Maharashtra residing in and around Jalgaon. Their age ranged between 19 to 24 years. After obtaining informed consent from the study participants we recorded the data in our proforma. Students with
significant systemic diseases, history of old fractures, orthopaedic malformation, developmental disorders, metabolic disorders which could have affected the bony growth were excluded from study. The measurements were taken at a fixed time of a day to eliminate diurnal discrepancy. Ulna is mostly subcutaneous throughout its length and easily approachable for measurement.

The length of the of the right and left ulna was measured with a standard venier calliper from the apex of the olecranon to the styloid process with the elbow in full flexion and the height of the individual was measured from crown to heel with head oriented in Frankfurt’s plane with a calibrated standing meter rule.

The measurements were tabulated in the proforma and the data was analyzed using SPSS version 24 statistical package. The linear regression formulae were also derived to determine the stature separately for males and females.

### Observation & Results

</tbody>
</table>
Above table shows the linear regression equation for height with length of ulna in male and female where,

\[
Y = \frac{\text{Height}}{\text{Stature (cm)}}
\]

\[
X = \text{Length of ulna (cm)}
\]

36.54, 36.73 are intercept (constant) of right and left ulna of male.

14.84, 20.45 are intercept (constant) of right and left ulna of female.

4.87, 4.81 are regression coefficient for male,

5.57, 5.41 are regression coefficient for females.

**Discussion**

Anthropometry is considered as the simple, inexpensive, non-invasive method to assess body proportions. Stature estimation methods cannot be universally applied due to the influence of environment among population, modernisation and social economic development between nations and even among people of the same nation. \(^7\)

In our study, correlation coefficient (r) of height and length of right ulna is 0.875 and of left ulna is 0.854 in males; 0.919 (right ulna) and 0.917 (left ulna) in females. In the study by Amit Mehta et al, the correlation coefficient (r) was 0.754 (right ulna) and 0.745 (left ulna) in males; 0.691 (right ulna) and 0.701 (left ulna) in females. \(^8\) The value of r shows a positive correlation which is also very highly significant (P < 0.001). The Correlation coefficient between the total height and length of ulna was found to be positive indicating a strong relationship between the two parameters. The positive correlation suggests if length of ulna increases or decreases, the height of the subject also increases or decreases and vice versa. \(^6\) It must be noted that estimates are mean values with appropriate standard deviations, so estimated stature of unidentified remains may be inaccurate by several centimeters. \(^9\) The data of the study can be used for estimation of stature amongst specific ethnic group.

Various authors have shown a significant correlation between height and length of ulna. Allbrook derived regression formulae for estimation of stature from the length of ulna in British population as: Stature: 88.94 + 3.06 (ulnar length) ± 4.4 (Standard error). Athawala derived a regression formula for estimation of stature in Maharastrians of India; Stature = 56.9709 cm + 3.9613 X average length of right or left ulna (cm) ± 3.64 cm. In our study the linear regression equation for males is stature= 36.12+ 4.86 x length of ulna and for females, stature= 16.98 + 5.52 x length of ulna. \(^2\)

In study by Babu RS et al, mean value of right ulnar length is 27.84 cm and that of left ulnar length is 27.75 in males. \(^3\) According to Borhani-Haghighi M. et al, the mean length of the ulna was 29.17 cm in males and 26.47 cm in females. In our study, mean length of right ulna was 28.54±0.93 and mean length of left ulna was 28.82±0.91 for males. For females mean length of right ulna was 25.81±1.07 and mean length of left ulna was 25.58±1.09. Similar were the observations by Bamne et al and Ashish Pande. \(^5, 6, 10, 11\) In the study by Anjali Prasad et al, gender differences in mean height and length of ulna were found to be highly significant and mean ulna lengths of the male were significantly larger than that of the females of all ages. The mean value of length of right and left ulna is statistically insignificant in males and also in females correlating with our study. \(^12\)

Abstract

Introduction - Forensic odontology helps in identifying any suspect involved in crime, in accidental cases, in disaster victim identifications. Teeth show variation in its anatomy as it has a very strong hereditary component. Variations in occlusal morphology of teeth include differences in the number of cusps and the fissure pattern. So, it is important to know the occlusal morphology of teeth in Forensic odontology.

Materials and Method - A descriptive study was conducted to evaluate the cusp and groove pattern in primary second molar of 3-6 year old children from Anganwadis of Faridabad. Hellman and Gregory's criteria for groove pattern were used to know the buccal groove pattern and cusps of primary molar. Data were analyzed with SPSS statistics software 23.0 version.

Result - The predominant groove pattern was “Y” (73.34%). Majority of the participants has 5 cusps in primary second molar. 67.45% of the study participants had 5Y occlusal morphology of primary mandibular second molar and it is mostly seen in male children.

Conclusion - This occlusal configuration will further help in various genetic, anthropological and forensic investigations. Furthermore, knowing common variations in dental anatomy and morphology about each individual tooth can help in providing dental treatments such as restorative, endodontic and orthodontic treatments.

Keywords – Cusps, grooves, primary molar, forensics

Introduction

Forensic odontology mainly includes use of teeth and oral structures. It helps in identifying any suspect involved in crime or in accidental cases. Sometimes forensic dentistry is involved in disaster victim identifications such as flood, tsunamis and earthquake. As oral structures are hard structures of body and can remain safe even in adverse conditions so they can be easily used for forensics. These structures can withstand high temperature as well as they are not easily decomposed by bacteria. So they can be recovered in case of mass fatality when where the other means of identification such as fingerprints and facial features are destroyed.

Anatomical characteristics of teeth and jaws helps in providing important information related to different species. Teeth show variation in its anatomy as it has a very strong hereditary component which helps in recording and assessing various evolutionary changes in a population. Within a population, some people have specific structure, while others do not. Further, there is variation observed in anatomy of different oral structures like teeth according to gender and age.

So, data regarding variation and diversities within population can also be obtained using Forensic dentistry. Dental characteristics such as tooth morphology, number, position, size, colour, rotation, malalignment,
filings, oral pathologies, tooth wear, and other dental anomalies provide a special identity to an individual which helps in identification of an individual. Further, various genetic and environmental factors as well as some oral habits influence the tooth structure formation. Tooth structure formation is a slow progressive process and involves a lot of molecular and cellular interactions.

The cusps, ridges, and grooves that are present on crown surface vary in number and form of tooth roots within different species of primates. Variations in occlusal morphology of teeth also include differences in the number of cusps and the fissure pattern. These morphological differences play a major role in clinical practice also. Dental practitioners and specialists should know these differences, as it can affect various dental treatments. Gregory allocated a cusp number according to its position to make it easy for description of mandibular molars (cusp 1, mesiobuccal; cusp 2, mesiolingual; cusp 3, distobuccal; cusp 4, distolingual; cusp 5, distal; and cusp 6, distomedial). Mandibular first molars are usually five-cusped.

Groove pattern are the fundamental arrangement of grooves and cusps on occlusal surface of primary and permanent molars. It is observed that this trait (fissure pattern) is polygenic, and its expression of this trait is determined by combinations of alleles at two or more loci. A total of six occlusal groove patterns are observed in permanent mandibular molars: 4+, 4Y, 5+, 5Y, 6+, and 6Y, where 4, 5, and 6 represent the number of cusps present and “+” and “Y” represents the groove patterns. The basic pattern is the “5Y” type.

The primary second mandibular molar is smaller in size as compared to permanent first mandibular molar. They both resembles in shape. The objective of the present study was to assess the occlusal morphology of the primary mandibular second molar in North Indian population.

Information regarding variations in the dental anatomy and morphology of each tooth can help in some dental treatments, like restorative, endodontic, and orthodontic treatments. Till today, there are very few studies on the frequency and expression of different types of occlusal grooves and patterns of the primary mandibular molars in North Indian population. Hence, the present study was undertaken to assess the number of cusps and occlusal groove patterns in the primary mandibular second molar of Faridabad district, North India.

Material and Method

A descriptive study was conducted to evaluate the cusp and groove pattern in primary second molar of 3-6 year old children from eight Anganwadis of Faridabad, North India. Four Anganwadis were selected from East and four from West Faridabad through cluster random sampling. A total of 484 children were examined for checking grooves and cusps pattern. Ethical approval to conduct the study was taken from institutional ethical committee. Permission from concerned authorities of Anganwadis and consents from parents was obtained to conduct the study after explaining the purpose of the study. Demographic details like age, gender were recorded. Intra Oral examination was done for number of cusps and grooves using moth mirror under natural light. Hellman and Gregory’s criteria for groove pattern were used. Inter examiner reliability was found to be 0.82. Y pattern was considered if the contact of metaconid with the hypoconid occurs. If there was no contact of the metaconid with the hypoconid then + pattern was considered.

Data were analyzed with IBM. SPSS statistics software 23.0 version (SPSS 23.0, IBM, Armonk, NY, United States of America). Children with fully erupted primary second molar, cooperative patients and molars showing clear occlusal outline with all cups and groove pattern were included in the present study. Broken teeth, filled teeth, decayed teeth, teeth with developmental defects of the structure and shape were excluded.

Result

The present study was conducted among 484 Anganwadi children. Among these study participants, 320 were males and 164 are females. In this population, five cusp pattern was most frequently observed. The predominant groove pattern was “Y” (73.34%). Table 1 shows distribution of cusp and groove pattern. Table 2 shows distribution of cusp and groove pattern according to gender are depicted in Table 2 and 3 respectively.

Discussion

It is very important to study oral anatomical characteristics like teeth as they are very valuable in forensic odontology and other anthropological studies. Forensic odontology provides information related to hereditary relationship and differences in characteristics within a population. There is inherent variability observed in human dentition, so it is very easy for a forensic odontologist to make dental identification. Further, if good evidence is there then identification can be done with high level of accuracy. Generally antemortem dental records include radiographs; dental charts, both intra- and/or extra-oral photographs, dental casts, and notes.

Occlusal anatomy of primary molars has been recognized as important feature in dental anatomy and clinical dentistry. There is basic arrangement of cusps and grooves on occlusal surface of primary second molar.
Expression of groove trait is determined by combinations of alleles at two or more loci. So, a dental trait in humans can be a valuable diagnostic tool in anthropological studies for differentiating and characterizing various ethnic groups. In past, various studies have been done to relate the prevalence of dental anatomy with different factors. Variations in the size, number of cusps, and groove pattern, have been observed in the mandibular molars of different populations.

The morphological features of the occlusal surfaces of the mandibular molars have been described by Gregory and Hellman. The present study aimed to determine the prevalence of different occlusal morphologies (number of cusps and occlusal groove patterns) of the permanent mandibular second molar in Faridabad district, North India.

In the present study, 5 cusps (87.6%) was the most commonly observed cusp type in primary second molar. 4 and 6 cusps types (6.19%) were seen equally among the study population. In contrast to the present study, study done by Phullari et al had seen that the 4 cusp form (88.4%) was the most frequent in second permanent molars. Similarly, in study done by Shetty el al and Dholia et al also, it has been observed that the 4 cusp form was the most frequent occlusal configuration in 86% and 93.5% of the study population respectively. The reason for this could be that majority of the study participants in the present study were males (66.1%) and it has been seen that variation in anatomical structure occur according to gender.

The most commonly observed groove pattern in the present study population was Y (73.34%). In contrast to the present study, in the study done by Shetty et al, the predominant occlusal groove pattern seen in mandibular second molar was a “+” shape (85%) followed by “y” pattern (11%) similarly, in the study done by Phullari et al and Dholia et al it was observed that the predominant groove pattern was “+” in 90.1% and 93.5% of study participants respectively. Again, the reason for this could be gender variation in these studies.

The most prevalent occlusal configuration of primary second molars in the present study participants was 5Y pattern. This configuration is important in forensic odontology and only 15% dental practitioners have formal training in collecting, evaluating, and presenting dental evidence. So, there is an increased need for dental surgeons to have a good knowledge about forensic odontology as it is useful in identification of an individual and also discover abuse among all ages.

**Conclusion**

The present study has been done in children of Anganwadi, Faridabad; it was observed that the most common occlusal configuration was 5Y. This occlusal configuration will further help in various genetic, anthropological and forensic investigations. Furthermore, knowing common variations in dental anatomy and morphology about each individual tooth can help in providing dental treatments such as restorative, endodontic and orthodontic treatments. Hence, studying the occlusal morphology of second molar will be helpful in forensic as well as clinical practice.

Health Status of Children in Assam

Chayanika Goswami
PhD Research Scholar, Dept of Economics, Gauhati University, Assam

Abstract

Children are the most valuable asset of a nation; their good health is the cornerstone for survival and development for current and succeeding generations which guarantee the sound and sustained economic development. Child health is a state of social, emotional, intellectual, mental and physical well-being which does not merely represent the absence of disease or infirmity. The term nutrition refers to a process of attaining necessary food for proper health and growth of human being. The nutritional status of children impacts their health, cognition and educational achievements. But underweight and malnutrition are most prominent health indicators in India and also in Assam (According to NFHS-3 & NFHS-4). Assam is situated in the North-East of India, bearing a considerable percentage of its population under the poverty line. Assam does not have shown much improvement in its health and nutrition indicators. Almost 36.4 percent children under age 5 are stunted and Infant Mortality Rate as high as 48 (NFHS-4). The health status of children in rural areas of Assam is very pathetic. 55 percent children are stunting in rural areas. Various reports states that though Assam has made progress in its health indicators, still there is a great need to strengthen its existing health care services especially in the rural areas. The present study has made an attempt to study the health status of children in Assam. This study may be able to provide a base line information and need for effective implementation of various schemes and programmes for the improvement of health status of children in future.

Keywords: Assam, Child, Economic Development, Health Care, Health Indicators, Nutrition.

Introduction

Childhood is a significant phase of life and deprivation during this period can have long term adverse impact on the well being of children. Child health is a state of social, emotional, intellectual, mental and physical well-being which does not merely represent the absence of disease or infirmity. The term nutrition refers to a process of attaining necessary food for proper health and growth of human being. According to World Health Organization (WHO), “Malnutrition means the cellular imbalance between, supply of nutrients and energy and the body’s demand for them to ensure growth, maintenance and specific functions.”

Healthy children have the fullest potentialities to attain proper weight in relation to height and resistance to diseases. Thus, it may increase life expectancy and help human beings to enjoy life fully, may also increase work capacity that results in increased productivity of nation and it enhances economic growth and development. Assam is situated in the North-East of India, bearing a considerable percentage of its population under the poverty line. Assam does not have shown much improvement in its health and nutrition indicators. Almost 36.4 percent children under age 5 are stunted and Infant Mortality Rate as high as 48 (NFHS). Various research article and study has reported that children in the developing country are most vulnerable as 50 percent of all deaths were occurring during the first 5 years of life. Despite inclusive efforts for improving malnutrition like ICDS programme, malnutrition among children remains a significant problem in India as well as in Assam.

The most common method used to assess the health status of children is given by World Health Organization (WHO). WHO growth standard can be used to assess
whether children are growing and developing. It can also be used to observe whether efforts to reduce child mortality and disease are effective. According to WHO, growth standard are:-

- If < -1 to > -2 Z-score implies Mild Malnutrition
- If < -2 to > -3 Z-score implies Moderate Malnutrition and
- If < -3 Z-score implies Severe Malnutrition

On the basis of the above growth standard, three common anthropometric indicators are used to measure the nutritional status are -

1. **Height-for-age (HAZ)**. HAZ is used to denote “stunting” - or low height for age, which is an indicator of chronic form of under-nutrition. It is caused by long-term insufficient nutrition intake and frequent infections.

2. **Weight-for-height (WHZ)**. WAZ or low weight corresponding to height stands for “wasting” or more acute or current form of under nutrition. It is a strong predictor of mortality among children under five. It is usually the result of acute significant food shortage or disease.

3. **Weight-for-age (WAZ)**. The WHZ, low weight for age, is an indicator of chronic form of under-nutrition, denoting “under-weight.”

**Objective:**

1. To study the health status of children in Assam.

**Methodology**

The present study is based on the secondary data that are collected from different government reports and organizations. The sources of secondary data are:-

i. The Department of Social Welfare, Government of Assam;

ii. National Family Health Survey -3 (NFHS-3)

iii. National Family Health Survey - 4 (NFHS-4)

iv. Census reports, Govt. of India.

v. Health and family welfare reports.

vi. Statistical Handbook of Govt. of Assam.

vii. Nutrition Policy reports of Govt. of India, etc.

**Results and Discussions**

Assam happens to be one of the worst performers in reducing child’s nutritional status. A scrutiny of the nutritional status of the children, the adults of tomorrow, is important to assess the wellbeing and health. Detailed studies were prepared by NFHS-3 and NFHS-4 and the main findings shows that stunted rate is 46.5 percent, wasted rate is 13.7 percent, severely wasted rate is 4.0 percent and underweight rate is 36.4 percent. However, according to NFHS-4, stunted rate has reduced to 36.4 percent and underweight rate also reduced to 29.8 percent. On the other hand, wasted rate and severely wasted rate has increased to 17.0 percent and 6.2 percent respectively. Again in Assam, the infant mortality rate and under 5 mortality rates is 48 and 56 respectively which is 66 and 84.

The following table shows the percentage of malnourished children in Assam –

<table>
<thead>
<tr>
<th>Table-1: Child Malnutrition Status in Assam</th>

<td>Infant Mortality Rate</td>
</tr>
<tr>
<td>Under Five Mortality Rate</td>
</tr>
</tbody>
</table>

Source: NFHS - 3 & NFHS - 4
In Assam, the percentage of stunted children has decreased from 46.5 percent to 36.4 percent whereas wasted and severely wasted children are increased from 13.5 percent to 17 percent and 4 percent to 6.2 percent respectively. But the percentage of underweight children has reduced from 36.4 percent to 29.8 percent.

The district wise nutritional status of children in Assam is shown in table 1.2. It can be seen from table 1.2 that Dhubri district has the highest number of “stunting” children with 47.4 per cent. Goalpara district has the highest number of “under-weight” children with 39.5 per cent. Cachar district on the other hand, has the highest number of “wasting” children with 30.6 per cent.

If we look at the table of health status of children of Assam in the geographical diversity category, it was found that the number of “stunting” children is highest in general area (66.1 per cent) followed by Char areas (61.8 per cent). According to the Human Development Reports (HDR) Assam-2014, the multiple diversity areas and border areas are more vulnerable to “under-weight” and “wasting” children. Number of wasting and under-weight children is highest in multiple diversity areas (24.6 percent and 45.8 per cent) followed by border areas (22.3 percent and 39.8 per cent). The following table shows the health status of children according to geographical diversity-

Source: Assam HDR, 2014

The HDR Assam-2014 studied the male-female break up regarding the nutritional status of children under age five and it was found that 55 per cent male children against 52.9 per cent female children are “stunting”, 17.7 per cent male against 16.1 per cent is “wasting”, 39 per cent male children against 35.7 per cent female children are “under-weight.” Again, the rural-urban break up has shown that 55 per cent rural children against 44.3 percent urban children are “stunting”; 17.1 per cent rural children against 15.6 urban children are “wasting” and 38.2 rural children against 30.4 urban children are “under-weight.” The following table shows male-female and rural-urban break up in the three category of nutritional status of children in Assam:-

Source: Assam HDR, 2014
Conclusion

From the above, we can conclude that Assam has made progress in its health indicators, but it is most urgent to strengthen its existing health care services especially in the rural areas. The percentage of proper nourished children in rural Assam is not very satisfactory. 55 percent children are stunting in rural areas. According to National Family Health Survey-4, the health profile of Assam shows that about 29.8% children below the age of 5 years are underweight. Besides, 35.7% children between the age group of 6-59 months are anemic and about 25.7% women have body mass index (BMI) below normal. It indicates the state of acute malnutrition which may be attributed to lack of proper nutritious foods, illiteracy among parents, lack of proper sanitization facilities, irregular health checkup, food scarcity and various socio economics factors that affect the nutritional status of children. Under National Rural Health Mission (NRHM) various quality development programme has been launched and under the Ministry of Social Welfare, ICDS programme has been introduced to facilitate regular health check-up, immunization, health education and other child health education programme.

Knowledge, Attitude and Behavior of Undergraduate Dental Students towards Cardiopulmonary Resuscitation: A Descriptive Study

Deesha Kumari1, Thara Chandran2, Bless Annie Philip3, Mithun K4, Shilpa M5

1Senior Lecturer, 2Senior Lecturer, 3Tutor, Nitte (Deemed to be University), AB Shetty Memorial Institute of Dental Sciences (ABSMIDS), Department of Public Health Dentistry, Mangalore, India, 4Senior Lecturer, Department of Orthodontics & Dentofacial Orthopedics, AJ Institute of Dental Sciences, Kuntikana, Mangalore, Karnataka, 5Senior Lecturer, Nitte (Deemed to be University), AB Shetty Memorial Institute of Dental Sciences (ABSMIDS), Department of Public Health Dentistry, Mangalore, India

Abstract

Context: Medical Emergencies can be encountered by any individual, and its occurrence is usually high in a Dental setting due to the procedures involved. Hence it is important that Dentists be equipped with the knowledge of Cardiopulmonary resuscitation (CPR).

Aims: The Study aims to assess the Knowledge, Attitude and Behavior of Dental Undergraduate students towards CPR training.

Methods and Materials: The present study was a Cross Sectional study conducted among 163 Final Year Undergraduate students and Interns of a Dental Institution in Mangalore. A validated Self Structured Questionnaire was distributed to the students.

Statistical Analysis: Descriptive and Inferential statistics like Student’s Unpaired T Test determined the difference in Knowledge, Attitude and Behavior among the participants.

Results: The overall Knowledge of Students regarding CPR was Poor, with Interns possessing a Significantly higher Knowledge than Final Year BDS Students. Amidst the poor Knowledge, 75.5% students were trained in CPR and 65.6% students were ready to perform CPR in an emergency situation thus displaying a Positive Attitude.

Conclusion: The present study showed that despite a dearth in CPR Knowledge among the Students, they exhibited a Positive Attitude and Behavior towards Training and Practice of CPR. Thus the study highlights the need to strengthen CPR training among Dental Students, by Inculcating and Standardizing it in the Undergraduate and Postgraduate curriculum.

Keywords: Undergraduates, Cardiopulmonary Resuscitation, Knowledge, Attitude, Behavior

Introduction

India, a developing nation has witnessed a paradigm shift in the burden of Non-Communicable diseases which can be attributed to the changing Lifestyle among the Population. Cardiovascular diseases are one among the major Non Communicable diseases which has been responsible for the rising Mortality rate. In 2016 Cardiovascular diseases accounted for 28.1% of the total deaths in India. Cardiac arrests are the most
common emergencies with grave consequences and thus has paralleled the need for all Population sectors to be competent in handling medical emergencies to increase the Golden Period for an ailing patient till medical care is available\(^2\).

Medical Emergencies are multi-factorial in nature. They can occur at any time, at any place and to any person. Dental Treatments being invasive in nature can predispose any individual to the risk of medical emergencies. A study by Haas D has quoted that approximately 19-44% dentists had encountered a medical emergency in a year especially during and after the application of Local Anaesthesia for Extraction and during Endodontic Procedures. Syncope and Hyperventilation were the most commonly reported medical emergencies\(^3\).

The enormity of these situations substantiates the need for Dental Professionals to be equipped with the skill sets of performing Cardio-Pulmonary Resuscitation (CPR). To bestow Dental Professionals with the knowledge to handle such emergencies, the underpinning established at the undergraduate juncture is crucial. CPR training although has been inculcated in the Undergraduate Curriculum, it is often overlooked by majority of the Dental Colleges as they impart only theoretical knowledge to the students rather than the Practical Aspects of the same \(^4\). Thus the competency of the students in handling Medical Emergencies are compromised to a large extent.

Studies in India and Globally have assessed the Knowledge, Attitude and Behaviour of Medical Students\(^5,6\), Nurses\(^7,8\) and Private Dental Practitioners\(^4,9-11\) towards CPR training. In India studies assessing Dental Students’ awareness on CPR are meagre\(^12,13\). Hence this present study aims to close the current gap by assessing the Knowledge, Attitude and Behaviour of Final Year Dental Undergraduates and Interns towards CPR training.

**Materials and Method**

The present study followed a Cross Sectional study design. It was conducted among the Final Year Undergraduate students and Interns of a Dental Institution in Mangalore during January to August 2019 after obtaining Ethical Clearance from the Institutional Review Board. All the Final Year Undergraduates and Interns in the Institution were approached to participate in the study following a Total Enumeration Method. Students who provided Consent and present on the day of the study were included.

A Self structured and validated questionnaire in English language was developed which consisted of 19 closed ended questions. 10 questions addressed the Knowledge Domain, 6 questions addressed the Attitude domain and 3 Questions addressed the Behaviour domain of the participants. After obtaining Written Informed Consent from the participants, the Questionnaire was distributed to them in their classrooms. Care was taken to ensure that no verbal or non-verbal communication could occur among the participants and no names were recorded to ensure anonymity in order to obtain immaculate data. The obtained data was entered into Microsoft Excel and analysed using SPSS version 23 for Descriptive Statistics and Inferential Statistics. The Year wise and Gender Wise differences in the Knowledge, Attitude and Behaviour of the students was analysed using Student’s Unpaired T Test with a significance level of p<0.05.

**Results**

The study obtained a response rate of 95.3%. Among the participants 78 (47.9%) were Final Year BDS students and 85 (52.1%) were Interns. 67.5% of the participants were Females.

Knowledge of students regarding CPR

The Knowledge Domain consisted of 10 Questions among which 7 questions received greater percentage of incorrect responses by the Participants indicating a Poor Knowledge among them. About 69.3% and 51.5% students were unaware of the abbreviations of CPR and Automated External Defibrillator respectively. 63.8% students were unaware of the recommended sequence of CPR (Table 1). Interns exhibited a higher Knowledge score (6.09±2.43) as compared to the Final Year BDS students (3.26±1.39) and this difference was statistically significant (p=0.000) (Table 2). While no significant Gender wise difference was found, Females had a significantly higher Knowledge score than Males \([p<0.05]\) (Table 3).

Attitude of students towards CPR training

75.5% of the students had undergone training in CPR and 65.6% of them were ready to perform CPR in an emergency situation, displaying a Positive Attitude. 73.6% of the students were of the opinion that dentists
need to be competent in performing CPR and hence wanted CPR training to be a part of the BDS Curriculum (Table 4). No Year wise or Gender wise difference was observed in the responses of the participants \[p>0.05\] (Table 2 and 3).

**Behaviour of students towards CPR training**

The behaviour of the students towards performing a Life Support mechanism during an emergency event was observed to be positive. 60.1% students said that on witnessing an unresponsive patient they would initiate CPR by checking for breathing (Table 5).

A Statistically Significant difference was observed in the Behaviour of Final BDS Students and Interns \(p=0.009\) (Table 2). However, no significant Gender wise difference was found \[p=0.065\] (Table 3).

**Discussion and Conclusion**

A stitch in time saves nine. Similarly, Cardio pulmonary Resuscitation is a procedure which can save an individual’s life if carried out at the right time and appropriately. Dentists are bestowed with the reverence of doctors and thus are often looked upon by people as a life saver in any emergency situation. Hence, they need to be equipped with this life saving skill set owing to the non-invasive procedures they perform. This study thus seeks to explore the Knowledge, Attitude and Behaviour of Dental Students towards CPR training.

In the present study, it was found that the Knowledge of students was found to be Poor. Majority of the Students in our study were unaware of the Recommended sequence of CPR, the recommended Compressions per minute or the Absolute Indications of CPR. The Interns displayed a significantly higher Knowledge as compared to the Final BDS Students. The findings of our study is in par with various studies conducted worldwide. Studies by Shamiri et al and Alotaibi et al showed that the Dental students and Faculty had Poor Knowledge regarding CPR procedure\(^{14,15}\). This lack of Knowledge about emergency procedures among the dental students can be attributed to the lack of emphasis on CPR training in the present curriculum. CPR Training is often overlooked by many of the dental colleges, some providing merely theoretical Knowledge.

Although in the present study, a poor Knowledge was displayed by the students, it was noted that 75.5% students had undergone training in CPR. However, 65.6% students were ready to perform CPR in an emergency situation. 73.6% students felt that CPR training was necessary for Dentists and should be part of the BDS Curriculum, thus displaying a positive attitude. The results are in par with the results of a study by Goel et al where 78.5% of the participants were ready to perform CPR\(^{16}\). However, the study results are in contrast to a study by Alotaibi et al wherein 63.2% students were reluctant to perform CPR\(^{15}\). On portraying situations of Medical Emergencies, majority of the students were of the opinion that they would check for breathing and perform resuscitation procedures, thus displaying their Positive Behaviour. The findings are in par with the results of a study by Laurent et al wherein despite poor Knowledge exhibited by the students, the Attitude and Behaviour towards performing CPR was Positive\(^{17}\).

The positive Attitude and Behaviour in students can be attributed to the fact that as doctors they realize the importance of emergency medicine not only in medical field but in general, which could save a person’s life. However, the level of training provided to the students in dental colleges could hinder their confidence in independently handling CPR.

The present study was a Questionnaire study and hence the possibility of Social Desirability Bias cannot
be ruled out. The study was conducted in a single dental institution with non-assessment of practical skills of students. Thus, further research is necessary involving all Dental colleges and all BDS students and Faculty.

The results of the current study highlight the existing gap in the curriculum and the incompetency of students in the practical management of Medical Emergencies. Emphasis should lay on implementation of Standardized and Regular training of Students and Faculty in handling Medical Emergencies. Continuing dental education with hands on workshops using Mannequin followed by practical skill assessment can prove to be an effective method in this regard. Nevertheless, once graduated the students may become ignorant in enhancing their skill sets in this field. Thus post assessment, after graduating from the dental school should be made mandatory. Similar regulations have been executed worldwide. The Dental regulatory boards across USA require mandatory completion of board-approved course in Infection Control and certification in Basic Life Support courses for license renewal 18. The present study uplifts the existing Knowledge among the future dentists which is an alarming situation. Thus stringent measures in enforcing regular training of Medical emergencies should be sought after and implemented at the earliest in Dental Schools, thus producing more competent doctors.

Effect of Therapeutic Shoulder Sling And Proximal Control Exercises on Shoulder Subluxation in Stroke Survivors

Devayani Mukund Moghe¹, Suraj Bhimrao Kanase²

¹MPTh Student, ²Associate Professor Department of Neurosciences, Faculty of Physiotherapy, Krishna Institute of Medical Sciences Deemed to be University, Karad, Maharashtra

Abstract

Background: Shoulder subluxation is the common problem as it causes shoulder pain and hinders activity. In flaccid stage, proprioceptive impairment, lack of tone and muscle paralysis reduce the support and normal stirring action of rotator cuff muscles particularly supraspinatus. Methods: Ethical clearance was obtained from Institutional Ethical Comittee, KIMSDU, Karad. An Experimental study was conducted with 50 subjects. Which were divided into two groups using consecutive sampling with random allocation with computer generated table. Group A was given conventional treatment for reducing shoulder subluxation in stroke survivors Group B was treated with the Therapeutic shoulder sling and proximal control exercises. The outcome measures were AP lat X-ray, VAS, Functional outcome measurement By Motor assessment scale :Upper arm function. Results: Within the group comparison for the X-ray was done with the pair t test which was very significant for group A with P value of 0.0301 and Extremely significant for group B with P value ≤0.0001. within the group comparison for visual analogue scale for both the groups is extremely significant with the p value of ≤0.0001. within the group comparison for motor assessment scale for both the groups is extremely significant with the p value of ≤0.0001 Conclusions: Therapeutic shoulder sling with proximal control exercises shows significant reduction of subluxation in shoulder x-ray as well as it reduces the pain and improves ADL activity. Keywords: Shoulder subluxation, therapeutic shoulder sling, Proximal control exercises, VAS, MAS

Introduction

Stroke is an acute onset of neurological dysfunction due to abnormality in the cerebral circulation with resultant sign and symptom that correspond to involvement of focal areas of brain Motor deficits are characterized by paralysis (hemiplegia) or weakness (hemiparesis), typically on the side of the body opposite the side of the lesion. The term hemiplegia is often used generically to refer to the wide variety of motor problems that result from stroke. The location and extent of brain injury, the amount of collateral blood flow, and early acute care management determine the severity of neurological deficits in an individual patient. Impairments may resolve spontaneously as brain swelling subsides (reversible ischemic neurological deficit Stroke is a global health care problem that is common, serious and disabling. In most countries stroke is the second or third most common cause of death and one of the main causes of acquired disability. The estimated prevalence rate of stroke range, 84-262/100,000 in rural and 334-424/100,000 in urban areas. The incidence rate is 119-145/100,000 based on the recent population based studies. There is also a wide variation in case fatality rates with the highest being 42% in Kolkata. In the absence of any cure for the initial pathology, rehabilitation is the most universally adopted treatment strategy to improve quality of life in patients with stroke. Rehabilitation, as described by Stucki et al can be defined as ‘the health strategy that aims to enable people with health conditions experiencing or likely to experience disability to achieve and maintain optimal functioning in interaction with the environment’. The
main aim of organised stroke rehabilitation is to achieve a level of functional independence that enables patients to return home and reintegrate into community life that lives up to their own expectations and desires as much as possible. Physiotherapy is perceived as one of the key disciplines in providing Organised stroke care. Early intervention after stroke improves the prognosis.

**Normal shoulder biomechanics** Shoulder joint is ball and socket type of synovial joint with 3 degree of freedom. it is most mobile joint of human body as it is mobility is more stability is compromised. Particularly if the abduction of complex is considers the main force couple acting is the supraspinatus and posterior fibbers of deltoid muscle.

**Pathomechanics in stroke responsible for subluxation** The normal stirring action of the force couple of supraspinatus and posterior fibres of deltoid is affected due to flaccid stage of the muscles. so while abduction and flexion movement due to gravitational pull to the head of humerus subluxates caudally.

**Shoulder subluxation in stroke**

Shoulder subluxation is the common problem as it causes shoulder pain and hinders activity. the reported incidence is 17% to 18% in flaccid stage, proprioceptive impairment, lack of tone and muscle paralysis reduce the support and normal stirring action of rotator cuff muscles particularly supraspinatus. the normal orientation of glenoid fossa is upward, outward and forward. so that it keeps the superior capsule taut and stabilizes the humerus mechanically. in the absence of support from the muscles any abduction or forward flexion of humerus or scapular depression and downward rotation reduces the stabilization and causes the humerus to subluxation.

**Management of shoulder subluxation in stroke**

**Education:** Caregivers/Health Professionals/Relatives need to be informed on the importance of proper handling of the arm. Stroke patients who have their arm unsupported and/or handled inappropriately by caregivers (pulling on the arm) are at a higher risk for traction neuropathy and injury. Hence, it is essential that caregivers of stroke survivors are adequately trained in handling the hemiplegic arm especially when shoulder subluxation is present. Positioning: Lap trays, Pillows and foam support help to keep the arm and shoulder supported in the correct position. Good positioning will help reduce strain on your ligaments and prevent frozen shoulder from occurring.

**Orthotic devices:** The use of shoulder supports is common early after stroke to decrease glenohumeral subluxation and support the shoulder joint. Examples of shoulder supports are the Henderson shoulder ring, Bobath roll, Harris hemi-sling, Rolyan humeral cuff sling, Cavalier shoulder support, arm trough or lapboard and shoulder strapping. A study conducted by Nadler et al found reducing vertical subluxation with a shoulder orthoses may reduce hemiplegic shoulder pain. Orthosis with proximal and distal attachments are more effective. In addition, care must be take in its usage to avoid contractures.

**Exercises:** In the early phase of rehabilitation passive range of motion exercises has been shown to be effective in preventing shoulder subluxation among stroke patients. Range-of-motion exercises for the shoulder joint include flexion-extension, abduction-adduction and external-internal rotation. It is important to know that if the exercises are improperly carried out, it can cause injury to the shoulder and increase the stroke patient’s risk for shoulder subluxation. Also, weight bearing exercises on the affected upper extremity proved to be beneficial. these exercises are included as proximal control exercises.

**Electrical stimulation** conventional trans cutaneous electrical nerve stimulation(TENS) is given to relieve pain.

Traditionally, slings have been applied to prevent or reduce shoulder subluxation after stroke but most of them have drawback of holding the limb in poor position that is likely to cause soft tissue contractures and also affect in terms of pain. conventionally the shoulder subluxation in stroke survivors is treated considering radiological changes in joint anatomy but the pain caused due to pull to joint capsule and surrounded soft tissue is untouched area. to consider this both the shoulder sling is modified with the inclusion of electrical modality of pain relieving that is TENS this newly invented therapeutic shoulder sling gives the treatment in corrected position of shoulder joint. by means of orthosis working on three point pressure system of forces.

**Materials and Method**

The study protocol was started after obtaining ethical clearance from ethical committee of Krishna Institute of...
medical sciences deemed to be University, Karad The subjects were selected according to the inclusion and exclusion criteria. Informed consent was taken from the patient or patients caretaker. the purpose of the study was explained to the participants and their care takers Randomization is done and the subjects was divided in two groups

- **Group A** conventional management for shoulder subluxation in stroke
- **Group B** Therapeutic shoulder sling with proximal control exercises

Patient was assessed for the neurological symptoms and the pre treatment shoulder x-ray for assessing the position of humeral head in glenoid fossa was taken. pre treatment VAS also was taken Patients were also assessed for functional scale by Motor assessment scale Intervention was given for 3 weeks .5days per week for both the groups.

**Statistical Analysis**

Post treatment assessment were taken Data was statistically analyzed by using software (INSTAT 3).Within the group comparison was done with pair t test and between the group was done by unpaired t test .

**Results**

In the study out of 50 participants from group A 10 were left hemiplegics and 15 were right hemiplegics.In group B 8 were left hemiplegics and remaining 17 were right hemiplegics

In the study group A was having 15 male and 10 female .group B was having 16 male and 9 female participants. In total sample of 50 31 were male and 19 female patients.

Mean age of group B was 45 years and for group A 46 years

Discussion

Shoulder subluxation is most likely to occur in the first 3 weeks after stroke, while the limb is still flaccid and, in particular, the supraspinatus muscle is inactive. For individuals with hemiplegia inferior shoulder subluxation develops as a result of a prolonged downward pull of gravity on the arm against hypotonic muscles, resulting in overstretch of both the glenohumeral capsule and the hypotonic supraspinatus and deltoid muscle. 19

Along with the subluxation the over stretch of soft tissue causes pain and relative decreased hand activities in daily living . Present study was done in patients with brunnstrom recovery stage 2 which were having shoulder subluxation secondary to stroke. Total 50 patients were included in the study fulfilling inclusion and exclusion criteria. Group A with 25 patients received conventional treatment for the subluxation and group B received therapeutic shoulder sling and proximal control exercises.

In the available research done by K Walsh Management of shoulder pain14 in patients with stroke stated that Foam supports or shoulder strapping may be used to prevent shoulder pain.6 treatment should include high intensity transcutaneous electrical nerve stimulation.

M .leandri, C.I Parodi in their study comparison of TENS treatments in hemiplegic shoulder pain concluded that high intensity TENS valuable for treating hemiplegic shoulder pain, whereas traditional low intensity TENS seems to be of no use in such case15. Evidences shows that shoulder subluxation can be reduced by the application of external devices such as orthosis. There is insufficient evidence to conclude whether slings and prevent subluxation, decrease pain, increase function or adversely increase contracture in the shoulder after stroke . The first systematic studies of the painful shoulder after a stroke or traumatic brain injury were conducted back in the 1970s. Krempen et al. Emphasise that there are many causes of a painful shoulder in neurological diseases. In the cases where the painful shoulder occurred in conjunction with a subluxation, effective pain relief was achieved using a conventional neck.]. Radiologic evidence of the reduction of subluxation was found when this shoulder sling was used. The authors also report a reduction of pain. However, no information was provided on the effect on the development or reduction of SHS. Zorowitz et al. also studied the effect of different orthoses (“single-strap hemisling”, “Bobath roll”, “Rolyan humeral cuff sling”, “Cavalier support”) for a shoulder subluxation [23]. For the study, 20 stroke patients were provided with 4 different orthoses and the change in horizontal, vertical, and absolute asymmetry compared with the unaffected side was determined by radiologic analysis. Ultimately, an improvement of subluxation was found for all orthoses, although different orthoses had the best result for different patients. The authors concluded that fitting with an orthosis for shoulder subluxation must be customised for the individual patient. This study did not investigate other effects of the orthosis such as relieving pain or reducing SHS .7

In flaccid paralysis, subluxation due to the absence of muscular stability was identified as the cause of pain. In addition to cautious use of the affected arm and systematic interdisciplinary care, continuous support of the arm was considered to be essential. Functional electrical stimulation (FES) to activate muscles could also be important. It was not specified how continuous support of the arm should be implemented in practice12. However, continuous support the arm must be ensured not only when sitting, but also when the patient is
mobilised when standing, walking, or during therapy. Consequently, merely positioning on a therapy table or immobilising the arm in a neck slings neither sufficient nor useful.

Ada et al. come to a similar conclusion. In a review, four studies were identified that investigated the effect of an orthosis on preventing subluxation, repositioning the humeral head, reducing pain, and improving the motor function of the shoulder after a stroke. In summary, no clear evidence was found for the use of a shoulder sling. Dajpratham et al. reach the same conclusion. They also found no significant reduction of shoulder subluxation when using two different neck slings.

There is insufficient evidence to conclude whether slings and prevent subluxation, decrease pain, increase function or adversely increase contracture in the shoulder after stroke.

Present study shows the significant effect of using therapeutic shoulder sling in treating the subluxation of shoulder after stroke. In the experimental group Pain is relieved in the corrected position of shoulder by applying the therapeutic shoulder sling. Proximal muscle control exercises also shown significant changes in the post treatment radiological measurements of experimental group supports the Available Observational studies suggesting that orthoses reduce vertical subluxation whilst in-situ conventional group also showed the changes after treatment as in reduction of pain and improvement in the functional scale measured for motor assessment of upper part of arm. The use of therapeutic shoulder sling have benefited patients because it gives the simultaneous effect of pain relief in the corrected position by application of orthosis.

Conclusion
Therapeutic shoulder sling with proximal control exercises shows significant reduction of subluxation in shoulder x-ray as well as it reduces the pain and improves ADL activity.

Assessment of the Prevalence of Refractive Error among School Children (6-16 Years) of Rural Field Practice Area of Kims, Malkapur, Karad

Ankitkumar Bhopalka¹, B.S. Joshi², V.H. Karambelkar³

¹Resident, ²Associate Professor, ³Professor And Head of Department, Department of Ophthalmology, Krishna Institute of Medical Sciences deemed to be University, Karad, Maharashtra, India

Abstract

Introduction: Refractive errors are among vital causes of visual disability globally and second principal cause of preventable blindness. Refractive errors among school children remains unnoticed which have an impact on overall development of child. This study has been undertaken to estimate the prevalence of refractive errors among school going children (6-16 years).

Materials and Method: This cross-sectional study was conducted in schools of Karad from October 2017 to May 2019. Sample size was determined to be 750. School Going Children of age 6-16 years of selected schools in the rural field practice area of KIMS, Karad fulfilling the inclusion and exclusion criteria were screened on school visit. All suspected students were called to Out Patient Department and subjected to Snellen’s chart, pin-hole test, torch light examination, slit lamp examination, manual refractrometry, direct and indirect ophthalmoscopy and cyclopegic refraction (retinoscopy followed by post mydriatic test) to detect refractive error in children. A questionnaire was structured to gather relevant information from the students. Data was collected from the students after informed consent.

Results: Prevalence of Refractive Errors was 8.4%. Most frequent refractive error found was Myopia (60.3%) followed by Astigmatism (23.8%) and Hypermetropia (15.9%). It shows that only 20.63% students were wearing spectacles whereas remaining 79.37% students were unaware of their problems.

Conclusion: Visual impairment due to refractive error should be addressed as early as possible, which is attainable only by screening at initial age and hence early recognition and management.

Keyword: Refractive error, prevalence, myopia, astigmatism, Hypermetropia, Screen exposure time.

Introduction

Refractive Error is the most common cause of Visual Impairment and second principal cause of preventable blindness¹. Preventable blindness accounts for 80% blindness. Childhood blindness is a global distress. Globally, chief sources of visual impairment are uncorrected refractive errors (Myopia, Hyperopia & Astigmatism) 43%, Cataract 33%, Glaucoma 2%². Roughly 12 million accounts for refractive errors out of 19 million visually disabled children. Addition of uncorrected refractive error would escalate estimates of the global preponderance of visual disability by 61%².

About 2.3 billion people globally have refractive errors, out of which 1.8 billion have ingress to adequate ophthalmic evaluation leaving aside 500 million populations, predominantly in developing countries with optical defect leading to either blindness or impairedvision³.

Data on the preponderance of childhood blindness in India is accessible from few regions- Andhra Pradesh (0.61/1000), West Bengal (0.51/1000) and Delhi (1/1000)⁴. Roughly 1.4 million blind children are less than 15 years age globally, out of whom 2/3rd resides in the developing countries.
Further majority of children of above mentioned age group cannot reveal about the optical defects and complications they encounter, so most of the eye diseases in these children go on undiscovered unless an attempt is made for their disclosure e.g. if amblyopia can be diagnosed at early age and treated strenuously, further sequelae can be curbed. If the vision is grossly poor and cannot be improved much, such children can be advocated vocational training where eyes are not strained much and they can make use of whatever trace vision they have and which will make them capable to take care of oneself and not to be a concern for the society.

National programme for Control of Blindness (1994) proposed School Eye Screening Programme. Another initiative Vision 2020-THE RIGHT TO SIGHT was ventured by WHO in 1999 to annihilate preventable blindness like Cataract, Xerophthalmia, Refractive Errors, Trachoma and other causes of childhood blindness by 2020. In India under Vision 2020, the priority consideration to curtail childhood blindness were refractive error, cataract related amblyopia and corneal diseases.

Schools are best platform to employ health awareness and prior recognition of ocular morbidity. The school survey was endorsed over house to house survey because school procures an organized and disciplined group of children. Hence, this study was conducted to assess the degree of refractive error in school going children of KIMS, MALKAPUR, KARAD.

Materials and Method

STUDY DESIGN - “A CROSS-SECTIONAL STUDY ON PREVALENCE OF REFRACTIVE ERROR AMONG SCHOOL CHILDREN IN THE FIELD PRACTICE AREA OF KIMS, MALKAPUR, KARAD”.

Duration Of Study- 18 Months.

Period of Collection of Data- 12 Months.

Period of Analysis and Compilation- 6 Months

Inclusion Criteria: All children from 6-16 years of age of selected schools in the rural field practice area of KRISHNA INSTITUTE OF MEDICAL SCIENCES, KARAD.

Exclusion Criteria – a) Mentally retarded children. b) Children with congenital disorder. c) Absentees on the day of examination. d) Children below 6 years of age and above 16 years age.

Source of Data – School Going Children of age 6-16 years of selected schools in the rural field practice area of KIMS, MALKAPUR, KARAD fulfilling the inclusion and exclusion criteria from OCTOBER 2017 to MAY 2019.

Rationale of Sample Size -

Considering the study done by Megala.M on Prevalence of Refractive error in school children, the prevalence rate of Refractive error (p) was 20.4%. The sample size is:

\[ \text{Sample size} (n) = \frac{4pq}{L^2} \]

Taking P VALUE as 20.4%

Taking L = 3% and q=100-p

The estimated sample size is 722, roundabout to 750.

Method of Data Collection

Based on existing prevalence of ocular morbidities in school going children, the ideal sample size was about 750. By selecting three schools by simple random sampling by lottery method, we obtained sufficient sample size to derive meaningful results.

All the students in the age group of 6 to 16 years (2nd to 10th standard) present on the day of assessment in those schools were examined. Principal of all the schools were approached before the screening and their granted permission was obtained and a date was fixed for screening. Two visits were given to each school and the students absent on the day of visits were missed.

A questionnaire was structured to gather relevant information from the students. Data was collected from the patient after informed consent. Patients fulfilling the inclusion and exclusion criteria were taken.

Refractive error was tested using following instruments:

1. Snellen’s chart.
2. Direct and Indirect Ophthalmoscopy.

**Results**

In the present study, out of total study participants (750), 51.6% were male students and remaining 48.4% were female students.

Table 1 shows that 53.4% students belong to the age group of 13-16 yrs, 27.9% students belong to the age group 10-12 years and 18.7% students belong to the age group 06-09 years. The mean age of study population is found to be 12.25 with standard deviation of 3.01.

84(11.2 %) out of Total study participants (750 students) were found to have refractive error (vision <6/6). Out of 84 cases detected with defective vision by the

### Discussion

In the present study, 51.6% were male students and remaining 48.4% were female students. Study by Vidusha KSS et al (year 2018) showed similar findings – 50.6% male students and 49.4% female students.

The mean age of study population is found to be 12.25. Similar Observation found in study by Naik R et al (9.5 years), Kalkivayi V et al (9.3 years).

8.4% rate of prevalence of refractive error found in present study. Similar prevalence rate was observed in study by Pradhan N et al (7.0%), Naik R et al (7.5%) but contrast findings were seen in Vidusha KSS et al (10.5%) and Sonam Sethi et al (25.32%).

Most frequent refractive error found was Myopia (60.3%) followed by Astigmatism (23.8%) and Hypermetropia (15.9%) in the present study. Similar impression was observed by Sonam Sethi et al - 63.3% students had Myopia followed by Astigmatism (20.4%) and Hypermetropia (11.4%). Pradhan N et al conducted a study on refractive error in Haryana showed – 61.9% had Myopia followed by Astigmatism (24.1%) and Hypermetropia (14%).

The study shows that students with refractive error were complaining more about inability to see blackboard from back benches than those without refractive error. It is also seen that students exposed to screen for longer time (=1hr/day) were having refractive error. Even students reading continuously (<30mins/day) complaint of symptoms relating to refractive errors.
“What our eyes cannot see, our mind cannot read”. Therefore, visual impairment due to refractive error should be addressed as early as possible, which is attainable only by screening at initial age and hence early recognition and management. The present study supports the fact that school age forms a high risk group of refractive error.

**Ethical Approval** : All procedures performed on human participants were in agreement with ethical standards of the Institutional and/or National Ethics Committee.

**Source of Funding** : In this project, the cost of investigations of the study participants was born by the institute research fundings.

An Autopsy Study of Fatal Thermal Burns in Married Women: A Prospective Study

Bandenawaz 1, Viswakanth B2

1Associate Professor, Department of Forensic Medicine and Toxicology, Navodaya Medical College Hospital and Research Centre, Karnataka, 2Associate Professor, Department of Forensic Medicine and Toxicology, Kanachur Institute of Medical Sciences, Mangalore, Karnataka

Abstract

Death of a bride by immolation either self or by the in-laws and their family members is a well-known phenomenon since many centuries in India. Even though our country is developing in all respects, but still we are unable to prevent these deaths due to various reasons. In this study, we have made an attempt to highlight the statistics of fatal thermal deaths in married women in one year with relation to Incidence, Age, element of dowry and cause of death.

Results showed that Incidence of thermal deaths in married females was 75.2% with maximum victims in the 18-22 years age group. Further it was noted that 39% of these victims were due to alleged dowry harassment and the cause of death in majority being septic shock.

Keywords: Burns, Dowry, dowry deaths, immolation, autopsy, thermal injury.

Introduction

India has a number of homicidal deaths of women every year. It may be due to various reasons, known instances include marital infidelity, sexual jealousy and bride burning. India has a number of bride burning cases every year and most heinous of them being dowry related deaths. A majority of these cases do not get reported, invariably being disguised as a kitchen accident. When a Hindu girl gets married, parents give presents to the bride and groom based on their social and financial position. The ancient concept was that the Hindu girl could not get part of the inheritance so the father would provide her material things in lieu. Over time concept of dowry has gotten distorted with the groom’s family making demand for lavish presents like cars, cash, house or gold. When the bride’s family is unable to satisfy these unreasonable demands, the in-laws can take the drastic step of dousing the girl with an inflammable liquid and setting her on fire. Husbands who indulge in this act of bride burning see it as a way of getting rid of their wives so that they can remarry for a bigger dowry.1

According to the Indian Penal Act, giving or asking dowry is prohibited. If anyone is reported, they can be arrested and tried under The Dowry Prohibition Act. According to Time Magazine the numbers of bride burning cases have increased from 400 in early 1980s to 5,800 in 1990s. It is not known whether the bride burning cases had increased or the number of police reports have increased. A women’s group located in Bangalore estimates that three to five women suffering from severe burn injuries are taken to a burns unit at Victoria City Hospital every day.

According to the statistics released by the Government of India in 2001, 7,000 women were killed by husbands and in-laws because of less dowry or inability to pay more dowries. Bride burning is a social stigma which India is trying hard to fight. However, women organizations claim that not enough is being done to protect women and women rights specially when witnesses can be intimidation or police are indifferent during investigation. Today, outdated, mythological misconceptions of women combined with the grossly manipulative practice of dowry means that bride-burning is as rampant today as it was 2,500 years ago and the Indian government and society implicitly sanction dowry murders by not adequately prosecuting it.2

A reality check is sorely needed. In this prospective study we analysed the trends and profile of fatal thermal burns cases involving married woman in around Davangere.
Methodology

A prospective autopsy study of sudden natural deaths which was conducted at JJM Medical College and Cigateri General Hospital, Davangere Karnataka, India for a period of 1 year from 1st November 2009 to 1st November 2010 formed the primary material of the study. Among them, cases of deaths due to burns in married women were selected based on purposive sampling. The objectives were to assess the Incidence, age, element of dowry, socio-economic background and cause of death among married women due to burns. Before starting the post-mortem examination, history from the relatives, police and treatment records if were obtained and recorded on a pre-made detailed proforma. In cases where the death was unwitnessed and the dead body was brought directly from site of death by the police for post-mortem examination, help of the investigating officer was sought to know the manner of death. Data was collected and analyzed statistically using appropriate statistical tools (namely Microsoft Excel 2007 and IBM SPSS V.20) with respect to the aforesaid objectives.

Observations & Results

During this study period, 881 cases were brought for medicolegal autopsies out of which 224 (25.4%) deaths were due to burns. Out of the 224 cases, incidence of married female deaths accounted to 94 i.e. 75.2% of total deaths. Further, incidence of alleged dowry deaths due to burns was found to be 39.3% of the total. [Table 1]. Among the 94 deaths due to burns in married females, maximum numbers of cases i.e. 49%, were observed in the age group of 18-22 yrs. [Table 2]. Majority of the deceased persons (68%) died to a degree of dermo-epidermal burns. [Table 3]. 54 % of the deceased persons were from rural areas of Davangere [Table 4]. Maximum deaths were observed in females belonging to the lower socioeconomic class i.e. 62 % [Table 5]. And majority of the victims (54.2%) died due to septicemic shock [Table 6].

Discussion

Seventy-two years after Independence, Indian women are still searching for these ideals visualized by “framers of modern India. Despite the enactment of laws, the formulation of reformatory legal processes, the provision of legal aid to the poor, the extensive use of the provision of legal aid to poor, the extensive use of the provision of Public Interest Litigation, and the creation of woman / family counseling centers etc., women in India still have a long way to go in converting the constitutional goals into reality. Religion, customs and age old prejudices have put Indian woman in a subservient and exploitable position in many domains of life. Factors such as low rates of participation in education, lack of economic independence and value biases operating against them have resulted in woman being dependent on the men folk of the family. They are usually ignorant of their rights and even if they are not, they do not have easy access to justice. The system of dowry is a social practice, which, on its own, has claimed the lives of scores of women. The incidence of cases found by us is in conformity with the study conducted by Naik et al. and Kumar et al. 4

Married outnumbered unmarried in the ratio of 3:1 i.e., married cases were 94 and unmarried cases were 31 out of 125 female victims. This clearly shows the magnitude of young married females being the victims. The married outnumbered unmarried ones in burns deaths. which is also consistent with the study of Naik et al. and Mabrouk AR et al. 5

Age is one of the important factors. Maximum number of deaths 49 occurred during the study of 1 years (2009-2010) in the age group 18-22 years, and second highest deaths occurred in age group of 23-25 years i.e., 21 cases. In age group 26-30 years 13 cases. As people from 18-30 years age group are exposed to high risk, because this is the age group which is involved in cooking purpose. Dowry deaths are also common in this age group. Mabrouk AR et al observed that majority of deaths (46%) occurred in 21-30 years of age group. Naik et al in a study on trends of burn deaths it was found that most of the victims were between 11-40 years with peak at 21-30 years (47.1%). And Mabrouk AR et al 26 in his, found that maximum cases seen in 18-26 years of age group. So, the present study is in accordance with the above studies.

In the Western countries, the old people and children are the most common victims of accidental burns. In our country, this difference may be possible due to better care of young and old people by the family members.

Highest number of cases i.e., 68, showed Dermo-epidermal burns, which is followed by epidermal burns i.e., 18 cases and lastly 8 cases showed deep burns. Sharma SR 6 found that major incidence of death due to burns was dermo-epidermal degree of burns (40%) followed by deep (65%) and epidermal degree of burns (12.1%). So, the present study is in consistent with the other study. The diagnosis of the depth of burns is not
entirely accurate because there are no definite clinical criteria for the depth of burns. There are various gradations of injury in the extensive burns. Also, the thickness of skin varies with age and body location.

In our study maximum cases of married female fatal burns seen in females from rural area than urban area and from lower socioeconomic classes. Similar observations were made by Sharma et al and Mabrouk AR et al.

The findings of the present series noting the sepsis as the most important factor for the cause of death, as the period of survival in maximum number of cases is more than 5 days. In the present study, out of 94 cases, maximum deaths i.e., 54.26% were due to septicemic shock and minimum i.e., 9.5% were due to neurogenic shock. This is because most of the victims of burns, who survived the initial 24 hours after burns, succumbs to infection of the burnt area and its complications. Burns cause devitalization of tissue leaving extensive raw areas, which usually remain moist due to the outflow of serous exudate. The exposed moist area along with the dead and devitalized tissue provides the optimum environment favoring colonization and proliferation of numerous microorganisms, which is further enhanced by the depression of the immune response. All these factors contribute towards sepsis in a burns victim. Tripathi CB et al, found 30.92% death due to septicemia, while Kumar et al found that 53% of cases died due to septicemia. So, the present study is in accordance with the above studies.

**Conclusion**

Accidental burns are mostly preventable by adequate safety measures and safety education. “Bridge burning” is a social evil unmatched in its cruelty and cynicism in today’s civilized society. Any discussion on its etiopathogenesis and remedial measures must take into account the sociocultural and economic ramifications underlying this scourge.

Legal measures however, harsh or deterrent, cannot suffice to combat this scourge due to complete dependence of the woman on her husband and in-laws.

Following measures are recommended:

**Social and Economic**

1. Safety education to combat domestic and industrial burns.
2. Public and professionals should be made to realize the magnitude and gravity of the problem.
3. Discouraging dowry demands and offers.
4. Promoting education among women to make them economically free and independent.
5. Social acceptance and security measures for the single woman who is deserted or left by the dowry seekers.
6. To strive for a social transformation so that both girls and boys choose their life partners.
7. Social boycott of those boys and their families in future marital negotiations by the society.

**Legal**

1. More stringent laws for possession and use of explosive and implosive and inflammable materials to prevent accidents.
2. Police task force-specially trained in the subject for timely investigation of the case and should provide detailed history and sketched diagram showing arrangements in bedroom and kitchen, with special reference to place of incidence and mode of catching fire.
3. Special legal aid cells for the victims and other relations.
4. Special courts to try the cases expeditiously.
5. Inquest by a magistrate in all cases of young female burn death and strict adherence to existing laws in this regard.
6. Visit to the scene of crime should be made compulsory by autopsy surgeon along with the expert in forensic science with a well-equipped team for proper and prompt investigation with modern techniques.

Abstract

A Prospective study was conducted in the Department of Forensic Medicine and Toxicology, JJM Medical College and Cigateri General Hospital, Davangere Karnataka, from 2010 to 2014 with regard to demographic, injury and mortality profiles among Medicolegal autopsies conducted in homicidal deaths and the same are presented in this paper. Results showed that male victims of the age group 31-40 years were more in number, with personal revenge being the usual motive of the perpetrators. Most of the deaths were due to combination of both blunt and sharp weapons with hemorrhagic shock as the most common cause of death.

Keywords: Homicidal Deaths, Injuries, Blunt force, Sharp Force, Medicolegal, Autopsy.

Introduction

Homicide in general means killing of one human being as a result of conduct of the other.¹ Several Indian authors have classified homicides into lawful (Excusable, justifiable) and unlawful homicides (Murder, Culpable homicide not amounting to murder) for the ease of understanding albeit no such terminologies exist in any Indian codes of law. ², ³ In this paper, the authors represent only Homicidal deaths amounting to Murder as per section 300 of the Indian Penal Code.

While homicides by death penalty do not involve the forensic pathologist, all other justifiable, excusable and unlawful homicides do include the role for a forensic pathologist in fixing the responsibility.

Murder is a heinous crime committed against a person be it due to any motive. It is indeed a major threat to the society due to its increase at an alarming rate all over the world including India. Such deaths demand a cautiously exercised post mortem examination and analysis of circumstances surrounding them. No part of the world is free from crime, and the city of Davangere is no such exception. Hence a selectively prospective study was undertaken to analyze the profiles of such homicidal deaths and observations thus made may show the impact of them on the society. The magnitude, if keenly observed by law enforcement agencies, can have a better understanding and can strategize a solution.

Material and Method

The study material consisted of 2260 medicolegal autopsies conducted in the department of forensic medicine and toxicology, JJM Medical College and Cigateri General Hospital, Davangere Karnataka, during a period of 4 years (from June 2010 to June 2014). Of these, 112 cases were homicidal deaths amounting to murder, which were studied selectively, descriptively and prospectively after obtaining clearance from the institutional ethical clearance committee.

Data for the study comprised of inquest reports, documented interviews from relatives, friends, and neighbors of the victims. A detailed proforma
for recording history, particulars such as age, sex, educational status and occupation, motive, and weapons/force and cause of death was prepared. The information thus collected, was analyzed using appropriate statistical tools (namely Microsoft Excel 2007 and IBM SPSS V.20).

**Results**

During the study period, 2260 cases were brought for Medicolegal postmortem examination, of which 112 (5%) cases were homicidal deaths amounting to murder.

Year wise analysis between mid-2010 to mid-2014 revealed skewed pattern of numbers not falling truly in ascending or descending order with highest number of homicidal deaths amounting to murder in the year 2013, where we encountered 27 cases (24%) [Table 1]. Maximum number of victims (46%) belonged to the age group ranging between 31-40 years [Table 2]. Observing sex wise death distribution, majority of the victims were found to be males (72%) [Table 3]. Enquiry made into the possible motive behind these deaths revealed that most victims succumbed due to interpersonal enmity and revenge (56%) [Table 4]. Majority of the Perpetuators involved had attained schooling up to primary level, considering their educational status (51%). When we considered occupational status, majority of the perpetrators were employed (72%). Considering the type of weapon or force or method used, maximum number of deaths were found to have been caused by a combination of both sharp and blunt force violence (37%) [Table 5]. Most common cause of death was found to be due to hemorrhagic shock (59%) [Table 6].

Discussion

In the present study the total number of homicidal deaths amounting to murder were 112 over a period of 4 years and it is almost similar to the observations made by Jhaveri et al and Kalpesh et al, however their study duration periods varied between One year and Two years respectively. This could only indicate that murder rates are comparatively lesser when taken year wise compared to their region of study. On the other side, when we compared our findings with those made by Shivakumar et al and Parmar et al, it is differing grossly in numbers under similar study duration period and region. While our study showed that bulk of the victims were belonging to 31-40 years age group, it did not correlate with observations made by any of the authors cited in the discussion section except with that of a study made by Rastogi et al. Majority of the victims in our study were males and this finding has correlated with the observations made by all authors cited above in this section. Further, the most common motive was Enmity and revenge which correlated with some authors cited above who once again included this parameter in their study. The Most common weapon or force used by the perpetrators here was a combination of both sharp and blunt force weapons, and the cause of death was Haemorrhagic shock which
also correlated with all authors cited above.\textsuperscript{4-8}

**Conclusion**

There seems to be a slight decrease in murder-related deaths every year, but it goes without mentioning that the numbers are showing a skewed pattern in this study. Moreover, the decrease is only by digits every year which we do not consider significant. The sudden drop noticed in the last year of this study (2014) is only due to the fact that it was conducted up to mid-2014, hence it will not be appropriate to call it ‘significant drop’ in reality. Unlike other conclusions related to homicidal deaths, we personally feel that murder-related death rate is either static or slightly rising, despite living in a sophisticated era of education.

It would be hard to point out where the fault lies, and it is pointless to suggest law enforcement agencies to take even more strict measures than what it is today in Metropolitan cities. We, the authors are of the conclusion that this menace can be overcome only if every individual makes an effort on his own to educate himself, learn civic sense and strictly observes the laws of the land. Effectiveness of Abdominal Drawing in Maneuver with Lumbar Pelvic Exercises on Swiss Ball for Spinal Flexibility Among Patients with Low Back Pain

Faldu Liza Jitendra¹, S Anandh²

¹Intern, Faculty of Physiotherapy, KIMSDU, Karad, Maharashtra, ²Professor, Department of Community Health Sciences, Faculty of Physiotherapy, KIMSDU, Karad

Abstract

Background: Patients with nonspecific low back pain have difficulty in their activities of daily living. Spinal flexibility problems are neglected in the patients with low back pain. These problems hamper the activities of daily living. Hence this study will help in improving their flexibility and perform ADL easily. Numerous studies have been done on spinal muscle strengthening, muscle activation to improve muscle endurance and posture in patients with low back pain but less attention has been given to spinal flexibility, which will help them to perform their ADL with ease. Low back pain is a big burden, as it causes more global disability and it is increasing among young individuals. There is paucity of studies as far as abdominal exercises in improving spinal flexibility is concerned.

Aim: To find the effect of abdominal drawing in maneuver and lumbar pelvic exercises on swiss ball among patients with non-specific low back pain.

Methodology: There were 35 participants in the study. The type of study is experimental. The participants involved were assessed for strength, pain and functional mobility. The participants are treated for pain, strength and functional mobility.

Result: There is improvement seen in participants. The results of the participants are calculated by mean and standard deviation. The post mean value of lumbar flexion was 5.926 which was more than pre mean value of lumbar flexion that is 5.558. The post mean value of lumbar extension was 1.378 which was more than pre mean value of lumbar extension that is 1.243. The post mean value of right lumbar lateral flexion was 5.565 which was more than pre mean value of right lumbar lateral flexion that is 5.121. The post mean value of left lumbar lateral flexion was 5.578 which was more than pre mean value of left lumbar lateral flexion that is 5.578.

Conclusion: Abdominal drawing in maneuver and lumbar pelvic exercises on swiss ball are effective in improving spinal flexibility among patients with non-specific low back pain.

Keywords: Low back pain, physiotherapy, abdominal drawing in maneuver, spinal flexibility, core.

Introduction

Low back pain (LBP) is the general problem which influences the majority of adults.¹ Low back pain has been and continues to be, one of the enigmas of the modern medicine.² The epidemic of LBP and the disability associated with it has appeared to escalate. Back pain has now become not only a medical problem, but a social, legal and political one as well.³ Minority of population undergoes LBP recurrence while the others feel constant pain.⁴ The majority of low back pain (LBP) patients are labelled as having non-specific LBP, which is defined as back pain of unknown aetiology.⁵
as symptoms without a clear specific cause (unknown origin). Survey suggests that the lifetime incidence of LBP ranges from 60% to 90% within 5% annual incidence. For younger than 45 years, mechanical LBP represents the most common disability than in person aged older than 45 years. It can be classified as acute (<6 weeks), subacute (between 3 weeks and 6 months), chronic (more than 3 months).

Core is a central and often foundational part. Stability is the property of body that causes it when disturb from a condition of equilibrium or steady motion to develop forces or moments that restore the original condition. Core stability is a generic description for training of abdominal and lumbo-pelvic region. Originally it is associated with the technical change of the surrounding tissues of the spine. Patients with LBP have weak deep muscles.

core stabilization dates back 50 years ago. Today using stability balls and balance boards develops core stabilization. The use of stability ball training for core muscle development has been popular for several years. Multiple studies have examined core muscle recruitment during various types of swiss ball abdominal exercises. These exercises are important for increasing the deep abdominal muscles and improving stability.

A good core conditioning program will decrease the likelihood of back and neck pain. We spend more energy maintaining misalign posture thus creating a situation for muscular and joint pain to arise.

**Material and Method**

There were 41 participants in the study. The study was taken place in Krishna institute of medical sciences. The study is effectiveness of abdominal drawing in maneuver with lumbar pelvic exercises on swiss ball for spinal flexibility among patients with low back pain. The treatment protocol was of 4 weeks. The participants were assessed for lumbar flexion, extension and lateral right and left flexion at first. The type of the study is experimental study. Sample size was calculated by the formula \(4pq/l^2\). Inclusion criteria is both male and female, patients diagnosed with non-specific low back pain, age group between 25-45 years, duration = subacute(between 6 weeks and 3 months). Exclusion criteria is any history of recent injury or medical conditions in past 3 months, any systemic illness, malignancy, spinal or disc pathologies, any recent abdominal or spinal surgery. Outcome measure used for assessing spinal flexibility is measuring range of motion using modified Schober’s test.

**Results**

The study was taken place in Krishna institute of medical sciences. The results were calculated by the pre and post assessment. The mean and SD were calculated. The significance of the study was calculated. The instat software was used to calculate all the results. The values are calculated by paired ‘t’ test. The P value for lumbar flexion is 0.044 which is significant, lumbar extension is 0.012 which is significant, right lateral lumbar flexion is 0.077 which is not quite significant, left lateral lumbar flexion is 0.091 which is not quite significant.

**Chart no. 1: Pre and post changes in lumbar flexion after treatment.**

Interpretation: the mean and SD of pre lumbar flexion is less than post lumbar flexion.

**Chart no. 2: Pre and post changes in lumbar extension after treatment.**

Interpretation: the mean and SD of pre lumbar extension is more than post lumbar extension.
Discussion

The study topic is on effectiveness of abdominal drawing in maneuver (ADIM) with lumbar pelvic exercises on swiss ball for spinal flexibility among patients with low back pain. The aim of the study is to determine effect of abdominal drawing in maneuver (ADIM) with lumbar pelvic exercises on swiss ball for spinal flexibility among patients with non-specific low back pain. The treatment was given by a fixed protocol. The study was taken place in Krishna institute of medical sciences. The number of participants included were 41. Female included in the study were 20 in number and male included were 21. The participants were taken according to the inclusion and exclusion criteria. The participants were assessed for lumbar flexion, lumbar extension and lateral flexion before the treatment. The appropriate treatment for improving spinal flexibility is given. Treatment protocol was for 4 weeks. A consent was taken by the participants before the treatment. After the treatment again the assessment is taken.

There are various studies on effectiveness of the core stabilization on swiss ball and floor with non-specific low back pain and core muscle activation during swiss ball and traditional abdominal exercises. According to a study by the author Wontae Gong, which was done in republic of Korea on effect of bridge exercise accompanied by the abdominal drawing in maneuver on an unstable support surface on the lumbar stability of normal adults showed that when using bridge exercise to improve static lumbar stability and dynamic lumbar stability, performing the bridge exercise accompanied by ADIM on an uneven surface is more effective than performing the exercise on a stable surface. This study supports the study as the outcome of the study is beneficial for the participants.6

Stability exercises is clinically applied as a treatment for patients with low back pain. Bridge exercise is a closed kinetic chain weight bearing exercise applied to improve muscle strength of gluteus maximus and hamstrings in patients with LBP.7

ADIM is the main for the strengthening of the deep muscles such as transverse abdominis, internal and external obliques. ADIM is the exercise method which increases the abdominal pressure by pulling the abdominal walls to the inside that transverse abdominis and obliques are contracted. Because of the increased abdominal pressure, lumbar trunk stability training is effectively accomplished.10

In this study, physiotherapy protocol consisted of following exercises:

1) Curl-up on swiss ball
2) Bridging with ADIM on swiss ball
3) Front plank on swiss ball
4) Side plank on swiss ball
5) Back extension on swiss ball
6) Side flexion on swiss ball

Individuals were instructed to do warm up exercises for 5 minutes. They were asked to perform these exercises for 4 weeks with 4 times in a week with 30 seconds break after each exercise with a cool down
period of 5 minutes at the end of each session.

- 1st week- 6 reps
- 2nd week- 9 reps
- 3rd week- 12 reps
- 4th week- 15 reps with 5-10 sec hold

Patients with low back pain have weak deep muscles so these exercises will increase the strength of deep muscles and improve lumbar stability.

**Conclusion**

Abdominal drawing in maneuver and lumbar pelvic exercises on swiss ball are effective in improving spinal flexibility among patients with non-specific low back pain.

**Acknowledgement:** I would like to express my sincere thanks to Dr. G. Varadharajulu Dean, Faculty of Physiotherapy, KIMSDU, all teaching and non-teaching staff of Faculty of Physiotherapy, KIMSDU, for their valuable suggestions and guidance.

I would like to express my most humble and profound gratitude to my respected Professor Dr. S Anandh, Professor, Faculty of Physiotherapy, KIMSDU for his inspiration, motivation, valuable guidance and suggestions throughout this project.

Saliva in identification of ABO Blood Grouping & Rhesus Factor

Harshada R
PG Student, Professor & Head, Department of Oral Medicine and Radiology, Sree Balaji Dental College and Hospital, BIHER, Chennai

Abstract

Aim: To assess the efficacy and reliability of saliva in identification of ABO blood grouping.

Materials and Method: The study was conducted in the outpatient department of Oral Medicine and Radiology. The serum and saliva of 50 participants were collected and the blood group of the individual from serum was identified by the slide agglutination method and from saliva by the absorption elution method.

Results: Data obtained were subjected to statistical analysis using Paerson’s chi square test and it showed high significance (P = <0.001).

Conclusion: The outcome of the present study showed that saliva can be used as an aid in forensics for identification of ABO blood grouping of an individual.

Key word: ABO blood grouping, Saliva, Identification.

Introduction

Karl Landsteiner discovered ABO blood grouping in early 1900. After his invention many other investigators like MN, Lutheran, Kell, Lewis, Duffy, Kidd, Diego, Dombrock have also described other types of blood grouping system, but till now ABO and Rh groups are in practice and considered as Gold standard method. The blood groups remain the same throughout the life of an individual and this forms the basis for the use of blood groups in medico-legal examination [1].Besides blood these antigens are secreted in various other body secretions such as saliva, semen, gastric juice, nasal secretions, vaginal secretions, sweat, tear, urine etc. Individuals could be classified as “secretors” and “non-secretors” according to their ability to secrete ABO blood group antigens in saliva [2].

Saliva was first analysed for the presence of anti-A and anti-B hemagglutinins in 1928 [3]. In some criminal cases like robbery, rape and hanging, saliva may be found in some form or other and may be the most important source in detecting blood group of a victim or suspected culprit in forensics [4].

There are two main methods for detecting ABO blood group in saliva. The Absorption-Inhibition method and the Absorption-Elution method. In this study an attempt has been taken to find the efficacy and reliability of saliva in identification of ABO blood groups through absorption elution method.

Method and Materials:

A cross sectional study was conducted in the outpatient department of Oral Medicine and Radiology after the approval of the Institutional ethical committee (ECR/761/Inst/TN/2015). The study consisted of 50 participants to whom the nature of the study was explained and written consent was obtained. Participants with haematological disorders were excluded from this study.

For ABO blood grouping in serum, slide
agglutination method was followed where blood was collected by capillary puncture method and placed over three glass slides to which Anti serum A, B and D were added and observed for Agglutination.

For ABO blood grouping from saliva whole saliva was collected by suction method and it was transformed to 3 test tubes to which Antiserum A,B and D were added and left for two and half hours at room temperature. This was kept in hot water bath for 10 minutes and after that 2 drops of fresh saline was added to it. Each sample was washed 3 times with cold saline solution (ie. centrifuged and excess removed by pipette sucking). A drop of patient’s blood (known blood group) was added and incubated for 15 mins at 37 degree centigrade and the test tubes were then centrifuged for 1 minute at 2000rpm. Then presence or absence of agglutination was observed in microscope.

Results

Out of 50 participants, 22 were male and 28 were female. The blood groups determined from serum and saliva are shown in (Table 1). The blood groups B+, AB+, B- have high secretor levels compared to other blood groups. The correlation of blood groups between serum and saliva were statistically analysed using Pearson chi square test. (Table 2) It was seen that there was high statistical significance between serum and salivary ABO blood grouping (P<0.001). Pearson chi square test value was 185.16 and the coefficient value was 0.887. The correlation between Genders is shown in Table 3.

Discussion

Determination of blood group is useful in identification of a subject especially in medicolegal cases like those involving child abuse, rape and murder, etc. In some situations blood may be absent at the scene [5]. In such conditions an alternative is required for identification of an individual. Although ABO and Rh factor in serum is the gold standard method, blood group specific antigens can also be found in other body secretions. Saliva is a biological fluid which not only helps in identification of systemic problems but also in forensic for identification. Saliva might be found on different substances at the scene of a crime.

Yamakami discovered the presence of A and B antigens in saliva [6]. In 1963, Outride compared the absorption elution and absorption inhibition method and concluded that the former is more sensitive [7] and the studies done by Kaur et al.[8] and Aye et al.[9] were in accordance to this. So in this study absorption elution method is followed in identification of ABO blood grouping in saliva. According to the study conducted by Igbeneghu C et al.[10] frequency of secretor was common in blood group O followed by A, B and AB. Emeribe et al. [11] and Jaff [12] reported similar findings in their studies. Saboor M et al.,[13] conducted a study to evaluate the ABH blood group among 101 healthy adult students and concluded that the frequency was highest in blood group B which was in accordance with our study. It is also seen that out of 50 subjects, 48 of them showed the secretor level similar to the study conducted by Pereira M et al.,[14] Kimura A et al.,[15] Parekh P et al.,[16] and Pawan Motghare et al [4]. This study also shows that the ability to secrete ABO blood group antigens in saliva was more common in males than in females. The correlation (Table 2) proves that saliva can be used in identification of ABO Blood grouping and Rh factor (p < 0.001).

The limitation of the study is that it has a small sample size and the segregation of secretors and non-secretors also play a significant role in determining the accuracy of the tests [17].

Conclusion

Saliva plays a major role not just in oral cavity but it also as a mirror of our body system. The outcome of the present study showed that saliva can be used in identification of ABO blood group but further studies on large sample size should be done to ascertain the diagnostic value of saliva in forensic.

Pattern of Injuries in Road Traffic Accidents – An Autopsy Study

K H Thippeswamy¹, Ravindra Kumar C N², H C Govinda Raju³

¹Associate Professor; ²Assistant Professor; ³Professor & Head, Department of Forensic Medicine and Toxicology, East Point College of Medical Sciences & Research Centre, Bidarahalli, Bangalore

Abstract

The present study is a retrospective study conducted in the department of Forensic Medicine and Toxicology at East Point College of Medical Sciences and Research Centre, Bangalore, for a period of one year, from September 2018 to August 2019. During this period a total of 46 cases of road traffic accidents were reported amounting to 34.6% of total medico-legal autopsies conducted (133 cases).

Among 46 cases of road traffic accident majority were males 39 (84.8%) and females account to 7 cases (15.2%). Majority of the victims belonged to age group of 31 - 50 years. According to the road user category involved in the accident the maximum were pedestrians (45.7 %) followed by the two wheeler (43.5 %) and the main offending vehicle involved in the accidents were two wheeler (43.5 %). High proportion of cases showed skull fractures (87 %), 52.2 % shows chest bone fractures, followed by lower limb (32.6 %) and upper limb (21.7 %) fractures. Most of the skull fractures were associated with brain injury (82.6%) in the form of laceration or contusions of brain or brain haemorrhages, followed by thoracic injuries leading to lung lacerations or contusions (30.4%). Following the road traffic accidents, most of the victims (80.4%) died at the scene before reaching the hospital.

Keywords: Road traffic accidents, skull fractures, thoracic injuries, safety measures.

Introduction

The number of road traffic deaths continues to rise, reaching 1.35 million in 2016. It is the eighth leading cause of death among people of all ages worldwide. It is the leading killer among children and young adults aged between 5 to 29 years. More than half of global road traffic deaths are amongst pedestrians, cyclist and motorcyclists who are still neglected in road traffic system design in many countries. However, the rates of death relative to the size of the world’s population has stabilized in recent years.¹

India accounts for about 10 percent of road accident fatalities worldwide, 85% of all road accident deaths occurring in developing countries, and nearly half in the Asia - Pacific region. The increased rate of fatal road traffic accident worldwide has been attributed to population explosion and increased motorization.²³ A road traffic accident can be defined as “an event that occurs on a way or street open to public traffic; resulting in one or more persons being injured or killed where at least one moving vehicle is involved”.⁴

A total of 4,64,910 road traffic accident cases were reported and among these 1,47,913 deaths were reported in India during 2017. In the same year Karnataka state reported 42,542 cases of road traffic accident.⁵ RTA is the public health issue and cost a lot to individuals, families, communities and nations. The estimated cost is around 1 - 2% of a country’s GNP in lower income countries.⁶⁷

In any road traffic accident cases, the pattern of injury, fatal and otherwise, varies considerably depending upon whether the victim is a vehicle occupant, a motorcyclist, a pedal cyclist or a pedestrian.⁸

Material and Method

The present study is a retrospective study of medico legal autopsies of all fatal cases of Road Traffic Accident brought to Morgue, East Point College of Medical Sciences and Research Centre, in east part of Bengaluru for a period of one year from September 2018 to August 2019.
Relevant information was collected from Post mortem registers/records, Inquest papers and Post mortem reports. The relevant details were analyzed and results were presented as frequency and percentage in figures and tables.

Results and Discussion

In the present study period a total of 133 medico-legal autopsies were conducted, among them 46 cases were due to road traffic accident comprising 34.6% of total cases, followed by hanging (26.3%). (Table 1) Among 46 cases of road traffic accident majority were males 39 (84.8%) and females account to 7 cases (15.2%). (Figure 1) Majority of the victims belonged to age group of 31 - 50 years (52.2%). (Table 2). These are similar to the studies done by Jha N9, Azmani w10, Aygencel G11, Menon A12, Montazeri A13, Harish D14, Bansal YS15. The high preponderance of males can be attributed to frequent use of vehicles by males and their high contact with the traffic. The young and middle age groups largely consisted of the working populace who travel using their own vehicles, use public transport or walk. In comparison to other age groups, the younger demographic seem more liable to meet RTA, presumably because their activities require them to travel more than the older demographics.

According to the road user category involved in the accident the maximum were pedestrians (45.7 %) followed by the two wheeler (43.5 %). (Table 3) In our study, main offending vehicle involved in the accidents were two wheeler (43.5 %). Ours being a rural part, the majority of the road users were either pedestrians or two wheeler users. The choice of manner of transportation was often influenced by the working pattern of that particular demographic area. The lack of a transport medium between rural roads to state or national highways requires commuters to either walk or use their personal vehicles to reach the nearest point of accessibility. This creates massive traffic managing issues in most parts of the city, also leads to traffic rule violations and increase in number of RTAs. An amplified number of vehicles and reduced attention of drivers and pedestrians related to the fatigue of the day; failure to follow traffic rules, associated with improper infrastructure like the absence of footpaths were the greatest cause of accidents. Other studies from different parts of the country showed pedestrians being the commonest victims.12,13,19,21,23,24.

In our study most of the skull fractures were associated with brain injury (82.6%) in the form of laceration or contusions of brain or brain haemorrhages, followed by thoracic injuries leading to lung lacerations or contusions (30.4%). (Table 5). A high occurrence of brain injury was due to the fact that majority of two wheeler users were not using helmets while light motor vehicle users were travelling without safety measures like seat belts causing dash-board or wind screen injury and in the pedestrian it can be explained due to the fact that after primary impact, it was produced by vehicle to being run over in most instances. Head injury was the most common cause of death which has also been documented by other researchers.12,13,19,21,23,24.

Following the road traffic accidents, most of the victims (80.4%) died at the scene before reaching the hospital. While (8.7%) of them died within 24 hours after the accident, 6.5% survived for a period of 2-6 days, 4.4% cases survived for a period of 7-10 days. (Table 6). These findings are similar to the studies by Menon A12, Montazeri A13.

In the present study high proportion of cases showed skull fractures (87 %), 52.2 % shows chest bone fractures, followed by lower limb (32.6 %) and upper limb (21.7 %) fractures. (Table 4). These findings are similar to the studies by Chaudhary et al19, Kumar A22, Kyada H C23.

Conclusion and Recommendations

This study showed that road traffic accidents contribute to majority of deaths, more common in the younger age groups and male sex. Majority of victims were pedestrians and main offending vehicle involved in the accidents were two wheelers. Higher incidence of skull fractures was observed along with associated brain injuries.

Road traffic accidents are an evolving problem in our country as the number of vehicles are increasing day by day. Stringent laws regarding speed limit, use of safety belts and helmets and other traffic violations together with better quality roads, provision for pedestrian walking and crossing and roadside illumination will go a long way in preventing much of such tragedies. A multidisciplinary approach consisting of public education, a proper pre-hospital trauma care system and definitive trauma care facilities coupled with rehabilitation is required to be put in place if any impact is foreseen on this ever growing epidemic on the roads.

Chromatographic Analysis of General OTC Anti-Allergic Drug: Cetirizine

Kaur Loveleen\textsuperscript{1}, Kaur Ridamjeet\textsuperscript{2}, Sharma Tina\textsuperscript{3}
\textsuperscript{1}Student, \textsuperscript{2}Assistant Professor, \textsuperscript{3}Assistant Professor, Department of Forensic Science and Toxicology, Chandigarh University, Mohali Punjab, India

Abstract

Cetirizine as general OTC anti-allergic drug was evaluated through paper chromatography. Twelve cetirizine compositions were analysed wherein each tablet and syrups were six in number. Seven solvent systems were experimented from which chloroform and methanol in ratio 50:50 proved to be best solvent system for both cetirizine tablet and syrup compositions. Other solvent system that showed clear separation of spots were n-hexane, toluene and diethyl ether in ratio 65:25:10 and acetone and methanol in ratio 90:10 for tablet and syrup preparations respectively. Iodine fuming technique and UV radiations were also utilized for visualising some unidentified and invisible spots during the examination procedures.

Keywords: Cetirizine, OTC drug, Paper chromatography, Iodine fuming, UV radiations.

Introduction

OTC medications are as opposed to professionally prescribed medications that do not require a specialist’s order and can be straightforwardly taken from any therapeutic shop \textsuperscript{1-2}. There are an expected 350,000 OTC medications which can be acquired from drug stores, supermarkets and comfort stores with no prescription. They incorporate analgesics, cold and hack drugs, stomach settling agents, antihistamines, narcotics and so on. The majorly abused OTC drugs included dextromethorphan, acetaminophen, ibuprofen, diet pills, sexual performance medicines, herbal ecstasy, cetirizine etc. in light of their simple accessibility, they can be used to ease assortment of day by day medical issues\textsuperscript{3}. Some OTC medications, when taken with liquor cause sleepiness, tipsiness, elation, anxiety, obscured vision, ringing in ears and so on. At a higher portion, these impacts are escalated alongside different side effects, for example, disarray, muscle jerking, sporadic heartbeat, tremors, seizures and so forth. They may weaken the capacity to securely drive a vehicle since they can cause laziness or edginess. Cases may incorporate mishaps because of the abuse of medications or conscious overdose or they could add to vehicle mishaps etc\textsuperscript{4}. The misuse of these medications is a genuine and developing general medical issue everywhere throughout the world. Enormous portions of OTC medications can be destructive. At the point when taken in overabundance sum reliance can be created. Maltreatment of OTC medications causes physiological reliance, mentally reliance or both. Cases had been reported in which death occurred due to toxic effects induced by ingestion of high amounts of cough–cold preparations\textsuperscript{5}.

Cetirizine is also a OTC drug that reduces brain activity and produces sleepiness, dizziness and low body activity when taken in prescribed amount. It will work as depressant for CNS if taken in excessive amount. A study demonstrated that 38 percent of illegal medication use among young people and kids from 1990 to 1999 included OTC medications. Studies suggest that teenagers and youthful grown-ups are at most serious danger of OTC medication misuse \textsuperscript{6-11}.

Number of studies for detection and quantification of active components in OTC cough and cold preparations using thin layer chromatography, high performance thin layer chromatography, reverse phase high performance liquid chromatography have been discussed in literature.
So far ultraviolet spectrophotometer for estimating the combined dosage of levocetrizine hydrochloride and phenylephrine hydrochloride has been used. Gas chromatography–mass spectrometry, liquid chromatography–tandem mass spectrometry and ultra-performance liquid chromatography–tandem mass spectrometry has been also mentioned to be used in identification of active components and their metabolites in toxicological samples using. Therefore, the present work has been attempted to analyse the Cetirizine as OTC drug by paper chromatography in both powder form as well as syrup form.

**Material and Method**

For evaluating the potentiality utility of chromatography in assessing cetirizine through chromatography twelve preparations of OTC drug was purchased in the form of tablets and syrups were purchased from the local market (Table No. 1). The standard sample of cetirizine hydrochloride was procured from the local chemical supplier. The samples were prepared from each six tablets by crushing them in pestle-mortar individually to powdered form. 0.5 mg powder from each tablet was taken and dissolved in 4-5 drops of acetone thoroughly in six different test tubes and kept for a few minutes. The contents were then filtered through Whatman filter paper no. 1. The filtrate was collected and centrifuged. The supernatant was transferred to another clean test tube for TLC analysis. Therefore, six test tubes were ready with tablet samples. Similarly, six Cetirizine hydrochloride syrup preparations were taken and two drops from each was dissolved in 10-15 drops of acetone in six different test tubes. Similarly, the standard Cetirizine hydrochloride powder of 0.5 mg was taken in a test tube and dissolved thoroughly. Hence, total 12 test tubes were ready to develop the each samples in each seven different solvent systems. Seven solvent systems were selected for the study and were prepared in different ratios to assess their potentiality in chromatographic analysis of cetirizine preparations (Table no. 2). The Whatman filter strips with 150 GSM were selected as stationary phase and cut into different sizes such as 3 X 8 cm, 6X 12 cm and 8 X 12 cm. Then TLC chamber of 300 ml was taken and was rinsed with acetone to remove dirt or oil. The solvent systems chosen were poured in twelve different chambers and kept aside for few minutes. In the mean time, spotting of samples was carried with micro capillary tube at the height of 1.5 cm above the base of paper. After that, strip was kept aside for a minute. Later on, each strip carrying the samples was placed in the TLC chambers vertically till completely run. The strips were taken out and allowed to dry and then examined physically, under UV light and with iodine fuming technique.

**Result and Discussion**

The results of chromatographic development of 12 samples of OTC cetirizine drugs have been tabulated Table no. 3-6. The samples were developed in seven different solvent systems. The developed strips were then examined physically, with UV light as well as by iodine fuming method too. The results were obtained in terms of number of spots and their respective hRf values were calculated and found to be different with different solvent system.

**FOR TABLETS:** It was noticed from table no.3 that solvent systems A was most suitable in developing and separating the cetirizine from all the five tablets and some spots were clearly visible physically and some were developed with iodine fuming techniques (Figure 1). The hRf were calculated for all the samples developed with mobile phase of chloroform and methanol with ratios 50:50. No spot developed under UV light in strips developed with solvent system A. Other mobile phases that showed positive results were D and E in tablet no 2 and 1 respectively whereas solvent system G had separated out the component in tablet no. 1,2 and 4. No spot was developed with solvent system B,C and F with any tablet. The hRf values were came to be 32, 49, 47,66, 70 for the 1-5 no. Tablets with A solvent system. The rest hRf values were 24 and 54 of tablet no 1 with E and G, 34 and 38 with tablet no 2 with D and G solvents system and 47 and 49 of tablet no 4 with E and G mobile phases.

**FOR SYRUPS:** It is apparent from table no.4 that solvent systems A and E was most suitable in developing and separating the cetirizine from all the six syrup preparations whereas mobile phases C,D and F showed positive results in few tablets [Figure 2]. No spot was developed with solvent system B,C and F with any syrup. The hRf were calculated for all the samples developed with mobile phase of chloroform and methanol with ratios 50:50 and n-hexane: toluene: diethyl ether in ratio 65:25: 10. No spot developed under UV light in strips developed with solvent system A. Other mobile phases that showed positive results were D and E in tablet no 2 and 1 respectively whereas solvent
system G had separated out the component in tablet no. 1, 2 and 4. The hRf values were came to be 76, 50, 79, 35, 34 and 15 for the 1-6 no. syrups with A solvent system and 23, 54, 79, 29, 28 and 42 with E solvent system. The rest hRf values were 54 and 46 of tablet no 1 and 4 with F, 42 with tablet no 1 with C and 51 and 29 with tablet no. 2 and 5 respectively with D solvents system.

Rest all the solvent systems showed no results under UV or with treatment to iodine fuming. Similar studies have reported where chloroform: ethanol (90:10) was found to be most suitable for cough cold tablets and syrups medications. Another studied and found the ethyl acetate, methanol and concentrated ammonia in the ratio of 85:5:10 is a suitable mobile phase to separate different components analyzed dextromethorphan hydro bromide using TLC.

Likewise, dextromethorphan hydro bromide was successfully examined under short UV radiation in toluene: methanol: chloroform: glacial acetic acid (65:1.5:1.5:0.5) as the best solvent.

Therefore, in the present study chloroform (70:30) was found to be the best solvent system for syrups as well as tablets. Iodine fuming was non-destructive method of visualization of invisible spots for the subsequent instrumental analysis of the eluted active components. Each sample of Cetirizine medicines showed a different number of spots. The prospective of the paper chromatography for separation of active ingredients of cetirizine medication in the study were found to be exceptional good. Hence, it can be utilised with great confidence for the analysis of citrezine components in syrups and tablets.

Table 1 showing description of cetirizine used used in study.

Figure 1 showing developments of spots for tablets with cetirizine composition in Acetone: methanol (90:10) solvent.

Figure 2 showing developments of six spots for six syrups with cetirizine composition in chloroform: methanol (70:30) solvent.

Conclusion

The complexity of OTC medication arrangements makes the distinguishing proof of their dynamic components very troublesome sometimes. Paper chromatography system is fast and economical strategy for the breaking up of dynamic segments in complex OTC medication. From this study, it has been established that chloroform and methanol in ratio 50:50 proved to be best solvent system for both cetirizine tablet and syrup compositions. Along with this, n-hexane, toluene and diethyl ether in ratio 65:25:10 and acetone and methanol in ratio 90:10 for tablet and syrup preparations respectively were the solvent systems that demonstrated unambiguous separation of spots. Iodine fuming technique was considered to be best for visualising some unidentified and invisible spots during the examination procedures than the UV radiations.

Pattern of Injuries Observed in Drivers Involved in Fatal Road Traffic Accidents in Tirupati

B. Venkatesulu1, Vishnu Vardhan Poluru2, M. Abdul Khalid3

1Assistant Professor, Department of Forensic Medicine and Toxicology, Sri Venkateshwara Medical College, Tirupati, 2Assistant Professor, Department of Forensic Medicine and Toxicology, Viswabharathi Medical College, Kurnool, 3Associate Professor, Department of Forensic Medicine and Toxicology, Apollo Institute of Medical sciences and Research, Chittoor

Abstract

Road Traffic Accidents (RTA) constitute a significant health problem. They constitute the 8\textsuperscript{th} leading cause of death. The aim of this study was to analyse road traffic accidents in Tirupati city and find out the pattern of injuries in drivers who were victims of fatal road traffic accidents.

This retrospective study was conducted at the Department of Forensic medicine, S.V Medical College, Tirupati during period 2016 to 2018. Specific findings regarding the injuries sustained to the drivers were noted.

A total of 904 people were killed in RTA and were brought to the morgue for postmortem examination. Out of all victims 170 (18.80\%) were drivers. Most common age group involved was 30 – 39 yrs. Most of the drivers were males. Polytrauma with lower limb injuries accounted for most common injury in drivers (40.35\%) followed by head injury (19.29\%) and thoracic injury (12.28\%). This study has shown the vulnerability of the vehicle drivers to fatal injuries during RTA. Hence, there is a need for road safety awareness, usage of seat belts, strict enforcement of laws, maintaining vehicle fitness etc. to protect the vulnerable group of people, to decrease the associated morbidity, mortality and reduce the economic burden to the society/ country at large.

Key words: Road traffic accidents, Drivers, Autopsy, Injury patterns

Introduction

Accidents are killing more people in India than terrorism or natural disasters and yet we never talk about them' Mr. Nitin Gadkari, surface transport minister\textsuperscript{1}.

Each year an estimated 1.35 million people die as a result of road traffic collisions with more than 3700 deaths each day\textsuperscript{2}. Road traffic injuries are estimated to be the eighth-leading cause of death globally for all ages and the leading cause of death in children and young people of 5 – 29 years of age\textsuperscript{2}.

India ranks 1 in the number of road accident deaths across the 199 countries reported in the World Road Statistics, 2018 followed by China and US. As per the WHO Global Report on Road Safety 2018, India accounts for almost 11\% of the accident related deaths in the World. In the year 2018, 1,51,417 persons got killed and 4,69,418 were injured in about 4,67,044 road accidents\textsuperscript{2}.

This study reviews the various postmortem reported injuries sustained by vehicle drivers among the road traffic accidents victims. The results of this study shall contribute for better understanding of RTA.
Materials and Methodology

This study is a retrospective review of various autopsy diagnosed injuries of drivers involved in RTA. Study was conducted at the Department of Forensic Medicine, Sri Venkateshwara Medical College, Tirupati, Andhra Pradesh. The data was collected from postmortem records spanning from 2016 to 2018.

The data extracted was grouped according to Age, sex and diagnosis. RTAs reported cases involving vehicle drivers were included in this study except those with incomplete or missing information on type of injury and cause of death. The data collected comprised of the following parameters
- Characteristics of road traffic accidents
- Year wise death of drivers
- Types of accidents
- Injury characteristics

Data was entered into SPSS version 20 database.

Permission for access to records was taken from appropriate authorities at the inception of this study. This study was approved by Institutional ethical committee, Sri Venkateshwara Medical College, Tirupati, Andhra Pradesh.

Results and Observations

A total of 904 RTA related deaths occurred during 2016 to 2018 (Table 1). This study had 167 (98.23%) males and 03 (1.76%) female drivers. The minimum and maximum age being 20 and 65 respectively with highest number of victims, 59 (34.70%) between 30-39 years age group (Table 2).

The most common trauma was fractures with 77 (45.29%) cases, followed by internal haemorrhage 40 (23.52%), lacerations 23 (13.52%) (Table 3). Extremities were most involved (45.61%) followed by head injury, 33(19.29%) and thoracic injury 21(12.28%). Spine injury had the least incidence with 3 (1.76%) cases (Figure 1).

The highest male driver incidence was between the ages of 30 -39 sustained more injuries than any other age groups. This age group being most active, working is more prone for RTAs. Kochar et al7 has reported that maximal fatal accidents have occurred in the age group of 31–40 years. Bener8 recorded high prevalence between 10 to 40 years while the nodal age range of Jha et al3 was from 20 to 49 years.

The least incidence was in 60 - 69 years age group, accounting for 3.52% of all injury cases. Jha et al3 and Ossie et al5 reported similar findings.

Most of the incidences in study period occurred in 2018, with 68 (40.0 %) cases followed by 2017, 55(32.35%) indicating the increase in number of driver fatalities. Rise in the number of vehicles and rapid industrialisation has led to overall increase in RTAs.

Among the type of injuries recorded, fractures were at the pinnacle accounting for 45.29% of all injuries, followed by internal haemorrhage, 23.52%. Similar findings were reported by Jha et al3 and Supriya et al9. In contrast Seid et al4 and Ossei et al5 recorded higher incidence of head injuries. The present study found that lower limbs (22.94%) were the commonest site for fracture, followed by fracture of upper limb (10.58%) and skull (6.47%). Similar findings were reported by Abdul Hameed Ali et al10.

According to the site of injuries, extremities (upper and lower limbs) accounted for 45.61% of all injuries followed by head injuries (19.29%), thoracic injuries (12.28%), pelvic injury (8.77%), abdominal injury
(7.01%) and neck injury (4.69%). Similar findings were recorded by B. Mishra et al\textsuperscript{11}, P.L. Chalya\textsuperscript{12} and P.J. Bhuyan et al\textsuperscript{13}.

Majority of the driver deaths, 135 (79.41%) were due to collision accidents with other vehicles or fixed objects. 35 (20.58%) cases were due to overturning accidents. Similar results were seen in study by Abdul Hameed Ali et al\textsuperscript{10}.

Conclusion

This study evidently points to an increasing mortality in RTAs especially among the drivers. Most of the drivers are the sole bread earners of their families. Thus the loss of sole bread earner is devastating to their family, leading to fall in income of the household and lowering of the living standards. This knowledge of injury pattern could be helpful while planning emergency and trauma care services and in designing and implementation of safety measures. There is also a need for road safety education directed towards the road users and strict adherence to driving rules and regulations.

Profile of Medicolegal Autopsy Cases Conducted at Tertiary Care Centre, Kalaburagi, Karnataka

Manish K1, Khaja Azizuddin Junaidi2, Deepak S3, Umesh SR4

1Associate Professor; 2Tutor; 3Assistant Professor; 4Professor and HOD, Department of Forensic Medicine, Gulbarga Institute of Medical Sciences, Kalaburagi, Karnataka

Abstract

Objectives: The profile of medico legal autopsy cases is important in order to know the death statistics in a region due to unnatural causes. The main objectives of the study were: a) To ascertain the various aspects of unnatural deaths, b) To analyze the probable reasons for the same & c) To find remedial measures to bring down the incidence.

Materials and Method: The present study is a retrospective study of autopsies performed at GIMS, District Hospital, Kalaburagi, Karnataka from January 2018 to December 2018. During this period a total of 647 autopsy cases were conducted. Relevant information and subjective data like age, sex, marital status & manner of death have been collected from medicolegal autopsy register from January 2018 to December 2018.

Results: Out of 647 cases analyzed, maximum number of autopsies were in the age group of 21-30 years with 204 cases (31.5%). Majority of victims were males 437 (67.5%). Hindus were majority in number with 540 cases (83.4%), married were 432 (66.8%) & unmarried were 215 cases (33.2%). In our study 73% were rural residents & only 27% were urban. Accident, Suicide and Homicide deaths were 282 (43.6%), 331 (51.2%) & 34 (5.2%) cases respectively. Natural deaths were seen in 14% cases. Maximum number of deaths were due to road traffic accidents with 212 cases (32.8%) followed by poisoning with 85 cases (13.1%). Out of total 647 cases maximum number of autopsy cases 317 (49.1%) were conducted in the month of May to August.

Conclusion: In our present study it is observed that maximum cases were in 3rd decade of life, Males outnumbered females, rural residents were more in number. Hindus being majority formed bulk of cases. RTA, Poisoning & burns were seen as leading cause of death & maximum deaths were in the month of May to August.

Keywords: Medico legal Autopsy, Road traffic accidents, Poisoning

Introduction

Autopsy means (autos=self, opis=view) to see for oneself. Necropsy (necros=dead, opis=view) is most accurate term for the investigative dissection of the dead body, but the term autopsy is commonly used and is more popular. Post-mortem (post= after, mortem=death) examination is an alternative term used but suffers from lack of precision about the extent of examination. In some countries, many bodies are disposed off after external examination without dissection, in such situation; the procedure is called as post-mortem examination.¹

The objective of medico legal post-mortem examination is to establish the identity of a body, when not known; to ascertain the time since death and the cause of death; and whether the death was natural or unnatural and if unnatural, whether it was homicidal, suicidal or accidental. In case of new born infants, the question of live birth and viability assume importance and should
The term “post-mortem examination” is often used as a simile for “autopsy”. Basically, it is not. In 2001 an estimated 1.26 million people died due to road traffic accidents worldwide, 90% of them in low and middle income countries. Mortality rate was 20.8 per 100,000 population. As per UN report Crude death rate between 2015-2020 is 8.1. By 2020 death & disabilities resulting from road traffic accidents in comparison to other diseases will rise from current 9 to 3 spot & the developing nations will account for 90% of world traffic fatalities.

A post-mortem examination means only what it says that the body was examined after death. It can mean and often does mean that the physician merely looked at the body, fully clothed, or that he “viewed” the body at a funeral home or in a morgue. A complete autopsy involves opening all body cavities and all organs of the trunk, chest, and head. In all cases, a complete and not a partial examination are more necessary in this country on account of the imperfectness of the preliminary evidence as to the possible cause of death.

Material and Method

The present study is a retrospective study of medico legal autopsies conducted at the mortuary attached to Gulbarga Institute of medical sciences, Kalaburagi, Karnataka, India from January 2018 to December 2018. Permission was not taken from Institutional Ethics Committee as it was a record based study without involving any live subjects or experimentation. Detailed information regarding the circumstances of death was collected from inquest, panchanama, hospital records and post-mortem register. During the study period 647 medico legal autopsies were conducted in the mortuary of district hospital, Kalaburagi. Data was compiled and analyzed as per age, sex, marital status, religion, calendar month, residence, causes of death & manner of death. Causes of death were grossly classified as trauma, thermal injuries, violent asphyxia, poisoning and other natural causes.

Results

A total of 647 medico legal autopsies were conducted during the period of 1 year from January 2018 to December 2018. Males outnumbered females (67.5%) with male to female ratio of 3:1. It was observed in the study that the maximum number of autopsy cases i.e. 204(31.5%) in both sexes were in the age group of 21-30 years followed by the age group of 31-40 years and 41-50 years.

Discussion

During the study period a total of 647 cases of medicolegal autopsies were performed at District hospital mortuary, GIMS, Kalaburagi. Out of 647 cases maximum number of autopsy cases was in the age group of 21-30 years which is the most productive year in one’s life. These findings are in consistency with findings of other authors [2,3,10,11]

In our study majority of victims were males(67.5%). Similar findings are seen in other studies by Murthy et al [6] who studied 150 cases out of which 123(82%) were males & 27(18%) females. Mugadlimath et al [7] studied 64 cases out of which 39(61%) were males & 25(39%) females. Bansude et al [8] studied 722 cases out of which 62.74% were males & 37.26% were females. Bhullar et al [9] and Sharma et al [10] found 66.5% males & 33.5% females. Similarly Singh et al [11] found 74.8% males & 24.2% females in their study and KV Radha Krishna et al [12] in which males were 69%.

The reason being that as males are bread earners and females usually doing household work, which makes the males more vulnerable to accidents, violence and stress & also males predisposed for addiction & risk taking behaviour.

In our study out of 647 cases autopsied, 83.4% were Hindus, and 14.5% were Muslims, the reason being Hindus are majority in number. In 2.1% of cases autopsied were unknown bodies in which religion could not be determined. Similar findings are observed in studies by other authors [2,3,12]. Rural residents were 73% and only 27% were from Urban locality. This finding is contradicting to results of other studies in which Urban residents were in majority [2,3,12]. This difference is due to our centre serves more rural population where in cases are referred to our hospital & hospital deaths for bulk of autopsies performed.

Deaths due to road traffic accidents & its complications constituted majority of cases 32.8 % followed by poisoning 13.1%, hanging 8.6% and burns 7.8%. Similar findings are observed in studies by other authors [2,3,12,13]. The reason being that in our centre, most of the accident cases and other medicolegal cases are referred to our hospital including from rural areas.

According to month wise distribution of cases, findings of our study showed more number of cases between May to August. These findings are in contrast with the studies by Patel et al [12] and similar findings were seen with findings of Awdesh et al [13] and Mugadlimath et al [7].

Maximum number of deaths due to poisoning were suicidal(95.2%) followed by accidental(4.8%).

Conclusion

Study conducted at Gulbarga Institute of Medical Sciences Kalaburagi, to know the profile of medicolegal autopsies during a period of one year from January 2018 to December 2018 comprising a total of 647 medicolegal autopsies. In our study we found that majority of cases were in 3rd decade of life, males outnumbered females, rural residents were more in number, Hindus being majority in number formed bulk of cases, RTA, Poisoning, hanging and burns were seen as leading cause of death, among road traffic accidents 2 wheeler accidents were more in number. Maximum number of cases were seen in the period between May-August. This study helps to interpret different types of medicolegal autopsy cases, thereby providing an insight to the policy makers, law custodians, and the community to look into the specific aspects of the cases and then to take proper measures accordingly for the benefit of the community people at large of this place. Following measures can be implemented to bring down the mortality rate especially due to road traffic accidents where in strict implementation of traffic rules with special attention to
be paid to drunken drivers, use of mobile phones and smoking while driving, rash and negligent driving and education the general public about road safety measures. The existing stringent laws against dowry death cases need to be further strengthened. Various other socio-economic factors responsible for high incidence of suicidal poisoning need early Government Policies. The sale of agrochemicals and other pesticides should be controlled through strict regulations & implemented by the concerned authorities.

**Conflict of Interest** - None

**Source of funding** - Nil

**Ethical Clearance** - Permission was not taken from IEC as it was a record based study without involving any live subjects or experimentation.

Liver Pathology in Autopsy Cases: A Retrospective Study in A Tertiary Care Center

Ekta Rani 1, Sarita Nibhoria1, Sanjay Kumar2,

1Assistant Professor, Department of Pathology, GGS Medical College -Faridkot, Punjab, India, 2Professor, Department of Pathology, GGS Medical College -Faridkot, Punjab, India, 3Professor, Department of Pathology, PGIMS Rohtak, Haryana, India

Abstract

Background: Liver is the site of many diseases, many become symptomatic while few are diagnosed only on autopsy. The cause of chronic liver disease varies in different geographic areas and influenced by socioeconomic status, diet, life style and regional diseases.

Method: This retrospective study was carried out in a tertiary care hospital in the department of pathology over a period of one year. A total of 40 cases of liver specimens, received as part of liver, constituted the material for the study. All were autopsy cases and the organs were received in 10% formalin. Routine grossing and staining with H&E stain were performed. Slides were analysed and the findings were noted in percentages.

Results: A total of 40 specimens were studied. Age ranges from new born to 70 years, with 92.5 % male cases. 32.5% of cases were autolysed. 25% were showing chronic venous congestion followed by fatty change (22.5%), hepatitis (12.5%). 2.5% each of cirrhosis, steatohepatitis and normal liver.

Conclusion: 1. Autopsy has an important role in identifying the cause of death.

2. To overcome the autolysis of the specimen, the medical practitioner performing the autopsies should be trained about how to carry post mortem and to preserve the viscera for histopathological examination so that cause of death could be noted.

Key words: Autopsy, Fatty change, Cirrhosis, Hepatitis, Congestion, Steatohepatitis, autolysis

Introduction

Even the chronic liver diseases in advanced stage may go undiagnosed because of delayed sign and symptoms. Mostly diagnosed incidentally on routine health check-ups, surgery or at autopsy.¹ Liver is susceptible to variety of diseases with aetiologies including metabolic disorders, microbial infections, toxins and circulatory disturbances. Rightly liver is called as “Custodian of milieu interior. To find out the cause of death and planning of treatment autopsy is beneficial.² Underlying cause of death varies in different parts of world.

Diseases in liver can be – congenital malformations, chronic venous congestion, hepatitis, fatty change, cirrhosis, Steatohepatitis, Pyogenic and amoebic abscess, hydatid cyst, storage disorders, hemosiderosis, tuberculosis, infarcts, actinomycosis, hepatocellular carcinoma, hepatoblastoma, metastatic deposits etc.³

Material and Method

This retrospective study was carried out in a tertiary care hospital in the department of pathology over a period of one year. A total of 40 cases of liver specimens, received as part of liver, constituted the material for the
study. All were autopsy cases and the organs were received in 10% formalin. Routine grossing and staining with H&E stain were performed. Slides were analysed and the findings were noted in percentages.

</table>

Table 2 shows that 32.5% of cases were autolysed. 25% were showing chronic venous congestion followed by fatty change (22.5%), hepatitis (12.5%). 2.5% each of cirrhosis, steatohepatitis and normal liver.

**Discussion**

Out of total 40 cases maximum number falls in the age group of 21-40 years constituting 44.5%. Similar to the studies of Bhagat et al showing 22% of cases in 21-30 years. Patel et al and Behera et al also studied that maximum cases were in age group 31-40 years (30.13%) and 20-40 years (23.44%) respectively.

Liver disease was most commonly seen in males 92.5% than females 7.5%, comparable to the studies done by Sotoudehamaesh R et al (86.7%), Behera et al (82.81%) and Bal MS et al. This may be attributed to
the alcohol consumption in male population.

<td>5.8</td>
<td>3.12</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

In our study 32.5% of the received specimens were autolysed, contributing the bulk which is not seen in any other study. Bhagat et al\(^1\) and Behera et al\(^5\) noted 5.8% and 3.12% respectively. The reason for the autolytic changes were:

1) Poor preservation of the specimen: The specimens were not received in formalin.

2) Number of Viscera’s and the size of container: All the viscera of a patient were received in a single container.

3) Delay in receiving the viscera.

So, to overcome the autolysis of the specimen, the medical practitioner performing the autopsies should be trained about how to carry post mortem and to preserve the viscera for histopathological examination so that cause of death could be noted.

Among the liver diseases, Congestion was the most commonly encountered (25%) which was in concordance with the studies of Behera et al\(^5\) (20.90%) and Alagarsamy et al\(^7\) (26%).

In present study Fatty change was seen 22.5% of cases. Behera et al\(^5\), Selvi et al\(^8\) and Alagarsamy et al\(^7\) also noted almost similar percentages of Fatty change in their respective studies (21.87%, 26.9% and 20%). Regular intake of alcohol between 40-80gm increases the liver weight and frequency of fatty changes in liver.\(^3\)

Hepatitis constituted 12.5% of total cases our study. This is in accordance to the studies conducted by Behera et al\(^5\) (12.5%), Bhagat et al\(^1\) (18.3%) and Selvi et al\(^8\) (13.9%).

Cirrhosis contributed only 2.5% of the liver diseases in the present study. This is similar to the study of Smita et al\(^9\) (4.43%) and Patel et al\(^1\) (2.44%). It is an end stage liver disease.

Steatohepatitis was seen in 2.5% cases showing concordance with Behera et al\(^5\) with 3.12% of hepatitis cases.

2.5% cases show normal histopathology which was very low as compared to the other studies of Bhagat et al\(^4\), Behera et al\(^5\) and Bal et al\(^2\).

### Conclusion

1. Most common age group involved was 21-40 years.
2. Liver diseases were most commonly seen in males 92.5% than females 7.5%.

3. Autopsy has an important role in identifying the cause of death.

4. To overcome the autolysis of the specimen, the medical practitioner performing the autopsies should be trained about how to carry post mortem and to preserve the viscera’s for histopathological examination so that cause of death could be noted.

Histopathological Study of the Freshwater Fish
*Ctenopharyngodon Idella* Exposed to Λ-Cyhalothrin 5% EC

G. Rajeswari,1 Lalitha Vinnakota1, V. Venkata Rathnamma2

1Research Scholars, 2Associate Professor, Department of Zoology and Aquaculture, Acharya Nagarjuna University, Guntur, A.P, India

**Abstract**

Present study Lambda cyhalothrin is a synthetic pyrethroid widely used for pest management and public health applications to control insects. It is categorized as a restricted use pesticide in Extension Toxicology Network for its toxicity to fish. But its usage for the control of major pest in agriculture is being continued in developing countries like India. The freshwater fish *Ctenopharyngodon idella* were exposed in sub-lethal concentrations (1/10 of lethal concentrations) of lambda cyhalothrin 5%EC for 1 and 12 days along with controls to study histopathological changes under light microscope in the selected tissues viz., liver, kidney and gill were examined. Swelling of the hepatocytes with diffuse necrosis and marked swelling of blood vessels were observed in the liver tissue. Tubules of the kidney were distended, with tubular cells of posterior kidney exhibiting marked necrotic changes. Pathology of the gill tissue showed shortened primary lamellae, loss of secondary lamellae and congestion of blood vessels and hyperplasia of branchial plates and the pathology increased with increasing exposure periods.

**Keywords:** *Ctenopharyngodon idella*, Lambda cyhalothrin 5% EC, Sublethal exposure, histopathology of Gill, Liver and Kidney.

**Introduction**

The toxicity of any environmental contaminant is either acute or chronic, and the chronic studies of the organisms; physiological studies alone do not satisfy the complete understanding of pathological conditions of tissues under toxic stress. Hence, it is useful to have consequence of the concentration of the toxicant and it is depend on exposure time. The damage of the particular tissue depends on the toxic potentiality of a particular contaminant accumulated in the tissue4. Aquatic vertebrates are susceptible to non-target effects, because of their relatively restricted mobility and also due to pesticide residue dispersion leading to lengthy period of exposure. Most of the histopathological changes can be interpreted as non-specific response to stress and a wide spectrum of pollutants, including pesticides, heavy metals and organic contaminants exposed to fish and other organisms16.

**Results and Discussion**

Histopathological studies provide information about the health status and functionality of different organs. Tissue injuries and damages in organs can
result in the reduced survival, growth and fitness, the low reproductive success or increase of susceptibility to pathological agents. The extent severity of tissue damage is a consequence of the concentration of the toxicant and is time dependent. Hence, in the present study, an attempt has been made to observe possible histopathological changes in certain vital tissues like gill, liver and kidney of the Indian major carp *Ctenopharyngodon idella* exposed to sublethal concentration of lambda cyhalothrin 5% EC for 1 and 12 days. In the case of 1 day sublethal there was no significant change was observed between control and 1 day sublethal of gill, liver and kidney.

**Pathology of Gill tissue under Lambda Cyhalothrin toxicity:**

Gills apart from being the primary respiratory organ in fishes, are also responsible for other vital physiological functions like excretion of nitrogenous wastes, acid base balance and ion regulation. So when fish are exposed to environmental pollutants, these vital functions are deleteriously affected and the functional impairment of gills can significantly damage the health of fish. The biological function of the inflammatory response is to destroy “WALL OFF” Irritating substance so that damaged tissue might heal. So the pesticide exposure causes severe alterations in the tissue biochemistry and histology of fish.

Present study Lambda Cyhalothrin exposed to the fish *Ctenopharyngodon idella* and the pathological changes in fish gills includes bulging in tips of primary gill filaments. The secondary gill filaments lost their original shape and curling of gill filaments was observed. The pillar cell nucleus showed necrosis and development of vacuoles in the secondary gill epithelium, and a tendency in fusion of disorganized secondary gill filaments. Shortened and clubbing ends of the secondary gill lamellae, fusion of adjacent secondary gill lamellae and necrosis in the primary lamellae were identified. Hyperplasia and hypertrophy of nuclei were also seen. The epithelial layer of secondary lamellae of gills forms a barrier between the fish blood and surrounding water. In fish, gills are the main organs to contact with the pollutant. Hence, it is more vulnerable to damage than any other tissue and the proliferation of gill lesions observed in some places after exposure to water soluble toxicants (Plate 1.B).

**PLATE- 1 (GILL)**

Fig.A .Control Fig.B.12 days sublethal

Degenerative changes in lamellar hyperaemia, lamellar oedemas, clumping, cellular, lamellar atrophy in gill of rainbow trout exposed to chlorpyrifos for 24, 48, 72 and 96 hrs. It also observed in the secondary lamellae and respiratory epithelium of the fresh water teleost *Channa punctatus* under exposure to Alachlor and states that the degeneration of respiratory epithelium and damages of gills tissue causes a decrease in energy metabolism. Toxicity of Formalin cause of pathological damage in the gill, gill dysfunction, osmoregulatory
and respiratory imbalance in ornamental fish Amazon blue spotted corydora (*Corydoras melanistius*) 17. Present study lamellar fusion caused by the filamentary epithelium proliferation and some lamellar aneurisms were also found. Hypertrophy; hyperplasia, lifting of epithelial cells and fusion of secondary gill lamellae were pronounced in the treatment of λ-cyhalothrin exposed to *Ctenopharyngodon idella*. The main histopathological changes in gills were showed edema, lifting of lamellar epithelia and an intense vasodilation of the lamellar vascular axis20.

**Pathology of Liver tissue under Lambda Cyhalothrin toxicity**

Hepatic cells are roundish polygonal, containing clear spherical nucleus and they are located among sinusoids forming cord like structures known as hepatic cell cords. In fish, these structures are generally obscure. Bile canaliculi, is centrally located in each cord and large quantities of lipid glycogen granules are also observed in the cytoplasm of fish hepatic cell cords (Plate.2 & Fig. A). Toxicity discrete pathological changes were observed in the liver tissue of the test fish *Ctenopharyngodon idella* (Valenciennes). These changes were degeneration of cytoplasm in hepatocytes, atrophy, formation of vacuoles, rupture of blood vessels, necrosis and disappearance of hepatocyte cell wall and disposition of hepatic cords. Formation of vacuoles cytoplasm in hepatocytes, atrophy, blood streaks among hepatocytes, intercellular empty space and blood cognation were observed and there was decrease in the size of nucleus of the hepatocytes also observed. (Plate: 2. & Fig: B).

Necrosis with inflammatory infiltration, vacuoles in the hepatocytes and hepatic sinusoids congestion in albino rats treated with dimethoate 10, 2. The changes may be attributed to direct toxic effects of pollutants on hepatic cells, since the liver is the site of detoxification of all types of toxic substances19. The sublethal effects of pesticide lambda cyhalothrin affect the liver histology of *Oreochromis mossambicus* under long term exposure to 0.0025 ppm of sublethal concentration the liver was comprised of polygonal hepatocytes with centrally placed nucleus15.

**PLATE-2 (LIVER)**

**Fig.A Control Fig.E.12 days sublethal**

Cytoplasm with nuclear degradation; cellular degradation and damaged hepatocytes were observed in fish *Cyprinus carpio* exposed to cadmium23. The necrosis of hepatocytes with enlarged sinusoid in freshwater fish *Cirrhinus mrigala* exposed to acute and chronic levels of cythion and also reported that significant alterations in the hepatocytes, pyknotic nuclei and necrosis in the liver of *Clarias gariepinus* exposed to cypermethrin24. Moderate focal necrosis, granular glycogen, nuclei piknosis, loss of architecture structure; onion-like cells were observed in fish *Cyprinus carpio* due to the presence of microcystins1. Vacuolization and presence of sinusoid spaces were reported.
in liver tissue of *Danio rerio* exposed to 200µg/L of chlorpyrifos for 24, 48, 72 and 96h\(^4\). Hyperaemia and degenerative changes in liver and lamellar hyperaemia, lamellar oedemas, clumping, cellular degeneration, hyperplasia and lamellar atrophy in gill were noted in the fish rainbow trout exposed to 2.25, 4.5 and 6.75 µg/L of chlorpyrifos for 24, 48, 72 and 96h\(^2\).

In the present study there is a strong link between liver damage and toxicants. Vacuolar degeneration, hemorrhage and necrosis noticed. It might be due to the presence of toxicants. Necrosis, haemorrhage, degeneration of hepatocytes and pyknosis in the liver tissue were witnessed in *Labeo rohita* exposed to zinc\(^9\). Vacuole formation, degeneration of hepatic cells, haemorrhage and necrotic lesions were noted in *Heteropneustes fossilis* exposed to sewage for 180 days\(^13\). In the present study degenerative changes are intensified in liver to sublethal exposures. They include degeneration of cytoplasm in hepatocytes, atrophy, formation of vacuoles, rupture in blood vessels, necrosis and disappearance of hepatocyte wall disposition of hepatic cords decrease in size of nucleus pyknotic and vacuolar degeneration within the nucleus was evident (Plate: 2, Fig B). The same degenerative changes in *Catla catla*, *Labeo rohita*, *Ctenopharyngodon idella* and *Channa punctatus* under Chloropyrifos, fenvelarate and butachlor toxicants\(^21\).

Pathology of Kidney tissue under Cyhalothrin toxicity:

The renal tubules are composed of cuboidal epithelial cells with densely arranged microvilli in the tubular lumen. In segment II, renal tubules are composed of cuboidal epithelial cells. Cilia and microvilli are found in the tubular lumen. In the distal convoluted segment, epithelial cells have no microvilli. The cells of this segment are stained with eosin more faintly than those of proximal convoluted segment (Plate. 3& Fig. A). Present study indicates the freshwater fish *Ctenopharyngodon idella* (Valenciennes) under cyhalothrin toxicity evidenced marked pathological changes in renal tissues. Highly degenerative changes were observed in haemopoietic tissue which include severe necrosis, cloudy swelling in renal tubules, cellular hypertrophy and granular cytoplasm. The epithelial cells of the distal convoluted tubule decreased in size. The interstitial renal tissue was less affected. It showed formation of vacuoles and cellular contours were not clearly distinguished (Plate.3 & Fig. B).

Lesions in the kidney tissues of fish exposed to deltamethrin, Tubular degenerations were noted in catfish, *Ictalurus punctatus* upon exposure to methyl mercury \(^8\). Diethyl phthalate induce changes in fish *Clarias gariepinus* had necrosis of epithelial cells of renal tubule, pyknotic in haemopoietic tissues and degeneration of glomerulus\(^12\). Degenerative changes such as necrosis in renal epithelium, Cloudy swelling in renal tubules, cellular hypertrophy granular cytoplasm and swelling of mitochondria in the renal tubules were observed in animals administered Pyraclostrobin\(^3\).

---

**PLATE -3(KIDNEY)**

Fig.A.Control Fig: B.12 days sublethal

**LEGEND FOR FIGURES:** PCS: proximal Convulated Segment, DCS: Distal Convulated tubule. DART: Degeneration and atrophy in renal tubules, DL: Decreased Lumen in tubules, DGHTE: Degenerating haemopoietic tissue with erythrocytes and FVRIT: Formation of Vacuoles in the renal interstitial tissue.
Reduced glomerular filtration rate, glomerular lesions, degeneration of cellular boundaries and clumping of glomeruli were reported at some places in the kidney of rainbow trout \((Onchorhynchus mykiss)\) exposed to fungicide captan.\(^6\) Disorientation in glomerular structure, cloudy swelling, dilation in the inter space urinary tubular. Necrosis in the haematopoietic tissue, appearance of vacuoles indicates the effects of toxicity in fish rainbow trout \((Onchorhynchus mykiss)\).\(^5\) The present observations are in agreement with the reports of all the above reports. Thus, when fish is exposed to pesticide, they suffer reparable architectural changes in various vital organs making the fish less fit for better survival. These histopathological changes can alter various physiological activities of the fish.

**Conclusion**

The present study title proved pyrethroid compounds damaged the fish active organs like gill, liver and kidney and the susceptibility of the fish in the context of environmental monitoring and the biomarker approach. The histopathological studies showed that \(\lambda\)-Cyhalothrin 5% EC at different sublethal concentration causes significant morphological and pathological changes in the selected tissues of *Ctenopharyngodon idella* at higher dose of toxicant than the lower dose level. In gill progressive degeneration, severe necrotic changes were noticed in the epithelial cells of secondary gill lamellae and it also caused profound pathological changes in liver tissue of the test fish such as degeneration of cytoplasm in hepatocytes, atrophy, and formation of vacuoles, necrosis. It showed severe cloudy swelling of renal tubules, disintegration of interstitial tissue, pyknotic nucleic, etc., in kidney.

**Acknowledgment:** The authors thank the aquaculture fish forms for the supply of fish in time for conducting experiments.

**Ethical Clearance:** The test fish *Ctenopharyngodon idella* is an edible fish so there is no need to take ethical clearance.

Abstract

Aim and Objective: To evaluate the usefulness of voice handicap index and seventy degree endoscopy for assessment of speech.

Materials and Method: The study was conducted in the department of Otorhinolaryngology, tertiary care hospital, between 2018 to 2019.

Results: Total of 42 cases underwent micro laryngeal surgery without any complications. Voice Handicap Index (VHI) and 70 degree scopy assessed after 10 days, 1st month and 3rd month interval. All cases improved voice on 10th day and symptoms were gradually decreased. Before surgery mean was 82.43 changed to 17.31 on 10th day to 1.45 on 3rd month follow up. p value <0.005

Conclusion: Early diagnosis is important to rule out malignant changes in cases with hoarseness of voice and early treatment with microlarynoscopy is very effective shows significant improvement on voice handicap index and endoscopy and with patients satisfaction.

Keywords: Hoarseness, speech, endoscopy, voice

Introduction

Your voice is one of the most important components of your identity. Each human being has a voice that is distinct and different from everyone else’s. We can identify someone from their voice fairly easily. Change in voice (hoarseness) affects person’s confidence level and behavior. There are many different etiological factors for hoarseness like voice abuse, smoking, laryngoparyngeal reflux, recurrent dry cough, foreign body sensation, vocal fatigue. Benign laryngeal lesions like vocal nodules and polyps are seen commonly in ENT OPD caused by voice abuse. With conventional indirect laryngoscopy and newer techniques like seventy degree rigid endoscopy or flexible fiber optic scope and stroboscopy helps for proper diagnosis. Medical Management of these lesions include antireflux therapy, speech therapy. There are different options available for surgical treatment. CO2 laser, cold instruments powered instruments. In our study surgical method used is micro laryngoscopy using cold instruments. Voice handicap index is currently gold standard for subjective assessment of voice which score between 0 to 120 accordingly severity of voice.

Material and Method

A prospective study was carried out at Otorhinolaryngology department, in tertiary care teaching hospital during July 2018 to June 2019. Total of forty two clinically diagnosed cases of vocal nodule and polyp found by seventy degree endoscopy were evaluated having age in between 20 to 60 years, irrespective of gender and willing to participate in the study were included. All cases having previous history of laryngeal surgery, malignant lesions, immunocompromised and
diabetes mellitus were excluded from the study. After pre anesthetic checkup cases were posted for micro laryngeal surgery under general anesthesia. Micro laryngoscopy were performed to expose lesions on vocal cord using operating ENT microscope with 400 mm objective lens, and the lesions were examined clearly. The cold laryngoscopic microsurgical instruments included microsurgical laryngeal forceps, scissors, and other instruments used for surgery. There are different methods like micro flap surgeries and direct cutting method. After sub mucosal injection of 2% lignocaine with Adrenaline in the vocal cord, lesions removed after pulling it in midline. Haemostasis achieved with 4% lignocaine with adrenaline solution. Postoperative care we used injection dexamethasone 8mg for 3 days with other antibiotic and analgesic cover and tincture benzoin inhalation and complete voice rest for 5 days. We assessed voice and vocal cord on 10th day, 1 month and 3 month interval.

**Table1:** Voice handicap index (VHI) assessment

For the subjective assessment, the tools used were voice Handicap index (VHI).(Refer table 1)

<table>

</tbody>
</table>

On 70 degree endoscopy vocal cord shows irregular edges with formation of pseudo membrane in 3 cases on 10th day then, 1 and 3 months follow up, the laryngoscopic examination shows a good healing, glottic closure and normal vocal cord movement. On 70 degree scopy 5 cases of bilateral vocal nodule and 3 cases with vocal polyp shows phonatory gap on 10th day which disappears completely on 3rd month follow up except 1 case. Postoperatively, 1 case had persistent of the symptoms and 1 vocal polyp had recurrence during the 3rd month of follow-up period. (Refer table 3)

Discussion

“Alexa, who am I?”...but no answer this is Amazon Echo’s voice-controlled virtual assistant, device cannot answer that question – yet. Artificial intelligence technology with other applications of speech technology, computer algorithms can recognise and identify individuals from voice recordings. Your voice is one of the most important components of your identity, each human being has a voice that is distinct and different from everyone else’s. we can identify someone from their voice fairly easily. Voice is produced by air column coming from lungs passing through larynx and vibrate vocal cords. Then it is modified by articulators (i.e. tongue, lips, teeth, jaw, cheeks) to make speech sounds. Each person has a unique voice which distinguishes them from another person. Voice has a number of features like pitch, volume, quality and resonance, which shows persons emotions.

Voice handicap index is currently gold standard for subjective assessment of voice assessment done on 3 parameters functional physical and emotional. Vocal nodules (e.g. singer’s nodes), also caused by vocal misuse. Typically these nodules are bilaterally symmetrical in the middle third of the vocal fold and located superficially on the vibrating free edge of the cord it is often difficult to diagnose different lesions of the lamina propria histologically (eg. nodules, polyps and Reinke’s edema) [1]. Therefore, the correct diagnosis cannot be made purely on histological examination, but requires a complete assessment including history, voice assessment and laryngoscopic [2]. The available therapeutic measures for nodules are conservative voice hygiene and voice therapy. The patient’s motivation, vocal requirements in social and professional life together with the correct diagnosis allows an appropriate conservative treatment plan to be formulated. The specifically tailored program, including targeted voice therapy, achieves better results than a generic program [3]. Surgical management methods like CO2 laser treatment and conventional microsurgery. Chances of CO2 laser thermal damage deepens the surgical trauma and delays healing. Micro surgery treatment as benefit of precise visualization of lesion complete excision with less intervention minimal invasive with early functional improvement and less hospital stay [4]. In our study patients voice gradually improved on 10th day, 1 month and 3rd month assessment. These results are consistent with the results of clinical studies maximum recovery seen on 1month bilateral vocal nodule voice Handicap index (VHI) changed to less than 10 on 1month and less than 2 on 1 month.

In study comparison of CO2 laser and conventional laryngomicrosurgery treatments of polyp and leukoplakia of the vocal fold by Ya Zhang et al shows that CO2 laser laryngomicrosurgery will not cause high impact on the vocal cords for benign vocal cord lesions. For precancerous lesions, it can improve significantly the morphology of vocal cords and the quality of pronunciation. CO2 laser laryngomicrosurgery is more effective than conventional surgery (cold instruments) [4].

Conclusion

Early diagnosis is important to rule out malignant changes in patients with hoarseness of voice and early treatment with Microlarynoscopy is very effective shows significant improvement on voice handicap index and rigid laryngeal endoscopy and with patients satisfaction.

Ethical approval: All procedures performed on human participants were in agreement with ethical standards of the Institutional and/or National Ethics Committee.

Knowledge Among Parents about Importance of Primary Dentition

Gayathri.P.S\textsuperscript{1}, Krithika. C\textsuperscript{2}, D.M.Jenisha\textsuperscript{3}, S.Kalaivani\textsuperscript{3}, V.Jenifercharuprabha\textsuperscript{3}, R.Nithyaedeinton\textsuperscript{4}
\textsuperscript{1Reader, Department of Oral Medicine and Radiology, \textsuperscript{2}HOD & Professor, \textsuperscript{3}Student-Intern, \textsuperscript{4}Post graduate, Thai Moogambigai Dental College & Hospital, Chennai, Tamilnadu, India

Abstract

Aim: Dental caries is very common in primary dentition because of improper oral hygiene and increased intake of sucrose. The parents are the one who take care of their children and make decision for them. Often parents are responsible for the oral care of their children. The aim of this study is to evaluate the knowledge among parents about importance of primary dentition.

Objectives: To evaluate the attitude and knowledge of parents towards importance of maintaining primary dentition in their children.

Materials and Method: The study was conducted among parents visiting dental institution, Chennai. A total of 200 questionnaire containing 15 questions were prepared for data collection and were personally distributed to parents. A number of 100 fathers and 100 mothers were included in the study.

Results: The study shows that literate parents had more knowledge about primary dentition when compared to illiterate parents.

Conclusion: Knowledge about primary dentition can be increased in parents by conducting oral awareness program in schools. There is a need cultivate positive attitude among parents to raise their knowledge about dental awareness.

Keywords: Parents, dental caries, primary teeth, oral habits.

Introduction

“Health is wealth”. Health is not only merely absence of disease but also complete state where in the person is physically, emotionally and mentally sound. General wellbeing is directly co-related to the oral health and vice-versa. Thus, general health cannot be maintained well with poor oral hygiene.

Dental caries is very common in primary dentition because of improper oral hygiene and increased intake of sucrose. The parents are the one who takes care of their children and make decision for them\textsuperscript{1}. Often parents who are responsible for the oral care of children believe that since primary teeth eventually shed off, it is not worthwhile to spend time/money on providing good oral health to children\textsuperscript{2}. Poor attitude of parents towards oral health of infants and young children are associated with increased caries prevalence\textsuperscript{3}. Hence they should have knowledge about primary teeth, their health and caring in order to build confidence in their children through primary teeth\textsuperscript{4}.

Objectives

To evaluate the attitude and knowledge of parents towards importance of maintaining primary dentition in their children.

Materials and Method

The study was conducted among parents visiting dental institution, Chennai. The ethical clearance was obtained from institutional review board and consent was obtained from the study participants. A preformed structured questionnaire preformed was designed in English and then translated in Tamil for illiterate parents.

All parents of children aged below 12 years who
reported to dental colleges in Chennai were invited to participate in the study. A total of 200 questionnaire containing 15 questions were prepared for data collection and were personally distributed to parents. A total number of 100 fathers and 100 mothers were included in the study.

The demographic details of the parents were collected such as name, age, gender and educational qualification. The responders were then asked to indicate the most appropriate answers form the given list of option in order to assess the knowledge, awareness and perception regarding the importance of primary tooth.

The answers were evaluated to assess the knowledge and awareness about the primary teeth, their function and effects on permanent teeth. Further assessment of parent’s attitude towards treatment of decayed or infected primary teeth and their willingness to comply with the treatment option for such teeth.

Collected data were tabulated and subjected for stastical analysis using statistical package for social sciences (SPSS) version 13.0.Distributed frequency which includes number and percentage were calculated. Chi-square analysis was used for comparison was done based upon the educational qualification grouped under literate and illiterate. The level of significance was set at p<0.05.

### Results

Caries related conditions such as pain, food impaction, sensitivity were found to be the common reason for visit to dental clinic.

**TABLE 1: Gender distribution among parents accompanying children for dental treatment**

There exists a highly significant P value difference between literate and illiterate parents in relation to the knowledge about reason for the visit to the dentist. Literates had better knowledge than illiterates. Most of parents stated that chronic pain or trauma as the main reason to visit to the dentist which was followed by 22% of esthetics, 17% for caries, 7% for bad breath and bleeding gums. (Chart 1)

Approximately 46.5% of literate parents had good knowledge about treating primary tooth. (Chart 2)

Most of the parents visit General Physicians nearby in case of child’s dental problem whereas 25% of parents visit Pedodontist in case of child’s dental problem. (Chart 3)

62% of parents were unaware of fluoridated tooth paste. (Chart 4)

About 80% of parents said that oral deleterious habits can harm the developing dentition, 9.5% of parents were unaware of oral habits and 10.5%of parents had no knowledge about the effect of oral habits over developing dentition.(Chart 5)

71% of parents said that night time bottle feeding can cause dental caries and 7.5% of parents said that night time bottle feeding is not the cause for dental caries. (Chart 6)

### Discussion

Attitude and practice among parents are the important factors influencing the prenatal health care of the children[5]. Earlier studies reveal that regular dental care among children is uncommon in developing countries. It was contraindicating to American Academy of Pediatric dentistry recommendation which states that ideally infant’s oral health begins with prenatal oral health counselling for parents[6].

Many studies found that these recommendations are not taken because of unawareness by the parents about the importance of primary dentition. In most of the studies we found that parents didn’t take care of their child’s primary tooth because of their unfamiliarity about dental treatment and poor socioeconomic status which was truly correlating with our study[7].

In our study 68% of parents stated that waste of money as the reason for not treating primary tooth which correlates with the study done by AnjanaMounissamy et al[8].

Relevant to prevention of caries, in our study 67% of parents selected the option all the above (reducing snack content, brushing twice a day, getting provision advice) but in the study of Mahesh Ramakrishnan et al 68% of parents reported reducing snack containing
sugar prevent caries. We found that there is increased awareness about prevention of caries among the parents in our study\[^{9}\].

In our study, when questioning to parents regarding the child’s dental problem 77% of parents visit the General Physician nearby which corresponds to study conducted by AnjanaMounissamy et al. Majority of illiterate participants in our study were not aware of consulting Pedodontist at right time\[^{8}\].

In case of treating primary tooth, most of the parents prefer to leave the treatment decision to the Dentist which truly correlates with the study conducted with the study conducted by JyothsnaVittobaSetty et al\[^{10}\].

In our study we found that 54% of parents took their child to dental clinic when child complains of pain which was similar to study conducted by Janhvi et al\[^{11}\].

We found that 62% of parents were unaware of regarding fluoridated tooth paste which correlates with the study done by Bhavneet Kaur et al. Our study shows that both literate and illiterate parents have low awareness of fluoridated tooth paste\[^{12}\].

The outcome of our study recommends effective oral awareness program among parents regarding caries prevention. However, all parents agreed that dentist played a most important role in achieving best oral health outcome in their children. We need to initiate more dental awareness program for parents as well as to spread the oral health awareness in our society.\[^{13}\]

**Conclusion**

Parents play an important role in promoting good oral habits in their children. There is a need cultivate positive attitude among parents to raise their knowledge about dental awareness.

**Conflict of Interest:** There are no conflicts of interest.

**Source of Funding:** Self–sourcing.

**Ethical Clearance:** Ethical committee approval is obtained from the university (DR.MGREDUCATIONAL AND RESEARCH INSTITUTE, MADURAVOYAL CHENNAI).

Clinical Profile of Amblyopia in Young Adults

Girish Gadre¹, Surabhi Khandelwal², V.H. Karambelkar³
¹Associate Professor; ²Resident, ³Head of Department, Department of Ophthalmology, Krishna Institute of Medical Sciences, Karad, Krishna Institute of Medical Sciences “Deemed To Be University”, Karad, Maharashtra, India

Abstract

Aim: To study clinical profile of amblyopic patients in relation to refractive status, socio economic status, use of glasses and social impact on society.

Results: Myopes improving with spectacles are 45% and mixed astigmatism 69%. Most common age group for detection of amblyopia in young adults is 21-30 years(47.1%) with predominance of female(55.7%) belonging from middle class families (81.4%) having studied mostly from Government Marathi medium school(45.7%) with previously not using given glasses(57.1%) and with taken amblyopia of only (7.1%) and with spectacles maximum correction with mixed astigmatism (54.2%) between 6/36-6/9 in right eye (43%) and in left eye (30%). Hypermetropes’ improving to 6/12 is only 13%. So there’s very few cases improving with the spectacles in hypermetropes in amblyopia.

Interpretation: Lack of school screening programs and awareness for health check-up delays the diagnosis of amblyopia leading to non-improvement of vision and due to lack of knowledge and social stigma girls especially avoid wearing glasses even after prescribing leading to amblyopia.

Conclusion: School health camps, proper health education, timely examination, and proper use of spectacles is must.

Keyword: MYOPICS: (M), HYPERMETROPICS: (H), Visual acuity: (VA)

Introduction

Amblyopia is a “developmental defect of spatial visual processing that occurs in the central visual pathways of the brain.” It presents most dramatically as loss of visual acuity in one or, rarely, both eyes, but amblyopia is more than this; certain forms of amblyopia also present with diminished contrast sensitivity, Vernier acuity, gratating acuity, and spatial localization of objects. These defects may be explained by the mechanism of lack of use of an eye because of media opacity or extreme refractive errors that cause a chronically blurred image to form on the fovea of that eye; however, the cause of amblyopia in an eye that has strabismus is not as straightforward and is the result of abnormal binocular interaction¹.

Types of amblyopia²:

1. Strabismic
2. Stimulus deprived
3. Anisometropic
4. Bilateral ametropic
5. Meridonal

• In the absence of an organic lesion, a difference in best corrected VA of two Snellen lines or more (or >1 log unit) is indicative of amblyopia³.

• Visual acuity in amblyopia is usually better when reading single letters than letters in a row. This ‘crowding’ phenomenon⁴ occurs to a certain extent in

normal individuals but is more marked in amblyopes and must be taken into account when testing preverbal children.

**Aim:**

To study clinical profile of amblyopic patients in relation to refractive status, socio economic status, use of glasses and social impact on society.

**Inclusion Criteria:**

- Patients of age <30 years
- Visual acuity less than log mar 0.2 in one eye or both eyes without any organic cause

**Exclusion Criteria:**

Vision affected due to any cause anterior segment or posterior segment cause

**Study Design:**

- Hospital based longitudinal non-randomized study.

**Materials and Method**

- All the young adults up to the age of 30 years coming to Department of ophthalmology, KIMS DU Hospital, Karad were screened out by taking visual acuity and correction with refraction for amblyopia over a period of 1 year from August 2018 to July 2019.

**SAMPLE SIZE:**

- 70 patients were enrolled

**Observations and Results**

**Observation:**

- **TABLE 1** This table shows that sample size of 70 cases when given the vision correction with refraction the result comes out to be 43 patients that is 50.2% of patients had spherical correction and amongst them 26 patients that is 37.1% are myopic correction and 17 patients that is 24.2% are hypermetropia correction.

This table also shows about the cylindrical correction which is minimum only in 8 patients that us 11.4% and remaining 19 patients that is 27.14% patients have mixed correction.

- **TABLE 2:** Taking results from above table now further extending our discussion regarding correction and its visual acuity relation, this table will discuss about relation of hypermetropies with its visual acuity correction.

Amongst the hypermetropies that is total 17 patients so here n=17 , out of them 10 patients power for refraction comes out to be between (+2.5- +5) and amongst the 10 patients only 3 patients that is 30% have full correction but 60% that is 6 patients have correction till log mar 0.4-1 and only 1 patient could have correction till log mar 1.

Rest of 23.07% patients have correction till +2 in which 75% patients have good visual correction ranging from log mar 0-0.3.

- **TABLE 3:** This table gives you the Relation of myopia with visual acuity correction. The total patients which comes out to be myopic are 26 that is 37.1% and amongst them 76.8% Patients who had myopic correction had spectacles of more than -2 power

  - Precisely, 38.4% patients’ spectacles range from 2-5sph and amongst them 70% patients their visual acuity correction is up to logmar0-logmar 0.3 which Is almost full correction and rest 38.4% patients have spectacles no. more than 5sph for which spectacles correction for 50% patients is > logmar1.

  - Rest 23% patient having spectacles correction <-2 visual correction ranges from log Mar o-logmar0.3

- **Conclusion—low myopic number have good spectacles correction but very high myopic number do not have full correction even if higher refraction is given.

  - **MOST OF AMBLYOPIC MALE (42.3%) AND FEMALE (53. %) ARE MYOPIC.**

**TABLE 4: RELATION OF AMBLYOPICS WITH THE TYPE OF SCHOOL STUDIED FROM:**

This table shows that out of 70 students, 56 students have studied from Marathi medium government school and 10 from semi-government and only 4 from private school.

**TABLE 5:**

This table shows the relation between the type of school to its regular school health check-up, and the socio-economic status regarding glasses advised and
still not using.

The results show that out of 56 Marathi medium students only 23 had school health check-up, and amongst them only 20 were advised glasses previously and only 10 students were using it.

Semi-govt schools are better in position as out of 10, 9 had school check-up and 5 were advised previously to wear glasses but only 4 are wearing.

Private schools are conducting school check-ups regularly as all 4 had previously school health check-up done and all 4 are wearing spectacles though not regularly.

Discussion

- This study is conducted on all the young adults up to the age of 30 years coming to Department of ophthalmology, KIMSDU Hospital, Karad by taking visual acuity and correction with refraction for amblyopia over a period of 1 year from August 2018 to July 2019. This study was approved from institutional ethics committee. This study is done with the primary aim to see clinical profile of amblyopic patients in relation to refractive status, socio economic status, use of glasses and social impact on society.

- In this study the sample size of 70 cases when given the vision correction with refraction the result comes out to be 43 patients that is 50.2% of patients had spherical correction and amongst them 26 patients that is 37.1% are myopic correction and 17 patients that is 24.2% are hypermetropia correction.

- And this study also shows about the cylindrical correction which is minimum only in 8 patients that us 11.4% and remaining 19 patients that is 27.14% patients have mixed correction.

- Rest of 23.07% patients have correction till +2 in which 75% patients have good visual correction ranging from log mar 0-0.3.

- In our study we also get the relation of myopia with visual acuity correction.

- The total patients which comes out to be myopic are 26 that is 37.1% and amongst them 76.8% Patients who had myopic correction had spectacles of more than -2 power.

- Precisely, 38.4% patients’ spectacles range from 2-5 sph and amongst them 70% patients their visual acuity correction is up to logmar 0-logmar 0.3 which Is almost full correction and rest 38.4% patients have spectacles no. more than 5 sph for which spectacles correction for 50% patients is > logmar 1.

- Rest 23% patient having spectacles correction <-2 visual correction ranges from log Mar 0-logmar 0.3.

- In our study we also correlate with the type of school which is in direct proportion to its socio economic status like Marathi medium and semi-govt school students are considered from lower status and private school students are higher socio-economic students.

- This study shows that out of 70 students, 56 students have studied from Marathi medium government school and 10 from semi -government and only 4 from private school.
• In this study shows the relation between the type of school to its regular school health check-up, and the socio-economic status regarding glasses advised and still not using.

• The results show that out of 56 Marathi medium students only 23 had school health check-up, and amongst them only 20 were advised glasses previously and only 10 students were using it.

• Semi-govt schools are better in position as out of 10, 9 had school check-up and 5 were advised previously to wear glasses but only 4 are wearing.

• Private schools are conducting school check-ups regularly as all 4 had previously school health check-up done and all 4 are wearing spectacles though not regularly.

**Conclusion**

• This study gives us following points to note down:
  1) Spherical number is more common than mixed or astigmatism
  2) Myopia is more common than hypermetropia (37.73%)
  3) Amongst demographic distribution male and female both have more percentage of myopic number.
  4) 58.8% of hypermetropies have spectacles number between 2-5sph with visual acuity improving up to logmar0.4-1
  5) Low myopic number have good spectacles correction but very high myopic number do not have full correction even if higher refraction is given.

• Most of the amblyopia detected patients (70%) are from marathi medium school and from middle class families where routine school health check ups are not conducted properly so not diagnosed on time, only 30% of students who studies in english medium private schools have proper school health check up so were detected for amblyopia.

• Out of those only 10% students were wearing spectacles so had full correction, but students belonging to middle class or low socio-economic status who had lesser awareness about the disease had not wore glasses due to which they donot had full correction.

• Our study focuses on the fact:

  Early detection of amblyopia by proper school health check-up and then treatment of amblyopia and also to avoid those factors causing amblyopia since childhood like proper use of glasses.

Why treats amblyopia? Direct benefits include potentially improved stereoptic appreciation and the occasional realignment of strabismic eyes with attainment of improved visual acuity. For most patients, the creation of a better-sighted “spare tire” should trauma or disease claim the sound eye is all that can be promised logically. Of interest is a study that showed a threefold greater risk of loss of the sound eye if the other is amblyopic.

• Ethical approval: All procedures performed on human participants were in agreement with ethical standards of the Institutional and/or National Ethics Committee.

• Source of Funding: Self

• Conflict of Interest: None.

Psychometric Properties of Hindi Version of Physical Activity
Recall Assessment for People with Spinal Cord Injury

Heeral Joshi1, Shambhovi Mitra2, Rajeev Aggrawal3

1Assistant Professor, MRIIRS, Faridabad (Haryana), India, 2Assistant Professor, ISIC.IRS, New Delhi, India, 3Consultant Physiotherapist, AIIMS, New Delhi, India

Abstract

Objectives: The most widely used type of physical activity measure is the self-report survey. Of the available self-report physical activity measures, the vast majorities were developed for use in the general population and typically focus on measuring participation in recreational and sport activities. As a result, the existing self-report measures are insufficiently sensitive to measure very low intensity activities that might account for the bulk of daily energy expenditure among people with SCI. The content of these measures also fails to capture activities that are part of SCI lifestyle. ‘Physical Activity Recall Assessment for People with Spinal Cord Injury’ [PARA-SCI] was published in August 2005. PARA-SCI is a measure of physical activity for individuals with SCI who use a wheelchair as their primary mode of mobility. It has been translated in various languages, thus the aim of the study is to study the psychometric properties of Hindi version of physical activity recall assessment-SCI.

Methods: PARA SCI was translated in phase 1 of the study and the reliability and validity of the instrument was done.

Results: There was significant correlation observed in test – retest reliability and Vo2 max calculated by 12 minute wheelchair test correlated with the subcomponent of PARA SCI.

Conclusion: The Hindi version of PARA-SCI is a reliable and valid instrument.

Keywords: Spinal Cord Injury, Physical Activity Recall Assessment - Spinal Cord Injury, Activity Daily Living, Leisure time physical activity.

Introduction

The spinal cord is the major conduit through which motor and sensory information travels between the brain and body. Spinal cord injury (SCI) affects conduction of sensory and motor signals across the site(s) of lesion(s), as well as the autonomic nervous system. 1

The incidence as well as the prevalence of SCI has been on the rise with the incidence rate being estimated to be from 15-40 cases per million world-wide. The number of people sustaining SCI has increased over the past 3 decades. 1

Persons with SCI face unique health challenges throughout their life and their injury dissociate the normally well integrated homeostatic responses of body system known to accompany physical activity. Depending upon level and type of cord lesion, persons with SCI are the most physically deconditioned of all humans. The physical activity limitation comes with secondary impairments like loss of cardio-respiratory and muscular function, metabolic and systemic dysfunctions.

Assessment of cardio respiratory fitness in persons with SCI requires specialized knowledge of both Exercise-Testing (ET) procedures and unique physiology that ensures SCI. ET modalities for these individuals commonly employed over the ground wheelchair propulsion on a treadmill or wheelchair rollers, cyclical arm ergometry and variations of electrically stimulated exercise. The mode commonly used in ET of person with SCI is the arm crank ergometer. It follows the same general protocols for as normals, but here as the VO2 peak is dependent on level of SCI, lower intensity loads are applied than those used in standard exercise testing. 3)
Exercise training has been shown to reduce pain and depression too among people with SCI. There is evidence that among persons with SCI, physical activity is associated with positive changes in disease risk factors such as triglyceride levels, body fat and insulin resistance. However, the specific activity types, durations, and intensities that produce these health outcomes have not yet been established within the SCI population. The lack of such information makes it virtually impossible to develop physical activity guidelines for the SCI population, and study in this area has been impeded by the lack of a valid and reliable self-report measure of physical activity for people with SCI.

The most widely used type of physical activity measure is the self-report survey. However, independent ambulation is uncommon among people with SCI and most of their energy expenditure is accounted for by activities of daily living and passive leisure activities. As a result, the existing self-report measures are insufficiently sensitive to measure very low intensity activities that might account for the bulk of daily energy expenditure among people with SCI. The content of these measures also fails to capture activities that are part of this population’s lifestyle.

An SCI-specific physical activity measure would help researchers to fill a number of voids in the SCI and physical activity literature. In particular, a measure that assesses the performance of specific activities and their associated intensities would facilitate collection of epidemiological data necessary to develop health-promoting, physical activity prescription guidelines for people with SCI. An SCI-specific measure would also allow researchers to develop and test activity-enhancing interventions for the SCI population.

‘Physical Activity Recall Assessment for People with Spinal Cord Injury’ [PARA-SCI] was published in August 2005. PARA-SCI is a measure of physical activity for individuals with SCI who use a wheelchair as their primary mode of mobility. PARA-SCI is widely used, it is already present in 13 other language Chinese, Czech, Dutch, English, French, German, Greek, Italian, Portuguese, Punjabi, Swedish, Spanish, Russian. It is self report physical activity measure for people with SCI. The assessment is completed using a semi-structured interview protocol. It aims to measure frequency, type, intensity, duration of physical activity performed by persons of SCI who use wheelchair as their primary mode of mobility. It utilizes 3 day recall and can be used in paraplegia and tetraplegia, and is designed to capture three categories of physical activity: first Leisure time physical activity (LTPA) that one chooses to do during free time, such as playing sports or working out at the gym. Activities of Daily Living (ADL) that are part of one’s daily routine, such as personal hygiene, household chores, work-related activity, passive leisure activity. And Cumulative activity: The combination of LTPA and lifestyle activity.

The English version of PARA-SCI is a valid and reliable measure. This type of self report instruments are able to access the fundamental dimensions of physical activity (i.e., frequency, intensity, type, duration) and can be easily administrated to large segments of population relatively easily and inexpensively. Given these advantages, it has played a crucial role in generating epidemiological data used to formulate physical activity prescriptions and guidelines for general populations. But till date there is no Hindi scale available for the same. So this study deals with the psychometric properties of Hindi version of physical activity recall assessment-SCI.

WORK PLAN

Study Centre – Indian Spinal Injury Centre, Institute of Rehabilitation Sciences, New Delhi. India

Study design – Methodological study

Sample size – 100

PROCEDURE OF STUDY-

First of all permission for Hindi translation from the author of “PHYSICAL ACTIVITY RECALL ASSESSMENT –SCI”, Kathleen Martin Ginis was taken through an e-mail.

Procedure consist of following two phases

1) Translation of instrument to Hindi language.

2) Psychometric Evaluation of Hindi version of PARA-SCI instrument.

PHASE 1 – Translation Phase

Forward translation

As per the procedure, two translators were recruited for forward translation; having there native
Hindi language speakers bilingual in English. They were provided with the original English version of questionnaire and was asked to independently translate it in Hindi language avoiding any technical language. Hence first phase of translation gave us two Hindi version of PARA-SCI questionnaire English version. This two versions were combined to form a single Hindi translated PARA-SCI questionnaire.

**Backward translation**

It involves English translation of Hindi translation obtained from forward translation this step again required two translators who had translated the Hindi version, without having any access to original English version of questionnaire. As per the procedure, the back translation was checked against original English version of PARA-SCI questionnaire and their accuracy was determined.

The scale was reviewed by the expert review committee. The comments and suggestion of the review committee was then sent back to the translators for corrections into the next intermediate Hindi version of the scale.

After repeating this process several times the final translate Copy had then used for pilot study.

**PHASE 2- Psychometric evaluation-** Test retest reliability and validity of scale was established.

**Test retest reliability**

The PARA-SCI scores are calculated by assessing the LTPA, ADL and Cumulative activity where, Leisure time physical activity (LTPA) that one chooses to do during free time, such as playing sports or working out at the gym. Activities of Daily Living (ADL) that are part of one’s daily routine, such as personal hygiene, household chores, work-related activity, passive leisure activity. And Cumulative activity: The combination of LTPA and lifestyle activity.

Test retest reliability was done by administrating the questionnaire to SCI patients with in a gap of seven days as the questionnaire is a three days recall questionnaire.

**Construct validity –**

The convergent validity of a physical activity scale is typically indicated by demonstrating expected relationships between the scale scores and measures of physical fitness.

**Inclusion criteria-**

- Subjects with traumatic spinal cord injury of duration more than 3 months.
- Age -18-60 years.
- Subject should understand Hindi.
- Subject should be a case of traumatic spinal cord injury below T1-L5 level.
- Subject should be able to propel manual wheelchair.

**Exclusion criteria-**

- Subjects diagnosed with any systemic/psychiatric illness, any infectious disease.
- Subjects having any neurological impairment which might hamper his/her participation in the study.
- Subjects diagnosed with any kind of visual or vestibular deficits.
- Subjects with memory deficit.
- Professional wheelchair sportsperson.

**Physical Fitness-**

**Muscle strength** - Muscle strength was assessed to determine the maximal load that could be lifted in one repetition (1RM) for chest press (unilaterally) and biceps curl (unilaterally). Tests was terminated at the participant’s point of fatigue.

Attainment of 1RM confirmed by participants indication that their last lift was “heavy intensity” activity, as defined by the PARA-SCI activity intensity classification system.

**Aerobic fitness** – The 12 min wheelchair performance test for cardio respiratory endurance.

Equipment required- 400 m running track, marking cones, recording sheets and stop watch.

Procedure – place markers at set intervals (i.e.) at every 50 m to aid measuring the completed distance. Participant wheel around track for 12 min, and the distance covered was recorded.
Scoring – Recorded the completed distance to the nearest 100 meters.

Calculate VO2 max from following formula:

\[ \text{VO2 max} = (29.623 \times \text{Distance}) - 10.916 \text{ mg/kg/min} \]

Data analysis –

Correlation was computed between the scores of PARA-SCI and muscular strength and cardio respiratory endurance. Factor analysis was done for validity.

Result

In first phase, The final synthesized version was reviewed by the committee members and the author and a final Hindi version of physical activity recall assessment for spinal cord injured people was obtained

In phase two, the participants were interviewed twice with a gap of seven days with the instrument and simultaneously the aerobic capacity and muscular strength was also measured to correlate it with PARA-SCI scores. The number of patients recruited was 40. (Table 1.1 Mean, S.D.)

Test retest reliability

Test retest reliability was tested with a gap of seven days with the scores of subscales of day 1 was compared with day 7 with pearsons correlation. Here day 1 ADL was significantly correlating with ADL (r >0.00) and LTPA (r >0.00) and with cumulative (r > 0.028) of day7. LTPA of day 1 was significantly correlating with ADL(r >0.00) and LTPA(r >0.00) only. There was an over lapping in assumption of physical activity division by patients which has affected the results. Where the cumulative activity of day 1 was significantly correlating with cumulative activity(r >0.00) and ADL (r >0.022).

Convergent validity

The convergent validity of a physical activity scale is typically indicated by demonstrating expected relationships between the PARA-SCI scores and measures of physical fitness.

The convergent validity Pearson’s method was used. PARA-SCI scores were correlated with chest press, biceps curl, vo2 max where the chest press was significantly correlated with biceps curl(r >0.00), distance (r >0.041) and vo2 max (r >0.041).here a negative correlation was found of chest press with LTPA (r >0.010) as due to overlapping of the physical activity subscales. (patients were confused for physiotherapy inactive an passive sessions where it should lie in ADL or LTPA.)

Biceps curl was significantly correlated with distance (r>0.006) and vo2 max (r>0.006). Distance was correlated with vo2 max (r >0.00).ADL was correlated with LTPA (r >0.00) and Cumulative (r >0.018).

TABLE 1.1- The Mean and S.D. were calculated. The number of patients recruited was 40.

Discussion

The objective of study was to establish the psychometric properties of Hindi version of physical activity recall assessment-SCI. The physical activity recall assessment (PARA-SCI) has been proposed as an essential measure for assessing SCI patients or a self reporting survey but till date there is no Hindi scale available for the same.

The whole study was done in two phases. Where in phase one, we have obtained the Hindi translated copy, which was reviewed by the expert review committee. The comments and suggestion of the review committee was taken and sent back to the translators for corrections. After repeating this process several times the final translate Copy was used for pilot study.

In phase two, Test retest reliability and validity of scale was established by administrating the questionnaire to SCI patients with in a gap of seven days. The convergent validity of a physical activity scale was typically indicated by demonstrating expected relationships between the scale scores and measures of physical fitness.

Limitations of Study-

- Overlapping was seen in ADL and LTPA activities as physiotherapy comes as a daily routine and active and passive physiotherapy both are part of routine.

- For assessing aerobic capacity instead of 12 min wheelchair test instrument gas analyzer could have been used.

- Cannot assess the physical activity of high cervical quadriplegics with AIS- A.

- Because of field method used to assess the aerobic capacity, minimum of 300 meters the patient should be able propel wheelchair as below that score the VO2 max value was going in negative.

Future Recommendations

- Other Psychometric properties in subscales of quadriplegics and paraplegics can be done and factor analysis using the age groups can be done.

- Study can be carried out on a large population.

Abstract

DNA isolation is a process used for isolation of DNA from different types of samples using a combination of physical and chemical methods. A comparative study is made to isolate DNA from 30 teeth samples with some pre PCR and post PCR modifications in the organic Phenol: Chloroform: isoamyl alcohol, Automate Express™ prepfiler BTA kit and QIAamp® DNA Investigator Kit. Our result showed significant results which will be helpful in short listing the array of these techniques.

Key Words: DNA, RT-PCR, PCR, STR Analysis, Forensic Science

Introduction

DNA fingerprinting analysis is used to solve the cases of murder, rape, paternity, child swapping, immigration, genealogical and medical research. DNA fingerprinting has proved to be very useful in the identification of victims of war, air crash, flood, earthquakes, Tsunami and mass disasters cases. Friedrich Miescher was the first person to formulate the process of DNA isolation in 1869. Various automated DNA isolation instruments have been designed by various companies to carry out the DNA isolation process in a very short time without the risk of contamination of the DNA isolates. The phenol–chloroform method is conventional and the most effective method used in the various laboratories to isolate the DNA from the samples. Automate Express™ with BTA prepfiler kit (applied biosystem) is an automated DNA isolation process using magnetic beads during isolation.

The QIAamp DNA Investigator Kit can be manually operated for the isolation of DNA from a variety of biological samples. Isolation steps involve: (a) disruption of cellular membranes (b) binding of DNA to the silica-based membrane (c) washing of contaminants and (d) DNA elution. The QIAamp DNA Investigator Kit is simple and easy to use yielding of good quality of DNA.

UV light was the first sterilization technique used to eliminate amplification products carryover contamination. The principle behind Ultra-violet light irradiation is the property of UV light to induce thymidine dimers and other covalent modifications of DNA that render the contaminating nucleic acid inactive as a template for further amplification. The technique is simple, inexpensive, and does not require modification of existing protocols.

Materials and Method

Thirty three (30) teeth samples from different cases...
were used for identification related to legal assessment.

Cleaning and grinding of teeth samples

Each teeth surface was cleaned. Soft tissue, dirt from teeth surfaces were removed. Teeth fragments were immersed in distilled water for 30 sec, followed by 100% ethanol for 30 sec. and dried at 50°C for 2 hours. Teeth fragments were pulverized under sterile conditions. The resulting teeth powder was then divided into three tubes. 50 mg were placed in each tube for the standard organic isolation method, for Automate Express™ and QIAamp® DNA Investigator Kit method. Weighing of powdered teeth samples was performed in a pre-PCR weighing room under sterile conditions using a Citizen balance.

PROCEDURE

1. Phenol-Chloroform-Isoimyl Alcohol : PCI is a manual method for DNA extraction. For each sample, a total of 50 mg of teeth powder was taken into 1.5 mL tube. The samples were decalcified three times with EDTA 0.5 M pH 8.0 (HIMEDIA) for 24 hours. The samples were centrifuged at 10000 rpm for 5 min. The supernatant was discarded, and the remaining teeth powders were resuspended in 1000 µl of milique water, mixed for 10 sec, and spun down at 1000 rpm for 5 min. The supernatant was discarded, and the milique water wash was repeated two more times. Then, 500 µl of Forensic Buffer (HIMEDIA), 100 µl SDS (HIMEDIA) and 15 µl proteinase K (20 mg/ml) (HIMEDIA) were added and incubated at 37°C for overnight. After centrifugation, the supernatant was transferred to a 1.5 mL tube containing 500 µl of phenol. The samples were mixed and the aqueous phase was separated by centrifugation at 10000 rpm for 10 min. The supernatant was transferred to a 1.5 mL tube containing 250 µl of phenol+250 Chloroform–isoamyl alcohol (24:1) (HIMEDIA).

The samples were mixed and the aqueous phase was separated by centrifugation at 10000 rpm for 10 min and transferred to a new tube. This extraction step was followed by another extraction, this time with 500 µl of chloroform–isoamyl alcohol (24:1). The aqueous phase was mixed with 500 µl isopropanol and 50 µl 3M sodium acetate (HIMEDIA) and samples were kept to rest for 30 minutes at -20°C. Samples containing DNA were put for centrifugation at 10000 rpm for 10 min. then washed with 70% ethanol (HIMEDIA) for centrifugation at 10000 rpm for 10 minutes for two times. Final washing was done with 100% ethanol (HIMEDIA) and put to dry at room temp. for an hour then eluted with 1X TE (HIMEDIA) in thermo mixture at 65°C for 45 minutes.

2. Automate Express™ (PrepFiler BTA Kit): The Automate Express™ (Applied BioSystem) Nucleic Acid Extraction System is an easy-to-use benchtop instrument that enables hands-free automation of the nucleic acid extraction process. For each sample, a total of 50 mg of the teeth powder was suspended into 1.5 mL tube with 300 µl PrepFiler BTA Buffer (Applied BioSystem) provided with kit and incubated for overnight at 37°C. Next day the incubated sample was centrifuged through Lysate tubes provided with kit and put the clear lysate sample in AutoMate Express™ in instrument as per the manual provided with the instrument. After 20 min. DNA isolate was obtained 10.

3. QIAamp® DNA Investigator Kit : For each sample placed 50 mg of powdered teeth into a 1.5 ml microcentrifuge tube. To each sample added 360 µl Buffer ATL and 20 µl proteinase K (20mg/ml) (QIAGEN) and incubated overnight at 37°C. Added 300 µl Buffer AL (QIAGEN) and mixed by pulse-vortexing for 10 sec. and incubated at 70°C with shaking at 900 rpm for 10 min. Centrifuged the tubes at speed 14,000 rpm for 1 min. and transferred the supernatant to a new 1.5 ml microcentrifuge tube. Added 150 µl ethanol (100%) (HIMEDIA) and mixed by for 15 sec. Transferred the entire lysate to the QIAamp MinElute column and centrifuged at 8000 rpm for 1 min. and discarded the collection tube containing the flow-through. Added 600 µl Buffer AW1 (QIAGEN) to the QIAamp MinElute column and centrifuged at 8000 rpm for 1 min. and discarded the collection tube containing the flow-through. Added 700 µl Buffer AW2 to the QIAamp MinElute column and centrifuged at 8000 rpm for 1 min. and discarded the collection tube containing the flow-through. Added 700 µl of ethanol (100%) to the QIAamp MinElute column and centrifuged at 8000 rpm for 1 min. and discarded the collection tube containing the flow-through. Centrifuged QIAamp MinElute column at speed 14,000 rpm for 3 min. to dry the membrane completely discarded the collection tube containing the flow-through. Dried the QIAamp MinElute column at 56°C for 3 min. Applied 50 µl Buffer ATE (QIAGEN) to the center of the membrane. Incubated at room temperature (25°C) for 1 min. and centrifuged at speed 14,000 rpm for 1 min. Now the microcentrifuge tube contains 20–30 µl Buffer ATE (QIAGEN) with DNA 11.
DNA Quantification

DNA samples were quantified by realtime PCR (Applied BioSystem). The internal PCR control (IPC) included in each sample was used to detect PCR inhibitors in the DNA isolates. PCR inhibitors retard the onset of exponential amplification in the PCR, which can be detected as an increase in the cycle threshold (Ct) value for IPC. Negative controls and reagent blanks were included in every step of the study\textsuperscript{12}.

Amplification and Analysis

DNA samples obtained from all the three methods were used for STR analysis using the AmpFlSTR Identifier Plus PCR amplification kit (Applied BioSystem). The DNA was diluted/concentrated to obtain 1 ng of DNA per µl of the DNA sample isolated with all these methods. PCR amplification consisted of a first cycle at 95°C for 11 min, 28 cycles at 94°C for 20 seconds, 59°C for 3 min and 1 cycle at 60°C for 10 min. STR fragments were analyzed on an Applied Biosystems 3500,3500 XL Genetic Analyzer (Applied BioSystem) using POP4 polymer (Applied BioSystem), Gene Scan\textsuperscript{TM} 500 LIZ Size Standard (Applied BioSystem), HiDi\textsuperscript{TM} Formamide (Applied BioSystem). Positive controls (provided by the manufacturer), negative controls, and reagent blank controls were analyzed in each run. The final data were analyzed by using GeneMapper ID-X v1.4 software (Applied BioSystem) to assign allele calls based on allelic ladders provided by the manufacturer with allele peak heights of at least 100 RFU.

Pre PCR modifications

Out of the 30 teeth samples subjected for DNA isolation through Organic PCI method, 18 samples gave complete DNA profiles. The 30 teeth samples were re-subjected to DNA isolation through organic PCI method. This time the incubation period was just for 4 hours at 56°C. After pre PCR modifications 3 more DNA isolates give a complete DNA profiles. Thus pre PCR modification gave 10% more increased DNA isolates.

Out of the 30 teeth samples subjected for DNA isolation through QIAamp® DNA Investigator Kit (QIAGEN) method, 12 samples gave complete DNA profiles. The 30 teeth samples were re-subjected to DNA isolation through QIAamp® DNA Investigator Kit (QIAGEN) method. This time the incubation period was just for 4 hours at 56°C. After pre PCR modifications 4 more DNA isolates give a complete DNA profile. Thus pre PCR modifications gave 13% more increased DNA isolates.

Out of the 30 teeth samples subjected for DNA isolation through QIAamp® DNA Investigator Kit (QIAGEN) method, 12 samples gave complete DNA profiles. The 30 teeth samples were re-subjected to DNA isolation through QIAamp® DNA Investigator Kit (QIAGEN) method. This time the incubation period was just for 4 hours at 56°C. After pre PCR modifications 4 more DNA isolates give a complete DNA profile. Thus pre PCR modifications gave 13% more increased DNA isolates.

Post PCR modifications

All the amplification PCR tubes, pipettes, pipette tips etc. were exposed to UV light (combination of 300-400 nm) for 10 min. followed by the addition of target DNA.

Out of 30 amplicons amplified with the DNA isolated through PCI method that were subjected to capillary electrophoresis, 19 amplicons gave complete DNA profiles while there were some allele drops in the DNA profiles of 2 amplicons. When these 30 amplicons were transferred to new UV sterilized PCR tubes and further subjected to Ultraviolet exposure in combination of 300-400nm for about 2 minutes. These 2 amplicons gave complete DNA profiles thus increasing the DNA profile up to 7%.

Out of 30 amplicons amplified with the DNA isolated through AutoMate Express™ (Applied BioSystem) method that were subjected to capillary electrophoresis, 19 amplicons gave complete DNA profiles while there were some allele drops in the DNA profiles of 1 amplicon. When these 30 amplicons were transferred to new UV sterilized PCR tubes and further subjected to Ultraviolet exposure in combination of 300-400nm for about 2 minutes. This 1 amplicon gave compete DNA profile thus increasing the DNA profile up to 4%.

Out of 30 amplicons amplified with the DNA isolated through AutoMate Express™ (Applied BioSystem) method that were subjected to capillary electrophoresis, 19 amplicons gave complete DNA profiles while there were some allele drops in the DNA profiles of 1 amplicon. When these 30 amplicons were transferred to new UV sterilized PCR tubes and further subjected to Ultraviolet exposure in combination of 300-400nm for about 2 minutes. These 2 amplicons gave compete DNA profile thus increasing the DNA profile up to 4%.
Results and Discussions

The quality and efficiency of a standard organic PCI DNA isolation method, Automate Express™ and QIAamp® DNA Investigator Kit were compared to obtain human DNA and short tandem repeats (STRs) profiles from 30 teeth samples. DNA samples were quantified by real-time PCR, and STR profiles were obtained using the AmpFISTR Identifier plus PCR amplification kit. After pre-PCR modification the Organic method recovered most DNA ranging from 0.19 to 2.95 ng/µl (average 1.43 ng/µl) followed by Automate Express™ BTA prepfiler kit ranging from 0.16 to 2.12 ng/µl (average 1.08 ng/µl) and QIAamp® DNA Investigator Kit ™ method recovered least DNA ranging from 0.11 to 1.98 ng/µl (average 0.84 ng/µl).

Out of 30 teeth samples tested, complete genetic profiles (15 STR loci plus amelogenin) were obtained from 21/30 (70%) DNA samples isolated using the organic extraction protocol, only 20/30 (67%) isolated with the AutoMate Express™ (Applied BioSystem) gave complete profiles while 16/30 (53%) profiles were obtained using QIAamp® DNA Investigator Kit.

After pre-PCR modification there has been an increase in the DNA STR profile by 10% from 60% to 70% by using the PCI method, an increase by 7% from 60% to 67% by using the Automate prepfiler BTA kit and an increase by 13% from 40% to 53% by using the QIAamp® DNA Investigator Kit [Figure1]. After post-PCR modification there has been an increase in the DNA STR profile by 7% from 63% to 70% by using the PCI method, an increase by 4% from 63% to 67% by using the Automate prepfiler BTA kit and an increase by 6% from 47% to 53% by using the QIAamp® DNA Investigator Kit [Figure2].

Rucinski et al. in their study “comparison of two methods for isolating DNA from human skeletal remains for STR analysis” described that EDTA decalcification steps used in organic extraction method significantly improved the amount of DNA recovered from bone. In our study by making simple pre-PCR and post-PCR modification, there is still the possibility of obtaining for better quality DNA for generating STR profiles from human teeth. Our aim was to optimize and standardize a DNA isolation method to improve the quality and quantity of the DNA isolates from degraded and decomposed human teeth which have very little chances to provide DNA Typing evidence in Forensic Sciences.

The amount of DNA recovered was greater from the organic extraction method than from Automate Express™ and QIAamp® DNA Investigator Kit Manual method. We cannot rule out pipetting errors. Different conditions of environmental temperature, fungal, bacterial growth, humidity and the presence of inhibitors might be factors that affect the quality and quantity of DNA obtained.

The principle behind the increase in the useful DNA STR profiles through pre-PCR modification may be inhibitors are co-purified and are still present in the DNA isolates. Re-isolation of the teeth samples with some modification increases the chance of removal of these inhibitors from the previous DNA isolates increasing the chances of better STR profiles. The principle behind the increase in the useful DNA STR profiles through post-PCR modification may be the property of UV light to induce thymidine dimers and other covalent modifications of DNA that render the contaminating nucleic acid inactive as a template for further amplification.
Figure 1: Result obtained after pre PCR modifications in 30 teeth samples

Figure 2: Result obtained after post PCR modifications in 30 teeth samples
Conclusion

After thorough and extensive work on the above three DNA isolation methods, our results indicate that the organic DNA isolation method is the most suitable and reliable method of DNA isolation for obtaining DNA quantity and DNA quality followed by Automate Express™ and then QIAamp® DNA Investigator Kit™ method. The present study has proved that simply by making some pre-PCR and post-PCR modifications these three techniques still hold the potential for providing better results.

Abstract

Objective: To find out the risk factors for preeclampsia.

Materials and Methods: a case-control study was between March 2018 and December 2018. Pregnant women who with gestational age of at least 22 weeks live in residential areas, exposed to smoke from combustion of tile or brick were divided into two groups. Cases were those diagnosed with preeclampsia. Controls were normotensive pregnant women who had a history of preeclampsia in previous pregnancy. CO (carbon monoxide) exposure in pregnant women was determined by examining COHb levels in the blood. Serum Nitric Oxide levels were measured using the ELISA (Enzyme-Linked Immunosorbent Assay) method. Data were analyzed by Chi-square test or Fisher’s exact test, Independent T-Test and regression analysis. Adjusted odds ratio (ORs) with 95% confidence interval (CI) was calculated.

Results: The results of Blood COHb levels were significantly higher in preeclampsia (4.58±1.2) than the case of control group (2.85±0.4). Serum nitric oxide levels in preeclampsia were significantly lower in preeclampsia (18.28±4.1) than the case of control group (35.15±7.2). Maternal age ≥ 35 years, nulliparity, high blood COHb levels > 3.5%, and low serum Nitric Oxide levels < 25 μmol/L were significantly associated with increased risk of preeclampsia.

Conclusion: Low serum Nitric Oxide levels (< 25 μmol/L) due to exposure to CO from the smoke of combustion of tiles or brick carried an increased risk of developing preeclampsia (ORs 25.5;95% CI 4.3-29.7). These results can help health workers in pregnancy care counseling and prevention of preeclampsia in pregnant women located in areas exposed to carbon monoxide from the smoke of combustion of tiles or brick.

Keywords: Nitric oxide, Carbon monoxide exposure, Tiles-brick smoke burning, Preeclampsia.

Introduction

Preeclampsia (PE) is the main cause of pregnancy and the development of 3-7% of pregnant women. Hypertension in pregnancy affects about 8% of pregnancies worldwide and significantly contributes to maternal and fetal morbidity and mortality.1,2 The high number of maternal deaths in Indonesia, as compared to neighboring countries in other ASEAN regions dominated by hypertension in pregnancy or PE. Likewise, the cause of death in Jepara District was 85.7% due to preeclampsia, both of which occurred during pregnancy and postpartum.3-5

PE is a pregnancy-specific disorder that is defined as the new onset of maternal hypertension and proteinuria after 20 weeks of pregnancy.6 Although until now there
is no known exact cause of preeclampsia.\(^{(2,7)}\)

PE is characterized by the migration of disturbed extravillous trophoblasts to the uterine spiral arteries which causes increased uteroplacental vascular resistance and vascular dysfunction, which results in reduced systemic vasodilation. Its pathogenesis is mediated by the bioavailability of biological Nitric Oxide (NO) and tissue damage caused by increased levels of Reactive Oxygen Species (ROS). Coagulopathy caused by ROS causes placental infarction and disrupts uteroplacental blood flow in PE. However, placental ischemia in PE reduces antioxidant activity, which results in increased oxidative pressure that causes the emergence of PE pathological conditions including hypertension and proteinuria.\(^{(6,8,9)}\)

In developing countries, pollution exposure also comes from burning biomass fuels (wood, cow oil and plant waste). Combustion by products include carbon dioxide, carbon monoxide, nitrogen oxides, sulfur dioxide, and small solids and liter.\(^{(10)}\) Carbon Monoxide (CO) is the pollutant that is most widely emitted from biomass combustion fumes that affect health.\(^{(11,12)}\) Examination of COHb blood taken through venous blood vessels is the only biological monitoring method to determine the level of CO exposure in the body.\(^{(13)}\) CO poisoning can increase Nitric Oxide (NO) activity and form free radical formation which stimulates leukocyte adhesion and activates the brain microvascular and then forms xanthine oxidase formation resulting in oxidative stress from radical superoxide (O\(^{2-}\)). Oxidative stress in pregnant women can cause placental ischemia and interfere with uteroplacental blood flow, finally produces lipid peroxidation in PE.\(^{(14)}\)

Materials and Method

A case-control study was carried out at Nalumsari Health Center, Mayong 2 Health Center, and Kalinyamatan Health Center, Jepara District between March 2018 and December 2018. Data from this study were collected from medical records of pregnant women at Nalumsari Health Center, Mayong 2 Health Center, and Kalinyamatan Health Center, Jepara District. Pregnant women with gestational age of at least 22 weeks, who live in residential areas exposed to smoke from combustion of tile or brick (Nalumsari Health Center, Mayong 2 Health Center, and Kalinyamatan Health Center, Jepara District) dan were inclusion criteria. Subjects were divided into two groups. Cases were those diagnosed with preeclampsia. Controls were normotensive pregnant women who had a history of preeclampsia in previous pregnancy. Pregnancies complicated with chromosomal or structural anomalies, incomplete clinical data and not willing to be a respondent were excluded.

The medical records of pregnant women were reviewed. CO exposure in pregnant women was determined by examining COHb levels in the blood. In accordance with ACGIH (2008), Biological Exposure Indices or permissible COHb levels in the blood were 3.5%.\(^{(15)}\) Nitric Oxide levels examined in this study were Nitric Oxide levels in the respondent’s serum. Normal serum Nitric Oxide levels were 25-45 μmol/L.\(^{(16)}\) Blood collection was carried out with the help of a Clinical Pathology Laboratory officer at the General Hospital of Kumalasiwi Kudus and then centrifuged on blood samples so that the Nitric Oxide serum was obtained for further analysis using the ELISA method while analyzed Blood COHb levels using spektotofometri.

Preeclampsia was defined as new-onset hypertension (systolic blood pressure of at least 140 mmHg; diastolic blood pressure of at least 90 mmHg), accompanied by proteinuria of at least 300 mg per 24 hours, or at least 1+ on dipstick testing after 20 weeks.\(^{(6,17)}\) Gestational age [GA] was calculated from the last menstrual period and confirmed by first or second-trimester ultrasonography.

All data were analyzed with SPSS. Continuous variables were compared using Independent T-Test and presented as mean. The normality of data distribution is recorded by the Kolmogorov-Smirnov test. Categorical variables were analyzed with Chi-square test or Fisher’s exact test as appropriated and presented as the percentage. Multivariate regression analysis was used to evaluate the association between preeclampsia and the various risk factors. The risk factors that produced a point estimate at a p-value of < 0.1 on the univariate analysis were entered into a multivariate regression analysis. Adjusted odds ratio (ORs) with 95% confidence interval (CI) was calculated. A p-value < 0.05 was considered statistically significant.

Results

The maternal and pregnancy demographics are shown in Table 1. The mean maternal age, and nulliparity proportion significantly higher in the preeclampsia group than in controls. However, gestational age at first
antenatal visit, family history of hypertension were not significantly different between the two groups.

Table 2 shows the comparison of Blood COHb and serum Nitric Oxide levels in preeclampsia than control groups. The results of Blood COHb and Serum Nitric Oxide levels between both groups were significant (p-value < 0.05). Blood COHb levels were significantly higher in preeclampsia. Blood COHb levels > 3.5% was found in 21 cases (66%) of preeclampsia. Serum nitric oxide levels were significantly higher in control groups. Serum nitric oxide levels in preeclampsia were low (18.28 μmol/L). There was no maternal death in the present study.

Discussion

The results of blood COHb levels were significantly higher in preeclampsia than the case of control groups. Blood COHb levels > 3.5% was found in 24 cases (75%) of preeclampsia. This is due to exposure to carbon monoxide from the smoke of combustion of tiles or brick (CO poisoning). Carbon Monoxide (CO) is the most pollutant emitted from biomass combustion fumes such as engine combustion, gas, oil, wood or coal-fired equipment, and solid waste disposal that affects health. (11,18) Meanwhile, CO poisoning can increase Nitric Oxide (NO) activity and form free radical formation, which stimulates leukocyte adhesion and activates the brain microvascular and then forms xanthine oxidase formation resulting in oxidative stress from radical superoxide (O2-). Oxidative stress in pregnant women can cause placental ischemia and interfere with uteroplacental blood flow, finally produces lipid peroxidation in PE. (14)

Serum nitric oxide levels were significantly lower in preeclampsia than the case control groups. Nitric oxide production has decreased in preeclampsia mothers associated with endothelial dysfunction so that it is thought to have an effect on vasoconstriction and hypertension in preeclampsia. (18) Its pathogenesis is mediated by the bioavailability of biological Nitric Oxide (NO) and tissue damage caused by increased levels of Reactive Oxygen Species (ROS). Coagulopathy caused by ROS causes placental infarction and disrupts uteroplacental blood flow in PE. However, placental ischemia in PE reduces antioxidant activity which results in increased oxidative pressure, that causes the emergence of PE pathological conditions including hypertension and proteinuria. (6,8,9) superoxide (O2-)

Nulliparity and maternal age ≥ 35 years were associated with a significantly increased risk of preeclampsia. This was consistent with previous studies. (19–21) In both animal and human models, increased blood pressure has been associated with oxidative stress in blood vessels. Excessive endothelial production of reactive oxygen species (ROS) can be a cause and effect of hypertension. In addition to nitric oxide synthase can also be considered as a major source of Specific Reactive Oxygen (ROS), possibly contributing to the development of hypertension. (22) The authors found that blood COHb levels increase to cause a decrease in serum Nitric Oxide levels. Therefore, prevention of preeclampsia can be conducted by pregnant women by avoiding exposure of combustion.

The present study has mentionable limitations. First, this study was not reviewing other smoke exposures besides tile and brick smoke were not examined in this study such as smoke from motor vehicles and cigarette smoke. Second, the 6-month duration of the present study, may not have been long enough to elucidate the long-term effects of this combustion.

Conclusion

The research results show blood COHb levels are significantly higher in preeclampsia than the case of control groups. However, serum Nitric Oxide levels are significantly lower in preeclampsia than control groups. Maternal age ≥ 35 years, nulliparity, high blood COHb levels > 3.5%, and low serum Nitric Oxide levels < 25 μmol/L were significantly associated with increased risk of preeclampsia. This study serves information about the roles of health workers as counselor to the prevention of preeclampsia especially pregnant women, which are located in areas exposed to carbon monoxide from the smoke of combustion of tiles or brick. Furthermore, prevention of PE by especially risk factors for exposure to carbon monoxide from tile and brick burning smoke should be encouraged to reduce the prevalence of PE. This role is very important in developing countries to cost efficiency.

What is already known on this topic?

Serum Nitric Oxide levels are significantly lower in preeclampsia. Low serum Nitric Oxide levels (< 25 μmol/L) due to exposure to carbon monoxide from the smoke of combustion of tiles or brick carried an increased risk of developing preeclampsia.

What does this study add?

This research has confirmed that blood COHb levels increase to cause a decrease in serum Nitric Oxide levels. Therefore, PE especially risk factors for exposure to carbon monoxide from tile and brick burning smoke can be prevented through reducing the intensity of carbon monoxide exposure.

Effect of Unilateral and Bilateral Shoulder Rehabilitation Exercise Protocol in Patients Secondary to Radical Mastectomy

Jasleen Kaur Sohal1, Poonam H. Patil2

1Intern, Krishna College of Physiotherapy, KIMS ‘Deemed to be’ university, Karad, Maharashtra, India, 2Assistant Professor, Department of Cardiopulmonary Sciences, Faculty of Physiotherapy, Krishna Institute Of Medical Sciences ‘Deemed to be’ university Karad, Maharashtra, India

Abstract

**Background:** Mastectomy is an operation which causes many changes in a woman’s body. Its consequence is, among other things, lymphatic edemas, limitation of movements and strength of the upper limb of the patient, experiences in the emotional sphere, difficulties related to the postoperative scar and the results of supplementing treatment such as radiotherapy or chemotherapy. Recent studies have shown the result of effective physiotherapy treatment postoperatively. There is a paucity of literature available showing the effect of bilateral approach rather than a unilateral one for the recovery

**Objective:** Objective of the study was to find out the effect of unilateral and bilateral shoulder rehabilitation exercise protocol in patients secondary to radical mastectomy

**Method:** A total of 20 females who underwent mastectomy procedure along with chemotherapy were included in the study. Demographic data and consent form were taken from the patients. Group A was received treatment for the unilateral i.e. the affected side and group B received treatment bilaterally for five days per week for eight weeks and pre and post assessment was done with shoulder pain and disability index (SPADI), range of motion (ROM) and manual muscle testing (MMT)

**Results:** Statistics results within the group values for Group A SPADI (p=0.6385) and mean difference (MD) was

**Conclusion:** A proper knowledge regarding ergonomics is important to avoid the development of musculoskeletal disorders, taking stretch breaks in between long working hours can provide a healthier working environment for nursing staff and maximize human resource efficiency.

**Keywords:** Shoulder rehabilitation, Mastectomy, Shoulder pain and disability index(SPADI), Range of motion (ROM), Manual muscle testing(MMT).

Introduction

Cancer is an abnormal growth of cells which tend to proliferate in an uncontrolled way and in some cases, to metastasize. When cancer cells metastasize to nearby tissues or to distant areas of the body it is known as malignant tumor. When cancer grows but does not spread it is known as benign tumor. prevalence of breast cancer in India is 25.8 per 100000 due to alterations in dietary habits, reproductive risk factors and increasing life expectancy there is a rapid rise in incidence of breast cancer. Most breast cancers start in the duct cells and only some in cells of lobules and other tissues. Breast cancer can be invasive carcinoma (malignant) or non-invasive carcinoma (benign). Invasive carcinoma is further divided into invasive ductal carcinoma, invasive lobular carcinoma, tubular carcinoma, medullary carcinoma. Non-invasive carcinoma includes ductal

carcinoma and lobular carcinoma.

Surgical mastectomy is the only curative treatment for the females with breast cancer. Among the other mastectomy procedures, radical mastectomy results in the removal of the breast tissue, axillary lymph nodes and the chest wall muscles. Mastectomy is an operation which causes many changes in a woman’s body. Its consequence is, among other things, lymphatic edemas, limitation of movements and strength of the upper limb of the patient, experiences in the emotional sphere, difficulties related to the postoperative scar and the results of supplementing treatment such as radiotherapy or chemotherapy. Significant complications after mastectomy are changes in body posture caused both by disorders in body static as a result of amputation and limitation of movements and soreness of the spine. The problem of changes in body posture, as a result of mastectomy is not well known. It seldom appears in scientific literature. It is, however, an important problem, both from the point of view of medical and psychological rehabilitation. Incorrect body posture may cause other somatic anomalies. For the patients good-looks related to body posture is the basis for better well-being 1,2.

Lower mortality risk and a higher quality of life are associated with higher levels of muscle strength.8 The increasing incidence of surgical mastectomy places breast cancer survivors at risk for development of upper extremity strength imbalances. Pectoralis major, serratus anterior, upper trapezius, rhomboid muscles, latissimus dorsi are involved in management of breast cancer that is these muscles are cut during surgery or exposed to radiation during radiotherapy) which causes difficulty in flexion, abduction, internal rotation, scapular elevation, protraction and retraction.10 Anthracyclines used in chemotherapy cause oxidative stress by two mechanisms: interaction with mitochondrial respiratory chain and through a nonenzymatic reaction with ferric iron. Anthracyclines based chemotherapy negatively affects noncancerous tissue along with striated muscles, which causes muscle fatigue and weakness in patients.11 It is seen that though the complications develop on the ipsilateral side, the contralateral side is also affected to a great extent. But the contralateral side is often neglected due to a greater number of complications on the ipsilateral side.

In healthy women, upper extremity strength should be equal bilaterally. However, compared to healthy women, breast cancer survivors have greater upper extremity loss of strength, leading to functional impairment. Side to side muscle imbalances increase the risk for acute and chronic injury and that bilateral shoulder rehabilitation can resolve these imbalances and decrease risk for injury.

Material and Methodology

Study Design

This study was an Interventional study.

Place of study

The study was conducted in the Oncology department in Krishna Hospital, Karad.

Sample size

The sample size was 20 subjects

Sampling method

The subjects were selected by simple random sampling technique.

Study duration

The duration of the study was 6 months

Treatment duration

The treatment was given for 1 hour per day and 5 days/ week.

Inclusion criteria were as follows: 1. Females between 30 to 50 years 2. Subjects who underwent modified radical mastectomy procedure along with chemotherapy or radiotherapy for breast carcinoma 3. Subjects who are interested to participate in the study

Exclusion criteria were as follows: 1. Bilateral mastectomy 2. Pregnancy 3. Open Wounds 4. Previous history of trauma to shoulder, surgery, untreated pathology or dysfunction.

Material used were: 1. Weights 2. Wand 3. SPADI Questionnaire 4. Shoulder ladder 5. Shoulder wheel

Resistance exercises – Shoulder flexion, extension, abduction, adduction, internal rotation and external rotation. Exercises are started with 2-3 sets of 10-15 reps with half a kg weight. Gradual progression is made to 1kg when the individual is able to perform complete 3 sets of 10-15 reps.
**Outcome Measures**

1) Shoulder pain and disability index (SPADI) – It is a self-administered questionnaire that consists of two dimensions, one for pain and the other for functional activities. The pain dimension consists of five questions regarding severity of an individual’s pain. Functional activities are assessed with eight questions designed to measure the degree of difficulty an individual has with various activities of daily living that require upper extremity use.

2) Manual Muscle Testing (MMT) – It is an integral part of physical examination as it provides information which is useful in differential prognosis and treatment of musculoskeletal and neuromuscular disorders. It is used to evaluate contractile units and their ability to generate forces. Muscle testing is an important evaluative tool to assess impairments and deficits in muscle performance, including strength, power and endurance. It is graded from 0 to 5 which is determined by the patient’s ability to move he tested body depending on muscle contractility, gravity assisted and antigravity position.

3) Range of motion (ROM) – It is a measurement of movement around a specific joint or body part. It is used to evaluate the integrity of the particular joint. Both active as well as passive range of motion should be evaluated. It should be compared with the normal range of motion of the joint.

**Procedure**

This study was conducted to find the Effect of Unilateral and Bilateral shoulder rehabilitation exercise protocol in patients secondary to Radical Mastectomy. Protocol and ethical clearance were done. Ethical consent was taken from the Institutional ethics committee of Krishna Institute of Medical Sciences “Deemed To Be University”, Karad. The subjects were divided into 2 groups based on the inclusion and exclusion criteria using simple random sampling. Informed consent was taken from the subjects. Subjects were assessed for shoulder pain and disability index, range of motion and strength prior intervening with the treatment. Subjects were explained about the procedure of the study.

Group A was conventional group and group B was experimental group.

Group A received treatment to the affected upper extremity. Shoulder flexion, extension, abduction, internal and external rotation was performed with weights, started with 2-3 sets of 10-15 reps. Exercises were started with weight of 0.5kg and progressed to 1kg. Low load long duration stretch was performed using 0.5kg weight. Pectoralis muscle stretch over the wall was done. Shoulder range of motion exercises using shoulder wheel, shoulder ladder and wand was done. The treatment was done 5 times a week for 6 weeks.

Group B received treatment bilaterally. Both the upper extremity was given the same protocol as above.

After six weeks the post treatment assessment for disabilities, range of motion and strength using assessment tools (SPADI, ROM and MMT) were done. The interpretation of the study was done on the basis of comparing pre and post test assessment of SPADI, Shoulder ROM and MMT. The study was concluded by statistical analysis of all the outcome measures.

Discussion

This study on “Effect of Unilateral and Bilateral shoulder rehabilitation exercise protocol in patients secondary to Radical Mastectomy” was conducted to compare the effect of unilateral and bilateral shoulder rehabilitation protocol in post mastectomy status. Strengthening was conducted using weights and find the efficiency on shoulder muscle strength and shoulder pain and disability index, range of motion exercises using wand and shoulder wheel and stretching using low load. Breast cancer survivors are benefited using free exercises to shoulder and progression is made to resistance training as it is effective in reducing muscle fatigue, increasing muscle strength and flexibility.

Conventional group showed improvement in shoulder pain and disability index (p=0.0494) with mean difference (MD=2.42), but did not show a significant result in strength for all the shoulder muscles and increase in the shoulder ranges. ROM for shoulder flexion (p=0.1949), MD=20.3, extension (p=0.8823) MD=5.1 and abduction (p=0.9269) MD=15.9. MMT for shoulder flexion (p=0.7699) MD=0.6, extension (p=0.9179) MD=0.7 and abduction (p=0.3207) MD=1.0. Experimental group showed improvement in SPADI score (p=0.0039) MD=29.2 and also exhibited better improvement in shoulder muscle strength and ranges. ROM for shoulder flexion (p=0.0003) MD=10.7 extension (p=0.0003) MD=2.2 and abduction (p=0.0003) MD=9.5 MMT for shoulder flexion (p<0.0001) MD=1.1, extension (p<0.0001)
MD= 0.9 and abduction (p=0.0013) MD=0.7. The between group values for SPADI (p=0.2365), ROM for shoulder flexion (p=0.0606), extension (p=0.0171) and abduction (p=0.0098), MMT for shoulder flexion (p=0.0378), extension (p=0.0260) and abduction (p=0.0041). The result concluded that bilateral approach for treating the post mastectomy is more effective than a unilateral approach. Treatment of the affected side is commonly followed in the treatment of the breast cancer patients; the bilateral approach would provide an overall improvement in the quality of life of the patient. The patient would have a full functional independence and be able to perform activity of daily living. The recovery of the patient would be occurring at a faster rate, further disuse atrophy of the muscles and better range of motion can be achieved if a bilateral treatment is given.

**Conclusion**

The present study with the statistical results that the group treated with a bilateral approach improved better than the group with unilateral approach with greater improvement in flexion, extension and abduction which promotes all the activities of daily life and that is confirmed again with the improvement of values in SPADI scores.

Effectiveness of Oropharyngeal Exercises on Daytimesleepiness, Snoring and Risk of Obstructive Sleep Apnea Among adults: Review

Jaspreet Kaur1, Kanika Rai2, Vinay Kumari3, Jyoti Sarin4

1Nursing Tutor; 2Professor, Department of Medical Surgical Nursing, M.M. College of Nursing, Maharishi Markandeshwar (Deemed to be University) Mullana, Ambala, Haryana, India, 3Chitkara School of Health Sciences, Chitkara University, Punjab, India, 4Principal cum Professor, M.M. College of nursing, Maharishi Markandeshwar (Deemed to be University) Mullana, Ambala, Haryana, India

Abstract

Introduction: Sleep disorders are very frequent among general population. The prevalence of sleep disturbances varies between 25 and 45%. Types of sleep abnormalities in which snoring is the common among all the adults. Oropharyngeal exercises are new, non-invasive, cost effective treatment modality for individuals having risk of obstructive sleep apnea, daytime sleepiness and snoring.

Methods: The study design was systematic review and it includes studies from databases of PUBMED, MEDLINE, Cochrane library, SCOPUS, Science direct, and Google scholar (2002-2017).

Result: Total 14 relevant articles were under taken. Studies included are related to prevalence, assessment, effect of different modalities and oropharyngeal exercises on daytime sleepiness, snoring and risk of obstructive sleep apnea and excludes those studies that involve other sleep disorders like insomnia, narcolepsy and circadian rhythm disorder etc. Abstracted information is related to their design, population characteristics, intervention and outcomes.

Conclusion: Oropharyngeal exercises are effective in reducing the daytime sleepiness, snoring and risk of obstructive sleep apnea among adults having snoring. Several studies came out with the result that oropharyngeal exercises are beneficial in reducing sleep disorders.

Key words: Oropharyngeal exercises, risk of obstructive sleep apnea, daytime sleepiness, snoring, adults.

Introduction

Sleep is one of the important factor in individual’s life.1 If sleep disturbance occur daily and creates a problem one may suffer from a sleep disorder. Fifty to seventy million US adults have a sleep disorder.2

Snoring is more prevalent in middle aged and older adults ranging from 10% to 20% in women and 29% to 30% in men. It is now suggested to be indicative of a significant clinical problem such as obstructive sleep apnea.3 Anatomical factors like congenital narrowing of nasal and or pharyngeal cavity, inferior position of hyoid bone, obesity, local deposition of fat in the pharynx and submental region and also supine position etc. More prevalent in males as compare to females.4 It progress over the course of years and leads to obstructive sleep apnea and it impairs ventilation raising nocturnal hypoxemia.5

Daytime sleepiness is one of the common sleep-wake complaints reported by older adults and has been associated with multiple adverse outcomes, including psychiatric disorders, metabolic abnormalities,

A frequency of 5 to 15 apneas and hypoapneas per hour of sleep is generally considered as mild sleep apnea, and a frequency >15/h indicates moderate to severe sleep apnea. Obstructive sleep apnea syndrome is a well-known cause of daytime sleepiness that is often associated with snoring.

Snoring is frequently denied, because it is a stigmatizing symptom that is poorly perceived by the beholder. Denial is the most common first reaction after hearing about the problem. Even people hesitate to take treatment for it hence non-invasive treatment is required for treating snoring which is affordable for them. Oropharyngeal exercises reinforce the oropharyngeal muscles and increase their tone, thereby dilating the upper airways during sleep. It is more physiological and may bring long-lasting benefits to the people.

**Materials and Method**

**Research design:** Systematic Review

**Inclusion criteria:** It includes the studies related to prevalence, assessment of snoring, daytime sleepiness and risk of obstructive sleep apnea among adults and also the effect of different modalities and oropharyngeal exercises on these phenomenon.

**Exclusion criteria:** The study excludes the studies those discussed about the other sleep disorders rather than snoring, daytime sleepiness and risk of obstructive sleep apnea

**Data Analysis:** Relevant article on the topic of snoring, daytime sleepiness and risk of obstructive sleep apnea and effect of other modalities and oropharyngeal exercises were identified by search of significant articles PubMed/Medline, Science direct, SCOPUS, CINAHL, Elsevier and Google scholar.

**Results**

A cross-sectional study was carried out to determine the prevalence of excessive daytime sleepiness and its associated with sleep habits, sleep problem and school performance in a sample of high school students of both genders between September and December. A total of 11 schools were randomly selected. Overall selected sample consisted of 3871 students (2703 boys and 1168 girls) in the 11th grade. It was measured using the Epworth sleepiness scale. The increased risk of EDS was related to perceived sleep insufficiency (p<0.001).

A study was conducted to assess the daytime sleepiness and the association of gender with sleep duration and daytime sleepiness was assessed among sixth to 12th grade students in Mangalore, India. The adolescents were randomly selected using stratified random sampling method. A total of 58 adolescents, 29 males and females each. Data was collected in July and August 2013. Daytime sleepiness was assessed using Cleveland adolescents sleepiness questionnaire. Sleep duration and daytime sleepiness by gender showed no statistically significant differences between male and female adolescents.

A prospective study was conducted to assess the gender difference in symptoms related to sleep apnea in a general population. A second cohort included patients referred for sleep apnea investigation in the same geographic region. A representative sample of 5,424 subjects aged 20 to 69 years living in northern Sweden were taken. Responses were obtained from 4,648 subjects (85.7%). The prevalence of snoring and witnessed apneas increased with age. The referral rate ratio for men/women after correction for population and prevalence of symptoms was 1.25:1 (p=0.012).

A descriptive study was done to assess the evaluation of Berlin Questionnaire Validity for Sleep Apnea Risk in Sleep Clinic Populations. Total 100 patients recruited to Kermanshah University of Medical Sciences. Patients completed a Persian version of BQ and underwent one night of PSG. For each patient, Apnea-Hypopnea Index (AHI) was calculated to assess the diagnosis and severity of OSA. BQ results categorized 65% of the patients as high risk and 35% as low risk for OSA. The sensitivity and the specificity of BQ for OSA diagnosis with AHI>5 were 77.3% and 23.1%, respectively.
A cross sectional study was done to assess the comparison of sleep questionnaire for screening obstructive sleep apnea. They took 234 patients. For sleep questionnaire (Berlin, Epworth sleepiness scale, STOP BANG sleep apnea questionnaire) were administered to the patients. Overnight attended polysomnography was done for all the patients. Out of 234 screened patients 87.1% had OSA, whereas 93.3%, 90.02%, 95.5% and 68.3% were classified as being risk by the Berlin, STOP-BANG questionnaire and ESS respectively.  

A population based survey done to determine the excessive daytime sleepiness assessed by the Epworth sleepiness scale and its association with health related quality of life in China. Total 3600 residents was selected randomly. The demographic information, Mandarin version of the ESS and 36-item short form health survey were collected. The average response rate of its 8 items was 97.92%. The ESS scores showed positive skewness in the selected sample with a median (Q1, Q3) of 6 (3, 0). 644 (22.16%) respondents reported subjective EDS.

Review related to the different modalities used for daytime sleepiness, snoring and risk of obstructive sleep apnea.

A randomized, placebo-controlled, double-blind study done to assess the effectiveness of the training given for tongue muscles improvement by giving Intraoral Electrical Neuro-stimulation among patients suffering from Apnea at University of Witten/ Herdecke, Germany. 67 patients were randomly assigned to 2 groups. Tongue related training was given in morning for 20 minutes and performed twice a day. Snoring is improved but not apnea improved with stimulation. Treatment efficacy was examined by polysomnography. Stimulation training, 47.5 ± 31.2; P< .05 but not with placebo training 62.1 ± 23.8 NS.  

Review related to effectiveness of oropharyngeal exercises on daytime sleepiness, snoring and risk of obstructive sleep apnea.

A randomized controlled trial done on 39 patients having diagnosed with snoring and also having the symptoms of mild-to-moderate sleep apnea. Patients are assessed at starting of study and asked about sleep questionnaires (Epworth, Pittsburgh sleep quality index) and check through polysomnography. No significant changes occurred in the control group and randomized to therapy experienced a significant decrease in the Snore Index, p = .017.

A semi-experimental study done on 30 patients with primary snoring, at Amiralmomen university hospital, Iran. They were provided with the sets of exercises for 1month and 30 min a day under the guidance of the speech therapist. It assessed snoring with the help of Visual Analogue Scale and Snoring Scale Score criteria before and after giving the session of exercises, Mean SSS before the study was 7.01 ± 1.72, while it was 3.09 ±2.7 after the study; and the mean VAS scores were 8.54 ± 1.89 and 4.69 ± 2.94 before and after the study, respectively (P = 0.0001).

A randomized study was conducted on patients with moderate obstructive sleep apnea syndrome. They take thirty-one patients with moderate sleep apnea in sleep laboratory, pulmonary division, heart institute, university of sa’o paulo medical school. They give daily 30 min exercises in experimental group (n=15), no exercises were given. It significantly decrease (P=0.05) neck circumference, snoring frequency, snoring intensity, and the sleepiness in day time obstructive sleep apnea severity.

A systematic review and meta-analysis was done to assess the effect of myofunctional therapy to treat obstructive sleep apnea in adults having snoring, and sleepiness. Data was taken from web of science, scopus,
MEDLINE, and the cochrane library. Nine adult studies (120 patients) reported polysomnography, snoring, and/or sleepiness outcomes. The pre- and post- MT apnea hypopnea indices (AHI) decreased, $P < 0.0001$. Polysomnography snoring decreased from $14.05 \pm 4.89\%$ to $3.87 \pm 4.12\%$ of total sleep time, $P < 0.001$, and snoring decreased. Epworth Sleepiness Scale decreased from $14.8 \pm 3.5$ to $8.2 \pm 4.1$. 21

A randomized control trial was conducted among 20 patients suffering from mild to moderate obstructive sleep apnea syndrome and were given oropharyngeal exercise therapy for 3 months. Epworth daytime sleepiness and Berlin sleep questionnaire, and full polysomnography were performed. There was significant reduction in the neck circumference ($38.4\pm1.3$ to $37.8\pm1.6$) after giving intervention. Significant improvement was seen in symptoms of daytime sleepiness, witnessed apnea, and snoring intensity. 22

**Discussion**

In the present study, the daytime sleepiness and risk of obstructive sleep apnea was found to be significant in experimental after giving oropharyngeal exercise intervention $p=0.001$, 0.01 respectively. The results were consistent with the findings of Guimaraes who reported the daytime sleepiness and risk of obstructive sleep apnea score in experimental group was significant $p<0.005$, $p=0.02$ respectively. 2

In the present study, the mean snoring score of adults in experimental and comparison group after intervention was $11.43\pm5.42$ and $15.13\pm5.16$ respectively ($p=0.01$). The findings were consistent with Shadman nemati et.al who reported the mean snoring scale score after the intervention in control and experimental group was $7.01\pm1.72$, $3.09\pm2.7$ respectively ($p=0.000$).29

**Conclusion**

The goals of oropharyngeal exercises are to tighten and strengthen the upper respiratory muscles at the back of the mouth, within the throat, and at the front of the neck. With the help of evidence based practice, literature can be added into the body of nursing knowledge to help the nurses and other health care professionals to reduce the problem of sleep related disturbances among people. Researchers should focus more on this area related to sleep disorders as most of the times people are unaware of their sleep related problems and less attention is given towards it.

**Conflict of Interest** - There is no conflict of interest between authors.

**Funding** - This research received no grant from any funding agency.

**Ethical Clearance** - Institutional ethical committee (IEC- 959) of Maharishi Markandeswarp (Deemed to be University), Mullana.

Effects of Aerobic Exercises for General Anxiety Disorders in Adolescents

Jhaveri Nikita H1, Malawade Mandar2

1Student, Krishna College of Physiotherapy, KIMS, Karad , Maharashtra, India,
2Associate Professor, Department of Pediatric physiotherapy, Krishna College of Physiotherapy, KIMS, Karad.

Abstract

Objective: The objective of the study were to determine the effect of aerobic exercises for the patients who were suffering from the general anxiety disorders such as depression, stress, and anxiety in adolescents.

Method: In this experimental study, 46 generally anxiety disorders patients were taken for the study, subjects were from the schools nearby with adolescents age group. Subjects were treated with aerobic exercises.

Result: The total of 46 cases were taken for the study who underwent through aerobic exercises. With statistical analysis of pre and post treatment, the exercises were found extremely significant with a p value of <0.0001.

Conclusion: The study concluded that aerobic exercises are effective in the management of generally anxiety disorders in adolescents.

Key words: Generally anxiety disorder, aerobic exercises, adolescents.

Introduction

Mental illness is a serious public health issue. It is expected to account for 15% of the global burden of disease by 2020, which would make it the leading disease burden.7 Suicide, depression, eating disorder, and anxiety are some of the conditions that affect young people in disproportionate rate in comparison to many other population groups.8

Mental health problems cause huge public health burden in juveniles globally, as evidenced by a 20% prevalence.1,2 Research has demonstrated that physical activity (PA) may provide physiological and psychological benefits.5,6 Several studies have described an improvement in mood of health of persons after participation in a physical activity programme.3,4

In seeking to understand the beneficial effects of exercise and how they are produced, it is important to consider separately what happens to mood and well-being immediately after an exercise workout and what the longer term benefits are of maintaining an exercise regimen. Two studies support the notion that physical activity improves mood and well-being immediately following an exercise workout. The effect of physical activity on mental health in children and adolescents has received significantly less attention than in adult population.9

For teenagers, it is suggested that low SE predicts adolescents’ report of mental status and health compromising behaviours, such as depression, anxiety, problem in eating and suicidal ideation. Low level of self-esteem in children and adolescents also predicts poor health, criminal behaviour, and limited economic prospects during adulthood. Thus it is important to determine effective interventions for improving self-esteem and self-concept for juveniles.16

Medications used to treat severe mood disorders such as quetiapine and lithium, are often associated with weight gain.10 Thus, alternative augmentation strategies
that target mental health and physical would be desirable.

Exercise represents a cost-effective and easily disseminated intervention that includes the benefits of minimal side-effects and improved physical health and mental health. The data on the efficacy of exercise as an intervention for MDD and Bipolar disorder have yielded effect sizes comparable to medications.11-15

Aims and Objectives

Aim:

The study is to find the effect of group aerobic exercise for psychological disturbed adolescents.

Objectives:

1. To assess the stress by the aerobic exercises in day to day life.

2. To overcome the psychological disturbances in adolescents by group aerobic exercises.

Materials and Methodology

- **Type of study**- Observational Study
- **Study Design**- Survey
- **Place Of Study**- Karad
- **Sample Size**- 46
- **Sampling Method**- Simple Random Sampling
- **Statistical Analysis** - with the help of pie diagrams and bar diagram.

Inclusion Criteria

- Patients with psychologically disturbed adolescents.
- Those are willing to participate.

Exclusion Criteria

- Patients with cardiovascular conditions.
- Patients with orthopaedic conditions.
- Patients other than depression, anxiety, etc.

Materials

- Assessment chart
- Writing Material
- Computer for online accessing

Outcome Measure:

0 = Not at all
1 = Just a little
2 = Somewhat
3 = Moderately
4 = Quite a lot
5 = Very much

Table no.1. The Goldberg Depression Scale

**Procedure:**
- An approval for the study was obtained from the protocol committee and institutional ethical committee of Krishna Institute of Medical Science ‘Deemed to be University’.
- Subjects taken for my study was from outdoor.
- On the day of enrolment, subjects were undergone detailed assessment to fulfil inclusion and exclusion criteria.
- As the subject fulfilled the criteria they were explained about the study and detailed information was given to them.
  - They were explained about:
    1. Pattern of study
    2. Need of study
    3. Information generated out of the study

4. Importance about the information generated
5. Its effect on general population.
6. Aerobic exercises were explained and performed
   - Consent was taken detailed, information was gathered and statistical analysis was then done in order to derive conclusion.

**Statistical Analysis and Result**

Statistical Analysis: It was done manually and by using the statistics software INSTAT so as to verify the results derived. Un-paired ‘t’ test was used for interpretation of post interventional values. According to standard deviation and the pearsons test we calculated the p value of each question in Goldberg scale for pre and post treatment, and they were extremely significant.

Result: In this study, the statistical analysis for Goldberg depression scale shows the extremely significant in post intervention. There is improvement in reduction of anxiety, depression and stress level after doing aerobic exercises for 6 weeks.

**Discussion:**

Mental illness is a serious public health issue and mental health problems are causing serious issues in adolescents. This leads to depression, anxiety, stress and which causes the increase in rate of suicide and many more disorders. This project was done in 6 weeks with sample size of 46 patients suffering through generally anxiety disorder. This research was undertaken with the aim to study the effect of aerobic exercises for generally anxiety disorder in adolescents. The study is to see the effect of aerobic exercises such as jumping jacks, burpees, jump rope, squat jumps, kickboxing, jogging in place on the adolescents to see the effect on generally anxiety disorders. The exercises were perform everyday with 10 repetitions of 3 sets each day with the pre and post examination of Goldberg depression scale. Prior consent was taken from the patients suffering from generally anxiety disorder. The outcome measure for this experimental study was goldberg depression scale and the intervention was aerobic exercises followed by
6 weeks. The results were extremely significant after the intervention and was confirmed by the Goldberg depression scale. The results were compare with pre and post values and the p values were <0.0001 for each question asked in scale. Hence, the exercises were beneficial for the patients suffering from generally anxiety disorder.

**Conclusion**

From this study, we can conclude that there is an effect of aerobic exercises in generally anxiety disorder for adolescence which shows aerobic exercises are effective to reduce anxiety, depression and stress level in age group of 18-21.

**Conflict of Interest:** There is no conflict of interest.

**Ethical Clearance:** An approval for the study was obtained from the protocol committee and institutional ethical committee of Krishna Institute of Medical Science ‘Deemed to be University’.

Gender Wise Difference in Presenting Signs and Symptoms of Stroke: Observational Study

Jhaveri Nikita H.1, Kanase Suraj B.2

1Final year, BPTh student, Faculty of Physiotherapy, Krishna Institute of Medical Sciences Deemed to be University, Karad, Maharashtra, India, 2Associate Professor, Department of Neuro physiotherapy, KIMSDU, Karad

Abstract

Objective: The objective of this study was to find the various presenting signs and symptoms of stroke, in association of presenting signs and symptoms with age, sex and to establish the correlation in gender.

Method: All patients with first ever stroke and of both ischaemic and haemorrhagic stroke with age group of 40 to 60 years, subjects were of Karad. Signs and symptoms were collected from the medical records, patient themselves and their relatives. Differences were calculated using standard deviation.

Results: The total of 260 cases were taken for the study, 130 were male and 130 were female. The presenting signs and symptoms of stroke were differed in gender. Women were most commonly seen with generalised weakness (p=0.0076) and headache (p=0.0152). Men were most commonly seen with pain (p=0.0001), nausea (p=0.0060), fever (p=0.0081).

Conclusion: This study concluded that, there were gender differences in signs and symptoms of stroke and due to lack of awareness many people ignored the signs and symptoms of stroke by making it less important.

Key words: Stroke, Signs, symptoms, age, gender difference.

Introduction

Stroke is defined by the ‘World Health Organisation’ as the clinical syndrome consisting of rapidly developing clinical signs of focal (or global) disturbance of cerebral functions with symptoms lasting for 24 hours or longer or leading to death, with no apparent cause other than vascular origin.8

There are two major categories of stroke:

A. ISCHEMIC STROKE:-

This is the most common type of stroke, 80% of individuals are affected by these. It is caused by a clot or other blockage within an artery leading to the brain. It is further divided into two types: -

1. Thrombotic Stroke :

If blood clots from inside of the arteries of the brain, then it leads to thrombotic stroke.

2. Embolic Stroke :

If blood clotted in other parts of the body’s arteries subsequently entering the brain, it leads to embolic stroke.

B. HEMORRHAGIC STROKE:-

It is caused by the blood vessel in the brain interrupting in result of blood leaking into the brain.9

Early Warning Signs of Stroke:

1. Sudden numbness or weakness of face, arm, or leg; especially on one side of the body.

2. Sudden confusion, trouble speaking or understanding.

3. Sudden trouble seeing in one or both eyes.

4. Sudden trouble walking, dizziness, loss of balance or co-ordination.
5. Sudden severe headache with no known cause.9

Risk factors:

Risk factors for stroke can be categorized as modifiable and non-modifiable. Age, sex, and race/ethnicity and genetics (family history) are non-modifiable risk factors for both ischemic and hemorrhagic stroke, while hypertension, smoking, diet, hypercholesterolemia, diabetes mellitus, obesity and physical inactivity are some of the more commonly reported modifiable risk factors.10

A number of stroke risk factors are specific to women such as early menopause (before 42 years of age), pregnancy, birth, first 6 weeks of postpartum especially in older women, preeclampsia, and etc.9

The correlation between the age and the stroke is that the risk for stroke increases with age, which means women have a higher risk of stroke. Although women have a lower age-adjusted stroke incidence than men. However, this reversed in the older ages, women live longer and at the oldest age have an elevated risk compared to men and making them more prone to die from stroke. Mostly many women’s are unaware of their atypical signs and have increased delay to treatment. More women than men die from stroke each year because older women outnumber older men.1

As the stroke is the leading cause of death and disability. The estimated adjusted prevalence rate of stroke range, 84-262/100,000 in rural and 334-424/100,000 in urban areas (approximately). 2

Aims and Objectives

Aim:

• To study the gender difference in presenting signs and symptoms of stroke.

Objective:

• To study the various presenting signs and symptoms in stroke.
  • To study the association of presenting signs and symptoms with age, sex.
  • To establish the correlation of presenting signs and symptoms and gender.

Materials and Method

□ Assessment chart
□ Writing Material
□ Computer for online accessing

Methodology

TYPE OF STUDY – Observational study

STUDY DESIGN – Survey

SAMPLE SIZE – Supposed to be 260 Subjects.

STUDY DURATION – 6 months.

PLACE OF STUDY – Karad.

Estimation of Sample size- Formula: \( n=\frac{4(SD)^2}{(M \times Ɛ)} \)

By assuming SD=14.5, M=73, Ɛ= 0.025

N=260

Inclusion Criteria

• Patients with both haemorrhagic and ischaemic stroke.
• Patients with first ever stroke.
• Both male and female data.
• Age: 40-60 years

Exclusion Criteria

• Neurological ill patients other than stroke
• Patients with Transient Ischaemic Attack.

Outcome Measures

• Signs and symptoms of stroke.

Procedure

• An approval for the study was obtained from the protocol committee and institutional ethical committee of Krishna Institute of Medical Science ‘Deemed to be University’
  • Department of medicine, neurosurgery has been explained about the topic make them aware for sample that are required to conduct the study.
• Subjects taken for my study was from indoor as well as outdoor.

• On the day of enrolment, subjects were undergone detailed assessment to fulfil inclusion and exclusion criteria.

• As the subject fulfilled the criteria they were explained about the study and detailed information was given to them.

• They were explained about:
  1. Pattern of study
  2. Need of study
  3. Information generated out of the study
  4. Importance about the information generated
  5. Its effect on general population.

• Consent was taken detailed, information was gathered and statistical analysis was then done in order to derive conclusion.

**Statistical Analysis and Result**

Statistical Analysis: According to the standard deviation and the pearsons test we calculated the p value of each sign and symptom and every sign and symptom has a different p value with significance.

Result: The results shows that in 50%(130) of female subjects were having pain 33%, generalized weakness 64%, ataxia 37%, headache 60%, language disorder 42%, visual disturbance 35%, weakness 45%, drowsiness 43%, dizziness 44%, nausea 38%, seizure 38%, dyspnoea 45%, loss of consciousness 44%, and fever 43% and in 50%(130) of male subjects were having pain 67%, generalized weakness 36%, ataxia 63%, headache 40%, language disorder 58%, visual disturbance 65%, weakness 55%, drowsiness 57%, dizziness 56%, nausea 62%, seizure 62%, dyspnoea 55%, loss of consciousness 56%, and fever 57%. In 260 subjects the p value of each sign and symptom is <0.0001 and was considered extremely significant.

Therefore, result of this study is that there are differences by gender in presenting signs and symptoms at presentation of stroke and suggest that there should be focus of stroke prevention education and awareness of signs of symptoms of stroke should be given to decrease the rate of stroke.

Discussion

Stroke is the leading cause of mortality and impairment, because many people are unaware of presenting signs and symptoms of stroke that are different in male and female. This project was done in 6 months with sample size 260. This research was undertaken with the aim to study the gender difference in presenting signs and symptoms of stroke. This observational study of presenting signs and symptoms of stroke in gender difference was conducted on 260 subjects, amongst which 130 were female (50%) and 130 were male (50%). This shows that there is a difference in presenting signs and symptoms of stroke in male and female.

Prior consent was taken from the patients suffering from stroke in hospitals. The outcome measure for this study was: - signs and symptoms of stroke.

Headache and generalized weakness were most commonly seen in female as sign and symptom. Pain, nausea, and fever were most commonly seen in male as sign and symptom. Other signs and symptoms including ataxia, language disorder, visual disturbance, weakness, drowsiness, dizziness, seizure, dyspnoea, and loss of consciousness were also seen in stroke patients.

Conclusion

Following the hospital based study, it was concluded that there are various signs and symptoms of stroke such as pain or generalized weakness are the most common seen in the patients as an early sign or symptom of stroke. There are also different signs and symptoms like headache which is mostly seen in the females as a warning before the stroke and fever seen in the male as a warning before the stroke and due to lack of awareness many people ignore the signs and symptoms of stroke by making it less important.

Conflict of Intreset: There is no conflict of interest.

Ethical Clearance: An approval for the study was obtained from the institutional ethical committee of Krishna Institute of Medical Science ‘Deemed to be University’

Source of Funding: Self.

Pattern and Distribution of Scalp Injuries in Fatal Road Traffic Accidents in Rohtak Region of Haryana - An Autopsy based Study

Jitender Kumar Jakhar¹, Naveen Yadav², Taitiksh Jakhar³, Sunil Dahiya², Kunal Gaba², S.K. Dhattarwal⁴

¹Associate Professor; ²Residents, Department of Forensic Medicine, Pt. B. D. Sharma PGIMS, Rohtak, Haryana, ³MBBS Student SDUMC, Kolar; ⁴Sr. Prof. and Head Department of Forensic Medicine, Pt. B. D. Sharma PGIMS, Rohtak, Haryana

Abstract

Head injuries are one of the leading cause of death worldwide as head being the most vulnerable part of the body. The present study was performed on 100 cases of road traffic accidents in which head injuries were present. In this study, males clearly outnumbered females. The highest incidents were seen in the age group 21 - 30 years (26%), followed by the age group 11 - 20 years (20%). In this study, special attention was given to the pattern and distribution of scalp injuries. Commonest scalp injury noticed in the present study was contusion, seen in 33% of cases, followed by lacerated wounds in 30% cases.

Key Words: Road traffic accidents, Scalp injury, Abrasion, Contusion, Laceration.

Introduction

An accident has been defined as “an unexpected unplanned occurrence which may involve injury”. In 1956, a WHO advisory group defined accidents as “an unpremeditated event resulting in recognizable damage.” India accounts for about 10 % of road accident fatalities worldwide. In age group of 5 to 44 years, mortality is as high as 10 percent. Among the various fatal injuries in road accident, head injury is the principal killer. Head injury usually refers to traumatic brain injury but is a broader category because it can involve damage to structures other than the brain, such as the scalp and skull. Scalp contusions are difficult to see with naked eyes but better felt. If, scalp laceration continue bleeding, it may lead to death. In this study, patterns of scalp injuries in road traffic accidents with regards to age, sex, season, type of injured and scalp injuries were recorded at the time of post-mortem examination.

Observations & results:

1. As per the Table no. 1, males accounted for 81 % victims females were involved in 11 % cases only.

Discussion

In this study, males outnumbered the females. Similar results were observed by Arora sandhya et al\textsuperscript{6}, Soni et al\textsuperscript{7} and Giri S et al\textsuperscript{4}.

In the age group analysis of the victims, maximum incidence was observed in age group of 21-30 years which was also noticed by the other authors in their studies like Arora sandhya et al\textsuperscript{6}, Soni et al\textsuperscript{7} and Giri S et al\textsuperscript{4}.

It is observed in this study that the road accident victims largely constitute young people in the productive age groups its major implication on economic cost of road accidents, apart from their emotional and psychological impact.

On seasonal analysis, maximum numbers of accidents occurred in monsoon season which was also observed in the studies conducted by Honnun gar SR et al\textsuperscript{8}, Banzal RK et al\textsuperscript{9} and Shiva Kumar BC et al\textsuperscript{10}.

In India, there is a big problem of destruction of roads during monsoon season due to heavy raining. The road pavement deteriorates due to various factors like poor drainage, low quality of pavement materials let the rain water to penetrate through the pavement due to which severe failure like cracks, potholes, depressions, rutting, ravelling etc. take place. The impacts of these failures also occurred on road transport system, accident is the major problem due to wet surface and widening of potholes.

Two wheeler occupants were most commonly involved victims which is similar to the findings of the studies conducted by the Kumar N et al\textsuperscript{11}. Two-wheeler accounted for the highest vehicle category-wise share in road accidents, because this is the category of vehicle preferably used by youngsters and this is the category which is also dominates the composition of registered vehicles in the country.

Among two wheelers, most of them were not using the helmet. Similar findings were observed in the studies conducted by Thumbe HR et al\textsuperscript{12}, Gupta V\textsuperscript{13} et al and Kumar P R\textsuperscript{14}.

Among scalp injuries, when taken in isolation, contusions were most common. Similar findings were observed in the studies conducted by Chakraborty Pradipta Narayan\textsuperscript{15}, Soni SK et al\textsuperscript{7} and Giri S et al\textsuperscript{4}.

Conclusion

The substantial increase in the use of two wheelers, particularly in developing countries like India, is being accompanied by an increase in the number of head and traumatic brain injuries. Head is the most vulnerable part of the body as shown in the various studies so raising awareness about traffic rules especially in two wheelers can decrease the morbidity and mortality in road side
accidents.

Comparative Analysis of Associated Risk Factors Amongst Young and Old Stroke Survivors

Joshi Madhura S.¹, Kanase Suraj B.²

¹Final year BPTh student, Faculty of Physiotherapy, KIMSDU, Karad, Maharashtra, ²Associate Professor, Department of Neuro Physiotherapy, KIMSDU, Karad

Abstract

Background: Stroke is an important health condition and is one of the leading cause of death worldwide. Disability and impairments following stroke makes the management challenging.

Aims and objectives: 1.To analyze the associated risk factors in young and old stroke. 2.To find the associated risk factors in young age patients having stroke. 3.To find the associated risk factors in old age patients having stroke. 4.To compare between the associated risk factors in young and old stroke.

Material and Method: Survey study was carried out in the department of medicine, neurosurgery and department of physiotherapy, KIMSDU, Karad. Sample size: 696 subjects with first ever stroke, both male and female above 18 years. Data was anonymously coded and entered into spreadsheet program before analyzed using statistical method. Statistical analysis was done using instat software. The chi square test was used. Percentage and frequency was calculated to summarize the response.

Results: The study included 434 were Male (62%) and 262 were Female (38%). The age distribution was, 335 people were belonging to 20-50 years (48%) and 361 people to 50 to 96 years (52%). This is analyzed that association of these risk factors is increased in young age stroke survivors. Patients with older age had higher frequency of Hypertension (HTN) and Diabetes Mellitus (DM). There is more no. of smokers in young age group. There is a more no. of male stroke survivors than female.

Conclusion: The influence of risk factors at different ages is different. Risk factors like HTN and DM were frequent in older age while more smokers in young age group. Awareness of stroke risk factors and preventive measures can reduce the burden of stroke.

Keywords: Stroke, age distribution, risk factors

Introduction

Stroke is defined by World Health Organization as ‘a clinical syndrome consisting of rapidly developing clinical signs of focal (or global in case of coma) disturbance of cerebral function lasting more than 24 hours or leading to death with no apparent cause other than vascular origin.'¹ Stroke is considered one of the leading cause of death and disability in India.² The Estimated prevalence rate of stroke range, 84-262/100000 in rural and 334-424/100000 in urban area.²

Stroke can be classified as follows:¹

- **On the basis of etiological categories:**
  - Ischemic stroke
  - Hemorrhagic stroke

- **On the basis of specific vascular territory:**
  - Anterior cerebral artery syndrome, middle cerebral artery syndrome and so forth

- **On the basis of Management categories:**

Corresponding author:
Dr Suraj Kanase,
Associate Professor, Krishna College of Physiotherapy
Karad. email: drsurajkanase7@rediffmail.com
Transient ischemic attack, minor stroke, major stroke deteriorating stroke, young stroke.

Young stroke is defined as a stroke affecting people younger than age 50. Young stroke has disproportionately large economic impact by leaving the individuals disabled before their most productive years. And this stroke in young adult causes morbidity in socioeconomically active age group. However, older stroke patients, with age 60-70 years above, were more dependent and disabled beforehand and after stroke, relatively even more dependent than young age people. So, to reduce stroke burden, preventive strategies are important.

Risk factors:

Risk factors for stroke can be classified as modifiable and nonmodifiable. Age, sex and race/ethnicity and family history are nonmodifiable risk factors for both ischemic and hemorrhagic stroke, while HTN, smoking, diet, hypercholesterolemia, obesity and physical inactivity are some of the more common modifiable risk factors.

Particularly in urban areas, potential triggers for stroke include sepsis, air pollution. Identification of these risk factors is important component of primary care.

Older patient group had higher frequency of HTN and DM while younger had obesity and elevated serum triglyceride level. Younger patients are more likely to be exposed to western type diet, which contains higher total fat.

Studies have concluded that prevalence of stroke is higher in individuals with family history of stroke, HTN, hyperlipidemia and physically inactive individuals mostly in males.

Changing lifestyle, physical inactivity, HTN, obesity are becoming the cause of stroke leading to premature death and disability in developing countries. Early detection of these risk factors leading to stroke, will help for better treatment. This early detection will also help to improve health condition in old age people. So, this comparative analysis of associated risk factors in young and old stroke survivors is necessary.

Aims and Objectives:

1. To analyze the associated risk factors in young and old stroke.
2. To find the associated risk factors in young age patients having stroke.
3. To find the associated risk factors in old age patients having stroke.
4. To compare between the associated risk factors in young and old stroke.

Methods & Methodology

Ethical approval was obtained from ethical committee of KIMSDU, Karad. An Observational study was carried out in KIMSDU, Karad. Study duration was 6 months with the sample size 696 calculated by the formula

\[ n = 4pq \]

Subjects with first ever stroke, both male and female, above 18 years were included in the study. Study was carried out with an outcome measure, distribution of risk factors for stroke.

Data was anonymously coded and entered into a spreadsheet program before being analyzed using statistical method. Statistical analysis was done using instat software. The chi square test was used for the study. Percentage, frequency was calculated to summarize the response.

Procedure:

Department of medicine, neurosurgery, physiotherapy and Hospital Record Room were explained about the topic to make them aware for sample that were required to conduct the study.

Subject taken for my study were from indoor as well as outdoor. On the day of enrolment, subjects underwent detailed assessment to fulfill inclusion and exclusion criteria.

Once the subject fulfilled the criteria they were explained about the study and detailed information was given to them. Subjects were explained about: Pattern of study, Need of study, Information generated out of the study, Importance about the information generated, Its effect on general population. Once the consent was taken detailed information was gathered and statistical
analysis was done in order to derive conclusion.

**Result**

Out of 696 patients, the age distribution was 335 people belonging to 20-50 years and 361 people to 50 to 96 years. (Table 1) There is a more no. of male stroke survivors than female. (Table 2) Multivariate analysis shows that difference among various risk factors is statistically significant. (Table 3) The frequencies of the various risk factors in different age groups are shown in Table 3.

</table>
Table 3 shows that maximum prevalence was found to be of HTN in older age group is 62% and 47% in younger age group and DM was found to be 48% and 20% in older and younger age group respectively. So, the risk factors HTN and DM were more frequent in the older group than in the younger group. Smoking was relatively common in younger age group than in older.

**Discussion**

Stroke is one of the leading cause of death and disability in India. This stroke registry based study analyzed the relation between different stroke risk factors and age. This study was done with duration of 6 months. This research was undertaken with the aim of comparative analysis of the associated risk factors in young and old stroke. Objectives of the study were to analyze the associated risk factors in young and old stroke survivors, to find the associated risk factors in young age patients having stroke, to find the associated risk factors in old age patients having stroke and to compare between the associated risk factors in young and old stroke. This study, Comparative analysis of associated risk factors in young and old stroke survivors was conducted on 696 subjects, amongst which 434 were Male (62%) and 262 were Female (38%). The age distribution was 335 people were belonging to 20-50 years (48%) and 361 people to 50 to 96 years (52%) i.e. above 50 yrs. This shows that, there is a more no. of old age male stroke survivors. But now days, even in young age also stroke is seen because of changing dietary habits, work habits, and changing lifestyle.

Prior consent was taken even from the hospital record room. The outcome measure for this study was: Distribution of risk factors. Patients were considered hypertensive if the average systolic blood pressure and diastolic blood pressure is 140 mm hg and 90 mm hg respectively. Prevalence of HTN in older age group is 62% and 47% in younger age group. Diabetes was defined by either of the following criteria: (1) if the patient is diagnosed with diabetes and (2) if at least two fasting glucose readings were 126 mg/dl or higher. And prevalence of DM was found to be 48% and 20% in older and younger age group respectively. So, the risk factors HTN and DM were more frequent in the older group than in the younger group. A patient is defined as smoker if he had been a current smoker in the past 6 months or more than 6 months. There is increased prevalence of smoking in younger age group (73%) Obesity is having body mass index above 25. Younger patients are more likely prefer to western type diet, which contains higher total fat. Changing dietary habits and lifestyle has increased the prevalence of obesity in younger age (43%) than older age (30%). Prevalence of Hypercholesterolemia was comparatively very less in older age group. Cardiac disorders like rheumatic valvular heart disease, endocarditis, coronary artery bypass graft, Atrial fibrillation increase the risk of stroke. Prevalence of heart disease was found to be 10% in younger and 40% in older age group. Alcohol and drug intake is also another considerable risk factor having prevalence 60% and 30% in younger and older age. Prevalence is increased in younger age than in the older age. Another risk factors for stroke are end stage renal diseases, chronic kidney disease, sleep apnea. Kidney diseases have prevalence about 8% and 18% in young and old age stroke survivors respectively. Patients with marked elevations of hematocrit are at an increased risk of occlusive stroke. Identification of these risk factors is important component of primary care.

Previous studies found that, Older patient group had higher frequency of HTN and DM while younger had obesity and elevated serum triglyceride level. Studies have concluded that prevalence of stroke is higher in individuals with family history of stroke, HTN, hyperlipidemia and physically inactive individuals mostly in males.

Early detection of these risk factors leading to stroke will help for better treatment. This early detection will also help to improve health condition in old age people.

**Conclusion**

Following this hospital based study, it was concluded that influence of risk factors at different ages is different. Risk factors such as HTN and DM were frequent risk factors in older age group. There is a more no. of male stroke survivors than female. Risk factors such as smoking and alcohol and drug intake is more common in young age group. Risk of heart disease is more in older age and less in younger age.

Knowledge and Practice of Bio Medical Waste Management in a Mortuary and Casualty of Tertiary Care Hospital

K Srinivasulu1, T Leela Manasa2, Dedipya2, Summaya begum2
1Professor & Hod Dept of Forensic Medicine & Toxicology. Mediciti Institute of Medical Sciences. Ghanpur, Medchal. Ranga reddy Dist. Telangana, 2Internee, Mediciti Institute of Medical Sciences. Ghanpur; Medchal. Ranga reddy Dist. Telangana

Abstract

Bio Medical waste management has been receiving highest priority in hospitals after the act was introduced by the Ministry of Environment and Forest, titled Bio Medical Waste Management and Handling Rules 1998. About 0.33 million tons of waste is generate per annum in India. Hospital acquired infections are on the rise due to improper waste management practice. A cross sectional, longitudinal study on Bio Medical waste management practice in a mortuary and casualty was conducted at a tertiary care teaching hospital from 1st July 2018 to 31st December 2018. The study focused on knowledge and practice of waste management in the casualty and mortuary. Interestingly, the practice of Bio Medical waste management was excellent in casualty and mortuary. Awareness of the hazards of improper waste management was poor among sanitary workers whereas doctors, nurses and other paramedical staff were well aware of the hazards.

Key words: Bio Medical waste management(BMW). Medical professionals. Mortuary. Casualty.

Introduction

Bio Medical waste is defined as waste generated in the hospital during diagnosis, immunisation, treatment and research activities1,3,4. Infections acquired from the hospital are known as nosocomial infections. Millions of the patients are affected by health-care associated infections. In fact, WHO statistics reveal that for every 100 hospitalised patients at any given point of time2, 7 in developed countries and 10 in developing countries will acquire nosocomial infections. WHO survey states that 8.7% of hospitalised patients suffered from hospital acquired infections. Similar to other developing countries, the magnitude of this problem is large in India2.

Mortuary is one of the locations in a hospital, where large amount of Bio Medial waste is generated. Potential for transmission of infectious diseases like Tuberculosis, diarrheal diseases, lung infections, Hepatitis, HIV and other communicable diseases increases due to improper medical waste management in the mortuary.

Health hazards due to infections in the mortuary not only affect the doctors and handlers of the bodies of the deceased, but also those in vicinity of the mortuary. Biomedical waste disposal practice is still primitive in mortuaries. Unfortunately, majority of the waste generated in mortuary is human anatomical waste which is very dangerous to the handlers.

Casualty is an emergency department; all types of waste is generated in this department, barring human anatomical waste. Most of the cases kept here for observation.

Most of the studies revealed that, lack of knowledge and awareness among the sanitary staff is the main reason for improper management of bio medical waste3,4.

Legal Aspects:

Bio Medical waste management and Handling rules 19981,4:

- Act means the Environment Protection (Protection)

• Authorization means permission granted by the prescribed authority.

• Authorized person means an occupier or operator authorized by the prescribed authority.

• Bio-medical waste means any waste, which is generated during diagnosis, treatment, immunization or in research activities.

• Bio-medical waste treatment facility means any facility wherein treatment and disposal of bio-medical waste is carried out.

• Occupier means a person who has control over that institution.

• Operator of a bio-medical waste disposal means a person who owns or operates a facility for the collection, storage, transport, treatment and disposal of bio-medical waste.

• AUTHORIZATION: Every occupier of an institution handling bio-medical waste shall make an application in Form 1 to the prescribed authority for grant of authorization.

• ADVISORY COMMITTEE: The Government of every State/Union Territory shall constitute an advisory committee. The State Pollution Control Board shall be represented. The committee shall advise the Government about matters related to the implementation of these rules.

• ANNUAL REPORT: Every occupier/operator shall submit an annual report to the prescribed authority in Form 11 by 31 January every year.

• MAINTENANCE OF RECORDS: Every authorized person shall maintain records related to the generation, collection, reception, storage, transpiration, treatment and disposal of bio-medical waste in accordance with these rules and any guidelines issued.

• ACCIDENT REPORTING: Any accidental injury while handling the bio medical waste to be recorded and report immediately to the authority.

• As per the Bio-medical Waste management rules, it shall be the duty of every occupier of Health Care Facility & operator of Common Bio-Medical Waste Treatment Facility to take all the steps to ensure that the Bio-Medical waste is properly handled and disposed off without any adverse effect to human health and the environment.

Segregation, Storage and Disposal of Bio Medical waste1,5,6:

Category Yellow: waste must be collected in yellow colored non-chlorinated plastic bags. The following waste should be collected in yellow color bags.

(a) Human Anatomical Waste: Human tissues, organs, body parts and fetus below the viability period. yellow colored non-chlorinated plastic bag

(b) Animal Anatomical Waste: Experimental animal carcasses, body parts, organs, tissues, including the waste generated from animals used in experiments or testing in veterinary hospitals or colleges or animal houses.

(c) Soiled Waste: Items contaminated with blood, body fluids like dressings, plaster casts, cotton swabs and bags containing residual or discarded blood and blood components.

(d) Expired or Discarded Medicines: Pharmaceutical waste like antibiotics, cytotoxic drugs including all items contaminated with cytotoxic drugs along with glass or plastic ampoules, vials etc.

(e) Chemical Waste: Chemicals used in production of biological and used or discarded disinfectants.

(f) Discarded linen, mattresses, beddings contaminated with blood or body fluid.

(g) Microbiology, Biotechnology and other clinical laboratory waste: Blood bags, Laboratory cultures, stocks or specimens of microorganisms, live or attenuated vaccines, human and animal cell cultures used in research, dishes and devices used for cultures.

Waste collected in yellow color bag/bin should be treated by Incineration or Deep Burial.

Category Red: Red colored non-chlorinated plastic bags or containers must be used to collect waste. All plastic and rubber contaminated Waste (Recyclable)
Wastes generated from disposable items such as tubing, bottles, intravenous tubes, catheters, urine bags, syringes and gloves. This waste can be treated by autoclaving or microwaving followed by shredding and recycling.

**White (Translucent) category:** All sharp material including Metals: Needles, syringes with fixed needles, needles from needle tip cutter or burner, scalpels, blades or any other contaminated sharp object that may cause puncture and cuts, these waste can be treated by Autoclaving or Dry Heat Sterilization followed by shredding and dispose by concrete waste sharp pit.

**Blue category:** Glassware: Broken or discarded and contaminated glass including medicine vials and ampoules except those contaminated with cytotoxic wastes and metallic Body Implants to be segregated in blue color bags. These waste can be treated by Disinfection or autoclaving or microwaving and then sent for recycling.

The points to be noted are:

1. Bio-medical waste shall not be mixed with other wastes.
2. Bio-medical waste shall be segregated into containers/bags at the point of generation in according to their color codes.
3. Biomedical waste shall be transported only in such vehicle which was authorized for the purpose by the competent authority as specified by the government.
4. No untreated bio-medical waste shall be kept stored beyond a period of 48 hours.
5. Instruments used in the mortuary during dissection can be reused after through washing and disinfecting with 1% sodium hypo chlorite solution.

**Precautions for Handlers:**

No one should handle Bio Medical waste with a bare hand, Handlers must wear gloves, head cap, mask, goggles and body apron. Every staff member must follow universal work precautions to protect from infections.

**Punishment:**

Whoever fails to comply with or contravenes any of the provisions of the act or rules made or directions issued there under, shall in respect of each such failure or contravention shall be punishable with an imprisonment for a term up to Five years or with a fine up to one lakh rupees or both, (EPA Act 1986).

**Aim of the study:**

The aim of this study is to assess practice of biomedical waste management in casualty and mortuary by doctors, nurses, technicians, and sanitary staff.

To identify any lacunae in the existing practice and guide the modifications deemed necessary.

**Materials and Method**

A cross sectional study on biomedical waste management knowledge and practice in a mortuary and casualty was conducted at tertiary care teaching hospital in Ranga Reddy Dist. from 1st July 2018 to 31st December 2018, after receiving permission from the hospital authority. We observed the existing method of practice regarding collection, storage and disposal of biomedical waste in the mortuary and casualty.

We also assessed the knowledge of BMW management among medical professionals handling waste by administering the questionnaire. However, before administering the questionnaire, the purpose of the study was explained to all participating employees and their names were left anonymous.

The following observations were made regarding the practice of biomedical waste management:

1. Whether the bins were available as per the color-coding system and maintained.
2. Whether the bins were located in accessible locations in the department.
3. Whether segregation of BMW was proper.
4. Availability of needle cutters.
5. Whether disinfection solution was available.
6. Any other specific observations.

The information collected into a data sheet for scientific evaluation.

**Findings**

Doctors, nurses, and technicians have better knowledge than sanitary staff regarding biomedical
waste management.

Knowledge regarding color-coding, waste segregation, transportation and disposal of waste was found to be better among doctors and nurses compared to sanitary staff.

Interestingly the Practice of waste collection, storage and transportation was excellent in casualty and mortuary even though the knowledge levels among sanitary workers were poor. All the storage bins with appropriate color and a symbol of bio medical waste were available in casualty and mortuary. The storage of the waste also found to be in accord with the existing guidelines. Needle cutters were available and in utilisation in casualty along with freshly prepared disinfecting solution. The storage bins were kept at proper accessible location in both mortuary and casualty.

Disposal facilities are not available in the institution, waste have been collected and disposed at common treatment facility.

All the staff members both casualty and mortuary were following universal safety precautions while handling biomedical waste. Staff was using a trolley for transportation of Bio Medical waste.

The amount of waste generated in casualty is high when compared to the mortuary. BMW in mortuary was very low in this institution due to lack of conduction of medico legal autopsies in the institution. Occasionally, however, pathological autopsies were conducted.

**Conclusion**

Bio medical waste management is an attitude and knowledge related programme. In majority of the studies we observed a lack of knowledge and awareness in sanitary staff is the main culprit for poor management of the programme. Though doctors and nurses are well trained but the practice is not up to the mark due to lack of knowledge at low level sanitation staff. For effective implementation, periodical training programmes focusing on practical aspects should be conducted to all the staff and sanitation workers of the hospital. Best team work and effective supervision is very much essential for better implementation of the programme.

Profile of Fatal Cases of Organophosphorus Poisoning at a Tertiary Care Centre, Mandya

K. Ashwini Narayan¹, K. Ashwini Narayan²

¹Associate Professor, ²Associate Professor, Department of Forensic Medicine & Toxicology, Mandya Institute of Medical Sciences, Mandya

Abstract

Organophosphorus Compound (OP) poisoning is the most common and the highest amongst fatal cases of poisoning consumption deal in MIMS hospital. It is the commonly abused poison amongst rural and urban population more so amongst our Farmers. Fatal cases of organophosphorus poisoning were analyzed during the study period from 01.01.2016 to 31.12.2018. The analysis was done on age, sex, occupation, socio economic status, motive of poison consumption and result.

Mandya District being dominated by agriculturists and sugarcane being the cash crop, drought, insufficient rain fall, raising costs of living, high debts, Cauvery water non available for agricultural use due to water sharing between neighboring states like Tamilnadu, Pondichery etc., increasing number of bore wells and ground water depletion, leading to crop failures and thereby resulting in Farmers suicide.

The major cause of death in these cases treated at MIMS were Respiratory failure.

Key words: Organophosphorus poisoning, Farmers suicide, Respiratory Failure.

Introduction

Despite the apparent benefits of Organophosphorus compounds (OPC’s) acute Organophosphate (OP) pesticide poison is a global increasing problem. It is very common pesticide used rampantly in agricultural fields and is easy accessibility is increasing the incidence of suicidal and accidental poisoning rates. Its action is by inhibiting the enzyme Cholinesterase, thereby the accumulation of Acetylcholine at myoneural and synaptic junction leading to cholinergic over activity.

The incidence of organophosphorus poisoning has steadily increased in recent past and has reached a level where it can be called a “Social Calamity”. Organophosphorus compound is seen with increasing frequency and carries 15-30% mortality in studies carried out at India. Respiratory failure is common complication of organophosphorus poisoning leading to high mortality therefore effective and timely treatment becomes crucial for survival. Hereby the retrospective study was undertaken to know the incidence and prevalence of fatal organophosphorus poisoning in cases autopsied at MIMS, Mandya.

Material and Method

This autopsy based retrospective study was conducted between Jan 2010 – Dec 2018 in Department of Forensic Medicine & Toxicology, Mandya Institute of Medical Sciences, Mandya. The data was collected from the postmortem reports. Out of 1581 cases OP Poisoning deaths autopsied at MIMS was 600 (3.79%). All the fatal cases autopsied confirmed by either clinical diagnosis RFSL reports were included in the study. The data analysis was done on the age, sex, motive of poisoning, cause of death, professional status, marital status, types of organophosphorus compound consumed.

Results

The age of patients varied from 11 yrs. – 80 yrs. (Table No1). The vast majority of patients were males 90% (Table No.2) with male to female ration being 8:1 period of survival ranged from 1day to 15 days. The commonest motive of poisoning was suicidal in both males 88.83% and females 9.16% followed by accidental 1.18% males and 0.83% in females. There was one case of homicidal poisoning (Chart 1). Financial debts (90%) followed by chronic health ailments reasons (05%) coupled with crop failures and loans was the reason. One case of homicidal poisoning was a deaf and dumb husband poisoned by wife and her paramour to get rid of him and gain his property, which the convicted lady admitted too. Respiratory failure 95% was the leading cause of death followed by Myocardial Infarction, Renal failure and Multi organ failure in (5%) cases noted. Agriculturists / Farmers (75%) students (13.33%) house wives(10%) own business / self-employed (1.6%) not known (0.7%). 85% of the study population were married 20%, 15% males and 5% females were unmarried. Dichlorvos 73%, 18.33% of cases showed Diazinon and 8.3% Parathion consumption.

Discussion

Acute organophosphorus compound poisoning is one of the commonest causes of acute poisoning in Mandya. In my study majority of the persons were males (88.83%) and they were aged between 11-80 years similar observation were noted in other studies5-9. Commonest motive of poisoning was suicide10. The probable cause of mortality relied on various factors like its easy availability, inadequate rainfall, low procurement prices for sugarcane, lack of of prompt payment of dues from sugar factories and high input costs and inability to move away from water – intensive sugarcane crop leading to financial crisis11. In other cases, it was because of failure in exams, financial midlife crisis, love failures.

Conclusion

Organophosphorus poisoning is the most common poisoning encountered at Mandya Institute of Medical Sciences, Mandya with a male predominance. Commonest motive of poisoning was suicidal 12-14. Economic crisis faced by Farmers and easy availability were the common cause of poisoning 15-16. To prevent and reduce the incidence of organophosphorus compound poisoning it is better to change the economic policies of the Government, waiving of Farmers loans, insuring the crops, educating the farmers about alternate methods of farming which is less dependent on water, promoting animal husbandry, creating more jobs to the youth. Similarly, strict implementation of pesticide act, Banking and Government sectors to change their policy decision, drought management schemes, educating the public and youth about the life-threatening effects of organophosphorus compounds can certainly make difference in the life of farmers and youths and reduce the mortality rates thereby due to organophosphorus pesticide consumption.

Study of Pattern & Distribution of Injuries in Fatal Road Traffic Accident Cases Autopsied at MIMS, Mandya

K. Ashwini Narayan

1Associate Professor, Department Of Forensic Medicine & Toxicology, Mandya Institute Of Medical Sciences, Mandya

Abstract

Accidents are now one of the major causes of death. The present study was carried out between Jan 2016 to Dec 2017 at Department of Forensic Medicine, Mandya Institute of Medical Sciences, Mandya, to study the type of injury, pattern and distribution of injuries, body parts involved, fatal injuries and causes of deaths noted at the actual autopsy examination of the victim. During the period of study 1013 total autopsies were conducted, out of which 15 cases were of road traffic accidents.

Keywords: Road traffic injuries, head injury, visceral injuries.

Introduction

The term accident has been defined as an occurrence in the sequence of events which usually produced unintended injury or death or property damage. (1)

Among all types of accidents, those caused by motor vehicles claim the largest toll of life and tend to be serious. There are almost 98,000 deaths from road accidents annually in India and total causalities worldwide is 1.2 million each year. Studies done by WHO shows that road traffic accidents accounts for 5% of total deaths in India and in age group of 10-50 years is amongst top three leading causes of death. (2)

According to study conducted by National Transportation Planning and Research Centre, Delhi, a person is killed or injured in every 4 minutes in traffic accidents in India.

Accidents constitute a complex phenomenon of multiple causation. There is steep rise in vehicular accidents in present Era due to urbanization, growth in transport sector, population explosion, compounded by high speeding, consumption of alcohol and inadequate traffic planning for the rising growth of population. (3)

The present study has been carried out at MIMS, Mandya regarding Epidemiological, medico-legal aspects of vehicular accidents in Mandya district making an effort to establish various causative factors, pattern and distribution of injuries and therapy to plan measures to prevent them in future.

Material and Method

150 cases of fatal road traffic accidents brought to mortuary department of Forensic Medicine, MIMS Mandya, during 2 years period 01/01/2016 to 31/12/2017 compromised the study population. Various demographic and Epidemiological characters related to victim’s accidents were gathered from Police or from guardians and relatives. The gender distribution, type of injury, body parts involved, cause of deaths were noted at actual autopsy examination of victim and analysed statistically.

Results

It was observed that out of 1013 cases received for postmortem examination at our department, 150 (14.80%) cases were of road traffic accidents. It was observed that 113(75.33%) subjects were males and 37 (24.66%) were females. As per WHO guidelines, cases were divided into five groups with respect to age wise...
distribution and the observation made was that maximum age group involved was between 20-40 years (56.66%).

**Discussion**

Motor vehicle accidents rank first among all total accidents throughout the world. The 150 cases of deaths due to road traffic accidents out of 1013 cases constituting (14.80%). This is accordance with Srivastav and Gupta. The most common age group involved was between 20-40 years and males outnumbered females. This study is similar to studies conducted by Mc Carrolet al, PK Ghosh and Tirpude et al 4, 8, 10.

Motorcyclist are commonest group of victims involved 70 cases (46.66%) followed by pedestrians. Similar trends were seen by Gallway & Patel, Sevitt.7

**Conclusion**

A total of 1013 cases of postmortem conducted out of which 150 deaths were due to road traffic accidents (14.80%). It was observed that males had out membered the females and maximum number of victims were motorcyclist and pedestrians, with cranio- cerebral injuries being cause of fatality.

This district being predominantly rural and agricultural population, human errors in the form of not wearing helmets and not obeying traffic rules, consuming alcohol and driving the vehicles were leading causes of mortality and morbidity. The other causes were mud roads / bad rural roads, absences of street lights and pavements for pedestrians in rural areas, no traffic signals or Police to monitor the traffic resulted in preventable human error related deaths. Following measures could reduce deaths due to road traffic accidents like compulsory helmet wearing for both Pillion rider and riders irrespective of age and sex, providing safe crossings, sidewalks for pedestrians, increasing public transport, improving the street lights at night, segregating two wheelers and pedestrians from
high ways, zebra crossing, avoiding drunk driving by strictly enforcing legislation and frequent checking by Police, emergency medical care training the medics and paramedics at Taluk and hobli level about intubation, airway maintenance transportation to tertiary care centers can certainly reduce the mortality.

There is no Panacea that will prevent road traffic accidents, what is required is an organized team work by multi disciplinaries like law enforcement agencies, Engineering and Medical graduates, public education and awareness creation.\textsuperscript{11}

Variations of Dermatoglyphic Patterns among Smoking and Smokeless Forms of Tobacco in Oral Potentially Malignant Disorders and Oral Cancer- A Review of Literature

K.V.Swathi¹, G.Maragathavalli²
¹Post Graduate Student, ²Professor and Head, Department of Oral medicine and Radiology, Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Chennai, India

Abstract

Dermatoglyphics is a scientific study which involves the study of fingerprints, lines, mounts and shapes of hands. This dermatoglyphics origin dates back to ancient India, were this ridge pattern study was known as “Samuda Sashtra. These dermatoglyphic patterns are usually genetically determined. In dentistry, dermatoglyphics have been applied for identifying syndromic cases and also been useful for determining caries susceptibility, identification of cleft lip and cleft palate. Here the variations of dermatoglyphic patterns among smoking and smokeless forms of tobacco in oral potentially malignant disorders and oral carcinoma has been reviewed.

Keywords: Dermatoglyphics, Fingerprints, Genetics, Oral Potentially Malignant Disorders

Introduction

Dermatoglyphics is a scientific study which involves the study of fingerprints, lines, mounts and shapes of hands.¹ The history and origin of dermatoglyphics dates back to 1823 with the work of Jan Evangelista Purkyne who had first studied the papillary ridges of hands and feet.² Sir Edward Henry in 1893 published a book on “The classification and uses of fingerprints” which gave way to the basis of fingerprint identification and other related systems.³

The term “dermatoglyphics” was first coined by Cummins and Midlo in 1926 and it is derived from the Greek wherein ‘derma’ means skin and ‘glyph’ means carving.⁴ The fingerprints are always unique for an individual as they are genetically determined with a polygenic pattern of inheritance.⁵

Dermatoglyphic analysis may help in personal growth as in strengthening the interpersonal communication and interaction skills, it can also enhance the emotional quotient (EQ) and adversity quotient (AQ).⁶

Dermatoglyphics in identification of genetic abnormalities

Dermatoglyphics have also been associated with various genetic abnormalities which can be useful in the diagnosis of congenital malformations. In case of Klinefelter syndrome, there is excess of arches on the first digit, increased frequency of ulnar loops in the second digit, overall there are fewer whorls and lower ridge counts for loops and whorls and significant reduction of the total finger ridge count.⁷ In Noonan’s syndrome, there is increased frequency of whorls on the fingertips and the axial triradius.⁸ In Turner’s syndrome, there is increased incidence of single transverse palmar crease and predominantly they have whorl patterns.⁹ In people with congenital blindness, they have an increased frequency of whorls on the fingertips and the axial triradius. In individuals affected with Down’s syndrome, they have increased ulnar loops and a distinct angle between the triradia a,t and d(‘atd’ angle).¹¹

In Rubinstein Taybi syndrome, individuals manifest with broad thumbs, low mean ridge count and fingerprint patterns in interdigital areas. In schizophrenia, the A-B ridge counts are lower compared to normal healthy individuals. In pseudohypoparathyroidism, there are short broad bands, high axial triradius and increased arch patterns.

**Methods of dermatoglyphic analysis**

The dermatoglyphic analysis procedure including collection of fingerprints, palmprints and foot prints. There are various methods of recording dermatoglyphics which includes the ink method, Faurot inkless method, transparent adhesive tape method, photographic method and other special methods.

The ink method is the most commonly used method and first begins with the application of ink (normally Kore’s duplicating ink is used) on the fingers and palms and stamped on a sheet of paper with firm, uniform pressure. The prints are then scanned into a computer software database and then the prints are analysed. The genetic sequence is then analysed. Based on the existing databases, the fingerprints are identified.

In Faurot inkless method, they use commercially available solutions with a specially treated sensitised paper.

Transparent adhesive tape method involves the application of a dry colouring pigment to the skin and lifting it off with a transparent adhesive tape.

Photographic method involves principles of total internal reflection which occurs when an object is pressed against a prism. The magnified image is photographed by a polaroid camera.

**Dermatoglyphics in Oral Potentially Malignant Disorders and Oral Cancer**

Oral Potentially Malignant Disorders (PMD) include a variety of lesions and conditions characterised by an increased risk of malignant transformation to oral squamous cell carcinoma. A study by David and Sinha on dermatoglyphic patterns in subjects with potentially malignant disorders and oral carcinoma revealed that the mean number of loops and the mean total ridge count were found to be higher in case of subjects with potentially malignant disorders and oral carcinoma when compared with controls. In patients with oral cancer, arches were more predominant.

In a study done by Lakshmana et al. in 2016 on the role of digital and palmar dermatoglyphics in early detection of oral leukoplakia, oral submucous fibrosis and oral squamous cell carcinoma patients, it was found that loops were found to be the predominant finger ridge patterns in these patients with oral leukoplakia whereas whorl pattern was found in controls.

In a cross sectional study done by Aditya et al. in 2016 on the analysis of fingerprints pattern in patients with potentially malignant disorders, they found that in patients with preleukoplakia, oral leukoplakia and OSMF there was an increased frequency of arches and loops whereas in the control group, the whorls and loops were more frequently seen.

A cross-sectional study by Shetty et al. in 2016 on dermatoglyphics as a genetic marker for oral submucous fibrosis, it was found that percentage of whorls in study groups was 24% and 20% in the right and left hand respectively as compared to 7% and 5% in controls group. The percentage of arches in the study group was 0% and 1% in the right and left hand as compared to the 8% and 7% in the control group. These results indicate that dermatoglyphics can be used to determine the genetic susceptibility of individuals to develop oral submucous fibrosis.

Gupta and Karjodkar et al. in their study on the role of dermatoglyphics as an indicator of precancer and cancerous lesions of the oral cavity in 120 individuals who were divided into four groups; where Group 1 consisted of 30 male patients with history of tobacco/areca nut intake with occurrence of oral squamous cell carcinoma, Group 2 had 30 male patients with history of tobacco/areca nut intake with occurrence of oral submucous fibrosis, Group 3 included 30 males with habit of tobacco/areca nut without any evidence of oral lesions while Group 4 had 30 males without any habit and oral lesions which were the control group. Overall, there was a significant increase in the arch and loop pattern frequency.

A dermatoglyphic study was done by Ganvir et al. in 2014 on the detection of genetic predisposition in OSCC and OSMF patients by qualitative analysis of finger and palm-print patterns. So in their study, they had mentioned that a predominance of whorl type fingerprint pattern can be used as a screening marker for identifying the susceptibility of OSMF and OSCC.
A qualitative and quantitative analysis of palmar dermatoglyphics among smokeless tobacco users by Vijayaraghavan and Aswath in 2015 was a prospective comparative study among 40 patients (Group 1- 10 samples of smokeless tobacco users with OSMF, Group II-10 samples of smokeless tobacco users with OSCC, Group III- had 10 samples without smokeless tobacco and Group IV-had 10 samples without smokeless tobacco habit without OSMF and OSCC and they were the control group). They found that there was a predominance of arches and loops configurations, presence of hypothenar pattern, decrease in the mean ATD angle (P<0.001) and total AB ridge count (P=0.005) in OSMF and OSCC patients.

Vinothini et al. in 2017 did a cross sectional study to evaluate the relation between palmar dermatoglyphics with OSCC and OSMF patients. They had included 15 individuals with OSMF, 15 individuals with OSCC and 15 individuals were controls with no habits or lesions. They found that loops were frequent among the cases, whereas whorl patterns were common among the controls (P<0.05). Loops were also common in the interdigital areas than in control (P<0.05).

A dermatoglyphics study by Dutta et al. in 2016 on the comparison of fingerprint patterns in patients with and without oral submucous fibrosis. In their cross sectional study they had included 30 subjects with history of gutkha chewing of 10 years wherein 15 patients had developed OSMF and 15 patients without OSMF. They found a decrease in arches pattern, radial loop pattern, whorl pattern and atd angle in patients with OSMF. The results were statistically significant in individuals with ulnar patterns (P<0.05).

In a study to assess palmar dermatoglyphics in oral leukoplakia and oral squamous cell carcinoma patients by Venkatesh in 2006, where they comprised of 30 subjects with oral leukoplakia and 30 individuals with habits and no lesions as controls. Arches and loops were more frequent in cases than in controls whereas whorls were more frequent in control group (P<0.01). The loop pattern were at a higher frequency in the interdigital areas in cases than in controls (P<0.05).

In a study by Munishwar et al. in 2015 on the qualitative analysis of dermatoglyphics in oral submucous fibrosis, 25 subjects were gutkha chewers with OSMF, 25 were gutkha chewers without OSMF and 25 subjects were healthy controls. There was significant increase in the percentage of loops among gutkha chewers with OSMF and controls and increase in the whorl patterns among control group. Among the digits, there was increase in the whorl pattern in the right index and right ring finger (P=0.0328 and P=0.0368 respectively).

A study by Patil et al. in 2017 on dermatoglyphics in oral potentially malignant disorders and oral cancer revealed that among the dermatoglyphic patterns, 60.66% of patients with potentially malignant disorders and 46% of the oral cancer patients had whorl patterns. There was also a significant decrease in the mean accessory tri-radii digital angle (37.13 degrees).

In a cross sectional study done by Singh et al. in 2016 where the fingerprints and palm prints were studied in 180 patients who were randomly divided into three groups: Group A consisted of 60 subjects with oral leukoplakia, OSMF and OSCC, Group B consisted of 60 patients with habits but no lesions, Group C consisted of 60 healthy controls. The arch pattern was the predominant pattern (60.7%) with a decrease in the whorl pattern (29.3%) in group A when compared with the controls (group B and C) (P=0.01). There was an increase in the mean total finger ridge count (P<0.675).

**Variations of dermatoglyphic patterns among smoking and smokeless forms of tobacco in OPMDs and oral cancer**

In general, there are many studies which state that the nicotine content is higher in the smoking form of tobacco like bidis, cigarettes in comparison to the smokeless form of tobacco which includes pan, gutkha chewing. In one such study by Amit et al. in 2018 where they had evaluated the nicotine content in smoking and smokeless forms of tobacco, they found that bidis had the highest content of nicotine, followed by chewed tobacco (pan masalas) and cigarettes. With increasing nicotine content, literature states that there is an increased malignant transformation risk of these OPMDs.

In a study by Gandham and Thajuddeen in 2018 wherein they had compared the dermatoglyphic patterns in 250 alcohol and/or tobacco smokers with 250 non consumers, they found a decrease in ‘ATD’ angle in both hands of male (P<0.001) and female (P<0.001) cases as compared to the controls. The percentage of ulnar loops (p=0.020), arches (p=0.010) and composite patterns (p=0.005) were less among males compared to male controls, the percentage of whorls was more
among males compared to male controls (P<0.001), the percentage of radial loops was more among the female cases group in comparison with the female controls (P=0.017).

Conclusion

Dermatoglyphics analysis play a very important role in identifying the susceptibility of an individual to a particular syndrome, disease or certain other disorders as it is based on the genetic makeup of an individual. This scientific study was mainly used in the branch of criminology for solving various crimes. In dentistry, now this scientific study has been gaining importance and is been mainly used for identification of syndromes as most of them are genetically inherited, useful in determining the susceptibility of an individual to dental caries, periodontal diseases, cleft lip and palate, OPMDs and oral cancer. More studies have to be conducted for bringing this dermatoglyphics method as routine identification systems in the future perspective.

Abstract

Background: The present study was planned to investigate the possible association between polymorphisms of superoxide dismutase, SOD1 (Cu,Zn-SOD), SOD2(Mn-SOD), SOD3(EC-SOD) and catalase genes and the risk of cervical cancer in rural population of Maharashtra.

Methods: A case control study included 350 proven cervical cancer cases and 400 healthy age matched control women. Genotyping of isoforms of SOD and CAT were done by polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) method.

Results: When we studied genotype frequencies of codon 326 and 262 region of promoter of CAT gene, there was no significant association between A to T transition at codon 326 (p=0.45) and CAT C262T polymorphism (p=0.30) with susceptibility to cervical cancer. The variant G allele of SOD1 at codon 251 significantly increased in cervical cancer patients as compared with the control women (OR=3.02, 95% CI: 1.72-5.31; p<0.0001).

Conclusion: Findings from this investigation confirms conceivable association of A251G of SOD1 and G172A of SOD3 genes with risk of cervical cancer in women of Maharashtra.

Keywords: Genetic polymorphism, Superoxide dismutase, Catalase, Cervical cancer.

Introduction

Cervical cancer (CC) is 4th most common cancer in women worldwide representing 570,000 new cases and 311,000 deaths in 2018 where 90 % of deaths from CC occurred in low or middle income and developing nations [1]. CC is the 3rd leading public health crisis in India where, the burden of CC is increasing with alarming rate accounting 97,000 new cases and 60,000 deaths occurred in women between age ranges (15 to 69yrs) because of this dreaded disease in 2018 which represent one-fourth of global burden of cervical cancers. It is surprisingly noted that the women residing at rural regions of India are at higher risk of developing CC as compared to their urban counterparts[2].The rate of CC causing deaths in women was highest in southern states of India which was followed by Maharashtra[3]. The predominant risk factors causing CC remained unnoticeable, but the epidemiological factors contributing to development

and progression of CC in underprivileged areas are early marriage age, sex at early age, poor genital hygiene, use of oral contraceptives, Human Papillomavirus (HPV) are considered. Apart from these factors the interactions between genetic and environmental factors have been shown to be associated with cervical carcinogenesis[4]. However, the exact mechanism of cervical carcinogenesis has not been fully elucidated till date. Growing studies evidenced that the reactive oxygen species (ROS) produced through inevitable consequences of oxidative stress may damage to cellular macromolecules and contribute to promotion of carcinogenesis[5].

To control the deleterious effects of ROS, the cellular machinery have antioxidant enzymes such as superoxide dismutase (SOD) and catalase (CAT) to brace against oxidative stress.

A single nucleotide polymorphism (SNP) in SOD or CAT genes may affect the stability and activity of enzymes, ultimately leading to altered expression of functional protein important for ROS detoxification. Several SNPs have been identified in SOD isoforms including, transition of A to G at 251 position of codon 251 in exon 10 of SOD1, Ile58Thr polymorphism at codon 58 in exon 3 of SOD2, transition mutation of G to A at position 172 in alanine to threonine substitution (Ala40Thr) in SOD3 gene associated with different types of cancers [6-10]. Similarly several studies have reported CAT gene polymorphism including A to T point mutation in codon 326 of exon 7 in the promoter region of CAT gene and C262T polymorphism in 262 region of promoter of CAT gene in multiple cancer risk [11-16]. However, the results remain inconsistent and inconclusive. Limited number of epidemiologic studies from India reported association of polymorphisms in SOD and CAT gene with series of cancers [8,17], but studies on SNPs in either SOD or CAT gene and their association with cervical cancer risk in any of Indian population are missing. Therefore in this study we hypothesized that the polymorphism in isoforms of SOD i.e, SOD1 (Cu, Zn-SOD), SOD2 (Mn-SOD), SOD3 (EC-SOD) and CAT genes which may contribute to etiology of CC in rural women of Maharashtra.

Materials and Method

Study subjects

350 women with proven cervical carcinoma and 400 healthy and age matched women as controls were included in this hospital based case-control study. All cases ranged in age from 20-80 years (yr) (Mean ± SD) (48.67 ±13.78) were enlisted immediately after being diagnosed during the year 2013-2018. Informed consent was obtained from all participants.

Genomic DNA isolation from whole blood

Genomic DNA was isolated from blood samples of 350 cases and 400 controls by the standard method describer earlier by Datkhile et al 2019 [18].

Genotyping assays.

Genotyping of SOD and CAT gene was performed by PCR-RFLP. The primers selected to amplify the specific SNPs of interest were; Forward primer (FP); 5’-AGTACTGTCAACCACTAGCA-3’ Reverse primer (RP); 5’-CCAGTGTGCGGCCAATGTG-3’ for codon 251of SOD1, 5’-AGCTGTGCTCCATATATTAG-3’RP ;5’TCAATTCAGGGCTGAGAT-3’ for codon 399 of SDO2, FP; 5’-GACATGTCGCGGAAAGGCAC- RP; 5’-AATCAGAGGCCAGTCCCTCCC- RP; 5’-TCGGGGAGCACAGAGTGTAC -3’ for codon 326 of CAT gene and FP: 5’-AATCGAGAGCCGCAGTCCCTCCC- RP; 5’-TCGGGGAGCACAGAGTGTAC -3’ for codon 326 of CAT gene and FP: 5’-AGAGCCCTGCACCCGGCGGACC-3’RP ; 5’-TAAGAGCTGAGAAAAGGCATAGCT-3’ for promoter region of CAT gene. The PCR reactions performed seperately in 20 µL reaction volume containing 100 nanogram of genomic DNA, 5 picomoles of each above mentioned primers, 200 micromolar each dNTPs, 10 mili molar (mM) Tris-HCl (pH 9.0), 50 mM KCl 1.5 mM MgCl2 and 1U of Taq DNA polymerase. After confirmation of amplification of specific fragments by agarose gel electrophoresis, each PCR products were allowed for restriction digestion with specific restriction enzymes at 37°C. 1 unit of MspI, EcoRV and BssHII restriction enzymes were used respectively for digestion of SOD1, SOD2 and SOD3 gene. Similarly HinFI and SmaI enzymes were used to digest codon 326 and 262 region of promoter of CAT gene. The restriction products were resolved on 2 or 3 % agarose gels according to the fragment sizes thereafter documented with UV transilluminator system.

Statistical Analysis

The association between the SOD, CAT genotypes and risk of developing CC were studied by logistic
regression model which was used to calculate the Odds ratio (OR) and 95% confidence intervals (CI).

**Results**

Total number of 350 cases (20-80 yr; median age of 50 yr) were included in this study. Clinically, most of the cases were in stage III well differentiated squamous cell carcinoma, enrolled in the study before receiving any of the cancer treatment. It was observed that CC occurred in patients (78.90 %) who were married at younger age and pregnant soon (15-20 yr) which showed significant association when compared to the controls ($p=0.01$). Surprisingly, age of cervical cancer occurrence in cases were below 50 years (61.40%; $p=0.03$) in rural population.

**SOD genotyping:**

The frequency distribution of SOD1 A251G, SOD2 C399T and SOD3G172A genotypes were determined in CC cases and control groups are shown in Table 1. When we observed the genotypic frequencies of SOD1 A251G polymorphism we found AA genotype (52.3%) in cases whereas controls with 63.00%. But, variant GG genotype frequency in cases was 12.60% which was significantly deviated from expected frequencies of controls which was not more than 5% which revealed that variant GG genotypes (OR=3.02, 95% CI: 1.72-5.31; $p=0.0001$) heterozygous AG (OR=1.55, 95% CI: 1.16-2.08; $p=0.003$) increased the risk of CC. The results of genotype frequency of SOD2 C399T showed C allele frequency of cases (4.9%) and that of control (1.2%) whereas variant T allele of cases (31%) and controls (33.2%) which did not show significant difference as expected frequencies on Hardy-Weinberg equilibrium.

**CAT genotyping:**

We also studied the genotype frequencies of codon 326 and 262 region of promoter of CAT gene summarized in Table 1. When we analyzed frequency distribution of A326T genotypes in codon 326 of exon 7, the A allele of cases (52 %) and controls (49.2%) where T allele in cases (7.4%) and control group (10.5%) which showed no association of either TT genotype or a combination of AT+TT genotype with CC risk. When we studied C/T and T/T genotypes of 262 promoter of CAT gene, we observed that T/T genotypes of cases (33.7%) and controls (28.5%) and C/T +T/T genotypes of cases (90.6%) and controls 89.5%) which also showed no association of C262T polymorphism with CC risk. However, there was no significant association between the CAT A326T polymorphism and susceptibility to CC, (T allele vs A allele, OR=0.67, 95% CI=0.39-1.13, $p=0.13$; AT+TT vs AA, OR=0.89, 95% CI=0.67-1.19, $p=0.45$).

Discussion

Cervical cancer is a major public health problem differentially distributed across different regions particularly abundant in rural parts of India. Comprehensive case-control study was attempted to discover the relationship of SNPs of SOD and catalase genes which could manipulate the risk of CC in the women representing rural population of Maharashtra. When we studied association of polymorphisms in isoforms of SOD and catalase genes with the help of logistic regression analysis, we observed that amongst three SNPs of superoxide dismutase genes (rs2070424, rs1141718, rs2536512), women carrying G/G genotype in SOD1 and A/A genotype in SOD3 were at higher risk of developing cervical cancer but there was no association of SOD2 C399T polymorphism with CC risk. Similarly, we assessed two SNPs in catalase gene (rs7943316, rs1001179) and found no association of polymorphism in this gene with risk of CC in rural women population of Maharashtra. Limited literature available on polymorphisms in oxidative stress associated antioxidant genes and their role in cancer development. SOD and catalase genes are briefly studied for their association with certain pathological disorders along with cancer. Up till now several studies reported positive association of polymorphism in SOD and catalase genes with cancer risk but with inconclusive results\textsuperscript{11, 19}. The polymorphism in SOD as well as catalase genes have found to be associated positively with increased risk of breast cancer\textsuperscript{6} but, in contrast no association was found in bladder\textsuperscript{20}, oesophagus\textsuperscript{21} and colorectal cancer\textsuperscript{22}.

Studies with limited information on association of polymorphism in either SOD or catalase gene and risk of cervical cancer is available in literature. The association of SOD\textsuperscript{23} and catalase polymorphism\textsuperscript{24} with cervical cancer susceptibility was revealed in some studies however, no association of SOD with cervical cancer
was reported by Attatippaholkun and Wikainapakul 2013(25). Earlier studies discovered the association of SOD2 gene polymorphism with multiple cancer risk(7, 26) but, surprisingly our results interpreted that SOD1 and SOD3 polymorphisms are associated with CC risk. Till date none of the Indian studies reported involvement of polymorphism in SOD and catalase with the risk of cervical cancer. To the best of our knowledge, present study is first to investigate the relationship of SOD and catalase gene with CC risk, where we found no association of SOD2 and catalase gene with risk of cervical cancer. Thus our results revealed for the first time that the SNPs rs2070424 of SOD1 and rs2536512 of SOD3 could increases the susceptibility of women towards CC risk from a pool of unexplored rural population of Maharashtra.

**Conclusion**

In conclusion, present study for the first time provides the evidence that SOD1 (G allele of rs2070424) and SOD3 (A allele of rs2536512) polymorphisms may express genetic susceptibility of CC in women of rural Maharashtra but the rs1141718 polymorphism of SOD2 and rs7943316, rs1001179 polymorphisms of catalase gene did not show association with cervical cancer development.

Abstract

Background: Buffalo milkers are more prone to de Quervain’s tenosynovitis due to their working process and repeated use of thumb, wrist and fingers. If there is any pain or problem in hand or wrist can have impact on milking ability which can lead to change in their economic status and quality of life. There are only few studies done on the population of buffalo milkers and problems regarding their occupation. Thus this study is designed to find prevalence of de quervain’s tenosynovitis in buffalo milkers.

Aim: The aim of this study was to find out prevalence of de Quervain’s tenosynovitis in buffalo milkers and aware them about this condition to avoid further damage.

Material and Method: Study was conducted with 92 subjects in and around Karad. Subjects were selected as per inclusion and exclusion criteria and consent was taken. Both males (43) and females (49) subjects were included for study. Then they were assessed with help of Finkelstein test and Visual analogue scale the data was collected and analysed accordingly.

Statistical Analysis: The simple random sampling is used to select the subjects for study and it is conducted in and around Karad Taluka. The sample size was calculated by de quervain’s tenosynovitis taken at 64%. Hence for calculation of sample size p=64% and q=100-p=36% sample size n=4pq/L² therefore n=92. Statistical analysis of the recorded data was done by using the software instat. MS Excel was used for drawing various graphs with given frequencies and the various percentages that were calculated with the software.

Result: After analyzing the data, it was found that there is a prevalence of de Quervain’s tenosynovitis. In all participants 43% people have de Quervain’s tenosynovitis. It is found that prevalence of de Quervain’s tenosynovitis is more in females than males and pain distribution is more in age group of 41 to 45 years.

Conclusion: The prevalence of de Quervain’s tenosynovitis is more in females and precautions should be taken by buffalo milkers by modifying their work strategies to avoid further damage.

Keywords: De Quervain’s tenosynovitis, Buffalo milkers, abductor pollicis longus, extensor pollicis brevis tendons.

Introduction

De Quervain’s Tenosynovities is a disease in which there is pain and swelling over the radial styloid process.

Corresponding author:
Dr. Pragati Salunkhe, Assistant professor, Department of sports physiotherapy, Krishna college of Physiotherapy, KIMSDU, Karad- 415110. Satara, Maharashtra, India.
Email id: drpragatisalunkhe@gmail.com

There is inflammation of common sheath of abductor pollicis longus and extensor pollicis brevis tendons.[1] The origin of abductor pollicis longus is ulna, radius, interosseous membrane and the action of it is abduction and extension of thumb, the origin of extensor pollicis brevis is radius and interosseous membrane and the action of extensor pollicis brevis is extension of thumb.[2]

There is tenderness over radial styloid process takes place.[1] Adducting the thumb across palm and forcing ulnar deviation causes aggravation of pain. The pain
causes due to thickening of fibrous sheath. The pain radiates proximal or distal from the first dorsal wrist compartment [1,2].

The confirmation of De Quervain’s Tenosynovitis is done by positive findings on finkelstein test. In this test, ask the patient to place his thumb in the palm of the hand and flex the digits around the thumb, if there is tenderness over the first dorsal wrist compartment then the test is positive[3,4].

De Quervain’s Tenosynovitis is associated with occupations which include over use of wrist and thumb. It is also associated with repetitive trauma.[5]

Buffalo milking is done by using hand. Because of hard teat sphincter muscle and their slow milk ejection reflex buffaloes are slow and hard milkers.[6] In hand milking there is massaging and pulling down on the teats of the udder and collecting the milk in bucket takes place. It includes two methods:

1. Between the finger and thumb, the top of teat is pinched and shut to trap milk in the lower part and squeeze by other fingers, the milk will come out through the tip of teat

2. By the finger and thumb, the top of the teat is pinching then slid down the teat to push milk towards the bottom.[7]

In buffalo milkers there is repetitive use of thumb and fingers associated with wrist takes place. De Quervain’s disease is a significant cause of musculoskeletal pain among people.[7,8]

**Methodology**

This study is cross sectional study undertaken to find out prevalence of de Quervain’s tenosynovitis in buffalo milkers and to create awareness about it in them. Buffalo milkers with age group of 30 to 50, both males and females were included. Buffalo milkers who have already undergone from fingers and wrist related surgery and those who are unwilling to participate are excluded. Written consent of the patient was taken. The study is ethically approved. The Finkelstein test and Visual analogue scale is used as study tool.

**Statistical Analysis**

The sample size was calculated by de Quevain’s tenosynovitis taken at 64%(as a study has shown as frequency of de Quervain’s tenosynovitis and its association with SMS texting is 64% as in SMS texting there is also repeated thumb movements takes place therefore 64% was taken into consideration for de Quervain’s tenosynovitis). Hence for calculation of sample size \( p=64\% \) and \( q=100-p=36\% \) sample size \( n=4pq/L^2 \) therefore \( n=92 \). The simple random sampling is used to select the subjects for study and it is conducted in and around Karad Taluka.

A. Graph 1:

![Graph 1](image)

**Interpretation:** According to the graph above 11(27%) of males and 32(73%) of females have
dequervain’s tenosynovitis. It also shows that 23 of buffalo milkers had dequervains tenosynovitis in age group 46-50 yrs. in 41-45yrs 12 subjects, in 36-40yrs 4subjects and in 30-35yrs 1of buffalo milkers had dequervain’s tenosynovitis and at rest, 20(50% ) people had mild pain, 7(18% )people had moderate pain, 13(32% )people with no pain and on activity 21(53% ) of people had severe pain,16( 40%) people had moderate pain and 3(7% )had mild pain.

Based on this study it was found that heel pain in farmers is statistically significant (p< 0.0001).

Discussion

The aim was to study the prevalence of dequervain’s tenosynovitis in buffalo milkers. Inclusion criteria was, Buffalo milkers both males and females. Age group of 30-50 years and Participants those are willing to participate. Exclusion criteria was Buffalo milkers who have already undergone surgery of wrist and fingers.

The study was conducted with 92 subjects in and around Karad. Subjects were selected according to the inclusion and exclusion criteria. Both male (43) and Female (49) subjects were included for the study. Subjects were explained about the procedure of the study. Written consent was taken from them and they were also asked if they suffered any other musculoskeletal problems. Then they were assessed with finkelstein test and visual analogue scale, survey was done according to the results obtained and hence the conclusion was given.

Buffalo milking is second most important way to earn money in farmers. Buffalo milking is done by using hand in which over use of wrist thumb and fingers takes place which causes pain swelling over radial styloid process. Inflammation can cause reduction in workability and impact on daily living activities.

Many studies have been conducted on De quervain’s tenosynovitis in another population like students, nursing staff etc.

As per the previous studies it has been seen that personal and work related factors were associated with de quervain’s tenosynovitis in working population in which there is bending and twisting movement of wrist takes place.

Previous studies are carried out to see risk factors of de quervain’s tenosynovitis in French working population by Audrey Petit Le Menac’h, the purpose of this study was to assess the relative importance of personal and occupational risk factors for de quervains tenosynovitis in working population.

So in buffalo milkers de quervain’s tenosynovitis can cause due to repetitive thumb movement and bending movement, that’s why it is necessary to find prevalence of de quervain’s tenosynovitis in buffalo milkers.

Even this study helped to create awareness amongst buffalo milkers about the de quervain’s tenosynovitis and its risk factors that might cause pain which would eventually affect their work. And benefit for betterment of them and help them to prevent further problems or injuries to surrounding structures.

In this study we came to know that females are primarily affected by this condition. De quervain’s tenosynovitis was also found statistically significant in present study. It was shown that 43% subjects are having de quervain’s tenosynovitis and 46-50 years of age group is mostly.

Conclusion

After analysing the data, it was found that there is a prevalence of de quervain’s tenosynovitis in buffalo milkers. 43% of subjects are having de quervain’s tenosynovitis. It is found that prevalence of de Quervain’s tenosynovitis is more in females than males and pain distribution is more in age group of 41 to 45years.

Acknowledgement: I sincerely thank the management of KIMSDU for allowing me to conduct this study by providing me the necessary requirements. I thank dean Dr.Vardharajulu sir for his support and guidance. My sincere thanks to guide Dr Pragati Salunkhe for helping me in my research. I take this opportunity to thank all those who helped to complete this study.

Conflict of Interest: There were no conflict of interest in my study

Source of Funding: This project is funded by self.

Ethical Clearance: The institutional committee has hereby given permission to initiate the research project titled, “Prevalence of de Quervain’s tenosynovitis in buffalo milkers.”

Abstract

Background: Age estimation is an integral part of the biological profile employed by forensic anthropologists in order to assist in achieving an identification of an unknown deceased individual. Its estimation is of paramount importance and requires special attention in cases where bodies are found in decomposed, mutilated state or only fragmentary remains are discovered.

Material and Method: The present study has been done on post-mortem cases referred to GMERS Medical College, Himmatnagar which is referral center. Very few studies have been conducted on sagittal suture closure in Himmatnagar region. Total 150 post mortem cases were taken and data collected.

Result: Present study reveal that Ectocranial obliteration of the various segments of the three main sutures of the skull is so inconclusive that neither does it help in estimating the age of the deceased nor does it provide any supportive evidence in determining the age of skeletal remain. Age was determined on the basis of endocranial suture fusion.

Conclusion: It was found that closure of Sagittal suture started in age of 20-29 yrs and closure completed at the age of 61 to 65 yrs.

Key words: Sagittal suture, Age, Relation

Introduction

Age estimation can be done in several ways by macroscopic examination of dental development and eruption, epiphyseal union of long bones, degeneration of pelvic articular surfaces, sternal rib ends and cranial sutures, as well as microscopic examination of bone in histological analysis.¹ Since the bone resists putrefaction and destruction by animals, they can lead to the reliable determination of age, sex, race, stature in decomposed bodies.²

Use of suture closure for age estimation is predicated upon the hypothesis that suture closure is part of the aging process. However, when suture closure patterns were first studied at the beginning of this century, there were two schools of thought (British and Italian) on this issue (Hershkovitz et. al. 1997:393). The British school maintained that sutural ossification and cranial immobility were normal conditions, whereas the Italian school maintained that they were pathologic in mature human adults (ibid.). In time, probably due to the increasing prominence of the English language in the scientific literature, the British approach toward suture closure became the dominant model in physical anthropology (without actually testing that hypothesis) (Hershkovitz et. al.1997:394).³

Reasonably a correct estimation of age in elderly people is essential in legal, medical, social and administrative matters i.e. to fixing of age for regularization of employment, superannuation, pension settlements, senior citizen benefits, old age and good behavior of the prisoner (Ullas Shetty ref).

This study was done to specify the relationship between progression of union of cranial suture and age of the subject. It also done to formulate practical method of estimation of age based on the status of the progression of the closure of sutures using the data collected and to establish a data base of fusion of cranial sutures for the population of Gujarat.

**Materials and Method**

The study was conducted on cases coming for medico-legal post mortem examination to the Department of Forensic medicine, GMERS Medical College, Himmatnagar, Gujarat during a period from November 2018 to November 2019.

**Study design:** A descriptive cross-sectional study.

Inclusion criteria:

1. The cases of known age coming for medico legal postmortem examination. Age was confirmed by documentary evidences like birth certificate, identification cards, ration card etc.

2. Subjects of more than 20 years of age were taken.

**Exclusion criteria:**

1. Unknown, unclaimed bodies where exact age cannot be confirmed.

2. Cases showing deformed or diseased or fractured skull, which may hamper the study of suture closure.

**Method**

150 cases of age 20 years and above were studied. After reflecting the scalp sagittal suture was studied by applying Acsadi-Nemeskeri scale ectocranially. For endocranial suture, same score system was applied after removing the calvaria by craniotome with taking due care to include complete sagittal suture. The calvarium was cleaned of soft tissues on both sides and was dried, which made the suture more prominent. Photographs were taken in all cases. The obliteration of the sutures was ascertained endocranially as well as ectocranially. In both cases degree of closure was scored in 16 parts of the main cranial sutures as has been done by Acsadi-Nemeskeri scale. We have studied the sagittal suture in four parts. Ectocranially the different sections were distinguished by differences in the character of the suture. Endocranially the sutures do not show these differences in character. Consequently the endocranial sutures were simply divided in sections of equal length.

**Scale for closure: Acsadi-Nemeskeri complex method:**

0 = open. There is still little space left between edges of adjoining bones.

1 = incipient closure. Clearly visible as a continuous often zigzagging line.

2 = closure in process. Line thinner, less zigzags, interrupted by complete closure

3 = advanced closure. Only pits indicate where the suture is located

4 = closed. Even location cannot be recognized.

Statistical Method

To estimate the possible relation between suture closure and age at death, analysis was done in excel and Epi info software.

Discussion

In this study, Age range can be given in range of 5 years. Whereas age from suture closure of skull can be given only in a range of decades.\(^8\) Study by Dr. S. V. Khandare et al range has been given in range of 5 yrs.\(^9\) According to J.B.Mukherjee, estimation of age from suture closure of skull can be given in a range of 5-10 yrs in age of 30-60 yrs, the range may even be more in higher age groups.\(^{10}\) In our study at Himmatnagar, we have observed that the sagittal suture, endocranially fusion started in first part at 20-29 years and completion at age of 50-59 years age group. In second, third and fourth part, fusion started in 20-29 years age group and completion in 50-59 years age group. This finding was compared with study by Dr.S.V. Khandare et all found that the sagittal suture, endocranially, started fusing at the end of 26 years and completion at the age of 61-65 years in 1\(^{\text{st}}\) part of sagittal suture, 46-50 yrs in II\(^{\text{nd}}\) part of sagittal suture, 41-45 yrs in III\(^{\text{rd}}\) part of sagittal suture and 26-30 yrs in IV\(^{\text{th}}\) part of sagittal suture.\(^9\) In study by Ullas Shetty have found that the sagittal suture, endocranially, starts fusing at the end of 20-29 years and completion is perfected at the age of 60-69 years. Similar finding also found in observation with that reported by Todd & Lyon (1924).\(^{11}\) It was in contrast to the observation reported by Pommerol (1869), and Topinard (1885), who indicated endocranial commencement of sagittal suture at a much later age at about 40 years. These latter workers have reported on very few specimens so it could not be considered as authentic.\(^{12,13}\) The other study for cranial suture closure of skull was done by Krogman(1978), Rentoul & Smith (1973) , T LPatil (1981) & Robert Shapiro (1960), had concluded that the study of ectocranial fusion was less significant than endocranial fusion because suture along the outer table were more or less serrated while at inner table they were comparatively straight, whereas the process was speedy and more uniform and complete in the endocranial surface.\(^{14,15,16,17}\) The phenomenon of lapsed union was more common in the Ectocranial surface, Todd & Lyon (1924).\(^{13}\) From this study we concluded that endocranial was more important than ectocranial fusion, similar finding also found from the study by Dr.S.V.Khandare et all it was evident that endocranial union was far better parameter for age determination than ectocranial union as also had been established byTodd & Lyon (1924 & 1925).\(^9\),\(^{11}\)

Conclusion

Ectocranial suture closure cannot be used for age estimation. Lapsed union is a major deterrent for age estimation. Suture obliteration starts earlier on endocranial surface than on the ectocranial. There is some correlation between endocranial suture closure and age upto 40 years, but then after there is no significant correlation. Any attempt to derive a reliable formula to estimate the age from score of suture closure was met with failure for the following reasons: 1) the trend of correlation is neither increasing nor decreasing with age, 2) the sample size is too small to derive a formula, 3) unequal distribution of males and females in the study sample. Although cross-sectional in nature, suture obliteration patterns (totally open, totally closed, partially open, and partially closed) are not temporary progressive stages on an age scale, but rather independent permanent phenomena. Ectocranially: Within the sagittal suture segments, pars lambdica (S4) closes earlier followed by pars bregmatica(S1), pars vertices(S2) and pars obelica(S3).

Endocranially: Within sagittal suture segments, pars lambdica (S4) closes earlier followed by pars bregmatica(S1), pars vertices(S2) and pars obelica(S3).

Endocranial union started at 20-29 age groups but progression is not uniform. Complete closure (mean value > 3.5) of sagittal suture occurs in the age group of 50-59 years. Ectocranial union started in 20-29 age group, but its progression is very erratic. Complete closure (mean value > 3.5) never occurred in ectocranial sutures. Maximum closure occurred in the above 70 years age group.

Abstract

Introduction: Technological advances have revolutionized teaching and learning processes. With the emergence of technologies and need for cost-effective teaching methods have led to the molding of teaching-learning practices. Considering these constant and rapid changes, it is crucial that learners in health care area should be taught with latest knowledge and keep pace with up to date information.

Method: The study design was systematic review and it includes studies from databases of PUBMED, MEDLINE, Cochrane library, SCOPUS, Science direct, and Google scholar (2008-2019). The included studies were focusing on the effectiveness of blended learning on nursing students’ knowledge, skills and attitude and the studies that discussed about other methods of teaching and conducted on other specialty students were excluded.

Result: The data was grouped and analyzed in terms of meta-analysis. Total 21 relevant articles were undertaken. Abstracted information is related to study design, population characteristics, intervention and outcomes.

Conclusion: Blended learning as a teaching method is effective in improving the learning outcomes in terms of academic achievements and performance of nursing students regarding various topics/ procedures. Students also possess favorable attitude towards blended learning. Several studies came out with the conclusions that blended learning is beneficial in improving the learning outcomes.

Key words: Blended learning, nursing students, learning outcomes, attitude

Introduction

All around the world, the online network is considered to be one of the rapidly flourishing and the most accessed technologies. Internet World Stats has shown a diffusion rate in Asia related to Internet is as high as 51.7% with about 40.9% in India.¹ Education in Modern World has been transformed into learning which is, occurring immediately, self-driven and online or it can be said as on the go learning. One of the important milestones developed and established in India is E-learning.²

Considering the constant presence of the Internet everywhere and the benefits it provides, it is obvious that educators would want to take advantage of it for educational purposes.³ Nursing education is most of the time delivered via the traditional approach of lecture as large number of nurses can be given information at the same time. But Nursing Educators nowadays are becoming much aware about the fact that E-learning is an innovative method for delivering education that is learner centered and interactive.⁴

The role of traditional classroom cannot be overlooked in the light of E-learning environment. Thus, a new teaching environment has been suggested by the
researchers named as blended learning to get the best of both worlds of learning, traditional classroom and online learning. Since the advent of blended learning, many institutes have started adopting blended learning so as to provide maximum benefit in the form of best learning environment to the students. [5–7]

**Materials and Method**

**Research design:** Systematic Review

**Inclusion criteria:** It includes the studies related to evaluation of blended learning on nursing students’ knowledge, skills, clinical-decision-making and attitude.

**Exclusion criteria:** The study excludes the studies those discussed about the other teaching interventions on learning outcomes and attitude of nursing students.

This review article was written after doing a systematic review of several studies, journals and articles on web. Ethical issues have been addressed as there is no direct involvement of human subjects in this study. The referred articles and studies have been properly cited in the reference section.

**Data Analysis:** Relevant articles on the topics of effectiveness of blended learning on knowledge, skills and clinical decision-making and those involving views and perceptions towards e-learning were identified by search of significant articles PubMed/Medline, Science direct, SCOPUS, CINAHL, Elsevier and Google scholar.

**Results**

A systematic review was done and total of 157 studies were selected for review, out of which 21 were found to be appropriate. Data was divided into two sections:

**Literature related to effect of blended learning on students’ outcomes**

Out of a total of 14 studies, nine (64.29%) were quasi-experimental studies and among these, 66.7% of the studies have concluded that blended learning was effective in improving knowledge, skills, satisfaction and critical thinking among nursing students. [8–10] The results of two (22.2%) studies have reflected that although there was an increase in students’ achievement scores when exposed to blended learning, but it was not a significant increase. [11,12] One study (11.1%) reported that there was no significant difference in the scores of nursing students’ when compared blended learning and traditional learning method of teaching. [13] Four (28.6%) out of 14 studies were RCTs or true experimental; results of these studies were in favor of blended learning. Although, three of these studies reported a significant increase in learning outcomes within the group but no statistically significant differences were found between the groups. [14–16] The results of a descriptive survey revealed that both classroom and blended methods of teaching are equally effective in improving the learning outcomes of nursing students. [17]

A quasi experimental research using non-equivalent control group design was conducted with the aim to verify the effects of blended learning on the critical thinking and learning satisfaction of nursing students. The content included watching a simulation video on nursing skills, discussion class and application of nursing examples using standardized patients. Convenience sampling technique was used to select a sample of 79 second-year nursing students, composed of 39 students in the control group and 40 students in the experimental group. The findings revealed that blended learning group had a statistically significant high score for critical thinking (t=-6.21, p<.001) and had a high but not statistically significant score for learning satisfaction (t=-.52, p=.683). It was therefore concluded that blended learning in nursing education was more effective in improving the critical thinking of nursing students than the existing nursing education curriculum. [10]

A randomized control trial was carried out to assess the effectiveness of a blended-teaching intervention using Internet-based tutorials coupled with traditional lectures in an introduction to research undergraduate nursing course. The study participants included 112 nursing students selected randomly. The effects of intervention were compared with conventional, face-to-face classroom teaching in terms of knowledge, satisfaction, and self-learning readiness. The results of the study indicated no direct impact on knowledge acquisition, satisfaction, and self-learning readiness among the students in both the groups. However, there was an interaction effect of motivation and teaching method on acquisition of knowledge. The students who were less motivated and received blended learning intervention were able to perform better. The conclusion drawn from the study findings was that the blended teaching method could suit the students according to their degree of motivation and level of self-directed learning readiness. [16]
A descriptive survey was conducted to compare classroom and online student perceptions of learning across the seven affective topics of the course. The study also examined the contribution of various technology-enhanced learning activities to the students’ perceptions of learning. Participants were enrolled in a master’s of occupational therapy professional program in the Midwestern United States. A sample of 25 students attended classroom teaching while 64 students received teaching by blended learning in groups of two. The results of the study indicated that while both formats increased students’ perceived understanding of topics related to affective learning, the blended learning group perceived a significantly greater understanding in four affective topic areas. Furthermore, blended learning students cited reading, online discussions, and unstructured out-of-classroom discussions as contributing to their learning significantly more than the classroom group. The conclusion of the study was that blended learning is an effective method of teaching when coupled with innovative components like discussion forum and availability of offline classes. [17]

Literature related to nursing students’ perception, views and attitude towards e-learning

Out of seven studies selected, six (85.7%) were descriptive studies highlighting the views and perceptions of nursing students towards e-learning or blended learning. The results showed that students had different views for blended learning based on their learning styles. [18] Most of the studies (83.3%) reflected high perception, increased learning satisfaction, positive reactions among students towards e-learning and they also mentioned it to be highly valued. [19–23]

A descriptive study was undertaken with the purpose to examine the students’ learning styles and their views on blended learning. The study was conducted among thirty-four students at Hacettepe University, Ankara, Turkey. The instruments used for the study were questionnaires to identify students’ views on blended learning and Kolb’s Learning Style Inventory (LSI) to measure students’ learning styles. Additional data were gathered from achievement scores of students; and records demonstrate students’ participation to e-learning environment. Results revealed that students’ views on blended learning process, such as ease of use of the web environment, evaluation, face to face environment etc., differ according to their learning styles. Results also revealed that the highest mean score corresponds to face aspect of the process when students’ evaluation concerning the implementation is taken to consideration. The overall findings showed no significant differences between students’ achievement level according to their learning styles. [18]

A quantitative cross-sectional survey was conducted to assess the attitudes of undergraduate nursing students towards e-learning at the University of the Western Cape, South Africa. A sample of 249 nursing students was selected by stratified random sampling technique. A questionnaire was used to assess knowledge and skills and a five-point Likert scale was utilized to assess the attitude of students. The findings revealed that learner satisfaction was influenced by perceived ease of use, gender, and study-year level of respondents. The findings also demonstrate a favorable attitude towards e-learning among nursing students. [24]

Discussion

A study conducted by Bloomfield J. et al. (2010) established a significant increase in Knowledge scores of nursing students. [14] Another study conducted by Hee-Jung J. et al. (2016) also reported that the students who participated in blended learning had a significantly high score for critical thinking. [10]

There were studies that found no significant difference between the scores of nursing students. Ahmad Al Sai et al. (2011) where it was found that there was not any significant difference between the different instructions in improvement scores of the students. The findings were also similar to the results given by Mehrdad N. et al. (2011) where it was also reported that students’ scores in e-learning and lecture method were not having any significant difference. Zhigang G et al. (2014) too reported that that there was a non-significant difference in students’ performance in academics before and after the administration of blended learning. [25–27]

Conclusion

Blended learning in the recent times, has shown a rapid growth and is now being widely used in Nursing education. Several studies in this review came out with a conclusion that blended learning is effective in improving the academic achievement scores and satisfaction of nursing students. Studies also concluded that a positive attitude and views are developed for blended learning among nursing students. Thus, it is recommended to
carry out more extensive research in this area so as to provide maximum benefits to the nursing students which in turn will favor provision of quality patient care as well.

Conflict of Interest- There is no conflict of interest between authors.

Funding- This research received no grant from any funding agency.

Ethical Clearance- Ethical consideration for conducting the study was obtained from the institutional ethical committee (ECR/296/Indt/PB/2019/ISFCP/40).

Development of Submerged Latent Fingerprints on Non-Porous Substrates with Activated Charcoal based Small Partial Reagent

Kavleen Kaur1, Tina Sharma2, Ridamjeet Kaur2

1M.Sc Student, 2Assistant professor, Department of Forensic Science and Toxicology, Chandigarh University, Gharuan, India

Abstract

The practice of using small partial reagent (SPR) for the visual development of latent fingerprints is the preferred choice, particularly concerning wet surfaces. In the present study, non-porous surfaces impinged with latent prints submerged in the water simulating acidic basic and salty water bodies were developed with activated charcoal based small particle reagent method. As evident from the observations, the activated charcoal-based SPR method was able to develop latent fingerprint submerged on the glass surface for up to 11 days and on aluminium substrate, up to 12 days but the quality of fingerprint observed was better on the glass substrate. The shelf life of the activated charcoal-based SPR method was found to be 52 days. The results have shown that the time-lapse of submersion and quality of fingerprint developed are inversely prepositional to each other. Although pond water submerged substrates showed good quality developed fingerprints for a longer period than other mediums but with increasing period of submersion the quality degraded.

Keyword: Forensic Science, Fingerprint visualization, SPR, Small particle reagent, latent fingerprint development.

Background

Fingerprints are formed by chemical and biological components present on the friction ridged skin 1. Different techniques for the visualization of latent fingerprints have been established to obtain clear ridge details 2. The choice of a specific technique for a specific substrate is advisable for the visualization of the latent fingerprint. The fingerprint residue constitute two types of components i.e. water-soluble components and non-water-soluble components depending upon the availability of the above-mentioned component at specific time and substrate, the choice of visualization method should be undertaken. The Visualization of latent fingerprints on wet submerged objects is quite difficult. Most of the previously tested methods demonstrate effective development with dry substrates. The development of latent fingerprints on wet porous substrates is one of the very difficult unsolved scientific problems. The use of Ninhydrin, DFO, and silver nitrate could not detect these latent prints on such surfaces, as the development of these type of fingerprints are mostly dependant on non-water-soluble components and the above-mentioned techniques mostly work with water-soluble components of fingerprints 3-7. In contrast to that, the probability of developing latent marks containing lipid / Non-water-soluble components left on the substrate is quite high concerning the SPR method. Some research studies have attempted to study various technical aspects of developing latent fingerprints on submerged surfaces. From the perusal of literature, it was observed that there is existence of direct correlation between choice of developing reagent, type of latent component(WSC or NWSC) present, type of substrate

on which latent fingerprint is present, time since submersion of latent fingerprint and nature of medium in which the submerged latent fingerprint is studied. The Visualization of latent fingerprints on underwater surfaces had been tried for eccrine rich and sebaceous rich marks with small particle reagent (black and white), Oil Red O, Sudan Black and gentian violet methods and cyanoacrylate on various substrates like glass and metal surfaces [7-9]. The results suggested the positive visualization of sebaceous-rich marks in comparison to eccrine-rich marks. It relies on the adhesion between sebaceous components present in traces and the hydrophobic tails of the reagent. The suspension is generally applied by immersion or spraying methods [10]. Very less work has been carried out on latent fingerprint development on submerged surfaces and effects of different mediums like pond water, salty, basic and acidic water on latent print visualization particularly with activated charcoal-based SPR. Henceforth the main goal of the present research work was to carry out the comparative analysis of small particle reagent to develop fingerprint submerged in different media concerning time-lapse and quality of the fingerprint developed.

Materials and Methods

Working solution formulation: Small particle reagent was prepared using activated charcoal black powder (Kerala Naturals). The suspension solution was prepared by dissolving 5 grams of activated charcoal in 75 ml of distilled water with the addition of 3 drops of surfactant (commercial liquid detergent).

The study was conducted in the month of summer season with a temperature range between 25°C to 40°C and relative humidity between 15-40%.

Simulation of Sea Water:
23.39 grams of NaCl was dissolved in 1 liter of distilled water. To the prepared solution, KCl (0.715grams), MgCl₂ (10.633 grams), CaCl₂ (1.455grams), Na₂SO₄ (4g) and Tris base (2.4 g) was added [6]. The solution was stirred with the help of magnetic stirrer for 1 hour and the pH of the solution was maintained 8 to 8.2 throughout the experiment.

Simulation of lake water Acidic:
To acidic simulate lake water pH of 11 distilled water was maintained near 5.5 to 7 with the help of HCl and NaOH solutions

Simulation of lake water Basic:
The deeper lakes with stratification constitute pH range slightly higher than neutral freshwater. To simulate lake water pH of 11 distilled water was maintained near 7.5 to 9 with the help of HCl and NaOH solutions

Muddy water:
The muddy water was collected from a natural pond, Mohali Punjab with pH 6

Sample Preparation: In the present study, five individuals were asked to deposit latent fingerprints on non-porous substrates like aluminium foil and glass slide. The fingerprints were immersed in different mediums like salty water, muddy pond water, acidic and basic lake mediums. These mediums were used to simulate the different conditions with respect to water bodies like the sea, ditches, drainage, etc where the offender could try to dispose of the evidence.

Visualization of Latent Fingerprints: 20 sets of each substrate i.e glass slide and aluminium foil containing latent fingerprints were immersed in 4 mediums. Each substrate was taken and sprayed with SPR formulation every day till viable results were available. The SPR was allowed for 1 min to react with the wetted latent fingerprint, which was then washed with distilled water to remove excess reagent then dried for photography. The composition of the developing reagent was tested under laboratory conditions. The shelf life of regent was observed to be about 52 days.

Results
The fingerprint score was accessed using (Soltyszewski et al. 2007) fingerprint quality assessment scale [11]. Fig-1 showcased the score with respect to the quality of fingerprints obtained. As evident from the observations, among all the mediums the best results were obtained in muddy medium on by aluminium foil followed by a glass slide. The SPR based reagent gave results on glass slide up to 5 days and on aluminium foil 8 days though a significant decline in quality of fingerprints was observed due to deposition of mud on print in subsequent days. The shelf life of SPR reagent was observed to be 52 days.
Simulated Sea water

Graph-1 shows very good quality fingerprints up to 3 days on aluminium foil followed by good quality fingerprints up to 5th day. Poor quality fingerprints were observed on the 6th to 7th day. On 8th-day bad quality fingerprints were observed followed by blur fingerprints on 10 and 11th day of observation. No fingerprints were observed on the 12th day.

Fig 1- Quality of Fingerprints depicted grade wise (a) Grade 5 (very good quality) (b) Grade 4 (Good quality) (c) Grade 3 (Poor quality) (d) Grade 2 (Bad quality) (e) Grade 1 (Blur quality)
On the glass substrate, high-quality marks were developed up to 2nd day of submersion in the medium. Poor to bad quality marks were obtained from 3rd to 4th day of submersion and blur fingerprints were observed between 5th day onwards until day 8. No fingerprints were observed on 9th day.

Salty water has a destructive effect on the quality of fingerprints due to its salinity thus the quality of fingerprint declined rapidly with an increasing period of submersion. So clear ridge density can be observed till day 5 in case of aluminium and day 2 in case of the glass substrate.

**Simulated Lake water Acidic**

Graph- 2 shows very good quality fingerprints were developed on aluminium foil up to 5 days of submersion, followed by the good quality on day 6th, poor quality on day 7 and blur fingerprints were obtained on day 8. No fingerprints were observed on the 9th day onwards.
On glass slide very good quality was developed up to 2 days of submersion in the medium and poor and bad quality fingerprints were developed between 3rd – 4th days. Blur fingerprints were recorded on the 5th -6th day. After 6th day no fingerprint visualization was observed. The quality of the fingerprints declined significantly with an increasing period of submersion because of the destructive effect of acid. Aluminium showed good viable results till day 6 in contrast to the glass substrate which showed comparable fingerprints only up to 2nd day of observation.

Simulated Lake water Basic

Graph-3 shows blur fingerprint Visualization up to 3 days of submersion and it was recorded that the aluminum foil degraded in the medium because of the corrosive action of NaOH.

![Graph 3- Developed fingerprint quality index depicted till day 11 on aluminium and glass surfaces submerged in simulated basic lake water](image)

Good quality fingerprints were obtained up to the 4th day of submersion followed by the good quality on the 5th day. Poor and bad quality fingerprints were observed on the 6th to 7th day. Very blur fingerprints were observed on the 7th day. Afterward, no fingerprint Visualization was possible. On the glass surface, high-quality fingerprints were obtained up to 4th days of submersion. No comparable fingerprints could be obtained on aluminium foil.

Pond water

Graph-4 shows the comparative analysis of fingerprints concerning the number of days successful Visualization of the latent fingerprint was observed. Out of the four mediums, pond water submerged latent fingerprints on aluminium substrate showed very good quality fingerprints up to 5 consecutive days, followed by good quality fingerprints up to 9th day and 10th day showed poor quality fingerprint. Although fingerprints got developed on 11th and 12th day yet very bad quality was observed. In the case of glass substrate high-quality fingerprints were observed up to 4th day, 5th-day good quality a shown in Fig-9 followed by 6th-8th day poor quality fingerprints were observed. Very blur fingerprints were observed on 10 and 11 days, yet on 12th day no fingerprint was observed.
Graph 4- Developed fingerprint quality index depicted till day 11 on aluminium and glass surfaces submerged in Pond water

SPR reagent on aluminium foil gave high quality marks up to 8th days as shown in fig and

Glass surface gave fairly good results up to 4th days as shown in Fig-1 with clear distinct ridges and medium quality marks were obtained from 6-8 days.

**Discussion**

The present examination uncovered the possibility of developing scores 4 and 5 quality fingerprints from submerged substrates. Usually, the weapon of crime is disposed of in nearby water bodies in order to destroy the possibility of identification. (Soltyszewski et al., 2007). In this present work, an SPR based reagent has been used to develop latent fingermarks on non-porous substrates soaked in a different medium, (muddy water, salty water medium, acidic medium and basic medium). As evident from the observations, among all the mediums the best results were obtained in pond water from aluminium foil followed by a glass slide. The SPR based reagent gave good quality results on glass slide up to 5 days and on aluminium foil 8 days. Afterward, though a significant decline in the quality of fingerprints was observed due to the deposition of mud on print in subsequent days.

As the time-lapse increased, the quality of latent fingerprints developed with SPR decreased. It may be because of the degradation of fatty deposits on latent fingerprints with a persistent stay in the water (Cadd et al., 2015). Basically in the SPR method lipid components of latent fingerprints are utilized to develop visualized fingerprints (Girod et al., 2012). The small particles of charcoal in the presence of surfactant is adsorbed on the fatty residues of latent prints thus visualizing latent prints, with time these deposits deteriorate thus resulting in bad quality fingerprints. Soltyszewski et al., 2007 used different methods to visualize latent fingerprints on submerged surfaces. This study utilized aluminum powder, ferromagnetic powder, and superglue fuming for the development of fingerprints with aluminum. On glass slides submerged in river, sea, tap, or distilled water and still alike inferences were drawn regarding the relationship between submersion time and quality of developed fingerprint despite the method used. The study also mentioned the significance of temperature as decreased temperature resulted in good quality fingerprints for a longer period of time.

Trapecar 2012 conducted a similar study on glass and metal substrates submerged in stagnant water with aluminum powder, ferromagnetic powder, and CA, the study concluded cyanoacrylate fuming as the best method for fingerprint visualization. In contrast to Trapecar 2012, the present study showed charcoal-based small particle reagent is the best method for visualization.
of fingerprints on aluminium and glass substrates submerged in pond water. The nature of water has a direct effect on the development process of fingerprints, concerning different substrates. Highly saline water causes serious damage to latent fingerprints which can be inferred from the quality of the prints developed. In the present study, good quality prints were observed up to day 5 on the aluminium substrate in comparison to the glass which showed good results only for two days.

Conclusion

The likelihood of developing latent fingerprints on submerged surfaces has been validated in the present research study with activated charcoal-based Small particle reagent. The study validated the relationship of time-lapse and quality of fingerprints, as with increasing time duration the quality of fingerprints deteriorates. The best results for a longer duration were observed on pond water. The acidic and basic medium lake water showed mixed results and suggested a straight association between the substrate on which latent fingerprint is being developed and the pH of the water. With increasing pH, the clarity of fingerprints on aluminium foil decreases, in contrast to that, with decreasing pH quality of latent fingerprint visualization increases. The results suggested the positive visualization of sebaceous-rich marks in comparison to eccrine-rich marks and studies also revealed the clarity of marks is directly correlated to the time since submersion and type of substrate on which latent fingerprints are present.

GC-MS Analysis of Methanol Extracts of Five Toxic Plant Seed For Detection of Bioactive Compounds

Kiran Kumari1, Saurabh Bhargava1, Rajvinder Singh

1PhD Research Scholar, 2Assistant Professor, Department of Genetics, Maharshi Dayanand University, Rohtak, Haryana, India

Abstract

The present work was carried out to explore the qualitative analysis of bioactive phyto-constituents present in methanolic extracts of five toxic plant seeds by using gas chromatography-mass spectrometry. The analysis of extracts revealed the presence of the different biologically active compounds including alkaloids, glycosides, flavonoids, phenols, fatty acid, ester, epoxide, steroids, and protein etc. Forensic toxicological chemistry deals with the chemistry and analysis of various types of poisons including plants. Diagnosing plant poisoning especially their seeds can be difficult and must be quickly done. In conclusion, the recovery of various toxic and therapeutically constituents could be helpful for forensic toxicologist.

Keywords: GC-MS, plant extracts, NIST, formulation

Introduction

Being habitat of wide diversity of traditional herb and herbal products, India is rightly called as the botanical garden of the world. There are approximately 4,00,000 species of vascular plants be present on the Earth. They produce thousands of metabolites but actual composition, function and supplementary other utility of many such phytochemicals are yet to be investigated. Phytochemicals are plant produced chemical compounds that are generally helpful against various types of pathogens. Some of these can act as poison be used as poisons whereas others for medicinal purpose. Plants synthesize a wide variety of medically (antibacterial and antifungal etc) important chemical compounds, which are classified as primary metabolites and secondary metabolites. They also show a number of protective functions for human consumers. These bioactive constituents may also act as cardiotoxic and neurotoxic on human beings and livestock. In the last few decades, the GC-MS has been considered one of the most efficient, easiest and fastest technique to identify the bioactive constituents in both plant and non-plant species. The analyses of bioactive constituents in plant material can play an important role in the development, modernization and quality control of herbal formulations. Considering a valuable addition to plant sciences and pharmacology, the current study was attempted to generate GC-MS based database of photochemicals in methanolic extract of seed of samples of Thevetia neriifolia, Jatropha curcus, Abrus precatorius, Datura inoxia, and Ricinus communis from Rohtak district of Haryana, India. This study is supposed to be a valuable addition to the literature based on the GC-MS analysis of bioactive compounds in toxic plant seed.

Materials and Methods

Collection and identification of plants: Five toxic plant seed samples of i.e. Thevetia neriifolia, Jatropha curcus, Abrus precatorius, Datura inoxia, and Ricinus communis, were collected during July- October 2018 from Rohtak district of Haryana. These plants were identified as based on their morphological features as well as molecular signature by using ITS marker in cases of Thevetia neriifolia (Accession No MH777018), Jatropha curcus (MH923185), Abrus precatorius (MH756599), Datura inoxia (MH762134) and by using rbcL marker Ricinus communis (Accession No-MK672874). All voucher specimens were deposited in the forensic chemical laboratory of the Department of Genetics, M.D. University Rohtak, Haryana (India).
Preparing of Extracts: All the seed samples of these toxic plants was washed individually with running water and left to dry at room temperature for about a week. Seeds were crushed to powder form and about 60 gram was extracted in 200 ml methanol in Soxhlet apparatus at a temperature of 60ºC. Extracts were evaporated to dryness in rotary evaporator and stored at 4ºC for further analysis.

**GC-MS of Extracts**

Phytochemical analysis of five toxic plant seed extracts was carried out using a GC-MS analyzer (BRUKER SCION 436-GC SQ). Extracts were dissolved in methanol (GC grade) and filtered through Whatman TM filter device, pore size 0.2 µm. Helium (99.99%) was used as a carrier gas, at a flow rate of 1 ml per minute in split mode. Restek Rtx®-5 capillary columns (Crossbond® 5% diphenyl/95% dimethyl polysiloxane) with 30 m length, 0.25 µm df and 0.25 mm ID column was used for separation of phytochemicals. Exactly 2 µL of the sample was injected in a column. The injector temperature was 280ºC. Oven temperature started at 70ºC and held for 2 min and then was raised at a rate of 70ºC per minute up to 320ºC; hold for 1 min. The temperature of ion sources was maintained at 250ºC. The mass spectrum obtained by electron ionization at 70eV and detector operates in scan mode 30 to 500 Da atomic units. Total running time was 30 min including 3 min solvent delay.

**Results and Discussion**

Results of many phytochemical compound in the seeds of Thevetia neriifolia, Datura inoxia, Abrus precatorius, Jatropha curcus, and Ricinus communis (Figure 1-5). The interpretation of mass spectra identified bioactive compounds by using the database of the National Institute of Standards and Technology (NIST) installed in GC-MS library.
Figure 2: Datura inoxia

Figure 3: Abrus precatorius

Figure 4: Jatropha curcus
GC-MS revealed several bioactive compounds in plant seeds materials some of which were used for therapeutic purposes. These bioactive compounds included 9,12-Octadecadienoic acid, ethyl ester (linoleic acid) having a properties of hypocholesterolemic, 5-alpha reductase inhibitor, antihistaminic, insectifuge, anti-eczemic, and anti-acne), antimicrobial properties has been reported of compound 4H-Pyran-4-one, 2,3-dihydro-3,5-dihydroxy, benzaldehyde, 4-Hydroxy-3-Methoxy, dodecanoic acid, octadecanoic acid. Some compounds like tetradeanoic acid hexadecanoic acid, methyl ester and n-Hexadecanoic acid having properties of antioxidant, cancer-preventing, nematicide, larvicidal and repellent activity, pesticide antiandrogenic, hemolytic and antifungal 8-11. Some of the compounds detected by GC-MS of plant extracts were, 3-Butanedione synonym diacetyl /di methylglyoxal potential toxic organic compound. It has been associated with several diseases includes Crohn’s disease, bronchiolitis obliterans, ulcerative colitis, nonalcoholic fatty liver disease, inborn metabolic disorders (celiac disease). All of this toxicity, this compound has been commonly used as a flavoring agent in artificial butter, and dairy fermented products at the current level in beverages (5 ppm) and food (50 ppm). 12. Literature reported various health issues with 2, 3-butanedione monoxime compound when it enters especially a concern when entering the central nervous system then increase blood pressure with increased heart rate as a result of cardiac arrest 13. Another important compound has detected 2(3H)-Furanone, 5-methyl which is a lactone (Butenolides) category commonly used in antimicrobial, antiproliferative, anti-inflammatory activities 14. Besides these therapeutic activities, a toxicological profile had been found in the case of Sesquiterpene lactones which induce toxic syndrome when it directs contact of the dermis in human and non-human 15. Dodecene compound shows toxicity at a high concentration that irritates eyes, nose, throats, and CNS depression when ingested or inhale had reported 16. A toxicity relevancy data of 2-Pentanone, 4-hydroxy-4-methyl with direct contact may cause sensation of pain, slight dizziness, burning, and itching irritation, by inhalation irritation, by inhalation neurological effects, and strong odor sensation reported 17-21. Literature had mentioned another saturated fatty acid such as myristic acid/1-tetradecanoic acid components of phospholipids of the plasma membrane, so even a small quantity of fatty acid is lost as a cell sloughing 22. The acute toxicity of myristic acid has been found in rats with the lethal dose > 5g/kg b.w. 11-12. Literature observed when it administered in a higher dose, the sign of toxicity had been observed such as depression, excessive salivation and serosanguineous discharge from the muzzle and eyes 22. In 1998, JEFCA released a current safety intake value of 1.2 µg/kg b.w./ day in the USA and 2.6 µg/kg b.w./day in Europe.

Misidentification of the nature of compounds that produce some toxicity reported in earlier investigation, most of the secondary metabolites synthesize in plants yielded toxicity in various ways including pyrrolizidine alkaloids, some unusual amino acids (canavanine...
and azetidine-2 carboxylic acid) and some analogs of these amino acid such as arginine and proline which is non-protein amino-acids that included into proteins but are present as free forms or act as protective defensive substance\(^5\). Phorbol esters are a tetracyclic diterpenoid that generally role to promote the action of diacylglycerol, tumor activities and also play a role of protein kinase activator which regulates different signal transduction pathways and other cellular metabolic activities discussed in\(^23\). Octadecanoic acid synonym stearic acid is a long-chain fatty acid with 18 carbon backbones. At high concentration of stearic acid gave a direct correlation to plasma cholesterol and fibrinogen that more promote thrombogenesis than oleic acid. Hence mortality caused due to cardiomyocyte which is a concentration dependence manner\(^24-27\). Besides the toxicity of the steric acid, it is used as a flavoring agent safety issues at the current level intake of 31 \(\mu\)g/kg/day in U.S.A. and 0.97 \(\mu\)g/kg per day in Europe\(^28\). According to HSDB online lauric or dodecanoic acid, a short-chain saturated fatty acid at dose 4.64 and 10.0 \(\mu\)g/kg in mice observed depression, mucoid diarrhea, excessive salivation, oily, unkempt fur and serosanguineous discharge from the muzzle and eyes\(^17\). Beside toxicity, lauric acid is in detergent and flavor purpose but it is quite safe to use 21 \(\mu\)g/kg b.w. per day in the USA and 9.9 \(\mu\)g/kg body weights per day in Europe\(^28\). Oleic acid is a C18 cis-monounsaturated fatty acid. It is highly absorbed and stored into adipose tissues or undergoes \(\beta\)-oxidation. For oleic acid catabolism, an additional isomerization pathway is required. It is mainly transported via the lymphatic system and it is reported that oleic acid can also penetrate the skin of rats. Since oleic acid is highly absorbed, it is poorly excreted\(^2\), \(\text{LD}_50\) in a rat of 74 \(\text{g/kg}\)\(^{21}\). Administration of oleic acid to rats up to 21.5 \(\text{mL/kg}\) caused neither deaths nor gross lesions at necropsy. However, signs of toxicity, including depression, excessive salivation, diarrhea and serosanguineous discharge from the muzzle and eyes, could be observed\(^29\). Rats that received a cream formulation containing 5 % oleic acid at the dose of 5 \(\text{mL/kg}\), showed weakness and colored urines and feces\(^30\). Another important fatty acid, 2-octanone produced from castor oil through a cracking process. During the process of cracking the ricinoleic acid is cut in two molecules: sebacic acid and 2-octanol Soluble in a most organic solvent or as a raw material as flavoring and fragrance purposes, paint coating, inks adhesives, lubricant, and fuels. Volatile compound combustible, by inhaling cause cough and sour throat, dry skin, red eyes, by ingestion feeling in burning sensation\(^31\). Literature mentioned castor oil contains 90% ricinoleic acid and their acute toxicity 0.3-3 \(\text{mg/animal}\) in guinea pigs which showed pro-inflammatory effects\(^32\). A case of allergy due to the presence of propylene glycol ricinoleate in lipstick has reported in the literature. In this case, the main constituents of allergy were confirmed by the positive reaction with a patch test to ester gum and ricinoleic acid presence in the lipstick sample. On the other hand, ricinoleic acid and 12-hydroxystearic acid are being to be considered the main constituents of allergens in hydrogenated castor oil and castor oil, some impurities might be risky and reason for definite allergens\(^33\). Methyl Hexyl Ketone form of colorless transparent liquid derived from castor oil by oxidation of nitric acid 2octanol to 2-octanone followed by further oxidation to a carboxylic acid\(^34\). This compound showed low toxicity when it directs contact with skin may cause defatting and irritation of the skin, by inhalation, may produce mild symptoms of eye, nose, and throat. Besides this toxicity, literature reported various application of esters in cosmetics, lubricants, food flavoring, fragrance and detergents, etc\(^35-36\). 

### Conclusion

Present work generated a data of bioactive constituents detected by GC-MS in of five toxic plant seeds. The study reports presence of some important components could be useful for the researcher working in the fields of pharmaceutical industries, environment science, and toxicology sciences including forensic toxicology.

**Acknowledgment:** Acknowledgment: We are thankful to the faculty of Aryabhata Central Instrumental Laboratory, M.D.University, Rohtak for analyzing the samples by using GC-MS.

**Author Contributions:** Equal contribution of all the authors in analysis and interpretations.

**Funding Information:** No Funding was received for this study.

**Conflicts of Interest:** No conflict of interest.

**Ethical Clearance:** No ethical issues involved as the study was analytical and did not violent any ethical principles.

Psycho Social Factors in Adolescent Suicides- A Psychological Autopsy based Study

Krishna Kumar Siva Sankara Narayanan1, Muthukumar Duraiappa2, Prajith Thekke Madathil1

1AssistantProfessor; 2Senior Resident, Department of Forensic Medicine, Govt.Medical College Kozhikode, Kerala

Abstract

BACKGROUND: Suicides among adolescents in India have become an alarming problem, especially among students. This study is to find out the recent and remote psychosocial and disease related stress and adverse life events that could have led these young people to commit suicide.MATERIAL AND METHODS: It is a Cross sectional study on adolescent suicides with history and postmortem findings being consistent with suicideconducted at Department of Forensic Medicine, Government Medical College, Kozhikode, Kerala state .FINDINGS: Informants of 55 cases were interviewed with the help of questionnaire. Most of the suicide victims belonged to upper middle class category. Maximum number of suicidal deaths are seen in victims having 1 sibling, living in a nuclear family. History of suicidal deaths among the family members of the suicide victim is seen in 7 out of 55 cases. Mood of maximum number of cases before the suicide attempt in the recent past, say 2 weeks, was depressed. Maximum number of suicide attempts were seen in the evening, mostly after the school and college working hours. Academic performance of 40.0% cases was average. 10.9% were socially isolated. 14.5% had a history of previous suicide attempt. 14.5% had shown anger, aggression and impulsivity in the recent past, say 2 weeks. CONCLUSION: The main purpose of this study is to find out the stressors that could have led these adolescents to commit suicide and to suggest a few strategies to prevent the suicides in the future.

Keywords: Adolescents, suicide, depression, psychosocial stressors, psychological autopsy.

Background

Adolescence is the transitional phase of growth and development between childhood and adulthood. Adolescent suicides in India have become an alarming problem, especially among students. Severe competition and fierce expectation from the parents, teachers, family and friends have created an enormous stress on them. Psychological autopsy studies have been used to construct an overall view of suicide by collecting all available relevant information on the victim’s life preceding his or her death.

The present study is about suicidal deaths among adolescents (aged 10 to 19 years) and pattern of life events preceding their deaths. This study is to find out the recent and remote psychosocial and disease related stress and adverse life events that could have led these young people to commit suicide and to suggest a few suicide prevention strategies.

Material and Method

It is a Cross sectional study on dead bodies in the age group between 10 to 19 years of both sexes with history and postmortem findings being consistent with suicideconducted at Department of Forensic Medicine, Government Medical College, Kozhikode, Kerala state during one year (1st June 2017 to 31st May 2018). To find out the life events and stressors preceding the suicide, the person(s) and the policemen/ the Investigating Officer, who accompany the dead body are interviewed first. If they are not aware of the circumstances, then the contact number and residential address of the any of the victim’s parents, spouse, close friends, close relatives or colleagues are collected and interviewed later with the help of questionnaire.

Findings

Informants of 55 cases were interviewed. Data were analysed using SPSS-18 software and the results are as follows.

Table 1: Socioeconomic status:

<table>
<thead>
<tr>
<th>Socioeconomic class</th>
<th>Number of suicides</th>
<th>Percent</th>
</tr>
</thead>
<tbody>
<tr>
<td>Upper class</td>
<td>4</td>
<td>7.3</td>
</tr>
<tr>
<td>Upper middle class</td>
<td>19</td>
<td>34.5</td>
</tr>
<tr>
<td>Lower middle class</td>
<td>15</td>
<td>27.3</td>
</tr>
<tr>
<td>Lower class</td>
<td>17</td>
<td>30.9</td>
</tr>
<tr>
<td>Total</td>
<td>55</td>
<td>100.0</td>
</tr>
</tbody>
</table>

Most of the suicide victims belonged to upper middle class category, accounting for 34.5% (19 out of 45 cases), followed by lower class category accounting for 30.9% (17 out of 55 cases) and lower middle class category accounting for 27.3% (15 out of 55 cases). Least number of suicidal deaths belonged to upper socioeconomic status, accounting for 7.3% (4 out of 55 cases).

Table 2: Number of siblings:

<table>
<thead>
<tr>
<th>Number of siblings</th>
<th>Number of suicides</th>
<th>Percent</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>3</td>

</tr>
<tr>
<td>4</td>
<td>1</td>
<td>1.8</td>
</tr>
<tr>
<td>Total</td>
<td>55</td>
<td>100.0</td>
</tr>
</tbody>
</table>

Maximum number of suicidal deaths are seen in victims having 1 sibling, accounting for 49.1% (27 out of 55 cases) and all those who had 1 sibling was living in a nuclear family, followed by victims having 2 siblings, accounting for 36.4% (20 out of 55 cases). Least number of suicides were seen in victims who have 3 or more siblings and those who live in joint family.

Table 3: Mood before suicide:

<table>
<thead>
<tr>
<th>Mood</th>
<th>Number of suicides</th>
<th>Percent</th>
</tr>
</thead>
<tbody>
<tr>
<td>No significant change</td>
<td>24</td>
<td>43.6</td>

</tbody>
</table>

Maximum number of suicide attempts were seen in the evening (from 06.01 pm to 12.00 am), mostly

Suicides in relatives who were living with the deceased (family members):

History of suicidal deaths among the family members of the suicide victim is seen in 7 out of 55 cases, accounting for 12.7%. Out of which, elder sibling (brother) of 6 adolescents had committed suicide within the past 1 year. Father of 1 adolescent female committed suicide by hanging 1 year back.
after the school and college working hours (19 out of 55 suicide attempts, accounting for 34.5%), followed by afternoon from 12.01 pm to 06.00 pm (18 out of 55 cases, accounting for 32.7%). 13 out of 55 cases accounting for 23.6% attempted suicide in the morning from 06.01 am to 12.00 am, accounting for 23.6%. 2 out 55 cases, accounting for 3.6% had attempted suicide in the early morning from 12.01 am to 06.00 am. The time of suicide attempt was unknown in 3 out of 55 cases, accounting for 5.5%.

**Table 5: Academic performance:**

<table>
<thead>
<tr>
<th>Academic performance</th>

<td>89.1</td>
</tr>
<tr>
<td>Total</td>
<td>55</td>
<td>100.0</td>
</tr>
</tbody>
</table>

6 out of 55 cases, accounting for 10.9% were socially isolated. Among these, one of the victims’ parents got divorced and were living separately; another one of the victims’ parents were working in different districts of Kerala and was under the care of grandfather. Other 4 victim’s fathers were working in Gulf Countries and were under their mother’s care. All 6 of them were school students with history of reduced rapport with their friends.

Death of family member, friend or relative during the past 1 year:

History of death of family member, friend or relative, during the past 1 year was seen in 10 out of 55 cases, accounting for 18.2% of suicides. 1 Close friend of 6 victims died during the past 1 year, out of which 4 of them committed suicide and 2 died in a road traffic accident. 1 Elder brother of 2 suicide victims committed suicide within the past 1 year. 54 Elder sister of one suicide victim died due to septic abortion within the past 1 year. Father of 1 of the suicide victims died following acute myocardial infarction within the past 1 year.

Expressing suicidal ideation verbally:

12 out of 55 suicide victims had expressed their suicidal ideation to any one of their family members or friends, within the past 1 month, accounting for 21.8% of suicides.

Previous suicide attempt:

8 out of 55 cases, accounting for 14.5% had a history of previous suicide attempt.

Subjects showing Anger, aggression, and impulsivity in the recent past:

8 out of 55 cases, accounting for 14.5% had shown anger, aggression and impulsivity in the recent past, say 2 weeks.

Discussion:

In this study, contrary to previous studies most of the adolescents who committed suicide, belonged to upper middle class category, accounting for 34.5% (19 out of 45 cases). In a previous Indian study, Low socioeconomic status was reported in 50 to 66% of suicide victims. A study at a tertiary care hospital in India among children and adolescents revealed that most of the suicide attempters were females (60.4%), from nuclear family, middle socioeconomic status and Hindu by religion. Maximum number of suicidal deaths are seen in adolescents having 1 sibling, accounting for 49.1% (27 out of 55 cases) and all those who had 1 sibling were living in a nuclear family.

In this study, relatives of 2 out of 55 suicide victims had significant psychiatric illness, accounting for 3.6%. The mother of both of these suicide victims had depression and they were on treatment. Suicidal
behaviour is highly familial. Relatives of persons who committed suicide are more likely to commit suicide. But results of adoption studies suggest that genetic factors are the determinants of familial concordance for suicidal behaviour. History of suicidal deaths among the family members of the suicide victim is seen in 7 out of 55 cases, accounting for 12.7%.

Mood of maximum number of adolescents before committing suicide was depressed in the recent past, say 2 weeks. 28 out of 55 suicide victims had depressed mood, accounting for 50.96%. There are studies which state that most of the suicide victims would have got depression in the recent past and they would have felt hopeless and many have a comorbid substance abuse or personality disorder. Maximum number of suicide attempts were seen in the evening (from 06.01 pm to 12.00 am), mostly after the school and college working hours (19 out of 55 suicide attempts, accounting for 34.5%). This is similar to a previous study, which states, majority of the young people who attempt suicide were females (81.6%), who attempted suicide between evening and midnight. Academic performance of 22 out of 55 cases was average, accounting for 40.0%. Only a few studies on Indian adolescents are available regarding the association of academic difficulty with suicidal ideation. They show that adolescents face multiple stressors such as criticism from the parents, teachers, peers, interpersonal problems, high parental expectations and academic worries. These stressors are not only faced by adolescents with academic difficulty but also by academically achieving adolescents.

4 out of 55 cases had history of depression and were on treatment, accounting for 7.3% of suicides. One of them was under irregular treatment. Depression is one of the most important predictors of suicide attempt. In a study conducted among 6 primary care settings including public and private in Kerala revealed an overall prevalence of 27.2% of depression and was higher in women. Past suicide attempt was identified in 6.9% of all out patients; higher in women than in men. Among the patients diagnosed to have depression, 21.3% had previously attempted suicide. 6 out of 55 cases, accounting for 10.9% were socially isolated. Previous studies state, two factors, namely social capital and social cohesion are very important in the development of adolescents. Studies have found that when adolescents have lower levels of social cohesion, they report poor mental status, higher crimes including suicides, homicides and even sex offences. In this study, history of death of family member, friend or relative, during the past 1 year, was seen in 10 out of 55 cases, accounting for 18.2% of suicides. In a previous American study, the logistic regression analyses indicated that family history of suicidality increased the risk of suicidal ideation and suicide attempts in children by 1.4 to 2.7%. Also, the offspring of parents who died by suicide, accidents and natural deaths showed higher rates of major depression and the children of suicide victims showed a higher rate of alcohol or substance abuse disorders. The level of complicated grief was higher in youth whose parents died through accidents than in those whose parents died by sudden natural death.

In this study, 12 out of 55 suicide victims had expressed their suicidal ideation to any one of their family members or friends, accounting for 21.8% of suicides. Previous studies state, Communication of suicidal intent is an event that often precedes suicidal behaviour (Robins et al. 1959, Barraclough et al. 1974, Kovacs et al., 1976, Wolk - Wasserman 1986, Isometsa et al. 1994, Handwerk et al., 1998, Zhou & Jia, 2012). It was evident that approximately half of the suicidal victims (48.8%) had verbally expressed their suicidal feelings to at least one of their family members. 8 out of 55 cases, accounting for 14.5% had a history of previous suicide attempt. A study found out that 5.1% of suicidal victims had actually attempted suicide, more in females than in males. Another study at Bangalore revealed that 7.69% of children had a history of previous suicide attempt. Suicide attempts in adolescents are at least twice as common in females than males. In this study, 8 out of 55 cases, accounting for 14.5% had shown anger, aggression and impulsivity in the recent past, say 2 weeks. The impulsive-aggressive behaviour is a high risk factor for suicide among adolescents. Adolescents with aggression and conduct disorders may be suicidal even in the absence of depression (Brent et al., 1993). Impulsivity increased the risk of suicide in the presence of negative life events. Higher impulsivity is more dangerous in young people.

**Conclusion**

The main purpose of this study is to find out the stressors that could have led these adolescents to commit suicide and to suggest a few strategies to prevent the suicides in the future. Family discord, poor communication, disagreements, lack of cohesive values and goals, and irregular routines and activities are common in suicidal children and adolescents who often
feel isolated within the family. Family intervention aims to decrease such problems, improve family problem-solving and conflict resolution, and thereby reducing the suicide among adolescents. Psychoeducational approaches can help parents clarify their understanding of childhood and adolescent suicidal behaviour, identify changes in mental state that may herald a repetition, and reduce the extent of expressed emotion or anger.

Awareness of Most Commonly Used Drugs in Dentistry Inducing Teratogenic Effects among Dental Practitioners

1Professor, 2HOD & Professor, 3. Reader, 4Senior Lecturer, Department of Oral Medicine and Radiology, Thai Moogambigai Dental College & Hospital, Chennai, 5Student-Intern, Thai moogambigai Dental College & Hospital, Chennai

Abstract

Aim: The aim of the study was to assess the awareness of most commonly used drugs in dentistry inducing teratogenic effects, among dental practitioners. Birth defects may be caused by many factors such as physical conditions, teratogens, environmental exposures, genetic defects, etc., Although prescription drug use is common during pregnancy, the human teratogenic risks are undetermined for more than 90% drug treatments approved in the USA during the past decades. A particular birth defect may have its origins through multiple mechanisms and possible exposures including medications. A specific chemical process may result in different outcomes depending upon factors such as embryonic age at which a drug is administered, duration and dose of exposure and genetic susceptibility. Estimating the risk of fetal malformations attribute to the use of medications is difficult and perception of risk by health professionals will impact their counseling and treatment of patients. Pregnancy is a unique physiologic condition and importantly specific drugs like folic acid use may have several benefits for pregnant mother. The patient should maintain a good gynecologist-patient-Dentist communication. For example a woman with two spontaneous abortions would be expected to be skeptical of any drug therapy in her next pregnancy and by communicating this to physicians and respective clinician. She may influence the physician and dentist perception. The clinician should be aware of all the newer drugs and its teratogenic effects. For health professionals this includes awareness of specific drug information and sources that provide realistic descriptions of risk beyond product monographs. A greater focus on this aspect may act to balance Risk perceptions. Physicians and dentists need to weigh risks and benefits of drug prescribing to pregnant patients based on the available knowledge.

Keywords: Pregnancy, trimesters, medications, teratogenic effects, Dental practitioners.

Introduction

Pregnancy is a most important and special physiologic condition. The drug treatment and prescription of the drugs is a special concern in pregnancy because the physiology of the pregnancy affects the pharmacokinetics of the medications used[1]. Certain medications can reach the fetus and cause harm to the fetus[1]. Pain is a main symptom of the upcoming complexity. Relieving a pain of the patient is the main duty of the doctor. We shouldn’t ignore the patient just because the patient is pregnant. The complete ignorance of pharmacological treatment in pregnancy is not possible because some women enter pregnancy with certain medical conditions that requires episodic treatment[1]. Management of pregnant women in dental office is challenging. The clinician should know the proper prescription and should give proper treatment according to their medical history and trimester[1]. In pregnancy, drug treatment presents a special concern due to the threat of potential teratogenic effects of the drug that causes damage to the fetus[1,2]. History dates back, pregnant woman who ingested thalidomide gave birth to children with phocomelia, but the same drug is now being used for several oro-erosive lesions. After all these dangerous events happened in 1979[1,2]. Food And Drug Administration developed a system that determined the teratogenic risk of drugs by considering quality of data from clinical and human studies, the pregnancy categories are A,B,C,D, X[1]. The dentist should be aware of prescribing the drugs to the pregnant woman is a prime concern[1,2,3,]. The patient should maintain good gynecologist-patient-Dentist communication. The communication helps to avoid more problems and that could enhance effective treatment.
Materials and Methods

A questionnaire based study was conducted in about 60 dental practitioners who had clinical experience of over 10 years. The study was conducted with their complete concern knowledge. The questions were got approved from the department of oral medicine and radiology- Thai moogambigai dental college and hospital. All practitioners in this study completed a paper based questionnaire consisting of 10 questions with 4 options. The questionnaire was printed and distributed to Thai moogambigai dental college practitioners and Maduravoyal dental practitioners. In this study 35 female practitioners and 25 male practitioners were participated. Particularly 47 specialized practitioners and 13 general practitioners. This study was conducted in practitioners who had clinical experience over 10 years of general and specialized. It excludes fresh practitioners and practitioners who had less than 10 years of clinical experience. The subjects were briefed about the study and informed consent obtained from them. Ethical committee approval was obtained from the university. First part of the questionnaire consists of demographic details of subject’s age, gender, clinical experience, and qualification. The questions in the questionnaire were designed to assess their knowledge. The data were analyzed using the excel 2013 software.

Results

![Figure 1](image1)

![Figure 2](image2)

![Figure 3](image3)
To question number 1, among 60 dental practitioners, 83.3% of the responders give their answer as don’t know whereas 16.6% responders are aware that Mepivacaine induced fetal bradycardia. To question number 2, among 60 dental practitioners, 78.3% practitioners prescribed Acetaminophen to pregnant women. To question number 3, among 60 dental practitioners, 20% of the practitioners are not prescribing Thalidomide to their pregnant patients. To question number 4, among 60 dental practitioners, 91.6% of practitioners do not prescribe opioids to their patients since it can cause severe teratogenicity and neonatal abstinence syndrome. To question number 5, among 60 dental practitioners, 78.3% of the practitioners didn’t prescribe Prilocaine to their patients, because it can induce methemoglobinemia. To question number 6, among 60 dental practitioners, 91.6% of the practitioners prescribed Amoxicillin to their patients. In human studies amoxicillin didn’t show any teratogenic effects. To question number 7, among 60 practitioners, 93.3% are not prescribing Aspirin to their patients, because it can cause serious teratogenic effect which is premature closure of ductus arteriosus. To question number 8, among 60 practitioners, 86.6% practitioners are not prescribing Ciprofloxacin to their patients, because it can induce fetal hepatotoxicity. To question number 9, among 60 practitioners, 61.6% of the practitioners are not prescribing Fluconazole to their patients because it can cause teratogenic effects. To question number 10 among 60 practitioners, 90% of the practitioners do not prescribe nitrous oxide sedation to their patients as it can cause serious birth defects and spontaneous abortions.

### Discussion

Pregnancy and child birth is one of the most beautiful phases a women goes through. Although being a wonderful phase, a woman has to go through a lot of discomfort and pain. As it is a physiologic journey, other concerns of pain also affects the individual like tooth ache etc., Hence when a pregnant women comes for a treatment not only the discomfort should be eliminated, it should be eliminated without causing any harm to the fetus. Mepivacaine and Bupivacaine are considered in category C and should not be used during pregnancy. Both have shown to cause fetal bradycardia and embryocidal effects at early stages in the gestational period. According to the recent study 83.3% of the practitioners given their answer as don’t know to the question “does mepivacaine induce fetal bradycardia?”. Drugs like Thalidomide has caused a huge disaster past causing phocomelia and hence its usage with pregnant women has stopped by 20% practitioners. Opioids can cause neonatal abstinence syndrome, hence 91.6% of the practitioners do not prescribe opioids to their patients. Prilocaine is not used frequently due to its association with methemoglobinemia-induced fetal hypoxia and hence 78.33% of the practitioners didn’t use prilocaine to their patients. Amoxicillin is considered as the safest antibiotic and hence 91.6% of the practitioners prescribe amoxicillin to their patients. Aspirin and other salicylate group cause delay in sort of labor, premature closure of ductus arteriosus, jaundice etc., According to the recent study 93.3% of the practitioners do not prescribe Aspirin to their patients. In albino rat study, Ciprofloxacin showed spontaneous abortion. In human study, Ciprofloxacin crosses the placenta and concentrates in amniotic fluid which leads to fetal hepatotoxicity. Hence 86.6% practitioners do not prescribe Ciprofloxacin to their patients. Antifungal drugs like Fluconazole and Ketoconazole cause birth defects. According to the gynecological study, 2% of the fetus presents with neural tube defects, so 61.6% of the practitioners do not prescribe Fluconazole to their patients. Use of Nitrous oxide sedation is very dangerous to pregnant women and it also causes abortions, hence 90% of the practitioners are not recommending nitrous oxide sedation to their pregnant patients.
Conclusion

The results of this survey showed an acceptable level of awareness about drugs that inducing teratogenic effects among dental practitioners. It also showed that clinician should know about all the newer drugs and its significance. The outstanding nature of physiology of pregnancy presents challenges for pharmaceutical treatment for acute and chronic as well as oral problems and the pain management of many complains associated with pregnancy. From the clinician to till the pharmacist should have responsibility to prescribe drugs to pregnant woman because fetal safety is most important one. The drugs termed as over the counter (OTC) should be avoided during pregnancy and the clinicians also not recommend that drugs to pregnant woman. As Dentist part, relieving tooth pain and any other oral pain is mandatory one. The clinician should know the newer drugs and its teratogenic effects. This all can improve clinical practice among dental practitioners.

Awareness of Oral Hygiene Aids among General Population

J. Manju1, C. Krithika2, P.R.Koteshwari 3, G. Manoj Kumar3

1Senior Lecturer, 2Professor and Head of the Department, 3Undergraduate Trainee, Department of Oral Medicine & Radiology, Tham Moogambigai Dental College & Hospital, Chennai, Tamilnadu, India

Abstract

Background: The objective of this study was to assess the knowledge of oral hygiene aids among general population.

Method: The study was conducted on general population in and around Chennai. A total of 100 members were selected and self-assessed questionnaire was formulated to assess the awareness on oral hygiene aids.

Result: About 72% of the population are aware of the commonly available oral hygiene aids; 42% population used tooth paste and brush as a method of cleaning their teeth; 50% brushed once daily; 51% used soft brushes to brush; 54% of the population change their brushes only after 6 months; 44% followed circular motion to brush their teeth; 43% don’t use mouthwash; 49% of population media is the source of information; about 83% of population know the importance of oral hygiene.

Conclusion: The present study shows better knowledge and awareness of oral hygiene aids but the oral hygiene practice seemed to be non-satisfactory. The awareness regarding the usage of oral hygiene aids, indicates that a mass educative programme should be conducted among the general population.

Keywords: Prevention, Health care, Medical care, Interdental aids, Oral hygiene.

Introduction

Oral diseases including dental caries, and periodontal diseases which can be prevented through a professional self-care activity which plays an important role in prevention of oral diseases(1). Oral health care practices have been proved to be an effective preventive measure for maintaining good oral health as part of general health. The use of oral hygiene aids may improve tooth cleaning effectiveness provided that cleaning is sufficiently through and performed at appropriate intervals.(2) Patients comply better with oral health care regimens when informed and positively reinforced. Lack of information is among the reasons for non-adherence to oral hygiene practices.(3)

Prevention of oral disease can be achieved by optimizing the oral health practices in the form of proper tooth brushing, use of dental floss, dental visits at regular intervals, & proper dietary practices.(4) The understanding of actual practices in keeping the oral health at standard based on patients’ perceptions of oral health care is vital.(5)

Although many studies have been carried out from time to time to assess the knowledge and behaviour of people about oral health, there is still a death of education regarding the same especially for rural people, who make up for more than 70% of the population in India. Furthermore, even the people living in cities, in spite of having easy access to dental care, fall prey to dental diseases due to their negligence in dietary habits and unhealthy life-style.(6)

Hence this survey was aimed at assess knowledge, awareness on oral hygiene aids among general population.

Materials and Method

The study was conducted on general population in and around Chennai. A total of 100 members were
selected and self-assessed questionnaire was formulated to assess the awareness on oral hygiene aids. The structured questionnaire consisting of 10 question (Table 1), each having four option were administered to the participants. The data collected was analysed by statistical package for social science (spss inc., )

Simple descriptive statistics was used to describe the distribution of data. Chi square test were used to analyse the statistical significance.

**Result**

The results are summarizing responses to each 10 questions in the survey. Table 1 shows the questionnaire prepared for the study.

On evaluating the dental awareness, it revealed that

1. **What are the most common oral hygiene aids you are aware of?**

Among 100 participants, Majority of the participants (72%) have knowledge about commonly used oral hygiene aids like mouth wash, dental floss, and interdental brushes. 18% of participants are aware of mouth wash, 7% of participants are aware of interdental brushes, 3% of participants on dental floss..

2. **What do you commonly use for oral hygiene practice?**

Among 100 participants, most of them (42%) of participants use Tooth Brush and tooth paste, 32% of participants use Tooth brush tooth paste and mouthwash, 23% of participants use Tooth brush, Tooth paste, Mouthwash, Dental floss & 1% of participants use Tooth paste, Tooth brush, Mouth wash, Dental floss.

3. **How many times you brush your teeth?**

Among 100 participants, 50% of participants brush their teeth once daily, 49% of participants brush their teeth twice daily, 1% of participants brush their teeth randomly.

4. **What type of brushes do you use?**

Among 100 participants, a higher proportion 51% of participants preferred to use soft brush, 38% of participant’s preferred medium brush, 9% of participants never noticed, 2% of participants used hard brush.
5. **How much time do you spend on brushing your teeth?**

Among 100 participants, 59% of participants brush their teeth more than 1 min, 19% of participants brush their teeth less than 5 mins, 18% of participants brush their teeth less than 1 min, 4% of participants brush more than 5 mins.

6. **How often do you replace your tooth brush?**

Among 100 participants, 54% of participants replace their tooth brush once in 6 months, 39% of participants replace their tooth brush once when the bristles begin to fray, 5% of participants replace their tooth brush once when the color of bristles changes, 2% of participants replace their tooth brush once in a year.

7. **What technique do you use for brushing?**

Regarding brushing technique among 100 participants, 44% of participants use circular motion for brushing, 24% of participants use random motion for brushing, 19% of participants use vertical motion for brushing, and 13% of participants use horizontal brushing.

8. **How frequently do you use mouthwash?**

Among 100 participants, 43% of participants never used mouthwash in their lifetime, 38% used mouthwash once daily, 14% of participants used mouthwash twice daily, 5% of participants use after every meal.

9. **What are the important means of information about the available oral hygiene aids?**

Among 100 participants, 49% of participants get information through media, 30% of participants get information through dental camps, 19% of participants through family members, 2% of participants through newspapers.

10. **Are you aware about the importance of oral hygiene?**

Among 100 participants, 83% of participants answered yes, regarding the awareness on oral hygiene, & 17 % answered may be, regarding they might know about the importance of oral hygiene.

**Discussion**

Oral Diseases are a major public health concern owing to their higher prevalence and their effects on the individual’s quality of life. According to the World Health Organization (WHO), “Promotion of oral health is a cost-effective strategy to reduce the burden of oral disease and maintain oral health and quality of life.”

For general awareness of Oral Hygiene Aids among general population, The survey was conducted among 100 participants in a general population. On comparison with previous survey articles, People who brush their teeth twice daily, 50% reported positive, which is higher than study conducted by Al-Johani. In the frequency of changing tooth brush, 54% of participants reported...
of changing brush every 6 months, where American Dental Association ADA recommends changing of tooth brush every 3-4 months. In our study, for source of information, the common information means is through media, which is most consistent with the study of Sharda et al. Participants relatively about 56% use improper brushing technique which is noted as a risky factor of developing gingival inflammation, but the result is identically lesser than previous study conducted by Zhu et al. The participants use oral mouthwash daily at a rate of 57% which is comparatively high related to the study of which is about 44%. Most of the people have a improper brushing pattern, where circular motion is commonly done at a rate of 44%, The most recommended among brushing technique.

Conclusion
Within the general categories of toothbrush, interdental aids and mouthwash, the choices can be over-whelming, because of the vast number of products available, it is important for the dentist to advice patients about what type of products to purchase, based on individual needs. There is need to educate people about the importance and usage of oral hygiene aids.

Our present study shows better knowledge and awareness of oral hygiene aids but the oral hygiene practice seemed to be non-satisfactory. The awareness regarding the usage of oral hygiene aids indicates that a mass educative programme should be conducted among the general population.

Conflict of Interest: There is no conflict of interest.

An Experimental Study to Assess the Effect of Disinfectants on the Shade Tab

Manoj Shetty, Isha Singh2, Anmol Chandhok2, Chethan Hegde3
1Head of Department, Department of Oral Implantology, 2Post Graduate Student, 3Head of Department, Department of Prosthodontics and Crown & Bridge, A B Shetty Memorial Institute of Dental Sciences, Mangalore

Abstract

Dentistry leaning towards esthetic restorations have made shade matching a crucial step in fabrication of restorations. It is important to ensure the restorations have the accurate shade, this warrants for a successful treatment. This study aims to evaluate the effect on the color of the shade tabs after disinfection. Shade tab guides from two different shade tabs were used and exposed to three different disinfectants. A Spectrophotometer analysis was done to check for the absorbance value after exposure to the disinfectants. The results showed maximum changes occurred after exposure to sodium hypochlorite. The changes observed increased with increase in the exposure time of the shade guides to the disinfectants. Thus, a standard protocol should be followed in clinics regarding disinfection of shade tabs and ensure a change in the shade guides after three to five years span.

Key words : Disinfection, Shade tab, Spectrophotometer, Absorbance value, Color

Introduction

Shade matching, a fundamental requirement in the fabrication of esthetic restorations depends on the observer completely which results in a successful treatment outcome. Most commonly used method of shade matching is still by comparing the shade tabs of commercially provided shade guides. Shade guides are non-invasive instruments, however, they may become contaminated with saliva during the process and appropriate decontamination procedures are recommended after each use. Disinfection of the shade guide holder or individual tabs is obligatory and any incorrect application will affect the physical and/or mechanical properties of materials undergoing disinfection.

Materials and Method

The Vitapan Classical Shade Guide used for shade matching of the Ceramic restorations and Esthete.x Shade Guide used for composite restorations were selected for use in the study because they are among the most widely used shade guides in Dentistry.

A total of 72 random samples, i.e, 36 shade tabs from Vitapan Classical Shade Guide and 36 shade tabs from Esthetex shade guide were selected. It was ensured to include all basic hues and a wide range of saturations and values.

The shade guide tabs were immersed in three commonly used disinfectants present in the Department such as Spirit (70% Isopropyl alcohol) (Advita lifesciences, India), 5.2 % Sodium hypochlorite (Vishal DentoCare Private Limited, India) and Novacide (3% w/v PHMB [poly(hexamethylenebiguanide) hydrochloride], 10% w/v DDAC (Didecyl dimethyl ammonium chloride) (Bioshields, India).

Shade tab guides, three each, were immersed in these disinfectants for various intervals such as Seven days, Ten days, 24 hours, Four hours. The duration of exposure to the disinfectant was calculated by an average level of exposure. In the department, as each shade tab is disinfected for 30 seconds three times a day. Using this frequency, it was estimated a four hour exposure was
equivalent to five months ten days exposure, 24 hours is approximately two years and eight months exposure likewise the estimate was calculated for exposure. In this study the maximum limit of exposure was approximately five years.

The solutions were replaced with fresh solutions everyday, as they get depleted with time.

Each solution along with the shade tab was placed in a plastic beaker with similar dimensions. Each beaker was marked so that it mentions the type of disinfectant present and duration of the exposure.

The spectrophotometric analysis was performed of the exposed shade tabs. Unexposed shade tab was used as a control for analysis. Before analysis each exposed shade tab was cleaned for 30 seconds under running water and 5mins in the ultrasonic cleaner to remove any residue of the disinfectant.

**Results and Discussion**

Currently, there has been an increase in knowledge and awareness among patients leading to rise in demand for esthetic restorations. Shade matching has now become a critical step and it should be followed with utmost care. According to American Dental Association (ADA), hospital level disinfectants which are tuberculocidal in nature should be used for decontamination protocol of the shade guide holder and individual tabs. Water based agents should be used as the organic agents have the tendency to dissolve the plastic.\(^1\)

The aim of this study is to investigate the effect of different disinfectants on the shade tabs exposed for different time periods.

The changes observed were expressed in terms of Absorbance value. Absorbance value is the measure of the quantity of light absorbed by a sample. Spectrophotometer passes a whole series of wavelengths of light and the difference in the light transmitted or absorbed is then evaluated. The change in absorbance value is a measure of change in the value of the shade tab guides.\(^2\)

Data between the groups were analysed using unpaired t tests. Within the groups were analysed using repeated measures ANOVA. If ANOVA was significant LSD multiple pairwise comparison tests were used. SPSS software was used to analyse the data. \(P<0.05\) was considered to be significant.

</table>

The results showed that on exposure to sodium hypochlorite, maximum change was seen in the absorbance value of the shade tab after 15 days exposure.

The changes observed with exposure to Novacide were also significant, although the effects were lower in comparison to Sodium hypochlorite.

Spirit (70% Ethyl Alcohol) did not cause any significant changes in the absorbance values. This is in contrast to the study done by Alshethri, who reported a greater color change in denture teeth treated with 70% alcohol. This difference can be attributed to the use of mixture of ethanol and isopropanol in the study.[3]

It was also observed that with an increase in the duration of exposure there was increase in the changes seen in the absorbance values, regardless to the disinfectant solution used.

Huang et al. (2014) conducted a study to evaluate the effect of different disinfectants on shade guides and concluded that there was significant difference in the color of the shade tabs. The difference observed was dependent on the type of disinfectant used. These findings were consistent with the findings of this study.[4]

According to Table 1-6, it was observed that more early and definite changes were seen in the composite shade tab in comparison to the ceramic shade tab. Similar changes were observed in the study conducted by Nijhawan et al. where they evaluated the effect of four disinfectants on the color of two different shade guides.[5]

Pohjola et al., evaluated standard shade guide for color change after disinfection in which they observed a statistically significant increase in the value and chroma of the shade tabs subjected to disinfection with Cavicide after 2 and 3 years of simulated treatment. Similar results in the measure of absorbance value were seen in the current study on exposure to Novacide.[6]

With respect to most of the studies performed prior the results were in approximation to the current study.

**Conclusion**

In this study following conclusions can be drawn:

- Regular disinfection after a period of three to five years of the shade tab guides has shown to cause change in the value leading to inaccuracies in the shade matching process.

In the current study, the exposure time and the type of disinfectant used are the factors attributing to the changes observed. With increased exposure to the disinfectant, amount of change in the absorbance value was more. The maximum changes observed was with exposure to 5.2% Sodium Hypochlorite. These changes will begin as early as two years of time span and will gradually reach to a higher level within a span of five years or more. Thus, it is recommended for the older shade tabs to be changed after a particular time so as to avoid inaccuracy in the shade matching procedure.

The material of the shade tab guides can affect the amount of change in the value. The observed changes in the absorbance value of the shade tabs were higher and detected earlier in the Composite shade tab in comparison to the Ceramic shade tab.

Radiological Study of Fusion of Tri-radiate Cartilage in hip bone in Bikaner Region in 14-22 Years Age Group

Mathur Indubala¹, Sajjad Hussain², Agrawal Anjali³, Sharma Yogesh⁴

¹Associate Professor & HOD, Department of Forensic medicine and Toxicology, PCMS & RC, Bhopal (MP), ²Assistant Professor, Department of Forensic medicine and Toxicology, PCMS & RC, Bhopal (MP), ³PG final year, Department of Forensic medicine and Toxicology, PCMS & RC, Bhopal (MP), ⁴Professor & HOD, Department of Forensic medicine and Toxicology, RNT Medical College and Hospital, Udaipur (Rajasthan)

Abstract

Correct age determination has of great importance in legal prosecution. The principle means, which enable one to form fairly accurate opinion about age of an individual, are general physical development, dentition, secondary sex characters and ossification of bones. Among them Radiological examination of ossification process is most accurate than any other method up to 25 years of age.

This study involves radiological examination of Pelvis (AP view) of 169 individuals for the study of age related appearance and fusion of ossification center of Tri-radiate cartilage in hip in the individuals of age group of 14-22 years of both male and female in S P Medical college, Bikaner, Rajasthan.

Keywords: Age Estimation, Tri-radiate cartilage, X- Rays.

Introduction

Estimation of reasonably accurate age, plays an important role in civil/criminal cases like personal identification, fixing of criminal responsibility, judicial punishment i.e. in cases of rape, kidnapping, criminal abortion, attempted or evident murder, theft, burglary, dacoity and in various schemes of Social Welfare department i.e. Employment, attainment of majority, marriage contract etc.

Various workers suggest that there is a variation in age estimation, not only in country to country but also in different states of India, so Survey Committee¹⁵ (1964) while reporting on medico legal practice in India has recommended to the government to encourage Zone wise study for the problem of determination of age.

Material and Method

This study is carried out in the Department of Forensic-Medicine and Toxicology in association with the department of radio-diagnosis S.P. Medical College and the group of Hospitals, Bikaner. The subjects are selected randomly from various schools, from neighborhood of various faculty members and staff as well as cases attending the OPD of the Forensic-Medicine Department of P.B.M. Hospital, Bikaner. The persons selected for study were grouped as per their stated age, viz:- 14-15 years, 15-16 years, 16-17 years, 17-18 years, 18-19 years, 19-20 years, 20-21 years and 21-22 years. Here age 14-15 years means person of 13 years or more but below 14 years. Age, as stated by them is further confirmed by secondary school certificate, any document reflecting their exact age or entry in their school record.

Selection Criteria for inclusion of person in present study:

1. They should be living in Bikaner region for more than 5 years.
2. They should be free from any physical disability or endocrinal anomaly.

Corresponding author :
Sajjad Hussain
email id: ksid786hussain@gmail.com,
dr.ibmathur@gmail.com
3. Person should have accurate record of their date of birth.

4. Informed expressed verbal consent of the subjects was taken before proceeding to their physical, dental and radiological examination.

Radiological Criteria for epiphyseal fusion –

The union is taken as complete when the:

a) Diaphyseo-epiphyseal space is completely obliterated and become bony in architecture and density.

b) There is continuity of the periosteum between epiphysis and diaphysis with no notching at the periphery of epiphyseal line.

c) Presence or absence of epiphyseal scar (a white, transverse line) has been disregarded in this connection and considered as recent complete union.

For generalization, fusion in more than 75% cases is relied upon as complete fusion. Radiological data of appearance and fusion of ossification center of triradiate cartilage in hip were reduced to table, of various age groups. Data thus obtained finally, were analyzed and compared with published work of various Indian and foreign workers.

In Boys - Table No. 1 shows appearance and fusion of ossification centre of tri-radiate cartilage in boys. The appearance of ossification centre of tri-radiate cartilage found in 91.67% of cases in 12-13 years, in 77.78% of cases in 13-14 years and in 100% of cases in 14-15 years age group and above. The complete fusion of the tri-radiate cartilage was observed earliest at the age of 15 year and 10 day in our study and found in 90% of case in 15-16 years of age group and in 100% cases in 19-20 years of age group and above. Average age of fusion of tri-radiate cartilage was observed at 15-16 years of age in our study. Age of oldest subject not showing complete fusion of tri-radiate cartilage was 18 years and 7 months in our study.
In Girls - Table No. 2 shows appearance and fusion of ossification centre of tri-radiate cartilage in girls. The appearance of ossification centre of tri-radiate cartilage was observed in 100% cases of 12-13 years age group and above. The complete fusion of the tri-radiate cartilage was observed earliest at the age of 15 year, 1 month and 1 day in our study. The complete fusion of the tri-radiate cartilage was observed in 100% of cases in age group 15-16 years and above. Average age of fusion of tri-radiate cartilage was observed 15-16 years of age in this study. Age of oldest subject not showing complete fusion of tri-radiate cartilage was 14 years, 8 months and 1 day in our study.

Discussion

In present study average age of fusion of tri-radiate cartilage was observed at 15-16 years of age in both male as well as female, which is consistent with the observation of the Nagi Abdul Wahab Abdulla et al (Yemen) as they observe that it is 15-16 years of age. The findings in our study are also consistent with the observation of the Alok Kumar et al (Kanpur) as they observe that it is 15 years of age. The findings in our study are consistent with the PC Dikshit, who stated that it is 15 years of age.

The finding in our study is slightly higher than the observation of study of Apurba Nandy that it is 14-15 years of age, finding of study by Pillai in Madrasian showed that age of fusion of Tri-radiate cartilage is 11-14 years of age which is far less than our present study’s finding and it is also higher than the age as stated by different authors of standard textbooks as VV Pillay and G Nagesh kumar Rao stated in their textbooks that it is 13-15 years of age, Krishan Vij stated that it is 11-14 years of age. and N.Reddy stated in his textbook that it is 14 years of age.

The finding in our study is slightly below than the age 16-17 years, as stated by authors of standard textbooks of anatomy as BD Chourasia.

But some of the studies also show variation in male and female as describes below:
In females - The findings in females, in our study is slightly higher than the observation of Galstaun \(^6\) (Bengal) as he observed that it is 14 years of age, Dharmesh Shilajiya \(^{14}\) et al in Gujarat that it is 14-15 years of age in female and also higher than the observation of Flecker \(^5\) (Australia), as he observed that it is 13 years of age in their studies. The finding in our study is slightly below than the age 16-17 years, as stated by authors of standard textbook of anatomy, Gray’s Anatomy \(^7\).

In Male: In present study we found the average age of fusion of tri-radiate cartilage was 15-16 years of age in male, which is consistent with the observation of Galstaun \(^6\) (Bengal) as he observe that it is 15-16 years of age in male and also consistent with the observation of Flecker \(^5\) (Australia), as he observe that it is 15 years of age and also it is consistent with the observation of the Davies & Parsons \(^3\) (England), as he observe that it is 16 years of age.

Dharmesh Shilajiya \(^{14}\) et al in Gujarat and Yatiraj Singi \(^{17}\) et al in their studies found the age of fusion of Tri-radiate cartilage is 16-17 years of age in male, which is slightly higher than the findings of our present study.

The finding in our study is slightly below than the age as stated by authors of standard textbook of anatomy, Gray’s Anatomy \(^7\) that it is 16-18 years of age.

**Conclusion**

Following conclusions are drawn from the present study that average age of fusion of tri-radiate cartilage in both boys as well as girls are 15-16 years of age in Bikaner region of Rajasthan.

Findings of our study are again giving the strength to the workers and Survey Committee \(^{15}\) report, as they suggest to the government to encourage Zone wise study for the problem of determination of age. This study is an attempt which may be a valuable aid to a forensic practitioner to give the approximate age certificate in medicolegal cases.

Effects of Circuit Training Program on Quality of Life of Children with Hemophilia

Mandar Malawade¹, Amrutkuvar Rayjade¹, G. Varadharajulu²

¹Associate Professor, Faculty of Physiotherapy, KIMS, Karad, ²Professor, Faculty of Physiotherapy, KIMS, Karad

Abstract

Introduction: Circuit training addresses both the components of exercise i.e. strength and aerobic which can be administered to participants in a playful manner. As the large number of children will have to gather at one place for the intervention, so it will be beneficial for the therapist also to conduct the session by incorporating them into small groups. Very few have shown the effects of circuit training in hemophilia Therefore it becomes necessary to provide an exercise regimen to children which will be interesting to perform in order to improve their general fitness level.

Methodology: Forty nine participants were selected and screened and were allocated into 7 groups. The intervention was given for 4 weeks period, once a day for 7 min with 50 sec for exercise and 10 sec to move from one station to the next. Pre and Post parameters were assessed for VAS for fatigue and Subjective Exercise Experience Scale.

Results: Data was analyzed using Graph-Pad InStat software version-trial version 3.03. The statistical measures utilized were mean, standard deviation and test of significance such as Paired ‘t’ test to analyze the data. The results were concluded to be statistically significant with p <0.05 and highly significant with p < 0.01.

Conclusion: The present study concludes that the circuit training is effective in hemophilic children as its multipronged approach improves various body systems.

Key words: Haemophilia, Circuit training, Fatigue, Group Exercises, Physiotherapy

Introduction

The existence of life-long bleeding disorders and their familial occurrence was noted early by Alsaḥaravius during tenth century.¹ Bleeding disorders are due to either defects in the coagulation mechanism, the blood platelets, vitamin K deficiency or deficiency of clotting factor. Haemophilia is one of the bleeding disorders, has been recognized as a clinical entity since Biblical times.² Haemophilia is also known as ‘the royal disease’ as one famous carrier was Queen Victoria, Queen of England and Ireland, India who transmitted the condition to three of her children.³

Haemophilia has been recognized all over the world, an available estimate range for incidence of haemophilia is from 1 in 20,000 to as high as 1 in 10,000 persons.⁴⁵ It is an X-linked inherited recessive bleeding disorder that is characterized by a deficiency of clotting factor.⁶ Clotting factors are proteins in the blood that controls bleeding.⁷ Haemophilia is traditionally classified as ‘mild’, ‘moderate’, or ‘severe’, depending on the level of clotting factor available in the body compared with that found in the general population.⁸ Patients with severe haemophilia have <1% clotting factor activity, moderately affected patients have 1-5% and mildly affected patients have 6-40%.⁹

Wound bleeding is the characteristic symptoms of all haemophiliacs. It is usually slow and persists for days to weeks. Bleeding into joint may be spontaneous or induced by minor trauma. The earliest joint hemorrhages appear most commonly in knee and ankle, because of the lack of stability of these joints as the toddler assumes an upright posture. Other joints that may be
involved are the elbows, hips, wrists, shoulder and small joints of hand and feet. Prophylactic treatment with the use of coagulation factor is efficient in reducing bleeding episodes in haemophilic children. Frequent musculoskeletal bleedings ongoing in persons with haemophilia result in limitations and deficiencies of the musculoskeletal system, affecting the performance of daily living activities. Clinical manifestations may include pain, muscle atrophy, abnormal gait, haemarthrosis, reduced joint range of motion or even the development of degenerative alterations in joint. The damage resulting from haemarthrosis may cause periods of joint immobilization, tendon weakness, stiffness and joint destruction with a higher risk of fractures and osteoporosis.

Besides pharmacological treatment physiotherapy plays an important role in rehabilitation of haemophiles. Physical fitness is generally defined as ‘the ability to perform daily tasks without fatigue’. It is an umbrella term incorporating the characteristics of cardiovascular fitness, body compositions, flexibility, muscular strength and endurance. It is important for the individuals with haemophilia because their disabling condition itself may interfere with their activities like their ability to move efficiently. Benefits of regular physical exercise for haemophilic patients are numerous and cover various physical and psychosocial aspects. Physical benefits include improvement in range of motion of the joints, muscular strength protecting joint from injury. The psychosocial benefits include higher self-esteem and socialization which leads to a better quality of life. However physical activity has been linked to improving psychological conditions, such as limiting emotional distress and enhancing self-esteem. Therefore selecting appropriate exercises and fitness activities that are safe for people with hemophilia is essential.

Circuit training (CT) is a type of exercise which involves exercises to perform in a sequence in a circular manner and designed to improve cardiovascular fitness, muscular strength and endurance. It comprises both forms of exercises i.e. aerobic and resistance or strength training.

Circuit Training is a fun, cost and time effective way and able to be administered to large groups of individuals at the same time, while still being effective. There is some evidence to suggest that Circuit Training leads to positive changes in body composition, which also improves motor control and fundamental movement abilities. Development of such abilities at a young age may be beneficial in the long term. However, few studies have assessed the effects of Circuit Training on both physical fitness and movement abilities. Thus, the aim of the present study will be to determine the effectiveness of CT program on Fatigue level and Psychological well-being in children with haemophilia.

Procedure:

Forty nine participants were selected for the study. They were randomly allocated into 7 groups. Details about the study and intervention were explained to the participants and written informed consent was obtained. Demographic details of each participant were noted including clotting factor level. Participants were assessed pre and post data for Visual Analogue Scale for fatigue and Subjective Exercise Experience Scale.

The intervention was given once a day for 4 weeks period, once a day, for 7min with 50 sec for exercise and 10 sec to move from one station to the next in the form of Circuit Training. A demonstration was given to the participants to make them understand how to perform the exercises and how to move in the Circuit. Exercises were done with music for having effective and enjoyable. At a time only one group was given Circuit Training followed by other in a circular sequence. Each participant in the circle performed respective exercise recommended to them at that particular station.
Exercises for respective joints were the followings:

**Exercise for Shoulder joint:** Keep both the hands on shoulders of the same side. Move the shoulders in outward direction in a circular way simultaneously.

**Exercise for Elbow joint:** Stand facing the wall. Place hands flat on wall with arms straight. Lean body towards wall allowing elbow to bend. Return to upright position by pushing with arms and straightening the elbow.

**Exercise for wrist joint:** Place palm of hands together with finger straight (in a prayer position) while keeping the hands pressed flat together move both the wrists in extension alternately.

**Exercise for Hip joint:** Stand by facing the wall. Place both the hands on the wall for support. Extend the hip by keeping the knee straight. Perform the same for both the hips alternately.

**Exercise for Knee joint:** Stand with the weight evenly distributed on both feet. Squat down partway keeping weight distributed evenly on both feet. Do not bend knees far enough to cause pain. Hold for several seconds. Return to upright position.

**Exercise for Ankle joint:** Stand with both legs adequately wide apart. Place both palms of hands on wall for support. Do the dorsi-flexion and plantar-flexion alternately.

**Exercise for Trunk:** Keep both the hands on low back for the support and gently extend as much as possible. Then come back to upright position.

**Data Analysis:**

Data was analyzed using Graph-PadInstat software trial version 3.03. It was entered into an excel spreadsheet, tabulated and subjected to statistical analysis. The statistical measures utilized were mean, standard deviation (SD) and test of significance such as Paired ‘t’ test to analyze the data. Paired ‘t’ test was used to compare the differences of scores on pre and post intervention within a single group. The results were concluded to be statistically significant with p < 0.05 and highly significant with p < 0.01.

**Fatigue Score:**

The rates of perceived fatigue were assessed byVAS. The rating of fatigue scores were recorded on the scale. Paired ‘t’ test was used to compare score within the group. The pre-intervention average score of fatigue score in participants was 1.40 and post-intervention was 1.87. There was highly significant increment in fatigue score for the group after intervention.

**Subjective Exercise Experience Scale (SEES):** Paired ‘t’ test was used to compare score within the group. The pre-intervention average score of Positive wellbeing in participants was 14.32 and post-intervention was 16.97. There was highly significant increment in Positive wellbeing score for the group after intervention.

The pre-intervention average score of Psychological Distress in participants was 7.14 and post-intervention was 4.83. There was highly significant reduction in Psychological distress for the group after intervention.

The pre-intervention average score of fatigue was 5.51 and post-intervention was 5.10. There was highly increment in positive wellbeing component as well as significant reduction Psychological distress component of SEES after intervention, whereas Fatigue component found to be significant.

**Discussion**

The study was done to evaluate the effects of circuit training in Haemophilic Children. In children with Haemophilia reduced muscle strength and cardiovascular endurance are main contributing factors to have poor fitness level and reduced psychological wellbeing compared to typically developing peer which results because of fear of getting bleed.

Circuit Training showed good improvement in Positive wellbeing, reduced psychological distress and fatigue to some extent. Circuit training being multipronged in its approach addresses the improvement in various systems of body and even psychological aspects. CT program was specifically designed to provide variation and stimulation in order to maximally engage children and to ensure adherence and enjoyment, whilst achieving positive changes in health and fitness outcome measures. The effects seen in this study were due to gradual effects of exercise which imposes demands on the different systems of the body such as enhancement of oxygen delivery systems, expanded plasma volume, maximum minute ventilation and increased cellular enzyme activity.23, 24

Most of the haemophilic children are sedentary and having reduced physical activity. Therefore fatigue had set in early. In the present study there was significant difference fatigue score.

A pilot study was done to determine the effect of an acute bout of exercise on the subjective exercise experience of Vietnam Veterans, and to determine which exercise intervention results in the most positive acute outcome. Specifically, this study included the use of a combination of traditional exercise modes and innovative exercise. Overall this pilot study has demonstrated that an acute bout of exercise elicits improved positive wellbeing and reduced psychological distress, and therefore warrants further research with a larger cohort to determine which exercise intervention results in the most beneficial subjective experience. The identification of specific exercise interventions that elicit acute positive exercise experiences has important implications for long-term exercise adherence in at-risk populations.

In the present study there were significant differences in the components of Subjective Exercise Experience Scale (SEES) with increase in positive wellbeing. Psychological distress showed reduction in score after intervention, whereas fatigue component also showed significant difference.

A study has proved that a school-based CT program had beneficial effects on a range of fitness measures. These movement skills are helpful in ensuring good general posture, and effective movement in a variety of physical activities, sports and game play. For these reasons, and given its low cost and suitability for large groups, CT maybe a useful exercise method to adopt in schools. This is in accordance with the research studies, CT program on the health, fitness, physical activity levels, and movement competency in young children.25, 26
An overview of literature review concluded that aerobic and resistant training intervention elicits some benefits for physical fitness and blood coagulation mechanisms, suggesting the application of physical training as a non-pharmacological treatment in association with conventional treatment. Adequate and periodized resistance training considering the disease severity, accompanied by physical education professionals could improve muscle strength, balance and proprioception. Aerobic training could reduce the risks of obesity and several metabolic and cardiovascular diseases. Another review article concluded important evidence on the recommendation of physical exercise and sport in haemophilia, the consensus on its suitability for the physical and social wellbeing of the patients and the need to increase scientific works in this respect.27

Researchers analyzed the current state of management of haemophilia and to suggest a comprehensive concept of rational and effective rehabilitation of children with haemophilia. The study concluded that current rehabilitation care is of good quality and necessary for effective lifelong therapy of haemophilia.28

Thus many researchers have proved that for achieving general fitness and maintaining psychological wellbeing in haemophilic children, exercise regimen and physical activities contribute major role which occurs due to physiological changes in various systems of body in order to prepare the body to control the new imposed demands while performing the exercise and physical activities.

Conclusion

The present study concludes that the circuit training is effective in haemophilic children as its multipronged approach improves various body systems.

Study of Pedestrian Injuries and Fatalities in Maharashtra Population

Mohammed Abdul Mateen
Associate Professor, Department of Forensic Medicine and Toxicology. Indian Institute of medical sciences and Research (IIMS & R) Warudi, Badnapur (Tq) Jalna (dist) Maharashtra

Abstract

Background- Pedestrians are the common road users India, with increasing traffic on road has lead to injuries and fatalities. The incidences of fatalities are higher than drivers of four wheelers or motor cyclist.

Method- Out of 734 Injuries and 213 fatalities were recorded in medico-legal records. The causes, types of injuries age group, causes of fatalities were also studied.

Results- The major age group was between 10-20 had 210(28.6%) followed by age group 61-70 had 142(19.3%). The major history of pedestrian were 210(28.6%) alcoholic, followed by 173(23.5%) were busy in mobile speaking. The major fractures were 69(9.40%) fractions of sternum, 176(23.9%) fracture of skull. 185(25.2%) intra-cranial hemorrhage. The major causes of fatalities were hemorrhage and shock 138(64.7%), followed by head injuries57(26.7%).

Conclusion-

Key words:- Injuries, Fatalities, Medico-legal, Hemorrhage, Fractures

Introduction

Pedestrians are the common road users in India, with increasing traffic on roads has lead to major injuries and fatalities of pedestrians.1,2. The incidence of injuries and fatalities is significantly higher than in car occupants or motor cyclists in road accidents, which are further increasing at an alarming rate. The cause of pedestrian’s injuries and fatalities are bilateral. It includes role of, drivers, pedestrians, roadway and environment 3. Apart from this hurry to cross the roads, by both drivers and pedestrians is one of the major cause of pedestrian injuries and fatalities. Hence attempt was made to analyze the various causes, types of injuries and fatalities in pedestrians.

Material and Methods

734 injured pedestrian were brought to IIMS & R Warudi, Jalna (district) Maharashtra were studied out of 734, fatality was 213 pedestrian

Inclusive criteria- The criteria pedestrian of different age group 10 to 70 years old were selected for study. Majority of them were alcoholic, visually, mentally auditory challenged.

Exclusion criteria – The patients had an intention to commit suicide and reported in MLC report was excluded from the study.

Method- Pedestrians with injuries and fatalities in road accidents were brought to IIMS & R Warudi: Jalna (Dist) Maharashtra was studied. Out of 734 injuries 213(2.9%) had fatalities. Injuries of the different parts of body, fractures of skull, intracranial hemorrhage, fracture of long bones multiple trauma were studied from x-ray, USG, CT scan/MRI in injured pedestrian, medico-legal case reports, additional information was collected from relatives and police department. The
duration of the study was April 2016 to Dec-2018,

**Statistical analysis-** The different age groups, cause of pedestrian injury to viscera. Head injuries were classified with percentage. The ratio of male and females were 2:1

**Observation and Results**

**Table-1** – Study of different age groups of pedestrian injuries and fatalities 210 (28.6%) victims between 10-20 years of age, 129 (17.5%) victims were aged between 21-30 years, 77 (10.4%) victims were aged between 31-40 years 66 (8.99%) victims were aged between 41-50 years, 110 (14.9%) victims were aged between 51-60 years, 142 (19.3%) were aged between 61-70 years.

**Table-2** – History of the pedestrian injured and fatalities 210 (28.6%) were alcoholic, 89 (12.1%) had visual problems, 20 (2.72%) had auditory challenged, 173 (23.5%) were mentality challenged, 147 (20%) were busy in mobile speaking, 95 (12.9%) were playing on roadside.

**Table-3**- Study of injuries to pedestrian 69 (9.40%) had fractures of sternum, 16 (2.17%) had injury to heart, 48 (6.53%) had injury to lungs 6 (0.81%) had injury to Aorta, 15 (2.04%) had injury to stomach, 59 (8.03%) had injury to liver 24 (3.26%) had injury to spleen 3 (0.40%) had injury to kidney, 176 (23.9%) had fracture of skull, 185 (25.2%) had intra-cranial hemorrhage 62 (8.44%) had fracture of long bone, 71 (9.67%) had multiple fractures.

**Table-4** - Cause of fatalities in pedestrians- 57 (26.7%) death was due to head injuries and intra-cranial hemorrhage 138 (64.7%) deaths due to hemorrhage and shock 13 (6.10%) had septicemia, 5 (2.34%) had Uremia.

Discussion

In the present study of pedestrian injuries and fatalities, of Maharashtra population. The age group study was- 210(28.6%) were between 10-20 years of age, 129(17.5%) were aged between 21-30 years, 77(10.4%) were aged between 31-40 years 66(8.99%) were aged between 41-50 years, 110(14.9%) were aged between 51-60 years, 142(19.3%) were aged between 61-70 years (Table-1). History of the pedestrian was 210(28.6%) were alcoholic,
89(12.1%) had visual problems, 20(2.72%) had auditory problems, 147(20%) were mentality challenged, 173(23%) were busy in mobile speaking, 95(12.9%) were playing on roadside (Table-2). The injuries to pedestrian 69 (9.40%) had fractures of sternum, 16(2.17%) had injury to heart, 48(6.53%) had injury to lungs, 6(0.81%) had injury to Aorta, 15(2.04%) had injury to stomach, 59(8.03%) had injury to liver 24(3.26%) had injury to spleen liver, 3(0.40%) had injury to kidney, 176(23.9%) had fracture of skull 185(25.2%) had intra-cranial hemorrhage 62 (8.44%) had fracture of long bone, 71(9.67%) had multiple fractures (Table-3). The cause of fatalities in pedestrians- 57 (26.7%) death was due to head injuries and intra-cranial hemorrhage 138(64.7%) deaths due to hemorrhage and shock 13 (6.10%) had septicemia, 5(2.34%) had Uremia (Table-4) These findings were more or less in agreement with previous studies4,5,6.

Pedestrian can be defined as a person on foot, walking running jogging, and hiking, sitting or lying down. Walking transport modes, where relatively unprotected road users interact with traffic of high speed and mass. This makes pedestrians vulnerable. They suffer the most severe consequences in collisions with other road users interact with traffic of high speed and mass. of the vehicle against him/her7. Collisions between pedestrians and bicyclist or motor vehicle are the major problems in the countries that are becoming motorized and high rates of walking and bicycling8. Pedestrians are commonly referred to as vulnerable road users because in collisions with motor vehicles the lack of protective structure and differences in mass height and make their injury susceptibility, protecting them is a challenge, because road infrastructure typically have built for motor vehicles with little attention to those that moving on foot who may wish to travel on or along side roads or cross them or change direction at intersections9.

The injuries and fatalities of the pedestrian can be divided into three phases (stages), pre-crash, crash and post crash, pre-crash is the phase of prevention. The crash phase is the traumatic event, that involves the exchange of energy or the kinematics (mechanics of energy). Lastly, the post crash in the phase of patients care10.

The pedestrian’s road crossing behavior has been explained in the terms of minimum gap acceptance value by using a rolling gap. The driver’s yielding this minimum gap acceptance plays vital role for pedestrian to escape from collusion which may cause injury or fatalities11. The pedestrian crossing or passing the unidentified or prohibited area may cause injuries and fatalities. Most of the pedestrian were impatient and could not wait for passage of trains, vehicles, Lorries etc, were more vulnerable to get injured and fatalities.

Summary and Conclusion

The present study of pedestrian injuries and fatalities highlights Causes and types of injuries and deaths. Moreover it is advocated that, wide, safe roads, deployment of more traffic police force, stringent punishment can mitigate such accidents. In addition to this awareness programs of traffic rules to both pedestrian and drivers will be more effective to control road accidents.

Abstract

Background: Medical course and dentistry have always been considered to be stressful to the students because of its depth, diversity and competitiveness. These are very extensive course spread 4 to 5 years in India. Stress sometimes can lead to anger, which cause even more stress. Prolonged stress and anger can take a toll on the students, both physically and emotionally. It is important to eliminate them by attempting control management and implication of positive coping strategies.

Aim: This study aims to investigate level and source of stress, anger, anxiety, depression and associated coping mechanisms among dental students.

Material and method: A link to an online questionnaires conducted through Surveymonkey was distributed among all third-year, fourth-year and final-year students.

Result: The first major stressor for the dental students was clinical requirements (61.3%) followed by patient’s behavior, peer pressure/competitiveness, education program and language barrier. Taking some time off to rest (20.3%), talking to a friend (%23.9) and listening to music (19%) were the most commonly reported coping mechanisms (Table 3).

Conclusion: The primary sources of stress as perceived by the dental students were peer pressure/competitiveness, patient’s behavior and clinical requirements. In the present study, female dental students reported higher stress levels and a wider range of coping than male students, hence a stress management program should be implemented that focusing towards dental students. The preventive and intervention must be sought and directed as this need early in the student years.

Keywords: Anger, dentistry, depression, pressure and stress

Introduction

Stress has a vast meaning which depending on different people under different situations. Claude Bernard first scientifically explained stress, about how cells and tissues respond to stress. They are surrounded by buffer system, ion concentration, gaseous exchange and other biochemical modalities in order to coordinate physiological process and establish homeostasis. Other Ancients such as Aristotle and Hippocrates were aware of the stress and its adverse effect but the most generic definition of stress was given by Hans Selye. Selye was the ‘father of stress’ and he defined stress as “a non-specific response of the body to any demand".¹

Dental course undoubtedly is stressful, extensive and exhaustive. Students commonly encounter numerous of stressor in the beginning of dental school life. The stress can be multifactorial, which is arising from academic and socio-cultural environment and social support issues. In addition, students in the health care field are

Telephone Number: +91 98415 04523
more vulnerable to stress due to the high demand of their education, demanding workload and intense theoretical education. Also, they are facing additional challenges such as providing care and treatment for patients, which can cause harm if performed inappropriately. As a result, dental students are repeatedly going through pressure and stress and put them under risk for depression, burnout and anxiety problems.

Many studies have been conducted to investigate level and causes of stress and findings have shown high stress levels among dentists and physicians. Two similar studies reported 38% of dentists and 44% of doctors having high stress. Significantly, the putative causes of stress for these two professions are to be differing. Dentists’ most common stressors are associated with difficulty to interact with patients, practice management pressure and ability to maintain high level of focus during procedure; doctors are constantly stressed with job and patient demands, constant interruptions and work conflict interfere with family life. As for students of dentistry and medicine, studies have shown that most these students are engaging in destructive coping mechanisms. Murphy et al also stated that dental students surprisingly perceive higher level of stress than medical students.

**Anger And Depression In Dentistry**

Anger is generally believed as a maladaptive attempt or effort to overcome a stressful condition, which causing inner conflict and personal discomfort physically and emotionally. On the other hand, anger is also said as an adaptive venture to achieve obstructed goals and perceived threats. An unhealthy anger happens when it is suppressed and collectively resulting to anxiety and depression. In addition, prolonged anger and temper can cause damage to relationships, lead to irrational thinking among the society followed by unpleasant consequences. Most studies have found that students under anger management training exhibit great self-control along with reduced aggressive behavior and attitude in classes and at home.

Depression is an illness that can occur at the average of mid-20s, which often related with anxiety disorders. A major depression generally involves the body, mood and thoughts. The first approach of managing depression can be done with a consultation and physical examination with physicians. The choice of treatment depends on the solid cause of depression after evaluations. Psychological counseling, antidepressant medication, stress management and self-help are some of the necessary components in overcoming depression. Self-help or self-guided improvement is the best help, which people have to exert a strong willing to manage the illness. This study was carried out to investigate level and source of stress, anger, and anxiety and to see associated coping mechanisms among dental students.

**Material and Method**

This study was conducted among all third-year, fourth-year and final-year students of Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences. Total participants of forty-four male and seventy female were involved and all the responses of the questionnaires were kept anonymous. Age ranged from 21 to 24 years.

A link to an online questionnaires conducted through Surveymonkey was distributed. The questionnaire contained 19 questions about level of stress, anxiety, anger, depression and coping mechanisms. Participation was voluntary and no concession was offered. Verbal informed consent was obtained before participation in the study.

The data was collected and analyzed using the descriptive statistics and comparisons made using the Chi-square test and level of significance was set at \( P < 0.05 \).

**Questionnaire design**

The questionnaire was based on the dental environment stress and was modified accordingly to suit the curriculum and grading system of Saveetha Dental College. The questionnaire was sectioned into demographic details, course-associated stress, enjoyment, feelings of stress, anxiety, anger and related behaviour and coping mechanisms.

Results and Discussion

This study investigated, compared reported stress levels and related behavior with the associated coping managements in three batches of dental students in Saveetha Dental College. Out of the 114 participants, 80 (70.2 %) were equally third and final year dental students and 34 (29.8 %) were the interns. Age range of the dental students was between 21 years and 24 years, and the mean age for all three years was 23.3 years.

Stress scores for each parameter per gender were summarized in Table 2. A definite relationship between gender and perceived sources of stress was observed; majority of female students were reported higher levels of stress than male students in any conditions. In the present study reported that students were most stressed about the patient’s behavior (45.6%) and clinical requirements (61.3%). A significantly greater proportion of (48 female) dental students reported feeling stressed on completing clinical requirements while 32 male students were highly stressful on the same. Language barrier was quoted as the least stressor among the students that 41.2 % of the dental students were not in pressure due to communication with patients. Only 37 (32.4%) of the students were moderately stress and 30 (26.4%) of them were highly stress on language barrier. 48 female students and 19 male students were moderately stressful while 17 female students and 21 male students were highly stress about the peer pressure or competitiveness with their batchmates. Same result was reported in the previous studies that students tended to have more stressed and pressured on items related to academic performance such as competition with peers and examinations and grades. This is also consistent with other studies, which showed that most of dental students had feeling pressure to compete with other students, which two-thirds of those reported associated with anger, anxiety and sadness. Also, one-fifth of the students lied about their grades to peers and parents.

Most respondents reported moderately stressful on the education program (28.9% equally on both gender). Only fewer students reported having more stressed on the education program (28.2%).

Taking some time off to rest (20.3%), talking to a friend (%23.9) and listening to music (19%) were the most commonly reported coping mechanisms (Table 3). There were closely followed by hobbies (11.5%) and practice mindfulness (19%). Strikingly, more than half of female students tended to talk about their stress and problems with the peers or friends. Resting and listening to music were highly reported in male students compared to female students. There was a statistically significant difference between genders, that 19 male students and only 4 female students were reported managing stress with exercising. Fewer dental students
(4.5%) reported being able to manage time properly as a means of coping. Previous studies reported majority of dental students preferred to rest, talk to people who care and indulge in hobbies. A minor population chose to spend their money, eating and consume medication as an alternative therapies. 15.3% of dental students and 19.5% of medical students were reported having some form of counseling or prescribed psychotropic medication during their studies. Prinz et al describes most students often manage their stress, anxiety, anger and depression by ‘active-functional coping’, which have been described as resting, talking to someone and social interactions. The students’ coping mechanisms were very similar to the findings of Ayers et al.

In the present study, just under one-third (35 students) were having trouble to control their anger and may have bad temper on occasional basis. On the other hand, two-thirds of the students often have trouble to sleep. Prabhu et al reported in his study that 70% of students had inclination of bad temper, with 3% of students said that they would ‘never’ suppress their anger and 62% of the students on the other hand chose to ‘occasional’ when it comes to tolerate their emotions. Potegal et al has pointed that anger episodes vary in duration and is confined to some factors such as its intensity, continued presence/absent of the offending person/object and mind of the person.

Overall, female dental students reported higher stress levels and a wider range of coping than male students, which are the strong cause for concern. Soh reported same finding that female students expressed a higher level of stress in dental training. Although that dentistry is a stressful profession, the findings are alarming. Detrimental emotions and adverse mental states among the students may lead to more serious problems as they progress into work force in future. It is very important to maintain stable mental health and well being, not only for their own good, but for the best interests of patients as well. This significantly emphasizes the needs of help in these areas and importance of self-care.

Conclusion

The primary sources of stress as perceived by the dental students were peer pressure/competitiveness, patient’s behavior and clinical requirements. In the present study, female dental students reported higher stress levels and a wider range of coping than male students, hence a stress management program should be implemented that focusing towards dental students. The preventive and intervention must be sought and directed as this need early in the student years. Also, future research is recommended to achieve a greater understanding of stress through dental education program.

Assessment of Salivary Flow Rate in Edentulous Patient

Nurul Afiqah Amani Binti Zaaba¹, Dhanraj²

¹Graduate student, Saveetha Dental College, Saveetha University, Chennai, India, ²Head of Department, Department of Prosthodontics, Saveetha Dental College, Saveetha University, Chennai, India

Abstract

Background: Complete denture help to re-establish the occlusion and aesthetic to such extent it mimic the previously missing teeth and other features which may be lose over the time. In a complete denture wearer, saliva is responsible for the retention of the prosthesis due to its lubricating function. It also aid in integrity, adhesion and stabilisation of dentures in position after the placement. It act as interposed salivary film which allowed the prosthesis to lie on the film rather than on the bare mucosa. This would help to protect the tissues from the hydration and forces of the denture base that acting on it. Therefore, maintaining normal pH and salivary flow rate is required, in order to achieve a better retention of denture as well as good oral health.

Aim: To investigate the relationship between the salivary flow rate before and after the placement of complete denture.

Materials and Method: There were 15 participants in the age group of 55 to 70 years old, which required complete denture prosthesis for the first time. The unstimulated or resting whole saliva and stimulated whole saliva was collected by using spitting method. Saliva production was stimulated by chewing paraffin wax. The time taken for saliva collection of 5 mL was recorded by using stopwatch. The data obtained was analysed by using paired t-test.

Results: There was significant difference between the unstimulated whole salivary flow rate and stimulated whole salivary flow rate before the placement of the denture, which was by 0.20 mL/min. Whereas, the difference between the unstimulated whole salivary flow rate and stimulated whole salivary flow rate after the placement also show significant changes which was about 0.14 mL/min. Chewing of paraffin wax as well as placement of denture act as stimulatory agents in production of saliva.

Conclusion: Stimulated salivary flow rate were higher than the unstimulated salivary flow rate which obtained before and immediately after the placement of complete denture. There was significant differences of the salivary flow rate before and after the placement of denture.

Keywords: Salivary flow rate, complete denture, edentulous patient

Introduction

All part of oral cavity play a vital role in maintaining the function, environment and also the harmony of the mouth and body. They are responsible for the mastication, phonetics, nutrients supply to the body and even for aesthetic purpose. Among these parts, teeth is considered as the most important in contributing to all of this action and function. Hence, most individuals and also dentist are focusing more on maintaining and restoring the status health of the dentition. However, saliva also help teeth as lubricating agents to protect soft tissues and also maintaining a good oral health and function [¹]

In a completely edentulous individuals, complete denture is one of the mode of treatment in replacing
the missing teeth. This type of denture is usually a removable prosthesis, where it can be easily placed and removed from the oral cavity. Complete denture help to re-establish the occlusion and aesthetic to such extent it mimic the previously missing teeth and other features which may be lose over the time. In a complete denture wearer, saliva is responsible for the retention of the prosthesis due to its lubricating function [2].

It also aid in integrity, adhesion and stabilisation of dentures in position after the placement [3]. It act as interposed salivary film which allowed the prosthesis to lie on the film rather than on the bare mucosa. This would help to protect the tissues from the hydration and forces of the denture base that acting on it [4,5]. Therefore, maintaining normal pH and salivary flow rate is required, in order to achieve a better retention of denture as well as good oral health.

In addition to this, retention of denture not only depend upon the physical factors like atmospheric pressure, vacuum, adhesion, cohesion, wettability, surface tension and viscosity, but it also related to flow rate of saliva [6,7]. Reduced in salivary secretion will result to discomfort to the wearer with oral functional impairment and also affecting the quality of life of the denture wearers [8]. In most of the situations, as complete denture is usually given to elderly individuals, age also give an effect on the flow rate of saliva as well as the overall status of the tissues in the mouth [9].

Hence, the optimum salivary flow rate should be recorded before and after complete denture placement, as complete denture may affect the salivary flow rate. In fact, increased or decreased of the salivary flow rate also may cause alteration in the pH as we’ll as the environment of the oral cavity. Therefore, this study was conduct to investigate relationship between the salivary flow rate in complete denture patient.

**Materials and Method**

1.1 Sample selection

The participants of this study were consisted of 15 edentulous patients in the average age group of 55 years to 70 years old. The participants were complete edentulous patient and received their treatment in department of prosthodontics of Saveetha Dental College and Hospital. The participants were given information about the study and their consents were obtained.

1.2 Criteria of the sample selection

**Inclusion Criteria**

- Completely edentulous
- First time wearer
- Healthy individuals
- No smoking or chewing habits

**Exclusion Criteria**

- Partially edentulous
- History of wearing denture or prosthesis
- Having systemic disease like diabetes mellitus, xerostamia or hypertension
- Smoking or chewing habits

1.3 Materials and armamentarium

- Distilled water
- Paraffin wax
- Disposable glass
- Graduated measuring jar
- Stopwatch

1.4 Saliva collection

For this study, two types of saliva were collected which were resting or unstimulated whole saliva and stimulated whole saliva. Saliva samples were collected from each participants on two different conditions which were before denture placement and immediately after placement of denture, by asking the patients to spit into the disposable glass. During both occasions, both unstimulated and stimulated saliva was taken for measuring the salivary flow rate of the participants.

Initially, the participants were asked to be seated in dental chair comfortably in upright positions where head were tilted downward in order to avoid postural changes [4], as well as to enhance the accumulation of saliva inside of the mouth. The participants were asked to rinse their mouth with 5mL of distilled water for 10 seconds followed by spitting of the watered initial swallow. This was done in order to remove any food debris and other non salivary elements which may influences the stimulation of salivary flow or interfered
with the measurements of salivary flow rate[10].

Then the unstimulated whole saliva was collected inside the disposable glass until 5mL of saliva is collected. The time taken for collection of the saliva was measured by using the stopwatch. After completion of the collection of unstimulated saliva, participants were asked to chew the paraffin wax, to stimulate the production of whole saliva inside the mouth. Then, the saliva was collected similar as the unstimulated saliva method over a period of time.

This steps were repeated immediately after the placement of complete denture, to measure the flow rate of saliva. Both unstimulated as well as stimulated saliva was collected. The salivary flow rate was calculated based upon the saliva collection, over the time taken to obtained 5 mL of saliva and was expressed in unit of mL/min. The data was tabulated and analysed by using paired t-test method by using SPSS software.

Results

Based on the experiments, the salivary flow rate of stimulated whole saliva was higher than unstimulated saliva in both occasions, which were before and immediately after the placement of denture. The mean of salivary flow rate was the highest immediately after the placement of complete denture.

Based on Graph 1, there was significant difference between the unstimulated whole salivary flow rate and stimulated whole salivary flow rate before the placement of the denture, which was by 0.20 mL/min. Whereas, the difference between the unstimulated whole salivary flow rate and stimulated whole salivary flow rate after the placement also show significant changes which was about 0.14 mL/min. Chewing of paraffin wax as well as placement of denture act as stimulatory agents in production of saliva.

**Discussion**

Whole saliva is the mixture of secretion that enter the mouth in the absence of exogenous stimuli like chewing or talking. In general, unstimulated salivary flow rate can be defined as the salivary flow in absence of exogenous stimuli or pharmacological stimulation, while stimulate salivary flow rate is produced by the pharmacological stimulation or gustatory stimuli \(^{11}\). Production of saliva in oral cavity was produced through secretions from the salivary glands, mainly parotid, submandibular and sublingual salivary gland \(^{12}\). Average daily secretion of saliva in oral cavity is in a ranges of 500 to 700 mL \(^{13}\).

Submandibular and sublingual salivary glands are mainly responsible to produce saliva at rest in ranges between 0.25 to 0.35 mL/min. Whereas, on stimulation the secretion rate is about 1.5 mL/min \(^{14,15}\). There is significant difference in secretion of saliva at rest and also stimulation. This is similar to the result obtained in this study, where the unstimulated salivary rate was at minimal and stimulate salivary rate was at the highest is both conditions.

In this study spitting method was used to collect the saliva, which able to be applied in a normal condition and even in condition of low rate of salivary flow. Therefore, this method can be accepted and the most reproducible for the collection of saliva. Next, paraffin wax was used as stimuli to trigger or stimulate the secretion of saliva. This was done in order to mimic the masticatory process and also phonetics.

The results obtained in this study was similar to the study done by Muddugannadhar et al \(^{11}\) and Yurdukoru et al \(^{16}\). They stated that there was increased in the unstimulated saliva after the placement of denture. In Sonthalia, A et al study \(^{4}\), they stated that unmedicated group (healthy), mean salivary flow rate was high at 24 hours after denture insertion when compared to before denture insertion. This show that the Placement of the complete denture inside of the oral cavity also act as the mechanical stimuli to enhance the production of saliva, along with chewing of paraffin wax.

However, increased in the secretion of saliva also may be due to psychological effect of the participants due to their anxiety during the denture insertion and...
also due to anxiousness about the success rate of the treatment in placing their missing teeth. Increased in the production of saliva will help to in retention of the dentures they provide a better adhesion, cohesion and wettability between the denture and tissues. Thus, it help to prolong the span of denture and provide a good integrity and stability for the denture. In addition to this, if the denture wearer is having systemic disease like diabetes mellitus or xerostomia, the medication taken to treat this diseases may influenced the flow rate of saliva. Therefore, healthy individual was included as the inclusion criteria in this study.

**Conclusion**

Stimulated salivary flow rate were higher than the unstimulated salivary flow rate which obtained before and immediately after the placement of complete denture. There was significant differences of the salivary flow rate before and after the placement of denture.

Assessment of Pattern of Suicidal, Accidental and Homicidal Cases Along with the Sort of Poisoning in North Indian Population

Qaiser Rasool Panzoo1, Abhishak Kumar Varshney2, Anuj Gupta3, R.N. Tandon4
1Assistant Professor, Dept. of Forensic Medicine, Saraswathi Institute of Medical Sciences, Hapur, 2Assistant Professor, 3Associate Professor, 4Professor, Dept. of Forensic Medicine, TMMC & RC, Moradabad

Abstract

Introduction: This study aims at determining the mode of suicidal, accidental and homicidal cases along with the sort of poisoning in north Indian population in relation to age, gender, profession, marital status, upshot of diverse cases of poisons and prerequisite of ventilatory support in dissimilar kind of poisonings.

Materials and Methods: The study includes patients who had been earlier exposed to the to poison either by domestic or farming pesticide, snakebite, toxic plants, stings, manufacturing pollutant, drugs or varied stuffs. The status of patients undergone through poisoning regardless of age, gender, sort as well as method of poisoning, constituent of poisons were recorded in a proforma as prescribed by WHO guidelines. Results: Poisoning was more during summer season was found to be having the majority of cases which comprised 35.0% of the total recorded incidents. Household and agricultural agents comprising of the 55.2% of the total were followed by bites and stings comprising 26.2% were allied with a large amount of poisoning. Conclusion: The prototype of poisoning in the current study is no exception with the patterns observed in most of the other associated studies, preponderance of fatalities comprised male and toxins used for agriculture affairs.

Keywords: Poisoning, Suicidal, Accidental, Homicidal, Victims, Deaths

Introduction

Suicidal deaths are counted approx a million each year whereas approx 3,70,000 deaths are reported due to conscious ingestion of pesticides every year. According to WHO, in the year 2012 an estimated count of 1,93,460 people died globally due to inadvertent poisoning. A total of 84% of these deaths happened in low-and middle-income nations. In the same year, an unintentional poisoning was reported causing the demise of more than 10.7 million years of vigorous life. Unfortunately the incidence of poisoning in India is rated highest in the world. Toxic exposure is considered to be one of the major causes of deaths. The count of deaths is estimated to be 50,000 each year from such incidence. Household agents were considered to be the major causes for such unfortunate events by National Poisons Information Centre, New Delhi. The total percentage of accidents arising from such incidents is reported to be 44.1% which is followed by incidents emerging from drugs 18.8%. Occurrences from agricultural pesticides mounts up to 12.8% followed by industrial chemicals with 8.9% . Animal bites and stings have a total percentage 4.7%. Plants, unknown factors and miscellaneous groups have lower percentages ranging 1.7%, 2.9% and 5.6% respectively.

In non-communicable diseases, poisoning is a major epidemic in the present era. The numbers of demises occurring from poisoning are so high that they are counted next only to the deaths arising from road traffic accident. Earlier , deaths from poisoning resulting from the consumption of pesticides were largely inadvertent
However, later on trouble-free accessibility, small price range, and unobstructed transactions led to an swell in suicidal and dangerous cases as well. Three million cases of poisoning worldwide every year has been estimated by World Health Organization (WHO). Developing nations are of great concern in this regard as 99% of such cases have been reported in these countries. Diverse geographical conditions, varied demography and differences in religious and cultural practices mark dissimilar cases in India and the frequency and mold of poisoning differ from one place to another. Therefore, it is enviable to carry out provincial studies sporadically to distinguish the level and fruition of the crisis. Aluminum Phosphate (ALP) and Organophosphate Poisonings (OP) are extensively used in western India to control vermin and insect and have turned out to be foremost providers of deaths resulting from poisoning. Snake bite in addition is a frequent medical crisis faced by rustic inhabitants. Early identification, cure and preclusion are vital in reducing the load of poisoning associated wound in any nation. Studies concerning to the epidemiology of poisoning have been done in very meager number in north India as compared to western part of the country. This study aims at determining the mode of suicidal, accidental and homicidal cases along with the sort of poisoning in north Indian population in relation to age, gender, profession, marital status, upshot of diverse cases of poisons and prerequisite of ventilatory support in dissimilar kind of poisonings.

As per the latest census in 2011, the entire populace of Pune, a city in state of Maharashtra in India, was 9.4 million establishing it the 4th most densely inhabited district in India. The city accommodates numerous industrial vicinity which offers effortless convenience to huge number of compounds and pesticides which in turn upshots into remarkable use of these agents for poisoning. The agricultural diversity of Pune has another aspect of happenings as it brings forth tremendous use of pesticides for determined self-harm and accidental revelation along with amplification in animal bites and stings.

Materials and Method

The total period devoted to the study was three years. The study includes patients who had been earlier exposed to the to poison either by domestic or farming pesticide, snakebite, toxic plants, stings, manufacturing pollutant, drugs or varied stuffs. The status of patients undergone through poisoning regardless of age, gender, sort as well as method of poisoning, constituent of poisons were recorded in a proforma as prescribed by WHO guidelines. The patients up to the 6 miles west of the middle town are served by the emergency department. Data collection was executed in accordance with the hospital guidelines after appropriate endorsement by the hospital establishment. The set for the study was the emergency department of an inner city level-one trauma center with just about 85,000 visits per year.

Cross sectional study was made and deployed utilization of exposition removal of data from evidence offered at the public and private teaching hospitals correspondingly. The entire poisoning cases obtainable in the medical record section were incorporated in the work. Data compilation was made in Predefined manners. Chi Square test was conducted to establish the connection between the variables. P<0.05 was deployed to settle on importance.

Results

In the entire period of the study, a total of 1050 cases were assessed over a length of 3 years. Exclusions made in the study were marital status and professional background. The reasons behind the exclusions were inappropriateness and unavailability of data in many cases. Else, the gender, reason of poisoning, age, poisoning route, seasonal deviations and agents implicated in poisoning is in accordance with the records presented. A total of thirteen cases were accounted dead on admission.

As compared to women, the preponderance of fatalities was of men comprising 66.1% of the total (table No.1). The majority of victims were married.

Discussion

The reason behind the elevated frequency of poisoning in the age group of 20-35 years might possibly be due to the familial, educational and service related strain. Moreover, the trouble-free accessibility of domestic agents in this manner clarifies the prevalence. Familial aggression, poignant standing of adolescent girls and their defenselessness to strain and anxiety for the duration of puberty is the cause for amplified feminine cases in age group of 13-19 yrs. Swift amplification in gratitude by farmers and collapse to repay due to the reason of ordinary catastrophe like draught could be the motive at the back of the augment in poisoning in times of summer period.\textsuperscript{6,7} Being an agriculture nation, handling of pesticides in country like India is a customary ritual by farmers and their family associates.

Unfortunately self poisoning is a very old method of attempting suicide. There are various incidents accessible from diverse sections of the globe bestowing prominence to a variety of stuff maltreated for heightened poisoning. Western nations have soporific and numbing as major and frequent material mistreated, with transience variable changeable between 0.4% and 2.0%\textsuperscript{8,9} crop sprays and drugs have been reported as the frequently maltreated toxic materials in central Asian countries like Sri Lanka and Pakistan. Uganda, in African countries illustrate crop sprays and drugs with known transience rates ranging between 2.0% to 2.1%\textsuperscript{10,11} The anguish in any case of heightened poisoning relies on an amount of reasons like character of poison used, dosage frenzied, stage of obtainable medical amenities and the period of hiatus amid consumption of poison along with period of time taken to come to the hospital, etc.

The outcome of the work exemplifies that a sum of 1050 patients were taken into the admission at hospital due to heightened poisoning. 186 patients comprising the ratio of 8.3% of the total admitted patients reported dead because of poisoning. The conclusion of the current work is in accord with a variety of reports from developed and emerging nations, which divulge a extensive hike in transience and morbidity happening because of poisoning.\textsuperscript{12-15} The outcomes of the work discovered an elevated prevalence of poisoning in male victims in comparison to the female patients in all age groups, substantiating added studies.\textsuperscript{12-14} There are conclusions drawn from some other nations where the female ration has a predominance.\textsuperscript{15,16} The greater part of such occurrences in male victims was from the age group of 21–30 years. The male prevalence seems to be the reason for major revelation to job-related vulnerability and strain as measured up with females in this part of the globe. Mortality resulting from organophosphates was maximum as per the present study which was very much alike to the study performed in South India. Aluminiumphosphide is experienced as the foremost reason of poisoning in South India. An amplified trending use of alcohol along with a toxic material for self harm was found, escalating the danger of aspiration, coma and respiratory breakdown leading to death. The possible reason for the maximum exposure during 6pm– 12 am might be the constant pondering over the problems in evening and in the night when victims had enough time after the routine tasks which ultimately resulted in harming themselves.

Conclusion

The prototype of poisoning in the current study is no exception with the patterns observed in most of the other associated studies, Preponderance of fatalities comprised male and toxins used for agriculture affairs. Some effectual steps to decrease the rate of poisoning and improvise the results may be as follows:

1) Poison information centers could of great use in this regard. However, there are certain such centers, which are operative in some places. This practice should be brought to a great level by making them prepared in every public hospital and government teaching hospitals.

2) Anti-dotes must be readily accessible in the primary health center.

3) Storages should be kept in good control in the houses of the farmers to prevent any unwanted situation arising from poison intake.

4) Lay persons should be made skilled by proper training on how to deal with poisonous substances.

The study was performed with hindsight by gathering the data from medical records. However, some crucial information was missed out of the records. These information were of social and economic stature of the patients, referred cases from other hospitals, intake timings of drugs and time of admission to the admission. Meager management and safeguarding of records was recurrently experienced in the public setting.

Importance of Forensic Odontology

Mutum Sangeeta Devi1, Manju J2, Rahul Rajpurohit1

1Senior lecturer, Madha Dental college and Hospital, Chennai., 2Senior Lecturer Thai moogambigai Dental College and Hospital DR. M.G.R Educational and Research Institute University Chennai

Abstract

Forensic dentistry is the connection between the dental professions and forensic professions. In fact, the teeth and jaws are highly resistant to degradation and decomposition by postmortem. For a number of different reasons and situations such as mass disasters, in criminal investigations and in the case of disfigured bodies due to fire and vehicle accidents, dental identification of humans happens. The different methods include x-rays, antemortem & post-mortem photographs, tooth prints, palatal rugae, lip printing, bite marking and molecular methods such as polymerase chain reaction for pulp DNA analysis.

Keywords: forensic, bite mark, lip print, tongue print, polymerase chain reaction

Introduction

Forensic Odontology is the branch of forensic sciences that aims to establish identity of dead bodies: as offenders or innocent, based on available dental records and is also called Forensic Dentistry.1, 2 Teeth, lips, tongue, facial bones and associated dental items like fillings, dentures etc. can be source for identification of dead human bodies, it helps in identification of destroyed body age, sex accordingly.3-5 Even in major accidents, violence, burial, or other serious exposure to the elements, they still avoid decomposition. For every individual the dental patterns are unique. This peculiarity is also due to the dentist’s variety of treatments. A person’s dentition is therefore useful for individual identification and comparison, if there are records for that purpose.5 Teeth can survived after mortem so it is the most reliable to use for identification.6

Forensic odontology in the recent scenario has following applications.

- Maxillo - mandibular investigation of hard and soft tissues.
- Situations of major casualties where criminal investigation is crucial.
- Situations where there are incidences of bite marks. Example - Physical maltreatment with child, inflicting sexual trauma, in situations of unarmed personal safety measures.7

Classification according to type of examination8:

- Examination of living individuals - Bite Injury, determination of sex and age.
- Examination of dead individuals - occlusal pattern variations of human dentition, dental restorative materials, prosthetic rehabilitations.
- Examination of physical materials: Identification of isolated human teeth
- Examination at the scene of crime or disaster-human skeletal remains with teeth intact tooth imprints
- Examination of dental records: By specific research team and dental experts

Recovery team:

The team members are supposed to collect the dead bodies and protect their identities by means of a numbering system, store the dental evidence safely in a proper transport media without interfering with them.9
Forensic odontologist should be part of this team and should search for onsite dental evidence to prevent contamination of the dental substances during transport to the mortuary.10

**Ante Mortem Team:**

The task of deciphering data of the missing person is assigned to the team. Family members of the missing person and health care providers play a crucial role in the purpose. Dental records including computed tomography scans, x-rays, dental models and facial photographs are collected and stored in the appropriate tabular format. It serves as proof.11

**Post Mortem Team**

This is a team that tracks their cumulative research from dead bodies. In natural and manmade disaster situations the teeth material is a tough organic material that remains intact. Dental pulp tissue is important for DNA sampling. Vital teeth are extracted and sent for proper matching to forensic DNA laboratories.6

**Dental Record Maintenance.**

Maintaining dental records is a dentist’s responsibility and an essential component that acts as a source of information for dentists and patients, both for medical, administrative and forensic purposes.12 The dental graph should be accurately registered. This provides information on descriptions of all the teeth found in the mouth, such as teeth present or missing, restorations, pathologies such as caries, involvement in furcations, root sections and periodontal health.13

**Sex determination**

Forensic odontologist can determined age from dental and skeletal remains.14 Woman has less cusp than male (distobuccal or distal cusp) in the mandibular first molar.15 The scale of the crown and the tuber of Carabelli to be bigger in males.16 Using Polymerase Chain Reaction (PCR) DNA from pulp tissue is used for sex determination.17 Sivagami et al. achieved 100% success in determining the individual’s sex. 18

**Age estimation**

Dentition is used to estimate the age of children and adolescents and adults in three categories, namely prenatal, natal and postnatal time.19 For children and young adults, age assessments are made using clinical methods such as the sequence of eruptions, radiographic methods such as the Schour and Masslers process, the Moorer, Fanning and Hunt method, the Demirijian, Goldstein and Taners method and the Nolla technique.20 The eruption of third molars is important in separating juveniles and adults.21 For adults, regressive alteration of the teeth, periodontal status such as loss of attachment, dentin translucency histologic changes such as gradual cement lines, radiographic assessment such as root resorption, cement apposition at the apex helps for age estimation.22 Gustafson developed a single tooth age estimation method that uses different stages of regressive teeth changes.23 Several studies show pulp of tooth ratio with volumes calculates the age.24

**Race determination**

Carabelli cusp variation, fissure system, morphological incisor patterns are measures to distinguish between Caucasian, Asian and black races.25
Socio economic status

Socioeconomic person can easily identify by seeing their teeth. Those who have number of caries and cheap material fillings, prosthetic, indicate low income status, protruded malocclusion in children indicate thumb sucking habit. Orthodontics appliance, expensive tooth fillings indicate high income.27

Palatal rugae.

The ridge present on either side of the midpalatine raphe in the anterior part of the palate is referred as palatal rugae. Palatal rugae is well covered by fat pad buccal teeth. This prevents decomposition. Palatal rugae pattern is special for every single person. Because of their anatomical position inside the mouth, the palatal rugae are well-preserved even after third degree burns. That keeps them well protected against trauma and isolated from high temperatures, more resistant to decomposition and thermal effect.282930 Thomas et al 31 has classified rugae pattern as Diverge, Converge, Curve, Wavy, straight, Circular. Palatal rugae can also aid in gender and race differentiation

Lip print

Tsuchitsashi et al have suggested 6 different types of groove pattern in the lip that might be useful in investigating crime. Every individual has a different lip print.32 Similar to the prints on the finger, thumb, foot and lip prints, these are also distinctive and do not alter during a person’s life.33 Recent studies have proven that lip prints are a superior method in gender determination compared to fingerprints and mandibular canine index.34

Tongue print

The tongue’s dorsal surface is special for each person. Even among identical twins, the characteristic features of the tongue display remarkable difference. For forensic odontology, lingual contact on the dorsal surface along with the lateral border has been proved useful. The tongue is a unique organ that exchanges many static and dynamic characteristics.35

Bite mark

In violent incidents such as sex-related crimes, cases of child abuse, and offenses involving physical altercations such as homicide, bite marks on human tissues can be observed. It can occur in situations where the attacker bites the victim or the victim bites the attacker as a defensive act, but it should be noted that in the cases, the bite victim may be the perpetrator. Male victims are most often bitten on their arms and shoulders, while female victims are most often bitten on their breasts, arms and legs.36 In bite mark analysis, dental findings should include all the teeth present and missing, interrelation between both jaws, both arches form, dimension of mesiodistals and any unusual features if any like fractured, supernumerary, rotated etc.37

DNA analysis

DNA can be extracted from dentin and pulp with success. DNA remains intact for a very long time in the teeth and bones, and is therefore a valuable source of information. The method of DNA extraction consists of the following stages.38 cell rupture or lysis, protein denaturation and inactivation by chelating agents and
proteinase final step involves DNA isolation

**SALIVA**

It has been shown that human saliva is an excellent source of high molecular weight DNA. Crime scene clothing, cigarette buds etc., can collect saliva samples. The isolated samples are analyzed and linked to suspicious reference sources.\(^{39}\)

**Figur 3 - Extraction of DNA samples from saliva\(^{40}\)**

**Conclusion**

Forensic dentistry plays a major role in identifying those individuals who can’t be visually or otherwise identified. Teeth and dental structures’ durability ensures there is a lot of information that can be used for human identification purposes. This branch of medical science is focused on the idea that physiological variations, anatomy and effects of dental hard and soft tissue therapy are special to each individual. That is also very useful in situations with medico-legal background. As the scope of forensic science is very wide and challenging, Forensic odontology-trained dental surgeons can make unique contributions in the administration.

Study of Otoacoustic Emissions and Brainstem Evoked Response Audiometry in Infants

Naman Pincha1, Vikas S Kulkarni2, Abhay D. Havle3, Disha Jain4, Ganesh M. Vihapure5, Swapna A Shedge6
1Resident, 2Asso. Professor, 3Professor, Department of Otorhinolaryngology, Krishna Institute of Medical Sciences Deemed To Be University, Karad, 415110; Maharashtra, India, 4CHL Hospital Indore, MP, India, 5Asst. Professor, Department of Otorhinolaryngology, 6Asst. Professor, Department of Anatomy, Krishna Institute Of Medical Sciences Deemed To Be University, Karad, Maharashtra, India

Abstract

Aim and objective: To evaluate the usefulness of otoacoustic emissions and brainstem evoked response audiometry for assessment of hearing loss in newborn.

Materials and Method: Total of 370 healthy newborns were subjected to ENT examination, otoacoustic emissions (OAE) within 3 days to 30 days of birth. All newborn with normal hearing at OAE were not studied further, and for refer cases OAE testing was carried out again at 3rd month of age. The infants who failed the second OAE were subjected to brainstem evoked response audiometry (BERA). All newborn with abnormal BERA were subjected to repeat BERA at 6th month of age.

Results: All 370 healthy enrolled babies underwent OAE testing. Of which 200 (54.05%) passed the test and 170 (45.95 %) were referred. All 170 referred babies underwent repeat OAE at age of 3 months. Of which 50 passed the test and 120 were referred again. All these 120 referred cases were subjected to further testing using BERA between the ages 3-4 months. 2 were found to be having profound hearing loss during BERA testing at 3-4 months as well as at 6 months.

Conclusion: Profound hearing loss was found in 2 out of 370 enrolled normal newborn. This also means that if only ‘at risk’ babies were screened there is likely chance of missing impaired hearing in newborn without any risk factor. Hence, during hearing assessment it is mandatory to include all newborns irrespective of their status normal or ‘at risk’.

Keywords: Hearing loss, Hearing tests, Newborn

Introduction

Hearing impairment is one of the most critical impairments with significant social and psychological consequences. Delay in detecting children with congenital or acquired hearing loss may result in lifelong deficits in speech and language acquisition, poor academic performance and personal-social and behavior problems 1,2. Significant hearing loss is the most common disorder, occurring in 1 to 2 newborns per 1000 in the general population 3,4. As compared to vocabulary of a 3-year-old child without any hearing impairment is 500-900 words. Similarly with hearing impairment if remediated at birth is 300-700 words; at 6 months is 150-300 words and at 2 years is 0-50 words. The hearing loss can be conductive or sensorineural and mixed. Sensorineural further can be either cochlear, retrocochlear or central. Many risk factors for congenital hearing loss are well known 5. Critical period for identification and remediation of hearing loss is before
the age of 6 months. It has been observed that practice of neonatal screening has dramatically lowered the age of diagnosis of deafness from 1½ - 3 years to less than 6 months of age. In view of the above, standard guidelines for early diagnosis of hearing loss are very much needed. We undertake this study about usefulness of otoacoustic emissions (OAE) and brainstem evoked response audiometry (BERA) as a part of two-stage screening protocol in early assessment of hearing in newborn. In this two tier screening program, the second tier BERA being relatively more expensive was used only for select a few, making the program more practical and viable. OAE are quicker methods unlike BERA for assessing hearing in newborns. OAE are sounds of cochlear origin recorded in the auditory meatus, produced by the action of healthy outer hair cells. In organ of Corti there are three rows of outer hair cells (OHCs) and one row of inner hair cells that sit on the basilar membrane and by the tectorial membrane on top. OAE test is performed by keeping a small probe in the child’s external acoustic meatus, click sound is delivered and response is detected by the probe and its graphical output in the form of display as well as print is obtained. In BERA test the clicking sound is presented in each ear separately by the earphone placed in external auditory canal, resultant action potential generated by the cochlea in auditory nerve is picked up by the skin electrodes placed strategically. This is further processed to generate graphical output. OAE and BERA are useful tools in determining the type and the site of lesion causing hearing loss. The timely intervention by stimulation of hearing is most important part in management of hearing loss in newborn. This study was made to evaluate the usefulness of OAE and BERA for early diagnosis of impaired hearing in newborn with no risk factor.

**Material and Method**

The study was carried out at Otorhinolaryngology department, in tertiary care teaching hospital. Total of 370 healthy newborn referred from the department of Obstetrics without any risk factors during period between October 2017 and April 2019 were included in the study. All newborn requiring active life support therapy, newborn with acute illness, congenital anomalies of ear such as atresia or stenosis of external auditory canal, any head and neck deformities and newborns whose parents did not consent for the procedure were excluded from the study. All enrolled cases were subjected to OAE using distortion product otoacoustic emission (DPOAE) screening after ENT examination. OAE testing was done as per referral at 3 days to 30 days of birth. All babies with normal hearing at OAE were eliminated from further study, and for refer cases OAE testing was repeated at 3-4 months of age. The infants who failed the OAE at 3-4 months of age were subjected to BERA for confirmation of hearing loss or without any deafness. All babies with abnormal BERA were considered as a probable candidate requiring stimulation of hearing either by way of hearing aid (HA) or cochlear implant (CI) after reconfirmation by BERA again at 6th month of age. All procedures performed on human participants were in agreement with ethical standards of the Institutional Ethics Committee.

**Informed Consent:** Informed consent was obtained from all the cases in the study.

**Statistical Method**

Using statistical analysis the frequency distribution of collected data was obtained with the help of IBM SPSS (Statistical Packaging for Social Sciences) IBM, INDIA, version 20.0 software.

**Observation and Results**

The present study was conducted on 370 newborn among whom 183 (49.5%) were males and 187 (50.5%) were females. 247 were in age group of 1-10 days, out of which 183 were male and 84 female. 93 were in age group of 11-20 days, out of which 48 were male and 45 female. 30 were in age group of 21-30 days out of which 17 were male and 13 female. Out of 370 neonates screened initially, 200 (54.1%) did not require further assessment as they passed first OAE between 3 days to 30th day. Remaining 170 (45.9%) referred cases were advised further testing by BERA (Refer Table 1). Out of 170 cases, 50 (29.4%) cases passed the second OAE at 3-4 months and did not require further assessment (Refer Table 1). Remaining 120 (70.6%) referred cases were referred cases requiring further testing (Refer Table 1). Out of 170 cases, 50 (29.4%) cases passed the second OAE at 3-4 months and did not require further assessment (Refer Table 1). Remaining 120 (70.6%) referred cases were advised further testing by BERA (Refer Table 2). At 3-4 months of age out of remaining 120 cases BERA was normal in 118 (98.33%) requiring no further testing and in 2 (1.67%) it was profound hearing loss, which was reconfirmed at 6 months. (Refer Table 2)

**Summary**

All 370 healthy enrolled newborn underwent OAE testing. Of which 200 (54.05%) passed the test and 170 (45.95 %) were referred. All 170 referred underwent
repeat OAE at age of 3 months. Of which 50 passed the test and 120 were referred again. All these 120 referred cases were subjected to further testing using BERA between the ages 3-4 months. 2 out of these 120 were found to be having profound hearing loss during BERA testing at 3-4 months as well as at 6 months. (Refer Table 3)

Discussion

The hearing loss is often overlooked because of its silent nature preventing the detection through routine clinical evaluation. The definition of early identification and intervention has evolved over the years. Early identification is considered to be as early as 3 months for diagnosis and 6 months for intervention. There are few surveys about finding incidence of congenital hearing loss in India. In this study the incidence of impaired hearing was 5.4 per 1000. Whereas, P.Nagapoornima, et al in 2006 found it to be 5.6 per 1000, and similarly Bhatt in 2015 found 5% in high risk newborns and 0.5% in normal newborns. In this study there were 2 cases having impaired hearing amongst 370 newborn without any risk factor. Out of remaining 368 cases 200 were eliminated from the study as they passed OAE at first visit and 168 failed became normal during further study. Johnson et al reviewed the results of 1317 ears of patients who initially failed the OAE test and then passed the BERA test. Therefore even though OAE is useful initially for early screening about hearing loss, BERA is for diagnosis as well as confirmation as in this study. Hence universal screening remains the ideal strategy for diagnosis of hearing impaired in newborn. This study has shown that the strategy of two-stage OAE screening and subsequent confirmation by BERA helped in picking up 2 newborn from not ‘at risk’ group which otherwise would have gone unnoticed if only ‘at risk’ were screened. These 2 newborn having profound hearing loss would otherwise be refrained from the benefits of early stimulation of their hearing either by way of hearing aid (HA) or cochlear implant (CI) for speech rehabilitation. The incidence of hearing impairment and other findings of this study are in accordance with previous studies.

Conclusion

Amongst 370 enrolled newborn 170 were referred in first OAE, 120 were referred in second OAE. Profound hearing loss was found in 2 by BERA during 3-4 months of age which further was confirmed by BERA again at 6 month. If only ‘at risk’ babies were screened initially there was likely chance of missing above 2 cases of profound hearing loss amongst 370 enrolled newborn without any risk factor. Hence, it becomes mandatory to include all newborn irrespective of their status normal or ‘at risk’ during hearing assessment for the benefits of early stimulation by way of hearing aid (HA) or cochlear implant (CI) and speech rehabilitation.

Ethical approval: All procedures performed on human participants were in agreement with ethical standards of the Institutional and/or National Ethics Committee.

Source of Funding: In this project the cost of investigations of the study participants was born by the Institute research fundings.

Conflict of Interest: None.

Role of Hand and Foot Print Dimensions in Stature Identification among Indian Population

Nandita K.P1, Srikant N2, Shweta Yellapurkar3, Srishty Pundir4, Akriti Kaul4

1Associate Professor, 2Professor & Head, 3Assistant Professor, Department of Oral Pathology and Microbiology, 4Intern, Manipal College of Dental Sciences, Mangalore, Manipal Academy of Higher Education, Mangalore

Abstract

Introduction: The four essential factors in Forensic Anthropology, representing in determining personal identification are age, sex, stature and ethnicity. Among this ‘big fours’ of the biological profile, determination of stature is considered as one of the main parameter of personal identification in forensic examinations. Thus, this study will aim to correlate relation between hand and foot measurements with stature of individual.

Aim of the study: The study aimed to estimate the relationship between statures of an individual on the basis of hand and foot prints, in Indian populations.

Materials and Method: The study group comprised of 100 subjects (age group above 18 years) with normal growth and development.

Measurement of height: The measurements of height was made using standard anthropometer by making the subject stand erect on the horizontal plane. The distance of the subject from the ground to the highest point of the vertex in the median sagittal plane was recorded.

a) Hand length and Hand breadth: Hand length (HL) was measured from mid-point below radial and ulnar tuberosity to tip of middle finger. Hand breadth (HB) was measured from base of 5th to 2nd metacarpus by drawing the outline of hand on paper.

b) Foot length and breadth: The foot length was measured as a direct distance from the most posterior point of back to tip of the Hallux or to tip of the second toe. The foot breadth was measured as the direct distance between the most prominent point on medial side and the most prominent on lateral side.

d) Heel Ball Index Measurement

The breadth of the foot at ball and at heel (BBAL, BHEL) were measured. The HB Index of the foot was calculated as (BHEL+ BBAL) x 100.

Results: Correlation of the various hand and foot parameters showed a regression coefficient range of 0.331-0.377. Among all variables measured, hand length exhibited the highest correlation with stature (r value of 0.377 p-value < 0.003). Further forward stepwise linear regression analysis [Height = 115.426+2.615* Hand length (Left)] established hand length to be the single best predictor of height (r value of 0.377 and standard error of 7.35cms).

Conclusion: Thus, the foot length provides highest reliability and accuracy in estimating stature of unknown males and females. Also this study will help to generate population-specific equations using a simple linear regression statistical method.

Key words: Anthropology, Stature, Regression formulae, hand and foot length and breadth

Introduction

Forensic Anthropology is described as the analysis of human remains for the medico legal purposes to establish identity, investigate suspicious deaths and identify victims of mass disasters. Identification of human remains is one of the prime factors addressing the victims in case of mass disasters such as fire accidents,
explosions and aircrafts and railway accidents.

The four essential factors usually represented in determining personal identification are age, sex, stature and ethnicity. Among this 'big fours'\(^1\) of the biological profile, determination of stature is considered as one of the main parameter of personal identification in forensic examinations. Stature is the height of a person in the upright posture and has a definite and proportional biological relationship with each and every part of the human body which helps the forensic experts to identify along with other evidences like dentition, foot prints and hand dimensions.\(^1\)

Thus, this study aim to correlate relation between hand and foot measurements with stature of individual.

Aim of the Study

The proposed study aim to estimate the stature of an individual (male and female) on the basis of hand and foot prints, in Indian populations.

Objectives of the study

· To determine the relationship between stature and hand dimensions (length and breadth) among males and females of Indian populations.
· To determine the relationship between stature and foot dimensions (length and breadth) and also to derive heel ball (HB) index among males and females of Indian population.

Materials and Method

The study group comprised about 100 subjects of age group above 18 years after their informed consent and after Institutional ethical committee approval.

Inclusion criteria:
· Subjects with normal growth and development.

Exclusion criteria:
· Physically and mentally challenged individual
· Malocclusion

Measurement protocol

**Measurement of Height\(^2\):**

The measurements of height was made using standard anthropometer by making the subject stand erect in the anatomical position that is on the horizontal plane, barefooted according to the Frankfort plane, aligning the posterior surface of heels, pelvic girdle, scapular girdle, and occipital region to the vertical plane. The distance of the subject from the ground to the highest point of the vertex in the median sagittal plane was recorded. \(^2\)

**Hand and Foot Measurements**

**a) Hand length and Hand breadth \(^3\):**

Hand of the subject (right and left hand) was kept straight and flat on table. Outline of hand was drawn on an A4 sheet of paper and the measurement were made respectively. Hand length (HL) was measured from midpoint below radial and ulnar tuberosity to tip of middle finger. Hand breadth (HB) was measured from base of 5th to 2nd metacarpus. \(^3\) [fig.1]

![Fig: 1 Hand measurements](image)

**b) Foot length and breadth \(^4\):**

Right and Left foot were taken for the measurement by placing on an A4 sheet of paper and drawing the outline of foot. The foot length was measured as a direct distance from the most posterior point of back [pternion] to tip of the Hallux or to tip of the second toe (acropodion) [fig:2]. The foot breadth was measured as the direct distance between the most prominent point on medial side (Metatarsal tibiale) and the most prominent on lateral side (Metatarsal fibulae). \(^4\)
Foot breadth at the ball (BBAL) was measured as the widest part of the foot at the ball while the foot breadth at heel (BHEL) was measured as the widest part of the heel. [Fig: 3]. The HB Index of the foot were calculated as (BHEL + BBAL) x 100.

**Method to make the outline of hand and feet**

The subject were asked to place his/her hand on an A4 sheet of paper. Outline of hand and foot were drawn using a pencil. Before lifting it from the paper, anatomical landmarks of the hand and feet were marked on the papers close to the hand and footprints which are mid-rear heel point and most anterior point of all toes in case of feet and mid-point below radial and ulnar tuberosity to tip of middle finger in case of hand.

**Statistical Analysis**

The data were then analyzed using linear Regression Analysis using the SPSS software to estimate the height of the individual based on and hand /foot indices. The regression equation with the R and $R^2$ values with standard errors of estimate were calculated to identify the most suitable predictor of stature of the individual.

**Results**

Correlation of the height of the individual with various hand and foot indices was done using Pearsons correlation coefficient (Table 1). The best parameters which correlated were the hand and foot lengths, with $r$ value ranging from 0.331-0.377 (Figure 1). Among all variables measured, hand length exhibited the highest correlation with stature ($r$ value of 0.377, $p$-value < 0.003). Forward stepwise linear regression analysis [Height = 115.426+2.615* Hand length (Left)] further established hand length (left side) to be the single best predictor of height ($r$ value of 0.377 and standard error of 7.35cms) [Table 2].

Figure 1: Scatter plot showing the correlation of height and hand and foot measurements
Discussion

Stature is considered as one of the important characteristic for identification of an unknown person and is usually evaluated based on the lengths of the limb bones based predominantly on the femur. Stature depends on gender, genetic make-up, racial and geographical origin, social stratum as well as physical activity. The primary objective of the present research was to study the ethnic peculiarities of the relationship between the stature and hand and foot measurements in Indian population and to estimate stature using the measurements of handprints in this population.

The results of the present study show that the dimensions of the hands and feet were statistically significant with positive correlation with stature of an individual. It also facilitates formulation of regression equations which can be successfully utilized for stature estimation among Indian population. In this study among hand dimensions, HL had the best correlation with stature were r value = 0.377 and p value =0.003 and a weak correlation was stated between HB and stature.

Present study has found that both Hand length as well as Foot length are showing positive and statistically significant correlation with stature, but Hand length is showing more correlation with stature as compared to Hand breadth. Such finding were also observed in Australian and Thai population in the study done by Ishak NI et al and Laulathapho P et al.

In the present study, the age of the subjects were between 18-30 years to avoid the process of bone loss after this age. In this regards, Firooznia et al. (1984) pointed out that bone loss with age is a natural phenomenon and bone mass peaks around ages 25–30 years and declines gradually thereafter in both men and women. The FL and FB were found to be increasing significantly on weight bearing between 3 and 19 years of age and in both genders (Hasegawa et al. 2009).

In the present study, values of mean hand length were found to be higher on the left side compared to right side which is in agreement with the studies of Kulaksiz and Gozil. Results of the discriminant analysis by Troy case etal clearly indicate that the left hand should be preferred over the right, and that the hands should be preferred over the feet, for determining sex based upon length measures. It is also clear in both the hands and feet, that the phalanges are better at discriminating sex than the metacarpals or metatarsals.

The human hand that is considered the most used and versatile part of the body and is of great importance to investigators in the field of anthropometry according to Rastogi et al’s study were HL was used for estimation of stature. In both, males and females, HL showed high positive value of correlation coefficient, which suggests a strong positive correlation between stature, HL, In the present study Regression equations for estimation of stature was derived as Height = 115.426+2.61 *(Hand Length of left side).

Length measurements of hand and feet differ substantively from the other measurements could be explained by the fact that they are less influenced by lifetime activity. The main impact on length measures will be genetic and nutritional. Evidence from stature and growth studies of living humans suggest that bone length is influenced.

Conclusion

The stature can be accurately and satisfactorily estimated for medico-legal and forensic purposes since bilateral and bisexual differences have been taken into account while devising the linear regression equation. However, if the age of the person is known, then better result can be obtained using the different linear regression equation as per age.

A Profile Study of Sudden Natural Death Cases in Vadodara Region of Central Gujarat

Neerav M. Rana1, Anil R. Pandey1

1Assistant Professor, Dept. of Forensic Medicine & Toxicology, Government Medical College, Bhavnagar

Abstract

Sudden death is said to be sudden or unexpected when the victim not known to have been suffering from any dangerous disease, injury or poisoning is found dead or dies within 24 hours after the onset of terminal illness (WHO). Incidences of sudden natural deaths are increasing now a days and specifically in healthy young individuals can arise suspicion of foul play. Our study may help to provide epidemiological data regarding the sudden death that can be used to control disease outbreaks, identifying emerging causes or changes in disease pattern so that appropriate action can be taken to reduce the morbidity and mortality. The present study undertaken to find the socio-demographic profile (age, sex and religion etc.) of the deceased of sudden death. This prospective study had been conducted on autopsy cases brought to tertiary health center of Vadodara, Central Gujarat for the period of one year. During study period total 2240 autopsies were conducted, of which 224 cases (10%) were sudden deaths. Most of the cases were from the 41 - 50 years age group. Of the 224 cases, 149 were due to diseases of cardiovascular system and 63 due to diseases of respiratory system. We observed that sudden death cases were higher in young age group and cardiovascular system was most commonly involved.

Key words:- Autopsy, Sudden Natural Death, Cardiovascular system

Introduction

All forensic pathologists deal not only with criminal, suspicious, accidental and suicidal deaths, but with a wide range of deaths from natural causes. Many of these are sudden, unexpected, clinically unexplained or otherwise obscure even though there need be no unnatural element in their causation.(1) Death is said to be sudden in a person if death occurring in less than 24 hours from onset of symptoms, not otherwise explained, death known not to be violent or instantaneous for which no cause can be discovered.(2) Some authors limit sudden deaths as those occurring instantaneously or within one hour of onset of symptoms.(3) An apparently healthy individual of any age when dies suddenly and unexpectedly , without any pre indication or even in case of natural death under suspicious state, with no medical attention and possibility of any disease being responsible for it being considered remote, a suspicion of foul play, injury, poisoning may arise in the mind of officials responsible for the certification of death.(4) Determination of cause of death in natural deaths, particularly when the death occurred suddenly, unexpectedly, or in the young, is an important part of forensic autopsy practice, for reasons including the following:(5)

- Performance of a complete and through autopsy on apparent natural deaths can provide valuable information in the interest of public health by identifying public health risks and monitoring disease trends.
- Identification of disease processes and patterns provides epidemiological data that can be used to control disease outbreaks, identify changes in disease patterns, or to identify reportable diseases.
- The timely and accurate diagnosis of medically important diseases can have a significant impact on the relatives of the deceased by allowing them the opportunity to seek treatment for certain hereditary
diseases in which the presenting symptom may in fact be sudden death.

Earlier studies have shown that cardiovascular disease was the most important cause of the sudden death. It was followed by respiratory disease, central nervous system disease and others. Several factors such as age, sex, occupation and marital status may also influence the sudden death which will be evaluated during this research.

**Material and Method**

This observational prospective study had been conducted in Department of Forensic Medicine and Toxicology, Medical College and S.S.G. Hospital, Vadodara during the period of 1 year from 1st March 2013 to 28th February 2014 which is tertiary health center of Central Gujarat. During this one year period 2240 autopsies were conducted and out of them 224 cases (10%) of sudden death were selected for present study in which relatives were ready to give informed written consent. Before starting the post mortem examination, a detailed history was taken from the relatives, investigating officer, inquest papers and from clinical papers. The information regarding the circumstances of death with special reference to any sign and symptoms suggestive of sudden death, family history, previous medical history, histopathology report and chemical analysis report in all cases were taken and data were filled in performa. All cases included in this study were examined meticulously during autopsy. Findings of this study were compared with the similar type of studies done by the Indian and foreign authors.

**Inclusion criteria:** All sudden natural death cases

**Exclusion criteria:** All cases where death occurred due to injury, poisoning.

- All cases where the victim dies after 24 hours from the onset of symptoms
- Decomposed and unidentified cases.

**Results**

**Discussion**

During the one year period of our study total 2240 medico-legal autopsy conducted and out of them incidence of sudden death was 224 (10%) cases. Almost similar incidence were noticed by Reddy(3), Nandy(6), Rao(8.67%) et al(7), Zanjad(8.92%) et al(8), Ambade(15.48%) et al(9). In contrast higher incidence of sudden death was reported by most of the studies done by foreign author’s e.g. Obiorah (55.6%) et al(10), in Escoffery and Shirley(51.3%) et al(11), Kuller(31.4%) et al(12), Avmak(28.9%) et al(13), and Nordrum(27.8%) et al(14). Higher incidence of sudden death outside India may be due to different type of case load, different geographical areas and different life styles of people.

Table no. 1 shows the distribution of cases according to their age and sex which shows that maximum number of the victims(27.2%) of the sudden death belonged to 41-50 years age group which was also observed by Kumar et al(15), Sarkioja et al(16) while Zanjad(26.78%) et al(8) and Ambade (20.75%) et al(9) found maximum cases in the age group 31-40 years.

Most of the studies done in India are showing that the maximum numbers of sudden death are happening in the middle aged people (31-50 years). It may be due to urbanization, westernization of Indian society, sedentary life style, increased smoking habit, stress and strain in life, lack of regular exercise and lack of regular medical check-up.

In our study majority of victims (84.79%) were male and 15.21% were female making male to female ratio of 5.57:1 which was also observed similarly by Zanjad et al(8), Kumar et al(15) and Rao et al(7) while study by Meina Singh et al(17) shows male to female ratio of 26.5:1. Thus from above studies, it was observed that males far predominate the females which is consistent with present study. During reproductive life women remarkably spared whose reason still unknown unless they have an underlying predisposition to atherosclerosis such as diabetes mellitus and hypertension. Also the habits of smoking and alcoholism are common in males and males are more prone for stressful conditions as compared to female.

It was observed that most of the victims (77.23%) were married as the occurrence of sudden deaths increase with aging. This coincides with study of and Gupta(63.49%) et al(18) and Kumar(59.8%) et al(15) where majority of sudden deaths were seen in married. The reason may be married people are more cautious and worried about their financial and other social issues.

We found that most cases were from middle and lower socio-economic class constituting 90.18% which comprises labourers, workers in industries, mills, shops, farms and other sectors, drivers and so on. These groups basically have lower income compared to higher class. They might not get regular medical checkups for early detection or even treatment for their diseases. Risk factors for coronary artery disease such as lack of physical activity, smoking, hyperlipidemia, hypertension, obesity, and diabetes are more common among individuals with middle socio-economic status. Higher socio-economic class contributed least to the sudden deaths (9.82%) which comprises businessmen, managers and executives. They had better knowledge and were more aware of the health importance. Their economic status also allowed them to have a better nutrition and healthier lifestyle.

Table no. 3 shows that workers in industries, mills, shops, farms and other sectors constituted highest cases (20.09%) and labourers (8.9%). It coincides with study of Kumar (30.6%) et al(15) where majority of the patients were from the semiskilled–unskilled group. The preponderance in this group is possibly due to low socio-economic status, lower education, neglect of alarming symptoms of illness, unaffordable treatment and physical stress etc.

We observed that maximum deaths were related to diseases of cardiovascular system constituting 54.38% which was very well supported by other similar studies e.g. Di Maio and Di Maio (60.9%) et al(19), Puranik(56.4%) et al(20), Avmak(55%) et al(13), Anderson(53.4%) et al(21), 45-50% by Reddy(19) and 45% by Nandy(22). Preponderance to cardiovascular system could be explained by changing social concepts and way of living, food habits- high concentration of fatty foods, physical and mental stress, lack of exercise with sedentary lifestyle, high salt intake, ice-cream, bakery items, urbanization, industrialization and progressive excessive indulgence of younger age groups in predisposing factors like smoking and alcoholism. In contrast to this study, very high cardiovascular disease...
rates were reported by Lorin (72.7%) et al(23) and Sarkioja(83%) et al(16). However, much lower rates of cardiovascular diseases were reported by Obiorah (23%) et al(10). There was involvement of more than one system in some cases.

The second most common cause of sudden death was related to respiratory system diseases 23% which very well supported by Yadhukul(27.45%) et al(7) and Escoffery and Shirley(23%) et al(11). Lung disease may be difficult to accept as a cause of sudden death in people who are not disabled by respiratory disease, but intermittent hypoxia may lead to ventricular arrhythmias in these patients. Pneumonia constituted 50.79% of all respiratory deaths in our study which was similar to in Nordrum (52.8%) et al(14) and in Obiorah (62.6%) et al(10). The high rate of death due to pneumonia is attributable to a lack of education, lack of health care, exposure to the cold and inadequate nutrition. Sudden deaths due to pulmonary tuberculosis was 5.11% which were more when compared to Azmak (0.7%) et al(13) and Kumar(3.1%) et al(15). Lower socioeconomic status, social stigma and treatment default may be the reason for higher incidence of pulmonary tuberculosis in our study.

The third commonest cause of sudden death was related to GI system(9.12%) which is consistent with Chaudhari(11.3%) et al(24). Fatty liver (40%) was the commonest cause followed by Cirrhosis (36%). The fourth commonest cause of sudden death was related to central nervous system diseases (6.20%) which was almost similar to Chaudhari et al(24). Intracerebral haemorrhage (52.94%) was the commonest cause followed by Subarachnoid haemorrhage (29.41%).

**Conclusion**

The present study illustrates a clear influence of age, sex, religion, occupation, marital status, socio-economic status and life style on the incidence of sudden death.

From this study we can conclude that diseases of the cardiovascular system are the major contributing factor for sudden deaths. The age distribution curve points out the fact that younger age group involvement appears to be slightly higher. Respiratory system diseases contributed the next major share of diseases. This can be attributed to poor hygiene, malnutrition and low socio-economic status.

This type of autopsy based information is vital in the planning of the health services, teaching and research programmes, particularly in a developing nation with a limited resources.

Effectiveness of Progressive Resistance Drills and Dynamic Balance Training on Functional Performance among the Patients with Osteoarthritis of Knee

Nikhil Jitendra Desale1, Shrinivasan Anandh2
1Intern, 2Professor, Department of Community Health Sciences, Faculty of Physiotherapy, KIMS “Deemed to be University”, Karad, Maharashtra, India.

Abstract

Osteoarthritis, degenerative joint disease in which the wearing down of the protective tissue at the ends of bones (cartilage) occurs gradually and worsens over time. The majority of people aged 40 years have radiographic evidence of knee osteoarthritis, is more common in women than in men.(1) Exercise has a wide range of health benefits in every individual. Mostly for middle aged population there is a clear evidence to support exercise in improving health and functional performance with well evidenced exercise programs.(2, 3) These programs have shown to improve the mobility of joints and strength of muscles around the joints by performing specific exercises for the specific muscles. This population people are often unable to undertake high intensity exercise programs. Therefore progressive resistance exercises are been used as an alternative. Many research studies have reported the benefits of resistance exercises as a physical activity for middle aged adults and individuals with limited movement.

Method: The subjects in the KIMSDU campus were screened and 41 subjects fulfilling the criteria were involved. Prior consent was taken. Treatment protocol consists of progressive resistance exercises for 4 days per week for 6 weeks The interpretation of the study was done on the basis of comparing pre-test and post-test assessment of Western Ontario and McMaster Universities Osteoarthritis Index(WOMAC) and BERG BALANCE TEST.

Result: Intra group comparison results showed that progressive resistance exercises are effective and WOMAC and Berg Balance Test were statistically extremely significant (p<0.0001) and (p<0.0001) respectively.

Conclusion: Progressive resistance exercises were significantly effective in improving the mobility and function and reducing the pain among the patients with osteoarthritis of knee.

Keywords: Osteoarthritis (OA), progressive resistance exercises, Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC), Berg balance Test.

Abbreviations: Western Ontario and McMaster Universities osteoarthritis index (WOMAC), Osteoarthritis (OA).

Introduction

Osteoarthritis is the most common type of arthritis which is usually found in elderly individual. It is degenerative, non-inflammatory disorder of synovial joint characterized by loss of hyaline cartilage, remodeling of surrounding bone and narrowing of joint space.(4) Osteoarthritis of knee is the most common type
of osteoarthritis and the prevalence is more in women than men. Due to the degenerative changes occurs in knee joint it mainly affect the cartilage of the knee joint and is one of the most common cause of functional limitation and dependency.

OA of knee is mainly diagnosed by symptoms such as:

1. Pain
2. Stiffness
3. Paresis
4. Tenderness
5. Effusion
6. Decrease in range of motion (ROM) secondary to pain
7. Muscle weakness.

In OA of knee, day to day physical activities like walking, squatting, stair climbing, cross leg sitting are mainly affected. OA of knee is a degenerative disorder so the line of treatment should be focus on reducing physical and psychological disability which includes patient education, physical activity, weight reduction and the use of assistive or orthotic devices. Muscle strength around the knee joint is significantly reduced in subject with OA of knee. Mostly the muscle which is get affected by OA of knee is quadriceps group of muscle. It acts as a shock absorber in the knee joint that is why the weakness in quadriceps muscle causes the reduction in functional performance at knee joint.

In OA of knee individual balance is also affected which may leads to injury to the knee joint. Muscle strengthening through resistance increases physical function, decrease pain and increase stability at the knee joint which is causes by OA and it also helps to reduce self-reported disability due to the OA.

The progressive resistance exercises are as follows:

1. Seated hip march
2. Heel raise
3. Step up
4. Walking
5. Squatting
6. Stair climbing

It is found in earlier studies that physical activities improve the metabolism and blood circulation. Resistance can be applied by various methods with progressively increasing manner like weight cuff, resistance band, body weight exercises, etc. Regular exercise including stretching and strengthening is an important component in managing OA irrespective of severity which is the standard care for individual with knee OA because it helps to reduce pain and improve function and stability at the knee joint. That is why it is important to evaluate the effect of progressive resistance drills and dynamic balance training on functional performance among the patients with OA of knee. However there is less number of articles available on effect of progressive resistance exercises on functional performance among the patients with osteoarthritis of knee.

Material and Methodology

Ethical clearance was obtained from the institutional ethical committee, KIMSDU, karad. This study included the 41 osteoarthritis of knee individuals according to inclusion and exclusion criteria. The study protocol was approved by the regional ethical committee. Individuals were selected according to inclusion criteria age between 40-70 years, men and female and exclusion criteria was individuals taking medication which influence the variable measured, any orthopedic condition that limit the exercise, unstable angina, uncontrolled hypertension – SBP ≥ 200 mmHg and DBP ≥110 mmHg. And they were perform progressive resistance exercises including warm up and cool down period of 10 min.

Progressive Resistance Exercise Protocol: (30 minutes)

1. WARM UP (6 minutes)
   - Seated hip march
   - Heel raise
   - Step up

   Each move will have 20 repetitions.

2. WORKOUT (18 minutes)
   - Walking
   - Slow walking
OUTCOME MEASURES

1. Western Ontario and McMaster Universities Osteoarthritis index (WOMAC). (11)

2. BERG BALANCE TEST.

STATISTICAL ANALYSIS

Statistical analysis of the recorded data was done by using the software INSTAT. 41 subjects were successfully completed assessment and were perform progressive resistance exercises for 12 weeks.

In present study the pre-test mean of WOMAC was 75.682±12.084, whereas post-test mean was 62.170±10.370. The pre-test mean of BERG BALANCE TEST was 61.365±10.495, whereas post-test mean was 77.682±14.138. Intra group analysis of WOMAC and BERG BALANCE TEST revealed statistically increase in post-test WOMAC and BERG BALANCE TEST scores. This was done by using paired t test. WOMAC (P<0.0001), BERG BALANCE TEST (P<0.0001).

In group statistical analysis for WOMAC and Berg balance test shows extremely significant in post intervention. There is improvement in strength in muscle around the knee which helps to reduce the pain due to osteoarthritis of knee in subjects. This patients performs the specified progressive resistance strength training show the significantly improvement in decreasing level of pain due to osteoarthritis of knee during activity daily living.

Discussion

Walking is the aerobic activity which can be used as the warm up which leads to pump up the body for the further training effect. The walking with progressive resistance use to train the lower extremities and it is largely used by the sports players as a part of exercise training. So, it is very effective to do exercise in middle aged individuals which helps in the weight reduction as well as improves the strength all over the body. This specified progressive resistance training are used to improve stamina, aerobic capacity and strength in the individual with osteoarthritic of knee. This exercise helps to improve strength muscles around the hip and knee which reduce the level of pain and increase the mobility of knee in the patient with osteoarthritic of knee. It also improves the balance of individual.(10)

Conclusion

From this study, we can conclude that there is significant effect of progressive resistance drills and dynamic balance training on functional performance among the patients with osteoarthritis of knee.

Conflict of Interest: There is no conflict of interest concerning the content of the study.

Source of Funding: This study was self-funded

Ethical Clearance: The study was undertaken after obtaining the approval of Protocol committee and Institutional Ethical committee of KIMSDU.

Abstract

The aim of the study was to evaluate the effectiveness of Calisthenics on self-esteem among elderly. Quantitative research approach, quasi experimental nonequivalent control group pretest posttest design was used to collect the data from 70 elderlies (35 in experimental group and 35 in comparison group) by using convenience sampling technique. The tools used were Sample characteristics performa and Rosenberg’s Self Esteem Scale. For both the groups pre-test, post-test-1and2 were taken on day 1st, 30th and 45th respectively. Calisthenics was given to experimental group thrice a week for four weeks. A significant difference was found in terms of self-esteem between the experimental and comparison group after intervention (t= 17.47 and p=0.001) at 0.05 level of significance. Hence, Calisthenics was found effective in increasing self-esteem among elderly.

Key words: Self-esteem, Calisthenics, Elderly.

Introduction

Ageing is a continuous process beginning at the time of conception and ending with death. It is the process of becoming older, a process that is genetically determined and environmentally modified.1

Older people, often experience greater rates of loneliness and social isolation which occurs for many reasons, including death of social ties, relocation to different types of living and care communities, and limitations in physical and mental health. This can lead to poor quality of life, lower self-esteem and poor sleep quality, which may further lead to anxiety and depression among older people.2

Self-esteem is individual’s attitude toward himself/herself which measures one’s feelings of self-evaluation and self-acceptance, and reflects one’s value, worth and respect built by perceived views across the significant surroundings.3 There are several factors that influence the development of one’s self esteem. Among them is the respect, acceptance, and attention received from significant people in one’s life, including family members.4

One of the research study conducted with elderly members of a community in Montreal, Canada, found that there was decline in the self-esteem which may contribute to deregulate the hypothalamic-pituitary-adrenal axis functions that can cause adverse outcomes to the health of the elderly, such as social isolation.5
The maintenance of high physical function is one of the key factors for successful aging. Staying physically and mentally active can not only delay the development of some chronic illnesses and disabilities, but also improve mental and physical health in older adults as it helps in reducing depressive symptoms and promotes self-efficacy.

There is no particular age to perform exercises; even in the old age, exercises can be performed. Many studies proved that exercises diminish the age related problems. Among all exercises calisthenics are simple exercises that can be easily performed by elderly group. Calisthenics is a type of arranged exercises made up of many different movements performed using simple steps. This exercise is an ideal way to increase flexibility by strengthening the muscle tone. Calisthenics is a widely practiced form of exercise and is recognized as a fun and healthy way to keep fit.

Materials and Method

The study was conducted during the period from March 2018 to May 2019 in the state of Haryana, India. A total of 70 elderlies those who were aged 60 years and above, willing to participate in the study, residing in selected old age homes, who are alert, oriented and comprehend to respond, able to understand and speak Hindi and who are able to move without walking aids / physical assistance were selected by using Convenience Sampling technique. The tools used for data collection are Sample Characteristics Performa and Rosenberg’s Self Esteem Scale. Self-report (interview) technique was used to collect the data.

Description of Tool:

Sample Characteristics Performa: It consisted of 13 items i.e. age, gender, marital status, education, previous occupation, duration of stay in old age home, relatives visit, nature of the previous habitat, financial support, health problems, regular physical activity, sleep medicines and mode of admission in old age home.

Rosenberg’s Self Esteem Scale: It is a standardized tool which measures in a 4 point Likert scale (0-3) consisting of 10 items related to self-esteem which has 5 positive items and 5 negative items where it can be categorized as (0-14) low self-esteem, (15-22) moderate self-esteem and (23-30) high self-esteem. The calculated Cronbach Alpha Internal consistency was 0.91. Prior permission from the tool developer and Hindi translation was done by the researcher herself after obtaining permission from the tool developer.

Procedure:

After obtaining formal administrative approval from concerned authority of old age homes, 70 elderlies (35 in experimental group and 35 in comparison group) were selected using convenience sampling technique. The subjects were informed regarding the purpose of the study. Written consent was taken from the subjects to assure the confidentiality of their response. Pre-test was conducted on day 1st with sample characteristic and Rosenberg’s Self Esteem Scale among elderly in both the groups. The total intervention was given from day 2nd to day 29th (4weeks). On the 2nd day, Calisthenics was administered to the experimental group individually in order to make the elderly follow the correct steps (Arm rotation, Trunk twisting in chair, Ankle rotation, Leg kick in chair, Hip rotation, Side bends and Forward bends, Stepping and Walking). Then from the 3rd day onwards Calisthenics was given in groups among experimental group, thrice a week, morning 25-30 minutes on alternative days for four weeks. Post-test-1 and post-test-2 was conducted on 30th and 45th day with Rosenberg’s Self Esteem Scale in both the groups.

Kolmogorov-Smirnov test was applied to check the normality of data distribution. Data was normally distributed; hence parametric tests were applied.

Findings

Homogeneity between the experimental and comparison group was checked by Chi – square test in terms of sample characteristics and found that there was no significant difference between the groups in terms of sample characteristics at 0.05 level of significance. Which infer that both the groups were homogenous and comparable.

Percentage distribution of experimental and comparison group in terms of level of self-esteem shows that more than half of the elderly were having low self-esteem in both the experimental (60%) and comparison (68.57%) group. Chi – square was applied to compare both the groups in terms of level of self-esteem and it was found to be statistically non-significant ($\chi^2 = 0.56$, \(p= 0.45\)) at 0.05 level of significance. Hence, it infers that both the groups were homogenous and comparable in terms of level of self-esteem at baseline.
After administration of Calisthenics, percentage distribution of elderly in terms of level of self-esteem results that in experimental group, most of subjects were having high self-esteem in post-test-1 (74.28%) and post-test-2 (68.57%) then the comparison group in both post-test-1 (68.57%) and post-test-2 (62.58%) as depicted in figure 1.

![Figure 1: Bar diagram showing percentage distribution of elderly in terms of self-esteem in experimental and comparison](image-url)
Further, in both post-test-1 and post-test-2, experimental group had higher mean score then the comparison group in terms of self-esteem. The calculated ‘t’ value for post-test-1 was 17.47 and p= 0.001 which was statistically significant at 0.01 level of significance. Similarly, in post-test-2, the calculated ‘t’ value was 16.27 and p= 0.001 which was statistically significant at 0.01 level of significance as depicted in table 1. Hence, it infers that Calisthenics was effective in increasing the self-esteem among the experimental group.

The results of Repeated Measure ANOVA reveals that in experimental group, the mean score of self-esteem in pre-test, post-test-1 and post-test-2 was 13.77, 24.34 and 23.34 respectively. Where the F value is 300.60 with calculated p=0.001 which was statistically significant at 0.01 level of significance. Whereas in comparison group the mean score of self-esteem in pre-test, post-test-1 and post-test-2 scores was 12.89, 12.83 and 12.74 respectively. Where F value is 0.17 with calculated p= 0.84 which was statistically non-significant at 0.05 level of significance as depicted in table 2. Therefore, it can be stated that Calisthenics was effective in increasing the self-esteem among elderly.

NS- Non significant(p≥0.05) **- significant (p < 0.01)
Additionally, post hoc test (LSD) shows that post-test-1 and post-test-2 score was better than pre-test score and post-test-1 score was better than post-test-2 in terms of self-esteem in experimental group.

Association of pre-test self-esteem score with selected sample characteristics among elderly was tested by using one-way ANOVA and ‘t’ test. The findings revealed that there was no significant association of self-esteem score with sample characteristics except in educational status i.e. (F= 2.82, p= 0.03) which was significantly associated with self-esteem among elderly.

Further, Post Hoc test was applied to reveal the mean difference of self-esteem in pre-test among elderly with selected sample characteristics (educational status) where it results that elderly who had primary education and secondary education were having higher self-esteem than those elderly who had higher secondary education and collegiate education.

Multiple regression analysis was used to explore the exact predictability of multiple independent variables on dependent variable. Based on basic assumption, step wise regression was applied. Data entered were raw/continuous variables, dichotomous variables and dichotomous dummy variables.

The stepwise regression results that Higher secondary education had prediction with variability of 7.90% ($R^2=0.079$) as calculated $F$ value=5.776 which was significant at 0.05 level of significance which further infers that changes of fluctuation or change in R value is less than 0.01. If Higher secondary education combines with duration of stay in old age less than 1 year, both variables together having prediction with variability of 14.50% ($R^2= 0.145$) as calculated $F$ value = 5.586 which was significant at 0.01 level of significance which infers that changes of fluctuations or change in R value is less than 0.006 as depicted in table 3. Hence, Higher secondary education alone as well as Higher secondary education with duration of stay in old age less than 1 year mostly had equal amount of predictability with self-esteem.

Table 3: Step Wise Regression Showing Predictability on Self Esteem by Multiple Independent Variables among Elderly (Multiple Correlational Coefficient) in Pre-test

<table>
<thead>

</tr>
</tbody>
</table>

* - significant (p < 0.05)  ** - significant (p < 0.01)

As there was predictability of Higher secondary education in multiple correlation coefficients, the direction of predictability for variable is, if chance of Higher secondary education increases by 1 point, the self-esteem increases by 2.6 points and if chance of less than 1 year duration increases by 1 point, the self-esteem gets decreases by 2 points. This infers that higher secondary education had continuous prediction in positive direction throughout the models which is shown in table 4.

Discussion

The present study population comprises with subjects who are age 60 years and above and among them, more than half of the subjects i.e. 57.1% were male and 42.9% of the study subjects were female in the experimental group. These findings were consistent to a study conducted by Deok-jo Kim, Sung-je Cho et al (2015) on Psychological State and Self-Esteem of Elderly in Relation to Socio-Demographic Characteristics where it was found that more than half of the study participants (53.8%) were male and the remaining 46.2% were female which is less than half of the subjects.9

In this present study it is found that 60% of elderly were having low self-esteem and 40% of elderly were having moderate self-esteem. The findings were consistent with the study conducted by Franak J, Malek M et al (2012) to assess the self-esteem among elderly in Kermanshah, Iran where they found one third of the elderly had a low self-esteem.10

Interestingly, the present study findings result a significant difference in the mean post-test self-esteem score among elderly between experimental and comparison group which infers that Calisthenics was effective in increasing the level of self-esteem among the elderly. These findings were consistent with the study conducted by Seong-Hi Park, Kuem Sun Han and Chang-Bum Kang et al (2014) on effects of exercise programs on quality of life and self-esteem in older people where it was found that exercise intervention was effective in increasing the level of self-esteem among older people.7

It has been previously argued that participation in the physical activity may have its greatest potential for enhancement of the levels of self-esteem. The present study findings certainly suggest the enhancement of the level of self-esteem among elderly after the administration of Calisthenics in the experimental group as there was a significant difference in terms of self-esteem from the pre-test score to post-test-1 and post-test-2 score. These findings were consistent with the study conducted by Edward McAuley, Jeffrey, Terry E, Shannon L el al (2001) on physical activity, self-esteem and self-efficacy relationship in older adults, where it was found that there was increased in the level of self-esteem upon completion of the intervention.11
Conclusion

Calisthenics was effective in increasing the self-esteem among elderly as there was a significant difference between the experimental and comparison group. There was a significant predictability for self-esteem by educational status and duration of stay in old age home.

Observational Study on Sexual Dimorphism of Carrying Angle among Natives of Ajmer region

Nirjhar Mathur¹, Anupam Johry²

¹Intern Student, J.L.N. Medical College, Ajmer; ²Associate Professor, (Forensic Medicine), SMS Medical College, Jaipur

Abstract

Introduction: - The carrying angle is the angle placed between the median axis of arm and median axis of forearm in full extension and supination position. This angle provides the forearms a clear movement with respect to the hips while walking and is important when carrying objects. Carrying angle is examined in various pre-placement medical examination. Carrying angle can be used to differentiate between male and female upper limb. This can be used in partial identification if rich regional data is systemically and statistically collected.

Objective:- To collect the statistical data values of carrying angle in both the sexes of Ajmer region. Observing any difference between the caring angle of dominant and non-dominant hand of same individual

Method: - A cross-sectional study was carried out with right handed 100 males and right handed 100 females and variations in carrying angle between males and females were calculated using Goniometer. The value is analyzed by mean, standard deviation

Results: - In males, mean carrying angle of both upper limbs is 10.72⁰ whereas in females mean carrying angle of both upper limbs is found 13.42⁰.

Conclusion: The present study showed that the carrying angle was greater in females than in males and it was greater in non-dominant arm than in dominant arm.

Key words: - Carrying angle, Goniometer, Extension, Variation

Introduction

The carrying angle is acute angle between median axis of the upper arm with fully extended and supinated forearm. This angle is associated with the lateral obliquity of arms¹. Secondary sexual characters in females² ³ ⁴ ⁵ ⁶ leads to greater carrying angle than males. In some cases it was also seen that females and males did not have variations in carrying angle on full extension⁷ ⁸ ⁹. As the skeletal configuration is affected by regional variation and no previous study had been conducted in the past on Ajmer region, therefore this study is planned to collect statistical data of carrying angle from Ajmer region. This study will also provide a sex specific data on variations in carrying angle on full extension, so that it can be used in identification purpose and sex determination in segmented/dismembered bodies. The carrying angle is examined in various medical examination for fitness of jobs especially meant for field services.

Materials and Method

This is a cross-sectional study among natives of Ajmer region. Carrying angle was measured in both arms of 100 males and 100 females aged between 18 to 24 years using goniometer¹.

Corresponding Author:-
Dr. Anupam Johry
Associate professor (Forensic Medicine), SMS Medical College, Jaipur

Data was manually collected on Microsoft Excel sheet and then analyzed statistically.

**Sample universe:** - MBBS Students studying JLN medical college, Ajmer

**Inclusive criteria:** - Cases with parents born in Ajmer were considered as natives of Ajmer. All the cases of age group 18 to 24 years are included in our study

**Exclusion criteria:** - Cases with history of previous fracture, congenital anomalies, contracture deformity of upper limb are excluded

-All cases with left handed dominance are excluded

**Study period:** - Sample was collected from 1st May 2019 to 31st 2019 at JLN medical College, Ajmer till sample size was achieved

### TABLE No. (1): Distribution of carrying angle among male and female

| SN | MALE | | | FEMALE | | |
|---|---|---|---|---|---|
| | No. of cases | Carrying angle (rt) | Carrying angle (lt) | No. of cases | Carrying angle (rt) | Carrying angle (lt) |
| 1 | 26 | 10.1 | 10.1 | 26 | 13.5 | 13.5 |
| 2 | 15 | 10.4 | 10.5 | 22 | 13.2 | 13.6 |
| 3 | 38 | 10.6 | 10.9 | 31 | 12.8 | 13.9 |
| 4 | 12 | 12.3 | 12.1 | 8 | 13.6 | 14.1 |
| 5 | 5 | 19.5 | 19.7 | 6 | 12.2 | 13.7 |
| 6 | 2 | 13.1 | 12.8 | 4 | 15.1 | 14.8 |
| 7 | 1 | 08.7 | 09.1 | 2 | 10.9 | 11.8 |
| 8 | 1 | 15.2 | 15.4 | 1 | 11.7 | 12.1 |

### Results

When carrying angle was measured out of 200 subjects, 26% did not have variations in carrying angles of their right and left arms. On an average, in males mean carrying angle of right arm was 10.66° with SD 0.919 and carrying angle of left arm was 10.78° with SD 0.779. The mean value of male of both arms is 10.72° where as in females, mean carrying arm of right arm was 13.14° with SD 0.644 and carrying angle of left arm was 13.71° with SD 0.369. The mean value of both arms in female is found 13.42° .Females had greater carrying angle than males.

### Discussion

We have studied variations in carrying angle between males and females. Females had greater carrying angle than males, i.e. arms are more laterally angulated and they have greater carrying angle°. Non dominant upper limb has more carrying angle then dominant upper limb in both sexes

### Conclusion

This data can be used in pre placement medical examination of various services especially required for natives of Ajmer region. There is difference in carrying angle of both side upper limbs so both sides carrying angle should be examined in borderline cases

### Suggestions

This data can be used cumulating and compounding with other studies for determination of average value of carrying angle in the population ,so that this can be used in determination of sex of an individual and also in various pre-placement medical examinations of armed forces. This data is useful in identification of segmented/ dismembered bodies

### Acknowledgement

We acknowledge the support of MBBS students, nursing and paramedical staff of JLN Medical College, Ajmer for their voluntary support for presenting themselves as case study.

Quasi Experimental Study to Evaluate the Impact of Psychoeducational Intervention on Level of Anxiety among Hospitalized Children

Niyati R. Patel¹, Vipin Vageriya²

¹M.Sc. Nursing Student, ²Assistant Professor, Manikaka Topawala Institute of Nursing, Charotar University of Science and Technology

Abstract

Background of the study: There are various ways to provide psycho-education (PI) to the patient admitted in the hospital. It is broadly steered by four main goals: transfer of information, medication and treatment support, training and support in self-help and self-care, and the provision of a safe place to vent emotional frustrations.

An excessive or persistent state of anxiety leads to devastating effects on children’s physical as well as mental health. Psych education is scientifically proved therapeutic intervention which helps the client along with family members to cope with illness and give the information as well as support to understand in a better way. Psych education helps the children and their family to minimize the emotional trauma during the hospital stay.

Objective:

1) To determine the impact of psycho-educational intervention on anxiety level among children with hospitalization.

2) To find out the association between socio-demographic variables with the pre-intervention anxiety level among hospitalized children.

Methodology: The study was executed by using quantitative research approach with quasi-experimental design. The study was conducted at three hospitals of Anand district, two hospitals of Vadodara district, and one Hospital of Ahmedabad District, Gujarat. 33 Hospitalized 6 – 12 year old children were selected for each experimental group and control group using convenient sampling technique. For both groups, Pre-intervention anxiety level assessment was done using Performa of demographic variables, Modified Hamilton Rating Scale. Psycho educational intervention included playbook and guided imagery administered to the 6-12 year old hospitalized children of experimental group for duration of 30 minutes for 3 consecutive days. On third day anxiety level have been done on third day after 5 hours from last intervention.

Result: Two sample t tests were used to determine the impact of psycho-educational intervention on anxiety level among hospitalized participants. As psycho-educational intervention has administered to interventional group there was statistically significant difference (p value <0.00010) found in post-assessment of anxiety level between experimental as well as control group. Comparison between interventional and control group calculated value of two sample test was 11.85.
**Conclusion:** Findings of the study came to the conclusion that psycho educational interventions consider a positive effect to reduce the anxiety level among children during hospitalization.

**Key words:** Psycho educational intervention, anxiety level, hospitalized children

**Introduction**

Hospitalization is a stressful and emotional event for parents and caretaker. It can be emotionally devastating to children. Hospital play interventions have been widely used to prepare children for invasive medical procedures and hospitalization. Hospitalization is a critical phase in the life of child. Hospitalization may leads to increase the stress and level of anxiety among children and their caretakers. An excessive or persistent state of anxiety leads devastating effect on children’s physical as well as mental health.[1]

Anxiety can be characterized by the feelings of tension and worry thoughts. It is a normal process in life. However, if the anxiety becomes severe or start to impair one’s life functioning, it can be categorized as a disorder or illness.

All parents would like to avoid their parents from hospital based anxiety and stress. Child also try to become less panic with health care industry environment. In all over child population numbers of children are admitted in hospital at least once in their early younger age which is about 30 per cent and all of them 5 per cent are frequently hospitalized.[2] Children’s psychological and physical needs should be vital, for the reason that continuation of the growth and evolution during the sickness will forestall the steady and irreversible physical and mental impacts of kids.[3]

Despite the specific illness, hospitalization of children in a new situation faces them with scary intervention, body pain and uneasiness. Causes creating stress and anxiety during hospitalization of children are: separation of children from their parents those who have loved, fear of the unknown, lack of control and autonomy, bodily injury leading to discomfort, pain and fear of the death. Kids’ reaction in crises situation is affected by different factors, included formative age, past experience, adaptable innate and adaptable abilities, severity and seriousness of the disease and the accessible emotionally supportive system.[3]

Kids having different kind of fear with regards to hospitalization, for example, fear of separation from the family, having blood tests and invasive procedure, long duration hospital stay, and being told “bad news” about their health. Among different kind of psychological treatments, there are sufficient research proof based on impact of behavioural intervention along with cognitive behavioural intervention for minimizing the fearfulness and anxiety. [3] Children commonly report feeling afraid or anxious as they anticipate and engage in healthcare settings with medical professionals.[4]

The American Academy of Paediatrics (Child Life Services for hospitalized children) recommended providing information, education, and formation of a trusting relationship between health care professionals and children and their parents by using various tools such as pictures, diagrams, orientation tours of surgical or treatment areas, therapeutic play, and puppet etc.[5]

Psychoeducation is an evidence-based therapeutic intervention for patients and their loved ones that provides information.

A research study found that about 10 to 15 per cent of children who are admitted to hospital after sustaining an injury develop post-traumatic stress disorder (PTSD), while for those admitted to areas such as the intensive care unit (ICU), the rate of psychological disorder in children is much higher – in the order of 20-25 per cent.

At the time of hospital admission, particular attention is paid to the improvement of the clinical symptoms of the disease and to a reduction in the psychological burden. As a result, play is often disregarded, or considered of minor importance. However, the role and value of play increases when the child is repeatedly hospitalized, mostly due to a chronic disease or disability, since it decisively contributes to emotional, mental well-being, self-confidence and self-esteem.

There are few techniques which can be utilized including guided imagery, play intervention, music therapy as a non-pharmacological treatment etc. One of intervention is psycho education intervention, which can be one of the viable treatments in decreasing the anxiety emerging from the hospitalization in kids.[3]

Psych education has been defined as “The evidence-
based therapeutic intervention for clients and their family members who help them to cope up with illness and give the information as well as support to understand in better way.” Psych education is helps to children and their family to minimize the emotional trauma during the hospital stay. [6] The central goal of therapeutic play is to facilitate the emotional and physical well-being of hospitalised children. [7]

Psychoeducational intervention seems very effective in various anxiety related disorders, personality disorders, psychotic illnesses, bipolar disorder, schizophrenia and clinical depression.

**Methodology**

The study was executed by using quantitative research approach with quasi experimental design. Quasi experimental research design: It involves the manipulation of independent variable to observe the effect on dependent variable, but it lacks at least one of the two characteristics of the true experimental design: randomization or a control group.

The target population for conducting research study were hospitalized children who are 6 – 12 year old. Using non probability convenience sampling technique 66 hospitalized children having anxiety were employed by calculating power analysis and then randomly allocated in two groups (33 each). Only experimental group had taken the intervention. Data collection was done using a researcher self-developed Performa of demographic variables and Modified Hamilton Anxiety Rating Scale. Before data collection, researcher introduced herself to participants with given explanation regarding the study and also obtained informed consent from the participants.

As per the part of psycho-educational intervention, one play book and one story for guided imagery has been prepared by researcher. Consecutively 3 days intervention had given to the experimental group for 30 minutes. Therapeutic play will be given for 20 minute and guided imagery will be given for 10 minutes, in that 7 minute for story and 3 min for take the review from the child about the story. Anxiety level should assessed by using Modified Hamilton anxiety rating (HARS) scale After 5 hours from last intervention.

The study was conducted at selected five hospitals of Anand district, Gujarat. Main study was done at selected three hospitals of Anand district, two hospital of Vadodara district and one Hospital of Ahmedabad District, Gujarat.

Moreover, the data was analysed and interpreted by using descriptive and inferential statistics.

**Operational Definition**

Anxiety: It refers to fear and worry among hospitalized children. It affects body and mind, leads to emotional stress. In Present study anxiety is assessed by Modified Hamilton Anxiety Rating scale.

Psycho educational Intervention: It is the cluster of the strategies which help to reduce the level of anxiety. In present study, play therapy and guided imagery used as a psycho educational intervention to reduce the level of anxiety among hospitalized children.

Hospitalized children: Refers to the children between the age group of 6-12 Years and who are admitted in the hospital with different diagnosis.

**Inclusion criteria:**

- Children those are 6 – 12 year old.
- Children those are admitted in selected hospitals for minimum 3 days.
- Children those are willing to participate in the study.
- Children whose parents are available at the period of study.
- Children whose parents are giving permission for intervention.
- Children who’s able to understand Gujarati Language.

**Exclusion Criteria:**

- Children those are admitted in intensive care unit.
Children those are not co-operative for intervention.

• Children those are physically and mentally challenged.

**Result**

Result shows that,

**Section 1: Findings related to socio-demographic variables in Experimental group and control group.**

In Analysis & interpretation of data, Frequency and percentage distribution of samples based on socio demographic variable

**In experimental group out of 33 samples,**

16 samples (48.5%) are 6-9 years old and 17 samples (51.5%) are 10 - 12 years.

Out of 33 samples, and 22 samples (66.7%) are male and 11 samples (33.3%) are female according to Gender.

In reason for area of hospitalization 21 sample (63.6%) are admitted in general ward, 12 samples (36.4%) are admitted in special ward.

In reason for hospitalization 19 samples (57.6%) having medical illness, 14 sample (42.4%) having surgical illness.

In family type, 18 samples (54.5%) belongs to joint families, 15 sample (45.5%) was living in nuclear families.

24 sample (72.7%) children experience of previous hospitalization and 9 sample (27.3%) children have no experience of previous hospitalization

In regards of duration of hospitalization, 18 sample(54.5%) children are admitted for 1-5 days, 7 sample (21.2%) children are admitted for 6 -10 days and 8 sample (24.2%) children are admitted for ≥ 11 days.

**In control group out of 33 samples,**

19 samples (57.6%) are in 10-12 years and 14 samples (42.4%) are 6-9 years old.

By 33 samples, 18 samples (54.5 %) are male and 15 samples (45.5%) are female according to Gender.

In reason for area of hospitalization 16 sample (48.5%) are admitted in general ward, 17 samples (51.5%) are admitted in special ward.

In reason for hospitalization 25 samples (75.8%) having medical illness, 8 sample (24.2%) having surgical illness.

In family type, 22 samples (63.6%) was living in nuclear families, 12 samples (36.4%) belongs to joint families.

24 sample (72.7%) children experience of previous hospitalization and 9 sample (27.3%) children have no experience of previous hospitalization

In regards of duration of hospitalization, 21 sample(63.6%) children are admitted for 1-5 days, 9 sample (27.3%) children are admitted for 6 -10 days and 3 sample (9.1%) children are admitted for ≥ 11 days.

**Section 2:**

Comparison between mean score of anxiety during hospitalization of interventional and non-interventional group.

Table 5: Comparison of post-test anxiety scores among interventional and non-interventional group

<table>
<thead>
<tr>
<th></th>
<th>Mean</th>
<th>SD</th>
<th>T value</th>
<th>P value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Exp Group</td>
<td>13.42</td>
<td>5.70</td>
<td>11.85</td>
<td>0.00010</td>
</tr>
<tr>
<td>Control Group</td>
<td>27.97</td>
<td>4.16</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Above table 5 consists description of comparison between interventional and non-interventional group post assessment score of mean [interventional group 13.42, non-interventional group 27.97] and standard deviation [interventional group 5.70, non-interventional group 4.16] of children according to impact of psycho educational intervention on level of anxiety.

P Value is 0.00010*p<0.05 is significant at 0.05% level. Hence null hypothesis $H_0$ was rejected. This indicates that Psycho educational intervention is highly effective in reducing level of anxiety among hospitalized children.

Findings related to association between level of anxiety and selected demographic variables of experimental group.

$\chi^2$ calculated value corresponding to the age in year, gender, Area of Hospitalization, Reason for Hospitalization; Types of family, History of previous Hospitalization, Duration of Hospitalization are found less than tabulated $\chi^2$ value. Hence, it is concluded that there is no significant association between levels of anxiety during Hospitalization with selected demographic variables in experimental group.

The above result can be compare with the result of a study that “Children who received the hospital play interventions exhibited fewer negative emotions and experienced lower levels of anxiety than those children who received usual care”.

Ethical Clearance- it is obtained from CHARUSAT ethical committee.

A Study on Sociodemographic Profile and Pattern of Injuries in Road Traffic Accidents amongst Pillion Riders in Chennai

P. Shruthi¹, S. Varsha²

¹Associate Professor, Department of Forensic Medicine and Toxicology, Saveetha Medical College, Thandalam, Chennai, Tamilnadu, ²IIyear MBBS, Saveetha Medical College, Thandalam, Chennai, Tamilnadu

Abstract

One of the widespread preventable cause of unnatural death is Road Traffic Accidents. A Retrospective cross sectional study of the sociodemographic profile of pillion riders being victims of Road traffic accidents, the circumstances leading to road traffic accidents, the pattern and severity of injuries of occurring in Chennai was conducted in Saveetha Medical College and Hospital, Thandalam, Chennai, Tamilnadu. A total of 2438 cases of Road traffic accidents were recorded for a year (JAN2018-DEC2018). Out of which 62 cases (2.5%) of Road traffic accidents deals with the injuries of pillion riders. Among the pillion riders, Male outnumbered the Females (1.11 : 1). The most vulnerable age group was 21-30 years (50%). Most frequent of all is Head and Neck injuries and Injuries on the Upper limb. The information obtained can serve as a guide for better management of victims of Road traffic accidents and to establish Road safety measures.

Key Words: Road traffic accidents, Head injury, Pillion riders, Two Wheeler Accidents, Demography.

Introduction

Accident is an event, occurring suddenly, unexpectedly and inadvertently under unforeseen circumstances (1). A Road traffic accident occurs when a vehicle that is moving along a roadway crashes with another vehicle or object. RTAs is the most frequent cause of death under the age of 50yrs. Road traffic accidents, being life threatening if untreated at the earliest, remains to be one of the fatal ordeal, especially in case of accidents involving motorcyclist. According to the Global Status Report on road safety released by WHO in December 2018, the total mortality rate caused by Road traffic accidents (RTAs) has reached 1.35 million (2). In India, about 4,80,652 cases of Road traffic accidents (RTAs) occurs annually (3). About 181908 cases of RTAs has been recorded in South India by Ministry of Road transport and Highways as of 2016 (3). As per the National Crime Records Bureau annually about 7,328 cases (9.3%) has been recorded in Chennai as of the year 2015 (4). Throughout most Asian countries, the motorcycle has become an important mode of transport for most families. Pillion rider is a passenger on a motorcycle who is positioned directly behind the rider, facing forward on a registered seat for a pillion passenger (5). In vehicular collisions, the pillion riders are the most vulnerable to injuries because limited or no physical protection with the most common type of injuries sustained being head injuries. Mortality rate remains higher for both the drivers and the pillion riders.

Materials and Method

This study was conducted retrospectively for a time period of 1 year (JAN 2018- DEC 2018) at Saveetha
Medical College, Thandalam, Chennai, Tamil Nadu. Required approvals were obtained from the respective institutional ethics and research committee. In this study, all pillion riders victims of RTAs who presented themselves to Emergency department of Saveetha Medical College (JAN 2018- DEC 2018) were included. Death occurring in RTAs due to other vehicles apart from 2 wheelers were excluded.

The data was collected as per the preformed and approved format. The Sociodemographic profile and injury profile were collected from the case records of the victims. The collected data was analysed by using SPSS Software.

**Results**

A total of 2438 cases of RTAs were recorded for a year (JAN 2018-DEC 2018) at Saveetha Medical College and Hospital, Thandalam, Chennai, Tamil Nadu. Out of which 62 cases[2.5%] of RTAs deals with injuries of pillion riders. Among the pillion riders Males(55%) outnumbered the Females (45%)[1.11:1][Fig.1]. The most vulnerable age group was 21-30 years among pillion riders followed by that of 31-40 years(19%)[Table 1]. Month of December accounted for highest number of RTAs with 14 cases(22%) respectively[Fig.2].

Majority of the accidents occurred during evening (6.01pm to 12:00am) (36%) followed by that between 6AM to 12 PM(32%) .It was observed that nature of accidents in majority of cases were due to skid and fall(66%) followed by a head on collision with another 2 wheeler (14%). Majority of the accidents were front impact/collision (79%). Almost 2/3 rd of the RTAs involving pillion riders has occurred at National highways(68%). Majority of the pillion riders involved in this study were residing at Semiurban areas(47%)[Table-2].

Most of the cases, area of impact was found to be Head & Neck and Upper limb(50%). Injuries in the abdomen were least common among these cases(2%) [Fig.3]. Abrasion(72%) was the most common pattern of injuries in these cases. Only 21% were using helmet at the time of accident[Fig.4]. There were no fatal cases of pillion rider RTAs reported in this one year study.

Discussion

The most vulnerable age group involved in pillion rider RTAs was found to be between 21-30 years which is similar to the findings of studies of R. Ravikumar et al shows that majority of pillion riders belong to age group between 20-29 yrs\(^{6}\). The reason probably being increased risk taking attitude of youth and reduced road safety measures. Male victims(55%) outnumbered the Females(45%). This finding was unlike a study by Urfi et al which showed that female victims(60%) outnumbered the male victims(40%)\(^{7}\). Males being the predominant working population and bread winner in the Indian families could be the reason for being the victims of RTAs.

In the present study, majority of the accidents occurred at December (22%). This season also has close similarity with winter season in India where number of RTAs are on the rise.

Most of the accidents took place at National highways(68%). Front on collision is the most common way of accident in pillion riders. Skid and fall(66%) was found to be the major cause for the RTAs among pillion riders. According to Nupur Pruthi et al most of the accidents had taken place due to skid and fall(45.5%)\(^{8}\). The drivers exceeding the speed limits, not following traffic rules and reduced road maintenances are some of the probable reason. In the present study, in 62 victims other than injuries to Head& neck and Upper limb together comprising of 50%, injuries to the lower limb was the common injury. It was present in 43% of cases, followed by Thorax(3%), Pelvis(2%) and Abdomen(2%). Abrasion(72%) was the most common pattern of injury followed by Contusion(8%), Fracture & dislocation(8%), Laceration (6%) and other injuries(6%).Unlike K. Prasannan et al and P.A. Sheeju et al study which showed that Chest injury(43.13%) was the major injury in RTA among pillion riders\(^{9}\). There were no fatal cases of pillion rider RTAs reported in this one year study. 79% of the pillion riders were not using helmet at the time of accident. Head Injury was more in pillion riders than the drivers. It may be due to the usage of helmet by the drivers.

Conclusion

Road traffic accidents continues to be a threat, causing heavy loss of valuable human assets, along with loss of future economic growth. Interventions in RTA should include integrated efforts from the society, governmental and non-governmental organizations. Political guidance, good governance and a unfailing technical team are the essential components. The information obtained can serve as a guide for better management of victims of road traffic accidents and to establish Road safety measures.
**Recommendation:**

- Strict rules should be implemented to ensure mandatory Helmet usage for both drivers and pillion riders.
- Road traffic rules and speed limits should strictly be followed.
- Educating the public on pillion rider safety by the government.
- An engineering intervention is needed that will address the injuries typically sustained by pillion riders. A device to be devised as safety backrest for pillion riders and also other measures that will protect the lower limbs, chest, abdomen, and neck.

A Retrospective study on Non Fatal Motor Vehicle Accident cases in the Emergency Department, Saveetha Medical College, Chennai

P. Tejesh Thanigavel1, Magendran. J2
1II MBBS, Saveetha Medical College, Thandalam, Chennai, India, 2Associate Professor, Department of Forensic Medicine, Saveetha Medical College, Thandalam, Chennai, India

Abstract

Aim & Objectives: To retrospectively study non fatal RTAs in the emergency department of SMCH with help of AR registers while studying various factors involving like pattern, site and time of injuries and age of the person involved.

Materials and Methodology: Data was collected for complete one year and all the cases in the year were included in the study, which thus constitute sample for the study. The retrospective study group consisted of all the RTA victims reporting to Emergency Department of SMCH in the study period from 1st January 2018 to 31st December 2018. These collected data were compiled with help of Excel.

Results: In this study a total of 911 cases were included who were admitted in the emergency department of SMCH. Males were the most commonly involved. Around 95% of the cases involved 2 wheelers. 65% of the accidents took place in the 6pm to 9pm range. Commonly involved age group is 18-30. 20% showed head injuries but the majority had injured their limbs.

Conclusion: This suggests that there has to be more awareness created amongst the youth population encouraging them to wear helmets and seat belts. More advancement is required in the field of automotive safety. Road safety must be embedded in the children’s curriculum from lower grade itself. More involvement of Traffic police, NGOs and other public awareness groups are required to enforce this.

Keywords: Accidents, Awareness, Non-fatal injury, Trauma

Introduction

A road traffic accident (RTA) is any injury due to crashes originating from, terminating with or involving a vehicle partially or fully on a public road. It is predicted that road traffic injuries will move up to the 3rd place by the year 2020 among leading causes of the global disease burden. An accident is not just 1 bad event; it’s the combination of a series of mechanical failures and a very bad luck.

Road traffic injuries are the 8th leading cause of death globally and sadly is also more prevalent in the most important age group that is needed for the growth of a country which is 15–29 years. WHO report says more than a million people die each year on the world’s roads and the cost of dealing with these consequences of these incidents runs to crores of rupees. Current trends suggest that by 2030 road traffic deaths will become the fifth leading cause of death (from 8th position) unless urgent action is taken.

Accidents are just not because of incompetence, but are due to carelessness, thoughtlessness and over confidence. The morbidity is particularly high in India is mainly because of our rapidly motorizing economy with poor or under developed roads with lack of proper road infrastructures and other safety needs on roads. The rules also play an important role as they don’t strictly enforce the rider to wear a helmet. When this is viewed from a better angle, it causes an economic problem nation wise, especially in developing and underdeveloped countries.
Most of us know the facts that, you’re most likely to die on the way to the airport than while you’re flying in an airplane. This means that car accidents are more incidental than air crash. 2008 Traffic Safety Facts Data says there are 1.27 fatalities per 100 million vehicle miles traveled. While the same report works out to nearly zero accidents per million flying miles. According to the aviation report, most of the mid air emergencies have been safely handled and no one died\(^1\). In actuality, driving is more dangerous, with more than 5 million accidents. Whereas there has been only 15 accidents on average per year. 2017 was the safest year with only 10 accidents throughout and only 44 lives were lost. This fact is true because of the volume of cars in the world when compared to airliners. All these facts show us that air travel is much safer. The odds of death in a car accident are to be 1 in 98 for a lifetime.

In 2004, the World Health Organization (WHO) and the World Bank launched the World report on road traffic injury prevention. It also aims to monitor the whole decade and to give suggestions on how to improve road safety\(^2\). In spite of all these efforts there has been no overall reduction in the number of people killed on the world’s roads: about 1.24 million deaths occur annually. But since there’s been a corresponding 15% global increase in the sales of number of registered vehicles, suggesting that interventions to improve global road safety have failed to account for this fact. And therefore there is still rise in RTA deaths except in about 8 developed countries which has successfully decreased their RTA mortality rates.

This lack of attention to road safety issues further adds to the load of problems of road traffic injuries and need public health concerns. Thus reducing the epidemic of accidents. This study was planned to understand the major causes/risk factors as well as nature, type and mode of occurrence of road traffic accidents in and around the areas of our hospital Saveetha Medical College, Thandalam, Chennai.

**Materials and Methodology**

This is a retrospective study. The study was conducted using AR (Accident Registers) logs available at the department of medical records, Saveetha Medical College, Thandalam, Chennai. The study period was from January 1\(^{st}\), 2018 to December 31\(^{st}\), 2018. A total of 911 cases were reported during this period. All of these cases were taken into the study. I took six factors for the analysis of the study. These are as follows;

- Age (person admitted)
- Sex (person admitted)
- Mode of transport involved (both parties)
- Time of accident
- Site of Injury
- Pattern of Injury

All these data were collected from the AR log books manually. It was then compiled with the help of Microsoft Excel (2007). These compiled data was then analyzed using SPSS software. All the frequencies and percentages were also obtained from this.

One important factor that was not included in this study is the cause of the accident which includes drunken driving, sleeping while driving or of exhaustion.

The minimum that was recorded in my study was 8 years and maximum was 69 years. So the age groups were split into groups of 15 years each. For example, 0-14 years and 15-29 years and so on. This makes it easier to study which age group is more affected and which is less affected.

Mode of transport involved were 2 wheelers, 4 wheelers, HMVs like lorry, 3 wheelers like auto rickshaws and pedestrians. The whole 24 hours of the day were split into a 3 hour segment. So there are 8 segments. Segment I is from 0000 hours to 0300 hours, Segment II is from 0301 to 0600 hours so on and so forth.

For the study of site of injury, I had split upper limb injuries into two (proximal and distal) and lower limb injuries into two (proximal and distal). Proximal in upper limbs are above the level of the elbow and distal means elbow and below level. In lower limbs proximal is above the level knee and distal means knee and below level. Trunk includes abdomen, thorax and back.

**Results**

In this study, all cases of poly traumatic injuries as well as simple trauma injuries. Multiple trauma is 55% of cases and 45% of cases came with simple traumatic injuries. It implies the presence of two or more separate injuries, at least one or a combination of which endangers the patient’s life\(^3\).
There were a total of 911 cases noted. Out of these victims who came to the ER, 87% of them were males and 13% were females.

However this couldn’t be because of the population distribution of Tamil Nadu, as it is 955 females per 1000 males according to the 2011 census. The most commonly involved age group was 15-29 years. This category contains the bunch of teenagers and young adults. Main reasons behind these accidents are carelessness, thoughtless driving and experimental stunting. This accounts to about 62.8% of the total accidents recorded. It amounts to 572 cases. The next highest category is the 30-44 years which accounts to about 21% which is 187 cases. Only 19 accidents involved children less than 14 years of age and 29 accidents were involved by senior citizens.

Traffic is of peak during 6pm to 9pm around Thandalam region. Therefore the accidents are also more during this time. 250 accidents were recorded during these hours. Second most highest is recorded in 9pm-12am part with 150 cases. Although we might tend to think that early morning accidents should be more common, these trends were not seen in my study.

This peak hour accidents could also be because of social factors like the mindset of the person who are returning home from office after a stressful day. Distractions also play a role. People using phones whilst driving, their spatial processing is reduced by 37%.

The number of 2 wheelers in urban areas like this significantly high, and so they are the most involved. The sales of 2 wheelers in India reached 20 million mark in 2018, which was double the number sold in 2010 which was at 11.24 million. This boom is very much evident in this study too as the two wheelers involved were 93.4% of total cases i.e. nearly 850 cases of 911 accidents. Less than 1% involved pedestrians.

Most of the injuries were of abrasion type. Abrasion is defined by an injury of destruction of the skin, which involves only the superficial layers of the epidermis and also doesn’t involve the whole thickness of skin. Number of cases which had abrasion type injury is 516 cases. This is the most common type of injury, as the study takes in cases only about non-fatal road traffic accidents. Abrasion is just mild. Others like laceration or contusion or even fracture can be fatal. Next commonest is laceration type with 36.3% of total cases.
This amounts to about 331. Followed by contusion and fracture at 5.3% and 1% respectively.

Data analysis is conclusive that most commonly injured sites are the distal parts of the lower limbs. This accounts to about 24.8%. All of the injuries were within close reaches of this value, that is, all of the bodies were injured equally. Next closest is Distal upper limbs at 23.4% followed by proximal upper limbs at 22.6%. Proximal lower limbs were at 20%. Unlike other case studies, head injuries involved in my study were surprisingly less. But this can be explained by the fact that this being a non-fatality study, prevalence of head injuries was low at a staggering 9%.

This rapid urbanization side by side with motorization must be addressed. But this can’t be stopped until we control the population explosion. All we can do is to prevent these accidents from happening. Encouragement of use of public transport can reduce this significantly. Doing this has double benefits: First of all it reduces accidents and number of vehicles on the road, and secondly it reduces the carbon footprints of all of us. But many of Indian population look down upon or refuse the use of public transport due to various reasons like to avoid the crowd and for reasons of hygenicity. So, in order to counteract this, the transport department must increase the frequency and number of buses or rails and ensure proper hygiene techniques are used.

From the school level itself we must create awareness among the children and teach them about the consequences. If bikes are the preferred transport, then proper driving equipment should be used. From wearing helmets to wearing gloves. To protect injuries to spine we have spine guards too. But for at least an average protection wearing of seat belts and helmets is to be made mandatory. Road safety measures are very simple solutions to these complex problems. There should be good road lighting and segregation of slow moving vehicles from fast moving vehicles, pedestrians safety in highways by use of Zebra crossing and sub ways for pedestrians(10). They can add proper signs along the sides of the road to warn the drivers(11). Nowadays there’s AI mediated driving technology growing.

Peak hour traffic can be managed by better road laying techniques and maintaining proper conditions of signals. In this study we found that 6pm to 9pm the accidents were the highest. This because of the traffic in the Thandalam area during that time. Strict implementation of rules by the court of law is much needed.

Last of all and most important change we have to bring in is the medical support. In case of an accident, ambulances must reach the site within a very short time and extensive training for paramedical staff is also one of the cornerstones to provide the first aid needed in the field. Better equipped ER with advanced trauma care must be in use.
Conclusions

This study was conducted in Saveetha Medical College, Thandalam, Chennai. Total of 911 cases were studied retrospectively about the non-fatal road traffic accidents that came to the emergency department during January 1st, 2018 to December 31st, 2018. Road vehicles have no respect for the human anatomical boundaries. They occur to people irrespective of age, sex, caste or religion.

The most involved age group was from 15-29 years. 87% were male. 55% had multiple injuries. Knees, legs and feet were the most injured parts with 56% of them had abraded type of injury. What we need is beehive coordination between doctors, engineers and government to tackle this problem and not some pinnacle of technology to save us.

1Associate Professor, Department of Conservative Dentistry and Endodontics, MCODS, Mangalore, Affiliated to Manipal Academy of Higher Education (MAHE), Manipal, 2Professor & Head, 3Selection Grade Lecturer, Dept. of Dental Materials, 4Professor and Head, Dept. of Oral Pathology and Microbiology, MCODS, Mangalore, Affiliated to Manipal Academy of Higher Education (MAHE), Manipal

Abstract

Introduction: Numerous direct filling materials are available to the modern dental practice from amalgams, GIC to modern bulk fill composites. Cention is an “alkasite” restorative. Alkasite refers to a new category of filling material, which like compomer or ormocer materials is essentially a subgroup of the composite material class. This new category utilizes an alkaline filler, capable of releasing acid-neutralizing ions. It is a tooth-colored, basic filling material for direct restorations. It is self-curing with optional additional light-curing. It is radiopaque, and releases fluoride, calcium and hydroxide ions. As a dual-cured material it can be used as a full volume (bulk) replacement material. Hence the Aim of the study was to compare the Alkasite (Cention N) with Silver amalgam, GIC and Composite to evaluate the Compressive strength & diametral tensile strength.

Materials and Method: Split molds of dimension 6 [height] x4 [diameter] was used to fabricate 15 samples of each material for testing the compressive strength and for tensile strength. And subjected under Universal Instron testing machine connected to a load measuring cell, to recorded load applied to the samples at a crosshead speed of 0.75 ± 0.25 mm/min till the samples fracture.

Results: Composite and Cention N showed significantly higher strength than Silver Amalgam and Glass ionomer cement.

Conclusion: Within the limitation of this study, it can be concluded that Cention N can be used as a superior alternative when compared with Silver Amalgam and Glass ionomer cement.

Keywords: Compressive strength, Diametral tensile strength, Restorative materials.

Introduction

Numerous direct filling materials are available to the modern dental practice – from amalgams through to modern bulk fill composites. Amalgam materials were first introduced to western dentistry in the 19th century, glass ionomer cements (GICs) were introduced around the 1970s, composites became standard during the 1980s, resin modified glass ionomers and compomers were introduced in the 1990s and the current decade saw the launch of several bulk-fill composites.

Dental amalgam is sufficiently strong to support moderate biting forces within the first hour. The clinical success of an amalgam restoration depends on various factors including: appropriate cavity preparation involving undercuts due to the non-retentive nature of amalgam, condensation technique, anatomical characteristics and final finish. Although the use of amalgam became popular in the west in the 19th century, its long history and popularity however have not shielded it from controversy.

Glass ionomers were invented in the late 60s, first described by Alan Wilson and Brian Kent in the
Indian Journal of Forensic Medicine & Toxicology, July-September 2020, Vol. 14, No. 3

early 1970s and introduced to the market soon after\(^6\). Despite their reasonable clinical performance in terms of retention, glass ionomers are usually far less esthetic than composite restoratives\(^7\). Glass ionomer cements offer depot ion-release and undoubtedly improve on the esthetics of amalgams but they provide far less strength and longevity. Both products clearly have certain drawbacks and represent a clinical compromise in one respect or another.

The advent of new composite restorative materials, together with new adhesives has brought enormous benefits - notably in terms of esthetics and strides towards minimally invasive dentistry. They may however be perceived as expensive, time-consuming and technique-sensitive. Their existence has not eliminated the need for or appropriateness of traditional “basic” dental materials.

Cention N is an “alkasite” restorative. Alkasite refers to a new category of filling material, which like compomer or ormocer materials is essentially a subgroup of the composite material class. This new category utilizes an alkaline filler, capable of releasing acid-neutralizing ions\(^8\).

Cention N is a tooth-coloured, basic filling material for direct restorations. It is self-curing with optional additional light-curing. It is radiopaque, and releases fluoride, calcium and hydroxide ions. As a dual-cured material it can be used as a full volume (bulk) replacement material.

Cention N consists of a separately packaged powder and liquid that are mixed by hand directly before use\(^8\). As a new category of filling material, it is essential to understand its mechanical properties with respect to the common existing permanent restorative materials. Therefore, in this study, it was decided to compare the diametral tensile strength of alkasite (Cention N) with Glass ionomer cement, composite resin and silver amalgam.

**Aim and Objectives**

To evaluate and compare the diametral tensile strength of Cention, GIC, Composite and amalgam.

**Materials and Method**

Materials used were Cention N, Fuji Type IX Glass ionomer cement, 3M ESPE Z 350 XT Composite resin and Dentsply Dispersalloy Silver Amalgam.

Diametral Tensile Strength Test:

Six specimens of 6.0 mm in diameter and 3.0 mm in height were prepared for each material. All the samples were made according to ADA specification number 27. The environmental temperature was controlled and the materials were prepared as per the manufacturer’s instructions except Composites. After mixing, the materials were put into into brass moulds, which were slightly over-filled with the materials. A piece of film was placed onto the material in the mould and covered with a glass slide. Hand pressure was then applied for 20 seconds while excess material was extruded from the top of the mould. Two minutes after the placement into the moulds, the assembly was placed in an oven at 37 ± 1 °C and 95 ± 5% relative humidity, for 15 minutes. Then, the specimens were ejected from the mould and stored in 6 mL of deionized water at 37 ± 1 °C. The diametral tensile strength was measured by placing disc shaped specimens of 6mm diameter and 3mm thickness on the lower platform of universal testing machine [Model:3366, Instron] and were loaded at a rate of 0.5mm/min until fracture. The DTS was calculated by dividing the highest load recorded during the test divided by area of the specimen and is reported in MPa [n=6]. Data were subjected to one-way analysis of variance (ANOVA) and a Post Hoc Tukey test for multiple comparisons (<0.001).

</table>

Comparison of Maximum Compressive stress (MPa) using one way ANOVA test shows that the mean value of Composite (65.906667) is highest followed by Cention (51.831667), Silver Amalgam (23.231667) least in GIC (15.933333). This difference is statistically Significant with a test value of 10.069 and p value of <0.001. Post hoc Tukey test shows that the difference between Cention and GIC is Statistically significant with a mean difference of 35.8983333* and p value of <0.001. The difference between Cention and Composite is Statistically significant with a mean difference of -14.0750000* and p value of 0.014. The difference between Cention and Silver Amalgam is Statistically significant with a mean difference of 28.6000000* and p value of <0.001. The difference between GIC and Composite is Statistically significant with a mean difference of -49.9733333* and p value of <0.001. The difference between GIC and Silver Amalgam is not statistically significant with a mean difference of -7.2983333 and p value of 0.324. The difference between Composite and Silver Amalgam is Statistically significant with a mean difference of 42.6750000* and p value of <0.001.

Discussion

Among all the restorative materials available, composite resin (Z350XT 3M ESPE) has become the material of choice for restoration of all teeth. The recognition of resin-based composite restoration has increased because of its excellent aesthetic and other favourable characteristics.
In the present study, comparing the results obtained, the null hypothesis was rejected as there was a significant difference in mechanical properties (DTS) among the newer posterior restorative material tested. The restorative materials used in the oral environment are subjected to various occlusal forces. In this study, the mechanical properties of various dental restorative materials were compared and studied. The analysis of DTS is important for the comparison of mechanical properties of dental materials which reflect which material is better to perform clinically and is resistant to the masticatory forces. The result of the study indicated that the four materials tested in the study differed statistically in terms of DTS with a p value of 0.001, which suggests a significant difference in mechanical properties. The findings of this work have shown that the nanofilled composite (Z350XT 3M ESPE) has relatively high DTS (65.90 MPa). Basically, the diametral tensile strength (DTS) is a property described by ADA/ANSI Specification 27 for characterizing dental restoratives. Diametral tensile was also high in Cention N (51.83MPa) as compared with the other tested materials. Composite (Z350XT 3M ESPE) and Cention N showed a statistically significant difference DTS with GIC (Fuji IX) and Silver amalgam with the p value significant at 0.001. The value of diametral tensile strength in Silver amalgam and GIC was 23.23 MPa and 15.93 MPa, respectively. The weakest mechanical properties were obtained by GIC (Fuji IX) with the mean value of 15.93 MPa in DTS. There are various studies with regard to the comparative evaluation of mechanical properties of restorative materials showing contradiction of results. This was in accordance with Kumar et al.9 and Chalissery et al.10 who did a comparative study on mechanical properties of direct core build-up materials. They concluded that the composite had high mechanical properties followed by Cention N and GICs showed the weakest; this is in agreement with our study.

**Conclusion**

In the present study, it can be concluded that the mean compressive strength and DTS values of all the four restorative materials were significantly different because the composite materials available have a variation in composition and viscosity. The nanohybrid composite Z350-XT has the highest DTS and the properties of Cention N were almost similar. Silver Amalgam and GIC (Fuji IX) exhibited the least values when compared with that of the other materials.

Correlation between Stature and Length of Clavicle in Female Population of Central India

Pande Varsha1, Patond Swapnil 2 Patil Bharat3

1Assistant Professor, Department of Anatomy, JNMC, DMIMS, Wardha Maharashtra, 2Associate Professor, Department of Forensic Medicine, JNMC, DMIMS, Wardha Maharashtra, 3 Associate Professor Department of Pathology, MGIMS, Sevagram Wardha

Abstract

Introduction: Anthropology plays an important role in various medicolegal aspects; apart from determination of Age, Sex and Race of individual, stature is also one of the important parameter of identification various civil and criminal cases. Therefore efforts have been made to determine association between stature and length of clavicle if any.

Materials and Method: The present research was carried out in department of Anatomy JNMC Sawangi (M) Wardha; was conducted on total 50 Female individual of age 17–24. The length was calculated with the help of osteometric callipers for clavicles from anatomical landmarks and stature was calculated in centimetres.

Conclusion. From present research it was concluded that the length of clavicle and stature reveals positive correlation and the linear relationship between the living stature and length of clavicle of each side was carried out in the form of regression equation.

Key: Anthropology, clavicle, stature, correlation.

Introduction

Anthropometry which deals with expressing human form in numbers has been widely used in forensic identification and Anatomy. Identification includes determining sex, age, race and stature of a person. Among these, the sex and stature are the most important. Along with Age, stature also plays key role in ante mortem and post-mortem cases in identification of in various medicolegal cases.

Determination of stature is one of the important factors amongst age, sex and race in various cases, which can be useful for identification in various medicolegal cases. Determination of stature plays significant role in various medicolegal cases. In the field of anatomical, forensic and anthropology measurement of individual body parts plays very a vital role and to assess the various parameters in determination includes height of an individual. Various authors have confirmed correlation between stature and measurements of several parts of the body which are often represented using linear regression equation derived from them. At present many inherent population differences present among the different population, thus giving rise to the need for different formulae to be derived from different populations. Many authors like Terry, Thieme and Oliver, tried to determine correlation between stature and different bony measurement including clavicle. There are very few literature available in India, Singh et al, Jit et al envisages effort to determine correlation between stature and clavicle length.

Materials and Method

The current study was carried out in the department of Anatomy JNMC Sawangi (M) Wardha; was conducted on total 50 Female individual of age 17–24.
The length of the both clavicle was measured by means of a centimeter scale from anatomical landmarks with skin marking pencil and re checked by vernier calliper. Stature was measured in centimeter.

Participant has been asked to stand barefoot on a plane surface on the ground in upright position and was measured from the vertex to the foot according to the anatomical position and Frankfurt plane. To avoid diurnal variation, Measurements were taken at a set time. Exclusion of participant with obvious deformity or defects.

**Result**

A sample of 50 Females were considered, and the measurements were taken randomly using standard tapes. The data obtained were analyzed statistically using Microsoft Excel software, and the average living stature for an adult female was determined. The linear association between the living stature of individual and length of clavicle of each side was carried out. It was clear that the clavicle length showed a positive correlation with the stature. The mean value of the stature of the individual was found to be 156.12 and the length of the clavicle was found to be 13.132 and 12.926 for right and left clavicle respectively. The correlation coefficient \( r \) was calculated, and it was found to be significant correlation. The data are shown in Table 1 and Figure 1.

**Table 1: Correlation of height with length of right and left clavicle**

**Graph 1 showing correlation between length of clavicle and height of individual**
Discussion

Determination of stature from decomposed skeletonised residue is crucial in establishing the individuality of unknown person. Study conducted by Jakhar et al suggests that there is positive association between the stature and anthropometric dimensions\textsuperscript{11}.

Study have been conducted by Krishan et al to estimate height from the human skeleton, they suggested that different methods can be used to estimate the stature from the bone. The simplest and trustworthy method is by regression analysis\textsuperscript{12-13}.

Along with Clinical, dental examinations; bone examination also plays an important role to arrive at the opinion in medicolegal cases.\textsuperscript{14 15} Similarly skeletal maturity also based on life style, dietary climatic behavioural factors there for study are recommended in every region of India for academic and judicial interest.\textsuperscript{16 -18}

By using multiplication factor or regression formulae approximate stature of the individual can be determined from different long bones\textsuperscript{19}. Nagrale N, Patond S, found that identification in case of unknown body by using various anthropometric measurements and regression formula was helpful for forensic experts in various medicolegal cases\textsuperscript{20}.

Similarly Patond S et al found that determination of the stature from decomposed or skeletonised body and from remains is very crucial in establishing the identity of unknown individuals in various Medicolegal cases if one parameter is known, then with the help of regression formula we can find out the remaining parameters\textsuperscript{21}.

Conclusion

From present research it was concluded that the length of clavicle and stature reveals positive correlation and the linear relationship between the living stature and length of clavicle of each side. If the dimension of clavicle is obtained, the stature can be determined, would be useful for forensic experts and anthropologists in various medicolegal cases.

Forensic Investigation and Comparison of Blood Sample Referring to Thalassemia

Pankila Khanna1, Surender Sehrawat2, KS Rana3

1 MSc-Forensic Science and Toxicology Student, UIAHS, Chandigarh University, Mohali, Punjab, India, 2Assistant Professor, Department of Forensic Science and Toxicology, UIAHS, Chandigarh University, Mohali, Punjab, India, 3Associate Professor, Department of MLT, Chandigarh University, Mohali, Punjab, India-140413

Abstract

Identification of an individual is one of the significant features of forensic investigation. The present study was conducted to study the difference between normal and thalassemic blood. The study was conducted on 40 blood samples aim to compare control and disease wet blood samples by using different methods of microscopy. The comparison was done based on the morphology of the RBCs and red blood cell count. A (monolayer) thin blood film is prepared on a slide with a wet blood sample and observed under a compound microscope. Red blood cell count is performed with the help of Neubauer’s chamber. Observation shows the changes in the morphology of red blood cells in the thalassemic population as compared to the control population, moreover based on total RBCs count the number red blood cell count found higher in the thalassemic population as compared to the control. Both morphology and Count significantly differed from the control population. Thus, the present method can be used in the daily routine at forensic science casework.

Keywords: Thalassemia, Forensic, Investigation, Neubauer’s chamber, RBC morphology

Introduction

Blood Disorders

Blood disorders affect one or more than one part of the blood and thus prevent the blood from doing its regular job that is transportation, regulation, and protection. Blood disorders can be inherited or other causes include some other diseases, side effects of some medicines and also can happen due to a lack of important nutrients in your diet.

Blood disorders mainly affect the three main components of the blood which are erythrocytes, leukocytes, and thrombocytes. These disorders affect the oxygen-carrying capacity of the blood, immunity and also the clotting property to heal the wounds.

Thalassemia is one of these disorders which generally affect the shape and size of blood cells.

Thalassemia

Thalassemia is a red blood cell disorder which is a rare genetic disease caused by the markedly decreases in accumulation of one of the globin subunits of hemoglobin. Hemoglobin is an iron-rich protein in red blood cells that carries the oxygen to different parts of the body, it also carries the carbon dioxide which a waste gas from the body to the lungs. Thalassemia is an anemic disease and the person can have both mild and severe anemia. Thalassemia is of two types one is alpha thalassemia and another is beta-thalassemia. Hemoglobin contains four protein chains i.e. two alpha globins and two beta globins. The two major types of thalassemia are named after a defect in this protein chains1.

Alpha Thalassemia

Alpha thalassemia is the disease that is the most common hemoglobin genetic defect which is caused due to the reduction in the alpha globin’s chains or due to the absence of alpha-globin chains2. The disease

Surendersehrawat.uips@cumail.in
is prevalent in tropical and subtropical regions. But recently this disease is spreading throughout the world because of massive population migration. This disease is occurred most frequently due to the deletion in both or one of alpha-globin and least commonly due to non-deletion abnormality\(^2\). Symptoms: The person suffering from alpha thalassemia will show abnormal hemoglobin, microcytic anemia, and abnormality in the immune system, gallstones, cognitive impairment.

**Types of alpha thalassemia:**

HbH disease is the mild form and results from a defect in one alpha-globin and the presence of only one functioning alpha-globin gene. Due to this, there is the presence of excess beta chains and they form beta 4 tetramers. HbH is unstable and they are prematurely breakdown in spleen hence consequently hemolysis formed.

Hb Bart hydrops fetalis syndrome: the second type of alpha thalassemia in this disease there is an absence of all four alpha globins alleles\(^2\). It is moderately insoluble and thus accumulates in the red blood cells. Its presence indicates that one or more of the four genes that produce alpha globin’s chains are dysfunctional, causing alpha thalassemia. Fetal hydrops fetalis is characterized by an accumulation of fluid in at least two fetal compartments and cardiac failure. This condition is so severe that the foetuses are either stillborn or die soon after death\(^3\).

**Beta Thalassemia:**

Beta thalassemia is a hereditary disease, which is characterized by abnormalities that occur in synthesis or accumulation of the beta chains of hemoglobin which results in severe anemia to clinically asymptomatic individuals. Anemia begins at the 3-6th month of age. It is caused by the reduction or absence of the synthesis of beta globins chains of the hemoglobin tetramer, as we know that hemoglobin tetramer contains two beta chains and two alpha chains, thus the mutation in beta chains cause beta thalassemia\(^4\). A large number of imperfect red cells destroyed in bone marrow, giving rise to ineffective erythropoiesis, a prominent feature of disease\(^1\). Beta thalassemia is further of three types that is thalassemia major, thalassemia intermedia and thalassemia minor also known as beta-thalassemia carrier state\(^4\). The person suffering from beta-thalassemia major shows the symptoms of severe anemia within two years of life and they require a regular blood transfusion. The person with this disorder shows various features such as diabetes mellitus, parathyroid, thyroid, liver fibrosis, etc.

**Fig 1. Showing Difference between control and thalassemia population**

In forensic science the blood act as very important evidence, blood residue acts as a weapon which helps the investigator in the identification purpose, reconstructs a criminal action and links the suspect to the crime. Various studies show that thalassemia is a disease in which there is changes occur in the morphology of the red blood cells. The shape, size, color of the cells show clear changes that can be identified with the help of microscopy. Thus in forensic science, it is easy to determine if blood is present in the crime scene then that blood is from a normal person or thalassemic patient.

Hence, this study was designed on thalassemia patients to identify their blood using a normal microscope and compare the shape of RBC with the control population to distinguish between thalassemic
and non-thalassemic patients. All these help to narrow down the search of the area by taking inclusion and exclusion, identification of the suspected person which ultimately provides a lead in the investigation and helps the investigator to link the person with the crime.

**Materials and Method**

**Chemicals**: Ethylene diamine tetraacetic acid (EDTA) used as an anticoagulant, Ethanol, 1% HCL, Leishman’s Stain, Buffer, Distilled water, Saline water.

**Glass Ware**: Glass slides, Coverslips, Dropper, Test tubes, Beakers

**Instruments**: Compound Microscope of Microcater instrumentation, Haemocytometer (Neubauer Chamber)

**Sample collection**

A total of 40 samples of blood were collected out of which 20 were collected from normal people and 20 were collected from the patients suffering from thalassemia. Samples were collected from the laboratories of hospitals (left after hematological test) and all the samples are stored in EDTA vials and labeled properly. Only waste blood samples were collected from the laboratories situated in hospitals in the Chandigarh region.

**Procedure for Microscopy.**

1. Blood films are prepared by placing the drop of blood on one end of the slide with the help of a micropipette.
2. The blood is dispersing over the slide’s surface to form a monolayer. The slide was left for a few minutes to air dry. The dried slide was fixed by immersing into methanol for 3-4 minutes. Afterward, the slide was stained with Leishman stain, 2-3 drops of dye were put on the slide and wait for left for 3-4 minutes.
3. The slide was diluted using the buffer for 7-8 minutes. Buffer is used to maintaining the pH so that cells do not get destructed. The slide was washed and observed under a microscope for morphology.

**Procedure for Neubauer Chamber**

1. A 1:200 dilution of blood was prepared.
   - A 20 microlitre of whole blood placed on the tube.
   - RBC diluting fluid was mixed and shaken with mechanical shaker for 2-3 minutes.
2. 10 microlitres of blood filled to each slide of the counting chamber. Once the counting chamber is filled with the sample allow the cells to settle for 2-3 minutes before counting.
3. Count of cells: Counting was done under a microscope

#### Result

Blood samples were taken both thalasemia and normal population and observed under the microscope and the changes in the blood were observed which are explained further.

On observing the blood sample of thalasemia patients, different shapes of erythrocyte were found. Out of which the hypocromic, microsite shapes were observed in greater number, other shapes like targeted, acanthocyte, basophilic, schistocyte, barr cell were also observed in the average number and limon cell were observed in the least number during the study wherein the control sample no such shape change observed and normal or basic changes were observed.

On comparing the blood sample on basic of cell count different level of cell volume or cell count was observed both in thalasemic and control population. The level of RBCs was found to increase in the thalasemic population as compared to the control population. The volume of erythrocyte observed in the control population was 4-5 million/microliter of blood...
where 6.8-7.2 million/microliter was observed in the thalassemic population. Hence thalassemia patients are richer in the count of corpuscles than control.

At the end of the observations, it results that the hypothesis made during the research is an alternative hypothesis.

**Discussion**

A total number of 40 samples were taken, 20 samples of normal blood and 20 samples of thalassemic blood. The study was designed in such a way that each sample was studied by using different methods and comparison is done between the normal blood and thalassemic blood. Two methods are used to study the wet blood those are microscopy and red blood cell count.

According to various previous studies change in the morphological shape of erythrocytes were observed due to the formation of methemoglobin and precipitation of globin. Bunyaratvej et al. in 1985 performed a study on thalassemia patients an analyzed the shape of RBC especially in Beta-thalassemia and observed the change in the shape from normal (biconcave) RBCs to torocytes, acanthocytes. Galanello and Origa in 2009, performed a study in beta-thalassemia patients, they also observed the morphological changes in the shape (speculated teardrop, elongated and nucleated) RBCs from normal morphology of RBCs. Galanello and Cao in 2011, work on alpha thalassemia patient Alpha thalassemia is a very rare disease that affects the shape, size, color and total count of the RBCs. RBCs number was found to be increased. Akrimim Jameeka Ali et al. in 2013 performed a study in a different type of anemia and study the effect on RBCs. They found 93% shape in RBCs was abnormal form the basic shape. Founded abnormal shapes were hypocromic microsite, targeted, acanthocyte, basophilic, schistocyte, barr cell, limon cell. All these abnormal shapes of RBCs are already reported in above given previous studies, from the comparison and cell characterization were made (Bunyaratvej et al. in 1985) (Renzo Galanello and Rafaella origa in 2009) (Renzo Galanello and Antonio Cao in 2011) (Akrimim Jameeka Ali et al. in 2013) all previous study supports and validate the current study.

Studies show that total RBCs count is higher in thalassemic blood as compare to normal blood because due to the lack of hemoglobin body is not able to get enough amount of oxygen thus to overcome this situation body tends to make more and more red blood cells to carry more and more oxygen. Evan and Jehle in 1991, studied on anemic population and reported that anemia can be categorized based on mean corpuscular volume and red blood cell distribution. Galanello and Rafella in 2009, worked on beta-thalassemia and reported the increase in the number of RBCs after splenectomy. Again, Galanello and Cao, worked on alpha thalassemia and reported that same observation as in previous research, the increase in the count of RBCs.

In the current study, number or count and volume of RBCs were analyzed, the results observed were the same as observed in previous studies. The count and the volume of RBCs were found to increase in the thalassemic population form normal volume and comparison to the control population. The volume of RBCs was observed on an average of 4-5 million/microliter where in thalassemic population volume was 6.8-7.2 million/microliter, which is far greater than the control population. So, it will be easy for the comparison between normal and anemic patients.

All the results observed are found the same as in the previous study which indicates that the previous study supported the present study, moreover the presented method can be used as a tool for identification of individual as class characteristics. As the class characteristic help in narrow down the area of investigation, the presented method also helps to narrow down the area of investigation and research, rather than used sophisticated instruments/methods and tests to narrow down the investigation. According to J. Ford in 2013 RBCs morphology can be used for identification in hematology laboratory and microscopy can easily help in identification. So, abnormal shape RBCs using microscopy can be used as a tool for personal
identification. Ja hyun, Yang and lee in 2012 stated that body fluids will give important insight into crime scene reconstruction by supporting a link between the donor and criminal act. 

According to Colah, Italia, and Gorakshakan, a low rate of thalassemia was found in India, on an average 10000-12000 thalassemic children born in India where specifically in Maharashtra and Gujarat per 1000 birth 0.28 and 0.39 % was born with thalassemia. Data is also available based on communities that reveal a minimum of 4% to a maximum 17% population was affected with thalassemia. The less prevalence of thalassemia used as a tool for the identification of a suspect or narrow down area of investigation. Blood sample comparison sets criteria for inclusion and exclusion of individuals with different blood diseases and saves time and gear up the investigation. Such types of evidence play a crucial role in criminal trials and help to link the suspect with the crime by determining whether they having a common source or not. (Thompson Williams).

Presented research can be used in analyzing of regular cases encounter with the forensic science investigation for further research and investigation.

**Conclusion**

The study shows that the comparison between the normal and thalassemic blood is possible based on the morphology/shape of the RBCs and total red blood cell count by using a wet blood sample. This study is helpful to compare the blood evidence found at the crime scene, based on this comparison it is possible to link the suspect with the crime and helps to narrow down the investigation.

**Limitations:** RBC count can only be done with the wet blood sample., Dry blood can also be used for investigation purposes.

**Further Scope:**

The size of the RBCs is also a factor that can also be used for the comparison; the size of red blood cells gets smaller and smaller in thalassemic blood.

The Colour of the RBCs can also be included as a factor for comparison.

Use of dry blood for all investigations.

Perspective of Maternal Deaths: A Retrospective Autopsy Study

Patekar M B., Jagtap N.S., Pawale D.A.

Abstract

Reducing maternal mortality has been a constant struggle globally. The major causes of maternal mortality remain to be ante and post-partum haemorrhage, anaemia, obstructed labour, hypertensive disorders and post-partum infections, liver disorders as observed in various studies. The present study was carried out with view to determine factors causing maternal deaths, and utility of autopsy with autopsy record as a useful and adjunct data source for ascertainment of maternal deaths. In this study we have retrospectively considered the autopsy of maternal cases during 2015 to 2019 referred to RCSM GMC Kolhapur, Kolhapur, Maharashtra. Of the total 66 cases of maternal deaths, maximum number of cases were seen in age group of 20 to 29 years comprising 42 out of 66 (63.63%), Maximum cases 53 (81.30%) were resident of rural areas. Maximum causes of death on autopsy were direct causes, of which hemorrhage was the predominant cause. Most of the cases (42 out of 66 ) died within 24 hours of admission to the hospital. The determinants of maternal mortality need to be studied through the lens of autopsy.

Key words- Maternal mortality, medicolegal autopsy, Direct Causes, Indirect Causes, Hemorrhage.

Introduction

In the past decade, India has been able to reduce maternal mortality from 206 to 181 maternal deaths per 100000 live births, but with 17 % (50000 maternal deaths) of all maternal deaths occurring in India, it still is the highest contributor of maternal deaths in the world followed by Nigeria (14%, 40000).

Maternal death is used as a proxy indicator to assess the country’s maternal and reproductive health status. World wide about 830 women die every day of preventable causes related to pregnancy and childbirth, 20 % are from India.

Maternal mortality is defined as “The death of a woman while pregnant or within 42 days of termination of pregnancy (delivery) irrespective of the duration and site of the pregnancy from any cause related to or aggravated by the pregnancy or its management, but not from accidental or incidental causes. Delivery includes, abortions (spontaneous, legal and illegal), live or stillbirths, vaginal or cesarean deliveries. WHO classifies maternal deaths causes into four groups:- 1) Direct 2) Indirect 3) late due to unanticipated complications of management, and 4) incidental deaths.

The four groups into which the cause of maternal death can fall are:

1. Direct causes: Direct obstetric deaths are those resulting from obstetric complications of the pregnancy state (including pregnancy, childbirth and the puerperium to 42 days), such as deaths as a result of obstetric haemorrhage or eclampsia.

2. Indirect causes: Indirect obstetric deaths are those resulting from previous existing disease or disease that developed during the pregnancy which was not a result of direct obstetric causes, but which was aggravated by the physiologic effects of pregnancy, such as cardiac conditions aggravated by pregnancy.

3. Unanticipated complications of management: these are deaths resulting from interventions, omissions, incorrect treatment or from a chain of events resulting
from any of the above during pregnancy, childbirth or the puerperium (up to 42 days).

4. Incidental: Cause unknown and thus not attributable to either direct or indirect causes.

High-quality antenatal, intra-natal and postnatal care and emergency obstetric care are the most important ways to reduce the maternal morbidity and mortality. This study was aimed to analyze the causes of maternal death through autopsy records.

Objectives-

1. To know the causes of maternal death subjected to autopsy.

2. To categorize the causes according to various groups.

3. To identify various factors which influence maternal deaths.

4. To suggest measures to prevent maternal deaths.

Material & methods:-

A total of 66 cases of maternal death which underwent medico-legal autopsy during the period of January 2015 to June 2019 were studied at the Department of forensic medicine and toxicology, RCSM GMC, Kolhapur, Maharashtra. The current study includes maternal death cases referred from private hospitals, peripheral government hospitals, remote areas, and the cases which were brought dead. The cases of maternal deaths which were treated at the same institute, were also brought for medicolegal autopsy. All the autopsies in maternal death were performed by a team of forensic expert, pathologist and a gynecologist, after an inquest along with the clinical papers were received for the same. Cases from the year January 2015 to June 2019 were studied retrospectively after detail analysis of the postmortem reports, inquest papers and histopathology reports.

The study involved a detailed analysis of the postmortem findings including the history of each case, with the external examination and internal findings pertaining to the maternal death. The pregnancy related findings apart from the organs of generation like the fetus if present, placenta, upper vagina, broad ligament, internal iliac vessels, etc were also studied to conclude the given cause of death after postmortem examination.

Observations & Results

It is observed from this study [table no.1] that out of the 66 cases of maternal mortality brought for autopsy in the study period, maximum number of maternal deaths were seen in age group of 20 to 29 years comprising 42 (63.63%) and 14 (21.21%) cases were found in the age group 30 to 34 years of age. Only 4 cases belong to the age category below 20 years and 6 cases above the age 35 years.

Maximum cases 53 (81.30%) were resident of rural areas where as rest 13 cases (19.70%) belonged to urban area [table no. 1]. Most cases (33) of maternal mortality were referred for autopsy from the government hospitals including the present institute where the study was conducted, while 27 cases were referred from the private hospitals, and 6 cases were directly brought as dead to the casualty. Most of the cases (34) were with full term gestation while only 2 cases belonged to the first trimester [Table no. 1]. Death occurring in the 3rd trimester were the second most with 20 no. of cases. 26 cases of maternal mortality were primigravida, and least no. of cases belonged to the 4th gravida and above [Table no. 1].

Maximum no. of 34 cases were liveborn in maternal deaths followed by 20 cases with intra-uterine fetal death in the last trimester and full term. Total 10 maternal deaths occurred in the first and second trimester with fetal outcome as abortion in 2 cases, premature delivery in 2 cases and death in utero in 6 cases [table no. 2].

Maximum causes of death on autopsy were direct causes, of which hemorrhage was the predominant cause (24 no. of cases) [Table no. 3]. Sepsis and respiratory infections during pregnancy and after delivery were responsible for deaths in 17 cases. Indirect causes were responsible for 12 cases of maternal death and only one case had incidental cause of death.

Most of the cases (42 out of 66) died within 24 hours of admission to the hospital, while about 12 cases died within one week of admission. 6 cases were declared as brought in dead before treatment [Table no 5].

**Discussion**

Worldwide about 830 women die every day of avoidable causes associated with pregnancy and childbirth, 20% are from India.\(^7\) Deaths due to conditions related to pregnancy and childbirth is considered the 6\(^{th}\) biggest cause following infectious and parasitic diseases, injuries, conditions not elsewhere classified, cancer, and cardiovascular diseases.\(^8\)

The various causes of maternal death are being highlighted depending upon the classification of maternal deaths into direct and indirect deaths. Indian subcontinent has a considerably greater maternal mortality attributable to sepsis, infection and hemorrhage.\(^9\)

A broad summary of the extent and distribution of the causes of maternal deaths is critical to reform reproductive health policies. With this vision we conducted the study based on the medicolegal autopsy done in cases of maternal deaths during the period of January 2015 to June 2019 at RCSM GMC Kolhapur.

In the present study, higher incidence of maternal deaths 42 (63.63%) in the age group 20 to 30 years is in accordance with that observed by Thomas et al\(^{10}\), Kuralkar et al\(^{11}\), Mukherjee et al\(^{12}\), Soni et al\(^{13}\), Patil et al\(^{14}\). 20-30 years age is the most fertile age of a female, with obvious dominance in maternal deaths is this age group.

Considering the residence pattern, 19.70% females were residing in urban area and rest 81.30% were from rural areas. The high proportion of females from rural area in maternal death was in consistency with the observations of Soni et al\(^{13}\) and Bangal et al\(^{15}\). However, these results are in dissimilarity with that observed by Kuralkar et al\(^{11}\) and Patil et al\(^{14}\) who noted dominance maternal deaths in urban section. Women from rural section belong to lesser awareness about the maternal health, ignorance to nutrition necessary during pregnancy, poverty along with distant health facilities at the rural areas in the vicinity of this region.

34 cases of maternal death were in full term gestation, while 20 cases were in the 3\(^{rd}\) trimester and only 2 cases belong to the first trimester. The predominance of the maternal deaths in full term gestation points the sudden risk involved during prelabour, labour and post labour period. Predominance of death in the full term gestation and 3\(^{rd}\) trimester was consistent with the observations by Badrinath et al (42.20\%).\(^{16}\)

26 cases of maternal mortality were primigravida, while 21 cases were of second gravida and least no. of cases belonged to the 4\(^{th}\) gravida and above. The long stages of labour in primigravida increases the period of risk of maternal complications. However, our observations were not in consistency with observations by Kuralkar et al where multipara (47.4%) dominated the primigravida (46.3%) in maternal deaths and in Mukherjee et al\(^{12}\) deaths in multipara (75%) were more as compared to primigravida (25%).\(^{11}\)

In this current study we observed that most common cases of maternal deaths were due to direct causes i.e 83.3%, among them hemorrhagic shock (39.39%) was the most common. It was followed by septicemia and infective causes (25.75%) and pregnancy induced hypertension (18.8%). Maternal deaths due to indirect causes which was 16.66% which included death causes like kidney infections, pneumonia, anemia, subarachnoid hemorrhage, hepatitis. One incidental cause due to swine flu infection to which was unrelated to pregnancy was observed in this study. Dominance of direct causes over the indirect causes was consistent with the observations by Thomas et al\(^{10}\) which included 60% direct causes over 37% indirect causes and by Kuralkar et al\(^{11}\) (89.4% direct causes over 10.5% indirect causes). In the current study, 12 cases died due to uterine atony induced postpartum hemorrhage as evident by soft, flabby uterus on autopsy. 3 cases died due to uterine rupture, 3 cases due to vaginal and cervical tears. One death was related to hemorrhage following lower segment caesarean section and one maternal death was related to post abortion complications.

Of the total 66 cases, 30 cases died at the same treating hospital while 6 cases were directly brought in dead at the casualty. In the study 30 cases were referred to higher treating hospitals, which involved 8 private hospitals and 22 cases were referred to this government tertiary hospital. Patil et al observed high referral from private hospitals which was in contrast with our study.\(^{14}\)

Of the 12 cases which were referred from government hospitals, 10 were from the primary health centers, signifying importance of gynecologists and
lack of proper facilities including timely transportation. Badrinath et al observed that comparatively high MMR probably because of the many complicated referrals from rural areas and the referrals were brought in the last stage of maternal complications, which is consistent with our observations. \(^\text{16}\)

In this study we observed that 63.63% cases died within 24 hours of admission, while only 2 cases died following a prolonged hospital stay of more than a week which was consistent with Mukherjee et al\(^\text{12}\). Considering the factors like delay in referral, sudden deterioration of the health in the health due to pregnancy and labour complications, early death even on hospital admission might be the reason for death within 1 day of admission.

**Conclusion**

Maternal death is not just a health issue, but a social injustice which leads to breakdown of the vital pillar of the family. Lack of acceptable referral facilities to provide emergency obstetric care for complicated cases also subsidize to high maternal mortality rate. To lower maternal mortality following steps must be taken into consideration.

- Training the medical officers in maternal health services can achieve remarkable improvement in maternal and perinatal outcome.
- Early recognition of high risk cases through ANC, timely sonography, good healthy communication between the health staff accompanied with proper transport facilities.
- Guidance from the hospital administration to implement the national health programmes of the Ministry of health like Janani Suraksha Yojna to prevent home deliveries or deliveries by unqualified staff.
- To discuss local cases of death or severe morbidity and identify immediately remediable local solutions in relation to maternal morbidity.
- Maternal death audit which should include the forensic experts, pathologists in addition to gynecologists to discuss reasons, factors and lack of proper management leading to maternal death.

Effect of Nordic and Normal walking on coronary risk factors among middle aged obese population: Comparative Study

Pradnya P. Ghadage¹, T. Poovishanu Devi²

¹Intern, Faculty of Physiotherapy, ²Associate Professor, Department of Cardio-Pulmonary sciences, Krishna Institute of medical sciences ‘deemed to be’ university, Karad, Maharashtra, India

Abstract

Background: In recent years, obesity significantly increased in all the age groups due to sedentary lifestyle. It can result into chronic heart disease. So walking is very beneficial for every individual therefore this study is aimed to compare the effect of Nordic and Normal walking on coronary risk factor in middle aged obese population. 32 middle aged obese individuals were participated in this study they were divided into 2 group. One group performed Nordic walking and other Normal walking and evaluate the efficiency of Nordic and Normal walking for the coronary risk factor.

Objective: To assess the W-H Ratio BMI, HDL and LDL level

To find out the pre and post effect of Nordic and normal walking on the coronary risk factors.

Methodology: The study subjects were 32 middle aged obese individuals. They were divided into 2 groups. The primary intervention to Group A consist of a Nordic Walking and Normal walking for group B. Individuals were selected according to inclusion criteria age between 45-65 years, Body Mass Index ≥30 kg/m², Waist – Hip Ratio > 0.9 cm for men and 0.8 cm in female, HDL < 40mg/dL, LDL > 130 mg/dL and exclusion criteria was individuals taking medication which influence the variable measured, any orthopedic condition that limit the exercise, unstable angina, uncontrolled hypertension – SBP ≥ 200 mmHg and DBP ≥110 mmHg.

Result: Statistical analysis for BMI, Waist – Hip ratio, LDL and LDL level was significant (P value = 0.0001) in individuals performed Nordic walking. In normal walking P value is changes in BMI, W-H ratio, HDL and LDL level which was not significant.

Conclusion: From this study, it can be concluded that the Nordic walking reduces the coronary risk factor in middle aged obese population than the normal walking.

Keywords: Nordic walking, Coronary risk factors – BMI, HDL, LDL, WHR , middle Age . Obesity

Introduction

Obesity is a medical condition in which excess body fat has accumulated to the extent it may have a negative effect on health [¹]. In recent studies have reported globally, more than 1.9 billion adults are overweight and the 650 million people are obese and approximately 2.8 million deaths are reported due to obesity. Its due to the sedentary life style, consumption of high energy dense food, lack of physical activity. In India prevalence of obesity and central obesity varies from 11.8% to 31.3% and 16.9% to 36.3% respectively and in urban population prevalence of obesity was12.7% compared to 5.4%in rural area [¹] According to WHO obesity defined as BMI greater than 30kg/m² is significant and it is linked to health problems such as increased LDL

level, total cholesterol level, reduce insulin sensitivity and diabetes, CVD, cancer and sleep apnea, joint pain such as OA. In previous studies they show that it affects the physical functioning, role limitations due to physical problems, bodily pain. They facing difficulty in walking, climbing upstairs, shortness of breath while walking\[^{12}\] and its negative impact on health-related quality of life in all the domains including physical, social and mental functioning.

Nowadays, walking is highly recommended in obese population for the physical reconditioning. It is an rhythmic, dynamic, aerobic activity, which can be provide a training effect. There are various health benefits of walking such as it increases the cardiovascular and pulmonary fitness, individual’s aerobic capacity, management of conditions like hypertension, high cholesterol, joint and muscular pain and stiffness and diabetes, Stronger bones and improved balance, Increased muscle strength and endurance and Reduced body fat.

The many previous researches proved that walking is beneficial in weight reduction which has positive impact on the coronary risk factors.\[^{1}\] But, in middle age i.e age group between 45-65 years there is change in musculoskeletal, cardiovascular system which reduces the exercise capacity. The middle age obesity has an important role in atherosclerosis and coronary artery disease And also obesity is main risk factor for the larger joint (Eg. Knee joint) osteoarthritis.\[^{3}\] Walking is a popular form of exercise but weight bearing is more during walking so it may be a critical source of biomechanical loads that link obesity and OA.

There are few studies have been conducted on how obesity affects the biomechanics in walking. In Spyropoulos et al. compared the stride length and joint angle difference between obese and normal weight men. They found that the obese males walked slower (1.09m/s) with wider steps and similar knee flexion. The peak knee flexion is during the loading response of the gait cycle increases as the walking speed increases. This will result in obese men might adopt a more flexed knee during stance phase.\[^{3}\] In Messier et al study they found that absolute peak vertical ground reactional force increased in almost directly proportional to the body weight. So as the weight increases the GRF increased over the larger joint this will increases pain on OA knee.

So, walking with the help of Nordic poles is more beneficial in obese population.\[^{3,4}\] Nordic walking has benefits on obese population. The walking distance and speed of walking increase which help in weight reduction. In , Kocur et al. reported significant effect on cardiovascular adaptation to effort, it mainly decreased heart rate compared to walking without poles.\[^{3}\] Walking with the help of poles uses the body’s various muscle group than the normal walking. The use of arm muscles mainly triceps and the shoulder girdle muscle due to arm swing while walking. Therefore, chest expansion is more in Nordic walking which help in reducing symptoms of dyspnea while walking in obese population. Also, walking with the poles reduces the joint load, maintain balance and co-ordination, improves the posture while walking than the normal walking.

**Material and Methodology**

Ethical clearance was obtained from the institutional ethical committee, KIMSDU, karad This study included the 32 obese individuals according to inclusion and exclusion criteria and the were divided into 2 groups. Group A (n= 16) and group B( n = 16). The study protocol was approved by the regional ethical committee. Individuals were selected according to inclusion criteria age between 45-65 years, Body Mass Index (BMI) ≥30 kg/m\(^2\), Waist – Hip Ratio (WHR) > 0.9 cm for men and 0.8 cm in female, HDL < 40mg/dL, LDL > 130 mg/dL and exclusion criteria was individuals taking medication which influence the variable measured, any orthopedic condition that limit the exercise, unstable angina, uncontrolled hypertension – SBP ≥ 200 mmHg and DBP ≥110 mmHg.

Group A was given Nordic poles for walking. And they were perform walking including warm up and cool down period 10 min. 30-45 min/ day walking for 3-4 time/ week for 12 weeks. Group B perform Normal walking and it also include warm up and cool down period 10 min, walking 30-45 min/ day for 3-4 times/ week for 12 weeks.

**Outcome Measures:**

The outcome measure was taken for this study were

BMI

Waist – Hip Ratio

HDL and LDL level
Statistical Analysis

Statistical analysis of the recorded data was done by using the software SPSS version 20.

16 subjects were successfully completed assessment and the 12-week Nordic walking program. 3-4 times / week. The result showed that mean BMI per 31.92 kg/m² and post intervention program 29.13 kg/m², WHR Previous 1.97cm and Post 0.8cm, HDL Previous 47 mg/dL and post 50.18mg/dL, LDL 126.44 mg/dL and post 103.94 mg/dL

**Result**

Thirty-two middle aged obese individuals participated in this study. Their basic BMI, W-H ratio and biochemical data are represented in Table no 1,2 and Table no 3,4 respectively. After 12 weeks of exercise performed according to Nordic and Normal walking. There is significantly reduction in BMI (on average 3.66 kg, 5.7%) and W-H ratio (on average by 1.17) were observed in Nordic walking. None of the participants showed a body weight increases. In biochemistry results statistically drops in LDL (-22.54mg/dL) and increases HDL (8.5mg/dL)

In Normal walking the statistics are BMI (on average 1.7 kg. 2.3%) and W-H ratio (on average 0.05) in biochemistry result LDL drops(-17.93mg/dL) and increases HDL (5.18mg/dL)
Discussion

Walking is the aerobic activity which can produce the necessary intensity to provide a training effect.[5] The walking with the specially designed poles, called Nordic walking and it is largely used by the sports players as a part of exercise training. So, it is very effect mean of exercise in middle aged obese individuals which helps in the weight reduction as well as improves the coronary risk factors.

The present study aimed to compare that the effect of Nordic and Normal walking on the coronary risk factor in the middle-aged obese population.

The objectives are to assess the BMI, Waist hip ratio, HDL and LDL level and To find out the pre and post effect of Nordic and normal walking on the coronary risk factors in middle aged obese population.

This study done was done in 12 weeks of duration with sample size 32 and age group 45-65 years. Later they were divided into 2 groups. One group performed walking with the help of poles and other without poles. Complete session required 60 min 10 min of warm up and cool down period 30-45 min of walking and other group same.[6] Consent from was taken from subjects and assessment were done pre and post treatment.

In this study, we observed a significant reduction in BMI, Waist – Hip ratio, increased in HDL level and reduced the LDL level in group A than group B in accordance to other study.[7,8] Moreover, the result demonstrate that there is no significant improvement in coronary risk factor in Normal walking. Weight reduction after 10-12 weeks of Nordic walking was also observed by other group of researchers.[9]

As mentioned above the comparative study of 12 weeks of Nordic walking program had positive effect on BMI (table 1) and WHR (Table 2) than normal walking. The Nordic walking program increases the HDL (table 3) and reduces the LDL (table 4).

Nevertheless, the complete clinical result of the Nordic walking program was associated with its hypolipidemic effect, and can be expressed as the reduce the risk of cardiovascular disease at least 20-25% (10% depend on LDL reduction and 10-15% dependent on HDL increase). [10]

Conclusion

From this study, we can conclude that the Nordic walking is an effective type of physical training which help to reduce the coronary risk factor in middle aged obese population.

Abbreviations:

BMI – Body mass index

WHR – Waist – Hip ratio

HDL - High density lipoprotein

LDL – Low density lipoprotein

Abstract

Background: Privacy and confidentiality in medical care are deeply rooted in core professional ethical standards across a variety of health professions. Present project aimed to study perceptions of intern doctors regarding privacy and confidentiality in medical practice.

Materials and methods: Total 100 intern doctors of GMERS Medical College, Valsad, Gujarat were subjected to pre-tested and pre-validated Likert scale type questionnaire regarding knowledge and awareness of privacy and confidentiality in medical practice after obtaining their informed written consent. Data obtained were analyzed via median score and tabulated.

Results: Out of 100 respondents, 58 were male and 42 were female. Knowledge and awareness regarding many of the facts related to privacy and confidentiality of medical practice found to be satisfactorily with median score of more than 3. Professional secrecy is implied term of contract between doctor and patient, patient can sue the doctor for damages if disclosure is done without his consent and harm him and not in the interest of public, etc. showed median score of 3. Disclosure to parents without consent in case of major and breach of professional secrecy is professional misconduct of doctor showed median score less than 3.

Conclusion: Intern doctors had little knowledge regarding disclosure to parents without consent in case of major and breach of professional secrecy is professional misconduct of doctor. Intern doctors were not sure about Professional secrecy is implied term of contract between doctor and patient and patient can sue the doctor for damages if disclosure is done without his consent and harm him and not in the interest of public. Knowledge and awareness regarding rest of the facts related to privacy and confidentiality of medical practice found to be satisfactorily among intern doctors.

Key words: Privacy, Confidentiality, Professional secrecy, Medical practice, Awareness, Intern doctors.

Introduction

Privacy and confidentiality in medical care are deeply rooted in core professional ethical standards and values across a diversity of health professions since years. For example, the Hippocratic Oath amongst physicians includes a pledge to protect patient confidentiality and privacy [1]. In one version, participants of the oath state that “I will admire the privacy and confidentiality of my patients, for their problems are not disclosed to me that the world may know” [2].

One of the essential features of professionals is that they are guided by ethical codes [3, 4], and ethics only are not adequate pointer of professional grade [5]. Another primary feature of professions is the skill to control
information\textsuperscript{[5]}, so anything that might alter it may affect inter or intra professional relationship. For example, invention of new technologies usually associated with inter-professional conflict, as well as test prevailing intra-professional practices and organizational routines \textsuperscript{[6, 7]}. The prevalent diffusion of new information and communication technologies into health care forms a revolution in at least the method that information is achieved and dispersed \textsuperscript{[8]}. Moreover, as access to health information rest on relations across numerous professional groups among socio-technical organizations \textsuperscript{[9]}, information and communication technologies may test the information regulator of multiple professional groups, causing additional troubles and potentials for alteration.

Evetts \textsuperscript{[10]} defines professional discourse as “the customs in which health professional as well as occupational workers are accepting, including and accommodating the idea of ‘profession’ and particularly ‘professionalism’ in their work.” Control and safety of patient information is considered as important part of the ethic by health professionals, while for other fields it is not much relevant. Professionals’ discourse regarding secrecy and privacy also give idea about how new information technologies and laws test prevailing practices of information regulation among health professional groups \textsuperscript{[10]}

In this study, perceptions of intern doctors towards privacy and confidentiality of medical practice were studied.

**Materials and Method**

Present study was undertaken at GMERS Medical College, Valsad, Gujarat. Study was done after obtaining ethical approval from the Institutional Ethical Committee. Questionnaire was designed to study perceptions of intern doctors regarding privacy and confidentiality in medical practice. Total 10 questions were prepared on Likert scale (1 to 5, 1 – Strongly Disagree, 5 – Strongly Agree) and checked for face and content validity \textsuperscript{[11-23]}

**Inclusion criteria:** Intern doctors who were willing to participate were included in the study after obtaining their informed written consent with full confidentiality.

**Exclusion criteria:** Those who didn’t want to participate were excluded.

Total 100 intern doctors of GMERS Medical College, Valsad, Gujarat were subjected to pre-tested and pre-validated Likert scale type questionnaire regarding knowledge and awareness of privacy and confidentiality in medical practice after obtaining their informed written consent. Data obtained were analyzed via median score and tabulated.

**Results**

Total 100 intern doctors were participated in the present study and their responses to questionnaire related to privacy and confidentiality in medical practice were taken into consideration for data analysis. Out of 100 respondents, 58 were male and 42 were female. There was no statistical difference among perceptions of male and female.

(SD- Strongly Disagree, D- Disagree, NS- Not Sure, A- Agree, SA- Strongly Agree)

Total 70 intern doctors were agreed upon that discussion of patient’s findings with spouse or friends without patient’s consent is breach of professional secrecy with median score of 4. Total 45 intern doctors were not sure about professional secrecy is implied term of contract between doctor and patient with median score of 3. Total 55 intern doctors were agreed upon that without confidentiality patient will not reveal everything with median score of 4. Total 55 intern doctors were not sure about that patients can sue the doctor for damages if disclosure is done without his consent and harm him and...
not in the interest of public with median score of 3. Total 56 intern doctors were not agreed upon that if patient is major, don’t disclose anything to his parents without his consent with median score of 2. Total 43 intern doctors were strongly agreed upon that don’t answer any enquiry by third party without consent of patient with median score of 5. Total 37 intern doctors were agreed upon that don’t disclose anything to master without consent of servant with median score of 4. Total 39 intern doctors were strongly agreed upon that don’t disclose patient’s identity with median score of 5. Total 38 intern doctors were disagreed upon that breach of professional secrecy is professional misconduct of doctor with median score of 2. Total 49 intern doctors were disagreed upon that in case of minor patients, disclosure of findings to parents or guardians leads to breach of professional secrecy with median score of 2 (Table – 1, 2).

Discussion

Many literatures on ethics focus on the skill to understand, describe, and handle information within their jurisdictions [5]. Such confidentiality is not only a basis of medical profession, but also need of statutory authority and healthy doctor-patient relationships, and of the skill to describe, convert and guard professional and occupational boundaries [24]. Codes of ethics for how professionals use and protect patient information aid to legitimize the control power as well as professional status in society [25]. However, other opinion claims that professional secrecy of patient information is not only about authority, independence and prestige, but is also essential to the faith embedded in doctor-patient relationships [10].

Professional secrecy and confidentiality of patient information, is core part of the ethical values and principles [26]. Professional secrecy and confidentiality is also essential requisite of the success of good professional, through the learning of codes of ethics [27]. Inculcation of core principles of ethics will make health professional oblige to his duty towards his patients including professional secrecy with his occupational boundaries [28]. In certain instances, professional secrecy can be broken as part of privileged communication in favor of state or large community [29].

Many previous studies have focused and analyzed the privacy of patients [30, 31, 32], few studies have focused at how health care professionals think about effect of new technologies on professional secrecy and confidentiality. In this study, perceptions of intern doctors towards privacy and confidentiality in medical practice were obtained.

As the time advances with technology, principles of ethics are also evolving gradually. Too much use of technology may mechanize the organization with lack of humanity and professionalism. Early in the 20th century, shift from treatment casebooks to patient based case files as a source of information management was initiation of increasing complexity in medical care. Then after era of emergence of new professional groups e.g. record librarians or record room in hospital. New information technologies such as electronic health records are being extensively implemented across health care. Electronic health records are playing vital role in improving the quality of health care in the USA and in other countries by facility of easy to access and retrieve health information but they also impart challenges in health professionals in their handling and secrecy. Those who are not well versed with use of technology, for them access of electronic health records are difficult especially for aged health workers.

Conclusion

Intern doctors had little knowledge regarding if patient is major, don’t disclose anything to his parents without his consent and breach of professional secrecy is professional misconduct of doctor. Intern doctors were not sure about Professional secrecy is implied term of contract between doctor and patient and Patient can sue the doctor for damages if disclosure is done without his consent and harm him and not in the interest of public. Knowledge and awareness regarding rest of the facts related to privacy and confidentiality of medical practice found to be satisfactorily among intern doctors. Privacy and confidentiality among medical care is very essential element of ethics and intern doctors must be abreast in knowledge and awareness regarding various issues of it. This can be achieved by contact session at the beginning of internship regarding medical ethics and law.

Abstract

Background: Optimum knowledge of medical records and duty of doctor is must for every doctor to enhance safe health care delivery in an unbiased standardized way. Present study was undertaken with aim to assess awareness of intern doctors towards medical records and duty of doctors.

Materials and methods: Present study was undertaken at Gujarat Medical Education and Research Society (GMERS) Medical College, Valsad, Gujarat after obtaining ethical approval from the Institutional Ethical Committee of Valsad. Total 10 questions were prepared and validated on Likert scale (1 to 5, 1 – Strongly Disagree, 5 – Strongly Agree) regarding medical records and duty of doctors. Total 100 intern doctors of GMERS Medical College, Valsad, Gujarat were subjected to pre-tested and pre-validated Likert scale type questionnaire regarding medical records and duty of doctors after obtaining their informed written consent. Data obtained were analyzed via median score and tabulated.

Results: Students were well aware about following facts like Maintenance of patients’ record is legal duty of hospital, Every operation required informed written consent of patient, Fail to attend patient during emergency is punishable, Patient has right to refuse treatment, and Carelessly leaving object into patient body during operation is negligent act. Students were not sure of facts like Patients’ records are property of patients, Refusing patient on religious ground is punishable, Not to treat patient due to HIV is punishable, and doctor has right to choose patient. Students were not aware regarding either doctor can refuse to attend medico-legal case or not.

Conclusion: Intern doctors had no awareness regarding duration of preservation of hospital records. Students were not sure of various aspects of medical records and duty of doctors. Compulsory internship in Forensic Medicine subject as well as sensitization workshop regarding medical records and duty of doctors for interns at beginning of their internship may build confidence among them to be aware with various duties of doctors.

Introduction

Legal aspects of medical practice were present in early civilizations such as Babylon and India [1]. Optimum knowledge of medical law, medical records, duty of doctor towards patient is must for every doctor to enhance safe health care delivery in an unbiased...
standardized way [2]. Forensic Medicine subject is usually dealing with teaching of medical law and ethics in Indian medical education set up. Present study was undertaken with aim to assess awareness of intern doctors towards medical records and duty of doctors.

Materials and Method

Present study was undertaken at Gujarat Medical Education and Research Society (GMERS) Medical College, Valsad, Gujarat after obtaining ethical approval from the Institutional Ethical Committee of Valsad. Questionnaire was designed to study perceptions of intern doctors regarding Medical records and duty of doctors. Total 10 questions were prepared on Likert scale (1 to 5, 1 – Strongly Disagree, 5 – Strongly Agree) and validated for face and content validity.

Inclusion criteria: Intern doctors who were willing to participate were included in the study after obtaining their informed written consent with full confidentiality.

Exclusion criteria: Those who didn’t want to participate were excluded.

Total 100 intern doctors of GMERS Medical College, Valsad, Gujarat were subjected to pre-tested and pre-validated Likert scale type questionnaire [3-15] regarding medical records and duty of doctors after obtaining their informed written consent. Data obtained were analyzed via median score and tabulated.

Results

Total 100 intern doctors were participated in the present study and their responses to questionnaire related to medical records and duty of doctors were taken into consideration for data analysis. Out of 100 respondents, 58 were male and 42 were female. There was no statistical difference among perceptions of male and female.

Students were well aware about following facts like Maintenance of patients’ record is legal duty of hospital, Every operation required informed written consent of patient, Fail to attend patient during emergency is punishable, Patient has right to refuse treatment, and Doctor has right to choose patient on certain ground.

Students were not sure of facts like Patients’ records are property of patients, Refusing patient on religious ground is punishable, Not to treat patient due to HIV is punishable, and either doctor can refuse to attend medico-legal cases or not.

Students were not aware of duration of preservation of hospital records.

Discussion

Students usually not do direct dealing with medico-legal cases during their undergraduate study period but acquire only theoretical and exam oriented knowledge about it in subject of Forensic Medicine. Many students understood basic principles of medical records and duty of doctors which is in accordance with the study done by Dash S.K. in 2010 [16]. During internship, various exposure of medico-legal cases, medical law and negligence is started and gradually students acquired reasonable practical exposure before actual practicing in society.

Written records of patients, including history, radiographs, investigations and photographs must be particular, and it is compulsory for the documents to
be signed by appropriate authority and dated properly. Legally, physician written records carry more weight than patient’s recollections [17]. Under Article 51 A(h) of the Constitution of India, there is a ethical duty on the doctor, and a legal duty, to maintain and preserve medical, medico-legal, and legal documents in the finest benefits of social and professional justice [18].

General awareness regarding informed written consent was present among intern doctors with its requirements, needs and applicability. The authority of doctor is barely ever challenged, and advice of doctor is thought in greater honor hence role of doctor in decision making is still more but nowadays patient’s standard is becoming popular [19]. Heywood R. in 2007 found that 98% of medical students found informed consent to be significant and essential for a surgical intervention [20].

Doctor should not refuse treatment on religious ground neither denied treatment to HIV positive patients. Fail to attend patient in emergency in punishable for doctor as well as patient has right to refuse treatment. Negligence in medical practice in simpler term is doing something which a reasonably competent doctor is not supposed to do or not doing something which a reasonable competent doctor is supposed to do. Doctor has right to choose patient but doctor should not avoid treating patient when it comes as medico-legal case. Doctor is bound to give first aid and basic life-saving treatment to every patient particularly in emergency without any bias or prejudice.

Conclusion

Intern doctors had no awareness regarding duration of preservation of hospital records. Students were not sure of various aspects of medical records and duty of doctors. Compulsory internship in Forensic Medicine subject as well as sensitization workshop regarding medical records and duty of doctors for interns at beginning of their internship may build confidence among them to be aware with various cases.

Effect of Tactile Stimulation and Joint Integrity Exercises on Hemineglect in Stroke Survivors

Prajakta S. Kadam¹, Suraj B. Kanase²
¹Internee, ²Associate Professor, Krishna College of Physiotherapy, Krishna Institute of Medical Sciences Deemed to be University, Karad, Maharashtra

Abstract

Background: Unilateral spatial neglect is likely to be associated with poor functional outcome in sub-acute phase. During this period, intensive rehabilitation is needed to obtain higher ADL scores. If greater efficacy of rehabilitation can be brought about by early intervention for unilateral spatial neglect, patients with unilateral neglect might achieve higher ADL goals.

Material and Method: In this pre-post intervention study 25 neglect patients were included with less than six month of stroke. Tactile stimulations and joint integrity exercise protocol was set for four weeks. After pre-post assessment, data was analysed with help of appropriate statistical methods.

Results: According to this study, there is increase in tactile stimulation (p=0.0023), kinaesthetic stimulation (p<0.0001), stereognosis (p<0.0001) and motor outcome (p=0.0001). This indicates an overall increase in sensory and motor outcome.

Conclusion: Tactile stimulation and joint integrity exercises appears to be beneficial for improving motor outcome in hemineglect patients after stroke.

Keywords: Stroke, hemineglect, tactile stimulation, joint integrity exercises.

Introduction

In accordance with the definition used by the World Health Organisation (WHO), Stroke was defined as “Rapidly developing clinical symptoms and/or signs of focal, and at times global, loss of cerebral function, with symptoms lasting more than 24 hours or leading death, with no apparent cause other than that of vascular origin”. Stroke is one of the leading causes of death and disability in India. The estimated adjusted prevalence rate of stroke range, 84-262/100,000 in rural and 334-424/100,000 in urban areas. Approximately 12% of all strokes occurs in the population less than 40 years of age.

Hemineglect has been defined as “the failure to report, respond or orient to novel or meaningful stimuli presented to the side opposite to a brain lesion, when this failure cannot be attributed to either sensory and motor defects”. Anosognosia is lack of awareness of the effects of brain lesions, including hemiplegia and hemianopia. Neglect is considerably more frequent among patients with right hemisphere lesions being present in 40-50% of right hemisphere patients acutely after stroke. It is common disabling disorder occurring after stroke and is found in 30% of all acute stroke patients.

Women have lower age-adjusted stroke incidences than men. Women with early menopause have twice the risk of ischemic stroke as women with late menopause. Women over 85 years of age have an elevated risk compared to men. Several studies indicate that neglect implies a wrong prognosis after stroke in terms of functional outcomes, length of hospital stay, and discharge to home than for stroke patients lacking this symptoms. Furthermore, patient with the neglect seem

Corresponding author:

Associate Professor, Department of Neurosciences
Krishna College of Physiotherapy, Karad
Email id: drsourajkanase7@rediffmail.com
susceptible to falls and wheelchair collisions. On the other hand, some studies shows that neglect has no influence on the functional outcomes.\textsuperscript{5}

Ischemic stroke is the most common type, affecting about 80% of individuals with stroke, and result when a clot blocks or impairs blood flow, depriving the brain of essential oxygen and nutrients. Haemorrhagic stroke occurs when blood vessels rupture, causing leakage of blood in or around the brain. Hemi spatial neglect is a common disabling condition following unilateral brain damage, particularly of the right hemisphere. It can be caused by various different pathological conditions; it is most often observed after cerebral infarction or haemorrhage and affects up to two third of right hemisphere stroke patients acutely.\textsuperscript{6} Patients with neglect often fail to be aware of or acknowledge items on their contralateral side (the left side for patients with right brain damage) and attained instead to items towards the same side as there brain damage.\textsuperscript{6} Neglect in its various forms and anosognosia are serious companions of primary right sided stroke with lesions in the parieto-temporal-occipital area.\textsuperscript{5}

Neglect is behaviourally defined as a deficit in processing or responding to sensory stimuli in the contralateral hemispace, a part of own body, the part of an imagined scene, or may include the failure to act with the contralateral limbs despite intact motor functions. Neglecting humans is frequently encountered after right parieto-temporal lesions and leads to multicomponent syndrome of sensory, motor and representation deficits.\textsuperscript{8}

Types of neglect:

1. Sensory Neglect: Sensory neglect is characterised by an unawareness of sensory information in the body and coming from the environment. This inability to recognize sensation usually occurs on the side of the body opposite to side to which the damage to the brain has occurred.

2. Motor neglect: motor neglect or output neglect is defined as the reduced ability to initiate movement in response to stimuli even though the patient is aware of the presence of the stimuli. This inability is not attributed to weakness of the muscles or to any primary motor deficit.

3. Representational neglect: Inattention to portions of internally generated images. Such images include visualizations including memories, dream and hallucinations. The patient will ignore half of the image on the opposite to where the brain damage has occurred.

4. Personal neglect: Lack of awareness to the side of the body opposite to the damage. E.g. A patient with personal neglect may deny ownership to a limb, ignoring its presence and claiming that it belongs to another person.

5. Spatial neglect: A patient who is unable to acknowledge stimuli originating in space opposite of damage is displaying spatial neglect. There are two types: Peri personal and extra personal neglect. Peri personal neglect is characterised by a patient’s inattention to items within reaching distance while extra personal neglect refers to the neglect of items that are farther away.\textsuperscript{6}

The best form of treatment for stroke that emerged over last several decades is stroke unit.\textsuperscript{9} Rehabilitation of a stroke patient begins as soon as any impairment is perceived and comprises traditional exercise programs and neuropsychological approaches with the primary aim of restoring mobility and function of patient.\textsuperscript{7} Though rehabilitation is proved to be the best treatment patients also prefer other mode of treatment approaches such as Medicine, Acupuncture, Ayurveda (Panchakarma), Chiropractic, Cupping, Dry needling, Brain stem stimulation, Stem cell therapy and Miscellaneous quack practice, etc.\textsuperscript{2,9-19}

Unilateral spatial neglect is likely to be associated with poor functional outcome in subacute phase. During this period, intensive rehabilitation is needed to obtain higher ADL scores. In rehabilitating unilateral spatial neglect patients’ deficits of spatial recognition and body image prevent them from learning efficient body movements and increase the risk of falls and collisions. Furthermore, they tend to be unduly limited to their activities because of fall risks. If greater efficacy of rehabilitation can be brought about by early intervention for unilateral spatial neglect, patients with unilateral neglect might achieve higher ADL goals.\textsuperscript{16}

**Materials and Methodology**

**Type of Study:** Experimental Study

**Study Design:** Pre and post

**Place of Study:** KIMSDU
Sample Size: 25 (Considering 10% dropout)

\[ n = \frac{4pq}{L^2} \]

Sampling Method: Simple random sampling method

Sampling Duration: Approximately 3 months

Inclusion Criteria:
- Subjects with right hemisphere stroke.
- Subjects with hemineglect following stroke.
- Acute phase (3 months) following stroke.
- Both sexes.

Exclusion Criteria:
- Subjects with neurological conditions other than stroke
- Subjects with left hemisphere involvement following stroke

Equipment's and Materials required:
- Sensory kit
- Assessment Charts
- Writing Material
- Computer for online access

Outcome Measures
- The Baking Tray Task

Time required to administer: anywhere from 1-5 minutes

Purpose of the study: The purpose of this assessment is to assess for unilateral neglect

Scoring:
- Normal: spreading the cubes out evenly across the tray
- Rightward bias: The cubes will be spread out across board, but cubes will be closer proximity to the right side of the tray. This score indicates unilateral neglect.

Nottingham Sensory Assessment

Patient position: Sitting and in suitable state of undress

Procedure: Apply the test sensation to the test area, to the left and right side in random order. Patient is asked to indicate, either verbally or by a body movement, whenever he or she feels the test sensation

1. Tactile sensation:

Procedure: If the patient has problems communicating being testing light touch, pressure and pinprick sections.

SCORING CRITERIA: 0 absent, 1 absent, 2 normal, 9 unable to test

2. Kinaesthetic Sensation:

Procedure: The limb on the affected side of the body is supported and moved by the examiner in various directions but movement is only at one joint at a time. The patient is asked to mirror the change of movement with the other limb.

Scoring: 0 absent, 1 Appreciation of movement taking place, 2 direction of movement sense, 3 joint position sense, 9 unable to test

3. Stereognosis

Procedure: Place the object in the patient’s hand for a maximum 30 seconds. Identification is by naming, description or by pair matching with an identical set. Affected side of the body is tested first. The object may be moved around the affected hand by the examiner.

Scoring: 2 normal, 1 Impaired, 0 absent, 9 Unable to test

Motor Assessment Scale

Findings

Out of the 25 subjects enrolled in this study, two were discharged early and did not came for follow up, while other one was not willing to participate in the treatment trails after two sessions.

Pre- and post-intervention data was analysed, tactile stimulation in sensory input considered very significant. (p=0.0023). The mean pre interventions for tactile stimulation of 1.5 (SD=0.51), changed to mean post-
intervention of tactile stimulation (SD=0.29), showing significant increase (p=0.0023).

Kinaesthetic stimulations were given to the patients to increase proprioception in neglected limb. Kinaesthetic stimulations shows extremely significant difference in pre- and post-assessments (p<0.0001). The mean pre-intervention of kinaesthetic stimulations 1.136 (SD=0.35), increased to mean 2.54 (SD=0.50). Stereognosis mean pre-intervention was 0.5(SD=0.51) and mean post interventions was increased to 1.72 (SD=0.45), shows extremely significant (p<0.0001). (Fig 1)

The motor assessment score are shown in Table 2 as the secondary outcome measure. The mean pre-intervention score was 9.818 (SD=3.11), which increased to mean of 24.04(SD=6.22). The changes in both pre- and post-interventions were extremely significant (p=0.0001). (Fig 2)
Conclusion

Tactile stimulation and joint integrity exercises were appear to be beneficial for improving motor outcome in hemi neglect patients after stroke.

Discussion

In this study we wanted to determine whether tactile stimulation and joint integrity exercises is effective in rehabilitation of neglect patient. Out of the 25 subjects enrolled in this study, two were discharged early and did not came for follow up, while other one was not willing to participate in the treatment trails after two sessions. Hemineglect subjects has a good potential to recover within first three weeks after stroke. Twenty five patients treated with sensory and motor stimulation for almost 4 weeks.

Pre and Post Assessments were taken with the two scales – Nottingham sensory assessment and motor assessment scale. According to roods, sensory input is required to produce a motor output. Purposeful movement, repetition of activity, or practice, play a part in learning motor skills. Tactile stimulation with the various textures applied to the patients with three strokes followed by 3 sec rest period. Pre- and post-intervention data was analysed, tactile stimulation in sensory input considered very significant. (p=0.0023). The mean pre interventions for tactile stimulation of 1.5 (SD=0.51), changed to mean post-intervention of tactile stimulation (SD=0.29), showing significant increase (p=0.0023).

Kinaesthetic stimulations were given to the patients to increase proprioception in neglected limb. Kinaesthetic stimulations shows extremely significant difference in pre- and post-assessments (p=0.0001). The mean Pre-intervention of kinaesthetic stimulations 1.136 (SD=0.35), increased to mean 2.54 (SD=0.50). Stereognosis mean pre-intervention was 0.5(SD=0.51) and mean post interventions was increased to 1.72 (SD=0.45), shows extremely significant (p<0.0001). (Fig 1)

Proprioceptors, exteroceptors and special sense organs were targeted for motor responses. The motor assessment score are shown in Table 2 as the secondary outcome measure. The mean pre-intervention score was 9.818 (SD=3.11), which increased to mean of 24.04(SD=6.22). The changes in both pre- and post-interventions were extremely significant (p=0.0001). (Fig 2) It would be beneficial to offer patients with hemineglect tactile stimulation and joint integrity exercises.

Offering variety of sensory stimulation (tactile / joint integrity) might have improved sensory functioning in patients that would have initiated the motor betterment. Variety of exercises & electrotherapy modalities must have played an important role in initiating neuronal plasticity to improve motor outcome. Conventional exercises, task oriented training must have improved interneuronal integration to improve sensory awareness. Structured program must have improved residual impairments to improve sensory mechanism. Electrical stimulation, hot fomentations have mechanisms to initiate sensory integration to improve motor as well as sensory response.

Conflict of Interest: There were no conflicts of interest in my study.

Source of Funding: Krishna Institute Of Medical Sciences Deemed to be University, Karad

Ethical Clearance: The Institutional Ethics committee has hereby given permission to initiate the research project titled, “Effect of tactile stimulation and joint integrity exercises on hemineglect in stroke survivors”

Clinical Evaluation of Ocular Foreign Bodies

Pranali Shah¹, V.H. Karambelkar²

¹ Resident, ² Professor and Head of Department, Department of Ophthalmology, Krishna Institute Of Medical Sciences To Be Deemed University, Karad, Maharashtra, India

Abstract

Background: Ocular foreign body can affect at any age as well as in both genders. Foreign body introduction in eye leads to various disturbances which can create significant health related problem. The study of the ocular foreign body gives unparalleled opportunities in reducing morbidity as well as for realizing significant savings for both financial as well as human terms.

Material and Method: This prospective study was conducted in ophthalmology department at of Krishna hospital, Karad, Hundred patients with ocular foreign bodies were included in study with consideration of inclusion and exclusion criteria.

Results: A study of 100 subjects showed that incidence of extraocular foreign bodies is very common compared to intraocular foreign bodies. Amongst that, corneal foreign bodies found to be have highest incidence. Commonest foreign body observed - iron particle (43%) and thorn/vegetative material (38%). Average age-40 years. Males are having higher incidence than females. Average interval between incident and intervention – 2.6 days (day 0 to day 10). Amongst the affected population, farmers and welders are maximum in number.

Conclusion: Though incidence of intraocular foreign body is very less, it has bad prognosis in relation with vision as well as progresses to endophthalmitis. Early visit to ophthalmologist showed better prognosis and thus visual outcome specially in cases of vegetative foreign body in which delayed treatment lead to further complications.

Key words: ocular trauma, ocular foreign bodies, incidence, visual outcome.

Introduction

An ocular foreign body can be any abnormal object or substance or material that doesn’t belong to the eye.¹ The highest incidence of ocular foreign body found in the industrial towns. Ocular foreign body can affect at any age as well as in both genders. Effects caused to the eye by foreign bodies are either mechanical effects or by introduction of secondary infection or by reactions due to specific materials.¹ Foreign body introduction in eye leads to various disturbances which can create significant health related problem. The study of the ocular foreign body gives unparalleled opportunities in reducing morbidity as well as for realizing significant savings for both financial as well as human terms.²⁻⁴

Superficial corneal foreign bodies can reduce the quality of vision either by causing scars / opacities in the visual axis or by causing secondary infections which may range from keratitis to endophthalmitis.⁵ Though Classification of Ocular Trauma states that injuries due to superficial foreign bodies are graded as mild one, based on severity of trauma, these foreign bodies tend to be very much uncomfortable leading to redness, watering, gritty sensation with pain in eye which increases every time with eye opening or closing.⁶ These injuries are responsible for various health care issues and thus they create an economic burden. Prevention of these FB accidents and potential serious consequences
caused by them is certainly possible. The investment in prevention of these problems can be easily justifiable. Use of appropriate protective goggles can prevent these accidents in large number. In addition to this use of glasses, personal protective measures can be added. It is very important to improve standards of workplace as well as to provide proper training for the supervisors.

**Inclusion Criteria:**

- All cases of ocular foreign bodies attending OPHTHALMOLOGY OPD

**Exclusion Criteria**

- H/o previous ocular foreign body with or without surgical intervention
- Blast injuries
- Age less than 5 years

**Materials and Method**

- The study was conducted in department of ophthalmology at of Krishna institute of medical sciences, Karad between October 2017 to May 2019 after obtaining clearance from ethical committee. Hundred patients with ocular foreign bodies were included in study with consideration of inclusion and exclusion criteria.
  - Informed consent was taken from the patients
  - A detailed history regarding nature of injury, nature of foreign body, time lapse between incidence and presentation, history of any prior intervention and previous ocular disease etc was taken
  - Visual acuity was checked by using Snellen's chart, with pinhole improvement
  - Thorough examination of adnexa and anterior segment was done using slit-lamp biomicroscopic and fluorescein staining was done wherever necessary
  - Posterior segment examination by Indirect and Direct ophthalmoscopy after dilatation with 0.8% tropicamide and 5% phenylephrine eye drops (if not contraindicated)
  - Radiological investigations were done in selective cases

- Necessary treatment was given.
- In our study most of the patients were having superficial surface foreign bodies (cornea or conjunctiva) which were managed on OPD basis only.
- These foreign bodies removed by using forceps, foreign body spud, 26 no. needle on slit lamp.
- In some cases of large epithelial defect in above mentioned cases, eye pad was given with plenty of eye ointment.
- All cases of OPD basis were called to OPD on immediate next day for follow up.
- Rest cases were admitted to ward and managed either by medical or surgical means depending on their need.
- Visual acuity on first follow up in OPD patients and at time of discharge in IPD patients were noted.
- It is taken as final visual acuity for statistics purpose.
- In cases of posterior segment complications, visual acuity also repeated after 1 month.

**Results**

**Age and sex**

It was observed that majority of patients were in age group 31-40 (44%) followed by 41-50 years (18%) and 21-30(17%) respectively. The mean age of the patients was 40 years. Majority of patients were male (80%) and females were 20%

**Laterality of eye**

It was observed that in 60% of cases left eye is involved while right eye involvement seen in 40% of subjects

**Occupation**

It was observed that commonest population affected by ocular foreign body belongs to welder (33%) followed farmers (27%) by their occupation.
It was observed that the most common foreign body observed in this study was metal (43%) followed by vegetative material (38%). Both together form a major portion.

Site of lodgement

It was observed that the most common site for lodgement of foreign body is cornea (67%) followed by conjunctiva (22%).
Number of foreign bodies

It was observed that 90% of the patients have single ocular foreign body, while only in 10% patients multiple foreign bodies found

Comparison Between Initial Visual Acuity and Final BCVA

In table no.1, there is comparison between initial visual acuity and final best corrected visual acuity. It was observed that this comparison is statistically significant with p<0.05.

Discussion

Nowadays, Ocular trauma is one of the leading cause of vision impairment worldwide. Most of the ocular traumas are associated with ocular foreign bodies. Annual incidence of trauma cases of eye exceed 2 million cases. In which more than 40000 people had permanent vision impairment to a significant level. The place of injury can be anywhere from work place to recreational area /agricultural area /rural settings.

Younger individuals are commonly affected. The male to female ratio being around 9:1. Financial penalty to person and family is aspect of IOFB. Because of recent micro surgical technique and instrumentation prognosis of IOFB has improved for the past decades. Safety glasses use in work places and health education are the two important factors which helps to reduce
The incidence and thus ophthalmologists can play an important role in giving education to the population.

The present prospective study was conducted for calculating incidence of various types of ocular foreign bodies and their various sites of lodgements with their relation to final best corrected visual acuity. The study was conducted in the Ophthalmology Department of Krishna Institute of Medical Sciences, Karad between October 2017 to May 2019. A total sample size of 100 patients with ocular foreign bodies taken into consideration.

In present study, it was found that majority of our patients were in age group 31-40 (44%) followed by 41-50 years (18%) and 21-30 (17%) respectively. The mean age of the patients was 40 years. Also, it was observed that majority of patients were male (80%) and females were 20%. Similar observation was observed by Napora et al in his study which shows majority of the patients were male with a mean age of 38.1 years. In another study, at Moorfields Eye Hospital done by Wickham et al. which was large retrospective cohort study a mean age observed was 34.6+/-12.4 years. Similarly, Maneschg et al. reported that all patients in their study were male with mean age of 28 ± 12.3 years. Koo et al. said that this occurrence of ocular FBs might be due to higher occupational exposure, higher involvement in dangerous sports and hobbies, alcohol use and risk taking behaviour in young men.

In present study it was found that commonest population affected by ocular foreign body belongs to welder (33%) followed by farmers (27%) by their occupation. This result is justified by fact that our locality constitutes both industrial as well as agricultural field. Most of the populations source of income depends on this only. That is why farmers and welders together constitute 60% of affected population.

In present study it was found that commonest foreign body observed in this study is metal (43%) followed by vegetative material (38%). Both together forms major portion. Evidences from many former studies are unanimous in proving metal object as the most frequent. Values of 91%, 85.3%, and 85.5% were reported previously by Woodcock et al., Feghhi et al. and Napora et al respectively. This difference of 43% metal FB in our study with 80-90% in other studies is because of increased incidence of vegetative FB in our study. This quite high incidence of vegetative FB as compared with previous documentation is because of more population working in agricultural fields in our area.

In present study it was found that in 60% of cases left eye is involved while right eye involvement seen in 40% of subjects. Dominance of left eye involvement explained by reason that most of people are right handed. So while working force of impact goes in direction towards left eye causing it as commonly involved in ocular FB.

In present study it was found that commonest site for lodgement of foreign body is cornea (67%) followed by conjunctiva (22%). A study done by A.R. Nalgirkar7 reported that Maximum number of foreign bodies were found in the cornea (41.6%) followed by conjunctiva (13.8%) whereas only 1 patient had an intra-ocular foreign body. Studies done by C Chiquet et al8 showed that corneal FB to be (58%), followed by the sclera (32%) and Zsuzsanna Suzijarto et al9 68% corneal and 32% sclera.

In present study, when comparison between initial visual acuity and final best corrected visual acuity done. It was observed that this comparison is statistically significant with p<0.05 with chi-square value of 32.198. Similar results observed in studies done by C Chiquet et al8 and Intiaz A. Chaudhry et al10 which shows that initial presenting visual acuity is significantly associated with final BCVA.

In present study, when comparison between time period from onset to presentation to OPD and final BCVA done. In our study, 67% patients presented to OPD before 24 hours. Out of them, 70% patients have Final BCVA better than 6/9. Amongst remaining 33% Patients who presented late to OPD, only 33% reached to visual acuity of 6/9. It was observed that this comparison is statistically significant with p<0.05 with chi-square value of 12.713. The study done by Tansu Erakguns, MD11 and Zsuzsanna Szijarto, et al9 states that if patient arrives late to the hospital, then it was significant association with poor vision outcome irrespective of age.

In present study, when comparison between site of lodgement of FB and Final BCVA is done, It was found that this comparison is statistically significant with p<0.05. this proves that corneal and conjunctival FB have better visual prognosis in comparison with other FBs. Iris FBs are not having good vision as there are posterior segment complications like vitreous haemorrhage and choroidal detachment due perforating nature of injury. Posterior segment FBs itself has bad prognostic value.
in comparison with anterior segment FBs which is proven otherwise. In our study, scleral FBs also didn’t show good Final BCVA. For one patient reason being late presentation to OPD i.e. after 10 days of incident with vegetative nature of FB (wood particle) and patient was non-compliant one. These multiple factors lead to deuteriation of patient’s visual acuity from 6/24 to Fc at 3 meter when he developed scleral abscess. Later on due to continuation on negligence on patients part, he land up into endophthalmitis. In other case of scleral FBs, multiple FBs and posterior localisation of FB required multiple surgeries. This could be the reason for less final BCVA in this patient.

**Conclusion**

1. Incidence of ocular FB is maximum in 4th decade with male preponderance.

2. Incidence of FB is common in welders and farmers i.e. 33% and 27% respectively.

3. Commonest FB found are metal followed by vegetative material i.e. 43% and 38% respectively.

4. Anterior segment ocular FB are far common than posterior segment. Amongst that cornea (67%) is most common site of lodgement of FB followed by conjunctiva (22%)

5. Extraocular FB have better visual prognosis in comparison with intraocular FB.

6. Time period between onset of incident and initiation of treatment is major prognostic factor in degenerating final visual outcome. Early visit to OPD have better visual prognosis than delayed visit and thus the treatment

**Ethical Approval** : All procedures performed on human participants were in agreement with ethical standards of the Institutional and/or National Ethics Committee.

**Source of Funding** : In this project, the cost of investigations of the study participants was born by the institute research fundings.

**Conflict of Interest** : None

Correlation of Perkins Hand-Held Applanation Tonometer with Non-Contact Tonometer

Prashant Bulchandani1, Girish A. Gadre2
1Senior Resident, 2 Associate Professor, Department of Ophthalmology, Krishna Institute of Medical Sciences, Karad, Krishna Institute of Medical Sciences “Deemed To Be University”, Karad, Maharashtra, India-415539.

Abstract

Aim: To correlate the IOP by the use of Perkins hand-held applanation tonometer (PAT) with Non-contact tonometer (NCT). Materials & Methods: Prospective cross-sectional study done on 148 eyes & 3 readings were taken for each method & mean calculated. Statistical analysis: Unpaired-T test & Correlation-coefficient, Sensitivity & Specificity were calculated for the NCT. Results: Mean age of subjects was 56.01±9.73 yrs. Mean IOP with PAT & NCT 15.43 mmHg (95% CI 15.14–15.76) & 15.13 mmHg (95% CI 14.81–15.46) respectively. NCT shows excellent agreement with PAT. Correlation coefficient(r) of IOP measured by NCT & PAT is 0.97 & 0.91 for RE & LE respectively with p value <0.05, showed strong positive correlation between the IOP measured by NCT & PAT. The NCT showed high sensitivity 86% & high specificity 97.9 % respectively, coming across an excellent agreement with PAT. Interpretation: NCT is easy to operate (non medical & Paramedical staff), minimum risk of infection & without any observer bias. Only drawback is the cost. Conclusion: The current study shows that the NCT compares well with the PAT. The NCT can be used as a reliable screening tool.

Keywords: Intraocular Pressure (IOP) ,Non-contact tonometer (NCT), Perkins applanation tonometer (PAT), Goldmann applanation tonometer (GAT), Right Eye (RE), Left Eye (LE).

Introduction

Glaucoma is a chronic progressive optic neuropathy caused by a group of ocular conditions which lead to damage of the optic nerve with loss of visual function invariably associated with increased IOP. Diagnostic criteria of glaucoma Raised IOP, Classical Field Changes, Classical Optic disc changes Any 2 of the above present are sufficient to diagnose glaucoma. Epidemiology Glaucoma is a major cause of irreversible blindness in the world [1] Globally, it is estimated that approximately 60 million people have glaucomatous damage & 8.4 million people who are blind as a result of glaucoma [2, 3] The prevalence of glaucoma is projected to increase with population growth & the ageing of the population, & by 2020 it is expected that the number of affected people will have risen to 80 million. Even in developed countries, only half of the people with glaucomatous damage are aware of the diagnosis [3] Early detection of glaucoma is crucial as effective & life long treatment for glaucoma prevents significant visual function loss.

Material & Method

A hospital based prospective clinical trial was conducted with 74 patients to correlate the IOP by the use of PAT with NCT.

Inclusion criteria

• Patient between the age of 40-70 years.
• Corneal astigmatism < 3D & Refractive error < ±2D spherical.

Exclusion criteria

• Age < 40 years
• Corneal astigmatism > 3D.
• Diagnosed case of glaucoma, patients with scarred or hazy cornea.
• History of corneal surgery including refractive surgery.
• History of corneal disease like keratoconus, microphthalmos.
• History of ocular infection like uveitis, conjunctivitis, corneal infections.
• History of hypersensitivity to topical fluorescein.
• Pregnant or Breast feeding women.
• Patient not willing to participate in study

Study Design: Cross- Sectional Study

Source of Data: This study was conducted on patients attending outpatient department of ophthalmology in a tertiary care centre. It was conducted from NOV 2017 to MAY 2019. This study was approved from institutional ethics committee.

Methodology

Data was collected using a proforma, with the informed consent of the participants. A detailed history was obtained from each participant followed by routine ophthalmological examination including visual acuity testing, anterior segment & fundus examination. Both the procedures will be explained to the subjects & participants were subjected to two methods of tonometry & NCT readings were recorded first, then PAT. 3 readings were taken two by residents & one by paramedical personnel & mean was calculated. PAT was calibrated at weekly. Measurements of IOP will be taken from 9 AM to 5 PM to avoid the effect of diurnal fluctuations on IOP. No specific attempts was made to separate the population on basis of gender. Disinfection was done according to the American Academy of Ophthalmology recommended guidelines.

Sample size: 74 cases

Statistical Analysis:

Statistical analyses were performed using SPSS (statistical packages for social sciences) 20.0 for Windows, IBM, India. IOP measurements were compared to those obtained by the PAT which was assumed to be the gold standard (Sensitivity, specificity, positive & negative predictive values). Regression Analysis was also performed to determine any causal relationship (Dependant variable- PAT IOP; Independent variables- NCT , IOP, age & gender). A Bland– Altman plot was constructed by using excel new version to investigate the resistance of any systematic difference between the different tonometry methods. Data was analyzed using Diagrammatic presentation, Mean ± SD, Un-Paired t-test & correlation coefficient was calculated.

Results

Both the eyes of all included patients have been studied. Therefore, for this analysis background characteristics including various study groups were calculated based on standard sample size of 74 patients as per the sampling technique used, while the remaining analysis was based on 148 eyes. The analysis of data obtained showed that, from a total of 74 patients, 39(52.70%) were males & remaining 35(47.30%) were females. The average age of patients was 56.01±9.73 yrs. The mean of IOP measured by PAT & NCT was 15.43 mmHg (95% CI 15.14–15.76) & 15.13 mmHg (95% CI 14.81–15.46) respectively. In this study the total participants were divided into 4 groups based on age for analysis purpose, as participants aged 41-50 yrs had 29(39%), 51-60 yrs had 21(28%), 61-70 yrs had 13(18%) & >or equals to 71 yrs had 11(15%) of participants.

Table No. 1 shows that mean IOP in RE for both male & females in age groups of 41-50 yrs, 51-60yrs, 61-70yrs, >or equals to 71yrs with PAT & NCT were 15.66mmHg, 15.42mmHg, 15.69mmHg, 14.73mmHg & 15.58mmHg, 14.63mmHg, 15.41mmHg, 14.13mmHg respectively for both tonometer with standard deviation of 1.6, 2.01,1.11,2.41 & 1.91,2.03,1.01,2.5 with p values of 0.86,0.71,0.73,0.83 respectively, & it showed that there was no significant difference between two tonometer.

Table No. 1 shows that mean IOP in LE for both male & females in age groups of 41-50yrs, 51-60yrs, 61-70yrs, >or equals to 71yrs with PAT & NCT were 15.52mmHg, 15.43mmHg, 15.85mmHg, 14.55mmHg & 15.3mmHg, 14.63mmHg, 15.41mmHg, 14.13mmHg respectively for both tonometer with standard deviation of 1.57,2.11,1.52,2.38 & 1.91,2.48,1.54,2.7 with p values of 0.65,0.27,0.47,0.7 respectively, showed there was no
significant difference between two tonometer.

**Table No. 2** shows that, age wise correlation of PAT compared well with the NCT for both eyes as evidenced by a r values of 0.97, 0.99, 0.86, 0.99 with a p value <0.05 for RE & 0.91, 0.90, 0.95, 0.96 with a P value <0.05 for correlation, for both male & females in age groups of 41-50 yrs, 51-60 yrs, 61-70 yrs, >70 yrs respectively, showed extremely significant correlation between tonometer.

**Table No. 3** shows, the correlation coefficient of IOP measured by PAT & NCT were 0.98 & 0.95 for RE & LE respectively with p value of <0.05 & were 0.97 & 0.88 for RE & LE respectively with p value <0.05, showed strong positive correlation between the IOP among males & females & also it was shows, the correlation coefficient of IOP measured by PAT & NCT were 0.95 & 0.84 for RE & LE respectively with p value of <0.05 in our study participants showed strong positive correlation between tonometer.
### Table 1: Mean IOP between PAT & NCT (in mmHg) among Total Participants by Age for both eyes.

Discussion

A hospital based prospective cross-sectional clinical trial was conducted with 74 patients to correlate the IOP by the use of PAT with NCT. In our study total participants were divided into 4 groups based on age for analysis purpose, as participants aged 41-51yrs had 29(39%), 51-60yrs had 21(28%), 61-70yrs had 13(18%) & ≥ or equals to 71 yrs had 11(15%) of participants. This study was done with the principle aim to correlate the measurement of IOP by the NCT with the gold – standard PAT. According to a study by George R et al. [4] approximately 11.2 million Indians above 40 yrs suffer from glaucoma, supports our study to include all participants above the age of 40 yrs. [6-8]

The analysis of data obtained showed that, from a total of 74 participants, 39(52.70%) were males & remaining 35(47.30%) were females. The average age of participants was 56.01±9.73 yrs. Participants aged 41-50 yrs had maximum number 29(39%) of participants. In our study according to the Bland & Altman plot, the Mean (±S.D.) measurement for PAT was 15.44 mmHg (±1.83) compared with 15.13 mmHg (±1.87) for the NCT. The bias of the method was 0.30 (95% CI 0.14, 0.74) & precession was 3.78 (95% CI = 2.9, 4.67). Our study showed a good correlation between NCT & PAT when similar set of samples are used. In our study scatter plot for RE & LE showed positive correlation between NCT & PAT. In our study Mean IOP for RE was compared...
between PAT & NCT which was 15.46 mmHg & 15.30 mmHg respectively with p value of 0.60, & for LE was compared between PAT & NCT was 15.41 mmHg & 14.96 mmHg respectively with p value of 0.18, showed that there was no significant difference between the IOP measured by the NCT & PAT & suggest very good agreement between PAT & NCT. These findings are comparable with a study done by Prabhakar SK et al.[5]

In our study Mean IOP for both male & females for RE in age groups of 41-50 yrs, 51-60 yrs, 61-70 yrs, > or equals to 71 yrs was compared between PAT & NCT & mean IOP was 15.66 mmHg, 15.42 mmHg, 15.69 mmHg, 14.73 mmHg & 15.58 mmHg, 15.2 mmHg, 15.55 mmHg,14.5 mmHg respectively for both tonometer with standard deviation of 1.6, 2.01, 1.11, 2.41 & 1.75, 2.03, 1.01, 2.5 with p values of 0.86, 0.71, 0.73, 0.83 respectively, & it was found that there is no significant difference between two tonometer which means there is very good agreement between two tonometer. These findings are comparable with a study done by Prabhakar SK et al.[5]

Mean IOP for both male & females for LE in age groups of 41-50 yrs, 51-60 yrs, 61-70 yrs, > or equals to 71 yrs was compared between PAT & NCT & mean IOP was 15.52 mmHg, 15.43 mmHg, 15.85 mmHg,14.55 mmHg & 15.3 mmHg,14.63 mmHg,15.41 mmHg,14.13 mmHg respectively for both tonometer with standard deviation of 1.57, 2.11,1.52, 2.38 & 1.91, 2.48, 1.54, 2.7 with p values of 0.65,0.27, 0.47,0.7 respectively, it was found that there is no significant difference between two tonometer which means there is very good agreement between two tonometer. These findings are comparable with a study done by Prabhakar SK et al.[5]

It was observed in our study the gender wise correlation coefficient of IOP measured between PAT & NCT were 0.98 & 0.95 for RE & LE respectively with p value of <0.05 in males, showed strong positive correlation between the IOP measured by PAT & NCT among males & the gender wise correlation coefficient of IOP measured between PAT & NCT were 0.97 & 0.88 for RE & LE respectively with p value of <0.05 in females, showed strong positive correlation between the IOP measured by NCT & PAT amongst participants. These findings are comparable with a study done by Prabhakar SK et al.[5]

An essential criterion for a good screening tool is high specificity & high sensitivity. The NCT has been shown to be a reliable screening tool by Shields & Moseley et al. In our study Non-contact tonometer showed high sensitivity 82 (95%CL: 56.8-90.5) i.e. very few false negative results as well as high specificity 95.9 (95%CL: 92.7-99.1) i.e. few false positive results; thus coming across an excellent agreement with PAT. Our results are comparable with study done by Moseley M. J et al. & reported that NCT has sensitivity of 85% & specificity of 95%. In our study Inter-observer variability more occurs with PAT while NCT records IOP automatically leading to less chance of observer bias which proves that the scope of change reading with NCT was very rare as compared to PAT. In our study 2 out 74 participants had conjunctivitis & 8 had epitheliopathy with PAT & no participants had conjunctivitis & epitheliopathy with NCT. Thus the NCT was found to compare well with the PAT & confirmed the finding of previous researchers Hsu et al. & Ogbuehi & Almubrad.

**Conclusion**

Advantages of PAT are Portability & is a choice of tonometer in bedridden patients. Disadvantages of PAT are Cooperation of patient is needed, Squeezing of lids can lead to falsly high readings, On successive reading can lead to applanation epitheliopathy, May spread infections like keratoconjuntivitis, Need for topical anaesthesia & fluorescein dye required for staining, Slow learning curve, scope of Inter observer bias is present. Advantages of NCT are faster & reproducible results. Topical anaesthesia & fluorescein dye for staining not required. Non-contact technique (avoids infections like kerato conjuntivitis). No Inter-observer
Bias. Participant’s acceptance for NCT is favorable and, with High Sensitivity & Specificity, makes it a reliable tool for screening at tertiary eye care centre. Faster Learning curve can be used by paramedical personnel. Disadvantages are Expensive, Fixation is essential. The current study showed that, the NCT compares favorably with the PAT. NCT can be used as a reliable screening tool.

Ethical approval: All procedures performed on human participants were in agreement with ethical standards of the Institutional and/or National Ethics Committee.

Theatrical Prosthesis – Widening Horizons of Prosthetic Dentistry – A Case Report

Prashant Kothari¹, Veena Hegde²

¹Senior Lecturer, Department of Prosthodontics and Crown & Bridge, Chhattisgarh Dental College and Research Institute, Rajnandgaon, Chhattisgarh, ²Professor, Department of Prosthodontics and Crown & Bridge, Manipal College of Dental Sciences, Manipal, Manipal Academy of Higher Education.

Abstract

A movie or a play is said to be great if it can imprint an image in our mind forever. To accomplish this, even the unnatural looking characters should look real. This case report describes a temporary prosthesis which alters the look of a theatre artist suited as a Dracula. Mock wax-up was done on the stone cast and an index of same was made using putty material. After dewaxing of the cast, tooth colored self-cure acrylic resin was mixed and poured into the index and stone cast with separating medium applied over it was pressed into the index. Prosthesis was retrieved, trimmed, polished and then delivered to patient.

Key Words: Theatrical Dentistry, Dracula teeth, canine prosthesis, vampire look

Introduction

The appearance of teeth plays an important role in depicting ones’ personality. Characterization of individual appearance using dentition includes various factors explained in dentogenic concept.¹

Theatre is collaborative form of fine art that uses live performers to present the experience of a real or imagined event. To provide the perception of the character, cosmetic alteration of the actor is done. This alteration also includes temporary modification in appearance of teeth. These have led to emergence of a new discipline called as theatrical prosthetic dentistry in which the alteration in appearance and functioning is done temporarily. It includes fabrication of prostheses that imparts characterized smiles. Theatrical dentistry deals mainly with two aspects of dentistry, namely aesthetics and phonetics. Alteration in both or either of them makes the basis of this new dimension.

Case Report

A patient reported to the department of Prosthodontics with demand of artificial teeth to attain a Dracula look for an act that he had to perform in one of the local theatres. Patient was explained about different types of removable and fixed prosthesis options. As the look was for a play, for a short time, fabrication of a removable prosthesis was done. For this -

1. Impression for Upper and lower arches were made with irreversible hydrocolloid material and casts were poured using dental stone [Fig 1].

2. Mock Wax-up was done and patient’s approval was taken for length and shape of extended canine [Fig 2].

3. A Poly Vinyl siloxane putty impression of diagnostic cast with mock wax up [fig 3] was made
which acted as an index for fabrication of the prosthesis.

4. Cast was dewaxed in a hot water bath and fit of Poly Vinyl Siloxane putty impression was checked on the cast.

5. Separating media was applied on the cast.

6. After matching the shade, appropriate shade of tooth coloured acrylic resin was mixed and poured into the putty impression.

7. Cast was pressed over the poured index till its fit.

8. Assembly was put in the pressure pot for about 15 minutes under 2 lbs pressure and acrylic was allowed to set.

9. Prosthesis was trimmed and checked intraorally for any occlusal interference [fig 4A, 4B].

10. Then it was polished and delivered to patient. [Fig 5A, 5B]
Discussion

Using tooth coloured self-cure acrylic resin provides the advantage of faster and cheaper fabrication of the prosthesis. Strength is sufficient for a short term use in theatre. Alternatively heat cure acrylic resin can also be used if more strength is needed. Self-cure acrylic prosthesis can be best indicated for theatrical use and heat cure acrylic resin can be used in situation when patient demand it for longer period as in for Halloween. These prostheses will be contraindicated if patient is allergic to acrylic resins, or in case where prosthesis cannot bear the occlusal load like in deepbite cases of heavy occlusal forces. Although, advent of newer materials and methods has led to increase in scope of theatrical dentistry, the designing of prosthesis will still play an important role in its longevity.

Conclusion

Prosthetic field has been explored for restoration of what is lost since ages. But now, exploring it to create newer dimensions has provided for us, a vast opportunity to use our prosthetic as well as artistic skills to fabricate something that is not only just conventional but something that were once just a imaginable character too.

Study of Unnatural Deaths of Women Brought to Raichur Institute of Medical Sciences for Medico-Legal Autopsy

Praveen Kumar
1Tutor, Dept. of Forensic Medicine & Toxicology, Raichur Institute of Medical Sciences, Raichur

Abstract
Discrimination against women in our society is deeply embedded within family context of the women. Women are subjected to violence from husbands and from their relatives in their natal as well as marital homes. This study was designed to determine unnatural deaths of females in Raichur during the year 2017. total 362 cases were autopsied where as 77 women of unnatural deaths were autopsied. Third and fourth decade were common age group. Most of the unnatural deaths were suicidal and road traffic accidents. This study reflects the susceptibility of women to unnatural deaths, thus needs to enhance the multipronged protective system, to curb these potentially preventable unnatural deaths of females

Key Words: unnatural deaths, females, suicidal, RTA, hanging.

Introduction
An unnatural death is an intentional or unintentional death due to external causes. this can often be violent, mutilating or destructive. when natural death involves women, it shatters the lives of the survivors and famil.

Suicidal death is one type of violent deaths which is caused by a deliberate act of decedent with the intent to kill himself.1,2data on such suicidal deaths in a geographic can give reflection of social and mental status of females. Suicidal deaths of married women have exponentially risen in Indian society in recent past. The women are often subjected to violence by husband and relatives in their natal as well as marital period. Violence against women includes not physical aggression but sexual abuse, psychological abuse and emotional abuse. Present study was conducted in Raichur to evaluate factors to unnatural deaths in females.

Materials and Method
This study is retrospective study undertaken at RIMS mortuary, Raichur during the year 2017.all cases of unnatural deaths of women were subjected to medico-legal autopsy during study period. The unnatural deaths were broadly classified as accidental, suicidal and homicidal depending on manner of death. Next as per the various pattern of modes of death encountered during the study, the unnatural deaths were classified as RTA’s, burns, fall from height, poisoning, assault, asphyxia deaths etc.,

Among motive of death menstrual pain is the commonest propelling factor for suicide followed by psychiatric issues due to various reasons stands second in the race.
Discussion

Incidence of unnatural deaths was 25%. Similar finding of Sharma et al\(^3\) where incidence was observed to be 28%.

In our study majority were in 2\(^{nd}\) to 4\(^{th}\) decades year age group which is consistent with other authors\(^4, 5\). Suicide and accidents were common modes of death in my study. This also observed by Sharma et al\(^3\). However accidental manner of death was more commonly reported by Sharma et al\(^3\).

In this study marital status showed that most cases of unnatural deaths were from married group which is consistent with other author. Accidents and hanging were most common cause of death followed by burns in my study. However these studies are not consistent with other studies\(^4, 5, 9, 10, 12\). Poisoning was commonest cause consistent with Prajapati P et al\(^7\).

Conflict of Interest: Nil

Source of Funding: Self

Ethical Clearance: obtained from rims ethical clearance committee

Recommendations

1. Early marriage of woman should be discouraged to prevent them from innate stressful exposure at an early age.
2. Anti-dowry cell and women protection cell should be established.
3. NGO’s and law protection should be established to prevent crime against women.
4. Counseling should be established at every district centre to counsel risk factors in women.

Profile of Brought in Dead Cases in a Tertiary Care Centre of South India

Prince M. Paul1, Stelin Agnes Michael2, Roney Thomas3, P. Babu4

1Assistant Professor, Department of Forensic Medicine, Pushpagiri Institute of Medical Sciences and Research Centre, Tiruvalla, Kerala, 2Assistant Professor, Department of Anatomy, Pushpagiri Institute of Medical Sciences and Research Centre, Tiruvalla, Kerala, 3Associate Professor, Department of Emergency Medicine, Pushpagiri Institute of Medical Sciences and Research Centre, Tiruvalla, Kerala, 4Professor, Department of Forensic Medicine, Pushpagiri Institute of Medical Sciences and Research Centre, Tiruvalla, Kerala

Abstract

Most of the times it is noticed that incidence of Brought in dead (BID) cases in a tertiary care hospital is very high. But there are limited data of the statistics of such cases due to lack of records or audit. These cases can be due to natural cause or unnatural. The doctor attending such cases should be aware of all procedures and formalities associated with BID cases. Diagnosis of death should be ascertained clinically and hospitals should be aware of the legal responsibilities of these cases.

This study was conducted in a tertiary care institution where BID cases were profiled with the available data and records. The study throws light in to not only the demographic profile like age, sex, month wise distribution but also to time of reporting to Emergency department (ED) as well as the probable cause based on history of the informant. Males dominated in the total number of 307 cases compiled in 4 years, i.e, 2015 to 2018. Age of above 60 years cases made the major share with sudden death as well as road traffic accident (RTA) being the major culprits. Maximum number of BID were reported during early morning hours (12am to 6 am) followed by late evening hours (6pm to 12am).

Key words: Brought in dead cases, Emergency department, demographic profile

Introduction

The incidence of brought in dead (BID) is high in tertiary hospitals, but there is a lack of proper audit and relevant data of these cases. Brought in dead cases are those cases, where the patient on arrival to the emergency department (ED) was found to be clinically dead, hence also named as ‘Dead on arrival’. Persons ‘brought in dead’ (BID) often contribute to hospital ED mortality statistics (1,2,3,4).

Even though not an emergency, ED of a hospital has to provide necessary documentation and has to undergo all the legal issues regarding a BID case. Most of the times, it is important for the emergency clinician to confirm the death and to distinguish it from ‘apparent death’. There are many factors associated with brought in dead cases which could be neglect from the patient attenders, concealing crime by offenders, lack of infrastructure or lack of awareness. Almost always, all brought in dead cases are considered medicolegal and it is the duty of doctor to intimate the police according to the law of land. It is also important to know about the premorbid conditions of patients and to collect the previous treatment records of the deceased. This study is an attempt to collect material data about such cases and to compile the demographic profile with associated parameters which is a unique one in this region.

Materials and Method

The demographic profile of all BID from year 2015 to 2018 were analysed, which were presented to ED of a tertiary care medical college hospital in South India by

Corresponding Author
Stelin Agnes Michael,
Mob – 8606202227, 9171935019.
E-mail: stelinagnes@gmail.com
a cross sectional study. The age wise, gender wise and month wise distribution were tabulated and graphically represented. The pattern of cases based on history and time of reporting to ED were also recorded.

**Results**

This retrospective study was conducted in an 800 bedded tertiary care private teaching institution from 2015 to 2018. In all the four years, males dominated in number of BID. The total number of cases in 4 years came up to 307. In the year 2015, 61% were males whereas the year 2016 there were 82.7% males. The year 2017 had 70.3% male cases and 2018 recorded 69.3% male dominance (Fig.1).

The age wise classification was done by grouping into <20 years, 20 to 40 years, 40 to 60 years and above 40 years. 43.6% cases belonged to above 60 years category from total number of cases in 4 years. There was clear majority of this age group BID in all the 4 years (Table.1).

Time of reporting to ED on given day were analysed for all the 4 years by classifying into four groups. Maximum number of BID was reported during 12 am to 6 am (39%) followed by duration of 6pm to 12am (35%) (Table.2).

The pattern of cases based on history available were recorded. Of which sudden deaths and RTA formed the major share (Fig.3). Most of the cases which belonged to elderly age group, i.e., above 60 years had various comorbidities in the past like COPD, CAD, renal failure, diabetes mellitus and systemic hypertension. BID following RTA belonged to younger age groups. Sudden death cases were also reported rampantly without any known comorbidities and chronic illnesses in past.

FIG. 1 GENDER WISE DISTRIBUTION OF BID FROM 2015 TO 2018

FIG. 2 MONTH WISE DISTRIBUTION OF BID FROM 2015 TO 2018

FIG. 3 BID PATTERN FROM 2015 TO 2018
Discussion

Death is permanent and irreversible stoppage of the all three vital systems of the body, including the circulatory, respiratory and neurological systems. The moment of death points to the exact moment when the person dies. Khan et al. has mentioned that about 10-50% of such deaths occur before reaching the hospital and hence recorded as brought in dead cases.[5]

In the present study, almost 43.6 % involved were above 60 years. The age group of 61-75 years constituted the largest group in a study done by Wang JS et al which is similar to our study [6]. The main reasons for the involvement of this age group may be the undiagnosed fatal illness or neglect of alarming symptoms of diseases in the community.

In our study, it was noted that there was clear cut male dominance in all the 4 years. This finding was consistent with other studies as well [7,8]. Month wise distribution of all the 4 years were also tabulated but no statistical significance or varied differences were noted.

It is interesting to find that most of the BID cases reported to the ED during 12 am to 6 am (39%) followed by duration of 6pm to12am (35%). This indicates that the late evening hours and early morning hours brings more BID cases to a hospital which may be due to delay in transport, inaccessibility and neglect.

Conclusion

The profile of BID cases presented to a tertiary care hospital in South India was similar to previous studies conducted. It is important for all hospitals to be aware of the legal formalities in handling BID cases. It is mandatory for all hospitals to maintain a proper BID register with all details. A doctor should be aware of his legal and ethical duties of such cases apart from confirmation of death.

Analysis of Medicolegal Cases in a Tertiary Care Hospital of South Kerala

Prince.M.Paul¹, Stelin Agnes Michael², Roney Thomas³, P.Babu⁴
¹Assistant Professor, Department of Forensic Medicine, ²Assistant Professor, Department of Anatomy, ³Associate Professor, Department of Emergency Medicine, ⁴Professor, Department of Forensic Medicine, Pushpagiri Institute of Medical Sciences and Research Centre, Tiruvalla, Kerala

Abstract

Medicolegal cases (MLC) are presented to Emergency department (ED) of almost all hospitals in our nation after the Supreme Court guidelines stating that ‘the paramount duty of a doctor is to save the life of a person’. Hospitals should be equipped with infrastructure as well as treating doctors in combating such cases where documentation and treatment should be meticulously done.

This study is conducted in a tertiary care hospital in South Kerala where profile of MLC was analysed during the years 2016 -17. A total of 10,001 cases were studied which is unique compared to previous studies. Males dominated in the MLC with road traffic accident (RTA), fall from height and work place injuries formed the major share in the pattern of cases. Most of these cases were presented to ED between first and sixth hour of occurrence.

Key words: Medicolegal cases, Emergency department, demographic profile

Introduction

Any case of injury or ailment where some criminality is involved is called a Medicolegal Case (MLC)¹. MLC are identified by the treating doctor based on history and clinical examination. In the Emergency department (ED) of a tertiary care hospital, MLC forms the major share of cases and it is important for the hospital to handle the legal implications of such cases. With the emergence of specialization in Emergency medicine, identifying and handling of MLC meticulously has significance in reducing the burden of a clinician. As per the guidelines of Supreme Court of India, it is the paramount duty of a doctor to save a patient in emergency. It is important for the hospital to tackle MLC and give lifesaving treatment as well as to do all necessary medicolegal certifications and formalities to the patients. Profiling of MLC is an integral aspect for the prevention of preventable causalities in future and to study the crime rate in that area². The present study was conducted in an 800 bedded postgraduate teaching institution in South Kerala.

Material and Method

The present study was conducted on 10,001 MLC patients admitted to the casualty department of Pushpagiri Institute of Medical Sciences, Tiruvalla from January 2016 to December 2017. The demographic profile based on age, sex, month wise distribution was done for various patterns of MLC presented to the ED. All the data were analysed and demonstrated using tables and graphs. Ethical approval was taken from ethical review board of the institution and the administration of concerned hospital ensuring data confidentiality.

Inclusion criteria

All the MLC registered during January 2016 to December 2017 in the medicolegal case record book were included.

Exclusion criteria

Cases found non-medicolegal were excluded.

Aims and Objectives

1. Profiling of MLC coming to the ED of Pushpagiri Institute of Medical Sciences, Tiruvalla

2. Suggestions for improving medico-legal work in Casualty.

3. To make recommendations to administrative authorities according to outcome of study.

Observations and Results

A cross sectional study on medicolegal cases presenting to the ED of a tertiary care medical college hospital was performed and the demographic profile and pattern of cases were analysed and tabulated. MLC of the years 2016 and 2017 were included.

In the year 2016, the total number of MLC was 4972. Of which, 3381(68%) were males and 1591(32%) were females. The age group classification was done and tabulated as < 20 years, 20 to 40 years, 40 to 60 years, 60 to 80 years and more than 80 years. Among all the age groups 20 to 40 years (40%) and 40 to 60 years (28%) constituted the major share with male gender preponderance (Table 1).

The patterns MLC studied were categorised in to road traffic accident (RTA), assault, fall from height, poisoning, burns, hanging, drowning, various bites and work pace and domestic injuries. Age wise and gender wise distribution was done. In the year 2016, 2163 RTA (43.5%) and 1686 fall from height (33.9%) were recorded and formed the major share. In both the categories there was male dominance (Fig.1). Among all the patterns of MLC, majority of cases belonged to the age group 20 to 40 years (59%) and 40 to 60 years (25%) (Table 1). Month wise distribution of cases were studied and September month (477) case recording the highest and November month (336) showing the least (Fig.2). The time of reporting to ED from time of incidence were also calculated for all cases. 30% cases reported within the first hour. 42% cases reported within 1 to 6 hours, whereas 26% presented between 6 to 12 hours. Only 2% cases presented to ED as late as more than 12 hours (Table 2).

In the year 2017 there were 5029 MLC cases recorded. There were 3623 males (72%) and 1406 females (28%). The age groups 20 to 40 years (54.1%) and 40 to 60 years (21.8%) formed the major share and age groups < 20 years (3.5%) and > 80 years (3.7%) contributing the least (Table 1). Among all the patterns RTA 2225(44%) and fall from height 1885 (37%) formed the major share. Males dominated in both the categories with age groups 20 to 40 years (46.5%) and 40 to 60 years (27.3%) were maximum affected compared to other age groups (Fig.3). August recorded with maximum number of cases (481) and February recorded the lowest (359) (Fig.4). 32% cases presented to ED within 1 hour from incidence whereas majority (43%) presented between 1 to 6 hours (Table 2).

FIG.1 MLC PATTERN IN 2016 WITH GENDER DISTRIBUTION

FIG.2. PATTERN OF MLC IN 2016 WITH MONTH WISE DISTRIBUTION
Discussion

In the present study, 10,001 MLC were studied for a period of 2 years (2016 – 17) which is a unique study for this geographical region. The study was conducted in an 800 bedded tertiary care private teaching institution situated in a municipal area serving nearly 25 km radius population. This institution was equipped with round the clock emergency facilities and services from speciality and super speciality departments.

The study indicated male dominance in number as well as most of the pattern of cases involved. This could be because of males who are mostly involved in outdoor
activities, travelling and heavy manual jobs. The similar findings were found in study conducted by A. Yadav et al. in 2013 where males were dominant (67.6%). Other studies in 2010 and 2011 also have similar results\cite{3-6}.

The age group of 20 years to 40 years, followed by 40 years to 60 years were involved in majority of cases. This also suggests the healthy adults in working class were mostly subjected to injury due to their involvement in trade, agriculture and other fields of work. The RTA were the majority in both the years which could be due to multiple factors including over speeding, bad roads and the influence of alcohol in these age groups. Fall from height and work place injuries also showed a good number which could be due to heavy work and lack of safety awareness and measures among the working class.

It is important to note that in both the years, poisoning and hanging cases were dominated by females. The manner of these cases is mostly suicidal points towards the atrocities and cruelty with gender discrimination which is still prevalent in the study population.

Time of reporting to ED after the incidence were studied. Most of the cases were reported within first hour and 6 hours. This indicates the awareness, cooperation of public along with good connectivity to this centre.

**Conclusion**

1. Males were predominant in most of the MLC in both years.

2. Young age group with working class were involved in most of the patterns of MLC. So, measures should be taken to prevent injuries by providing safety awareness, security checks, and by maintaining strict laws by the Government authorities.

3. The bulk of cases up to 10,001 in two years shows the importance of a tertiary care in a densely populated area. This should be an eye opener for the government as well as Planning Commission to know about the need of establishment of such tertiary care centres in our country.

Abstract

Recently the use of tilted implants has been considered as a preferable option in case of atrophic edentulous arches. The tilted longer implants can be of use to ward off the important anatomical structures while also permitting cantilever reduction.

Since the load transfer mechanism of an implant can be altered significantly by the number of implants and its location in the edentulous ridge, the present study evaluates and compares the stress patterns in the edentulous mandibular bone around two implant retained, four implant retained over denture and all on four concepts under different loading conditions using finite element analysis.

Purpose: The biomechanical behaviour of the ‘All-On-Four’ system was compared with that of the two-implant-supported and four-implant supported mandibular overdenture using the three dimensional finite element method (FEM). Thereby evaluating the von Misses stresses induced on the implants under different loading simulations.

Materials & Method: Three dimensional models representing mandible restored with ‘All-On-Four’, two-implant-supported and four-implant-supported prosthesis were developed in the three dimensional design software and then transferred into FEM software. The models were then subjected to four different loading simulations (full mouth biting, canine disclusion, load on cantilever, load in the absence of cantilever). The maximum von Mises stresses were localized and quantified for comparison.¹

Results: Among the three models, under all loading simulations, the maximum stress concentrations were along the neck of the implant. The stress levels for full mouth loading simulation was highest for two implant supported overdenture design and the least for All-On-Four overdenture design. In all three designs, the least stress was when the implants were loaded in a lateral direction. The stress levels for cantilever and non-cantilevered designs were nearly the same for all the simulated designs.

Conclusion: When tested under different loading simulations, the three models showed similar location and distribution of stress patterns. Thus from the study it can be concluded that the All-On-Four Concept is a
clinically applicable treatment option for the atrophic edentulous ridges and induces least amount of stresses on the edentulous ridges. Therefore the overall longevity of the prosthesis is greatly enhanced.

**Key words:** atrophic mandible, biomechanics, finite element analysis, implants supported prosthesis, tilted implants.

**Introduction**

Dental implant treatment is considered as the most favorable treatment option for the partially or the completely edentulous patients.\(^1\) Although implant treatment is well documented and reliable, implant placement may be limited by the anatomy of the patient like in regions of posterior maxilla or the posterior regions of mandible, the use of implants is usually limited by extensive bone resorption and poor bone quality. In addition to this, there are various anatomical limitations like presence of maxillary sinuses in the maxilla and superior position of the inferior alveolar nerve in the mandible.\(^2\)\(^-\)\(^5\) Hence in such situations prosthetic rehabilitation of implants in the posterior region may necessitate the use of long cantilevered prostheses, thereby increasing the risk of implant failure.\(^6\)\(^-\)\(^8\).

Recently the use of tilted implants has been considered as a preferable option in case of atrophic edentulous arches as confirmed from the study by Watanabe et al. The tilted longer implants can be of use to ward off the important anatomical structures while also permitting cantilever reduction. Hence to simplify the treatment of atrophic maxilla or mandible using tilted distal implants, a technique named, ‘All-On-Four’ was developed.\(^1\)

The use of tilted implant concept offers good support by reducing cantilever length, enhancing primary stability by using areas of high density bone and also allows a favorable inter-implant distance. But poorly designed implants can create regions of increased stress in peri-implant bone and induce severe resorption, leading to gradual loosening and finally complete loss of implant \(^1\)\(^,\)\(^2\)\(^,\)\(^6\).

The stress and strain generated have been evaluated by methods like the photo elasticity, strain gauge analysis and finite element analysis. The photo-elasticity provides good qualitative information on the overall location and concentration of stresses but provides limited quantitative information. The strain gauge movements provide accurate data regarding strains only at the location of the gauge; the finite element method is capable of providing detailed quantitative data at any location within a mathematical model. Two and three dimensional finite element analysis has been used to evaluate the stresses around various dental implant systems.\(^2\)\(^,\)\(^5\)\(^,\)\(^10\)

An in-depth understanding of stress profiles encountered by the implant and more importantly in the surrounding jawbone can be gained through the use of FEM. It is of great importance that the clinician gains an understanding of the methodology, applications, and limitations of FEA in implant dentistry, and become more confident to interpret results of FEA studies and interpret these results to clinical situations.\(^1\)\(^,\)\(^4\)\(^,\)\(^9\)

Since the load transfer mechanism of an implant can be altered significantly by the number of implants and its location in the edentulous ridge, the present study is evaluating and comparing the stress patterns in the edentulous mandibular bone around two implant retained, four implant retained over denture and all on four concepts under different loading conditions using finite element analysis.

**Aim**

To compare the stress patterns in the edentulous mandibular bone around two implant retained, four implant retained overdenture and the prosthesis restored with All-On-Four Concept using finite element analysis.

**Objectives**

To compare the biomechanical behaviour of the prosthesis restored with All-On-Four Concept with that of two implant supported and four implant supported mandibular overdenture using three dimensional finite element analysis.

To localize and quantify the Von Mises stresses induced on the implants under different loading simulations.
Material & Method

Poorly planned implant placement can create regions of increased stress in peri-implant bone and induce severe resorption, leading to gradual loosening and finally complete loss of implant. Hence a detailed analysis needs to be done to evaluate the stress distribution with various implant designs.

The present study was carried out at the

► Department of Prosthodontics and Crown & Bridge, Manipal College of Dental Sciences, Manipal
► Department of Aeronautical Engineering, Manipal Institute of Technology, Manipal.

Armamentarium used for the study

● CT Scan of edentulous mandible
● Replace Select Tapered TiU NP 3.5 x 13mm (Nobel Biocare)
● The Profile Projector (METZ- 801)
● Cylindrical Retainer of 4mm diameter.
● ANSYS - 11 Workbench Software.

Preparation of FEM model of the Edentulous Mandible. 1-4

A Computerized tomography image of the human edentulous mandible was obtained and introduced into the Computer Aided Design Software. Using the ANSYS software, the CT image of the mandible was later simplified into an arc shaped bone block with dimensions of 7.5 mm thick and 15mm high. A 1mm cortical bone layer was established overlying the entire mandible whereas trabecular bone was used in the internal structure, simulating the type III bone. Once the computerized 3-Dimensional model was obtained, incorporation of the implant design into the model was planned.

Preparation of the FEM implant model

The study was done to compare the stress patterns in the edentulous mandible under various implant supported overdenture designs, so the accuracy and contour of the threaded implant was a major concern. But the contour, shape and depth of the threads in the implant could not be evaluated and reproduced in the 3-dimensional model with the help of the computerized tomography, hence an instrument called ‘Profile Projector Optical System’ was used in this study. The values that were obtained from the profile projector were then used to prepare an accurate 3-D model of the threaded implant along with the retainer.

Profile Projector (METZ -801) Optical System

All profile projectors display magnified images on an appropriate viewing screen, as an aid to more precise determination of dimension, form and occasionally physical characteristics of sample parts. These optical projectors are able to display a two dimensional projection of a part rather than a simple linear dimension as with most other gauging devices.

This instrument creates work piece image on the projection screen at desired magnifications (10x, 20x, 50x) to provide accurate dimensional measurement as well as inspection of the contour and surface condition of the work piece.

The METZ- 801 features a large Projection Screen 300mm diameter and the combination of high performance projection lens and an optical system minimizing the magnification error, which may occur due to insufficient or improper focusing and ensures accurate measurements over the entire projection screen. The accuracy of this instrument is known to be 0.001mm.

Preparation of the working model

Three dimensional working models were constructed using 3D computer aided design software (ANSYS). The models represented the mandible restored with 2 - implant supported prosthetic design, 4 implant supported prosthetic design, and the design restored with the All On Four Concept. A rigid type III gold prosthetic bar, 6mm thick and 4mm high and in the shape of an arc was then designed and joined to the abutments.1

For the 3-Dimensional two implant supported prosthesis model, the threaded implants were strategically placed vertically in the region of lateral incisors bilaterally.

For the 3- Dimensional four implant supported prosthesis model, in addition to the mesial implants placed bilaterally, distal implants were vertically placed bilaterally in the premolar region.

For the 3- dimensional ‘All-On-Four’ model, Two anterior implants were placed vertically in the
position of the lateral incisors and two implants were placed bilaterally in the position of second premolars and tilted distally to 30º angle.

- Loading 1: Full mouth biting – bilateral and simultaneous vertical static loads of
  - 200 N was applied on the occlusal surface of the first molars (Cantilevers)
  - 150 N on the occlusal surface of second premolars
  - 150 N on the occlusal surface of first premolars
  - 100 N on the distal of canines
- Loading 2: Lateral Load – Unilateral static load of 50 N applied in the region of left canine.
- Loading 3: Cantilever Load – Unilateral vertical static load of 200 N was applied on the left cantilever.
- Loading 4: Load without the cantilever - Unilateral vertical static load of 200 N was applied in the region adjacent to the left second premolar, simulating absence of cantilever.

The results of the mathematical solutions were later converted into visual results and expressed in colour gradients, ranging from shades of red, orange, yellow, green and blue, with red representing highest stress values. The stress values in the three models were collected and compared, with the points of greatest magnitude identified by the Von Mises equivalent stress levels.

Loading Situation

This study was carried out on FEM models simulating two implant retained prosthesis, four implant retained prosthesis and the prosthesis restored with the All-On-Four Concept under a) Full mouth load, b) Lateral load, c) Cantilever load, d) Load without cantilever.

Results

The results of the numerical analysis are shown in Table 2 for Von Mises stresses occurring for the FEM models simulating

Graph 1 represents the biomechanical behavior of the two implant supported overdenture FEM modes when subjected to different loading simulations. The graph depicts maximum stress levels during full mouth loading simulation which was 2226.7 Mpa followed by cantilever loading simulation which was 813.09 Mpa and load without cantilever shown as 531.39 Mpa. The least stress for this model was found during the lateral loading simulation which was 64.76 Mpa.

Graph 2 represents the biomechanical behavior of the four implant supported overdenture FEM models under different loading simulations. The maximum stress level in this model was found during the full mouth loading simulation which was 303.51 Mpa followed by load simulating cantilever loading which was 187.34 Mpa and load simulating load without cantilever which was 125.09 Mpa. The least stress was found during lateral loading shown as 57.35 Mpa. The stress levels in the four implant simulation were comparatively much less than the two implant supported overdenture model.

Graph 3 illustrates the graphical representation of the biomechanical behavior of the FEM model simulating the prosthesis restored with the All-On-Four Concept. The maximum stress in this simulation was found during full mouth loading which was 253.37 Mpa followed by load simulating lateral load which was 88.01 Mpa and load simulating the cantilever load which was 85.22 Mpa. The least stress was found when load without cantilever was simulated which was 60.21 Mpa.

From the graphs it can be inferred that among the three models, the stress levels for full mouth loading simulation was highest for two implant supported overdenture design and the least for All-on-four overdenture design. For all three designs, the least stress was when the implants were loaded in a lateral direction. The stress levels for cantilever and non-cantilevered designs were nearly the same for all the simulated designs.

Graph 1- Peak stresses in Two implant supported overdenture
Discussion

Various studies revealed that the occlusal load was one of the main contributing factors. The load transfer from implant to the surrounding bone depends on type of loading, bone-implant interface, length and diameter of implants, shape & characteristics of the implant surface, prosthesis type and quantity & quality of the surrounding bone. So the dentist has specific responsibilities to minimize overload to the bone implant interface. These include a proper diagnosis leading to a treatment plan providing adequate support. Among the various methods for the stress-strain analysis, the finite element method is capable of providing detailed quantitative data at any location within a mathematical model. Two and three dimensional finite element analyses have been used to evaluate the stresses around various dental implant systems.

Keeping in mind the consequences of unwanted stresses, this study was an attempt to compare the Von Mises Stresses around the implant by different loading conditions, on three different finite element models. The models were simulated on the basis of implant number, position, angulation and the type of prosthesis which is a Type III gold bar.

Exploring Thoughts of Victims of School Bullying Through Drawings

Rekha Negi
Shyama Prasad Mukherji College for Women, University of Delhi

Abstract
This study explored the underlying thoughts of victims of school bullying through analysis of their drawings. Eighty senior secondary students (studying in classes 9 to 11) identified as victims based on the Illinois Victimization Scale participated in the study. Participants drew their victimization experiences and provided elaborations of their drawings. Analysis of participants’ responses involved the framework method. Results showed that thoughts of bullied participants were related to the (1) outcomes of being victimized (2) dealing with the bullies, and (3) the reason for bullying. The participants evinced various thoughts related to direct or indirect coping, victim-related reasons, and bully related reasons as gauged by their drawings. The findings of this study were interpreted in the light of developmental-ecological framework and research. The article indicates implications for future research and professionals to help the victims of school bullying.

Keywords Drawing · Coping · School bullying · Qualitative method

School authorities and practitioners working in the area of child and adolescent mental health across the world are realizing the importance of tackling the issue of school bullying. This has motivated vast research on school bullying. Extant research on bullying and cognitions relates bullying and victimization to the theory of mind[1], conduct disorder and theory of mind[2], executive functions[3], social-cognitive factors [4], and Cognitive Behavior Therapy intervention[5]. The above-referred studies focused on cognition and its relation to bullying but did not investigate the actual content of thoughts, an aspect which is uniquely considered in the present study. In the context of school bullying, a victim is defined as “a student who is exposed, repeatedly and over time, to negative actions on the part of one or more students” [6]. Due to repeated victimization in schools, bullied children report symptoms of depression, headaches, anxiety, stomachaches, and academic difficulties. In response to school bullying, school-based intervention programs have produced a dramatic decline in the rate of school bullying [7] and have led to the upsurge of research in cognitive and non-cognitive aspects of bullying.

Neisser[8] defined cognition as “the activity of knowing: the acquisition, organization, and use of knowledge.” Cognition involves a variety of functions such as thinking, learning, perception, attention, memory, retention, decision making, reasoning, and problem-solving. This study aimed at examining children’s thoughts about their bullying experiences. The study chose thoughts because of their ability to predict children’s current and future behavioral and emotional reactions to negative situations.

Questionnaires provide limited information about bullying. Victims’ drawings of school bullying allow researchers to understand actual lived experiences from their perspective, and to realize the underlying emotions and motivations in bullying[9]. Bosacki et al. [9] argued that a conventional method to assess bullying does not allow the participants to report their complete bullying experiences. The use of drawings in interventions like art therapy is very useful for adolescents with anxiety issues [10]. Drawings enable the investigators to understand the bullying experience of the victimized child, the power dynamics between the bully and the bullied [11], and the context of bullying. This study set the following objectives: (1) to identify the victims of school bullying and (2) to understand victims’ experiences by analyzing their thoughts.

Method

Research Design
This research employed the qualitative participatory
visual method and semi-structured interviews. Past research has shown the relevance of participatory visual methods or art-based methods with children\[12\]. Semi-structured interviews investigated children’s depictions. Steps involved in data analysis are described in the analysis section.

**Participants**

Participants were selected from among the students of 9th-11th grades studying in different schools located in Delhi, India. Only students who volunteered to participate with the approval of parents and school principals were involved in the study. The study used purposive sampling, and 300 participants were selected according to two criteria which include classes of 9, 10, and 11 and gender (male and female). Illinois victimization scale\[13\] was administered to identify the victims. The final sample comprised 80 participants (60 male and 20 female) in the age range of 16-18 years.

**Measures**

The study used the Illinois victimization scale to identify the victims. The material used for the drawing task comprised A-4 size paper, pencil, pen, eraser, and sharpener.

**The Illinois Victimization Scale.** It is a subscale of the Illinois Bully Scale\[13\] which includes 18 items on bullying phenomenon and fighting. The present study adopted and administered only the “victimization” subscale to identify victims of school bullying. The Victimization subscale comprises four items (that measure frequency of being picked on, made fun of, called names, and hit or pushed). It is a five-point Likert-type scale. Espelage and Holt\[13\] found a Cronbach alpha coefficient of .87 for their scale. Espelage et al.\[14\] found significant correlations with peer nominations of bullying, which showed acceptable concurrent validity of the scale.

**The drawing task.** The drawing task involved the depictions of participants’ victimization experiences in school. The drawing task was followed by semi-structured interviews based on the elaboration of participants’ drawings.

**Procedure**

The Victimization subscale of Illinois Bully Questionnaire\[13\] was administered to three hundred participants for identifying the victims of school bullying. It was followed by the drawing task. After checking the familiarity with the word “victim” and “school bullying” the task was administered in 40 mins in groups on separate days in different schools. The instruction for the drawing task was, “Draw a scene of your victimization taking place in school and also show in drawing what you were thinking by a thought bubble”. The researcher followed the drawing task with individual semi-structured interviews with the prior permission of participants. During the interview, the researcher asked each participant to describe and provide details of the drawing. Each interview lasted for about 15 min. Towards the end of the semi-structured interview with all the participants, the researcher debriefed the participants and thanked them.

**Analysis of Drawings**

The drawings were shown to two judges: the researcher and a freelance counselor well trained in art therapy and qualitative research. The judges initially independently surveyed the drawings and developed themes. The judges sorted out any discrepancies in the emerging themes through discussion and mutual agreement. The inter-judge reliability was satisfactory (95 percent agreement on emerging themes). Further analysis used only those themes on which the judges agreed with each other.

The researcher transcribed the interview data and used the “Framework method” to analyze the data. The Framework method is a five-stage qualitative analytic process espoused by Ritchie and Spencer\[15\] and comprises familiarization, identifying a thematic framework, indexing, charting, mapping, and interpretation. A brief explanation of these five stages according to Ritchie and Spencer is presented: Familiarization involves reading and re-reading the transcript, and listening back to the audio-recoded content of interviews, to gain the basic information about the collected data. Identifying a thematic framework or indexing involves the emergence, sorting, and sifting of the coded themes and categories obtained after the familiarization stage. Indexing refers to the process whereby the thematic framework or index is systematically applied to the data in its textual form. Themes corresponding to the selected parts of data are identified and annotated for further analysis. Charting is the next step which involves the presentation of the coded data in a matrix for each theme. The chart shows for each participant a clustered theme embedded within various codes, supporting annotated data, and reference
Mapping and interpretation involve analyzing the data as a whole comprising the various obtained themes, categories, and descriptions for all participants. The present study dealt with the contextual question, i.e., identifying the thoughts of bullied students and therefore framework method was considered as an appropriate method for addressing contextual questions[15].

**Results**

For the present sample of the study, a Cronbach alpha coefficient of .82 was obtained for the Illinois Victimization scale. All the participants produced complete drawings. The steps involved in the ‘Framework’ method and as used in the present study are described above in the analysis of the drawings section. Figs. 1-6 present drawings drawn by six participants to discuss the results. Table 1 shows the three themes that finally emerged from the analytical framework, along with the codes and their descriptions. Table 2 presents the thoughts related to the outcomes of victimization. Table 3 summarizes the thoughts related to dealing with the bullies, and Table 4 provides thoughts related to the reason for victimization. The italicized statements in the tables show the participant’s written responses used for analysis.

Discussion

The present study could achieve the objectives to identify the bullied in selected schools and to understand victims’ thoughts related to bullying. The overall thoughts of the victims regarding the consequences of bullying centered on their apprehensions of reporting for help from teachers, friends, parents and preferred hiding their bullying experiences. The findings of this study find support from the developmental-ecological framework [16]. Mohr [16] argued that the contexts of a child in crisis range from their microsystem (immediate
Participants’ depictions also made these contexts clear. A majority of the victims also reported thoughts about defensive reactivity, which refers to the “proneness to negative emotional reactivity in the face of threat” [17]. Thoughts of taking revenge from the bully and reduced motivation were also evident in depictions of the participants identified as bullied.

In the responses illustrative of thoughts related to dealing with the bullying situation, participants expressed various thoughts about active and passive coping. The current findings are in congruence with the previous research finding that victimized children generally think to speak about their bullying more often to their parents than to their teachers [18] and recommend passive strategies such as avoiding the bullies with a greater likelihood as they have a fear of retaliation by the bullies [19]. These results are consistent with Sittichai and Smith’s [20] findings that victims tell a teacher or parent about their bullying and the finding has implications for the pertinent role of duly held parent-teacher meetings in preventing bullying.

Telling others and seeking help when bullied has often been found to be an effective response to bullying [21]. The metacognition that is “thinking about thinking” of bullying the perpetrator, was also clear in the responses of some participants. Metacognition, along with attributional complexity, has a significant effect on resilience [22] and thus facilitates effective adaptation in negative situations, including bullying.

While portraying thoughts related to the reason for bullying, the victims attribute the causes of victimization more to their stable, internal, and global factors which are the most maladaptive ones [23], than to the bullies for just having fun [24] and being strong. The present findings also show that the victims revealed more information when asked to draw and elaborate on their bullying experiences. A scholarly debate regarding the best method for assessing bullying and victimization [25] exists in the bullying literature, and the present findings with the use of drawings along with a semi-structured interview seem to offer a good alternative to the existing conventional methods to assess bullying.

Some limitations of the present study could offer future research scope. First, the study focused on the thoughts of the victims of school bullying only. To further explore this topic, future studies could design the attribution retraining program. Second, future studies can design and implement the interventional program for victims of school bullying and test their efficacy.

Acknowledgment: I am thankful to Sujata, the freelance counselor, and all the children who participated in the study. I am also thankful to Narendra K. Sharma for his comments on the draft of this manuscript.

Conflict of Interest: None

Source of Funding: Self

Compliance with Ethical Standards

Ethics approval was obtained from the school ethical committee. Informed consent was obtained from both the parents and students and the information about anonymity, confidentiality, and the right to withdraw from the study at any stage were provided to all the participants.

Analysis of Factors Affecting the Implementation of “Remaja Sehat” Application

Riris Diana R¹, Pulung Siswantara¹, Muthmainnah¹, Astri Meidah Setiawati¹
¹Faculty of Public Health Universitas Airlangga Surabaya, Indonesia,

Abstract

This study aims to determine the effect of relative profitability, compatibility, complexity, trialability, and observability about knowledge regarding adolescent reproductive health in the use of the “Remaja Sehat” application. Implementation of the use of the media “Aplikasi Remaja Sehat” was carried out by 302 students of SMAN 19 Surabaya and SMA Muhammadiyah 7 Surabaya. Effectiveness measurement used pre-experiment methods with post-only design. The results of this study showed that there are relative advantages (0.013) and trialability (0.000) have an effect while compatibility (0.666), complexity (0.464) and observability (0.281) have no effect on the implementation of the use of “Remaja Sehat” application.

Keywords: Relative advantage, compatibility, complexity, trialability, observability, implementation, adolescent reproductive health.

Introduction

Indonesia so far has implemented various education regarding adolescent reproductive health. Adolescents have been given education with not a short period of time¹. Starting from education in schools, counseling in health facilities, and most importantly, environmental support and parents. Indonesia itself is a country that has a variety of cultures and religions. It is well known that different eras will cause cultural change with the increase of technological sophistication which makes it easy to share information. In Indonesia, the lecture method is still used in providing information and discussion about adolescent reproductive health. However, with social, cultural, and even religious changes in every era, the lecture method is less capable in the process of adolescent education².

One of the applications “Remaha Sehat” is a media as a channel of information regarding adolescent reproductive health apart from the education provided from schools, and from parents or health workers. This application explains various information related to HIV/AIDS, Sexuality, and Narcotics. In addition to the information, there is also a game in the form of a quiz about reproductive health with scores and discussions so that the adolescents will be encouraged to get the best score. After the adolescents use the application and implement it in the form continuously using the application, choose to not uninstalling the application and implementing it in daily life, whether the application will be more effective or not in terms of relative benefits, stability, complexity, trialability, and observability according to adolescents.

Material and Method

Research Design

This research used pre-experiment. Researchers will present an application “Remaja Sehat” to the students then the researchers will provide a questionnaire related to the relative advantages, stability, complexity, trialability, and observability of the application. This research design used a post-only design.

Research Location

This research was conducted in SMAN 19 Surabaya and SMA Muhammadiyah 7 Surabaya.

Population and Sample

The population in this study were SMAN 19
Surabaya and SMA Muhammadiyah 7 Surabaya’s students whose age around 15-19 years old. The sample in this study amounted to 302 students conducted by simple random sampling.

**Data Collection**

Data collection techniques and instruments in this study after being given an explanation regarding the study and filling in informed consent for 5 minutes, the researcher will present an application “Remaja Sehat” and a questionnaire will be given afterward. The instrument used for data collection in this study was a 30-minute questionnaire, a post-test has been prepared to find out about five variables of the application of “Remaja Sehat” and “Remaja Sehat” applications.

**Data Analysis**

Analysis of the data in this study used a computer that is first to provide code and grouping to facilitate data entry, the second will be scoring which is to give a score in each result, the data will be analyzed afterward. Univariate analysis is used to see the depiction and description of each variable and bivariate analysis used Logistic Regression.

**Research Result**

**Characteristic of Responden**

Table 1: Characteristics based on age, residence and gender

<table>
<thead>
<tr>
<th></th>
<th>Frequency</th>
<th>Percentage (%)</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Age of Respondents</strong></td>
<td></td>

</tr>
<tr>
<td>Female</td>
<td>181</td>
<td>59.9</td>
</tr>
</tbody>
</table>

The frequency distribution of respondents by age can be seen that most respondents at the age of 17 years with the number of students 161 students or 53.3%. Students aged 16 years were as much as 124 students or 41.1% and students aged 18 years were 17 students or 5.6%.

The frequency distribution of respondents by residence is known that most of the student resides in a house with a total of 293 students or 97% while the students who live in a boarding house as much as 9 students or 3%.

The frequency distribution of respondents based on gender showed that most of the respondents are female with the number of student 121 students or 40.1% while the male respondents are as much as 181 students or 59.9%.
Discussion

Table 2: The effect of relative advantage, compatibility, complexity, trialability, and observability on implementation

<table>
<thead>
<tr>
<th>Dependent Variable (x)</th>
<th>Independent Variable (y)</th>
<th>Significant</th>
<th>α</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Relative Advantage</td>
<td>Implementation</td>
<td>0.013</td>
<td>0.05</td>
<td>There is influence</td>

<tr>
<td>Observability</td>
<td>Implementation</td>
<td>0.281</td>
<td>0.05</td>
<td>There is no influence</td>
</tr>
</tbody>
</table>

The result of the relative advantage with implementation showed that \( p = 0.013 \) which means more than \( \alpha = 0.05 \). The result of compatibility with implementation showed that \( p = 0.666 \) which means more than \( \alpha = 0.05 \). As for complexity with implementation showed that \( p = 0.464 \) which means more than \( \alpha = 0.05 \). The result of trialability with implementation showed that \( p = 0.000 \) which means less than \( \alpha = 0.05 \). While the result of observability with implementation showed that \( p = 0.281 \) which means less than \( \alpha = 0.05 \).

This “Remaja Sehat” application is used as a medium of learning or education regarding adolescent reproductive health. Not only lecture learning method, but this application also follows the adolescents’ nowadays that can’t stay far away from their smartphones. According to Wahidin 2018, the media in education apart from only giving messages but has to attract students’ attention by means of creative, innovative and varied methods(3).

An innovation of “Remaja Sehat” application can be measured how effective it is based on the decision and implementation to use and install the “Remaja Sehat” application. Decisions and implementation in the use of “Remaja Sehat” applications can be showed from the relative advantages, compatibility or the level of conformity with the needs or experiences of the students regarding adolescent reproductive health, complexity or the level of complexity of using “Remaja Sehat” applications both in terms of understanding information or games, trialability or can be tested and observability.

This research proved that there is an influence of relative advantages and trialability or can be tested but there is no influence of complexity, compatibility, and observability. This happens because students feel the “Remaja Sehat” application has the advantage of getting information easily by downloading it on a smartphone and can be used every day. In addition, students can use at any time not only in the learning process at school but also in any condition at home, or in other places students can still use this application. Based on the results of the questionnaire, students answered that this application was considered important in discussing adolescent reproductive health. A lot of benefits felt by students in using the “Remaja Sehat” application has made the students can implement to use this “Remaja Sehat” application.

According to Roger theory, trialability or can be tested is an innovation that can be tried or not by the recipient(4). The more innovation can be tested, the faster it will be accepted by the users or students. This “Remaja Sehat” application has been tested beforehand so that students can entrust this application as a medium of education or education regarding adolescent reproductive health. Student’s trust in the trial of this application can affect the implementation of the use of “Remaja Sehat” applications.

Compatibility, complexity, and observability do not affect the implementation of the use of “Remaja Sehat” applications on the students. This is alleged because of the students who have been accustomed to using a cellphone in their daily lives. According to
Roger Theory, compatibility is a consistent level of existing values, past experience\(^{(4)}\). In this “Remaja Sehat” application students assess in the process of using this application and showed the consistent with the existing value of adolescent reproductive health and past experience. In accordance with the research showed that there is a suitability of the material to the goals to be achieved by users so that in the case of this study if there is conformity and can cause curiosity then it does not affect students in implementing the use of “Remaja Sehat” applications\(^{(5)}\).

After taking the decision to adopt and use the “Remaja Sehat” application and it is felt there is no difficulty and easy to understand then the students will be easier to implement to use this “Remaja Sehat” application. This is because the students find it way simpler or easier compared to today’s games that require more challenges to win it. According to Apriyani, the characteristics in the easiness of usage are the existence of trust in technology that is flexible, easily understood by users and easy to be used\(^{(6)}\). While the game in the “Remaja Sehat” application, if compared to other games, is way easier, since it in the form of a quiz. Individuals will not be determined by curiosity and interest, but there is a sense of obligation to use the information system in financial management. Students do not feel the difficulty of using this “Remaja Sehat” application. Although there are games that support adolescent reproductive health information so that students willing to continue to play while learning, students do not feel the difficulty in operating this application. The complexity or complexity does not affect the implementation of the use of “Remaja Sehat” applications. Students will continue to use this application because they thought that adolescent reproductive health is important to be learned. Adolescents are supposed to be the pioneer of adolescent health program (from, by and for the adolescents) thus they need to say to the stakeholders (decision maker and provider) that there are: adolescents’ problems, experience by themselves or others; need for adolescent health program; availability of adolescents to be actively involved in the implementation of ACHS program. The adolescents hope that there will be an adolescent health program which is in tune with the characteristics, needs and capacities of them\(^{(7)}\).

This study showed the results that there is no significant effect between observability on the implementation of the use of “Remaja Sehat” applications. This happens because the observability of the innovation or application of “Remaja Sehat” has succeeded in influencing users. It is through friends and the surrounding that recommend to use and spread the benefits of using “Remaja Sehat” applications. This is supported by the research showed the results that there is a relationship of peer support to healthy behavior among students\(^{(8)}\).

**Conclusion**

Based on the results of this study the more the students feel the suitability in their needs, the ease of applying, and observability of “Remaja Sehat” then it will not affect the implementation of the use of “Remaja Sehat” applications. On the other hand, the relative benefits that will lead to user gain in its implementation and have been tested that brought up students’ trust in using “Remaja Sehat” applications affect implementation. The more students feel the benefit the application brings and can be tested it will improve the implementation of the use of “Remaja Sehat” applications.

The students feel the relative advantages and trialability can be seen more in the use of “Remaja Sehat” applications rather than the complexity, compatibility, and observability. The more students feel the benefit the application brings and have been tested, the more they decide and implement or vice versa if the students feel unprofitable in use of the application or not tested and reduce the students’ trust then the students will rethink of implementing the use of “Remaja Sehat” applications.

**Recommendation**

The next researcher is suggested to intervene using enough time to intervene so that the purpose of monitoring and can see the implementation well also the decisions in the use of “Remaja Sehat” application.

Clinical Study of Optic Neuropathies

Rohini Sangoram1, V.H.Karambelkar2, B.S.Joshi3

1Resident, 2Professor and Head of Department, M.S., 3Associate Professor, M.S., DNB, Department of Ophthalmology, Krishna Institute of Medical Sciences To Be Deemed University, Karad, Maharashtra, India

Abstract

Introduction: Optic neuropathy is a frequent cause of vision loss encountered by ophthalmologist. The diagnosis is made on clinical grounds. The history often points to the possible etiology of the optic neuropathy. A rapid onset is typical of demyelinating, inflammatory, ischemic and traumatic causes. A gradual course points to compressive, toxic/nutritional and hereditary causes. The classic clinical signs of optic neuropathy are visual field defect, dyschromatopsia, and abnormal papillary response. Study objectives were to study etiological factors causing optic neuropathies.

Materials and Method: This analytical study was performed in Krishna Medical College Hospital, Karad for a period of months. The initial examination was started with anterior segment examination on slit lamp and fundus examination with direct ophthalmoscope. The material for the present study consists of 65 optic neuropathy patients during the 18 months period from November 2017 to May 2019.

Results: During this study, in Krishna Hospital karad we noticed that glaucomatous optic neuropathy is the most common type of optic neuropathy and traumatic optic neuropathy is the second most type.

Conclusion: Glaucoma being frequent cause of vision loss , is unfortunately not diagnosed at early stage and as age advances the risk of glaucoma increases also hypertension is one of the risk factors, so routinely every patient >40 years of age is to be assessed for glaucoma by noting optic disc changes and intra ocular pressure. If necessary Dynamic Perimetry is to be done for further evaluation.

Keyword: Optic neuropathy, Dyschromatopsia, Glaucoma, Glaucotuotous optic neuropathy, Traumatic optic neuropathy, Dynamic perimetry.

Introduction

Optic neuropathy is one of the common causes vision loss encountered by the ophthalmologist. The diagnosis is mainly on clinical grounds. The history often points to the possible etiology of the optic neuropathy. Optic nerve damage from any cause is called as Optic neuropathy. Damage or death of the nerve fibres, Leads to the characteristic features of optic neuropathy. Posterior or Retrobulbar optic neuropathies are associated acutely with a normal optic disc appearance. Anterior optic neuropathies are those with the swelling of optic nerve head. In almost all cases, at the end of 4 to 6 weeks after the onset of damage or visual loss, optic disc becomes pale, even when vision recovers and is referred as ‘Optic atrophy’.

A rapid onset is typical seen in demyelinating, inflammatory, ischemic and traumatic causes. A gradual course of disease is suggestive of compressive, toxic/nutritional and hereditary causes. The classic clinical signs of optic neuropathy are decreased vision , dyschromatopsia, abnormal pupillary Response and visual field defect.

There are ancillary investigations that can support the of optic neuropathy diagnosis. Visual field testing by either manual kinetic or automated static perimetry is very important in the diagnosis. In optic neuropathies like demyelinating and compressive type, it is essential
to do neuro-imaging of the brain and orbit.

**Materials and Method**

A cross sectional case study on the optic neuropathies and a study on the recent classification of Optic neuropathies depending on the etiological factors was conducted in the department of Ophthalmology, Krishna hospital, Karad.

**Source of data**- All eligible optic neuropathies patients according to inclusion criteria, presented to the OPD at Krishna Hospital during November 2017 to May 2019 were included in the study.

Sample size : 65 cases

**Inclusion criteria:**

All cases of optic neuropathies

**Exclusion criteria:**

- Paediatric cases
- Unconscious patients
- Optic neuropathies in mentally retarded patients

**Ocular examination included**

- Anterior segment examination: Slit lamp biomicroscopy.
- Pupillary reaction : RAPD.
- Posterior segment examination: Direct ophthalmoscope.
  - Indirect ophthalmoscope.
- Perimetry.

**Results**

There were 46 males (70.77%) and 19 females (29.23%) out of 65 participants in our study. The most common age group in our study was 61-70 years with 19 patients (29.23%), followed by 51-60 years with 13 patients (20.00%), 71-80 years with 12 patients (18.46%), 41-50 years with 10 patients (15.38%), 31-40 years with 6 patients (9.23%), 21-30 years with 3 patients (4.62%) and 81-90 years with 2 patients (3.08%).

Majority of the patients, 44 out of total 65 (67.69%) did not have any systemic disease. 11 patients (16.92%) had hypertension, 6 patients (9.23%) had both diabetes and hypertension while rest 4 patients (6.15%) had only diabetes.

</table>
The most common visual field defect was arcuate/ double arcuate vision seen in 14 patients (35.90%), followed by various scotomas seen in 12 patients (30.77%), tubular vision in 10 patients (25.64%).

2) TOXIC/ NUTRITIONAL OPTIC NEUROPATHY

Out of total 7 eyes with visual field defects in Toxic/ nutritional optic neuropathy, 5 were Centrocecal (71.43%), one eye each had Arcuate/Double Arcuate defect and various scotoma.

3) RETINITIS PIGMENTOSA

Out of 8 patients having Retinitis pigmentosa, 6 had peripheral constriction

4) POST PAPILLOEDEMA OPTIC ATROPHY

All 3 eyes out of 4 (75%) of post papilloedema optic atrophy have visual field defect of type ‘Enlargement of Blind spot’.

5) OPTIC NEURITIS

3 out of 4 eyes (75%) with optic neuritis had field defects. Each eye showed visual field defect Arcuate/ double arcuate scotoma, centro cecal and various scotoma.

6) DIABETIC PAPILLOPATHY

Both eyes of diabetic papillopathy had field defects of type ‘Peripheral constriction’

7) COMPRESSIVE OPTIC NEUROPATHY

Two eyes each had bi-temporal visual field defect and pie on floor defect in compressive optic neuropathy

8) NON ARTERITIC ISCHEMIC OPTIC NEUROPATHY (NAION)

Two eyes with Non-arteritic ischemic optic neuropathy (NAION) have field defect of type ‘Altitudinal defect’.

$X^2 = 36.13, \ p < 0.0001$ – highly significant

Highly significant association was seen between the type of field defects in glaucoma and other diseases ($p < 0.0001$), where 36 out of total 42 field defects (85.71%) seen in glaucoma were either Tubular vision / Arcuate/ Double arcuate / various scotomas as compared to the majority of the other optic neuropathies contributing to 23 out of total 26 (88.46%) field defects in other categories. This shows that the field defects in glaucoma were either Tubular vision / Arcuate/ Double arcuate / various scotomas which were significantly higher than other field defects seen in other optic neuropathies.

**Discussion**

The present cross-sectional study was conducted on total 65 patients with optic neuropathies. The data was collected from patients regarding demographic profile, detailed history, detailed ophthalmologic examination and relevant investigations like G1 Dynamic Octopus perimetry in all the patients with good fixation.

The analysis of study data obtained showed that out of 65, 46 were males (70.77%) and 19 were females (29.23%). Most common age group in our study was 61-70 years with 19 patients with a range of 26-82 years.

When we considered systemic diseases like Hypertension, Diabetes and optic neuropathies, it was noted that individual Hypertension is associated in 11 cases(16.9%), Diabetes in 4 cases(6.2%) and combined hypertension and diabetes in 6 cases (9.2%). Both the patients of Non Arteritic AION had history of Hypertension and in studies like Tsai et al(1998)$^1$; McCulley et al(2005)$^2$ have shown that hypertension is one of the risk factors for developing NAION in patients with the age above 50 years.

Majority of the patients, 59 out of total 65 (90.77%) had RAPD in any of the eyes which is suggestive of unilateral or asymmetrical optic neuropathy. Rest 6 cases were of almost symmetrical optic neuropathy or bilateral optic atrophy cases. Majority of the patients, 36 out of 65 (55.38%) were having glaucomatous optic neuropathy which is found to be the most common type.

In our study all cases of toxic optic neuropathy had addiction history of tobacco and alcohol of more that 15 to 20 years of duration. In studies like Behbehani R et al(2007)$^3$ and Foulds WS et al(1974)$^4$ it has been discussed that addiction of tobacco and alcohol is major risk factor for developing Optic neuropathies especially Toxic/ Nutritional optic neuropathies.

In our study, 8 patients with glaucoma had hypertension (22.22%), 5 had both diabetes & hypertension (13.90%) and 3 had only diabetes (8.3%) \.While some studies like P. Mitchell et al(1996)$^5$, L. Bonomi et al(2000)$^6$, N. Orzalesi et al(2007)$^7$ reported that systemic hypertension is a risk factor for glaucoma.

In Glaucoma patients ,when the comparision of vision and cup disc ratio was done separately in right eye and left eye , it was found significant association between the vision & CDR of RE ($p < 0.001$) in glaucoma patients as well as there was significant association between the vision & CDR of LE ($p < 0.001$) in glaucoma patients.

Out of 130 eyes of 65 cases , in 93 eyes perimetry was done and in rest 37 eyes perimetry was not done because of low vision and loss of fixation. Total 81 eyes showed visual field defect out of 93 eyes.

Visual field defect types in glaucoma: The most common visual field defect was arcuate / double arcuate vision seen in 13 patients (33.33%), followed by various scotomas seen in 12 patients (30.77%), tubular vision in 10 patients (25.64%). Similar things has been showed in Kedar et al(2011)$^8$, that Arcuate scotoma is caused by lesions to the retinal nerve fibres or to the ganglion cells in superior or inferior arcuate nerve fibre bundles. Glaucoma is the most frequent cause of an arcuate scotoma.
Out of total 7 field defects in Toxic/ nutritional optic neuropathy, 5 were Centroccecal (71.43%), one eye each had Arcuate/Double Arcuate defect and various scotoma. Central, cecocentral visual field defects in Toxic/nutritional optic neuropathy were also seen by Behbehani R et al(2007)³ in their study. In Forsek I et al(2016)⁴ showed that Cecocentral scotomas are frequently associated with nutritional/toxic optic neuropathies and commonly present bilaterally.

3 out of 4 eyes (75%) with optic neuritis had field defects. Each eye showed visual field defect Arcuate/ double arcuate scotoma, centro cecal and various scotoma.

In study Behbehani R et al(2007)³ it has been discussed that usually a central scotoma is brought on by a lesion in the papillomacular bundle or fovea and lesions responsible for this type of defect are Leber’s hereditary mitochondrial optic neuropathy (LHON), toxic-nutritional optic neuropathies, vascular lesions, multiple sclerosis, glaucoma, and optic neuritis.

In compressive optic neuropathy, we found 2 eyes of pituitary macroadenoma had bi temporal visual field defect and in case of craniopharyngeoma (two eyes) there was Pie on the floor type of field defect. In study T J Walsh et al(1985), it has been discussed that hemianopic defects can arise from a variety of causes, some of which are: lesions to the optic tract, tumors, trauma and lesions at the visual cortex in the occipital lobe. T J Walsh et al(1985) and Behbehani R et al(2007)³ observed arcuate and hemianoptic type of field...
defects in patients of compressive optic neuropathy.

Out of 8 patients having retinitis pigmentosa, 6 had peripheral constriction (75%) and 2 patients had tunnel vision (25%). All 3 eyes out of 4 (75%) of post papilloedema optic atrophy have field defect of type 'Enlargement of Blind spot'.

Behbehani R et al (2007) also explained that the hemianopic field defect which respect the vertical midline indicate the lesion at or posterior to chiasma and a junctional scotoma, known as the ipsilateral nasal half field defect and the contralateral temporal half field defect is suggestive of lesion compressing at the junction of optic nerve and chiasm.

In our study, highly significant association was seen between the type of field defects in glaucoma and other diseases (p < 0.0001), where 35 out of total 41 field defects (85.37%) seen in glaucoma were either Tubular vision / Arcuate/ Double arcuate / various scotomas as compared to the majority of the other optic neuropathies contributing to the 23 out of total 27 (85.19%) field defects in other categories.

This shows that the field defects in glaucoma were either Tubular vision / Arcuate/ Double arcuate / various scotomas which were significantly higher than other field defects seen in other optic neuropathies.

Conclusion

In a clinical practice setting, it is not easy to find out the cause of optic neuropathy. In a variety of clinical conditions have visual loss which is accompanied by the color desaturation and RAPD is often present. In the last decade the spectrum of the optic neuropathies has expanded enormously. As we now know that optic neuropathies could be the initial presentation of a number of closely related diseases which require the early and accurate diagnosis for the treatment to be successful. A good detailed clinical history and examination supported by a judicial choice of investigations and knowledge of the different clinical conditions that result in the optic neuropathy allow us for a quick diagnosis as well as early intervention.

Among Optic neuropathies ,Glaucoma being most common and preventable cause of blindness the Glaucoma screening and awareness programmes to be conducted along with cataract evaluation.

Our hospital being situated near National highway, all most all Traumatic optic neuropathies were because of Road traffic accidents.

Glaucma being frequent cause of vision loss, is unfortunately not diagnosed at early stage and as age advances the risk of glaucoma increases also hypertension is one of the risk factors, so routinely every patient >40 years of age is to be assessed for glaucoma by noting optic disc changes and intra ocular pressure. If necessary Perimetry is to be done for further evaluation.

Ethical Approval: All procedures performed on human participants were in agreement with ethical standards of the Institutional and/or National Ethics Committee.

Source of Funding: In this project , the cost of investigations of the study participants was born by the institute research fundings.

Conflict of Interest: None

Abstract

Background: Gross motor and fine motor activities are important to achieve as it is important aspect for ADL activities. It is widely known that when trunk control is affected, gross and fine motor activity is also affected. For efficient distal movements, proximal stability should be sufficient i.e for hand usage, development of trunk stability and central axis control is one of the important prerequisites. Recent studies have showed that there is positive correlation between trunk control and upper extremity functions. There is paucity of literature available showing effect of gross motor and fine motor activities on trunk control in cerebral palsy children, hence this study would be helpful to analyse the same.

Objectives: Objective of this study was to find out the effect of gross motor and fine motor activities on trunk control, on hand function and also to find out the correlation between trunk control and hand function.

Methodology: There were total 35 subjects, out of which 21 subjects were participants of this study. This is a study of effect of gross motor and fine motor activities on trunk control in cerebral palsy children. Demographic data, assent and consent was taken from the child and his/her parents, respectively. Pre and post assessment was taken on the basis of Gross Motor Function Classification System for Cerebral Palsy, Manual Ability Classification System and Trunk Control Assessment before and after 6 weeks (total 16 sessions) of the treatment respectively. Each session was of 45 mins. Later evaluation and interpretation of data was done.

Result: The 9.1% improvement is seen in pre and post treatment GMFCS, 18% improvement is seen in pre and post treatment MACS and 16.2% improvement is seen in pre and post treatment TCMS.

Conclusion: There is significant effect of gross motor and fine motor exercises on trunk control in subjects with spastic cerebral palsy.

Keywords: spastic cerebral palsy, gross motor and fine motor, hand function, trunk control, physiotherapy.

Introduction

Cerebral palsy is defined as non progressive disorders which restricts activities in developing foetus or infant brain. The most prevalent form of physical disability is cerebral palsy in children¹. Cerebral palsy can result from brain injury occurring during the prenatal, perinatal or postnatal periods, because brain development continues during the first two years of life². Sensory, cognitive, communication, behavioural and perceptional problems, with epilepsy and other seconday musculoskeletal system problems are seen along with the motor disorders in cerebral palsy. Inability to use movement control for balance and also inability to use the hands for reaching and manipulation in day to day activities is one of the

romitashah108@gmail.com
major problem in cerebral palsy children\textsuperscript{3}. The ability to maintain centre of gravity within the base of support, without affecting the balance can be defined as postural control. The trunk plays a crucial role because it maintains centre of all body mass and therefore centre of gravity, as it organizes postural control and balance reactions\textsuperscript{4}.

For efficient distal movements, proximal stability should be sufficient i.e for hand usage, development of trunk stability and central axis control is one of the important prerequisites\textsuperscript{1,9}. In children with cerebral palsy, brain lesions will affect hand functioning, making it difficult for them to perform many manual activities. Hand functioning requires integrity of the central nervous system, which may be altered by different brain disorders. Hand function is impaired due to increased or varying muscle tone leading to imbalance and sometimes even contractures. Hand function includes different components such as gripping and releasing objects, reach, speed and accuracy, grip strength and sensations\textsuperscript{5}. Arm hand dysfunction is present in almost 50\% of cerebral palsy children. The hand and its components i.e muscles, joints, and bone, and also several body functions i.e muscle strength, control of rapid co-ordinated movements, sensations and stereognosis may be affected in cerebral palsy children\textsuperscript{3}.

Skills are divided into two groups such as gross motor and fine motor skills. Manipulation of large objects controlled with arm and hands movements are often included in gross manual motor skills, whereas manipulation of smaller objects controlled with hand and fingers are included in fine motor skills. For daily life activities and overall functioning, fine motor skills are necessary\textsuperscript{7,9}.

In cerebral palsy children, gross motor dysfunction is the primary problem\textsuperscript{8}. For various activities of daily life, arm movements such as reaching and grasping are very essential\textsuperscript{6}.

Fine motor skill is dependent upon the development of gross motor skills. For many day to day activities such as dressing, feeding, holding objects, cutting, etc their development is necessary. Children have less control over the movements and almost all the movements are dominated by primitive reflexes at the time of birth. Reflexes disappear and are replaced by sophisticated intentional movements as the development takes place, and are controlled by the brain. Children should have ability to pinch and grasp little objects between the fingers, at the end of first year of life\textsuperscript{9}.

It is especially important for the children having motor problems to use their hands to support themselves in activities like sitting, standing, and walking, or during transfer activities. They also have difficulty in coordinating their fingers while gripping and releasing their grip. The ability to perform and participate in day to day activities needs proper upper extremity functioning. There is a strong positive correlation between trunk control and upper extremity in cerebral palsy children. Hence, it is important to understand the effect of gross motor and fine motor activity training on trunk control in cerebral palsy children\textsuperscript{1}.

**Methodology**

Total 35 subjects were approached in Krishna college of physiotherapy and out of them only 21 subjects were selected for the study according to the inclusion and exclusion criteria. Inclusion criteria were age group between 6-12 years, have a diagnosis of cerebral palsy and GMFCS level 3 and 4 and the exclusion criteria were previous surgery or pain in the upper limbs, vision and hearing problems, Cardio- respiratory problems and previous BoNT-A injections in the upper limbs. Demographic data and assent and consent form was taken from the child and his/her parents, respectively. Pre and post assessment was taken on the basis of Gross Motor Function Classification System for Cerebral Palsy, Manual Ability Classification System and Trunk Control Assessment before and after 6 weeks (total 16 sessions) of the treatment respectively. Each session was of 45 mins\textsuperscript{6,11,12,13}.

Exercise protocol was started with warm up exercises i.e stretching for wrist flexors, followed by somato-sensory stimuli (finding objects in beans, rice or sand, pulling piece of clay off a ball of clay, pushing fingers into clay, stretching rubber bands around finger), then gross motor activities (objects of different shapes like rectangular and circular, with different texture like rough and smooth, and also heavy or light in weight), and then fine motor activities (ADL activities, picking up buttons, wooden beads, marbles, hold thick crayons or thick chalk, pencils and scribble on paper and also begin screwing action)\textsuperscript{10,15}.

**Statistical Analysis**

Statistical analysis of the recorded data was done by
using the software SPSS version 20. The paired T-test and one way ANOVA test were used for analysis of data.

Interpretation: In this study, pre interventional Mean±SD was 7.810±1.078 for static sitting balance, Mean±SD was 5.952±0.9735 for dynamic sitting balance, Mean±SD was 4.524±0.8136 for Dynamic reaching balance and Mean±SD was 18.286±1.056 for total score. Post-interventional Mean±SD was 9.048±1.431 for Static sitting balance, Mean±SD was 6.905±1.70 for Dynamic sitting balance, Mean±SD was 5.571±1.248 for Dynamic reaching balance and Mean±SD was 21.286±3.379 for Total score. 16.2% improvement is seen in pre and post TCMS.

Discussion

Cerebral palsy is defined as non progressive disorders and it is the most prevalent form of physical disability in children. Cerebral palsy can result from brain injury occurring during the prenatal, perinatal or postnatal periods, because brain development continues during the first two years of life. Inability to use movement control for balance and also inability to use the hands for reaching and manipulation in day to day activities is one of the major problem in cerebral palsy children. The ability to maintain centre of gravity within the base of support, without affecting the balance can be defined as postural control. The trunk plays a crucial role because it maintains centre of all body mass and therefore centre of gravity, as it organizes postural control and balance reactions.

This research was undertaken with the aim to study the effect of gross motor and fine motor exercises on trunk control in subjects with spastic cerebral palsy.

The study was carried out and the result was drawn by Gross Motor Function Classification System, Manual Ability Classification System, Trunk Control Measurement Scale and NPRS.

An approval for the study was obtained from the Protocol committee and the Institutional Ethical Committee of KIMSDU. Total 35 subjects were approached in Krishna college of physiotherapy and out of them only 21 subjects were selected for the study who fulfilled inclusion criteria. The procedure was explained and consent was taken from those willing to participate and written assent was taken from caregivers.

Demographic data of the subjects was taken. The individuals were explained about the purpose of the study. Also, they were informed about the procedure. Subjects were selected for the study according to the inclusion and exclusion criteria using convenience sampling method. Demographic data and assent and consent form was taken from the child and his/her parents, respectively. Pre and post assessment was taken on the basis of of Gross Motor Function Classification System for Cerebral Palsy, Manual Ability Classification System and Trunk Control Assessment before and after 6 weeks (total 16 sessions) of the treatment respectively.
Each session was of 45 mins.

Exercise protocol was started with warm up exercises i.e stretching for wrist flexors, followed by somato-sensory stimuli (finding objects in beans, rice or sand, pulling piece of clay off a ball of clay, pushing fingers into clay, stretching rubber bands around finger), then gross motor activities (objects of different shapes like rectangular and circular, with different texture like rough and smooth, and also heavy or light in weight), and then fine motor activities (ADL activities, picking up buttons, wooden beads, marbles, hold thick crayons or thick chalk, pencils and scribble on paper and also begin screwing action).

It was found that among 21 subjects, 57% subjects belonged to 6-8 years of age group and remaining 43% belonged to 9-12 years of age group. In age group 6-8 years, there were total 12 subjects out of which 5 were males and 7 were females. In age group 9-12 years, total 9 subjects were there, out of which 5 were males and 4 were females.

Among 21 subjects, 7(33%) subjects showed changes in their level of Gross motor function classification system and remaining 14(67%) subjects showed no change in their level. In the present study pre interventional mean and standard deviation of GMFCS was 3.571±0.5071, whereas post-interventional mean ± SD was 3.238±0.6249. It concluded that interference was considered significant (p=0.0156). This was calculated by Wilcoxon test (W=28.00).

In total 21 subjects, 14(67%) individuals showed changes in their level of manual ability classification system, whereas remaining 7(33%) individuals showed no change in their level. In the present study pre interventional mean and standard deviation of MACS was 3.667±0.7303, whereas post- interventional mean ± SD was 3.0±0.8367. It concluded that p value was 0.0001 and interference was considered extremely significant. This was calculated by Wilcoxon test (W=105.00).

Out of 100%, 57%(12 subjects) had changes in their trunk control measurement scale and remaining 43% (9 subjects) had no changes in their scoring. In this study, pre interventional Mean±SD was 7.810±1.078 for static sitting balance, Mean±SD was 5.952±0.9735 for dynamic sitting balance, Mean±SD was 4.524±0.8136 for dynamic reaching balance and Mean±SD was 18.286±1.056 for total score. Post-interventional Mean±SD was 9.048±1.431 for Static sitting balance, Mean±SD was 6.905±1.70 for Dynamic sitting balance, Mean±SD was 5.571±1.248 for Dynamic reaching balance and Mean±SD was 21.286±3.379 for Total score. It concluded that interference was considered extremely significant (p=0.0003).

Passive stretch is used to improve range of motion and also improves flexibility. Somato-sensory stimuli helps to activate or facilitate muscle motor response. Gross motor exercises are used to improve grasping and fine motor exercises are used to produce small precise movements.

It concluded that, 9.1% improvement is seen in pre and post treatment GMFCS, 18% improvement is seen in pre and post treatment MACS and 16.2% improvement is seen in pre and post treatment TCMS.

**Conclusion**

On the basis of the results of the study, it can be concluded that gross motor and fine motor exercise program is effective in improving trunk control in spastic cerebral palsy. Effect of gross motor and fine motor exercises on trunk control was found more within the age group 6-8 yrs as compared to 9-12 yrs.

**Conflicts of Interest:** There is no conflict of interests in this study.

**Ethical Clearance:** This study has undergone ethical clearance through the university level ethical committee of Krishna institute of medical sciences, deemed to be University, Karad. Protocol number 0101/2019-2020.

**Funding:** This study was funded by Krishna institute of medical sciences’ deemed to be’ university, karad. (Maharashtra).

Effect of Different Shoe Lacing Pattern on Different Types of Foot in Recreational Runners

Rushikesh Rajendra Mangale, Amrutkuvar Rayjade

1Intern, Faculty of Physiotherapy, KIMS “Deemed to Be University” Karad, Maharashtra, India, 2Associate Professor of Department of Musculoskeletal Sciences, Faculty of Physiotherapy, KIMS “Deemed To Be University” Karad, Maharashtra, India

Abstract

Background: There has been an increase in the overall prevalence of obesity in India. There has been a 26% rise in the obesity among the young adults of India. At the same time, an awareness about fitness and health has also been on a rise in our country. Jogging and running have been on a rise in popularity among the youth of India. Heel-to-toe drop, styles of running, brand, fit and shoe lacing are some other factors that affect running. Out of these shoe lacing is one of the simplest factors to modify. It can be done by anybody and is an extremely cost effective measure.

Methodology: An experimental study is being conducted with a sample size of 33 subject in karad. The population under study is Recreational runners age group of 20-40 years both male and female subjects. VAS and Foot Posture Index were the outcome measures used.

Result: There was a significant effect of modifying shoe lacing patterns on FFI scores. (p=<0.001) There was also a significant effect on FPS (p <0.001) and FDS (p <0.001) subscales whereas there was no significant effect on ALS subscale (p >0.05). A significant decrease in pain was also noted. (p <0.05)

Conclusion On the basis of the results of the study, it was concluded that there was a significant effect of modifying shoe lacing patterns on amateur runners.

Keywords: Amateur, Runners, shoe lace, foot type

Introduction

There has been an increase in the overall prevalence of obesity in India.1 There has been a 26% rise in the obesity among the young adults of India.2 At the same time, an awareness about fitness and health has also been on a rise in our country.3 The number of fitness centres and health awareness programs have in turn increased as well.4 However, not everybody has the means necessary to avail the benefits of these facilities.

Jogging, on the other hand, does not require any form of equipment except for a pair of shoes. This makes it easily accessible to a large portion of our population. Thus, jogging and running have been on a rise in popularity among the youth of India.5

Choosing the perfect shoe is dependent on many factors other than the size or brand of the shoe.6,7 It is very important to first assess the type of your foot i.e. the anatomical basis of the foot. There are mainly 3 types of foot; Pronated foot, Neutral foot and Supinated foot.8

The pronated foot is characterized by a very low or flat arch, the supinated foot has a very high and rigid arch and the neutral foot is between the pronated and the supinated type. It is the most common type of foot.8

Normally, while running the foot lands on the heel first and the rolls forward, until the impact is distributed evenly across the forefoot.9 The neutral foot follows this same pattern while the pronated foot rolls inwards and the supinated foot restricts the impact of the stride largely to the outer edges of the foot.

Heel-to-toe drop, styles of running, brand, fit and shoe lacing are some other factors that are also considered. Out of these shoe lacing is one of the
simplest factors to modify.\textsuperscript{10,11} It can be done by anybody and is an extremely cost effective measure. Using the right lacing technique and proper knots will significantly improve the individuals running. Despite being a minor issue, getting the lacing perfectly will make a big difference in the overall support and comfort of the shoes. It can alleviate pain, prevent injuries and relive foot problems.\textsuperscript{12}

However, it is often left out and forgotten by most. There is a vast variety of shoe lacing patterns that are available. They are categorized based on the types of foot and the type of running performed by the individual. The conventional method of lacing is the crisscross to the top of the shoe, which works best for the majority of people.\textsuperscript{13}

Many modifications exist, such as in heel slippage, if your heel slips too much or you need a little more toe room, a lace lock can be made at the top of the shoe. This will pull the foot back into the heel of the shoe and help stop the slippage for a more comfortable fit.

In a supinated foot, the shoe generally fails to provide enough volume for the foot to fit. Thus, a more spread out pattern of lacing increases the available space for the foot to move. In a pronated foot, the exact opposite occurs. There is more space in the shoe compared to the size of the foot which causes the foot to slide around too much inside the shoe. Here, a more snug pattern of lacing is used to avoid this problem.\textsuperscript{13,14}

To assess the effect of these lacing pattern we used the Foot Function Index(FFI). It is a self-administered index consisting of 23 items divided into 3 subscales which helps measure impact of foot pathology on function in terms of pain, disability and activity restriction.\textsuperscript{15} Both sub-scale scores and total scores are calculated. Test-retest reliability of the FFI total and subscale scores ranges from 0.87 to 0.69.\textsuperscript{16}

Visual Analogue Scale (VAS) was also used to assess the amount of pain and discomfort experienced by the runners. VAS was used before and after administration of the treatment to determine the difference in the individual’s pain. VAS is sufficiently reliable to be used to assess acute pain.\textsuperscript{17}

Provision of guidance regarding something as simple as tying a shoelace may prove to be effective in improving the individuals performance and reducing their risk of injury and pain at the same time. According to our knowledge, few studies have been performed to assess the effect of lacing in non-professional runners. Thus, it is important to conduct this study to improve the knowledge of the common man and provide them with better dynamics or running.

**Methodology:** The ethical clearance was taken from the institutional ethical committee of KIMSDTBU, Karad. An experimental study was conducted with a sample size of 33 subject in karad. The population under study is Recreational runners age group of 20-40 years both male and female subjects. The material used in this study include foot posture index, goniometer data collection sheet and consent form. VAS pain scale and Foot Posture Index are the outcome measure that are going to be used. The subject will pre and post assessment can taken. The data will be collected and analysed.

Discussion

The aim of this study was to study and find the effectiveness of various shoe lacing patterns in amateur runners. The objectives of this study were to determine the effect of administration of shoe lacing patterns according to their foot type on their performance and foot pain. An effort to find the association between the effects of shoe lacing patterns on runners before and after its administration was made.

In this study, 40 individuals who ran for recreation were taken. Individuals in the age group of 20-40 years were included in this study, out of which 34 (85%) individuals were in the (20-24) age group and 6 (15%) individuals were in the (25-30) age group.

The reason behind such a significant discrepancy in the distribution of age groups may be due to the fact that generally the young adults between the ages of 20-24 years are more conscious about their health and appearance thus leading to an increase in their interest in running. Whereas, those between the ages of 25-30 years normally belong to the working class and seldom get time or have the motivation to run.

They were also divided according to their gender. Out of the total 40 runners, 26 (65%) were male and remaining 14 (15%) were female.

Our study is male dominant, maybe because the region included in our study is a rural-urban area where not many women are exposed to recreational activities. Thus, the female population engaging in running as a hobby/ recreational activity is less compared to the males.

Their foot type was also classified. 7 (17.50%) runners had a high arch or a supinated foot, 18 (45%) runners had a neutral arch or a normal type of foot and 15 (37.50%) runners had a low arch or a pronated type of foot out of the total of 40 runners.

Pain score according to Visual Analogue Scale (VAS) and Foot Function Index score of subjects of both the groups were taken before the treatment/intervention was given.

The mean pain score measurements prior to the intervention was 6.53 and after the intervention was 3.93. Statistical analysis of the pain score before and after intervention was done. The comparison for pre and post pain scores was found to have a p-value of (<0.05) which was significant.

The reason behind such a significant difference between the pre and post scores may be due to the fortifying effect of the shoe lacing patterns which reinforce the movement of the foot within the shoes. This in turn improves comfort and also reduces the risk of the foot being injured while running due to slippage. Thus, there is an overall increase in comfort and reduction in pain.

To analyse the impact of foot pathology on function in terms of pain, disability and activity restriction of foot was done by using the Foot Function Index (FFI). It is divided into 3 subscales viz; Foot Pain subscale (FPS), Foot Disability subscale (FDS) and Activity Limitation subscale (ALS) which consists of 23 items. Same as Pain score, measures of FFI were taken before and after the treatment. The mean score of FFI pre intervention according to the FPS was 35.3, FDS was 51.80 and ALS was 5.13, and post intervention, FPS was 15.50, FDS was 26.82 and ALS was 5.05. Here, the difference in scores of FDS was found to be more among the three subscales. Statistical analysis was done to compare the mean pre and post intervention scores of Foot Function Index subscales to confirm whether they were significant or not and FDS was found to have a p-value of (<0.001) which was very significant, FPS had a p-value of (<0.001) which was very significant and ALS had a p-value of (>0.05) which was not significant.

We have already seen that there was a significant reduction in pain thus in relation to that the FPS scores also have a significant reduction in them. Here, the difference in scores of FDS was found to be more among the three subscales. This may be due to the disability subscale consisting of questions related to activities of daily living such as walking, climbing and descending stairs, getting up from a chair etc. All of these activities involves use of the foot dynamically thus aggravating pain. Hence, the scores already were very high for FDS and due to that a very significant difference can be seen in the score post treatment. ALS did not have any significant change in their scores maybe due to the fact that it involved questions which were relevant only when the pain and disability were extremely high and in our study the participants did not have a high pain score to begin with.

The mean scores of pre and post intervention of FFI were 42.51 and 23.40 respectively. Statistical analysis
was done to compare the mean pre and post intervention scores of Foot Function Index to confirm whether they were significant or not and was found to have a p-value of (<0.001) which was very significant.

According to Hagan & Hennig, 2009 and Hagan et al., 2008, lacing variations can improve shoe fit-to-foot, optimize biomechanical assistive components of footwear, and influence perceived comfort and stability without affecting mass of the shoe. They also concluded that the amount of motion of the foot in a shoe can alter biomechanical efficiency and perceived comfort. The results of these studies also show that foot movement in heel–toe running is influenced by the lacing pattern of the shoe. Therefore, shoe lacing has to be considered when undertaking biomechanical comparisons of running shoes.9,10

Another study by Hong et al., 2011 also had similar findings in their research where they studied changes in running mechanics using conventional shoelace versus elastic shoe cover.18

Thus, it can be said that modifying the shoe lacing patterns in recreational runners has a significant impact on their performance as well as on the prevention of injuries and reduction of pain. This small modification will in turn encourage the runners to participate more and will give them the ability to modify their shoes by themselves. It will also improve the specificity of the fit of the shoe as it can be changed according to the individual needs of the runners.

Conclusion

On the basis of the results of the study, it was concluded that there is a significant effect of modifying shoe lacing patterns on amateur runners. The effect was most profound on foot disability, then on foot pain and the least on activity limitation. The pain score of individuals who had undergone shoe lacing modification was significantly lower compared to the pre intervention pain score.

Abstract

Background: Seventy five per cent of patients who outlive stroke have inadequacies whilst walking and the hemiparetic gait is the most prevalent form of walking. The asymmetric pattern of walking is most commonly seen in hemiparetic gait.

Aim and Objectives: To find the effectiveness of gluteus maximus strengthening on gait in patients with hemiparesis.

Materials and Method: The hemiparetic patients were assessed for the MMT and gait, prior to the treatment. The muscle strength and gait was assessed by Manual Muscle Testing and objective method respectively. Subjects signed the consent form then total number of three exercises were given-i) Standing leg lifts with trunk supported, ii) Quadruped leg lifts, iii) Standing extension. Statistical analysis was done once the data was collected.

Results: In this study the gluteus maximus strengthening had effect on the gait of the hemiparetic individuals. The gait parameters taken in this study step length, step width, stride length, cadence and speed significantly increase after the treatment.

Conclusion: On the basis of the result of this study, it was concluded that the strengthening of gluteus maximus muscle has effect on gait in patients with hemiparesis. The gait parameters taken in this study such as step length, step width, stride length, cadence and speed has increase in the averaged values before and after treatment.

Keywords: Gluteus Maximus, Strengthening, hemiparesis, Stroke, Gait.

Introduction

Weakness of muscle usually occurring after stoke is referred as paresis. Patients are generally unable to generate the force which is necessary to initiate and control the movement (¹). The word ‘hemi’ means ‘one side’ while ‘paresis’ means ‘weakness’ so hemiparesis denotes the weakness of the one side of the body. (²)

World Health Organization defines stroke as ‘rapidly developed clinical sign of focal disturbance of cerebral function of presumed vascular origin and of more than 24 hours’ duration’. Ischemic stroke, one of the types of stroke, is due to occlusion or atheroma or emboli in the artery. This type of stroke shows symptoms of headache, hemiparesis or dysphasia. The other type, Hemorrhagic stroke is usually due to hypertension which causes lipohyalinosis in the small penetrating arteries in the brain. The symptoms are severe headache, vomiting, and

loss of consciousness.\(^{(3)}\)

Gluteus Maximus is the largest muscle of the body situated superficially. It originates from outer slope of the dorsal segment of iliac crest and posterior gluteal line and dorsal surface of lower part of sacrum and it’s deep fibers are inserted on the gluteal tuberosity and the greater part of the muscle is inserted into the iliotibial tract.\(^{(4)}\) This important muscle is different in its characteristics with other primates as a result of progression in postural alteration from quadrupeds to bipeds. First and foremost it serves the hip extension and lateral rotation because of its attachment. Gluteus maximus has a major function in pelvis stability. This muscle carries out many daily activities like lifting, walking, running.\(^{(5)}\) The studies has shown that more importance should be employed on contraction in the course of early phase of the lift to provide pelvic stability which will enable a secure and well-organized movement to occur.\(^{(5)}\)

Seventy five per cent of patients who outlive stroke have inadequacies whilst walking and the hemiparetic gait is the most prevalent form of walking.\(^{(6)}\)

**Gait**

The period from heel strike of one extremity to heel strike of same extremity is described as gait cycle and includes a stance and swing phase.\(^{(7)}\) Gait includes Time and distance variable. Temporal variable include stance time, single-limb and double limb support time, swing time, stride and step time, cadence and speed. The distance variables include stride length, step length, width, and degree of toe out.\(^{(8)}\)

**Gluteus Maximus in Gait**

A basic understanding of a role of gluteus maximus is mandatory as a complete discussion on muscles contributing throughout the gait cycle fall outside the scope of this topic. The flexor moment during the loading response is coordinated by the hip extensor muscles, and the hip extension is initiated by the gluteus maximus muscle. A posterior lurch of the trunk occurs at foot contact with loss of extensor function to shift the centre of the gravity of the trunk, posterior to the hip.\(^{(9)}\)

**Gait Alterations in Hemiparesis**

The gait after stroke is mostly considered as decelerated at speed of walking.\(^{(10)}\) The symptoms such as contralateral motor weakness, motor control deficits, sensory and/or proprioceptive loss, and/or ataxia associated with the asymmetric pattern of walking are most commonly seen in hemiparetic gait.\(^{(11)}\)

**SPATIOTEMPORAL PARAMETERS**

The distance taken to complete one gait cycle is referred as stride length. The distance between heel strike of an ipsilateral limb to heel strike of the contralateral limb step length. The number of steps per unit time (minute) is defined as cadence. The distance per unit time is referred as walking speed and, is the most important interpreter of ambulation status after stroke. In hemiparetic individuals the walking velocity, stride length, step length, cadence, single-stance duration and stance duration is decreased while double-stance duration and swing duration is increased.\(^{(11)}\)

So the paucity in the literature regarding this field denotes the need to study.

**Methodology**

Prior to the commencement of the study the ethical clearance was taken from the Institutional ethical committee. The purpose of this study is to find the effectiveness of gluteus maximus strengthening on gait in hemiparetic patients.

Individuals with hemiparesis were selected as per inclusion and exclusion. The informed consent was taken from the subjects. The sample size for this study was 40. Prior to the treatment the pre-treatment assessment of the muscle strength and gait was assessed by Manual Muscle Testing and objective method respectively. To assess the muscle strength of the gluteus maximus muscle the subjects were asked to do side lying position on plinth with testing limb superior to the other limb. Once the patient acquires suitable position, patient is asked to extend the hip. The gait assessment was executed by a 10m pathway which was covered with white cardboard for every subject. The participants were asked to put their foot in coloured talcum which as kept in a tray. Then subjects were instructed to walk in their normal way along the pathway. Then cardboard was preserved for foot print analysis.

Then detailed instructions were given to the participants about treatment protocol. Total number of three exercises were given out of which first was standing leg lifts with trunk supported in which the patients stands on the edge of the plinth with trunk supported on the table. Then patient is asked to extend both the hips one
by one. In the second exercise, Quadruped Leg Lifts, the patient acquires quadruped position. Then patient is asked to perform alternate hip extension while keeping the knee flexed. The third exercise is standing extension. In this the patient position is single leg stance and patient is directed to extend the opposite hip. Patient was instructed to perform these exercises two times per day for 6 weeks.

After treatment the post-treatment assessment of manual muscle testing and gait were done. Then derived values were entered in the master chart and the collected data was sent for the statistical analysis.

**STATISTICAL ANALYSIS AND INTERPRITATION:**

**Table 1. MMT of Gluteus Maximus Muscle before and After Treatment**

<table>
<thead>
<tr>
<th>MMT of Gluteus Maximus Muscle</th>
<th>Mean</th>
<th>SD</th>
<th>Paired t-value</th>
<th>p-value</th>
<th>95% CI</th>

</tbody>
</table>

Result

The above table revealed effectiveness of strengthening program on speed of the gait. In this study the speed parameter had paired t value and 95% confidence interval ranging -2.290 to -1.710 respectively. Therefore it is proved that there is extreme significance with p value <0.0001.

Results

In this study the gluteus maximus strengthening had effect on the gait of the hemiparetic individuals. The gait parameters taken in this study step length, step width, stride length, cadence and speed significantly increase after the treatment.
Discussion

Seventy five per cent of patients who outlive stroke have inadequacies whilst walking and the hemiparetic gait is the most prevalent form of walking. The purpose of this study is to find the effectiveness of gluteus maximus strengthening on gait in hemiparetic patients.

Individuals with hemiparesis were selected as per inclusion and exclusion. The sample size for this study was 40. Demographic data including name, age, gender, address was collected .Prior to the treatment the pre-treatment assessment of the muscle strength and gait was assessed by Manual Muscle Testing and objective method respectively.

Then total number of three exercises were given -i) Standing leg lifts with trunk supported, ii) Quadruped Leg Lifts, iii) Standing extension. Patient was instructed to perform these exercises two times per day for 6 weeks.

After treatment the post- treatment assessment of manual muscle testing and gait were done. Then derived values were entered in the master chart and the collected data was sent for the statistical analysis.

In this study the statistical analysis of the recorded data was done by using the software SPSS version20. Arithmetic mean & standard deviation was calculated for each outcome measure. MS Excel was used for drawing various graphs with given frequencies and the various percentages that were calculated with the software.

Combined Task-Specific Training and Strengthening Effects On Locomotor Recovery Post-Stroke: A Case Study concluded that functional locomotor recovery was associated with increase in magnitude of the paretic leg gluteus maximus and gluteus medius activation during gait. Their study analysis confirmed an increase of hip and knee extension throughout stance and swing (12). Hence Outcome measure used in this study , Manual Muscle Testing, had positive effect of strengthening protocol with paired t value of 27.92 when the p-value <0.0001. The 95% confidence interval was -0.1072 to -0.9276.

The effect of strengthening exercises on biomechanical parameters of gait in chronic hemiparesis following stroke ,supported that the muscle strength training has a positive effective in improving gait patterns as well as velocity and stride length in the chronic stage of rehabilitation following stroke(13). In this study the paired t value and 95% confidence interval for this parameter was 13.79 and -1.290 to 0.09601 respectively. Here we obtained extreme statistical significance when the p-value was <0.0001.

The effect of step climbing exercise on balance and step length in chronic stroke patients, concluded that the step climbing exercise improved the muscle strength in the lower limbs of the stroke patients, as well as their timed Up and Go results and step lengths(14). The present study the step length parameter had the paired t value of 9.56 while the 95% confidence interval ranging from -1.636 to 1.064 .we had found the extreme significance with p-value <0.0001.

The effect of water exercise on gait characteristics in the elderly post- stroke patients” stated in the results of their study that there was significant increase in the gait velocity, step length & step width after the water exercises(15). For this parameter of gait, step width, the paired t value and 95% confidence interval was 8.832 and -1.229 to -0.7710 respectively with p-value <0.0001. It was found that there is extreme statistical significance.

Effects Of Aerobic Treadmill Training On Gait Velocity, Cadence, And Gait Symmetry In Chronic Hemiparetic Stroke: A Preliminary Report” have stated in their results that the exercise training given to the patients produced a 9% increase ‘straight-away-walk’ cadence from a mean of 89 ± 9 to 97 ± 8 steps/min(16). In this study the cadence parameter had the paired t value <0.10 and 95% confidence interval ranging from -11.861 to -82.34. Hence it is found that there is extreme statistical significance when p value <0.10.

Effects Of Muscle Strengthening And Physical Conditioning Training On Temporal, Kinematic And Kinetic Variables During Gait In Stroke Survivors” provided evidence in their study that gait speed at post-training was 0.76 ± 0.37 m/second, which was significantly faster than speed observed at baseline 37.2%. Associated with improved speed, increase in cadence and stride length was observed(17). In this study the speed parameter had paired t value and 95% confidence interval ranging -2.290 to -1.710 respectively. Therefore it is proved that there is extreme significance with p value <0.0001.

Thus , the present study is postulating evidence that the strengthening of the gluteus maximus muscle has significant effect on gait in patients with hemiparesis. Hence the alternative hypothesis is accepted.
Conclusion

On the basis of the result of this study, it was concluded that the strengthening of gluteus maximus muscle has effect on gait in patients with hemiparesis. The gait parameters taken in this study such as step length, step width, stride length, cadence and speed has increase in the averaged values before and after treatment.

Role of Rigor Mortis in Assessment of Time Since Death

Sabina Bashir1, Deepak Walia2

1JR, Department of Forensic Medicine, 2Professor & Head, Department of Forensic Medicine

Abstract

Background: Evaluating time since death is an fundamental part of medico-legal investigations. Rigor Mortis is determined by routine conventional method of corpse examination and detecting development of postmortem changes which are affected by many internal and external factors.

The study was done on 100 medico-legal autopsies. Presence of Rigor Mortis in the cadavers was observed both in voluntary and involuntary muscles. Voluntary muscles were tested by gently moving the parts (eyelids, jaw) or by gently flexing the joints. Involuntary muscles like heart by slightly compressing it.

Most of the cases belonged to 21-40 years of age group (45%) followed by 41-60 years (32%). 78% of the victims were males while only 22% were females. 66% of the cases were reported to be the Road traffic accidents, 13% were poisoning cases, 7% natural death and 4% hanging. Majority of the cases seen were those of brought dead cases i.e; 57% and the hospital deaths recorded were 43%. 99% of victims were clothed. Mean maximum temperature was 33.86±6.6hrs and minimum temperature noted was 24.31±6.5hrs &percentage humidity recorded was 33.51±20.2 . In this study 95% Rigor Mortis was recorded in eyelids, 95% of Rigor Mortis was seen in jaw, 95% in the neck, 96% in the right upper limb, 94% in the left upper limb, 80% cases in right lower limb and 80% in the left lower limb. Minimum Postmortem interval recorded was 4 hrs and maximum postmortem interval reported was 36 hrs. Mean PMI reported was 14.80±5.87 hrs. Majority of the cases were reported from two police stations Mullana, which were 46 in number and from Barara ,24 in number.

Key words: Rigor Mortis; Postmortem interval; Time since death; Autopsy; Forensic case work.

Introduction

Estimating the time gap in between death and autopsy is an important aspect of every medico-legal case after death.

Determination of approximate time since death is important in all the unnatural cases and criminal cases which include homicide, accidents, and suicide cases. Development of Rigor Mortis is based upon different physical and chemical changes known to occur within the dead body.1

The term Rigor mortis is a Latin origin word which means stiffness of death. It is one of the identifiable signs of death, which is characterized by stiffening of the muscles of the body caused by chemical changes that occur in muscle postmortem.2 The primary reason for the development of rigor mortis is the loss of adenosine triphosphate from the anoxic tissue3,4. Rigor mortis starts to develop 2–4 hours after death and develops fully by 6 to 12 hours and gradually dissipates until approximately 72 hours after death. It has been found that post-mortem muscle proteolysis is responsible for the relaxation following rigor mortis5,6.

The onset of Rigor Mortis after death depends on the surrounding temperature. The biochemical changes that take place in the dead body is chemical breakdown of energy molecules i.e; ATP in the muscles, which is
the source of energy required for activity. In absence of ATP, myosin molecules adhere to actin filaments and the muscles become firm, hard and rigid\(^7\).

Various factors affecting the process of Rigor Mortis are age and condition of the body, mode of death, surroundings, various environmental conditions have an effect on the development and disappearance of rigor mortis like in various tropical and temperate zones.

Work regarding the appearance, duration and disappearance of stiffness in various muscles in a cadaver has been extensively carried out both in India and abroad by many researchers.\(^8,9\) These researchers have conducted this study for assessing the time of death from the onset and time span of Rigor Mortis which rely on many factors including weather.\(^10,11\) India is having diverse weather conditions that exist throughout its various parts at a given time. Haryana is one such place in North India which experiences extremes of weather conditions.\(^12,13,14\)

The factors that interfere with the onset and duration of rigor mortis are temperature, existing antemortem pathologies, age, body muscular mass, presence of infections, temperature, climatic conditions and the degree of muscular activity immediately before death.\(^15,16,17\)

District Ambala is one such place in North India, which experiences extremes of weather conditions. Available literature on this topic is patchy and scanty especially from this geographical location. As per best of my knowledge, no study has been conducted on factors influencing rigor mortis from Ambala. Therefore, it was planned to study the effect of temperature, humidity and other factors on the onset, duration and sequence of appearance and disappearance of rigor mortis in subjects of Ambala.

**Aims and Objectives**

- To correlate the known postmortem interval with the extent of Rigor Mortis.
- To ascertain the effect of local temperature and humidity on Rigor Mortis and variation in the post mortem interval.
- To correlate and evaluate the variation of various external and internal factors which influence the Rigor Mortis.

**Material and Method**

The study conducted was a cross-sectional study in which total of 100 cases were collected which were preserved in deep freezer at a temperature between 0-4\(^\circ\)C. Presence of Rigor Mortis in the corpses was observed in the both voluntary as well as involuntary muscles. Voluntary muscles were be tested by gently moving the parts eyelids, jaw, neck, upper limbs, lower limbs or by gently flexing or moving the joints. Involuntary muscle like heart was tested by slightly compressing it. Rigor Mortis of the iris was observed from the dilatation or constriction of the pupils.

**Inclusion Criteria**

Those cases were selected where the time of death was known which would help to ascertain the appearance, progress and disappearance of Rigor Mortis at various intervals.

**Exclusion Criteria**

The following dead bodies were be excluded from the study;

1. Decomposed bodies.
2. Artificially preserved bodies.
3. Bodies showed heat stiffening, cold stiffening and instantaneous Rigor.

**Statistical Analysis**

All the cases were entered in proforma & statistical analysis was done. Chi-square test was applied in our study. The data were presented as mean ± Standard deviation for determining Post-mortem Interval.

**Observations & Result**

The present study of Rigor Mortis was to estimate Post-mortem interval was conducted on 100 medicolegal necropsies which were performed in the Mortuary of Department of Forensic Medicine and Toxicology, Maharishi Markendeshwar Deemed to be University, Mullana, Ambala w.e.f 1\(^\text{st}\) April 2017 to 15th May 2019. Only those cases were selected in which the exact time of death was known and no artificial means of preservation had been employed.
### TABLE 1: AGE AND GENDER WISE DISTRIBUTION OF THE CASES

<table>
<thead>
<tr>
<th>Age group (in years)</th>
<th>Male</th>

Table: 2 Result showed that the maximum postmortem interval recorded was 36 hours while minimum postmortem interval recorded was 4 hours. Mean PMI was found to be 14.80± 5.871 hours.

![FIGURE 3 Testing of Rigor Mortis in Upper Limb](image)

**Discussion**

In the present study 100 medico-legal cases were taken. Among those, 78% of the participants were males while only 22% were females. Age and sex wise distribution of the study cases showed that among male cases large proportion of them fell in the age group of 21-40 years (42.3%), followed by 41-60 years (32.1%). Among females majority of the cases were also in the age group of 21- 40 years (50%) followed by 41-60 years (31.8%). In my study the main cause of death was found to be Road traffic accident which constitutes 66% of the cases, followed by 13% of the poisoning cases, 7% natural death and 4% hanging. In my study majority of the deaths were brought dead cases they were 57%, while 43% death cases were those which were admitted in hospital. 99% of the cases were wearing clothes. Mean TMAX in the present study was calculated to be 33.86± 6.6 hours, mean TMIN was found to be 24.31±6.49 hours and mean HUM% was estimated to be 33.51±20.5 %. In my study among 95% of the cases were those in which Rigor Mortis was present in the eyelids and 5% were those in which rigor mortis is seen to be disappearing. In 95% of the cases Rigor Mortis was present in the jaw, 95% cases of Rigor Mortis was seen in neck, in 96% in the right upper limb, in 94% in left upper limb, in 80% cases in right lower limb and in 80% of the cases in left lower limb. Also from my study the maximum number of cases that came to mortuary for autopsy were seen in the month of April i.e 22 while the minimum number of cases seen were in January and February i.e 2. Also the minimum duration of Postmortem interval was 4 hours and maximum duration of Postmortem interval was 36 hours. The mean postmortem interval calculated was 14.80±5.87hrs.

Similar finding were observed by Dalal J et al presented with almost same findings .he has done his study on rigor mortis from the Amritsar which is bordering state adjacent to Haryana where present study was done.

In this study also the mean duration for completely developed Rigor Mortis was 18 hours and 19 minutes, the shortest duration being 3 hours and 15 minutes and the longest 33 hours and 40 minutes. 94.6% of cases. Rigor Mortis was found to establish first in the muscles of eyelids followed by lower jaw, neck, upper limbs, trunk, lower limbs and lastly fingers and toes. It regressed in the same manner in which it had appeared. However, in 5.4% cases course was found to be uncertain.
Similar study conducted by R.K Gorea from Amritsar in which 128 cases were selected from various medicolegal cases brought to mortuary complex of medical college, Amritsar. In this study if the rigor mortis has not appeared PMI is less then 3 hrs & 15 minutes,while longest duration in which rigor mortis had not completely appeared in the body as 14 hrs. Rigor mortis gives us a satisfactory PMI when due weightage is given to temperature and humidity.

Similar study was conducted by M. sugatha et al. This study was a cross-sectional study in which 500 medicolegal autopsies done at Osmania General Hospital mortuary were the exact time of death was known and the body had been kept at prevailing room temperature. Effect of various factors on the appearance and disappearance of the rigor mortis like temperature, humidity clothing was also observed in the same manner with almost same results.

**Conclusion**

From the present study, the following is concluded:

1. Rigor Mortis is a definite sign of death and is a indicator of postmortem interval when many environmental factors are shown to have an effect upon it like temperature and humidity.

2. Sequence of onset and disappearance of Rigor Mortis is first in eyelids, then lower jaw, neck and rest of the body. It lasted the longest in the lower jaw.

3. Most of cases follow the normal course of appearance and disappearance of rigor mortis but rule of twelve does not apply to all cases.

4. Rigor Mortis is affected by other factors besides temperature and humidity like nourishment, clothing, illness and activity prior to death.

Though much study has been done on animals, a bigger study is required on human corpses beginning from time of death till the time of disposal especially in hospital deaths where disposal is delayed so that hour by hour estimation of time since death from Rigor Mortis can be done. Also while transferring of a dead body from emergency to mortuary rigor mortis get distorted and various factors affect the rigor mortis that should also be taken into consideration in future.

**Acknowledgement:** Authors are thankful to Dr Kanika Kohli, Dr Munish Sharma, Dr Rajinder Kumar for their help at various stages of this project.

**Ethical Clearance:** After taking Institutional Ethical committee clearance the data was collected from the victims coming to the mortuary of the forensic department of MMU university, Mullana

An analysis of Socio-Demographic Profile of Asphyxial Deaths in Western Mumbai Region

Sachin s. Sonawane¹, Rajesh B. Sukhdeve²
¹Associate Professor ²Professor Department of Forensic Medicine, H. B. T. Medical College, Juhu, Mumbai

Abstract

Background: the study is conducted to determine epidemiology of violent asphyxia deaths in the western Mumbai region and variation in types of asphyxia deaths in relation to age and gender.

Methods: Study was conducted in department of forensic medicine of H. B. T. Medical College & cooper Hospital, Mumbai for period (2 years) of January 2015 to December 2016. Total 3114 of autopsies were conducted during the period of which 187(6%) were asphyxial death which are included in this study.

Result: 187 out of 3114 medicolegal autopsies were of asphyxial death making incidence rate 5.87% of asphyxial death. Age group most commonly involved in asphyxial death was 21-30 years constitutes 28.8% cases. Male victims constitute of 60.42% cases and female victims were 39.58% cases. Drowning is common in age group 1-20 years constitutes 94.4% of all drowning deaths. Age group 1-10 years all the asphyxial deaths were due to drowning. Hanging is commonest in age group 21-30 years and it constitutes 41.22% of hanging case.

Conclusion: Males and young age group population between 11–40 years are more susceptible victims of violent asphyxial deaths. Hanging and drowning was most common cause in this age group. Both types of asphyxial deaths in young population are preventable and needs to be rectified.

Key words: Asphyxial deaths, hanging, drowning, ligature strangulation, unnatural deaths.

Introduction

The term asphyxia commonly means ‘lack of oxygen’. However, etymologically, the term has been translated from the original Greek, implying ‘pulselessness/absence of pulsation’. How the lack/absence of oxygen is related to pulsation may be explainable on the fact that the air (pneuma) necessary for maintaining life is carried through the blood (i.e., through the oxy-Hb) and therefore, this movement of air obviously will come to a standstill when movement of blood ceases, i.e. pulselessness occurs. Hence, failure or interruption of one function is inevitably linked to the each other¹.

Violent asphyxial deaths have significant contribution to unnatural deaths (suicidal, homicidal and accidental). There are various types of violent asphyxial deaths like hanging, strangulation, smothering, throttling, traumatic asphyxia, choking and drowning. The hanging is most common type of asphyxia death and it is one of the leading methods of committing suicide ².

Strangulation is one of the forms of asphyxial death where compression of neck structures caused by a constricting force other than the body’s own weight. The constricting force exerted by different means such as ligature (ligature strangulation), by hand (throttling), by elbow (mugging) and by bamboos (bandsola).³

In drowning, access of air to lungs is prevented by submersion of body in water or fluid medium. Drowning is most commonly accidental in nature. Study conducted by United Nations World Health Organization reveals that in South Asia, about 90,000 people are drowned to death every year. Most South Asian countries have higher drowning death rates than the world average ⁴.

Traumatic asphyxia” or Crush asphyxia” is other form of mechanical asphyxia where asphyxiation is caused due to mechanical fixation of chest and abdomen by restricting respiratory movements and thus prevents inspiration. It provides the most extreme demonstration of the ‘classic signs’ of asphyxia i.e. cyanosis, petechial haemorrhages and congestion. Traumatic asphyxia
occurs in two main conditions building collapse and stampede.

The present study is conducted to aim to study and evaluates the socio- demographic factors of the asphyxial deaths which will help to know the incidence of asphyxial deaths amongst the population of western Mumbai region.

Material and Method

The present study of violent asphyxia deaths was conducted at department of forensic medicine and toxicology at H.B.T. Medical College for the period of two years i.e. 1\textsuperscript{st} January 2015 to 31\textsuperscript{st} December 2016.

The data includes cases of asphyxia deaths referred for post-mortem by police station from western Mumbai (western suburbs) region which comes under the jurisdiction of H. B. T. medical college.

The study includes the asphyxia deaths of victim with age more than year (infant deaths exclude) and case of asphyxia deaths due to environment suffocation.

The preformed proforma was used to record the various parameter of study like age, sex, type of asphyxia death, post-mortem findings and cause of death. The information of cases was obtained from police inquest, ADR forms, statement of relatives of victims, hospital papers, and history obtained from relative, friends accompanying with deceased person.

Observations and results:

Table 1: Total number of autopsy and its relation to asphyxia death autopsies

<table>
<thead>
<tr>
<th>Period</th>
<th>Total autopsies</th>
<th>Asphyxia deaths (%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Jan 2015- Dec 2015</td>

<td>1590</td>
<td>96 (6.03%)</td>
</tr>
<tr>
<td>Total</td>
<td>3114</td>
<td>187 (5.87%)</td>
</tr>
</tbody>
</table>

Total 3114 autopsies were conducted in period of two year i.e. Jan 2015- Dec. 2016 out of which total 187 (5.87%) cases were of asphyxial deaths.

Figure 1: Age and sex wise distribution of asphyxia deaths

The study reveals the predominance of male victims 113(60.42%) over female victims which account for 74 cases (39.58%). Maximum number of victims 52 (28.80%) were found in the age group of 21-30 years, followed by age group of 11-20 years accounts for 45 (24%) of cases. Together age group of 11-30 years accounts for more than half of cases 97 (52.8%) and 31-40, 35(18.7%) of cases were belong to 31-40 years age group. Least numbers of cases 5(2.6%) seen in age group of 51 years and above.

Table 2: Distribution of cases based on the region of deceased.

<table>
<thead>
<tr>

<td>2.67</td>
</tr>
<tr>
<td>Total</td>
<td>187</td>
<td>100</td>
</tr>
</tbody>
</table>

It was observed most of asphyxial deaths were from the Mumbai district region (79.68%), followed by adjacent district Thane (16.58%) region like Meera road, Palghar, Vasai and virar.1.02% deaths were from the rest of Maharashtra. While 2.67% cases were from rest of India region from Bihar, Rajasthan and utter Pradesh.

Table 3: Distribution of asphyxia deaths on the basis of its types

</table>
Study reveals that maximum number asphyxia deaths due to hanging were in the age group of 21-30 years and accounts for 41.22% cases. All the asphyxial deaths in age group of 1-10 years were due to drowning alone. Maximum number of ligature strangulation seen in age group of 31-40 years accounts for 45.45% ligature strangulation cases.

Discussion

In present study asphyxial deaths accounts 5.87% of total autopsies. Finding of this study was consistent with study of Neha Chaurasia, SK Pandey and Amarnath Mishra study which accounts 6.95% of asphyxial death in the city of Varanasi, study conducted by Bhim Singh, Mithun Ghosh et al. reveals that the asphyxial deaths accounts for 8.87% of total autopsies in the city of Meerut. Mangesh R. Ghadge, Dinesh R. Samel study of 10-year duration in thane region reveals that 12.8% of total autopsies were of asphyxial deaths. Patel Ankur P., Bhoot-Rajesh R et al. Study of violent asphyxial death in the Ahmedabad shows Incidence of violent asphyxial deaths is 5.63% of total autopsies and consistent with present study. Srinivasa Reddy P, Rajendra Kumar R, Rudramurthy study of asphyxial deaths at District hospital, Tumkur, Karnataka shows that total 19.14% autopsies were of asphyxial deaths. Syed Zubair, Ahmed Tirmizi, Farhat Hussain Mirza and Hamid Ali Paryar study of Medico legal investigation of violent asphyxial deaths in Karachi Pakistan shows the incidence of asphyxial deaths 7.08% of total autopsies conducted.

Present study shows male predominance in asphyxial deaths comprising of 60.42% of all asphyxial deaths and female constitutes 39.58% of asphyxial deaths. Most common age group involved is 21-30 years constitutes 28.80% of cases followed by 11-20 years comprising 24%. Age group 11-30 together constitutes 52.80% of cases. Neha Chaurasia et al. study in Varanasi reveals predominance of male victims 60.89% and females were 39.11% of total violent asphyxial death and most common age group involved in violent asphyxia death was 21-30 years (35.79%), followed by 11-20 years (20.30%) which is consistent with our study. Bhim Singh et al. study of asphyxial deaths in Meerut city revealed male victims comprising of 68.03% and female victims 31.96% showing predominance of male victims and most common age group involved was 11-30 years constituting 41.55% of asphyxial deaths, this is in consistent with present study. Mangesh R. Ghadge et al. study in thane region also shows predominance of male victims which constitute 64.2% of cases and female were of 26.8% of cases and most common age group involved was 21-30 years (37.9%) followed by age group 31-40 years (17.4%). Patel Ankur P study of 388 asphyxial deaths in Ahmadabad region reveals predominance of male victims male to female ratio was 1.69:1 and most common age group involved was 21-30 years 32.99% cases these findings are consistent with present study. Srinivasa Reddy P study of asphyxial deaths in Tumkur shows predominance of male victims 59.14% and female victims were of 40.86%, most common age group involved was 21-30 years comprising of 34.93% of cases followed by age group 11-20 years constituting 20.105% of cases. These findings are consistent with present study. Syed Zubair et al. study in Karachi reveals the male victims were of 75.68% case and females were of 24.32% of cases. Most common age group involved was 15-25 years (33.1%) followed by age group 25-35 years (27.7%). Zahid Hussain Khalil et al. study in Peshawar also shows predominance of male victims in asphyxial deaths (68.46%) and female victims comprising of 32.64% case and most common age group 20-40 years 64.5% case.

Present study revealed most of asphyxial deaths were from Mumbai region (79.68%) from the area of study followed by adjacent region Thane (16.58%). Mangesh R. Ghadge et al. study finding is similar with present study showing the maximum asphyxial deaths were from region of study i.e. Thane region 81% cases followed by adjacent region of study 8.8%. Rest of Maharashtra constitutes 0.6% of asphyxial deaths followed by 0.3% of asphyxial deaths were from rest of India.

In present study commonest type of asphyxial death found was hanging in 60.9% cases followed by drowning (28.8%) and ligature strangulation 5.8%. Neha Chaurasia et al. study in Varanasi reveals most common type of asphyxial death was hanging 52.21% followed by drowning 45.02% and strangulation 2.21% these finding consistent with present study. Bhim Singh et al. study of asphyxial deaths in Meerut city shows similar finding with most common method of asphyxia was hanging 60.73% cases followed by drowning 19.63% cases, ligature strangulation 9.13% cases and manual strangulation 5.47% cases. Mangesh R. Ghadge et al. study in thane region also reveals most common type of asphyxial death was hanging 62.5% case followed by drowning 31.2% cases. Patel Ankur P et al.
study in Ahmadabad region found most common type of asphyxial death was hanging comprising of 82.48% cases followed by drowning 14.43% cases and ligature strangulation 3.09%. Srivinasa Reddy P et.al.\textsuperscript{9} study of asphyxial deaths in Tumkur reveals most common method of asphyxial death was hanging constituting 61.19% of cases followed by drowning 31.96% cases and ligature strangulation 4.34% cases. Findings of study in Pakistan, Karachi region by Syed Zubair et.al.\textsuperscript{11} also similar to present study showing most common type of asphyxial death was hanging constituting 36.48% cases followed by drowning 32.43% cases and ligature strangulation 16.21% cases. However, Findings of study in Pakistan, Peshawar region by Zahid Hussain Khalil et.al.\textsuperscript{12} inconsistent with present and other study discussed above showing most common method of asphyxial death was ligature strangulation comprising of 69.2% cases followed by smothering 10.8% cases. Cause of this inconsistent finding may be difference in geographical region/ country.

In present study major types of asphyxial deaths i.e. hanging (59.64%), drowning (61.11%) and strangulation (63.6%) were common in males compared to females. Neha Chaurasia et.al\textsuperscript{6} study also shows similar finding hanging (54.5%) and drowning (68.6%) was common in males. Mangesh R. Ghadge et.al.\textsuperscript{8} study reveals hanging (74%) and drowning (81%) was common in males however ligature strangulation was common in females (84%). Patel Ankur P et.al.\textsuperscript{9} study found hanging (60%) and drowning (85.7%) was common in males however strangulation was common in females (66%). Srinivasan Reddy P et.al.\textsuperscript{10} study found hanging (57.83%) and drowning (69.28%) was common in males however strangulation was common in females (78.9%). Syed Zubair et.al.\textsuperscript{11} study shows hanging (72.2%), drowning (97.9%) and ligature strangulation (58.3%) was common in males compared to females.

Present study found drowning is common in age group 1-20 years constitutes 94.4% of all drowning deaths. However, in the age group 1-10 years all the asphyxial deaths were due to drowning. Hanging is commonest in age group 21-30 years and it constitutes 41.22% of hanging cases. Bhim Singh et.al.\textsuperscript{7} study also found that drowning was commonest in age group 1-10 years and hanging was commonest in age group 21-30 years. Mangesh R. Ghadge et.al.\textsuperscript{8} study found that the drowning is commonest among the age group 1-20 years and it constitutes 42.2% of drowning cases. Hanging is common in the age group 21-30 years and it constitutes 43.8% of hanging cases. Finding of this study is consistent with present study. Patel Ankur P et.al.\textsuperscript{9} study reveals that drowning was common in age group 1-20 years and constitutes 49.23% of drowning cases, hanging was common in age group 21-30 years and it constitutes 40% of all hanging cases.

Conclusions

Present study reveals that males and young age group population between 11–30 years are more susceptible victims of violent asphyxial deaths. Suicidal deaths as a result of hanging and accidental deaths as a result of drowning in this age group are the major causes of asphyxial deaths constituting both together 49.73% asphyxial deaths in present study. This young adult group is most active group of population and more exposed to external environment and stress and strain of life which leads to suicide by means of hanging in this age group. However accidental deaths by drowning are second common cause of asphyxial deaths in young group indicates lack of supervision and carelessness. Both these types of asphyxial deaths part of young population are preventable and needs to be rectified.

Abstract

Background: Teenage is the time of shaping health behaviour and preventing postural defects and improving respiratory fitness. The teenagers possess insufficient knowledge about their respiratory system. Postural defects are commonly seen among teenagers due to lack of physical activity and poor postural habits which can lead to non harmonious development of organs and affect respiratory system as well. For efficient respiratory function, moderate intensity exercises with posture correction would be useful. There is paucity of literature showing effect of posture correction and moderate intensity exercises on respiratory system in teenagers, hence this study would be helpful to analyse the same.

Objectives: To find out effect of posture correction exercise on respiratory system in teenagers. To find out effect of moderate intensity exercises on respiratory system in teenagers.

Methodology: The study was carried out in karad area. The subjects were selected according to inclusion and exclusion criteria. Total 35 subjects were participated in this study. Prior consent and assent form was taken. Aim and procedure were explained to the subjects in their preferred language before data collection. Pre and post assessment was done by 6 minute walk test for respiratory function and flexicurve was measured using flexible ruler to recognize spinal postural defect. Peak flow meter was used to measure lung function

Result: In conducted study, 6minute walk test, peak flow meter and flexicurve showed statistically significant difference between pre and post treatment values.

Conclusion: On the basis of the result of the study, it can be concluded that posture correction and moderate intensity exercises helps in improving respiratory function in teenagers.

Keywords: Moderate intensity exercise, spine posture correction, teenagers.

Introduction

Teenage is the time of shaping health behaviour. Throughout the life there is various body posture changes occur. Teenage is the age where most dynamic changes occur. The type of posture depends on many factors such as age, gender, day today activities.¹

If the postural defects are left untreated it may cause spinal deformities in the spine and also can affect development of lungs and other motor organs. Further it can also affect respiratory function due to low oxygen consumption. Lack of physical activity can also cause spinal deformities. Conditions of the external environment in which individuals live have great impact on the posture.² Nowadays teenagers spent most of their time in leisure activities such as watching television and playing video games and mostly play
indoor games. Also habits like wearing school bags on one arm only, maladjustment of school desk to the individual’s height, standing with stressing on one leg, and other psychological factors can also cause poor postural habits.  

Obesity and overweight are most commonly seen in the society which leads to lack of physical activities, inability to cope in sports. Back pain is commonly seen in the individuals with postural defect. An increasing deformity in the spine can also affect psyche of the individual and lack of acceptance of body image. Neglected or untreated postural habits can further cause defects like scoliosis, rounded shoulders, flat back, kyphosis. Postural defect are more commonly found in girls compared to boys. Where the thoracic hyperkyphosis were prevalent in boys at the age of 14 years.  

Low level of physical activity not only affects the posture but also the development of osteoarticular system and thus future development of the body. The physical development is marked by increase in sources of energy that are provided in the anaerobic metabolism. The effect of this change improves exercise capacity. These abilities close by the end of the maturation. Hence it is important to stimulate physical activity in younger age because it has beneficial effect on health which also influences adult life.  

Metabolic equivalent (MET) is defined as resting metabolic rate, that is, amount of oxygen consumed at rest, which is equal to 3.5 ml O2 per kg body weight per minute. METS are used to describe the functional capacity of the individual and provide repertoire of activities in which individual can safely participate. Activities requiring only 1- 4 METS are considered low intensity activities and are not suitable for improving respiratory function in normal individuals. Activities in the 5-8 METS are considered as moderate intensity activities and are sufficient for sedentary persons. Activities in the METS above 8 is considered as high intensity activities and are vigorous for fit individuals.  

Moderate intensity exercises are beneficial for respiratory health. Physically active individuals have controlled blood pressure, favourable plasma lipoprotein profile. Respiratory endurance training is associated with increased levels of circulating high density lipoprotein and reduction of triglyceride level.  

**Cardiac effect:**  
They stimulate small myelinated and unmyelinated fibres in skeletal muscles and increase myocardial activity. It involves sympathetic nervous system response which includes peripheral vasoconstriction in nonexercising muscles, increase in heart rate, increase in systolic blood pressure.  

**Peripheral effect:**  
It causes generalized vasoconstriction that allows blood to be shunted from non working muscles to working muscles. There is increase in stroke volume, heart rate, cardiac output, blood flow through working muscles because increase in myocardial contractility. There is also increase in systolic blood pressure.  

**Respiratory response:**  
Gas exchange increases across the alveolar capillary membrane. Alveolar ventilation also increases by 10 to 20 fold during exercise to supply additional oxygen requirement.  

**Posture correction:**  
Posture correction exercise contributes to an increase in lung capacity and increase in depth of breath. Posture correction exercise also positively affect nervous system through simulating the process of maturing the motor areas of brain which contribute to the locomotor skill. All the above factors help in improving posture.  

Relaxed or slouched posture is characterized by shifting the entire pelvic segment anteriorly resulting in hip extension and shifting of thoracic segment posteriorly, resulting in flexion of thorax. This is mostly caused by relaxed posture in which muscles are not used to provide support.  

Flat back posture is characterised by decreased lumbar lordosis and posterior tilting of the pelvis. This is caused by continued slouching or flexion in sitting or standing attitude.  

Scoliosis is lateral curvature of spine and it commonly causes due to faulty or poor postural habits. These all types of postural defects most commonly seen among teenagers due to poor postural habits, poor respiratory fitness and due to weak muscles.  

Prevention of postural impairments is very difficult procedure of securing general health both physical and
mental. This problem is commonly seen among teenagers and adolescents because during this phase there are many risk factors which can cause posture disorders and these disorders can affect future life. Thus posture correction exercises and moderate intensity exercises can help in improving respiratory system.

**Material and Methodology**

This was a study to find the effect of posture correction and moderate intensity exercises on respiratory system in teenagers. The study was carried out in karad area. The subjects were selected according to inclusion and exclusion criteria. Total 35 subjects were taken according to inclusion criteria. The inclusion criteria were subjects with age group between 12 to 18 years and subjects having spinal postural defect. The exclusion criteria were subjects with any recent surgery, any recent trauma, structural deformity, any systemic diseases, and unexplained weight loss. Demographic data of the subjects was taken. Prior consent and assent form was taken. Aim and procedure were explained to the subjects in their preferred language before data collection. Pre and post assessment was done by 6 minute walk test for respiratory function and flexicurve was measured using flexible ruler to recognize spinal postural defect. Peak flow meter was used to measure lung function. Included participants received moderate intensity exercises for 30 minutes daily for 5 times a week. Exercises are run and jump in place, jumping jacks, side to side hop and standing side hop. Participants also received exercises for posture correction. Exercises are chin tuck in 3 sets 10 repetition, scapular retraction 3 sets 10 repetition, cat and camel 3 sets 10 repetition. Patient was taught about reinforcement to reinforce proper performance by using cues throughout the day to check correct posture. The effect of treatment was noted using outcome measures. The experimental results were statistically analyzed.

**Statistical Analysis**

The paired T test and one way ANOVA test were used for analysis of data. Statistical analysis of recorded data was done using the software SPSS version 20.

**Findings**

**AGE AND GENDER WISE DISTRIBUTION**

**Discussion**

Teenage is the time of shaping health behaviour. Throughout the life there is various body posture changes occur. Teenage is the age where most dynamic changes occur. The type of posture depends on many factors such as age, gender, day today activities. If the
postural defects are left untreated it may cause spinal deformities in the spine and also can affect development of lungs and other motor organs. Further it can also affect respiratory function due to low oxygen consumption. Lack of physical activity can also cause spinal deformities. Conditions of the external environment in which individuals live have great impact on the posture. Nowadays teenagers spent most of their time in leisure activities such as watching television and playing video games and mostly play indoor games. Also habits like wearing school bags on one arm only, maladjustment of school desk to the individual’s height, standing with stressing on one leg, and other psychological factors can also cause poor postural habits.

This research was undertaken with the aim to study the effect of posture correction and moderate intensity exercises on respiratory system in teenagers.

The study was carried out and the result was drawn by 6 min walk test, peak flow rate and flexicurve by using flexible ruler.

The study was carried out in karad area. Subjects with a sample of 50 were screened for inclusion and exclusion criteria. Subjects fulfilling inclusion criteria were recruited in the study with a sample of 35. Total 35 Prior consent and assent form was taken. Aim and procedure were explained to the subjects in their preferred language before data collection.

Pre and post assessment was done by 6 minute walk test for respiratory function and flexicurve was measured using flexible ruler. Peak flow meter was used to measure lung function

Included participants received moderate intensity exercises for 30 minutes daily for 5 times a week. Participants will also receive exercises for posture correction.

According to previous study of Michel Latalski, Jerzy Bylina, Marek Fatyga, et al Risk factor of postural defects in children at school age. The study concluded that there is relation between physical activity and occurrence of postural defect in children and identification and recognition of risk factors may facilitate their elimination. Hence postural correction exercises may help to prevent postural defects.

Also moderate intensity exercises increases gas exchange across the alveolar capillary membrane. Alveolar ventilation also increases by 10 to 20 fold during exercise to supply additional oxygen requirement.

It was found that among 35 subjects, 64% subjects belonged to 12-15 years of age group and remaining 36% belonged to 16-18 years of age group. In the age group there were 21 subjects out of whom 10 were males and 11 were females. In the age group there were 14 subjects out of whom 8 were males and 6 were females.

Pre interventional mean and standard deviation of walking distance in 6 min walk test was 508± 126.37, whereas post interventional Mean± SD was 544.14± 121.95. It concluded that interference was considered extremely significant. (P- 0.0007, t- 3.719)

According to American lung association there are three zones used to measure peak flow rate. They are Green zone (G) which indicate 80 to100 percent of your normal peak flow rate and condition is under control. Yellow zone(Y) which indicates 50 to 80 percent of usual or normal peak flow rate and airways are narrowing and may require treatment and red zone which indicates less than 50 percent of normal rate. It shows that airways are severely narrowing and its medical emergency. As per the present study there were no subjects in the red zone. In pre interventional study 21 subjects were in Y Zone while 14 subjects were in G zone whereas in post interventional study 9 subjects were in Y Zone and 26 subjects were in G zone. This was calculated by chi-square test. It concluded that interference was considered extremely significant. (p- 0.0079)

According to the study of WENDY RHEAULT, MA, STEVE FERRIS,et al , Intertester reliability of the flexible ruler for the cervical spine , the study was done to determine whether flexible ruler had intertester reliability for the cervical spine curvature in normal subjects and the data suggested that flexible ruler is reliable tool for measuring cervical spine curvature.15 As per the present study pre interventional mean and standard deviation of cervical lordosis index using flexible ruler was 31.142± 5.151, whereas post interventional Mean± SD was 29.857± 4.440. It concluded that interference was considered extremely significant. (P-0.0007, t- 3.707)

According to the study of Teri L Yanagawa, Murray E. Maitland, Keith Burgess, et al. Assessment of thoracic kyphosis using the flexicurve for individuals with osteoporosis, the study was done to assess the test-retest reliability of the measurements of thoracic kyphosis using flexicurve ruler with individuals with osteoporosis
and the study concluded that flexicurve ruler can be used for the measurement of kyphosis in elderly women with osteoporosis based on reliability outcome. As per the present study pre interventional mean and standard deviation of kyphosis index was 34.74 ± 5.83, whereas post interventional Mean ± SD was 31.44 ± 5.74. It concluded that interference was considered extremely significant. (P < 0.0001, t = 5.732)

Pre interventional mean and standard deviation of lumbar index was 48.45 ± 11.622, whereas post interventional Mean ± SD was 45.94 ± 11.877. It concluded that interference was considered extremely significant. (P = 0.0095, t = 2.750).

Moderate intensity exercise and posture correction is used to improve respiratory function. Moderate intensity activities are beneficial for respiratory health. Physically active individuals have controlled blood pressure, favourable plasma lipoprotein profile. Respiratory function improvement is associated with increased levels of circulating high density lipoprotein and reduction of triglyceride level.

**Conclusion**

On the basis of the result of the study, it can be concluded that posture correction and moderate intensity exercises helps in improving respiratory function in teenagers.

**Conflicts of Interest:** There is no conflict of interest in this study.

Mandibular Canine Index as A Tool in Gender Identification - A Study in Malwa Population

Sandhya Jain¹, Merin Kuriakose²

¹Professor and Head of The Department, Department of Orthodontics and Dentofacial Orthopedics, Government College Of Dentistry, Indore, Madhya Pradesh, India, ²Postgraduate Student, Department of orthodontics and dentofacial orthopedics, Government college of dentistry, Indore, Madhya Pradesh, India

Abstract

Teeth are the hardest tissue in the body. Mandibular canines are important tooth in the human body which shows significant sexual dimorphism. Mandibular canine index can be used for gender identification during mass disasters and crime scenes. The purpose of this study was to investigate the accuracy with which gender can be differentiated in Malwa population by using the Mandibular Canine Index and sexual dimorphism.

Materials and Method: The study sample includes 300 Mandibular casts of people residing in Malwa. It included 137 males and 163 female participants. Mesio distal diameter of mandibular canines were measured from mesial contact point to distal contact point of right and left mandibular canines. Inter canine distance was measured between tips of both canines. These were used for deriving MCI and determining sexual dimorphism exhibited by mandibular canines.

Results: The mesiodistal width of mandibular canine were larger in males than in females. The mean difference of MCI between males and females were more on the left canine, thus making it highly significant (P Value<0.001). The standard mandibular canine index for Malwa population was obtained as 0.262. Sexual dimorphism of right mandibular canine was estimated as 4.30% and for left mandibular canine was 5.58%. Sexual dimorphism of mandibular canine is more on left side. The overall percentage accuracy of sex prediction using standard mandibular canine was found to be 65.52%. Conclusion: Tooth remains obtained from crime scenes or disasters can be used for gender identification as this method is very simple, accurate and useful.

Keywords: Canine, Mandibular Canine Index, Sexual Dimorphism, Gender Identification, Forensic odontology, sex prediction.

Introduction

Teeth are the hardest tissues in the body which can withstand most of the physical, chemical and thermal insults to a great extent. Forensic odontology or forensic dentistry is the application of dental knowledge to those criminal and civil laws that are enforced by police agencies in a criminal justice system. Forensic dentistry is the proper handling, examination and evaluation of dental evidence, which will then presented in the interest of justice.

Sexual dimorphism refers to the differences in size, stature, and appearance between male and female. This can be applied to dental identification also because no two mouths are alike¹. Various features such as tooth morphology and tooth size are characteristics of male and female.

The human males have permanent canines that are more masculine in form². The mandibular canines usually exhibit greater sex difference in mesio distal crown size and canine separation or arch width. These
teeth erupt by the age of 12 years, mean age of eruption being 10.87 years. Canines are less affected by periodontal diseases than other teeth and are usually the last teeth to be extracted with respect to age. Canines are also better likely to survive severe trauma, major disasters, natural calamities etc. These findings indicate that the mandibular canines may be considered as the ‘key tooth’ for the purposes of personal identification.

The purpose of this study was to investigate the accuracy with which gender can be differentiated in Malwa population by using the Mandibular Canine Index and sexual dimorphism.

**Materials and Method**

The study sample includes 300 Mandibular casts of patients visiting outpatient department of Government college of Dentistry Indore.

**Inclusion criteria**

- Age group between 15 and 35 years
- Having all fully erupted teeth
- Healthy periodontium
- No caries
- Non attrited teeth
- No restorations

**Exclusion criteria**

- Partially erupted and ectopically erupted teeth
- Teeth showing wear and tear (e.g. attrition, abrasion, abfraction, erosion)
- Patients with oral habits (e.g. bruxism)
- Trauma
- Carious teeth
- Restorated teeth

**Measurement of the Mesiodistal Width**

Mesio distal diameter of mandibular canines were measured from mesial contact point to distal contact point of right and left mandibular canines with the help of dividers. The divider was then held against the digital Vernier calipers accurate to 0.01 mm and read. Each reading was taken 3 times, and the average of three values was obtained to minimize the intra observer error.

**Intercanine distance measurement**

Intercanine distance was measured between tips of both canines. The divider points were applied to the tips of the right and left mandibular canines. The divider was then held against the Vernier caliper, and read.

The Mandibular Canine Index (MCI) is derived as a ratio between canine crown width and canine arch width (measured in mm and is calculated as follows:

\[
MCI = \frac{\text{Mesio distal crown width of mandibular canine}}{\text{Mandibular canine arch width}}
\]

The standard MCI value was used as a reference to differentiate males from females, which is obtained by applying following formula:

\[
\text{Standard MCI (MCIs)} = (\text{mean male MCI} - \text{SD}) + (\text{mean female MCI} + \text{SD})/2
\]

Calculation of sexual dimorphism can be done according to the formula given by Garn et al.

\[
\text{Sexual dimorphism in mesio distal width} = \frac{\left(\frac{Xm}{Xf} - 1\right) \times 100}{Xm} = \text{Mean value of canine width in males} \\
Xf = \text{Mean value of canine width in females.}
\]

**Results**

The present study involved 300 samples (mandibular casts) of people residing in Malwa. It included 137 males and 163 female participants.

The results are shown in Table 1 and table 2.

The result showed that the mean value of right mandibular canine width in males was 7.328±0.470mm and in females 7.02±0.444mm. The mean value of left mandibular canine width in males was 7.381±0.496mm and in females 6.990±.389mm. The mean inter canine width in males was 27.41±2.42mm and in females 26.69±1.90mm.
The mean value of right mandibular canine index in males was 0.268±0.0227 and in females 0.263±0.017 (chart 1). The mean value of left mandibular canine index in males was 0.270±0.025 and in females 0.262±0.017 (chart 2). The mean difference between males and females were more on the left canine, thus making it highly significant (P Value<0.001).

The above mentioned formulae is in the format of the discriminant formula

\[ y = a + b \cdot (p) \] Where, Gender(y) = a + b*(Parameter)
For MD dimension assessed, several stepwise univariate discriminant function statistics were used to develop a formula to determine sex [Table 3]. Coefficients and sectioning points were calculated for each dimension. The group centroids indicated the average discriminant scores for each sex. Sectioning point is the mean of male and female group centroids.

Unstandardized coefficients (b) are the discriminant function coefficients used to calculate the discriminant score. To assess the sex, tooth dimensions are multiplied with the respective raw or unstandardized coefficients (b) and added to the constant (a). If the values (y) thus obtained were greater than the sectioning point the individual was considered a male and if less than the sectioning point the individual was considered female.

\[ y = a + b \times x \]

where x is dimension of the tooth in millimeters.

[Graph 1. Shows the discriminant function values for 300 samples of MCI. The accuracy of predicting males using MCI is 66% and females is 51.8%.

The prediction accuracy for males was found to be 66% and for females it is 51.8% using discriminant analysis.

The overall percentage accuracy of sex prediction using standard mandibular canine was found to be 65.52%. The standard canine index for Malwa population was obtained as 0.262. Sexual dimorphism of right mandibular canine was estimated as 4.30% and for left mandibular canine was 5.58%. Sexual dimorphism of mandibular canine is more on left side.

**Discussion**

In this present study, the values obtained for mesiodistal width of right and left canine, intercanine width, right and left mandibular canine index was found to be significantly higher in males than in females. This is consistent with results of similar previous studies. The mesiodistal width of right and left canines were
larger in males than in females similar to other previous studies\(^7\)\(^8\).

In this study, the mean right mandibular canine index for males was obtained as 0.268±0.0227. The mean right mandibular canine index for females was obtained as 0.263±0.0179. The mean left mandibular canine index for males was obtained as 0.270±0.025. The mean left mandibular canine index for females was obtained as 0.262±0.017. The independent samples ‘t’ test (Student’s t) reveals that the mean values of MCI on the left and right canine were significantly different between males and females (slightly higher in males compared to females). The mean difference between males and females were more on the left canine, thus making it highly significant (\(P\) Value<0.001). This finding is in agreement with previous studies done by Rao et al\(^3\), Reddy et al\(^12\), Yadav et al\(^13\), Kaushal et al\(^5\).

The studies conducted in other countries by Sherfudivin et al\(^9\) and Al Rafaiy et al\(^11\) on Saudi Arabian population and by Bishara et al\(^10\) on the population of the United States Egypt, and Mexico showed that the mesiodistal width of the mandibular canines is more in males than females, and the difference is statistically significant. Similar results were obtained by Ibeachu et al\(^14\) in Nigerian population, Alia O et al\(^15\) in Egyptian population and Lew and Keng\(^16\) in Chinese population.

Table 4. Shows the standard MCI values obtained in various studies in Indian populations.

</tbody>
</table>

In the present study, sexual dimorphism of right mandibular canine was estimated as 4.30% and for left mandibular canine was 5.58. Left mandibular canine shows more sexual dimorphism.

Garn et al., in their study in Caucasians in 1967, had found that the left mandibular canine showed the maximum sexual dimorphism at 6.4%\(^4\) and right mandibular canine showed sexual dimorphism of 5.7%. Study by Patel et al\(^19\) exhibited 8.42% sexual dimorphism for right mandibular canine while the left canine exhibited 8.40%. Study by Kaushal and Patnaik (2004) who reported 9.058 and 8.891%, on the right and left sides, respectively. Study by Nair et al\(^7\) on South Indian population reported that the left mandibular canine exhibited a sexual dimorphism of 7.7% and the right mandibular canine exhibited 6.2%. Study by Ibeachu et al\(^14\) on Nigerian population exhibited left mandibular canine sexual dimorphism of 16.74% while the right mandibular canine was 15.23%. In all studies left mandibular canine showed maximum sexual dimorphism. So left mandibular canine can be a useful
tool for gender identification in forensic odontology.

In this study the overall accuracy in predicting gender using mandibular canine index was found to be 65.52%. The percentage accuracy of gender determination in males was found to be 66% and for females 51.8%. Discriminant analysis is used for calculating accuracy of gender prediction.

**Conclusion**

The mesiodistal width of mandibular canine were larger in males than in females. The right and left mean mandibular canine index in males and females showed statistically significant difference. Left mandibular canine showed more sexual dimorphism. The predictability of gender using standard mandibular canine index is also reasonably accurate ie, 65%.

Tooth remains obtained from crime scenes or disasters can be used for gender identification as this method is very simple, accurate and useful in forensic odontology.

Effectiveness of Short Foot Exercises Versus Towel Curl Exercises to Improve Balance and Foot Posture in Individuals with Flexible Flat Foot

Sayali N. Pisol1, Khushboo Chotai2, Smita Patil2

1Internee, 2Assistant Professor, Krishna College of Physiotherapy, Krishna Institute of Medical Sciences deemed to be University, Karad, Maharashtra

Abstract

Background: Flexible flat foot is a condition of foot in which the medial longitudinal arch is lowered which is visible in weight bearing foot. This condition may be asymptomatic and needs to be treated to prevent further overuse injuries. Many of the literature suggest that individuals with flexible flat foot shows imbalances in the strength of IFM like abductor hallucis, flexor hallucis brevis, flexor digitorum brevis and interosseous muscles which plays major role in maintaining stability. The dynamic balance is found to be more affected in flexible flat foot which needs to be treated by strengthening the IFM. Strengthening IFM with greater efficacy can improve the dynamic balance and also have impact on foot posture of individuals with flexible flat foot.

Objective: to find the effect of 2 different types of IFM strengthening on dynamic balance

Material and Method: In this pre-post intervention study 40 individuals with flexible flat foot were included. They were randomly divided into 2 groups with 20 individuals in each group. Group A was instructed to perform short foot exercises and Group B was instructed to perform towel curl exercise for four weeks. After pre-post assessment, data was analysed with help of appropriate statistical methods.

Results: According to result the in Group A and Group B there is significant increase in both right and left anterior, posteromedial and posterolateral directions with p value < 0.0001.

Conclusion: Both short foot exercise and towel curl exercise are found to be equally effective in improving the dynamic balance in individuals with flexible flat foot. The impact of these exercises on foot posture needs to be taken into consideration.

Keywords: Flexible flat foot, intrinsic foot muscles (IFM), short foot exercises, towel curl exercise, Y balance test, foot posture index.

Introduction

Flat foot (pes planus) is a condition of foot in which the medial longitudinal arch (MLA) is lowered such that it is close or in contact with the ground. [2] There are two types of flat foot, rigid (congenital) flat foot and flexible (acquired) flat foot. [12] The characteristic feature of rigid flat foot is lower medial longitudinal arch in both weight bearing and non-weight bearing foot. [12] Flat foot is normal in infants and young children that is up to 2-3 years of age as there is presence of fat pad in the longitudinal arch of foot. As the child starts walking and bearing weight on the foot the fat pad is reduced and gradually the flat foot is diminished. In children congenital flat foot is most common. The characteristic feature of flexible flat foot is presence of normal medial longitudinal arch in non-weight bearing position and lower medial longitudinal arch in weight bearing position. [4] Flexible flat foot may be present due to number of factors such
as poor postural habits, malalignment of body weight on foot in standing, improper foot wear. Flexible flat foot may be asymptomatic but may lead to lower limb pain, fatigue, overuse injuries and also postural instability. [10]

There is a relationship between medial longitudinal arch and balance. The foot structure and the functions of the foot arches like shock absorption, even distribution of body weight on foot are related to each other and has its effect on posture and stability while walking or propulsion of body. [4] Many literature suggest that there is postural instability or balance issues in individuals with flat foot. Foot complex is the major component on which the whole body weight is equally distributed and balanced. Foot complex plays a measure role in gait, posture and balance and any imbalance is this component may alter the functions. The bony structures, muscles and ligaments play a measure role to maintain the stability. [6] Literature suggest that there are imbalances in the intrinsic foot muscle (IFM) strength in individuals with flat foot as IFM supports the medial longitudinal arch. It is believed that IFM plays a major role in providing stability. [4] The intrinsic foot muscles that is abductor hallucis, flexor hallucis brevis, flexor digitorum brevis and interosseous muscles become weak in flat foot due to which there are balance issues in individuals with flat foot. [11]

The intrinsic foot muscles need to be strengthened in individuals with flexible flat foot in order to improve the balance and to prevent further complications in these individuals. [5] As this condition is sometimes asymptomatic in many individuals, it remains undiagnosed and hence untreated. Many of the literature suggest that asymptomatic flexible flat foot needs seldom treated or should be treated only if symptoms such as pain or associated injuries are evident. [10] But in fact flexible flat foot if remains untreated may lead to overuse injuries or severe postural deformities due uneven forces acting on the foot. There is presence of pronated foot in individuals with flat foot which increases the risk of overuse injuries. [2] Hence Intrinsic Foot musculature training exercises must be incorporated in the management of flexible flat foot. [4]

There are mainly two forms of intrinsic foot musculature training according to the recent studies, short foot exercises and towel curl exercises. Both forms of exercise focus on the intrinsic foot muscle strength. These exercises have their own effects on foot and is believed that both are helpful in increasing strength of IFM. [4]

There are several methods to assess dynamic balance test; Y balance test, modified star excursion balance test (SEBT). [5]

In this study dynamic balanced was assessed by using Y balance test. It is a simple yet reliable test. The reliability of this test is 95%, Interrater test reliability for maximal reach is 0.80-0.85 and interrater test reliability for average reach of 3 trials 0.85-0.93 which indicates good reliability.

This test is very simple to perform and requires minimal equipment and can be performed in multiple settings and safer environment. So in this study Y balance test was used to assess dynamic balance. [5]

In this study foot posture was also assessed to find the presence of flexible flat feet. There are several methods to assess the presence of flexible flat feet such as foot posture index 6, foot posture index 8 and navicular drop test. [1]

In this study foot posture index 6 was used as it indicates good reliability with inter-tester reliability ranging from 0.81-0.91. This test is simple to perform, can be conveniently performed in multiple setting and requires minimal equipment and hence this test is used to assess the presence of flexible flat feet in this study. [1]

Materials and Methodology

· Type of study: Experimental study
· Study design: Pre and post study
· Sampling method: Simple random sampling
· Sample size: 40

Formula:

\[ N = \frac{(SD_1^2 + SD_2^2) * (Z_{1-a/2} + Z_{1-b})^2}{D^2} \]

\[ D = 16.81 \]

\[ SD_1 = 6.2 \]

\[ SD_2 = 7.1 \]

\[ N = \text{Size of sample} \]

\[ Z_{1-a/2} = \text{Value of standard variable at given confidence level i.e. at 85% CI.} \]
$Z_{1-b}$ = Value of standard variate at given power

$D$ = Difference between two means that practically meaningful.

$SD$ = Standard deviation

- **Study duration**: 4 months.
- **Place of study**: Karad
- **Inclusion criteria**:
  1. Younger individuals between the age group of 18 to 25 years
  2. Individuals with presence of flexible flat foot.
  3. Individuals willing to participate.
  4. Individuals with dynamic balance impairment.
- **Exclusion criteria**:
  1. Individuals with history of recent lower limb surgeries.
  2. Individuals with history of recent lower limb injuries.
  3. Individuals with any structural deformities of foot.
  4. Individuals with recent low back injuries.
  5. Individuals with neurological deficits which will hinder the balance.

- **Material**:
  - Tape
  - FPI-6 data collection sheet
  - Inch tape
  - Consent form.

- **Outcome measures**:
  - Y balance test
  - Foot posture index.

**PRODUCTION**

All the subjects were selected for the study according to the selection criteria. Demographic data and consent from were taken from them. Included participants will be divided in 2 groups by simple random sampling method. Pre and post assessment will be taken after 4 weeks of the treatment respectively with the help of outcome measures.

Group A received Short foot exercise. Participant were instructed to raise the medial longitudinal arch of the foot by drawing in the metatarsal heads towards the calcaneus without flexing the toes and holding an isometric contraction for 5 seconds during each repetition. Participant were instructed to perform 100 repetitions of the prescribed exercise on a daily basis for 4 weeks.

Group B received Towel curl exercise. Participants were instructed to place a towel on a slick surface (tile or hardwood floor) and place their toes on the edge of the towel. They were then instructed to drag the towel under their foot by flexing their toes, generating a strong grip on the fabric and hold for 5 seconds per repetition. Participant were instructed to perform 100 repetitions of the prescribed exercise on a daily basis for 4 weeks.

The effect of the treatment given to each group was noted immediately using the outcome measures. The experimental results was statistically analysed. The significant difference between the two groups was investigated with the un-paired t test and within the group with paired t test.

**Findings**

Pre and post data was analysed, according to the result the within the Group A the anterior, posteromedial and posterolateral direction of both right and left are considered extremely significant with p value <0.0001.

The mean pre intervention of Group A for Right anterior is 61.27 (SD=3.6), for posteromedial direction mean is 62.20 (SD=5.2) and for posterolateral mean is 62.19 (SD=5.5), changed to post intervention mean for anterior direction 66.49 (SD=3.4), for posteromedial direction mean is 66.9 (SD=5.1) and for posterolateral direction mean is 66.8 (SD=5.13). (Fig.1)

The mean post intervention of Group A for Left anterior is 61.47 (SD=5.2), for posteromedial direction mean is 60.62 (SD=5.0) and for posterolateral mean is 61.1 (SD=5.2), changed to post intervention mean for anterior direction 65.64 (SD=5.0), for posteromedial direction mean is 65.08 (SD=5.0) and for posterolateral direction mean is 65.1 (SD=5.08). (Fig.2)
According to the pre and post data analysis within the Group B the anterior, posteromedial and posterolateral direction of both right and left are considered extremely significant with p value <0.0001.

The mean pre intervention of Group B for Right anterior is 64.08 (SD=2.4), for posteromedial direction mean is 64.26 (SD=3.0) and for posterolateral mean is 64.08 (SD=2.2), changed to post intervention mean for anterior direction 66.8 (SD=2.2), for posteromedial direction mean is 66.7 (SD=2.5) and for posterolateral direction mean is 66.58 (SD=1.9). (Fig.3)

The mean post intervention of Group B for Left anterior is 63.4 (SD=2.4), for posteromedial direction mean is 63.8 (SD=2.2) and for posterolateral mean is 63.60 (SD=2.3), changed to post intervention mean for anterior direction 65.25 (SD=2.1), for posteromedial direction mean is 65.32 (SD=2.1) and for posterolateral direction mean is 65.20 (SD=2.2). (Fig.4)
Conclusion

On the basis of the result of the study it is concluded that the short foot exercises and towel curl exercises appears to be equally effective in improving the dynamic balance in individuals with flexible flat foot. The impact of these exercises on the foot posture needs to be taken into consideration.

Discussion

The aim of this study was to study the effect of short foot exercise versus towel curl exercise to improve dynamic balance and foot posture in individuals with flexible flat foot with an objective of finding the benefits of each exercise and comparing its effects to fulfil the aim of the study.

The individuals included in this study had flexible flat foot which was assessed using foot posture index.
(FPI-6) measure and individuals were scored according to the outcome measure were included in the study.

There were 40 participants which were selected according to the criteria and they were randomly divided into 2 groups (group A and group B) with each containing 20 participants. Group A was asked to perform short foot exercises according to given procedure and group B was asked to perform towel curl exercises. This study was carried out for 4 weeks on daily basis and pre and post assessment was taken using Y balance test after 4 weeks. After the pre and post assessment the data was statistically analysed.

According to this both the exercise groups appeared to be equally effective in improving the dynamic balance in the participants and were considered extremely significant with p value <0.0001 for both right and left leg.

According to a literature variety of exercises must have been used in improving balance. Some literature suggest that the short foot exercises were helpful in improving the muscle activity of intrinsic foot muscles and balance in flexible flat feet. [11] The short foot exercise must have appeared to be more effective than towel curl exercise in improving the static and dynamic balance in some literature but this study was done in individuals without any lower limb pathology or in participants with normal posture. [4]

Conflict of Interest: There were no conflicts of interest in my study.

Morphometric Study of External Nose for Sex Determination and Ethnic Group Differentiation

Senthil Kumar B

Assistant Professor, Department of Anatomy, Head – Central Research Laboratory for Biomedical Research, Vinayaka Mission’s Kirupananda Vairiyar Medical College & Hospital, Vinayaka Mission’s Research Foundation (Deemed to be University), Salem, TamilNadu, India

Abstract

Background: External nose is one of the anatomical structures that give a look in an individual’s face. The size and shape of the nose vary from one individual to another individual.

Aim: To determine the sex based on morphometry of external nose.

Materials and Methods: This cross-sectional study was done on 100 Malaysians and 100 South Indians of age group (20 to 30 years). The morphometric measurements of the external nose such as nasal length (NL), nasal breadth (NB), nasal height (NH), nasal depth (ND), width of columella (WC), nostril breadth (NB), alar length (AL) and alar width (AW) were measured using digital caliper by standard procedure.

Results: The nasal width was found to be larger in Malaysian females as compared to that of Indian females. The nasal height was found to be larger in Indian males followed by Indian females and vice versa in Malaysian population. When compared among the population the nasal length was lengthier in Indian population and in Malaysian males when compared to Malaysian females. Alar length slight difference was found between male and female of both the population when compared on both the sides. The alar width was found to be more in Indian population when compared to Malaysian population. The nostril breadth was found to be wider in Malaysian population when compared to the Indian population.

Conclusion: The present study shows that their do exist gender difference in nasal morphometry and nasal index of both males and females.

Key words: Nasal morphometry, Nasal index, Indian population, Malaysian population.

Introduction

The external nose is one of the anatomical structures which continue to get modified and enlarged throughout our life even after the attainment of skeletal maturity.1

External nose is one of the anatomical structure that give a look to an individual’s face. The size, shape and proportions of the nose provide beauty as it is at the center of the face. The shape of the external nose varies from one to another considerably.2 Ethnic variation do exist which can be identified on careful examination of different features of nose. Every race has their specific nasal features as in case of Caucasian, Africans or Asians.3 The unique shape of the nose among the race, ethnic and sex is more important for a forensic expert. The morphometry of external nose provides a baseline data to interpolate the ethnic and racial differences.4,5 Anthropometric parameters vary with age, sex, and ethnic background, and several authors have documented the normative values which may serve as references for forensic experts.6 A sound knowledge on the anatomy of
human nose is essential for plastic surgeons undertaking esthetic repair and reconstruction of noses. Congenital anomalies, pre- and postnatal abnormalities in nose dimensions and shape can be found in various genetic disorders. Individuals with Down’s syndrome during prenatal ultrasonography findings shows absence of nasal bone or hypoplasia, coupled with a flat facial profile. Thus, the morphometry of external nose gains its importance in many fields. As the morphometry of external nose is essential for sex determination and ethnic variations the following study was designed and carried in two different races.

**Aim and Objectives**

The aim of the study is to determine the sex based on morphometry of external nose.

**Primary Objective:**

Ø To compare the morphometric data of external nose between right and left side.

**Secondary objective:**

Ø To compare and correlate the morphometry of external nose among two groups of population - South Indian vs. Malaysians.

**Materials and Method**

The study participants include 100 Malaysians (50 males and 50 females) and 100 South Indians (50 males and 50 females) of age group (20 to 30 years). An informed consent was taken before starting the measurements of external nose. This present cross-sectional study was a part of facial morphometry analytic study which was approved by Institutional Ethical Committee; reference (VMKVMC/IEC/18/02) of Vinayaka Mission’s Kirupananda Variyar Medical College & Hospitals, Salem. The present study was carried out in 2 constituent colleges, VMKV Medical College & Hospitals, Salem, TamilNadu and Penang International Dental College, Salem Campus. In both the population group the volunteer participants were chosen by random sampling method. Volunteers with any anomalies on external nose were excluded from the study. Various morphometric measurements of external nose such as nasal length (NL) nasion to pronasale, nasal breadth (NB) between 2 alacrepidon, nasal height (NH) nasion to subnasale, nasal depth (ND) pronasale to subnasale, width of collumella (WC) between 2 alare, nostril breadth (NB) nasion medial to nasion lateral, alar length (AL) pronasale to alacrepidon and alar width (AW) alacrepidon to nasion posterior (fig. 2) were measured using digital caliper.

**Statistical Analysis**

The data’s were tabulated and analyzed by One way ANOVA to find out the significance among the sex and populations and Post HOC pairwise comparison for comparison among the groups. The analysis was done using the online graph pad calculator (Free version).

**Results**

The morphometric data was collected and analyzed by one way ANOVA to find out the significance among the population and Post HOC pairwise comparison to compare between the sexes.

M – Male, F – Female, vs – versus, n = 100 in each population with 50 males & 50 females, NS - non significant, S - significant, P value *P<0.05, Statistical analysis – Post HOC Pairwise Comparison.

Nasal index was calculated by using the formula width of nose/ length of nose X 100. The nasal index showed the gender difference in Indian population (Male - 91.35 and female - 82.12) whereas in case of Malaysian population it showed a wide difference (Male – 103.4 and female – 96.6).

Alar length slight difference was found between male and female of both the population when compared on both the sides. The alar width was found to be more in Indian population when compared to Malaysian population and the difference was found to be statistically significant when compared on both sides. The nostril breadth was found to be more in Malaysian population when compared to the Indian population but was not statistically significant when compared on both sides. The alar length and nostril breadth was not statistically significant whereas the alar width was statistically significant when compared among the population (Table 3 & 4).

Discussion

Racial origin can be identified by different features of nose. Each race such as Caucasian, Africans or Asians has got specific nasal features. Each race has its own special beauty [11]. In an Indian morphometric study, the mean width of the nose was 3.5 cm in total, 3.74 cm in male and 3.43 cm in female respectively. The width of the nose was significant when the male and female groups are compared. In the present study the mean width / breadth was 3.7 cm in male and 3.4 cm in female similar to that of Snehal Deulkar et al study. Kurulkar et al reported the width of nose as 3.56cm in male and 3.26 cm in female respectively in 200 adult Bombay populations and also reported that there is a similarity in columellar width between Chinese and Indians. Generally, surgeons plan the surgical procedures of external nose reconstruction based on their surgical case experiences, which includes the subjective as well as the objective factors. The subjective factor includes the nasal esthetics varies depending on the ethnic background as well their geographical and cultural differences. Springer et al., reported that there exist gender related effects with respect to the assessment of nasal shape in women as compared to men. In a morphometry study, the narrow noses were predominated in 46 (78%) females than in 39 (70%) males and a total of 85 cases (74%) narrow nose among all subjects.

Ray et al reported that males have a significantly higher nasal index than females (P < 0.05) similar to that of the present study (Table 5). This confirms the existence of sexual dimorphism in nasal parameters among south Indian and Malaysian population.

In a study done by Sforza et al.,¹ nostril breadth in male was 2.2cm and female was 1.9cm whereas in the present study it was 1.2 cm in both Indian male and female. In case of Malaysians it was found to be quite wider when compared to Indians, male (2.0 cm) and female (2.1cm). Ogah et al reported that the mean nasal length, width, height were higher in males than in the female as incase of the present study. The existence of sex difference in morphometric measurements of nose were due to genetic the make-up and inheritance which can be manifested as sexual dimorphism in this study in both the populations.
Conclusion

The study shows that there exist gender differences in nasal morphometry and nasal index of both males and females. This morphometric data of this study including nasal index can serve as a baseline data for various purposes such as reconstructive nasal plastic surgery including rhinoplasty, medico-legal aspects of identifying an individual along with other facial morphometric data’s.

Abstract

The present study is a retrospective study conducted in Raichur institute of Medical sciences, Raichur Karnataka. During the study period that is from January 2017 to March 2017, out of 547 medico-legal cases which came to casualty, 164 cases were poisoning. Among 164 poisoning cases, 13 cases died in hospital and postmortem examination is done in mortuary RIMS Raichur hospital. The most common type of poisoning case in and around the Raichur district was organo-phosphorus poisoning (58.53%) followed by kerosene poisoning (13.41%). Males (55.48%) were the more common victims of the poisoning. Age group between 11-20 years (32.92%) was most commonly affected. Majority of poisoning cases was suicidal (84.14%) in manner. In 26.56% the motive for suicidal poisoning was financial crisis leading to depression and consumption of poisonous substance.

Key Words: Poisoning, Demographic profile, Manner of death

Introduction

Poison is any substance which if introduced in the living body by any route could cause ill health or death. Poisoning both accidental and intentional is a significant contributor to morbidity and mortality throughout the world. According to WHO data in 2012, an estimated 1,93,460 people died worldwide from unintentional poisoning. Of these deaths, 84% occurred in low- and middle-income countries.

Poisoning forms a major problem in developing countries like India too, though the type of poison and the associated morbidity and mortality varies from one place to another and it may change over a period of time owing to availability and access of poison socio-economic status cultural and religious influences, life style, urbanisation, agricultural growth, industrialisation, geographical factors. The exact incidence of poisoning in India remains uncertain, but 1 to 1.5 million cases occurs every year, of which almost one third are fatal. It has been estimated that in India five to six persons per lakh of population die due to acute poisoning every year. Poisoning is the fourth most common cause of mortality in rural India. The mortality rate due to poisoning in developed countries is only 1%-2% but in developing countries like India, it varies in between 15% -30%.

Suicides by poisoning are increasing in the recent past in an exponential manner. Adaptation of modern life style and effects of globalization and urbanization might be the reason. Wide spread use of chemicals in the form of pesticides and herbicides in agricultural field, unrestricted use of wide variety of chemicals in industries and extended use chemicals for household work also reason for increased incidence of accidental poisoning.

Materials and Method

This is a retrospective cross sectional descriptive study of poisoning cases admitted in Raichur institute of medical sciences, Raichur. The study period is from
January 2017 to March 2017. During the study period we gathered data from poisoning cases, which were admitted, treated and discharged from the hospital as well as from postmortem examination report where death occurred due to poisoning case. The required information was collected from outpatient department card, inpatient department sheet, police inquest report, postmortem examination report, RFSL report. The data collected in performa was later statistically analyzed with respect to age, sex, rural / urban, type of poison and manner of poisoning, expressed in number of cases and percentage. Snake bite and scorpion bite cases were excluded from the study group. Ethical clearance was taken from institutional ethical committee.

Observation and Results

During three months of study period i.e January 2017 to March 2017, we noticed that a total of 547 medico-legal cases were admitted in our RIMS Raichur tertiary care hospital, wherein 164 cases (29.98%) belong to poisoning cases. Among 164 poisoning cases, 13 cases (7.92%) died in hospital and postmortem examination is done in mortuary RIMS Raichur hospital.

In our study, age group between 11-20 years (32.92%) were common sufferer of poisoning, followed by age group 21-30 years (29.26%), 31-40 years (17.07%), children age less than 10 years (9.75%).

In our study, we observed that, people from rural background (76.22%) were more troubled by poisoning cases compared to urban people with 23.78% cases of poisoning and married (53.05%) persons were more affected than unmarried (46.95%) persons.

In our study, males (55.48%) were the more common victims of the poisoning cases and females accounted for 44.52% of cases and suicidal manner was common (84.14%) followed by accidental (15.86%) poisoning cases. There were no homicidal poisoning cases.

</table>

In our study, we noted that, in 34 cases (26.56%) the reason for suicidal poisoning was financial crisis leading to depression and consumption of poisonous substance. We also observed that farmers were the major group of people who faced major hurdle of financial crisis. In 29 cases (22.91%) chronic psychiatric illness was the reason behind the poisoning. In 23 cases (18.17%) a chronic ill health which neither improving nor the person able to bear the expenses of the treatment was reason. In 19 cases (15.01%), chronic alcoholism leading to various hampered interpersonal relationship, financial burden on family, frequent quarrels leading to depression was
the issue. In 7 cases (5.53%), interpersonal problems among the family members with respect to dowry, land, expenses, habits etc lead to arguments and conflicts was the reason. In most of these cases females were the victims. In 6 cases (4.74%), students who were not doing well in school or failed in annual exams took a self destructive extreme step. In 3 cases (2.37%), mentally disturbed pre-menstrual syndrome sufferer took an extreme step of poisoning themselves.

</tbody>
</table>

In our study, 92 cases of poisoning were seen in uneducated (56.1%) peoples. In 19 cases (11.58%) the level of education was PUC followed by 17 cases (10.36%) in degree and 6th-10th class level education. In 14 cases (8.53%) child was less than 6 years of age and all were accidental in manner.

**Discussion**

Among the medico-legal cases admitted in our hospital, 29.98% cases belong to poisoning cases which was far higher than study done by Guntheti BK et al (11.65%) and Mugadlimath A et al (6.67%). Contrary to above observations, study conducted by Panda BB et al observed that, most common poisoning was insecticidal poisoning (26.92%) followed by alcohol (11.53%), rat poisoning cases (11.53%) and sedatives (11.53%). Study done by Guntheti BK et al observed that, organophosphorus compound poisoning (74%) is most common followed by zinc phosphide poisoning (5.8%), benzodiazepines (3.18%) and medicinal drugs (3.18%) were equally abused.

In all the studies including ours, most common type of poisoning was due to organo-phosphorus insecticides (51.63%) followed by alcohol poisoning cases (10.31%). Study conducted by Panda BB et al observed that, most common poisoning was insecticidal poisoning (26.92%) followed by alcohol (11.53%), rat poisoning cases (11.53%) and sedatives (11.53%). Study done by Guntheti BK et al observed that, most common poisoning was insecticidal poisoning (26.92%) followed by alcohol (11.53%), rat poisoning cases (11.53%) and sedatives (11.53%). Study conducted by Mugadlimath A et al observed that, during the study period 21 (5.55%) of the patients had mortality due to poisoning. Study conducted by Ali I et al observed that, 83.91% poisoning cases improved while 16.09% expired. Mortality was higher with use of aluminium phosphide poisoning (57.38%) and organophosphate consumption (9.84%). Study done by...
Guntheti BK et al observed that, 17.33% deaths were due to insecticide, maximum with organo-phosphorus compounds (82.75%) followed by zinc Phosphide (13.79%), organochlorines (6.89%) and carbamates (6.89%).

In our study, males (55.48%) were the more common victims of the poisoning cases and females accounted for 44.52% of cases. Male to female ratio was 1.2:1, the same observation was made by various authors.

A high incidence of poisoning among men may be attributed to high degree of stress in academic, love affairs, financial crisis and emotional disturbances, inability to achieve targets and also due to easy accessibility to poisons. However, some studies show that incidence of poisoning was more in women than men.

In our study, age group between 11-20 years (32.92%) were common sufferer of poisoning, followed by age group 21-30 years (29.26%), 31-40 years (17.07%), children age less than 10 years (9.75%). Contrary to our observation, majority of studies observed that age group 21-30 years were the major victims.

In our study majority of cases (32.92%) were from age group 11-20 years. This can be explained by the fact that the persons of this age suffer from stress of the modern lifestyles, failure in love, failure in education, impulsive behaviour. Second most common age group 21-30 years (29.26%) the reason may be unemployment, marital problems, failure in love, family problems etc.

In our study, we observed that, people from rural background (76.22%) were more troubled by poisoning cases compared to urban people with 23.78% cases of poisoning. The same observations were made by various authors with varying percentage of rural background from 75% to 85%.

More prevalence of poisoning cases in rural area in our study may be due to widespread use of pesticide in agriculture sector. Poverty, failure of crops, family problems and easy availability of the poison in their household, made people of rural area more prone for poisoning. However, some studies from state of Karnataka, the incidence was more in those who were from urban background.

In our study, married (53.05%) persons were more affected than unmarried (46.95%) persons. Similar observations were made by Ali I et al, Guntheti BK et al, Mugadlimath A et al. Contrary to above studies, in Panda BB et al study most of the victims found were unmarried (53.86%).

Ali I et al observed that, 68.34% were suicidal in nature and in 31.66% cases poison was consumed accidentally. Study conducted by Panda BB et al observed that, Suicide was the most common manner of poisoning (65.39%), followed by accidental pattern (34.61%). Study done by Shetty VB et al observed that, commonest manner of poisoning was suicide (78%) followed by accidental poisoning accounting for 22.67%. Acute poisoning in children is almost entirely accidental; while in adults it is mainly suicidal. Not a single case of homicidal poisoning was observed in any of the above studies.

Table No.3

Similar observation was made by Subhash Chandra Joshi et al study, where financial crisis was the reason for suicidal poisoning in 53.22% cases.

Contrary to our observation, Ali I et al observed that, marital discord (33.20%), love affairs (4.25%), family problems like problems/altercations with family members other than spouse (46.33%), financial difficulties (1.16%), addiction/friend dispute/depression (5.79%) and unknown (9.27%) were the various reasons for consuming poison.

Table No.4

Ali I et al observed that, one third of the patients (33.77%) were illiterate. Educational status of 36.68% patients was up to high school, 13.72% intermediate and rest 15.83% were graduates/postgraduates.

Contrary to our observation study done by Guntheti BK et al observed that, most of the victims was either literate (71.91%) or educated up to high school level and 28.08% illiterate. Authors like Guptha BD et al, Eddleston M et al and Joshi SC et al also observed in their studies that poisoning was more common in literate people.
Conclusion

A complete and accurate knowledge about the nature and depth of the problem in a particular area is essential for early diagnosis and treatment which in turn help in making new policy by government for prevention of poisoning cases because nature, profile and burden of poisoning varies significantly in the different parts of India.

We suggest the policy making bodies should regulate the import, manufacture, sale, transport, distribution and use of insecticides and pesticides meticulously. Upgrading the peripheral health centres to manage cases of poisoning in emergency including training of staff to give first aid treatment of poisoning including timely intubation and respiratory support on AMBU bag and make sure the availability of antidote in sufficient quantity. Further we need to establish a poison information centre in this region and manage a Clinical Toxicology Unit for the better management and prevention of poisoning cases. Simultaneously increase the public awareness about the seriousness of problem through health education. Proper and correct implementation of various social and economic projects aimed for upliftment of the rural poor population will definitely decreases the burden indirectly.

An examination of Some Commonly Utilized Techniques for Perception of Secret Writing

Shipra Rohatgi\textsuperscript{1}, Shruti Gupta\textsuperscript{2}, Madhulika Sharma\textsuperscript{3}

\textsuperscript{1}Research Scholar, \textsuperscript{2}Assistant Professor, Amity Institute of Forensic Sciences, Amity University, Noida, Uttar Pradesh, India, \textsuperscript{3}Ex-Director, State forensic Science Laboratory, Govt. of NCT of Delhi, Madhuban Chowk, Sector 14, Rohini, New Delhi, India

Abstract

Secret writing is the art of covered or hidden writing. The art of secret writing is meant to create a message unreadable by a third party however doesn't hide the existence of the secret communication. This paper is meant as a technical introduction to secret writing for those unacquainted with the field. Invisible inks are generally used for secret writing. These are fluids used to write hidden messages that do not appear unless exposed by a revealing process. Invisible inks can be classified into three main categories: those that are revealed by heat, those revealed by chemical reactions and those that are visible under ultraviolet light. Some common household invisible inks are diluted fruit juices, vinegar and laundry detergent, all which can be applied by a paintbrush, special invisible ink pen or even a toothpick, Historically, used in times of war by governments and insurgents alike. The chemical processes of invisible inks are well known, so a variety of detection methods exist. The simplest invisible ink experiment consists of dipping a brush in vegetable juice, biological fluids and different chemicals and writing on a piece of blank varieties of paper. When the “ink” dries, it will be invisible to the naked eye, but if the paper is held up to a moderate heat source such as a light bulb, a radiator or an iron using UV lamp to deciphering invisible writing. Many other mild chemicals also used for restoration of secret writing.

Keywords – Secret Writing, Invisible inks, decipherment, physical, chemical methods

Introduction

Invisible inks are used for secret writing. These are fluids used to write hidden messages that do not appear unless exposed by a revealing process. Invisible inks can be classified into three main categories: those that are revealed by heat, those revealed by chemical reactions and those that are visible under ultraviolet light. Some common household invisible inks are diluted fruit juices, vinegar and laundry detergent, all which can be applied by a paintbrush, special invisible ink pen or even a toothpick, Historically, used in times of war by governments and insurgents alike. The chemical processes of invisible inks are well known, so a variety of detection methods exist. The simplest invisible ink experiment consists of dipping a brush in vegetable juice, biological fluids and different chemicals and writing on a piece of blank white paper. When the “ink” dries, it will be invisible to the naked eye, but if the paper is held up to a moderate heat source such as a light bulb, a radiator or an iron using UV lamp to deciphering invisible writing. Many other mild chemicals also used for restoration of secret writing.

Invisible Inks

Broadly, invisible inks can be categorized as: organic fluids and sympathetic inks. The former consists of the “natural” methods many of us tried our hand at as kids: lemon juice, vinegar, milk, sweats saliva, onion juice, and even urine and diluted blood, to name a few. These organic invisible inks can be developed through heat, such as with fire, irons, or light bulbs, and some can be seen when placed under ultraviolet light. The organic fluids alter the fibers of the paper so that
the secret writing has a lower burn temperature and turns brown faster than the surrounding paper when exposed to heat. Sympathetic inks are more complicated chemical concoctions. Sympathetic inks contain one or more chemicals and require the application of a specific “reagent” to be developed, such as another chemical or a mixture of chemicals.3-6

An acidic citrus juice, of which lemon juice is most often the preferred choice because it dries without leaving any evidence it has been applied. The juice takes the place of ink, and is applied by swabbing with cotton. After the juice dries, the acid remains on the paper, which it weakens, and therefore the message is readily exposed when heat is applied to the paper. Other liquids for invisible ink include milk, which is mildly acidic, as well as white wine, vinegar, or apple juice. In the past, prisoners of war have used their own sweat, saliva, or even urine, all of which contain acidic secretions that adhere to the paper, weakening it, even after the water in those bodily fluids has evaporated.7

A slight variation on this technique is the use of a baking soda and water mixture as the invisible ink, and, after drying, applying grape juice concentrate with a paint brush. The acid in the grape juice reacts with the baking soda (a base or alkali in chemical terms), exposing the message.8

Types of Invisible inks

· Heat-Activated Invisible Inks: Iron the paper, set it on a radiator, place it in an oven (set lower than 450° F), or hold it up to a hot light bulb.

9. Soapy Water
10. Sucrose (Table Sugar) Solution
11. Urine

· Inks Developed by Chemical Reactions:
These inks are sneakier, because you have to know how to reveal them. Most of them work using pH indicators, so when it doubts, paint or spray a suspected message with a base (like sodium carbonate solution) or an acid (like lemon juice). Some of these inks will reveal their message when heated with vinegar.

1. Phenolphthalein (Ph Indicator), Developed by Ammonia Fumes or Sodium Carbonate (Or Another Base),
2. Thymolphthalein, Developed by Ammonia Fumes or Sodium Carbonate (Or Another Base),
3. Vinegar or Dilute Acetic Acid, Developed by Red Cabbage Water,
4. Ammonia, Developed by Red Cabbage Water,
5. Sodium Bicarbonate (Baking Soda), Developed by Grape Juice,
6. Sodium Chloride (Table Salt), Developed by Silver Nitrate,
7. Copper Sulfate, Developed by Sodium Iodide, Sodium Carbonate, Potassium Ferricyanide, Or Ammonium Hydroxide,
8. Lead (II) Nitrate, Developed by Sodium Iodide,
9. Iron Sulfate, Developed by Sodium Carbonate, Sodium Sulfide, Or Potassium Ferricyanide,
10. Cobalt Chloride, Developed by Potassium Ferricyanide,
11. Starch (E.G., Corn Starch or Potato Starch), Developed by Iodine Solution,
12. Lemon juice, developed by iodine solution.

Inks Developed by Ultraviolet Light: Most of the invisible writing visible under UV light gives characteristic fluorescence.

1. Dilute laundry detergent (the bluing agent glows),
2. Body fluids,
3. Tonic water (quinine glows),
4. Vitamin B-12 dissolved in vinegar.

**Materials & Method**

**MATERIAL USED:** Organic fluids mainly Fruit juices (lemon juice, onion juice), Biological fluids (saliva, urine) and three types of paper mainly copier, bond paper and cheque of different GSM.

**METHOD:** The paint brush was dipped in the required invisible ink and messages were written over the papers. The papers with secret messages were marked at the top, with date of sample preparation, name of the invisible ink and the respective day on it is examined. Extra samples of secret messages were also prepared in the same manner. The papers containing written messages were kept under a running fan, so that the inks dry up.

**Results**

**Visibility of Organic Fluids on Bond Paper (A4 Sheets) 74 GSM**

**Lemon Juice (S2)- Visibility with the use of Physical and chemical methods**

- Direct light
- Oblique light
- Transmitted light
- UV
- Heat (By Iron)
- Iodine fuming

**Visibility of Organic Fluids on Cheque 95 GSM**

**Lemon Juice (S4)- Visibility with the use of Physical and chemical methods**

- Direct light
- Oblique light
- Transmitted light
- UV
- Heat (By Iron)
- Iodine fuming

Secret writing written with samples it turns into Brown in color when heated. This is because these samples are either mildly acidic or alkaline in nature and such as an acid or base weakens the paper. When the paper is then held near a heat source these acidic parts of the paper burn or turn brown faster before the rest of the paper revealing the message. These samples were visible under UV light because of their fluorescence or the differentiation of absorbance or reflection of UV rays of them. The reason that lemon juice shows slightly brown fluorescence in most of the cases may due to more concentration of juice.

Iodine fluming of samples revealed secret message in white paper contain starch and when iodine fumes come in contact with the paper they react with starch and produce purple color.

Secret writing written by different organic fluids by using silver nitrate gives brown color and with phenolphthalein gives pink(Colorless) results but in all types of paper the results were negative.

Discussion

Secret writing samples written with different biological fluids and vegetable juices were deciphered by physical and chemical methods. Secret writings written with biological fluids and vegetable juices turned brown in color when heated. This is because these fluids are either mildly acidic or alkaline in nature and such an acid or base weakens the paper. The acid or base from these fluids remains in the paper after the water has evaporated and the paper has dried. These fluids were visible under UV light because of their fluorescence or the differential absorption and reflection of UV rays by them.

The reason that lemon juice showed slightly brown fluorescence in most cases, may be due to more concentration of the juice. Iodine fuming of fruit juices revealed secret messages in white color with purple-brown background because the paper contains starch and when iodine fumes come in contact with the paper, they react with starch and produce purple color while the fruit juices do not react with the fumes and remain colorless. Iodine fuming of chemical and biological fluids revealed
the writing in brown color. Some of the invisible inks appeared transparent when treated with phenolphthalein solution. This may be due to the fact that these fluids are mildly acidic in nature and phenolphthalein is colorless in acidic condition.

The appearance of brown color in case of apple juice, when treated with silver nitrate solution, may be due to some chemical reaction between silver nitrate and certain salt present in the juice. As we know that, certain salts react with silver nitrate and produce a silver salt that decomposes to silver metal on exposure to light and this metallic silver gives brown color. The visibility of the invisible inks used in this project, differed over a period of one month. Although, some of the inks showed neither decrease nor increase in their visibility for the whole month. The visibility of some of the inks, as expected, decreased with time. The constant visibility exhibited by some of the inks may be because they require longer than one month for their fading.

Conclusions

From the results obtained in this study, it could be concluded that the secret writings written with different vegetable juices and biological fluids can be deciphered by physical and chemical methods. Among physical methods, heating is the best for deciphering these fluids as it does not take much time and the document is also not affected if it is heated carefully. Visualization under UV light also doesn’t ruin the document, but all the invisible inks cannot be visualized easily under it, so it becomes time consuming and will require effort for the visibility of messages. Among chemical methods, iodine fuming is the best because it does not spoil the documents extensively, like the phenolphthalein and silver nitrate solution does, for further testing. The purple color of iodine fades away after a few minutes. However, it requires a little more time than heat treatment to develop the secret messages. Both of these methods give good results up to one month. Further studies considering a larger sample size and considering more factors will help gain a better understanding of the visualization methods most suitable for developing secret writing.

Immediate Effect of Stretching Versus Strengthening Exercises on Blood Glucose Level in Chronic Diabetes Mellitus

Shweta M Mehta¹, Smita Patil²

¹Intern Physiotherapy, ²Assistant Professor; Department of Musculoskeletal Sciences of Physiotherapy, Krishna College of Physiotherapy, Krishna Institute of Medical Sciences Deemed To Be University, Karad

Abstract

Background: Diabetes mellitus affects the muscles as muscle play notable role in the regulation of blood sugar level. The lack of glucose can lead to muscle cells atrophying and therefore loss of muscle mass. Stretching can increase cellular glucose uptake. Strengthening may improve strength, enlarged muscle mass and to improve insulin sensitivity and glycaemic control. Their paucity of literature on immediate effect of stretching versus strengthening exercises on blood glucose level in diabetes mellitus.

Objective: To find out immediate effect of stretching on blood glucose level in diabetes mellitus individuals.
To find out immediate effect of strengthening exercises on blood glucose level in diabetes mellitus individuals.
To compare the immediate effectiveness of stretching and strengthening exercises on blood glucose level in diabetes mellitus individuals.

Methodology: The study was conducted in Krishna hospital, in physiotherapy department. 44 subjects were selected with simple random sampling method. Chronic type 2 diabetes mellitus individuals were divided into two groups. Group A (stretching) and group B (strengthening exercises) was given. The pre- and post–treatment postprandial Blood glucose values was measured by glucometer.

Result: In conducted study, postprandial BGL showed statistically significant difference between pre and post treatment values in both group A and B.

Conclusion: From the above conducted study it concludes that both stretching and strengthening exercises are effective in decreasing postprandial blood glucose level in type 2 diabetes mellitus, as there is no significant difference between both the groups. Strengthening exercises increased more flexibility in females than passive stretching and males were benefited with both stretching and strengthening exercises.

Key words: type 2 diabetes mellitus, stretching, strengthening exercises, postprandial blood glucose level (BGL).

Introduction

Type 2 Diabetes mellitus (DM) is a long-term metabolic disorder that is characterized by high blood sugar, insulin resistance, and relative lack of insulin¹. There are two types of diabetes mellitus; Type 1 diabetes mellitus: insulin dependent and Type 2 diabetes mellitus: non-insulin dependent¹. In India, there are about 50.8 million adults with DM². In Maharashtra there are 9.3% of people with type 2 DM, 51% in females and 49% in males². The onset of this chronic condition and associated comorbidities, a life-long reduction of quality of life and premature mortality due to micro- and macro vascular complications occurs³. Diabetes mellitus (DM) causes disturbance of carbohydrates, fat and protein metabolism resulting in defect in insulin secretion⁴. In DM muscle atrophy is caused by an imbalance in contractile protein synthesis, degradation and overall poor glucose control. As it reduce muscle quality and affects muscle functional capacity to perform physical activities which ultimately can increase secondary complications such as mortality, long term DM damages, inability to function
and failure of organs such as kidneys, eyes, heart and blood vessels\(^{(5,6)}\).

As there is lack of physical activity causing sedentary lifestyle. Hence, body mass index (BMI) increases which leads to obesity. The evidence shown that hemoglobin A1c (HbA1c) is the gold standard for monitoring glycemic control, may to find for diabetes hence, there is changes in HbA1c .In type 2 diabetes mellitus ,the maximal oxygen uptake Vo\(_2\)max values are lower than comparatively normal individuals. This causes alteration in oxygen delivery.\(^{(7)}\)

The type 2 DM is also known as adult onset diabetes which include insulin deficiency and having combination of three main metabolic problems – reduced beta cell function with decreased insulin production, insulin resistance in peripheral tissues, increased hepatic glucose production.\(^{(5)}\)

To achieve good glycemic control in type 2 DM individuals ,an adequate exercise therapy is needed.in aerobic exercise muscles get activated to extract energy in the form of adenosine triphosphate (ATP) it includes jogging ,walking etc.\(^{(6)}\) stretching can increase glucose level uptake when sustained tension develops in muscles trough external forces.\(^{(4)}\) As strengthening exercises can increase muscle strength and enlarge muscle mass and to improve insulin sensitivity and glycemic control.\(^{(5)}\)

**Material and Methodology**

Patients presenting with the history of chronic type 2 diabetes mellitus were diagnosed by physician of KIMS hospital, karad who reported to physiotherapy department of KIMS hospital volunteered to participate in the study were selected as subjects. An approval for the study was obtained from the protocol committee and ethical committee of KIMSDU. Each of the subjects was screened as per inclusion and exclusion criteria and they were briefed about the study and intervention. Informed consent was taken from the subjects. The subjects in group A and group B, stretching and strengthening exercises groups respectively assessed for postprandial BGL by glucometer and exercise regimen was carried out 2 hours after meal according to their allocated groups. Pre and post-exercise blood glucose were measured and documented.

A total no. of 44 subjects were divided into 2 groups (18 females, 26 males) with simple random sampling method. In group A (9 females ,13 males) and in group B (9 females, 13 males).Age group selected for exercise was 40 to 65 years\(^{(5)}\).

The exercise regimen consisted for 10 mins warm up phase, 40 mins intervention phase, 10 mins cool down phase. The intervention for both the groups were carried out for 60 minutes duration. The intervention done on two muscles of upper limbs (biceps brachii, triceps brachii) and two muscles of lower limbs (quadriceps, hamstrings) in both the groups. Both the groups initially treated with free exercises for 10 minutes before and after the intervention phase. Circular rotation of both hands, Anti-circular rotation of both hands, Jogging, Walking. In group A (stretching exercise),Patients were given passive stretching for 40 minutes. Each muscles was held in the stretched position for 30 sec and was repeated for 3 times followed by 10 sec relaxation between 3 sets and different stretches were separated by minimum 1 minute. Biceps stretch, Triceps stretch, Quadriceps stretch, Hamstring stretch bilaterly and in group B (strengthening exercises); Strengthening exercises was performed with theraband for 40 minutes. The patients were asked to performed 3 sets of the exercise with 10 repetition each set with 30 sec relaxation period between the sets for each muscle. The muscles selected for the exercise were similar to the stretching group\(^{(4,5,11)}\).

**Findings**

*Table no. 1.1 Comparison of pre and post postprandial BGL values within group.*

</table>
INTERPRETATION: The pre-interventional postprandial BGL values were 126.9 ± 10.37 in group A and 131.4 ± 12.92 in group B respectively, whereas the post-interventional BGL values were 123.4 ± 10.37 in group A and 128.2 ± 13.15 in group B respectively. Intra-group changes in the postprandial BGL values showed statistically very significant reduction in A group and extremely significant reduction in BGL values in group B. This was done by using paired ‘t’ test.

INTERPRETATION: The pre-interventional postprandial BGL values were 127.85 ± 9.82 in males and 125.75 ± 11.62 in females respectively, whereas the post-interventional BGL values were 124.1 ± 10.17 in males and 122.4 ± 11.19 in females respectively. Intra-group changes in the postprandial BGL values showed statistically extremely significant reduction in male and not significant reduction in BGL values in females. This was done by using paired ‘t’ test.

INTRODUCTION: The pre-interventional postprandial BGL values were 131.34 + 13.61 in males and 131.4 + 12.66 in females respectively, whereas the post interventional BGL values were 128.27 + 13.95 in males and 128.14 + 12.73 in females respectively. Intra group changes in the postprandial BGL values showed statistically extremely significant reduction in both males and females. This was done by using paired ‘t’ test.

Discussion

Diabetes mostly contributed by type 2 diabetes mellitus which constitutes 80% to 95% among the total diabetic population. Type 2 diabetes mellitus is formerly called adult onset diabetes.

In DM muscles get atrophy due to insulin resistance and pancreas loses its ability to secret enough insulin. As it reduce muscle quality and affects muscle functional to perform physical activities which ultimately leads to secondary complications such as mortality, long term DM damages, inability to function and failure of organs such as kidneys, eyes, heart and blood vessels. Individuals with type 2 DM having lack of physical activity causing sedentary lifestyle.

This research was undertaken with the aim to study and compare the immediate effect stretching and strengthening exercises on blood glucose level in chronic diabetes mellitus.

44 patients (18 females, 26 males) of type 2 DM, age group 40 – 65 years approaching to OPD of Krishna college of physiotherapy participated in the study. They were divided into two groups. Each group had 22 patients. A thorough diagnose was done in medicine OPD before application of treatment strategies.

Group A was treated with passive stretching. 9 females and 13 males participated in the group. and group B was treated with strengthening exercises with theraband. 9 females and 13 males were included in this study. Two muscles of upper limb (biceps, triceps) and lower limb (quadriceps, hamstring) were taken for treatment for both the groups. Pre-treatment outcome measure for postprandial blood glucose level was done with glucometer. The specific protocol was given to the patients according to the groups. The time taken for the both groups was 60 minutes and at the end of the treatment, blood glucose level was measured by glucometer. Statistical analysis was done using paired ‘t’ test within group and unpaired ‘t’ test was applied to compare the results between the two groups.

In the study pre-interventional postprandial BGL values were 126.9 + 10.37 in group A and 131.4 + 12.92 in group B respectively, whereas the post interventional BGL values were 123.4 + 10.37 in group A and 128.2 + 13.15 in group B respectively. Group A (p = 0.0014, t = 3.680), group B (p <0.0001, t = 12.931). Intra group changes in the postprandial BGL values showed statistically very significant and reduction in postprandial BGL values in A group and extremely significant difference and decreased in BGL values in group B. Inter group analysis for postprandial BGL showed statistically not significant difference between group A versus group B (p=0.2191, t= 1.332).

In the study gender-wise comparison within group A the pre-interventional postprandial BGL values were 127.85 + 9.82 in males and 125.75 + 11.62 in females respectively, whereas the post interventional BGL values were 124.1 + 10.17 in males and 122.4 + 11.19 in females respectively. Males (p <0.0001, t = 7.117), females (p = 0.1890, t = 1.436). Intra group changes in the postprandial BGL values showed statistically extremely significant difference and reduction in males and not significant difference in postprandial BGL values in females.

In the study gender-wise comparison in group B pre-interventional postprandial BGL values were 131.34 + 13.61 in males and 131.4 + 12.66 in females respectively, whereas the post interventional BGL values were 128.27 + 13.95 in males and 128.14 + 12.73 in females respectively. Males (p<0.0001, t = 8.035), females (p<0.0001, t = 14.116). Intra group changes in the postprandial BGL values showed statistically extremely significant difference and reduction in both males and females.

In above study, 60 mins of treatment were divided into 3 phase ( warm up phase, treatment phase, cool down phase.) for both the groups.

Free exercises to warm up the body and activate the muscles for further treatment for both the groups. Even after treatment (cool down phase),free exercises which helped in muscle relaxation.

In group A, Passive stretching improved flexibility, elongated a shortened muscle-tendon unit and peri-articular connective tissues. It helped to remove...
contracture formation and other soft tissues that had adaptively shortened. It was found to be extremely significant in males compared to that of females. The other group i.e Strengthening, produced muscle tension and increased in the maximum force – producing capacity of muscle and increased in muscle fiber size and flexibility. Insufficient muscular strength caused major functional losses of even the most activities of daily living\(^{(5,6,8,9,10)}\).

Therefore strengthening increased more flexibility in females than passive stretching and males were benefited with both stretching and strengthening exercises. statistically it was found that the results were not significant difference between group A and group B.

**Conclusion**

Thus, from the above conducted study it concludes that both stretching and strengthening exercises are effective in decreasing postprandial blood glucose level in type 2 diabetes mellitus, as there is no significant difference between both the groups. Strengthening exercises increases flexibility in females than passive stretching and males were benefited with both stretching and strengthening exercises.

Origin of Parisian Laws and Regulations in India: “Fons et origo of Zoroastrianism”

Shyamantak Misra¹, Prafulla Chandra Mishra²
¹Research Scholar, ²Dean, School of Law, KIIT, Bhubaneswar, Odisha, India

Abstract

The present article is elucidation of Parsi’s and their personal laws to make it a less confused and more comprehensible study matter. The title “Fons et origo of Zoroastrianism” means the source or the origin of Zoroastrianism. Those who believed that there’s only one Supreme God namely “Ahura Mazda” are known as Zoroastrians. The researcher has discussed the status of Parsis from its inception till date. This piece of work starts with a detailed study of their origin, simplifying their upbringing and tracing their movements and further stressing on the enactment & application of their laws in India. This piece of literature, emphasizing on the origin of the Zoroastrians further focuses on the legal provisions relating to Parsi marriages, divorce and maintenance as well. In Toto it’s a compilation of the most needed information and majorly required provisos relating to Parsis.

Keyword: Parsi, Zoroastrian, Personal laws, Marriage, Divorce, Maintenance.

Introduction

“In all religions we hear of the seven planetary genii: The Hindu tells of seven Rishi, The Parsi of seven Ameskaspentas, The Mohammedan of seven Archangels & The Christian religion has its seven spirits before the throne” Max Hoindel

As per my style of upbringing i.e a “typical Hindu”, I was always thought that “God is one” and “All religions are path to the same God” but as I grew to learn the upbringing of every religion, I find differences in origin source, style and words but the essence of a “common truth” remaining constant. Zoroastrianism being a uniquely different on drew my attention first the Parsi people who may also be addressed as the “Tajiks of Afghanistan”, or Tajikistan and Uzbekistan” or the “Tats of Eastern Caucasus (Republic of Azerbaijan)” were a major nomadic branch of the Iranian population that entered Iran during the 10th century B.C.

Varieties of terms were derived from the Greek word “Persis (e.g. Persia) to refer to such people who occupied the major portion of the Pars Province (or Fars), cultural capital of Iran The term “Persia” soon become an official name for all of Iran for many years.1 Soon the western world became familiar to the term “Persian” to refer the Inhabitants of Iran.²

However, it is essential to know who a Parsi is? It is a fairly, well known that the Parsis came from Persian Province of ‘Pers’or“Pars’ from which the word Parsi’, has been originally derived. The Parsis are said to follow “Zoroastrian” religion. The words “Zoroastrian” & “Parsi” are used interchangeably. Although their original faith does allow conversion amongst Parsis but Zoroastrian religion is a non-convertible religion. In India it was held that: “conversion to Zoroastrian religion is against usage and customs”. Thus Parsi means those Persons who are descendants of original Persian emigrants or Person whose father is or was a Parsi and mother an alien but admitted to Zoroastrian faith or Zoroastrians from Iran who are or have been residing in India.

Rise of Persian Empire:

However according to the “Black Obelisk of Shalmaneser III and Merriam Webster online dictionary, the first Persian empire was founded by Cyrus the great in 550 BC which was a small collection of semi nomadic tribes that raised sheep’s, goats & chattel on the Iranian Plateau but by defeating the nearby kingdoms of Media, Lydia & Babylon & so on and bringing them under a single rule, he soon established the world’s first super power uniting: Mesopotamian civilization, Egypt’s Nile Valley Civilization and the Indus Valley Civilization”
known as Achaemenid Empire or Persian Empire.

The above-mentioned empire stretches from Europe’s Balkan Peninsula (in parts of Bulgaria, Romania, Ukraine) to the Indus River Valley in Northeast India and South of Egypt.

The Persian people were highly talented. Their works includes architecture, weaving, painting calligraphy, metalworking, painting, sculpture, stone masonry, literature, music etc. Their art is considered to be one of the richest art heritages in world history. They were the people who developed the various means and routes of communication between Africa, Asia and Europe, and the world’s first portal services as well.

The Persian Empire witnessed the dominance of Islamic religion after the Arab conquests and early Islamic conquests. Thereafter Zoroastrianism prevailed as a religion in the first Persian empires under the beliefs of monotheistic faith of the founder of Zoroastrianism, Prophet Zoroaster (Zarathrustra in ancient Persian) Parsis are followers of Zoroastrianism in India.

A group of these above-mentioned Zoroastrian emigrated from Persia to prevent themselves from the Islamic religious persecution by the Muslim majority after the early Muslim conquests.

The symbol of Zoroastrians was fire purity symbols for Persians were that of fire & water. They worshipped in “fire temples”. Each temple had an altar with an eternal flame that burnt continuously or never extinguished. These were said to have come dulcetly from “Ahura Mazda” (Zoroastrian God).

The most unique feature of Zoroastrian religion being the “sky burial” of the dead. The dead were exposed to the local vultures by putting them on flat, circular toped towers called “dakhmas” or the towers of silence. Their corpse had to follow this procedure until the bones were picked clean & bleached and further collected and placed in ossuaries (lime pits).

In the present time Zoroastrians bury their dead under concert slabs in Iran because of the declaration that “Dakhmas” are illegal in Iran since 1970s. The last “dakham” in operation is located near Mumbai, India. The 19th century novel by the German philosopher Friedrich Nietzsche named “Thus spoke Zarathustra” made the Zoroastrian founder famous amongst the Europeans. In the mentioned novel Nietzsche follows Zaurastra in his travels.

In a similar way Zoroastrianism became known to the western culture through the works of the famous British musician Freddie Mercury who was a Parsi descent and even his funeral was performed by an Zoroastrian priest in London.

Even the American novelist George R.R. Morlin creator of the fantasy series “A song of ice and fire” played a vital role in spreading the concept of Zoroastrianism. Since this novel was later adapted into HBO series “Game of Thrones, developed the legend of “AzorAhai” form Zoroastrianism, where AzorAhai was a warrior demigod who defeated darkness with the help of a fire God “R’hllor”. Here “R’hllor” s’ concept is said to be derived from the Zoroastrian fire God “Ahura Mazda”.

After the doom of the invasion of Greece by Xerxes I IN 480 B.C the Persian Empire entered a period of decline due to the depletion of the funds of the empire leading to a heavier taxation amongst the Persian subjects.

Finally, the Achaemenid dynasty was captured by the invading armies of Alexander the great.

Subsequently the rulers tried to restore the Persian empire to its original boundaries but could not succeed to regain the boundaries, that it had achieved under Cyrus the Great.

Thus, the Indian Parsis belong to the Zoroastrian faith, whose foundation is the belief in one God and on the basic tenets of good thoughts, good words and good deeds. The Indian Zoroastrians enjoy a non-proselytizing faith.

In Sir Denshaw M. Patel V. Sir Jamsetji Jiji Bhaiit was stated that it is against the usage and customs of the Parsis of India. (i.e. conversion to the Zoroastrian religion)

Hindu ruler at the time of immigration of Parsis to Indian had a condition imposed on them that “they would adopt Hindu customs of marriage. However later Parsis were greatly influenced by the customs which were followed by Hindus.

**Application of Parsi Laws**

In modern times Parsi laws apply to:
Ø Persons who have descended from the original Persian emigrants, who are or were born of Zoroastrian parents and profess Zoroastrian faith.

Ø Persons whose father is or was a Parsi and whose mother an alien but has been admitted to Zoroastrian faith

Ø Zoroastrians those who are from Iran but who are either temporarily or permanently residing in India.

Five conditions laid down by the Indian ruler for Parsis were:

Ø “They should adopt the local language.

Ø They should translate their holy teats into the local language.

Ø Their women should wear saree and not their attire.

Ø They should follow the local rites of marriage.

Ø They should surrender their arms.”

(cabinetmaker 1991: 2-3)

Thus, on agreeing to the above five conditions the king allowed them to build their fire temples.

During the rule of East India Company in India, the British charters explicitly saved the customs and usages of Hindus and Muslims in civil matters as they were deemed religious, unlike the Paris’s, Jews, Americans etc.

In exercise of the discretionary powers granted to the Judges, on the English principles of Justice, Equity & Good conscience, the residuary communities of Jews, Parsis etc. were operated under these English Laws. Later the English Common laws were applied to the Parsis and their proper descendants subject to certain exceptions relating to marriage and bigamy. In Sec. 50 & 56 of the Indian Succession Act, 1925 there are special rules for Parsi Intestacy. Arsis are also governed by the Parsi Marriage and Divorce Act of 1936.

There’s no legal adoption been followed to amongst the Parsis and therefore if a Parsi couple adopts a child, such child won’t be able to enjoy the automatic rights of inheritance.

Being one of the most progressive communities Parsis have always been into such conflicts between liberal & orthodox viewpoints.

However, in my opinion the old traditions and cultures should be preserved since India is a country of rich heritage but some sensitization efforts should be made to reform the current personal laws and creating new codified laws in order to preserve such small communities like Parsis, Christians etc. and their rich cultural heritage as well.

Marriage Under Parsi Law:

Marriages under Parsis are being governed under “THE PARSI MARRIAGE AND DIVORCE ACT, 1936 (ACT 3 OF 1936) (23rd April, 1936)” in India.

Parsis or the Zorastrians are generally opposed to inter-caste marriages and most practice endogamy (marrying within their own community or like groups namely, Yazidis, Druze, Mandaens etc.)

A Parsi most likely marries a fellow Parsi because they believe being an ethno religious group, so that one can only become a Parsi if one is born out of such a marriage.

The requisites for a valid Parsi marriage are:

“(1) No marriage shall be valid if:

(a) the contracting parties are related to each other in any of the degrees of consanguinity or affinity set forth in Schedule 1; or

(b) such marriage is not solemnized according to the Parsi form of ceremony called ‘Ashirvad’ by a priest in the presence of two Parsi witnesses other than such priest; or

(c) in the case of any Parsi (whether such Parsi has changed his or her religion or domicile or not) who, if a male, has not completed twenty-one years of age, and if a female, has not completed eighteen years of age.

(2) Notwithstanding that a marriage is invalid under any of the provisions of sub-section (1), any child of such marriage who would have been legitimate if the marriage had been valid, shall be legitimate.”

In cases where the father is a Parsi but the mother is not a Parsi, in those cases the child will be accepted in the religion only if the father applies for the child to be admitted into the religion through proper ceremony and steps as prescribed in their laws and customs.
Chinnappa Reddy, J. in Jorden Diengdeh v. S.S. Chopra observed: “that the law relating to judicial separation, divorce and nullity of marriage is far from being uniform. Surely time has now come for a complete reform of the law of marriage and to make it a uniform law applicable to all the people irrespective of religion caste and creed.”

**Divorce Under Parsi Law:**

Under the Parsi Marriage And Divorce Act 1936 the grounds of divorce has been stated under section 32 as follows: “Any married person may sue for divorce on any one or more of the following grounds, namely:

(a) that the marriage has not been consummated within one year after its solemnization owing to the willful refusal of the defendant to consummate it;

(b) that the defendant at the time of the marriage was of unsound mind and has been habitually so up to the date of the suit:

Provided that divorce shall not be granted on this ground, unless the plaintiff (1) was ignorant of the fact at the time of the marriage, and (2) has filed the suit within three years form the date of the marriage;

12(bb) that the defendant has been incurably of unsound mind for a period of two years or upwards immediately preceding the filing of the suit or has been suffering continuously or intermittently from mental disorder of such kind and to such an extent that the plaintiff cannot reasonably be expected to live with the defendant.”

Under section 32A the proviso relating to “Non-resumption of cohabitation or restitution of conjugal rights within one year in pursuance of a decree to be ground for divorce” have been stated as:

“(1) either parties can sue for divorce under these following grounds:

(i) that there has been no resumption of cohabitation as between the parties to the marriage for a period of one year or upwards after the passing of a decree for judicial separation in a proceeding to which they were parties; or

(ii) that there has been no restitution of conjugal rights as between the parties to the marriage for a period of one year or upwards after the passing of a decree for restitution of conjugal rights in a proceeding to which they were parties.

(2) No decree for divorce shall be granted to the plaintiff if he has failed or neglected to comply with any order for maintenance passed against him under section 40 of this Act or under section 488 of the Code of Criminal Procedure 1898 or section 125 of the Code of Criminal Procedure 1973.”

Under Section 32B of Parsi Marriage and Divorce Act 1936 the proviso for Divorce by mutual consent have been stated as:

“(1) Subject to the provisions of this Act, a suit for divorce may be filed by both the parties to a marriage together, whether such marriage was solemnized before or after the commencement of the Parsi Marriage and Divorce (Amendment) Act, 1988, on the ground that they have been living separately for a period of one year or more, that they have not been able to live together and that they have mutually agreed that the marriage should be dissolved:

Provided that no suit under this sub-section shall be filed unless at the date of the filing of the suit one year has lapsed since the date of the marriage.

(2) The Court shall, on being satisfied, after hearing the parties and after making such inquiry as it thinks fit, that a marriage has been solemnized under this Act and the averments in the plaint are true and that the consent of either party to the suit was not obtained by force or fraud, pass a decree declaring the marriage to be dissolved with effect from the date of the decree.”

**Claim For Maintenance By Parsis:**

Parsis can claim from their partners for maintenance through criminal/civil proceedings or if interested they can even pursue for both the procedures simultaneously. However, the religion matters in case of Civil Proceedings but not in case of the criminal proceedings. In cases where the husband refuses to pay maintenance the wife can inform about the same to the court as it would be treated as contempt of court. Such husband can be sentenced to imprisonment and may be detained unless he pays.

Under the Parsi Marriage And Divorce Act 1936 both alimony pendente and permanent alimony has been recognized.
Indian Journal of Forensic Medicine & Toxicology, July-September 2020, Vol. 14, No. 3

The Bombay High Court in Hirabai Bharucha v. Pirojshah Bharucha where, a writ entitled to maintenance under section 40 of the Parsi Marriage and Divorce Act 1936, gave up her right in terms of an agreement.

Conclusion

The urge for migration of the Parsis was not driven by chance but its due to their individual determination to work hard and do the best possible for their Parsi group and family in light of the changing conditions that have occurred in India both socially and economically in the last few decades. Zoroastrianism might ultimately be accepted as the group which has abundant contribution to the society at large not specifically their group but others as well who were in need of spiritual dimension to enhance their personal lives.

Ethical Clearance: Not required, as the research article is based on origin of Parsi Laws and its legal provisions. The research is doctrinally undertaken.

Abstract

Lip prints are a constant anatomical structure and are absolutely unique to an individual and thus are an infallible means of personal identification. The present study was conducted in the Department of Forensic Medicine & Toxicology, on Undergraduate students (2015 batch) of Osmania Medical College, Hyderabad, Telangana. Sample size comprised of 196 students (78 males & 118 females) and aged between 17 and 20 years. In the present study, it was found that, Type I lip pattern was most commonly seen among males i.e. 70 out of 78 individuals studied (90%) and among females also type I lip print pattern was seen predominant i.e. 99 out of 118 individuals studied (84%). It was recorded that Type I lip print pattern was found to be more frequent among both the genders followed by type I lip print patterns. The analysis of presence of lip print in each quadrant among 196 individuals shows that the most common lip print pattern is in Upper right quadrant (URQ) of male lip was Type I’ 71 (91%), while among females these patterns are found to be 103 (87%). In upper left quadrant (ULQ) Type I’ was found among 71 (91%) males, same as that of 1st quadrant, while in females it is 98 (83%). In lower left quadrant (LLQ) among the male lip Type I’ [72 (92%)] was mostly seen, while in females it is same with type I’ pattern of 99 (84%). In lower right quadrant (URQ) of male showed Type I’ [68 (87%)], while among females type I’ pattern [98 (83%)] was found.

Key words- lip prints, type I pattern, upper right quadrant.

Introduction

Lips are highly sensitive mobile folds, composed of skin, muscle, glands and mucous membrane. They surround the oral orifice and form the anterior boundary of the oral cavity. There are two different kinds of lip covering - skin or mucosa. When the two meet, a white wavy line is formed- the labial cord which is quite prominent in Negroes. Where identification is concerned, the mucosal area holds the most interest. This area, also called Kleint’s Zone, is covered with wrinkles and grooves that form a characteristic pattern- the lip print. However, this is not the only area that deserves careful study. In fact, in cheiloscopy, one should also analyze lip anatomy, considering their thickness and position. The lips can be horizontal, elevated or depressed and, according to their thickness; it is possible to identify the following four groups:

1. Thin lips (common in the European Caucasian)
2. Medium lips (from 8 to 10mm, are the most common type)
3. Thick or very thick lips (usually having an inversion of the lip cord and are usually seen in Negroes) and
4. Mix lips (usually seen in Orientals)¹

Aims and Objectives

1) To determine the identity from lip prints.

2) To determine whether sex can be determined by lip prints.

3) To discover the most common pattern of the lip prints in the study group.

Materials and Method

Lip prints were collected from the subjects after obtaining their informed consent in the month of October.
Dark colored lip stick was used for printing over the rough surface of drawing chart. The subject was asked to rub his/her lips after application of lip stick. Prints were taken on the rough surface of drawing chart with centre portion of lips dabbed first and then pressing it uniformly to either side. Lip prints studied based on KAZUO SUZUKI and Y TSUCHIHASHI classification. For recording the finger prints, imprints of the fingers were taken on a plain white paper using ink pad. Observation of prints done by magnifying lens.

I) Inclusion Criteria
- Subjects willing to participate in the study and providing informed consent
- Subjects free from any active or passive lesions on their lips.

II) Exclusion Criteria
- Gross deformities of lips like cleft lip, surgical interventions, ulcers, traumatic injuries on lips, cracked lips.
- Known allergy to the lip stick ingredients.

III) Sampling Design
- Purposive sampling technique

IV) Study Design
- Observational study

V) Place Of Study
- Department of Forensic Medicine, Osmania Medical College, Hyderabad.

Observations and Results
The present study was conducted to assess the quadrant wise and gender wise predilection of Lip print patterns. Lip print impressions were obtained from both males and females and were classified by Suzuki’s classification. The distribution of lip print types in males and females in each quadrant were compared.

Table 1 depicts the overall results of the present study. The distribution of various types of lip prints in all the four quadrants of both males and females have been summarized here.

Discussion

Studies in relation to lip identification and evaluation have been carried out for more than half a century, and its importance has been recognized and accepted worldwide. Research has characterized lip prints in order to ascertain their features and characteristics, with lip print types, forensic application of the technique, and the method of acquiring lip impressions at the crime scene. Despite of the lip growth with age, the lip print invariably remains the same. A post mortem study revealed that lip prints can be obtained clearly if taken less than 24 hours after death.

Unlike fingerprints, unanimity still does not exist between examiners to accept cheiloscopy as a method of human identification. Some researchers are trying to relate characteristic lip patterns with person’s gender,
and detected DNA in latent lip prints.\textsuperscript{11} Research suggests that there is a conclusive evidence that lip prints are suitable for the successful comparison, analysis and identification of a person to a crime. In fact there have been convictions of perpetrators who were positively identified via the analysis of their known lip prints to those found at the crime scene. There is a need to develop one cohesive cheiloscopy system, practicable in forensic medicine.

In present study common lip print pattern was calculated by considering all the four quadrants among 196 subjects (78 males & 118 females). It was recorded that in males, 85% had type I lip pattern, 90% with type I’ pattern, 73% with type III pattern, 26% with type IV pattern and 2% had type V pattern. In females 73% had type I lip pattern, 84% with type I’ lip pattern, 65% with type II pattern, 24% with type III pattern, 9% with type IV pattern. Type V lip pattern was totally absent among female subjects. Present study had shown that type I’ lip pattern most commonly seen among all the study subjects.

In the study conducted by Amith HV et al\textsuperscript{9} shown that type I’ lip patterns were seen in 45% of males followed by type I pattern which is of 16% in males in the first quadrant.

In the study conducted by Augustine et al had shown that most predominant pattern in the entire study population, taking both the upper and lower lips together, was type III which constituted 48.2\%, followed in order by type II (18.92\%), type IV (17.44\%), type I (11.10\%), type I’ (2.54\%) and type V (1.58\%). The present study did show 51\% of males and 24\% of females had type III lip pattern\textsuperscript{1}.

The present study had showed that type I’ (type I variant) lip patterns are most predominant in all the quadrants followed type I patterns, type II, type III and type IV lip patterns in both males and females. These results are in contrast to the previous studies conducted on lip prints by, Kulkarni et al (2013)\textsuperscript{12}, Ghimire et al (2013)\textsuperscript{13}, Supraneni et al (2015)\textsuperscript{14}, Vahanwala et al (2000)\textsuperscript{2}. Type I pattern was found to be dominant in females in third and fourth quadrants and type II was dominant in males in third and fourth quadrants as reported by Vahanwala et al\textsuperscript{2}. In his study all four quadrants having the same type of patterns was predominantly seen in female subjects. In this study all the four quadrants having same type of patterns and was seen the same both in male and female subjects.

**Conclusion**

This study concluded that lip prints are a constant anatomical structure and are absolutely unique to an individual and thus are an infallible means of personal identification, if collected and analyzed carefully. Even the prints of the upper lip were different from the lower lip. Such is the uniqueness and it is unchangeable even if taken after some time from the same person. Each lip print pattern never occurred singly but present as a combination of all the 4 patterns.

In the present study, we found that Type I’ is common in all the quadrants in both sexes followed by Type I, Type II, Type III and Type IV. The latter two types III and IV are present predominantly in males. Type V lip pattern is present exclusively in males. In finger prints loops are the commonest in both sexes.

With reference to sex, lip prints vary from males and females in the following manner.

1) Grossly, the lips of males are larger in size in length and breadth in comparison to the females.

2) The Vermilion border in males is ill-defined due to the interference of the mustache whereas in females it is well defined with Cupid’s bow.

3) Branching and intersection of grooves is more prominent towards the peripheries of all quadrants in both males and females but it is more significant in males.

4) Patterns 3 and 4 are predominant in all the quadrants in males.

5) The least common pattern is Type V which is not found in females but present only in males.

Assessment of Mandibular Condylar Morphology Using Digital Orthopantomogram in Chennai Population

Sridhar M1, Sreedevi Dharman2
1Graduate Student, 2Reader, Department of Oral Medicine and Radiology, Saveetha Dental College, Saveetha Institute of Medical and Technical Science, Saveetha University, Chennai, India

Abstract

Objective: The present study was performed to evaluate the variation in shapes of mandibular condyle, determine the predominant shape and to assess any peculiarities in either gender in an Orthopantamogram (OPG).

Materials and Method: Radiographic evaluation of 3200 condylar heads after analyzing 1600 digitalized OPG’s were done. On analyzing, there were four different morphology of condyles observed. Variations occurring in the shapes were assessed, and combinations of the condylar shapes present in the population were established.

Result: Of 1600 pairs of condylar heads evaluated, 78% were oval in shape, followed by diamond (12%), crooked finger (6%) and least being bird beak (3%). Oval-oval was commonly occurring combination (60.5%) whereas crooked finger-bird beak combination was found to be very rare.

Conclusion: Dental professionals must have thorough knowledge in differentiating between normal and abnormal condyle morphology in an OPG as it possesses a diagnostic challenge for them. Asymmetries that occur in condyle morphologies radiographically in absence of clinical signs and symptoms of TMDs are considered to be normal.

Keywords: Orthopantomographs, Bird beak, Crooked Finger, Oval, Diamond, Condyle, TMJ.

Introduction

Mandibular condyle is seen roughly as ovoid in outline. Its dimensions are 15-20 mm mediolaterally and 8-10 mm postero-anteriorly. Many assumptions were made towards the shape of a condyle. Most commonly reported shape of condyle was convexity throughout and it should be symmetrical on both the sides i.e. right and left sides of the same individual. Hence, anything, which deviates from this convex morphology, was considered as pathology but normal variation in shape of condyle does occur.

Morphological alterations in the condyle can be due to simple developmental variability or as remodeling of condyle to cope with developmental variations, malocclusion, trauma, endocrine disturbances and radiation therapy. Hence, a thorough understanding of the morphology of mandibular condyle is essential to distinguish between normal variant from abnormal conditions.

The basic morphology of mandibular condyle is thought to be established early, and modified throughout life according to functional load. Condyle morphology variations occur with age, gender, facial type, Occlusal force and also even between condyles on either sides.

Orthopantomographs is of diagnostic importance as it is both cost efficient and it relatively reduces the dosage of radiation received by the patients. Panoramic
radiography remains the main screening modality for TMJ abnormalities if clinical examination suggests any joint pathology. Hence, OPG’s are valuable for determining the presence of osseous changes.

Our study aims to evaluate and document the variations in the shape of condyle on an OPG that aids in diagnostics i.e. distinguishing varying normal condylar shapes from abnormalities. The objective of this study is,

1. To evaluate the variations in shape of condyle seen in Chennai Population.
2. To determine the shape predominant in that population
3. To assess whether there is any peculiarity in either gender
4. To determine the occurrence of symmetry in shape of condyle on either side.

Materials and Method

Digital Panoramic Radiographs (OPG) (Planmeca-exposure parameters: 10 mA, 70 Kvp) which showed a full view of mandibular condyle on right and left side with optimum density and contrast were selected from the Oral Medicine and Radiology Department, Saveetha dental college. This is a retrospective study.

The present study comprised of radiographic evaluation of 3200 condylar heads after viewing 1600 digitalized OPG’s taken for routine radiographic investigation among Chennai Population. In our study, radiographs of 807 males and 793 females ranging from the age 18-65 years were included. OPG’s in which condyle heads can be visualized clearly were included in this study. OPG’s taken for patients who came for treatment of multiple dental caries or generalized periodontal disease were selected. OPGs of patients with history of TMD’s, Trauma, occlusal discrepancy, developmental abnormality, were excluded from this study. Condylar morphology of four types by Chaudry et al were identified which are

1) Type I - Oval shape.
2) Type II - Bird Beak Shape
3) Type III - Diamond shape.
4) Type IV - Crooked finger shape.

Results

A total of 3200 condyles were analyzed from 1600 subjects with age ranging from 18 to 65 years, out of which 807 were male and 793 were female.

A. Type of shape commonly seen: The shapes suggested by Chaudry et al were seen namely i) Oval, ii) Diamond, iii) Bird beak and iv) Crooked finger.

1. The most common shape was found to be Oval (78%), followed by Diamond (12%), Crooked finger (6%) and least being Bird beak (3%).

2. The most common shape observed among both males and females is Oval shape which accounted for about 74% in males and 72% in females respectively.

3. The combination of commonly seen shape among both male and female is Oval-oval which accounted for about 63% and 57% respectively as shown in Figure 1-6.

B: The gender wise distribution of shapes was evaluated. In males, Oval shape (74%) was predominant followed by Diamond shape (18%), Crooked finger (6%) and Bird beak shape being least common (2%). In females, Oval shape accounted for about (72%) followed by Diamond shape (18%), Crooked finger (6%) and Bird beak (4%).

C: To evaluate the combination of shapes occurring radiographically, revealed Oval-oval being the commonest shape which accounted for about 60.5% and Crooked finger-Diamond and Crooked finger-Bird beak is the least common combination which accounted for about 0.02% and 0.03% respectively.

Figure 1: OPG shows Crooked Finger appearance of mandible on either sides.
Figure 2: OPG reveals Diamond Shape of condyles on both the sides of mandible

Figure 3: OPG reveals Bird beak and Crooked finger shape Combination
Figure 4: This OPG shows Oval and bird beak shape combinations of condyle

Figure 5: This OPG reveals Oval and Crooked finger shape combination of condyle

Figure 6: This OPG shows Diamond and Crooked Finger combination of condyle on either sides
Discussion

Condyle responds to continuous stimuli throughout the remodeling process, and thus plays an important role in the final morphological dimensions of the adult mandible. The condyle has a special importance in growth of mandible.

**Figure 1: Shapes of Condyle on a Radiograph**

The appearance of mandibular condyle varies in different shape and size among different age groups and individuals. In 1961, Yale et al. was the first one to report about the different shapes of mandibular condyle. Initially Yale classified condylar head based on superior view into three categories namely concave, convex and flat, however later on he simplified it into five categories namely convex, flattened, angled, rounded and concave.

Evaluation of the shape of condyles upon surgical exposure of TMJ revealed that most of the condyles had a normal size and shape. Other varieties like excavated form, oblique shape, small round condyles and flattened condyles were noted.

Using different radiographic techniques many studies were done to detect the condylar morphology, to compare the accuracy of detecting condylar changes in temporomandibular disorders.

The most prevalent morphologic changes are detected in the TMJ of elderly persons due to the onset of joint degeneration.

The normal morphological variations like diamond, bird beak, crooked finger, oval should not be mistaken with TMJ pathologies like flattening of articular surface, erosions, pencil shaped condyles, osteophytes, anterior lipping of condyle and ely’s cyst.

Flattening is loss of an even convexity of condyle surfaces, Osteophyte is local outgrowth of bone arising from a mineralized joint surface, Erosion is local area of rarefaction in the cortical plate of a joint surface, Sclerosis is thickening of the cortical bone on a joint surface, Ely’s cyst is sub cortical cyst is rounded radiolucent area that may be just below the cortical plate or deep in trabecular bone.

Radiological variations of condyle should be always correlated with clinical signs and symptoms to arrive at the diagnosis of TMDs. Anuna Laila Mathew et al. in their study revealed that, radiographic abnormalities in the condylar morphology increased with age. They were seen more frequently in patients with clinical signs and symptoms of TMD.

Small asymmetries between left and right condyles were common. Small asymmetries are expected to develop during normal condylar growth, but the manner in which this asymmetry occurs has to be differentiated. Asymmetries in size differs from shape, volume or position asymmetries.

Asymmetries in condyle morphology without clinical signs and symptoms of TMD’s, careful radiological examination of condyle are required to rule out TMJ pathologies.

Our study aimed to detect the most common shapes on the head of condyle seen in a radiograph among Chennai Population. Of 3200 heads 78% were oval in shape, followed by diamond (12%), crooked finger (6%) and least being bird beak (3%). Our results showed a variation to previous study done by Sonal V et al, where the most common shape was found to be oval (60%), followed by bird beak (29%), diamond (9%), and crooked finger (2%).

In the same study, the oval was the most common shape in both males and females which accounted for about 61% and 46%. Similar results were obtained from our study in which oval being the commonest shape showed a high prevalence of about 74% in males and 72% in females as shown in the figure 3.

Combination of condyle shapes in OPG revealed that Oval-oval combination, was 60.5%, followed by Oval-diamond combination (12.25%), Diamond-diamond (7.6%), Bird beak-bird beak (5.43%), Oval-crooked finger(5.31%), Crooked finger-crooked finger (4.93%) and Crooked finger-Diamond and Crooked finger-Bird beak is the least common combination which accounted for about 0.02% and 0.03% respectively. In the similar study conducted by Sonal V et al, Oval-oval combination (67%) was most prevalent followed by Oval-bird beak (25%), Oval-diamond (5%), Bird beak-bird beak (3%) and Crooked finger- crooked finger is least common combination which accounted for about 1% only.

In the study Sonal et al, the combination of shapes commonly seen in male and females were evaluated where oval-oval combination was seen most prevalent in 58% of female population and 42% of male population. In our study, Oval-oval combination was seen in 63%
of male population and 37% of female population.

Gender wise distribution of shapes was recorded. In males, Oval shape (74%) was predominant followed by Diamond shape (18%), Crooked finger (6%) and Bird beak shape being least common (2%). In females, Oval shape accounted for about (72%) followed by Diamond shape (18%), Crooked finger (6%) and Bird beak (4%). But in previous study done by Sonal V et al, only the prevalence of commonest shape was recorded which showed Oval being most common in both males (62%) and females (46%).

Panoramic radiography is a screening tool for diagnosing TMDs. Various advanced imaging techniques are needed to confirm any pathology in addition to diagnosis made by OPG such as Radionuclide bone scanning which is a useful technique for showing early functional and biochemical bone changes, CT images which are highly accurate for osseous abnormality and Cone-beam computed tomography images which are superior over others for the bony morphology of mandibular condyles and detection of condylar cortical erosion. CBCT is a useful tool to measure and evaluate the condylar dimensions.

**Conclusion**

Dentists should have thorough knowledge on the characteristic normal mandibular condyle variations to give a diagnosis of TMD’s. Amount of condyle morphology asymmetry is considered as ‘normal asymmetry’ in the absence of signs and symptoms of TMD’s. Genetic, acquired, functional factors, age groups, individuals have a role in morphologic changes of condyle. Thus variability in the shapes and sizes of condyles should be an important factor in diagnosing the disorders of temperomandibular joint. OPG’s are preferred imaging technique as it is easily prescribed by most of the dental surgeons and is a screening tool for TMD’s. Hence, Dental professionals must have thorough knowledge in differentiating between normal and abnormal condyle morphology in an OPG, as it possess a diagnostic challenge for them.

Awareness of Medical Negligence among Practitioners

Sudharshan S1, Magendrann. J2
1II MBBS, Saveetha Medical College, Thandalam, Chennai; 2Associate Professor, Department of Forensic Medicine, Saveetha Medical college, Thandalam, Chennai, India

Abstract

Introduction The cases of medical negligence in the recent years have been gradually increasing. Unless knowledge about medical negligence is strictly implicated in the medical practice the rate of medical negligence will increase. Nearly 50 lakh Indians die due to medical negligence every year.

Aim & Objective The present study was aimed to assess the level knowledge and awareness regarding medical negligence among medical practitioners.

Materials & Method The present cross sectional study was conducted in saveetha medical college and hospitals, Chennai. A total of 100 practitioners were studied. The study period was from 24th February to 12th March 2019.

Result; In total, 100 medical practitioners were studied, of which almost all had knowledge about medico legal cases, only 88 of them take precautions during handling medico legal cases. only 47% were aware of the punishments given for medical negligence.

Conclusion The awareness among the practitioners is satisfactory. But 37% of the practitioners couldn’t differentiate medical negligence from medical errors. The knowledge about the punishments given for an act of medical negligence is not satisfactory only 40% had knowledge in that area. The attitude of taking precautions during handling a medical legal case was satisfactory, only 12% of them don’t take precautions.

Keywords: Negligence, Medical practitioners, Knowledge and awareness, Medical negligence.

Introduction

An act or omission (failure to act) by a medical professional that deviates from the accepted medical standard of care, is one definition of medical negligence.

Black’s Law Dictionary defines negligence per se conduct, whether of action or omission, which may be declared and treated as negligence without any arguments or proof, as to the particular surrounding circumstances, either because it is in violation of statute or valid municipal ordinance or because it is so probably opposed to the dictates of common prudence that it can be

without hesitation or doubt that no careful person would have been guilty of it. As general rule the violation of a public entry enjoyed by the law for the protection of person or property so constitutes.

Medical profession at present has changed from motive of service to commercialization.

Medical profession includes the knowledge of various disease, their treatment and understanding human feelings with care taking aspect. Nowadays the skills and knowledge of the practitioner is applied carelessly.

Medical profession is considered as the most divine of all professions worldwide. A doctor is placed second to god, his mission is to improve quality of life and help people from their sufferings.

Corresponding author:
Magendrann. J, MBBS, MD
Associate Professor, Department of forensic Medicine, Saveetha Medical College, Thandalam, Chennai, India.
Mob: +919841449887, E-mail: drmagi83@yahoo.com
Creating a rapport with the patient builds a relationship between a doctor and a patient. Speaking of which this have become the talk of the olden days. With commercialization spreading like a wild fire it has captured the medical profession under it’s hood

All doctors should know about medicolegal cases Concerned procedure and felt relevant Provisions . Usually what happens is that medical legal duties of a registered medical practitioner I thought in second year of MBBS graduation and then fortunately afterwards nobody bothers about it till one faces some problems in composition of a case of negligence

Okay surely the obstetricians and gynecologists have to face the challenges of negligence on or the cases of alleged contaminations off MP, PCPENDD act, and how to defend themselves in the courtroom. Hence from the legal point of view relations in the duties and obligations, or lapses or Ignorance (advertent or in advertent) committed by doctors give rise to Litigations related to civil and/or criminal legal liabilities

Indian society is experiencing a growing awareness regarding patient rights. In India, the consumer protection act(CPA) came into action in 1986, which was enacted for the better protection of the interests of consumers. The provision of consumer protection act now covers deficiency of service by medical professionals in such case to provide redressed to the patient

In the decisions Rendered by the Supreme Court of India, namely doctor Laxman Balakrishna Joshi vs. Dr. Trimbak Bapu godbole & Anr., 1969 [13] and A.S.Mittal bs. state of U.P.,1989[7],It was laid down .That when Dr consulted by a patient, the former, namely, Dr close Owes To his patient certain duties which are (a) duty of care deciding whether to undertake the case; (b) duty of care deciding what treatment to give; (c) A duty of care in the administration of the treatment

The 3 ingredients of negligence:

1. The defendant owns a duty of care to the plaintiff
2. The defendant breached the duty of care
3. The plaintiff has suffered injury

Negligence is the breach of a legal duty to care. It means carelessness in a matter in which the law mandates carefulness. A breach of this duty gives a patient the right to initiate action against negligence

A doctor can be held liable for negligence only if one can prove that she/he is guilty of failure that no doctor with ordinary skills would be guilty of if acting with reasonable care.

However, no human being is perfect and even the most renowned specialist could make a mistake in detecting or diagnosis the true nature of a disease. And this comes under the medical error(6) not under medical negligence. In this judgement, reliance was placed on the decision of the house of lords in White House vs. Jordan & Anr., (1981)[2] Lord Fraser, While receiving the judgement of Lord Denning (Sitting in the court of appeal), observed as under :

“The true position is that an error of judgement may or may not be negligent, it depends on the nature of error.

An error of judgment constitutes negligence only if a reasonably competent professional with the standard skills that the defendant professes to have, and acting with the ordinary care, would not have made the same error.

Indian criminal law has placed the medical professional on a different footing as compared to an ordinary human. Criminal law and medical negligence section 304A[10] of the Indian penal code of 1860 states that “whoever causes the death of a person by rash or negligent act not amounting to culpable for a term of two years, or with a fine or without.”

Getting an informed consent is an crucial thing in medical practice. The patient must be told the nature and purpose of the procedure/treatment, its benefits and potential risks/side effects. Failure to communicate and disclose potential risks is considered medical negligence.

Nearly 50 lakh Indians die due to medical negligence every year in different hospitals

Ignorance of law is no excuse for violating it. It is duty of everyone to know the law which concerns him or her nowadays practising medicine is hazardous & risky. Mutual faith replaced with mutual suspicion. This study was taken up assess the knowledge of medical negligence and professionalism among doctors working in Saveetha medical college, Thandalam

**Methods and Materials**

The present cross-sectional retrospective study was
conducted in Saveetha medical college and hospitals, Chennai. Medical practitioners were included in this study. A total of 100 medical practitioners were studied. The participants include practitioners from both clinical and non-clinical departments of Saveetha medical college and Hospital, Chennai. In this study 105 doctors were approached, out of which 100 of them were willing to take part in the study. They were given the liberty to pull of from the study whenever they wanted if they felt unsafe or uncomfortable. Only the questionnaires in which consent was filled properly were included in the study. The study period was from 24th February to 12th March 2019. Institutional Ethical committee clearance (IEC) was applied and obtained before starting. All the medical practitioners who took part in the study was briefed on the study’s purpose, and requested to participate in it. The questionnaire was distributed after describing the purpose of study. The participants were assured that participation is voluntary and confidentiality would be maintained. A structured, self-administered questionnaire containing 20 questions relating to awareness and knowledge about medical negligence was devised and pretested based on previous research studies and in consultation with faculty members of the department of forensics and state medicine. Each question had 3 options. Those who refused and who weren’t present on the third visit was excluded from the study.

Consent was obtained from which respondent. Confidentiality was maintained. After collecting the data, it was entered in the excel spreadsheet and the data was analyzed using SPSS software and frequencies and percentages were obtained and presented with graphs and chart.

**Result**

100% of the medical practitioners who participated in the survey had knowledge about medico legal cases.

Among 100 participants, 88% take precautions and 12% take precautions to some extent while handling medico legal cases.

The graphic analysis given below describes that 26% saying yes, 46% saying NO, and 28% saying don’t know, that whether Red Cross emblem belongs to doctors?

![Figure 1](image-url)
From the above graph For the statement “wrong diagnosis followed by wrong treatment is considered negligence” 35% agree

37% Disagree 28% Not sure

For the question “duration for which medical records for MEDICO LEGAL CASES of the hospital have to be maintained?” The analysis showed that 7% opting for 5yrs, 69% opting for 10yrs, 24% opting for 7yrs.
For the question “are you aware of punishments of medical negligence?” The answer percentages were 47%-yes, 26%-no, 27%-not sure

All of the practitioners get informed consent.

**Discussion**

Negligence within the medical world has assumed nice importance in reference to the medical malpractices suits in numerous countries Asia, Europe, USA And a lot of therefore in India.

Almost every participant in the study have knowledge of informed consent on this. Concerned requires that the patient fully understands the information given, but if the patient is debilitated be due to serious illness/mental condition, a suitable Surrogate should make decisions.
Written records, as well as medical record, chart notes, radiographs, and images should be meticulous, and it’s necessary for the documents to be signed and dated. Under article 51 A (h) of the Constitution of India, there is a Moral obligation on the doctor, and a legal duty, to maintain and preserve medical, medico-legal, and legal documents in the best interest of social and professional justice.

The findings of the present study shows the knowledge and awareness about medical negligence among the medical practitioners in Saveetha Medical College, Chennai. The participants of this study included both doctors working in clinical and non-clinical departments of the college.

In the present study, most of the participants had knowledge and awareness about medical ethics. The respondents think that their main source of knowledge about medical negligence was during various workshops, seminars, and clinical training.

The questionnaire consist of various questions about the awareness of medical negligence, precautions to be taken during medico-legal cases, record maintenance, legal punishment, proper consent, rights of the patients, euthanasia, Medical errors and lawsuits.

During the survey 100 practitioners from the clinical department of Saveetha Medical college it was observed that everyone had knowledge about medico legal cases. Around 80% of the respondents do take precautions during handling medico-legal cases, while 12% of them don’t and remaining to some extent. Almost every participant in the study have knowledge of informed consent, since everyone here takes proper consent before any examination or procedure.(5)

Around 2/3rd of the participants agree that refusing to attend a patient during emergency is negligence.

It is important do differentiate Medical negligence from medical error. Wrong diagnosis followed by wrong treatment is considered negligence is the statement but it is a medical error. Equal number of respondents agree and disagree on or not sure about the statement Wrong diagnosis followed by wrong treatment is considered as medical negligence. More than half of the participants aren’t aware of the punishments given for medical negligence. Maintenance of medical records and documents is Mandatory for hospitals. And duration for which the records has to be maintained Is also important. Very few respondents know the actual time period for which the medical records has to be maintained.

**Conclusion**

Most doctors have good knowledge on medical negligence but few lacked proper and detailed knowledge on medical negligence. Since there is a growing awareness about medical negligence among patients, doctors also need to have a strong knowledge of medical and medico legal cases. The knowledge about medical negligence, and as precautions to avoid medical negligence should be emphasized in the MBBS under graduate so also in post graduate syllabus and examination. The results of the study are consistent in the previous studies by Haripriya.A (1) and Dave. D . S.D.Nanandkar, G.S.Chavan have suggested that periodical CME programmes, re orientation programmes and medical ethics and acts related to medical practices in postgraduate curriculum to solve the lack of awareness among doctors.(5) There is always a continuum between practice and education a medical career is of a life-long learning.

Spinal Cord Belt (MSB) as a Method of Reducing the Level of Low Back Pain in Cashier Pos Ticket Worker at Panakkukang Mall in Makassar

Suharni A. Fachrin¹, Masriadi²

¹Lecturer of Faculty of Public Health, Universitas Muslim Indonesia, Makassar; ²Associate Professor, Department of Epidemiology, Faculty of Public Health, Universitas Muslim Indonesia, Makassar

Abstract

Background. PT.Centerpark in collaboration with Panakkukang Makassar Mall is a formal company engaged in providing parking services. Worker in this company work every day with an average of 8 hours a day, in a day worker is able to sit for 7 hours. So the risk of complaints pos ticket workers is very high. The purpose of this study was to determine the effect of using MSB on decrasing complaints of low back pain in the cash register cashiers at Panakkukang Mall Makassar in 2019. This study used pre and post tests to assess the level of low back pain in workers. Material and Method. The type of research used was an experimental quasi. The sampling method uses simple purposive sampling. The study was conducted in November - February 2020. The number of sampling was 30 people. The data analysis technique used in this study is Chi-square and Mann Whitney test. Results. The results showed that as The average level of low back pain before and after the use of MSB in the intervention group before using MSB the mean value is 4.93 mg/dl (SD = 1.03) after using MSB the mean value is 2.53 mg/dl (SD = 0.91). The use of MSB on the level of low back pain after treatment in the intervention group p (0,000) < p (0.05). The use of MSB on the level of low back pain after treatment in the control group was p (0,317) > p (0.05). There was a difference in changes in the scale of low back pain before and after using MSB in the intervention and control groups p (0,000) <p (0.05). Conclusion. There is a difference in the average level of the lower back before and after the use of MSB on the basis of the time before the use of MSB the average value of the worker level is 4.93 mg/dl (SD = 1.03) after using MSB 53 mg/dl (SD = 0.91). It is recommended for workers to use MSB tools every time they work.

Keywords: Spinal cord belt (MSB), Low Back Pain, Method of Reducing, age, length of work, years of service

Introduction

Back pain is a complaint that is found in everyday life. Almost everyone has experienced back pain. Lower back pain remains a major public health burden throughout the industrial world. Epidemiological data show that lower back pain (LBP) ranks 19th (27%) and lifetime prevalence is 60%. [1] The World Health Organization (WHO) explains that 2-5% of employees in industrialized countries suffer from low back pain every year, and 15% of absenteeism in the steel industry and trade industry is caused by low back pain (LBP). [2]

The application of modality can reduce low back pain needs to be applied, one of them by using the spinal cord belt (MSB). MBS is useful for reducing pain, correcting incorrect posture at work, and is also used as a prevention tool. Spinal cord belt is a tool that is used on the body, especially in the waist that serves as a body buffer to make it more stable and comfortable when work activities take place, spinal cord belt is recommended for people with LBP complaints as stabilizing the lumbar region, facilitating bending movements, and reduce pain.

This research was conducted at formal sector postal cash register workers at Panakkukang Mall in Makassar. The results of preliminary observations have found that
research has not been carried out specifically in the area of occupational health and safety. Cashier at the mall often does not pay attention to the compatibility between work facilities and work attitude, causing complaints of low back pain. This is seen by the presence of lower back pain complaints felt by the worker.

Material and Method

The type of research used was quasi experimental. The sampling method uses simple purposive sampling. The study was conducted in November-February 2020. The number of sampling was 30 people (intervention group 15 people, control 15 people). This research will involve intervention and control groups. The intervention group (workers use SBM 3 hours per day for 2 weeks) and control (no treatment is given) will each be pre-tested, namely the measurement of pain scale. The data analysis technique used in this study is Chi-square and Mann Whitney test.

Results

The number of ticket workers who experience LBP in this study is 30 people (intervention group 15 people, control 15 people). The results of these measurements can be seen in the following table.

Table 1. Distribution of Pretest and Posttest Back Pain Levels Based on Age, Work Period, and Length of Work at the Cashier Post Shop Ticket

<table>

Table 4 shows that the mean rank value for the intervention group is smaller than the control group, the change in the back pain scale of the intervention group (8.00) is smaller than the control group (23.00). The statistical test results using the Mann-Whitney Test p = 0.000 <p (0.05).

**Discussion**

Table 1 shows that there are differences in complaints of pretest back pain and means that there is a change in complaints of low back pain in this case back pain decreases from moderate pain to mild pain. The control group of mild pain pretest results 14 people changed to 13 people in the posttest, meaning that there was a change in pain complaints, namely increased pain complaints because the control group did not use MSB tools. Tarwaka (2015) explains that the complaint factors of low back pain are caused by work factors (type of work tenure, body posture at work, length of work and equipment), individual factors (age, sex, nutritional status, disease, and physical activity and sports), As well as physiological factors (scoliosis, HNP, spondylitis and osteoporosis). [3]

Other factors that cause LBP are poor health problems, psychological and psychosocial problems, degenerative arthritis, smoking, mayor scoliosis (more than one hundred and a hundred degrees), obesity, excessive body weight, work-related things such as prolonged sitting, or standing for hours, vibration, lifting, carrying weights, pulling weights, bending, twisting, and growing. [4], [5] The results of this study indicate that the lack of awareness of workers who do not pay attention to ergonomic posture while working and the lack of occupational health and safety knowledge in cashier workers who experience complaints of low back pain.

In this study, the largest number considered was 60% intervention group, 93.3% control group. Age is a predisposing factor that can restore the lower back and is usually suffered by people who open, change the shape
of the body made of bone so it is not elastic anymore like when young. Age of lower back recovery associated with aging increases, including increased degeneration of the spine at an increased risk of lower back pain. [6], [7], [8] Uninstalling, even though he was still a teenager but could experience lower back recovery, this happened to the cash ticket manager at the Makassar. Amod, et al (2015) conducted a study with no significant correlation between age and lower back pain in truck drivers in Nagpur India p 0.060 > 0.05. [9]

A person who works in daily work without rest can spend days and reduce the body’s work power decreases. Based on the distribution of the rate of recovery of pretest backs in the intervention and control groups based on the length of work (8 hours) in postal cashier workers showed in the intervention group with mild comfort (0%) and those who improved moderate pain (100%), while the control group with mild care comfort (93.3%) and those experiencing moderate pain (6.7%).

The researcher assumes that all respondents in the intervention group experienced moderate pain before treatment due to static work positions, long sitting for more than 3 hours and un ergonomic positions and uncomfortable worker chairs. Therefore, researchers recommend that workers’ chairs be replaced with chairs that have back cushion or backrest. This is supported by the research of Tomita et al. (2015) which shows that NBP does not increase during sitting 1-3 hours per day but NBP is related to sitting for more than 3 hours. [10]

Based on the distribution of the backpain level of the control group based on the length of work (8 hours) at the cashier post workers before treatment was obtained (6.7%) experienced moderate pain, after treatment was obtained (13.3%) who experienced moderate pain. The level of back pain in workers has increased because when assessing the level of pain there was an error because the assessment of pain was only assessed on a subjective basis. This is consistent with the results of research conducted by Tonapa Veny about factors associated with complaints of Lower Back Pain in Workers in Plantation PT. Toarco Jaya Kab. North Toraja in 2016, there is no relationship between length of work and complaints of low back pain. [11]

However, with long-sitting work activities and non-ergonomic sitting positions, cashier workers will need to mobilize large amounts of energy, but do not have enough time to rest so that the risk of experiencing muscle pain will increase. Respondents in this study are contract workers determined by the company with a contract system every 6 months contract renewal, so there are very few workers who work for more than five years. Based on the results of the study obtained that the highest percentage of cashier workers with complaints of low back pain is in the category of long years of working more than one year who experience complaints of moderate pain (93.3%) the intervention group (26.7%) control group and the length of service category less than one year experienced mild pain complaints (6.7%) in the intervention group, and (73.3%) in the control group.

The high level of pain is at the cashier workers whose work period is less than one year due to the high stress of the workers due to the low salary with high workload. This research is in accordance with the theory put forward by Tarwaka (2015) which states that the working period causes a continuous static burden if workers do not pay attention to ergonomic factors will more easily cause complaints of low back pain. [12]

Boshuizen reports that respondents who have more than 1 year of service have a higher risk of NPB exposure compared to respondents whose tenure is less than 1 year, this is due to the results of long-term spinal loading in the disk cavity that is permanently narrowed and also causes bone degeneration behind which will cause LBP. Most patients with acute low back pain have a previous history and therefore need a perfect clinical examination. The main purpose of the initial examination is to try to identify “danger signals” and to make certain diagnoses. [13], [14], [15]

Table 2 shows that there is a difference in the average level of low back pain before and after the use of MSB in the intervention group where before the use of MSB the mean value of worker pain level is 4.93 mg / dl (SD = 1.03) after using the MSB mean value of pain level is 2, 53 mg / dl (SD = 0.91) with p 0.000 < 0.005. Table 3 and 4. shows the It can be concluded that there is no difference in the average rate of return before and after the use of the MSB control group. The statistical test results using the Mann-Whitney Test p = 0.000 <p (0.05) means that there is a significant difference in effect between the groups that use the Medulla Spinalis Belt (intervention) and the groups that do not use the Medulla Spinalis Belt (control). The results showed that there was a decrease in pain scale in the intervention group after using the Medulla Spinalis Belt (MSB).
Because this tool when used causes a feeling of massage on the back because of this tool there is a buffer on the back. This can be seen from the decrease in pain scale felt by respondents.

Researchers use MSB to overcome this which is useful to reduce or eliminate lower back pain, MSB is made from simple materials namely from rubber and fabric, as well as a reinforcement tool that serves to avoid loose tools when used made of plastic material, MSB is functioned or useful to provide comfort to the lower back at work, especially to reduce pain when doing long sitting activities such as the cashier workers. This study gives the result that there is a decrease in the average pain scale in the intervention group due to the use and compliance of respondents in using MSB, so that it can cause the comfort of workers when sitting as a cashier and provide comfort when after the respondent works.

In most sufferers of low back pain have a tendency to experience improvement within a period of two weeks to three months. During this time period, when complaints of low back pain are in the process of resolution, or if back pain is chronic, it is necessary to consider appropriate conservative management. [16]

Conclusion

There is a difference in the average level of the lower back before and after the use of MSB on the basis of the time before the use of MSB the average value of the worker level is 4.93 mg/dl (SD = 1.03) after using MSB 53 mg/dl (SD = 0.91). It is recommended for workers to use MSB tools every time they work.

Rewa Road Old Bridge, near to Yamuna, Naini, Prayagraj, Uttar Pradesh

Abstract
Heavy metals can incorporate into humans by contaminated drinking water and can then be distributed into different tissues, which leads to an internal accumulation that can induce different alterations, adverse effects and acute/chronic metal poisoning. Nails can be used as bio-indicator for biological monitoring for the purpose of forensic examination in poisoning cases, assessment of metal exposures, as occupational marker and for health risk assessment. This paper deals with the comparative quantitative study of iron, lead, zinc, cadmium, copper and nickel concentration in nails of male subjects drinking and not drinking water from river. The levels of these metals were analyzed by Atomic Absorption Spectrophotometer (AAS). The result of this study showed Fe and Cu were significantly higher in concentration in the nail samples of people consuming river water whereas Zn concentration was slightly higher in the nail sample of people not consuming river water and Cd, Ni and Pb showed negative result in the both type of subjects. The present comparative study showed significant difference in heavy metal concentration in both the type of subjects. So it can be stated that people consuming river water are more affected, due to continuous exposure from these metal through the river. This study can prove that nail samples can be used as biological indicator and biological monitoring tool for assessment of heavy metal.

Keywords: heavy metals, nails, AAS, Biological monitoring, Bio-indicator, Forensic examination, Health risk assessment.

Introduction
The effect of environmental exposure to heavy metals on human health has received a great deal of interest in recent years. People are exposed to variety of heavy metal pollutants that are released into the environment as consequences of their living place and workplace activities. These heavy metal pollutants can be incorporated into the human by drinking water and can be stored and distributed in different tissues, consequently have a potential to lead an adverse health effect and/or disease. Prayagraj is blessed with most scared and important rivers i.e Ganga, Yamuna and third mythical river “Saraswati” (the point where Ganga and Yamuna River meet is called as Saraswati, Sangam in Sanskrit). Due to increased urbanization and industrialization these rivers are under intimidation of high-water pollution, the heavy metals contamination (such as- Mn, Cr, Pb, Zn, Fe and Cu) in the river water of various sites of Prayagraj region was found exceeding. 1

Nail have many advantages when compared to other biological materials in monitoring heavy metals:

1. They can easily be sampled and analyzed for accumulated toxic and essential metals in the tissue. So nails can be used as bio-indicators. 2-4

2. The higher concentrations of residues are found in nail samples, when compared to those on blood and urine.

3. Unlike blood that gives transient concentrations, nails can provide a continuous record of the metal concentration in body. 5
4. The capacity of nail to accumulate metals during extended periods, reflecting up to 1 year of exposure.

Nail can be the ideal matrix for most common heavy metal forensic examination due to its reliability, nail as evidences can be easily transported and stored for longer period of time, obtained without injuring the donor, have significant role in identification of suspected death through heavy metal poisoning (e.g. arsenic), also socio-ethically better option than post-mortem medico-legal findings.

**Methodology**

(1) Studied Area and Sample Collection

Study area is situated in the southern part of Uttar Pradesh in the Prayagraj (Allahabad) district (fig.1). People living near Arail Ghat mostly depend on the river water for drinking purpose because most of the people’s occupation is boat sailing and they do not carry water bottle with themselves, also because of spiritual believes that Ganga/Yamuna river water is the purest whereas as people living far from the river consume regular government tap water for drinking purpose.

![Figure-1 shows map of studied area.](image)

Finger and toenail clipping from 10 people drinking river water (living near Arail Ghat) and 10 non-drinkers of river water were collected. In all 20 samples 6 metals were analyzed (Iron, Copper, Nickel, Zinc, Lead and cadmium). Distal edge/Free margin (margo liber) of nail plate were cut with clean stainless steel nail cutters. All the nail samples were sealed in plastic bags prior to analysis.

(2) Procurement of Nail Samples

Nail samples of males (age range 30-50 year) were collected from both the types of subject. Following details of subject were collected:

a. Gender
b. Age
c. Drinker or non-drinker of river water
d. Occupation

Followed by this, fingernails and toenails of the relevant subjects were collected.

(3) Washing of Nail Samples

The nail samples was kept soaked in non-ionic soap solution for 2 hours in a labeled glass beaker and wash to free from debris then the sample was soaked in acetone for 1 hour to remove external contamination subsequently sample was rinsed five times with distilled deionized water and finally oven dried at 60-110 degree Celsius and kept in desiccator for further procedure.

(4) Digestion of the nail samples

Dried nail samples (0.5 grams) were placed in muffle furnace at 550 degree Celsius for four hours. After four hours in muffle furnace the nail samples became ash. The ashes were then digested with 10 ml of 6:1 mixture of concentrated nitric acid and per chloric acid, kept overnight at room temperature to prevent excessive foaming and subsequently the samples were heated at 160-180 degree Celsius until the mixture become water clear and reduces to 1 ml. Each sample solution was then diluted with 0.1N nitric acid and made to volume of 50ml with distilled water.

(5) Analysis of heavy metal concentration in nail samples from AAS

Metal concentrations of each sample were assayed by using Perkin Elmer-400 AAS with air acetylene flame. A series of standards were prepared in deionized water for instrumental calibration by diluting commercial standards containing 1000 ppm of the metals. All reagent used were of analytical grade.
Table-1 Parameter used for metal analysis in Atomic Absorption Spectrometer Unit (AAS) Perkin Elmer analyst 400 is shown in below table.

The results of this comparative study showed that heavy metals in the nails of both type of subjects accumulate differently based on exposure. It was observed that highest concentration of Fe (4.9mg/L) and Cu (3.4mg/L) was obtained in the nail sample of people drinking river water whereas highest concentration Zn (0.63mg/L) was obtained in the nail samples of non-drinkers of river water.

The level of Fe and Cu concentration were significantly higher in the people drinking river water when compared to the results of metal concentration of non-drinkers of river water, such differences recorded might be attributed to exposure of the people to heavy metal by drinking the studied area river water. Similar trend was observed for highest Fe and Cu concentration in the river water of studied area i.e. Fe 1.939mg/L > Cu 1.712mg/L. This indicates that the concentration of metals in the nail is a function of metal concentration in the work environment or exposure, this was in line with the work of Adulrahman et al. Metabolic activity is absent in nails. Hence it acts as a reliable diagnostic tool for environmental contamination assessment.

Zn concentration was higher in the non-drinkers of river water but concentrations were almost same in both the types of subjects. The reason behind such result may be because in natural surface waters, the concentration of zinc is usually below 10 µg/L, and in groundwater, 10–40 µg/L. In tap water, the zinc concentration can be much higher as a result of the leaching of zinc from piping and fittings. Drinking-water usually makes a negligible contribution to zinc intake unless high concentrations of zinc occur as a result of corrosion of piping and fittings.

Ni, Cd and Pb showed negative result in both types of subjects. The reason for the negative results of Ni, Cd and Pb concentration in the nail of the people drinking river water might be because of the fact that these metals were not present in high amount in the river i.e. Ni- 0.345±0.0093mg/L, Cd- 0.33±0.0013mg/L and Pb- 0.284±0.0525mg/L which is comparatively very less than the concentration of Fe-1.939±0.0494mg/L and Cu- 1.712mg/L. The reason for the negative results of Ni, Cd and Pb concentration in the nail of the people not drinking river water might be because they are not exposed to these heavy metals in daily routine.

**Conclusion**

Fe and Cu concentration was significantly high in the nails of people drinking river water and Zn concentration was slightly higher in the nails of non-drinkers of river water whereas negative results were obtained for Pb, Cd and Ni in both the type of subjects.

Abstract

This research aims to analyze and carry out theoretical criticism related to the open court principle, in the implementation of courtroom television in Indonesia. There are differences in the implementation of courtroom television in several cases in Indonesia. As in the case of Jessica Kumalawongso, the entire trial process, including the verification process, was broadcasted live. The research method is the social-juridical method. In such events, the presumption of innocence principle and the principle of witnesses being prohibited from communicating with each other were also damaged. The implementation of courtroom television affected the defendant’s psychological condition. Thus, this research will conduct a theoretical study related to the open court principle in the implementation of courtroom television in Indonesia and its consequences.

Keywords: Open Court, Courtroom Television, Psychological, Defendant, Principle

Introduction

Screening of court proceedings via television or what is known as courtroom television shows the influence of information technology advantages in the legal world. [1] Until now, there is no definite definition of the term courtroom television, but in his book, Paul Lambert states that courtroom television is “...one of central concerns in relation to television courtroom broadcasting is that television cameras or television operators will distract the various people who are required as part of the courtroom process. This includes witnesses, the jury, judges, lawyers, and court staff.”[2]

Screening of criminal case trial proceedings has also taken place in America, namely courtroom television of the O.J Simpson case in 1994.[3] Courtroom television is also carried out in Indonesia, in the case of a planned murder trial with cyanide coffee. The defendant was Jesica Kumala Wongso and this event reaped a lot of pros and cons. Also, a courtroom television was held for the blasphemy case against the accused Basuki Tjahaja Purnama or Ahok (ex governor of Jakarta Special Territory).

The implementation of courtroom television is inseparable from the discussion regarding the open court principle. Also, the application of courtroom television certainly has various consequences. Another interesting thing about it is the independence of judicial power in deciding a case amid the multiple public perceptions of the trial process, which is broadcasted live on television. [4] As is known, the truth should not influence a judge to shift their views according to the public or social trust. “Judges are accountable to God, not to social trust.” The magnitude of the judges’ responsibility to God and the important role of enforcing justice in the society require the realization of judicial power freedom from various influences, especially public opinion.[5]

That’s why what is more important is how the power of the media should be used to guard the people, and the media is also expected to have a conscience (the conscience of the press).[6] Courts in the UK also apply the open court principle. English criminal trials are held in public. A fundamental principle of the law of many modern societies is that justice should be done in public before an open court. An open court principle is one way to maintain public confidence.[7] Another purpose of the open court principle is “to protect trial fairness
by preventing abuse judicial authority. “[8] This certainly affects the court process and it indirectly impacts the evidence. So, the manifestation of the criminal law procedure’s function to seek and to find material truth or to come close to material truth is null and void.[9]

The trial process, as a process of law enforcement in the context of prosecution must be independent. It is part of the judicial power duty. The independence, after this referred to as the independence of judicial power, is a complex idea, not merely as a value, but also a useful instrument to pursue other higher values, namely the rule of law. [10] Independence implies giving authority to a judiciary that is free from interference from any party and is also free from the influence of other powers.[11]

The application of open court principle in the era of information technology development has shifted and may cause multi-interpretations. As a result, three is the trial by the press, which becomes a consequence of this open court principle. It has the potential to violate other principles, such as the principles of legality, the defendant’s presumption of innocence of, and the principle of where witnesses may not communicate with each other. Also, the implementation of the courtroom television is still different in each court in Indonesia. This is because the trial broadcasting permit policy is returned to each related court.

It is undeniable that openness by conducting broadcast in court is a demanded for transparency. It is an effort to maintain the integrity of judges as law enforcers, and also to control the proceedings of the judicial process. However, if this openness turns out to have consequences that damage other principles and other rights in a fair trial, [12] including the condition where the defendants are disturbed as they receive the public’s judgement before receiving verdict, there needs to be an idea to regulate the implementation of the broadcasting process by the mass media in the judicial process.

Based on the explanation above, it becomes a crucial question for sure, how the meaning of the open court principle shifted in the era of information technology development and the consequences of applying courtroom television in Indonesia. This is the urgency of the research.

**Research Method**

The method used in this paper is a legal research method. This research will explain the shift in the meaning of the open court principle in the era of information technology development and the consequences of the implementation of courtroom television in Indonesia, so that it can find a solutive regulatory model related to courtroom television. This study uses a statutory approach, a conceptual approach, a comparative approach, and a case approach.

**Results And Discussion**

1. Conceptual Meaning of the Open Court Principle

The principles of law are the basics or directions (richtlijn) in the formation of positive law. Regarding the, Meuwissen explained, [13] “From that principle, positive law obtains its legal meaning. It also contains criteria by which the quality of the law can be assessed ... the code can be understood against the background of a principle ... a principle that underlies”.

When we come to the discussion of the law principles, we also discuss the most important and the most essential elements of the rule of law. It is reasonable that the principle is interpreted as the heart of the legal regulations.[14] Because the legal principle holds ethical requirements, the legal principle is a bridge between the legal regulations and social ideals and the ethical views of the people. So, it can be said that through this legal principle, the rule of law changes its nature and becomes part of the ethical level. [15]

Fuller put forward an opinion to fathom whether we can talk about the existence of a legal system. The measure is mentioned in eight principles which he called the principles of legality. Fuller himself said that the eight principles he proposed were actually more than just requirements for the existence of a legal system, but instead, he gave qualifications to the legal system, as a legal system that contained an absolute morality.[16]

If we examine, there is a contradiction between the application of the open court principle which is achieved through courtroom television, with the presumption of innocence and also how the defendant’s psychological condition is affected by the public’s judgement. The absence of laws related to the courtroom television implementation subsequently violates the values of the other. The presence of courtroom television’s excessive reports on judicial cases in the process of the trial also has an indirect impact on judges, witnesses, and defendants.
It is what puts pressure on the psychological burden on the defendant regarding the judge’s decision.

Besides contradicting the principle of the presumption of innocence, the implementation of courtroom television that has no clear boundaries will also conflict with other provisions. It is contrary to the regulations governing the protection of witnesses and victims to maintain their security, safety, and comfort in providing their statements in the court. The domino effect of courtroom television can cause law enforcement to be hampered. It may even be dangerous for the defendant and their psychological mind.

2. The Shift in the Open Court Principle Meaning in Criminal Law Procedures

Criminal law procedure has principles which accompany the act. One of them is the open court principle. Basically, in a criminal case, an open trial is the right of the defendant, namely the right to be tried in a trial that is open to the public. Everyone can see and monitor the proceedings of the trial. The law requires the trial to be conducted not only by the parties concerned but also by the public. The purpose is to create a fair trial, to avoid arbitrary or deviant hearings so that the trial process becomes a media of educational prevention. It may also give information to the general public.

The practice of courtroom television in the narrow sense is by broadcasting the proceedings of the trial directly, whether it is a translation by the press in interpreting the open court principle or not. As a principle, of course, the sentence has an intense philosophical foundation. The nature of technology in a mediating position changes from the quality of transparency in the relationship to the quality of opacity in the hermeneutical relationship.

The development of courtroom television in response to the demands for openness in the era of information technology development turned out to be a boomerang for the parties in the trial. Judges, defendants, witnesses, and victims were targeted by the community’s opinion and the media to be discussed during the trial process. Public enthusiasm about the trial’s direct broadcast became very high. These methods of press reporting can lead to “trial by press or trial by masses opinion” and because this contradicts the principle of presumption of the defendant’s innocence, where a person must be deemed as not guilty before a definitive ruling from an unauthorized public judge.

Although sometimes the coverage made by the mass media related to a case is not entirely true, with the continuous reporting through various media, it can ultimately lead to public opinion and make people believe that the defendant must be guilty. This phenomenon is also influenced by what is called the post-truth, which can turn a thousand lies into a truth. At this stage, justice begins to experience siltation. Justice only becomes a textual narrative and is separated from the context. Justice brings about simplification, which reduces various details of the value it contains, because it is covered by the post-truth reality. As an illustration, there is an artificial reality in the tangible court, in the emergence of various kinds of public opinion regarding negative opinions created by the mass media related to the defendant which affects the truth value of the community, that the defendant must be convicted.

3. Ideal Concept of the Courtroom Television Implementation in Indonesia

Openness is a human right and is a means to maintain the spirit and integrity of the judiciary. The government and all law enforcement devices have committed to carrying out justice based on the open court principle. With regard to the process of applying the open court principle in America, the United States also did not allow coverage in any form in the courtroom, but in 1994 in the O.J. Simpson case was broadcasted due to the demands from public to access the progress of the case. Finally, the court conducted courtroom television for the O.J. Simpson’s case. But, the trial process which was broadcasted live by the mass media was apparently able to lead the opinion of the public that O.J. Simpson was innocent. The public opinion was able to influence the decision of the jury who has the authority to determine someone guilty or innocent. On October 3, 1995, O.J Simpson was found not guilty.

Therefore, in the implementation of the principle to open to the public in Poland, the practice of courtroom television is common. The courtroom television project is referred to as the Re Court Project. The difference between the implementation of courtroom television in Poland and other countries is that the witnesses who are asked for witness evidence by judges can directly see the recording of themselves live on the live broadcast appearance screen. Based on the implementation of courtroom television in the United Kingdom, America,
and Poland, it can be concluded that they apply strict rules and restrictions for the application of courtroom television for trial processes. These strict limits are aimed to maintain a noble court spirit, to minimize the misuse of recording results, and to protect the identity and security of all parties in the court.

Based on comparison with several countries, Indonesia must also make strict rules and limits related to the reporting and broadcasting mechanism of the trial process that is open to the public. So, the authors provide recommendations for setting courtroom television in Indonesia as follows: The strict regulation on the mechanism of courtroom television in Indonesia is expected to be able to prevent and minimize various interventions in the trial process. It is hoped to guarantee the fulfillment of the presumption of innocence principle, to protect the psychological mind of defendant from public judgement, and to protect the safety of the parties in the trial. These regulations are also aimed to create a fair trial.

**Closing**

**Conclusions**

The meaning of the open to the public trial principle underwent a change along with the development of the information technology era. At first, the meaning of ‘open to the public’ meant that the general public could attend and witness the proceedings in the courtroom. In its development, the public wishes to be able to witness the trial process anywhere, both inside and outside the courtroom, and also anytime. Then courtroom television came as an answer to the demands of openness in the trial process in the era of information technology development.

However, in its practice, the implementation of courtroom television in Indonesia, has various consequences. These consequences include broadcasting the trial process directly by the media and that the press can continuously create public opinion, which can then lead to trial by the press. It may also disturb the psychological condition of the defendant. In addition, the limitless courtroom television violates the defendant’s rights and may disturb the principle of presumption of innocence. In fact, broadcasting the trial directly which highlights the parties in the trial also endangers the security of these parties, both directly and indirectly.

Abstract

Background- Cerebral palsy is a permanent and non-progressive group of disorders in the development of movement and posture causing functional and activity limitations. Children with cerebral palsy have dorsiflexor weakness and ankle deformity, which negatively affect their gait. This study mainly focuses on facilitation of dorsiflexors to improve gait. Facilitatory techniques are useful for facilitation and enhancement of muscle activity to achieve improved motor control.

Objective: To find effect of ankle dorsiflexors facilitation on gait in cerebral palsy.

Material and Methodology- In this pre-post interventional study 25 cerebral palsy children with gait abnormalities were included. Treatment protocol including facilitatory techniques was set for 6 weeks. After pre-post assessment data was analysed by using appropriate statistical techniques.

Result- According to this study there is an improvement in gait parameters and ankle joint range of motion with P value <0.0001, which considered extremely significant. This indicates an overall improvement in gait of children with cerebral palsy.

Conclusion- This study concludes that facilitation of dorsiflexors is beneficial for improving gait in cerebral palsy children.

Key Words- Cerebral palsy, ankle dorsiflexors, facilitatory techniques, gait.

Introduction

Cerebral palsy is a group of permanent movement disorders caused by abnormal development or damage to the brain. It occurs during pregnancy, during childbirth or shortly after birth¹. It is the most prevalent physical disability originating in childhood², ⁶. A diagnosis of cerebral palsy is often made based on the abnormal muscle tone or posture, delayed motor milestones, or the presence of gait abnormalities³, ⁴.

Signs and symptoms can vary greatly in cerebral palsy children. Movement and coordination problems associated with cerebral palsy includes- abnormal tone, involuntary movements, lack of balance, rigidity, delayed milestones, excessive drooling, difficulty with fine motor skills, difficulty in walking, etc.⁵ However , as child gets older some symptoms might become more or less apparent. And muscle shortening and muscle rigidity can worsen if not treated properly. The hallmark of cerebral palsy is a motor control deficit that differs in distribution, presentation, as well as severity across children. Promoting, improving or restoring the ability to walk is the most common goal in neurological physical therapy⁵, ⁶.

Cerebral palsy children show complex and heterogeneous motor disorders that causes gait deviations. They are primarily related to deficits such as
muscle spasticity, muscle weakness and loss of selective motor control, and secondary deficits such as muscle contractures and bony deformity. Foot drop and toe walking are among the most frequent clinical problems in children with cerebral palsy. The main underlying cause of these problems is reduced force in the ankle dorsiflexors and reduced motor control.

Management of gait deviations in cerebral palsy is complex and requires early identifications and better understanding of the gait deviations. Cerebral palsy present various possible combinations of impairments that can be managed by numerous types of treatments. Physiotherapy is certainly the most common treatment.

One of the major goals of physical therapy for children with cerebral palsy is to promote independent mobility. To accomplish this, children must have adequate active range of motion which is not hindered by spasticity, dystonia or contracture, sufficient strength to maintain body weight support, and motor control abilities to allow them to advance their limbs forward to take steps in an effective and efficient manner. The speed and energy costs of walking are also major factors in how functional the gait pattern will be for an individual child. Intense task specific training has been shown to be effective in several neurological populations as well as cerebral palsy.

Walking is essential for activities of daily living and social participation. Depending on the severity of gait impairment children with cerebral palsy are subject to different types of functional limitations and these functional limitations pose adverse effects on their health related quality of life. Because of the impact of gait abnormalities on participation and quality of life, the main focus of physical therapy interventions is often on improving gait.

Equinus or foot drop is a common deformity in children with cerebral palsy which occurs due to reduced motor control of ankle dorsiflexors. Facilitation and enhancement of muscle activity to achieve motor control are the key to many of the techniques used in neurological rehabilitation, it is a system of therapeutic exercises enhanced by cutaneous stimulation for patients with neuromuscular dysfunctions.

Facilitation of dorsiflexors can be done to achieve improved motor control of ankle joint and to improve or initiate gait. It includes various proprioceptive manoeuvres like positioning, joint compression, stretch and resistance, the more emphasis is given on exteroceptive applications such as tapping, brushing, icing, pressure and vibration in order to achieve optimal muscular action.

Material and Methodology

An experimental study was conducted with a sample size of 25. An ethical clearance certificate was obtained by Institutional Ethical Committee. The population under study is the cerebral palsy children with gait abnormality and/or dorsiflexor weakness. The study sample included individuals within the age group of 5 to 15 years. Subjects were chosen according to the inclusion and exclusion criteria. The motive and procedure of the study was thoroughly explained to them. Appropriate consent was taken from the guardians of the participants. A pre-assessment was taken by using gait parameters and range of motion. The patient underwent treatment using facilitatory techniques to ankle dorsiflexors to improve motor control and to train the gait, which included joint positioning, joint compression, stretch, resistance and various exteroceptive applications such as tapping, brushing, icing, pressure and vibration. The treatment was given for 6 weeks, 3 days/week for duration of 40min/session. After 6 weeks of treatment protocol, post assessment was taken by using outcome measures to study the level of improvement. According to the result obtained a conclusion was given.

Statistical Analysis and Results

Statistical analysis of the recorded data was done. Study design is pre and post. Arithmetic mean and standard deviation was calculated for each outcome measure. Paired T test was done. The study has P value <0.0001 and is extremely significant.
Cerebral palsy is one of the prevalent movement disorder originating in childhood. Although the condition is non-progressive, the musculoskeletal impairments and functional limitations associated with cerebral palsy are indeed progressive if not treated. Equinus or foot drop is one of the common deformity in cerebral palsy children and also a cause for the gait abnormalities. This deformity occurs due to loss of motor control, muscle shortening and contractures of ankle dorsiflexors. Improving gait and promote independent mobility is most common motor goals in neurorehabilitation. To achieve this, children must have adequate range of motion, muscle strength to maintain body weight.

**Discussion**

Cerebral palsy is one of the prevalent movement disorder originating in childhood. Although the condition is non-progressive, the musculoskeletal impairments and functional limitations associated with cerebral palsy are indeed progressive if not treated. Equinus or foot drop is one of the common deformity in cerebral palsy children and also a cause for the gait abnormalities. This deformity occurs due to loss of motor control, muscle shortening and contractures of ankle dorsiflexors. Improving gait and promote independent mobility is most common motor goals in neurorehabilitation. To achieve this, children must have adequate range of motion, muscle strength to maintain body weight.
Facilitation of dorsiflexors can be performed to improve ankle joint range of motion, to correct the deformity, to gain motor control and to improve or initiate gait.

In this study we wanted to determine whether facilitation of ankle dorsiflexors is effective for improving gait in cerebral palsy children. This study was completed with 25 cerebral palsy children of both sexes who were between the age group of 5 and 15 years with dorsiflexor weakness.

Applying facilitatory techniques to ankle dorsiflexors might have improved motor control and gait, which included various proprioceptive manoeuvres such as joint positioning, joint compression, stretch, resistance and exteroceptive applications such as tapping, brushing, icing, pressure and vibration.

Facilitatory techniques is useful to achieve improved motor control. Joint positioning is used widely to prevent joint contracture and to depress unwanted reflex activity. Proprioceptors are involved with the awareness of joint position and movement which are stimulated by joint compression. Joint compression facilitates posture extensors which are needed to stabilise the body. Stretching achieves its effect via stimulation of muscle spindle primary endings which results in reflex facilitation of the muscle. Resistance is used to improve strength and achieve sustained muscle contraction.

The maximum importance is given on exteroceptive applications. Three to five taps over muscle belly is used to assess reflex activity with brisk muscle contraction. While brushing and icing are used to facilitate movement response and enhance static hold. By using vibration and pressure sustained muscle contraction can be achieved.

The ankle range of motion assessment and gait parameter assessment score as shown in figure 1 and 2 respectively indicates improvement in gait with P value <0.0001, which considered extremely significant. According to the data analysis study concludes that ankle dorsiflexors facilitation is beneficial for gait in cerebral palsy children.

Conclusion
This study concludes that facilitation of dorsiflexors is beneficial for improving gait in cerebral palsy children. The data analysis shows an improvement in gait parameters and ankle joint range of motion, thus resulting in an overall progression in gait.

Conflict of Interest: The authors declare that there is no conflict of interest.

Ethical Clearance: An ethical clearance certificate was obtained from the Institutional Ethical Committee Krishna Institute of Medical Sciences Deemed to be University, Karad.

Acknowledgement: The authors would like to express their special gratitude towards all the patients that participated in the study. We would also like to thank our families and institution for their everlasting support which enabled us to continue our research activities.

A Study of Histochemical Characteristics of Mucosubstances in Normal Endocervical Glands

Swapna Shedge A1, Padmaja. A Havle2, Megha A. Doshi3, Priya Roy4

1Assistant Professor, Department of Anatomy, 2Assistant Professor, Department of Obstetrics and Gynaecology, 3Professor and Head, Department of Obstetrics and Gynaecology, 4Associate Professor, Department of Anatomy, KIMS, Deemed To Be University, Karad and Maharashtra

Abstract

Background: The apical epithelial surfaces of mammalian respiratory, gastrointestinal, and reproductive tracts are coated by mucus, a mixture of water, ions, glycoproteins, proteins, and lipids. Mucins are mainly of two types- Neutral and Acidic. Mucus plays an important role in reproductive function and defence of the female reproductive tract. Objectives: To know the mucin distribution in normal endocervical glands.

Methodology: This is a retrospective, observational, analytical, case control study aimed to evaluate mucin histochemical pattern in normal endocervical glands. Ten histologically proven blocks of normal endocervical glands were taken. Tissue sections were stained by, PAS, PAS-diastase, Phenylhydrazine-PAS, Alcian blue pH 2.5, Alcian blue pH 1, combined Alcian blue-PAS, Aldehyde fuschin and combined Aldehyde fuchsin-Alcian blue techniques. Results: Results were tabulated according to colour intensity into different grades ranging from + to +++++. Regarding mucin histochemistry of normal endocervical glands; the epithelium and glands show mixture of both neutral and acidic mucins. Acidic mucins are more in amount than neutral. In acidic mucins, sialomucins are predominantly seen.

Conclusion: Mucin histochemical patterns serve as valuable, cost-effective tool for diagnosis in histopathology and for the researchers in histology, where a slight change in the mucin pattern may help in the early diagnosis of the disease process.

Keywords: Mucosubstances, Special stains, Cervical mucins, Normal

Introduction

Mucus is a complex viscous adherent secretion synthesized by specialized goblet cells in the columnar epithelium that lines all the organs that are exposed to the external environment. This includes the respiratory tract, the gastrointestinal tract, the reproductive tract and the oculo-rhino-otolaryngeal tracts.1,2 Mucus plays an important role in reproductive function and defence of the female reproductive tract.3 Cervical mucus, reported to be secreted at a rate of 20-60 mg/day, 3,4 provides a barrier to sperm and pathogen entrance into the endometrium and provides a protective covering for the vaginal epithelium. Just before ovulation, mucus character changes from a viscous to a watery consistency to allow sperms to penetrate into the uterus. Alterations in mucus quantity and quality are related to hormone/reproductive status changes, infections, and pathology of the female reproductive tract.3,4

Mucins are high molecular weight glycoproteins that are found dispersed throughout the epithelia of the gastrointestinal, respiratory and reproductive tract.5 The term mucosubstances is used, as recommended by Spicer, Leppi and Stoward (1965), to denote all tissue components other than glycogen, rich in carbohydrates, which are present in connective tissue or as secretion of certain epithelial structures.6 Connective tissue mucosubstances are called “mucopolysaccharides”, while those secreted by epithelia are referred to as “mucins”.7

Mucins perform a wide variety of functions like lubrication, protection against acids etc. The

Mobile:+91-9850816966,
Email-ID: swapna.shedge@gmail.com
Mucosubstances also contain immunoglobulins primarily of IgA type, lactoferrin which chelate the iron necessary for growth of some bacteria and lysosomes which destroy some of the bacteria. Hence they act as antibacterial and antiviral agents and have protective mechanism.8

Mucins are classified into two main categories namely,

a) Neutral mucins, b) Acidic mucins.

Neutral mucins are slightly alkaline in nature and mainly help for reducing the pH and toxicity of substances. They are first to appear during development in intrauterine life by fourth to fifth month. Acidic mucins are subclassified into weakly acidic and strongly acidic.9, 10, 11 weakly acidic mucins contain terminal carboxyl groups and are called as carboxylated mucins or sialomucins. They contain chelating agents and have antibacterial and antiviral property. Strongly acidic mucins contain sulphate groups and are called as sulphomucins. They are thick, viscous and help for formation of protective coat for lubrication.10, 11

In malignancy, the malignant cells change their behavioural pattern and secrete different types of mucin than normal. During carcinomatous changes, cells revert back to their embryonic stage. Secretory changes occur even before the nuclear changes are visible and hence study of mucins may help to identify cancerous conditions at an early stage.12

Material and Method

The present study was conducted in the Department of Anatomy, Krishna Institute of Medical Sciences, University, Karad from May 2010 to June 2012. The type of study was observational, analytical and case control study. Sample size was 10 blocks of histologically proven normal endocervical glands. Staining with special stains as PAS, PAS-D, PAS-PH, AB 2.5 and 1, AF, combined AB-PAS, AF-AB was carried out and results were interpreted.

1) P.A.S. -- Periodic acid Schiff reagent stains all carbohydrates including mucosubstances. Therefore mucosubstances are P.A.S. positive.

2) P.A.S. Diastase -- Diastase dissolves glycogen like carbohydrates, but mucin remains unaffected. This stain is used for confirmation of mucosubstances.

3) P.A.S. Phenyl hydrazine -- Phenyl hydrazine dissolves neutral mucosubstances only and hence used to prove their presence.

4) Alcian blue -- This stain can be used at various pH levels.

   a) AB pH 1.0 -- This stain is highly acidic and stains sulphomucins only.

   b) AB pH 2.5 -- This stain is weakly acidic and stains both carboxylated and sulphomucins.

5) Aldehyde Fuchsin -- This stain only stains sulphomucins and confirms their presence.

6) Combined AB-PAS -- This staining procedure will stain all different types of mucin.

   Neutral –Magenta ; Carboxylated –Blue ; Sulphated --Purple.

7) Combined AF-AB - This staining procedure helps for differentiation and confirmation of carboxylated and sulphated mucins.

   Carboxylated –Blue; Sulphated--Purple.

All the results obtained were tabulated according to colour intensity into different grades ranging from + to ++++.13, 14, 15

Observations and Results

During the period from May 2010 to June 2012, ten blocks of histologically proven normal endocervical glands were collected. Histological technique with special stains as PAS, PAS-D, PAS-PH, AB 2.5 and 1, AF, combined AB-PAS, AF-AB was carried out.

All the results were tabulated according to colour intensity into different grades ranging from + to ++++.13, 14, 15

Colour Index:

++++ : Very strong positive reaction.

+++  : Strong positive reaction.

++   : Moderate reaction.

+    : Weak reaction.

-    : Negative reaction.

**Inference:**

Regarding mucinhistochemistry of normal endocervical glands, a mixture of mucosubstances was observed. The epithelium and glands are showing mixture of both neutral and acidic mucins. Acidic mucins are more in amount than neutral. In acidic mucins, sialomucins are predominantly seen.

Discussion

The term “mucosubstances” is used to denote all tissue components, other than glycogen, rich in carbohydrates which are present in connective tissue or as secretion of certain epithelial structures by Spicer et al.6, 15

Numerous types of mucins occur depending on the site of production. Example of connective tissue mucins are chondroitin sulphate, heparin sulphate, keratin sulphate and hyaluronic acid. Epithelial mucins may be neutral or acidic. Neutral mucins are hexosamine units which may be associated with glucoronic or sialic acid; the reactive group being carboxyl. In sulphated mucins this group is blocked by a sulphate group which becomes the active group16. Strongly sulphated mucins are of connective tissue type; the weakly sulphated groups are of epithelial type. The non-sulphated mucins are sialic acid and hyaluronic acid (carboxylated D-glucoronic acid). These can be enzymatically digested, though enzyme resistant forms do occur.16

The presence of carboxylated or sulphated groups was determined by various staining techniques and confirmed using enzyme digestion methods.16

With the development of new histochemical methods by special stains, specific chemical composition of mucosubstances is documented by various scientists. But there have been very few studies on human endocervical mucosubstances such as by J. N. Bulmer et al (1988), Vatsala Misra et al (1997), Zhao Shumei et al (2003) and Hayashi, Isamu M.T et al (2003).
