Skeletal muscle regeneration is a highly regulated process, very complicated. It involves many factors in the process, among other specific muscle genes, satellite cells, and extracellular matrix was instrumental in muscle fibers reconstruction. The synthesis and degradation of proteins unbalanced also leads to the loss of muscle mass. Research shows that more than a standard protein diet: 0.8 g/kg/day reduces skeletal muscle mass and the condition of negative protein balance. Malnutrition in HIV infection causes a decrease in the immune response and progression of HIV. The state of malnutrition causes endocrine changes, which led to the mobilization of amino acids, especially skeletal muscles that affect skeletal muscle regeneration.

Skeletal muscle regeneration is mediated by satellite cells, although generally in calm conditions. Satellite cells become active due to muscle damage, subsequently undergo proliferation, differentiation, and fusion to form new muscle fibers, resulting in tissue regeneration and restoration to normal function. Satellite cells closely associated with Pax7, and together with MyoD, determine the fate of satellite cells. Pax 7 expression on calmsatellite cells, and the muscle injury, will stimulate satellite cells to proliferate and rapidly induces the expression of MyoD (Pax7+/MyoD+). Most satellite cells active, differentiated, ensued repression Pax7 and increased expression of Myogenin, and MRF4, a small portion back to the conditions (Pax7+/MyoD-) who responded the next muscle injury, and repair. Muscle regeneration via the activation of many signaling pathways. Activation of Notch signaling increase satellite cells to self-renew and inhibits differentiation by suppressing the expression of MyoD. Notch and Wntsignaling play an essential role in myogenesis, and Wntsignaling stimulates the expression of Pax7.

Physical exercise as a non-pharmacological therapy in people living with HIV in Indonesia has not become standard therapy. There is no formal physical training for people living with HIV on the intensity, duration, frequency, and type. The treatment given to people living with HIV in this study is regular physical exercise as aerobics HIVA, 2x per week frequency, duration of 23 minutes of physical exercise, moderate-intensity 60-70% of maximal heart rate, type of training with weight-bearing activities, for eight weeks or 16 times. The profile of HIV infection is continually changing, and some people regard it as a progressive disease and lethal.
Most people living with HIV who get antiretroviral therapy showed a chronic illness and treatable. Chronic conditions reflect an increase in disability in people living with HIV\textsuperscript{18}, but physical exercise is a crucial strategy for overcoming disabilities.

Paired box transcription factor (Pax7) activate transcription and controls the expression of a myogenic regulatory element in the quiet and active satellite cells \textsuperscript{19}. Paired box transcription factor (Pax7) expression increased within 24 hours after muscle injury and when the satellite cells have been heterogeneous. Research McKay et al. \textsuperscript{20} showed that satellite cell humans have always shifted in the cell cycle, from the phase G\textsubscript{0}/G\textsubscript{1} to S and G\textsubscript{2}/M within 24 hours after contractions that cause muscle injury. In the first 24 hours after muscle contraction, obtained Pax7 increase (36\% in phase G\textsubscript{0}/G\textsubscript{1}), then Pax7 + (59\% in S phase), and the next satellite cells obtained Pax7 + (202\% in G\textsubscript{2}/M phase). These data indicate that the development of satellite cells in the cell cycle lasted 24 hours until at least 72 hours after muscle injury\textsuperscript{21}. This condition means that the active satellite cells did not coincide but in varying cell cycle phases\textsuperscript{20}. In adult muscle under physiological conditions, satellite cells express Pax7. Satellite cells are ready to respond to molecular stimuli from physical training, injuries, and diseases. They can self-renew, extend themselves, proliferation as myoblast or myogenic differentiation for fusion, and restore muscle damage. Satellite cells are the primary contributors to the growth, maintenance, and repair of skeletal muscle after birth \textsuperscript{22, 23}. Some studies in mice have shown that Pax7- will lose satellite cell lineage in all muscle groups\textsuperscript{16, 24} by contrast, research Lepper et al. \textsuperscript{25} reported that Pax7 does not need the normal function of satellite cells anymore after adolescence.

Increased Pax7 expression in this study because muscle contractions produce IGF-1, which stimulates anabolic and myogenic processes and plays a role in modulating muscle growth’s size. Insulin-like growth factor-1 stimulates the metabolism of protein in muscle fibers and increases myonuclei’s number through the proliferation, differentiation, and fusion of satellite cells\textsuperscript{26}. Liu et al.\textsuperscript{27} show that muscle activity and weight-bearing were influential in increasing the level of IGF-1 muscle.

This study indicated that satellite cells’ activation increased significantly in the intervention group (Pax7, \(p = 0.002\), and MyoD1, \(p = 0.010\)). Biopsy in this study was conducted 24 hours after the last physical exercise. Each marker of active satellite cell Pax7 and MyoD1 showed an increase that is not the same. These data concluded the phase difference, some satellite cells in a phase of activation and are already experiencing proliferation. Increased expression of Myogenin showed differentiation and fusion. The myogenesis process is dynamic so that the steps of activation, proliferation, differentiation, and fusion are always changing. These data showed the most significant increase in myogenin expression, which means there is already a fusion of new muscle fibers in the biopsy 24 hours after moderate-intensity HIV-A physical exercise for eight weeks.

Myogenic differentiation factor D (MyoD) is a protein that plays a vital role in regulating muscle differentiation \textsuperscript{28}. MyoD is one of the early markers of myogenic commitment, expressed at low levels in quiet satellite cells and satellite cell fusion. This study showed that the expression of MyoD1 in the intervention group is higher than in the control group. These results are consistent with Charge and Rudnicki’s \textsuperscript{22} research, which shows an increased expression of MyoD in satellite cells and muscle fibers mature in cell proliferation and differentiation for subsequent cell regeneration hypertrophy.

Several myogenic regulators could examine muscle regeneration evaluation after the physical exercise in the vastus lateralis muscle. Satellite cell activation is an essential key in muscle regeneration. During regeneration, satellite cells undergo proliferation, differentiation, and fusion to form new muscle fibers, and it is necessary to compensate for muscle hypertrophy\textsuperscript{29, 30}. The MRF controlled Muscle regeneration (MyoD, Myogenin, and MRF5). MRF plays a role in the regulation of muscle response to changes in physical exercise or activity.
This study increased MyoD1 and Myogenin after HIVA physical exercise as monitor satellite cell activation to physical activity. Myogenic differentiation D (MyoD) is an important regulator involved in skeletal muscle adaptation to HIVA exercise. Research by Kosek et al. shows increased expression of MyoD after physical activity. On activation of satellite cells, MyoD increased within 12 hours of activation or physical exercise. Increased MyoD until more than 36 hours, and would be significantly reduced after one week. In this study, increased expression of MyoD has occurred 24 hours after the last physical exercise. Pislander et al. also show similar results that find an increase in temporary (transient) in the expression of MyoD in response to muscle strengthening exercises.

Contrary to the role of MyoD, Myogenin plays an essential role in muscle differentiation, consistent with a subsequent regulatory function in the process of particular types of muscle fibers. Myogenin expression increased significantly from the results of the biopsy were performed after eight weeks of physical exercise. This research shows that Myogenin increased within one week after physical therapy; these data are similar to those reported by Carson and Booth.

Physical exercise can influence the muscle fibers’ function, modify the structure, metabolism, and increase growth factors. Other signals are paracrine for the activation of satellite cells. These data increased expression of Pax7 and MyoD1 so that the HIVA physical exercise, going on satellite cell activation causes an increase in skeletal muscle regeneration. Increased Pax7, MyoD1, and Myogenin mean that the provision of HIV A physical exercise repeatedly improved the regeneration of skeletal muscle indicated with activation and proliferation (increased expression of Pax7 MyoD1) and satellite cell differentiation (increased expression of Myogenin).

Conclusions

Moderate-intensity HIVA physical exercise in a clinical-stage II HIV infection increases skeletal muscle regeneration. The addition of muscle mass to people living with HIV prevents HIV progression of muscle wasting.

Professional Socialization among Nursing Students

Sruthi M1, Aleena Baiju2, Swathi Krishna T P2
1Lecturer, Department of Mental Health Nursing, 2B.Sc. Nursing Students, Amrita College of Nursing, Amrita Viswa Vidyapeetham, Kochi, Kerala, India

Abstract

Objective: The objectives of our study is to determine the professional socialization among nursing students, to find out the association between professional socialization and demographic characteristics and to find the subgroup comparison of level of professional socialization among outgoing batch students and first year B.Sc. nursing students

Methodology: A descriptive study was conducted among all four years of nursing students of a private nursing college. Nursing students who meet the inclusion criteria (357) were selected using purposive sampling.

Results: The majority of the students are ‘Experts’ in maintaining professional socialization. But in the subgroup comparison of level of Professional socialization among the final year students with first year showed a 1.1% less in ‘Expert’ category. The results showed a significant association of level of professional socialization with ‘Gender’, ‘Mode of Admission’ and ‘Reason for selecting nursing as a profession’

Conclusion: The need for developing professional socialization has to be considered at the most priority. The results of this study shows the need for introducing new plans to make sure that the students level of socialization

Keywords: Professional Socialization, Autonomy, Competence, Commitment, Group participation, Nursing Students.

Introduction

Socialization is the process during which people learn the roles, statuses and values necessary for participation in social institution. Socialization is a lifelong process that begins with learning the norms and the roles of the family and subculture and making self-concept as individual grow older and join new groups and assume new roles, they learn new norms and redefine their self concept1.

Nursing as the largest part of professional personal in forefront line of delivering services in health care systems have multiple and expanded roles and duties. The roles of nursing are multiple and complex and nursing as a professional work require responsibility, attention and caution2. Development of the concept of socialization in nursing literature dates back to before 19853 and socialization is described as a major issue in nursing4.

Socialization is a process of acquiring individual identity in which he learns required values, norms and skills for serving his social task as an effective person his unique position5. Socialization a basic concept in nursing that is due to interaction among interpersonal, intrapersonal and work functional relationships6. These relationships give members the opportunity to organize themselves and their resources and solve their problems
by cooperation. In fact, professional socialization is a learning process of the professional roles. It consists of anticipatory, accommodation, and role management. The process to achieve required professional norms, values, and skills for professional survival is not well known.

A study was conducted in Ilam University of Medical Sciences in 2016 for assessing the level of professional socialization in nursing students. 130 nursing undergraduate students were studied, in that 21.4% of them have average socialization level and 78.6% were at high level, it was assessed based on the developed questionnaire.

A similar study was done on concept analysis of professional socialization in nursing. And they were able to identify that professional socialization varies depending on time, context, and different disciplines. The result of the study describes professional socialization as a complex, inevitable, diverse, dynamic, continual, and unpredictable process. In addition, they found that for individuals to be successfully socialized into their profession, measures such as the provision of comprehensive educational programmes, competent role model, supportive clinical and educational structures, and opportunity for field experience and constructive feedback are some determining factors.

Another study which was conducted among the students and graduate nurses and the results show that the most significant time of stress for student and graduate nurses is when in the clinical practice environment, new comers express that learning how to behave appropriately in the workplace is more difficult than bridging the gap between the theory and practice.

Professional attitude and commitment is seen decreased as compared to the older times among nursing professionals. Social behavior must be built among nurses from the student period onwards. Proper identification and processing of the determinants of professional socialization like knowledge, skills, and attitude in early stage of nursing can acquire professional identity, adapting with the professional role, professional, and organizational commitment and hence improve the overall nursing care quality and interpersonal relationship.

A qualitative research study on professional socialization was conducted among undergraduate nursing students and registered nurses with work experience with 8 to 25 years. The finding shows that nursing profession still struggles with problems that can alter professional identity and there should be an increase in providing educational experience to improve professional identity.

The results of all these research studies show the significance of studying about the professional socialization in undergraduate nursing students and hence to provide interventions to improve socialization in nursing profession.

As the nursing profession is in need to improve in their socialization with their co-workers and with the patients and relatives, the significance of studying professional socialization is increasing. Thus, this study is needed to assess the professional socialization of nursing students and to improve the nursing care quality.

**Methods and Materials**

The aim of the study was to assess the professional socialization among undergraduate nursing students which is developed during the nursing undergraduate period.

We started data collection on 3/10/2020. The consent and the data were collected through google forms. Students were given the google form links after 4 pm. From the purposive sampling the students who didn’t meet the inclusion criteria and those who were not willing to participate in the study are not included in the research study.

The study questionnaire was developed from previous research study on professional socialization, whose result had indicated some variables that influence the professional socialization process. These questionnaires were validated by different educators.
The study questionnaire was consisted of 5 parts: demographic data, professional autonomy, professional commitment and belonging, group participation, and professional competence. The study was conducted in 357 undergraduate nursing students through developed questionnaire.

The result scoring are based on Benner’s stage on clinical competence. Total we have 40 questions and the minimum score is 40 and the maximum score is 280. According to the Benner’s stage of clinical competence, the results could be divided into 5 stages: 40-88 novice, 89-137 advanced beginners, 138-184 competent, 185-232 proficient, and 233-280 expert.

Descriptive statistics and inferential statistics is done for data analysis. The tests used were frequency, percentage, mean and Standard Deviation for finding the distribution of personal characteristics. Independent t-test and Analysis of Variance (Anova) for finding the association between variables. SPSS software 18 is used for analysis and the significance level considered was $p \leq 0.05$.

According to Benner’s Clinical Competency Scale, the structured tool for assessing professional socialization was graded as Novice (40 – 88), Advanced Beginner (89 – 137), Competent (138 – 184), Proficient (185 – 232) and Expert (233 – 280). From the study, the examined samples (n=357) showed a result that a lion’s share (81.2%) were Experts in Professional socialization were as the outvoted were only (2%). This is an inarguable result that clearly emphasizes how the samples taken from the particular college is keeping a high level of socialization in nursing profession. The mean is 246.08 and SD is 17.14. There are no students in the categories Novice and Advanced beginner.

<td>1</td>
<td>1.4</td>
<td>15</td>
</tr>
</tbody>
</table>

Table 4 represents the subgroup comparison of level of professional socialization of first year B.Sc. Nursing and fourth year B.Sc. Nursing students shows that 78.9% of first year students shows expert socialization whereas 77.8% of fourth year shows expert socialization. The mean value of samples in first year is 244.06 with a SD 19.03 and that of fourth year is 245.26 with a SD of 18.02.

Table 5: Independent t-test results

<table>
<thead>
<tr>
<th>Levene’s test for equality of variances</th>
<th>T – test for equality of variances</th>

</tr>
</tbody>
</table>

Table 5 illustrates the results of independent t-test, clearly depicts that there is no significance at the level of p <0.05 because the Sig.(2 – tailed) is 0.783 which is > 0.05 p value. Hence there is no significance in the level of professional socialization of first year and fourth year B.Sc. nursing students when they are compared.

Discussions

Nursing is a health care profession which differ from other healthcare providers by their approach to patients and scope of practice. They identifies the issues in each patients individually and plans care, implements it with interdisciplinary collaboration. Hence nurses
needs to collaborate with other health care providers throughout their care and here is the importance of studying Professional Socialization among student nurses. The objectives of the study were to assess the level of professional socialization among the samples, to find its association with personal characteristics and to find subgroup comparison of level of professional socialization with first year and fourth year B.Sc. Nursing students. The study was conducted among 357 samples out of 375 total students of a nursing college who were selected by purposive sampling.

The assessment of level of professional socialization among the students shown that the majority of the students came under the category of experts (81.2%) and only 0.6% came as competent. Also it has to be noted that no students came in the first two levels, ie; novice and advanced beginner, which is an excellent result that shows the students are fit enough to be in nursing profession.

A study done by Nebhinami M Kumar and et.al on Stress and Coping Strategies among undergraduate students, in Western Rajasthan says that students are facing lot of stress during their academic period and active coping was used as the most common coping strategies. This result is quoted here to exclaim that his study samples also may be using such coping strategies for overcoming stress and this helped the majority to keep the professional socialization at its maximum.

The association of level of professional socialization and personal characteristics shown that there is a significant association with ‘gender’, ‘mode of admission’ and ‘reason for selecting nursing as a profession’. A study done by Cherkil S and et.al on coping styles and its association, done in medical students also have a similar association. The study results shown a positive results on ‘self-expectation’ and stress score. This result can be read along with the results of present study that ‘reason for selecting nursing as a profession’ and ‘self-expectation’ brings up the same meaning at the end.

When the third objective, subgroup comparison of level of professional socialization, was done with first year and fourth year B.Sc. Nursing students, the analysis gave the result that there is no significance in the comparison. The results also shown a 1.1% more experts in first year than fourth year. This difference need to be addressed. A few studies will give a support to this result. One study was done by Raghunathan D et.al among dental students on prevalence of depression and the other study was done by Sreedevi P A et.al in nursing students of the same college on correlation of assertiveness and self-esteem of undergraduate students. The first study shows the result of a few protective factors and a few risk factors and concludes with the call for implementing interventions for those at high risk of developing depression. The second study which was done on nursing students came out with the result of need for including assertiveness training in nursing education programme. Both the above said studies shows how the extraneous variables are affecting the students on their academics and on their mind. Farrell SM et.al had done a study on wellbeing and burnout in medical students and the study concludes that majority of the samples experience burnout and this needs to be addressed.

All the above quoted studies gives the picture that even though the research results are near to the accepted ones, the unnoticed variable areas surrounding the samples also need to take into account.

**Conclusion**

Nursing is one among the precious profession which is emerging day by day, with the advancement in science and technology and with the increasing needs of human population. The need for developing professional socialization has to be considered at the most priority. The results of this study shows the need for introducing new plans to make sure that the students level of socialization is keeping its needed status and the students are able to practice this in their professional life also.

Case Report

Management of Urolithiasis in Cat with Special Diets

Steven Taufic Leo¹, Lita Rakhma Yustinasari², Juliano Mwenda Ntoruru³

¹Veterinary Practitioner, Sunset Vet Clinic, Kuta Bali, Indonesia, ²Lecturer, Department of Veterinary Anatomy, Faculty of Veterinary Medicine, Universitas Airlangga, Indonesia, ³Research Assistant, Meru University of Science and Technology, Kenya

Abstract

Introduction: The current study is focused on the treatment of a cat with urolithiasis. The main goal is to help provide a greater understanding of how to treat the cat with special diets.

Case Description: Struvite urolithiasis was found in a 3-year-old female domestic short-haired cat with the complaint of straining for a week during urination. Ultrasonographs indicated the existence of two calculi in the bladder that were also detected by radiographic examination (7 mm in diameter each). Bladder stones were getting smaller by dissolution diets therapy. In this case, the cat was treated by melox 1.5 mg/ml (dosage 0.1 mg/kgBW) for 14 days, tramadol for 28 days (2mg/kg BW) and also special diets (struvite).

Conclusion: After a month treatment, the stones were almost cannot be seen radiographically. This report describes a cat with urolithiasis case which was successfully treated with special diets for struvite without any surgery.

Keywords: cat, struvite, dissolution diets therapy, urolithiasis

Introduction

Urolithiasis in cats can result in morbidity and even mortality for affected animals; the most common uroliths in cats (more than 80-90%) are struvite (magnesium ammonium phosphate) and calcium oxalate. Diet is very important for both treatment and prevention of urinary calculi, and some specifically formulated diets can promote struvite stone dissolution and reduce its recurrence. Most experts agree that struvite stones should be medically dissolved (unless contraindicated) with dissolution foods and/or medication. Struvite uroliths in cats appear to be between 2 and 7 years of age and female cats appear to have higher increased risk. The knowledge gained about urolithiasis is an outstanding achievement towards the treatment and control of the disease. However, eradication of the disease is the most challenging as it requires total examination of all the factors that are responsible for the formation of uroliths.

Case History and Clinical Observation

A 3-year-old female domestic short-haired cat weighing 15 kg was presented to Bali Vet Clinic, Kuta Bali, Indonesia with the history of straining since a week during urination and after urination she seems like dragging her bum on the floor. The cat was housed indoors and fed a commercially dry food with ad libitum drinking water. The cat was vaccinated periodically. Physical examination of the animal revealed pale mucous membrane with gingivitis and some plaque as well, tartar grade 2/5. Other vital signs such as blood pressure, body temperature, heart and respiratory rate were normal.
Abdominal palpation was detected the pain in belly area and a sensation was felt when the bladder is palpated. Struvite crystal and no bacteria were found on sediment examination. Urinalysis was not being evaluated because the cat’s owner agrees for sediment examination only. The cat was suggested to do a complete radiographic examination of the tract; radiopaque calculi about two stones (7 mm each in diameter) were visible inside the bladder. Ultrasonographic examination showed a thickened bladder wall. A cystotomy was not performed because the cat’s owner refused a surgery.

**Clinical Evaluations and Management**

A diagnosis of urolithiasis was made based on the radiographic and urine sediment examination. We offered two options: doing surgery or treatment with special diets for struvite. The cat’s owner decided to try medication and also food s/d (struvite) first. We suggested to observe the cat’s condition in a month and come for ultrasonograph and another radiographic as well. If the stones not getting smaller then may need surgery. The cat was properly treated with melox 1.5 mg/ml (dosage 0.1 mg/kgBW) for 14 days, tramadol for 28 days (2mg/kg BW) and also special s/d food (struvite) at home. We need transition periods over at least 1 week from the normal diet to the dissolution diet. We reminded owner that possibility for blockage (because this stone could go to urethra and stuck there). Reradiograph cats on dissolution diets was done after 30 days. The stones almost cannot be seen due to tiny on (Fig. 1). Ultrasonographic showed the stone’s size becomes < 3 mm in diameter. We suggested to the cat’s owner for maintaining her condition with special food (for struvite calculi) until the stones were no longer visible radiographically.

![Fig. 1. Radiograph image before treatment (A) showed a several calculi inside the bladder; after 30 days treatment with dissolution diets (B) showed that calculi almost could not be seen.](image)

**Discussion and Conclusion**

Urolithiasis is a nutritional disease that attacks domestic carnivores. Three main contributing factors which important to mechanisms involved in urolith formation are matrix, crystallization inhibitors, and precipitation crystallization factor. Uroliths are not produced unless sufficiently high urine concentrations of urolith-forming constituents exist and transit time of crystals within the urinary tract is prolonged. For struvite stones, proper pH must also exist. These criteria can be affected by urinary tract infection, diet, intestinal absorption, urine volume, frequency of urination, therapeutic agents, and genetics.8
Nutritional management is the best preventive strategy against urolithiasis. As such it may not replace the surgical procedures but may surely help in decreasing the recurrence rate of uroliths, since long-term pharmacological therapy and its potential side effects often lead to subsequent failure. Struvite dissolution diets are magnesium-reduced, acidifying diets. Struvite dissolution diets do not dissolve non-struvite uroliths and are less effective if a persistent UTI is present or the cat is fed anything in addition to the dissolution diet. The rate at which uroliths dissolve is proportional to the surface area of the urolith exposed to the undersaturated urine. Cats fed with low-magnesium, urine-acidifying dry foods had successfully reduction in urolith size at 2 weeks.4,9

In conclusion, dissolution diets therapy is safe and effective in management of sterile struvite calculi in cats. The key goals of dissolution diets include manipulation of urine pH < 6.0 and reduction of dietary magnesium. Early detection of recurrence may allow nonsurgical therapies to be used. Ultrasonography and radiography are complementary to each other where prediction can serve as an alternative to distinguish urolith mineral composition whenever performing surgery is difficult to retrieve the urolith in an unstable patient to choosing medical treatment.12

Electro-acupuncture Combined with Medical Treatment for Successful Management of Legs Paralysis in a Dog

Steven TauficLeo¹, LitaRakhma Yustinasari², Juliano Mwenda Ntoruru³

¹Veterinary Practitioner, Sunset Vet Clinic, Kuta Bali, Indonesia, ²Lecturer, Department of Veterinary Anatomy, Faculty of Veterinary Medicine, UniversitasAirlangga, Indonesia, ³Research Assistant, Meru University of Science and Technology, Kenya

Abstract

A 5-year-old Siberian Husky female dog was referred with concerned maggots and legs paralysis. The dog was examined clinically and radiographically. She was positive of E. canis and Anaplasma. Major clinical sign showed the dog unable to lift the body. Neurological exam was performed, deep pain on all limbs were delayed. The dog got wound treatment and electro-acupuncture through perpendicular insertion into acupuncture points: BL-23, BL-26, BL-40, BL-60, ST-36, and LIV-3 for 20 minutes/day, 70 Hz and 5A, continuously, for 15 days and then reduce to 3 times/week. Significant improvements were observed, finally the dog being recovered. This case showed favorable therapeutic response by alternative treatment.

Keywords: canine, leg paralysis, acupuncture, alternative treatment

Introduction

Peripheral nerve damage is often the cause of leg paralysis. While some conditions can be remedied through surgery, others may not be able to be treated and will require supportive, lifelong care as the limb will not be functional. A variety of research studies have confirmed the efficacy of acupuncture for neurological disorders in veterinary medicine.¹,²,³,⁴,⁵

Case History and Clinical Observation

A female Siberian Husky, approximately 5 years old, came with concerned maggots and paralyzed on all legs. The owner has put her inside cage for 3 years and never go out. She started to be paralysis a week before brought to Sunset Vet Clinic, Bali. Physical examination was normal, mostly laying down, and could not lift her body. She has maggot accumulation on both lateral of pelvic area and both elbow. Blood test was performed, HCT was decreased, biochemistry was normal and she got E. canis and slightly positive of Anaplasma. Neurological exam was performed as well and all proprio were negative, deep pain on all limbs were delayed, all withdrawal was negative. Both plain and myelograph X-ray were performed and no abnormality found, she just laid down laterally and unable to move at all.

Treatment and Discussion

The patient got wound treatment with Sangobion, Doxycycline, and Clindamycin for a week. Her condition was improved, she started to move her head. Two weeks after treatment, her both front limb started to be responsive and she started to lift her head and tried to change her position to ventral position. We explained that what we can do now trial with acupuncture since we do not have CT Scan/MRI for further checkup while see her response.

Electro-acupuncture treatment technique was used, with identifying of the meridian known as responsible for leg paralysis and adjacent regions affections. It may be a simple method of indirectly applying an electrical stimulation to deep tissue. Considering the very small

Corresponding author:
Lita RakhmaYustinasari
E-mail:lita-r-y@fkh.unair.ac.id
(about 0.2mm) diameter of an acupuncture needle used for this purpose together with the shape of its tip, electro-acupuncture will cause only minimal tissue damage. In our case, the major meridian was the Bladder channel (BL), Stomach channel (ST), and Liver channel (LIV) with a total of 6 acupuncture points: BL-23, BL-26, BL-40, BL-60, ST-36, LIV-3 (Table 1).

As technique, it was used an electro-acupuncture device and sterile acupuncture stainless steel needles (0.25 x 25 mm) for single use perpendicularly inserted into the acupuncture points. BL-40 (He–sea point) was chosen as primordial acupuncture points for master point for the caudal back and coxofemoral joints, further acupuncture points being selected on the basis of individual response. The electro-acupuncture treatment session duration was 20 minutes/day, 70 Hz and 5A, and lasted continuously, for 15 days and then reduced to three times a week. Electro-acupuncture treatments using high frequencies (80-120 Hz) induced a stronger local analgesic effect than electro-acupuncture treatments using low frequencies (20 Hz). The duration of acupuncture treatment accorded to individual response, which was evaluated by continually monitoring symptoms as they evolved during treatment and in the subsequent weeks.

</tr>
</tbody>
</table>

In the first treatment, the patient responded positively. However, she did not show any sensitivity and did not support at all the pelvic limbs. After a week, significant improvements were observed, mainly related a gradually increased sensitivity of all limbs, which proprioceptive on both front limb are better than both hind limb. Unfortunately, the total support hindquarters were accomplished yet only for a very short period of time (10-15 seconds), not yet strong enough to stand up by herself. After eleventh treatment, she was stronger on both front limb and she started to use both hind limb, proprioceptive on both hind limb changed from negative...
to delayed. Right hind limb was stronger than left hind limb. She also got physiotherapy and massage. After a month, she can stand up after lay down by herself. Following four electro-acupuncture sessions settling the animal’s entire recovery.

![Figure 1](image1.png)

**Fig 1.** The case with leg paralysis. (a. Two weeks after medical treatment, the dog’s front limb started to be responsive and she started to lift her head; b. A week after acupuncture treatment, the dog not yet strong enough to stand up by herself; c, d. A month after acupuncture treatment, the dog can stand by herself and walk again)

Electro-acupuncture combined with standard conventional medical treatment were more effective for leg paralysis in dog. Treatment consists in the use of local acupuncture points around the affected nerve, combined with corresponding distant meridian points. The success rate of acupuncture is likely to be inversely proportional to the degree of the nerve damage. From a Traditional Chinese Veterinary Medicine (TCVM) point of view, the treatment of acupuncture is aimed to induce and promote the flow of Qi and blood to the extremity. Electro-acupuncture can deliver an electric current of low frequency via needle electrodes. It can be used to apply electric currents directly to deep tissue, and mainly used for pain control. By improving the circulation, the nerve tissue of the affected area can be nourished, thereby restoring the nerve function and reducing pain.

Comparison in Synergetic Effect for Silver Nanoparticles that Produced from *P. aeruginosa* and *P. luteola* with Oil Extract of *Cymbopogon citraus* on Different Types of Pathogenic Bacteria

Suaad Ali Ahmed¹, Hussam Mahmood Hasan¹

¹Researchers/ Department of Biology/ College of Science/ University of Baghdad/ Iraq

**Abstract**

Silver nanoparticles have been found to possess both anti-bacterial and anti-inflammatory properties, In addition Many reports refered to the antibacterial activity of lemongrass oil against different organisms. Two species of Gram negative bacteria *Psuedomonas* (*P. auroginosa* and *P. luteola*) were tested for the ability of bearing silver nanoparticles by using LB medium, the two isolates of bacteria were appeared brown color when mixed the supernatant of bacterial culture with AgNO3 solution, that referred the biosynthesis of Silver nanoparticles (Ag NPs). UV–visible spectrophotometer was utilized for estimation of (Ag NPs). The antimicrobial activity of silver nanoparticles arranged from the two isolates was tested against different types of pathogenic bacteria. lemongrass oil was extracted and three different concentrations (v/v) of lemongrass oil with dimethyl sulfoxide (DMSO) 0.5%, 5% and 10%, were prepared to determin the MIC by using well diffusion method. The synergetic effect was demonstrated by combining the (Ag NPs) that produced from , *Pseudomonas aeruginosa* and *Pseudomonas luteola* with MIC of lemongrass oil (0.5%) against same types of clinical bacteria.

**Keywards:** *Pseudomonas luteola*, *Cymbopogon citraus*, *LB medium*

**Introduction**

Human being are often infected by different microorganism like bacteria, molds, yeasts, and viruses, present in their living environments, the development of resistant or even multi-drug resistant pathogens has become a major problem(1). Nanotechnology refers to an emerging field of science that includes synthesis and development of various nanomaterials (2). Recently, different metallic nanomaterials are being produced using copper, zinc, titanium, magnesium, gold, alginate and silver (3). Silver ions and there derivative compound are highly toxic to microorganism. (3) Silver is safe inorganic antibacterial agent used for centuries and it has the ability of killing different type of diseases causing microorganisms (4). Additionally, when compared with other metals, silver presents the lowest toxicity for animal cells (5) Silver nanoparticles have been found to possess both anti-bacterial and anti-inflammatory properties that can promote faster wound healing. (6). Biological synthesis of nanoparticles in spot light due to the fact that it is eco-friendly as compared to other methods of nanoparticle synthesis (7) . Nanoparticles have been successfully synthesized from bacteria, actinomycetes, algae, sugar, plants, and from many more substrates (8). Lemon grass (Cymbopogon Citraus) is a native aromatic tall, it is a perennial herb widely cultivated in the tropics and sub-tropics, is a great interest due to its commercially valuable essential oils and widely used in food technology as well as in traditional medicine (9). Many reports refered to the antibacterial activity of lemongrass oil against different organisms comprising gram positive and gram negative bacteria, yeast and fungi (10) . In this work, (Ag NPs) were synthesized by two types of bacteria, *Pseudomonas aeruginosa* and *Pseudomonas luteola*. The antibacterial activity of
synthesized silver nanoparticles with Lemon grass oil extract on different kinds of bacteria was explored.

**Materials and Method**

**Organisms and Lemon grass oil extraction**

Two species of *Psuedomonas* (*Psuedomonas auroginosa* and *Psuedomonas luteola*) were used in this work. They were cultivated on brain heart infusion broth for 24h at 37 °C, then purified. For extraction of lemongrass oil, 25 g of lemongrass was weighted and cut it into small pieces. 300 ml of distilled water was added to the flask containing the grass and set the apparatus for distillation. The mixture was boiled and collected the distillate until no more oily drops can be seen passing over. The distillate was extracted with hexane, dried them at 45° C, yellow colored oily liquid with fresh lemon like tone was obtained.

**Biosynthesis and characterization of silver nanoparticles**

*Psuedomonas aeruginosa* and *Psuedomonas luteola* were cultured in LB medium. The culture flasks were incubated on shaker at 37°C and agitated at 200 rpm for 24 hours, then harvested and centrifuged at 10000 rpm for 10 minutes. The supernatant was collected for silver nanoparticles biosynthesis, supernatant (10 ml) was mixed with 5ml of silver nitrate solution (10 mM) and incubated at 30°C for 24 h in dark. The silver nanoparticles (AgNPs) were purified by centrifugation at 10,000 rpm for 5 min twice, and collected for further using. (Ag NPs) was estimated by using UV–visible spectrophotometer (300–900 nm), the colored nanoparticle solution shows a peak ~400 nm.

**MIC Determination of lemongrass oil and antibacterial action of (Ag NPs)**

Lemongrass oil MIC and the antibacterial activity of (Ag NPs) prepared from *P.aeruginosa* and *P.luteola* were calculated as procedure of well diffusion method. Three different concentrations (v/v) of lemongrass oil with dimethyl sulfoxide (DMSO) 0.5%, 5% and 10%, were prepared. different types of bacteria including *Staph. aureus, Enterococcus faecalis, Strep.agalactiae, Klebsiella pneumoniae, E. coli, Acineto.bomannii* (clinical isolates) were used in this work. The plates were incubated for 24 h, the diameters of inhibition zones for the Lemongrass concentrations and (Ag NPs) extract when used alone and together were measured.

**Results and Discussion**

**Producing organisms**

Among the noble metals, silver is the best choice metal in the field of biological system. Selection of eco-friendly nontoxic agents are the most important issues which must be considered in green synthesis of nanoparticles. Two species of genus *Psuedomonas* (*P.aeruginosa* and *P.luteola*) were obtained from Department of Biology, College of Science, University of Baghdad used in this work after purification on MacKkonkey agar and Nutrient agar. Bioproduction of (Ag NPs) was investigated by mixing the bacterial supernatant with (AgNo3) solution. The two bacterial isolates showed the brown reported in another organisms like *Bacillus methylotrophicus* and in fungi as *Fusarium semitectum, Aspergillus fumigatus*.

**Estimation of silver nanoparticles**

The biosynthesis of silver nanoparticles for the two bacterial isolates was done by UV.Spectrophotometer at a wavelength range of 200-900 nm. This method has been appeared to be appropriat sensitive way to check the intense surface plasmon resonances of (Ag NPs) in the range of waves 300–600 nm. The results apppeared that high absorption peak at 371 nm was observed from *P. aeruginosa* while *P.luteola* perceived the high absorption peak at 369 nm. Wavelengths 300 – 800 nm are generally used for characterizing metallic nanoparticles ranging in size from 2 nm up to around 100 nm. The exposed to the AgNo3 solution exhibit the wide spectrum range 390 to 410 nm. The presence of the broad resonance refers the aggregation of the silver nanoparticles in the solution, 370 nm indicated to the transverse plasmon vibration in silver nanoparticles.
MIC of Lemongrass oil

Treatment using plant-based medicine appears to be an alternative approach because of the adverse effects associated with the use of synthetic drugs (9). The MIC of lemongrass oil was determined against different types of pathogenic bacteria. The MIC for all bacterial isolates was 0.5% (Figure 1, Table 1). Lemongrass essential oil is applied for its medicinal value to cure acne, oily skin, scabies, flatulence, headaches, blood circulation problems and excessive perspiration due to its antimicrobial and antibacterial activities. It has also been used as carminative, stimulant, emmenagogue, diuretic and antiseptic (16).

Figure(1): MIC of Lemongrass oil extract on Mullar Hinton Agar
Antimicrobial activity of silver nanoparticles

Silver is a nontoxic, safe inorganic antimicrobial agent adopted for centuries and it has the inclination of killing different type of diseases motive microorganisms. Silver has been published to be a sturdy antibacterial, antifungal and antiviral agent. The antimicrobial action of biosynthesized (Ag NPs) from two bacterial isolates were investigated facing a span of pathogenic microorganisms by applying well diffusion method. The diameter of inhibition growth zone is monitored in (Fig 2 and Table 2). The results appeared that the antibacterial activity of (Ag NPs) from *P. aeruginosa* was higher than (Ag NPs) from *P. luteola* against *Staph.aureus, Strep. agalactiae and Entero.faecalis*, while the antibacterial activity of (Ag NPs) from *P. luteola* was higher against *E.coli*. The antibacterial action of (Ag NPs) from the two species was equal against *Kleb.pneumoniae and Acinetobbaumannii*. Most of the antibiotic resistance mechanisms are irrelevant for nanoparticles (NPs) because the mode of action of NPs is direct contact with the bacterial cell wall, without the need to penetrate the cell; this raises the hope that NPs would be less prone to promoting resistance in bacteria than antibiotics. Therefore, attention has been focused on new and exciting NP-based materials with antibacterial activity (17).

Figure(2): Antibacterial activity of (AgNPs) from two isolates on Mullar Hinton Agar

Synergetic effect of combined (AgNPs) from *P. aeruginosa and P. luteola* with MIC of Lemongrass oil extract

Several studies regarding the synergistic activity of nano-Ags in combination with other compounds have been reported (18). The result showed increasing in antibacterial activity when combined AgNPs that produced from two species of *Pseudomonas* (*P. aeruginosa and P. luteola*) with Lemongrass oil extract against all clinical types of bacteria that used in this study, but the synergetic effect from *P. aeruginosa* was more than *P. luteola* against all types of clinical bacteria except in bacteria *E.coli* the synergetic effect of *P. luteola* was the highest (Figure 3 and Table 3). Synergistic activity was done by using lemongrass (*Cymbopogon citratus*) essential oil associated with silver nanoparticles (AgNP) synthesized by green synthesis against *Candida albicans* (19). Other combinational activities of AgNPs...
with antibiotics and detergents were also seen\(^{(18)}\).

Figure(3): Synergetic effect of (AgNPs) from two isolates with Lemongrass oil extract against different clinical bacterial types on Mullar Hinton Agar
Conclusion

Silver nanoparticles which are zerovalent, can be a valuable alternative to ionic silver. Nano-Ags are a non-toxic and safe antibacterial agent for the human body. In addition, nano-Ags are also reported to possess antifungal activity, anti-inflammatory properties, antiviral activity and anti-angiogenic activity (18). AgNPs that produced from two species of Pseudomonas (P. aeruginosa and P. luteola) showed increasing in antibacterial activity when combined with MIC of Lemongrass oil extract against different clinical types of bacteria. The synergetic effect from P. aeruginosa was more than P. luteola against most types of clinical bacteria.

Predisposition Factors in Exclusive Breastfeeding in Infants
(Literature Review)

Subagyo1, Suparji1, Nana Usnawati1, Vilia Tri Erlina2
1Lecture, 2College Student Jurusan Kebidanan, Politeknik Kesehatan Kementerian Kesehatan Surabaya, Indonesia

Abstract
Background. Nutritional intake in the first thousand days of a child’s life up to 2 years old is very important for growth and development. The low number of exclusive breastfeeding is still to be concern of the Indonesian government. Based on data from Magetan District Health Office in 2019, the coverage of exclusive breastfeeding in the Poncol Puskesmas was 48.4%. The purpose of this systematic literature review is to systematically review some of the results of recent research on the drivers that influence the success of exclusive breastfeeding, namely the factors of knowledge, education, employment, and attitude. The type of research used is systematic literature review (SLR) using the Preferred Reporting Items for Systematic Review and Meta Analysis (PRISMA) approach. The database used are DOAJ and SINTA (Garuda), the last 5 years publication limits, analytical research, cross sectional research designs, full text articles, research areas are Indonesia. From the research results found 546 journals and after screening obtained 9 relevant journals. Regarding education, 3 out of 4 journals stated that there was a relationship between education and exclusive breastfeeding. On the employment factor, 4 out of 5 journals stated that there was a relationship between work and exclusive breastfeeding. In the knowledge factor, all of journals stated that there was a relationship between knowledge and exclusive breastfeeding. While in the attitude factor, 3 out of 4 journals stated that there was a relationship between attitude and exclusive breastfeeding. The majority, of journal stated that there is relationship between education, knowledge, employment, and attitude of mother’s breastfeeding. It is hoped that the results of this review will be able to bring change to readers, especially health workers who have a very important role in providing education and promotion regarding exclusive breastfeeding.

Keywords: Knowledge, Employment, Education, Attitude.

Introduction
One of the priorities for health development in Indonesia is to improve and improve the health of mothers and babies. A healthy baby is supported by several factors, one of which is nutrition. Nutritional intake in the first thousand days of life of children up to 2 years of age is very important for growth and development.

Breastmilk (ASI) is a very good intake in the first thousand days of birth. According to Pitaloka, mothers often lack information about the benefits of exclusive breastfeeding and the impact of not being exclusively breastfed. The low rate of exclusive breastfeeding is still a concern of the Indonesian government.

The Indonesian government has a target of achieving exclusive breastfeeding of 80%2. Based on data obtained from the results of the National Riskesdas in 2018, the achievement of exclusive breastfeeding in Indonesia is only around 37.3% of the expected target. The East Java government stated in 2016 that the target for exclusive breastfeeding was 80%. However, in fact, the results of Riskesdas reported that exclusive breastfeeding
coverage in the East Java region only reached 40.05% \(^2,^3\). According to data from the Magetan District Health Office, the achievement of exclusive breastfeeding in 2019 was 69.4%, which has met the expected target of 50%. However, there are 3 working areas of the Community Health Center that still do not meet the expected target for achieving exclusive breastfeeding, one of which is the Poncol Community Health Center. Based on data obtained from the Poncol Community Health Center 2019, the number of babies (0-6 months) in a period of 1 year is 157. Of these, 76 babies (48.4%) get breastfeeding exclusively, while the rest a total of 81 babies (51.6%) were not exclusively breastfed\(^4\).

Breastfeeding behavior is a mother’s action based on her knowledge and experience in breastfeeding. According to Green’s theory in Notoatmodjo 2012, a person’s behavior is driven by several factors, including predisposing factors, enabling factors, and reinforcing factors\(^5\). Based on Rizky’s research in 2017, predisposing factors that cause the low achievement of exclusive breastfeeding are the lack of knowledge and experience of mothers, low education, and reasons for work that cannot be left behind\(^6\). A part from that, it is also supported by the fact that there are facilities and an exclusive breastfeeding campaign at the time of antenatal care. Lack of family support and the influence of the mass media on advertisements for infant formula milk also influenced mothers not to exclusively breastfeed\(^7\). The impact of babies who are not exclusively breastfed can suffer from vomiting and diarrhea, so that death due to vomiting increases 23.5 times and diarrhea is 17 times more frequent in infants who are given formula milk\(^8\). Haryono & Setianingsih say that babies who are not given ASI have lower endurance than babies who are breastfed\(^9\).

Efforts to increase the use of breast milk have become a worldwide goal. Every year on August 1-7 is the world breastfeeding week \(^2\). Exclusive breastfeeding program in Indonesia is a top priority where the government participates in exclusive breastfeeding by stipulating PP RI No. 33 of 2012. Provision of breastfeeding facilities in the workplace has also become a concern of the government in order to increase motivation to provide exclusive breastfeeding \(^2\). In addition, to support the realization of the exclusive breastfeeding program, the Magetan Regency Government is also promoting MAYANGSARI cadres who are expected to provide information to mothers about the provision and benefits of breastfeeding\(^2,^4,^10\).

**Materials and Methods**

The type of research used in this research is systematic literature review (SLR) or in Indonesian it is called a systematic literature review. According to Kitchenham and Charters 2007 systematic literature review is a literature review method that identifies, assesses, and interprets all findings on a research topic to answer predetermined research questions\(^11\). SLR is a term used to refer to a particular research or research methodology and development carried out to collect and evaluate research related to a particular topic focus\(^12\).

In this literature review, the research design used is the PRISMA (Preffered Reporting Items for Systematic Review and Meta Analysis) approach. The databases used are Sinta (Garuda) and DOAJ (Directory of Open Access Journals) with publication limits for the last 5 years. from 2015-2020, full text articles, research areas are in Indonesia. The keywords used in the search were the factors of exclusive breastfeeding mothers’ education, knowledge of exclusive breastfeeding mothers, occupation of exclusive breastfeeding mothers, and attitudes of exclusively breastfed mothers.

**Results**

The search results according to the keywords obtained as many as 536 articles and after being selected according to the inclusion criteria, 9 articles were obtained. The following is a discussion of each of the factors that will be reviewed, namely the factors of education, work, knowledge, and attitudes.

Discussion

The Effect of Breastfeeding Mother’s Education Level on Exclusive Breastfeeding

The relationship between education and exclusive breastfeeding. After reviewing several studies, there were different results, namely 3 out of 4 journals stated that there was a relationship between education and exclusive breastfeeding. The three journals are research by Ana Mariza 2015, Ledy Octaviani Iqmy 2017, and Refi Lindawati 2019. Meanwhile, the journal from Diah Ayu Pitaloka, Rumaidhil Abrory, Ayu Deni Pramita 2018 states that there is no relationship between education and exclusive breastfeeding. Of the five journals, the majority of breastfeeding mothers do not exclusively breastfeed their babies. The research sample taken was mostly mothers who had low or basic education. The education level classification of the research respondents is different. In one of the classifying journals of the level of education based on RI Law no. 20 of 2003 concerning the National Education System, divided into 3 levels, namely primary education, secondary education, and higher education. While the other four journals, the classification of education is divided into 2 levels, namely low / basic education and higher education. Overall, the five journals are easy to understand, starting from the abstract, introduction, research methods, data collection, discussion, and delivery of research results. However, in the journal Ana Mariza 2015 and Ledy Octaviani Iqmy 2017, the research instrument is not clearly explained. Whereas in the journal Ledy Octaviani Iqmy 2017, the title used is too long so it is not persuasive. According to Barker and Schutz (1972), the length of the research title is a maximum of 20 words, made short, and eliminating unnecessary words.

According to Nursalam in Refi Lindawati, 2019, the higher level of education will facilitate the process of finding and receiving information so that the knowledge they have is also more and more. One’s education improves cognitive abilities (knowledge), affective (attitude determination), psychomotor (ability to perceive). According to Notoadmodjo in Yulita Defi 2018, someone with a higher education is usually more receptive to new things and is more open about their health. In addition, mothers who have higher education usually have great curiosity and try to find information or experience. This is able to increase knowledge for the mother so that it is hoped that the mother will be able to overcome the problem and can improve the health of themselves and their families. Through this learning process, a person has the awareness to make changes in an effort to improve health. Education also affects the response to something that comes from outside because it is able to think more rationally. Mothers with low education ability to think rationally are not as good as mothers with higher education. The ability to understand something new is a little difficult or there is even a misunderstanding of capturing the information. The low level of maternal education results in a lack of knowledge of mothers in dealing with problems, especially in exclusive breastfeeding. However, if mothers with low education are given a good understanding by health workers so that there is no misunderstanding in receiving information, it is hoped that the mother will be able to provide breastfeeding exclusively.

The Influence of Type of Breastfeeding Mother’s Occupation on Exclusive Breastfeeding

According to journals that have been analyzed by researchers, 3 out of 5 journals state that there is a relationship between maternal work and exclusive breastfeeding. The three journals are research by Ana Mariza 2015, Defi Yulita 2018, and Nelyta Oktavianisya & Sri Sumarni 2017. Meanwhile, 2 journals from Rizky Tri Utami, et al. (2015) and Ledy Octaviani Iqmy 2017, state that there is no relationship between maternal occupation and exclusive breastfeeding. In the journal Ledy Octaviani Iqmy 2017, states that in processing data using the chi square statistical test, the results obtained p value = 0.31 with the interpretation that there is no relationship between maternal occupation and exclusive breastfeeding. The result of p value => 0.05, then H0 is accepted with the interpretation that there is no relationship between maternal occupation and exclusive breastfeeding.
breastfeeding. In the five journals, the majority of mothers who do not provide exclusive breastfeeding are mothers who work13,14,15. According to Nursalam in Ana Mariza (2015), work is a necessity that must be done, especially to support the life of her family. The dual role of caring for children and working outside the home often makes it difficult for mothers to manage time due to the large number of working hours and also the distance between work and home is far. By working, mothers cannot have full contact with their babies. As a result, mothers tend to give formula milk and it is given by bottle. This causes the frequency of breastfeeding to decrease and milk production to decrease. This situation will cause the mother to stop breastfeeding. Working mothers who provide exclusive breastfeeding must have high commitment and seriousness. Because it takes a lot of time and is a big challenge for breastfeeding mothers14,15.

According to the authors, working mothers should be able to exclusively breastfeed their babies. Work is not an absolute factor that causes mothers to not be able to provide exclusive breastfeeding. If the mother has good knowledge about the importance of exclusive breastfeeding, how to express and store breast milk, and exclusive breastfeeding, it can increase exclusive breastfeeding. In addition, support from the closest people and the work environment can influence mothers to continue to provide exclusive breastfeeding. As stated in Law no. 36 of 2009 concerning Health, that during breastfeeding, the family, government, and society must fully support the mother by providing special time and facilities held in the workplace and public advice13,15.

**The Effect of Breastfeeding Mother’s Knowledge Level on Exclusive Breastfeeding**

The results of the journal search found 4 journals about knowledge and the entire journal stated that there was a relationship between maternal knowledge and exclusive breastfeeding. The five journals include Defi Yulita (2018), Rizky Tri Utami, et al. (2015), Ledy Octaviani Iqmy (2017), Refi Lindawati (2019), and Theafilia Golda Beatriks Harisa, Iyam Manuwe, Kusmiyati (2019). According to Reber (2010), knowledge is a collection of information that a person has that is generated from any process, whether born from innate or achieved through experience. Knowledge is a determining factor in how humans think, feel and act (Oemarjoedi in Defi, 2018). Knowledge can be obtained through seeing, hearing, experiencing real events, or through formal and informal education. Mothers who have low knowledge will have limited knowledge. Knowledge is one of the predisposing factors that influence a person’s behavior. Mothers who do not receive information about exclusive breastfeeding during pregnancy will influence the mother’s behavior in giving exclusive breastfeeding to her baby later (Suhartono in Refi Lindawati, 2019). Correct knowledge about exclusive breastfeeding will encourage a further response from the mother, namely in the form of exclusive breastfeeding13,14,19,22,23.

Currently there are still many mothers who do not know about the benefits of providing exclusive breastfeeding for babies and for mothers, besides that mothers are still influenced by the hereditary tradition of the family that the mother’s milk will not be sufficient to be given to the baby so that the baby must be given additional food (milk), formula, honey, team porridge, etc.) before the baby is 6 months old. Therefore, the role of health workers is very important in providing understanding and promoting exclusive breastfeeding, not only to mothers but also to families and the wider community. Even though the mother has good knowledge about exclusive breastfeeding, if it is not supported by health facilities and health workers, then the mother will find it difficult to realize this behavior (Yulita Defi, 2018). According to Refi Lindawati (2019), there are also mothers who have good knowledge but do not apply exclusive breastfeeding behavior. This can be influenced by several factors, for example because mothers are lazy, mothers are busy, there is no support from health workers and their families, the absence of supporting facilities, the influence of the promotion of formula milk from the mass media. In addition, if the information provided is inaccurate, the information received will also be wrong or cause misunderstanding14,19.
The knowledge factor has an important role in providing influence as an initial impetus for someone to behave. Behaviors that are based on knowledge will be more durable than behavior that are not based on knowledge. Mothers who have high knowledge about the benefits of exclusive breastfeeding will give breastfeeding exclusively to their babies after giving birth compared to mothers who have low knowledge. This is because mothers who have high knowledge about exclusive breastfeeding generally know the various benefits of exclusive breastfeeding (Ledy, 2018). From the journals above, the results presented are very clear about the importance of providing good knowledge or information to mothers from the time of pregnancy. Health workers have an important role in providing counseling and promotion to increase maternal knowledge about exclusive breastfeeding22,24.

The Effect of Breastfeeding Mother’s Attitude on Exclusive Breastfeeding

According to the results of the search for journals that have been conducted, 3 out of 4 journals have found that there is a relationship between mother’s attitude and exclusive breastfeeding. The journal is the result of another research by Rizky Tri Utami, et al. (2015), Nelyta Oktavianisya & Sri Sumarni (2017), and Chintya D.C, Adisti A.R, Ardiansa A.T.C (2019). Whereas 1 journal that has different research results is research from Theafilia Golda Beatriks Harisa, Iyam Manueke, Kusmiyati (2019). According to Secord and Backman (in Nelyta, 2017), attitude is a certain order in terms of feelings (affection), thoughts (cognitive), and predisposition of one’s actions (konasi) to an aspect of the surrounding environment. Attitudes that become an evaluative statement towards an object will further determine individual actions towards something. Attitudes can be divided into: (1). A positive attitude, namely an attitude that shows or shows, accepts, agrees to the prevailing norms where the individual is located, and (2). Negative attitude, which shows rejection or disagreement with the prevailing norms in which the individual is located16,18,22,24. A person will do an action if he has a positive view of the action and believes that other people want him to do it. This belief affects a person’s attitude and behavior to do an action. This belief can come from the experience concerned or be influenced by information obtained about this behavior25.

The realization of this positive attitude in order to become real action requires a factor of support from certain parties, such as health workers, family or closest people. The surrounding environment plays an important role in influencing this. The best decisions are influenced by the immediate environment. In addition, self-desire is not strong enough as a determining factor for breastfeeding if it is not conditioned by other driving factors, enabling factors, and reinforcing factors. In the four journals, the majority of mothers have a positive attitude towards exclusive breastfeeding and give exclusive breastfeeding to their babies. In the research of Theafilia Golda Beatriks Harisa, Iyam Manueke, Kusmiyati (2019), the discussion section states that the results of the Spearmen Rank Correlation Test regarding the relationship between attitudes and exclusive breastfeeding behavior obtained a value of p = 0.134> α (0.05), this shows no The relationship between maternal attitudes and exclusive breastfeeding behavior, however, the data obtained shows that more mothers have positive attitudes towards exclusive breastfeeding, so there is a conclusion, the researchers concluded that there is a relationship between maternal attitudes and exclusive breastfeeding17.

Conclusion

Conclusions from the results of a review of journal articles on predisposing factors for exclusive breastfeeding, currently there are still many mothers who do not know about the benefits of providing exclusive breastfeeding for babies and for mothers, besides that mothers are still influenced by the hereditary tradition of the family that the mother’s breast milk will not be sufficient. to be given to babies so that babies must be given additional other foods (formula milk, honey, team porridge, etc.) before the baby is 6 months old. Therefore, the role of health workers is very important in providing understanding and promoting exclusive
breastfeeding, not only to mothers but also to families and the wider community. Even though mothers have good knowledge about exclusive breastfeeding, if it is not supported by health facilities and health workers, then mothers will find it difficult to realize exclusive breastfeeding behavior.

Screening of Healthy Women Using Visual Inspection with Acetic Acid For Detection of Cervical Cancer

Suchitra A Rati1, Jayashree Pujari2
1Prof. Vice Principal, HOD, 2Associate Professor Department of Community Health Nursing, BLDEA’S Shri B M Patil Institute of Nursing Sciences-Vijayapur

Abstract

Background: Cervical cancer is the fourth most common cancer in women worldwide and second most common cancer in developing and under developing Nations. The higher incidence of cervical cancer in developing countries is mainly because of lack of resources, lack of effective screening technologies and poorly organized health care delivery in the rural area.

Objective: To determine the prevalence of cervical precancerous lesion among healthy women.

Materials and Methods: The study was conducted for 600 Healthy women who were selected by using purposive sampling technique. The prevalence of precancerous cervical lesion was assessed by Visual Inspection with acetic acid and the data was analyzed by using inferential and descriptive statistical methods.

Result: It was also observed that prevalence of cervical Precancerous lesions in healthy women was 5.0%. It means that 30(5.0%) out of 600 healthy women had risk of cervical precancerous lesions in this present study. Among the study samples who suspected to be positive, off them 10(3.3%) had two or less quadrant involved, and 5 (1.7%) had three quadrants involved. About action taken 30(5.0%) were referred for confirmation, 230(38.3%) followed up after 3 years, 340(56.7%) had referred medical treatment and VIA test after six months. The study result shows that Reveal that prevalence of cervical Precancerous lesions was highly associated with visual examination findings such as cervicitis, white discharge, and abnormal findings.

Conclusion: The study results conclude that VIA test can be used as an alternative screening technique for early diagnosis of precancerous lesion among women at low resource setting.

Key words: Healthy women, precancerous lesion, VIA Test

Introduction

Death Rate from Cervical Cancer Higher Than Thought

Cervical cancer is a major public health problem in developing countries such as India and it has lead to the greatest economic and social impact on the population. It mainly affect the women in reproductive age group. Cervical cancer is a taboo issue in many places as it is linked to sexual transmission. Unless women come forward and break this stigma and come forward for the health check up, we contribute to larger number of mortality and morbidity related to oral cancer.

Cervical cancer is the fourth most common cancer in women worldwide and second most common cancer in women living in less developed regions, which preferably effects the women within the age group of 18 to 45 years and it is commonly caused by human papilloma virus. The higher incidence of cervical cancer in developing countries is mainly because of lack of resources, lack of effective screening technologies and poorly organized health care delivery in the rural area.

India with a population of 436.76 million women aged 15 years and above are at the risk of developing oral cancer. It has been estimated that every year 122844 are diagnosed with cervical cancer and 67477 people die.
with cervical cancer as per the statistics of 2012.  

According to World Health Organization (WHO) Report estimated 530,000 new cases of cervical cancer globally (estimations for 2012), with approximately 270,000 deaths (representing 7.5% of all female cancer deaths). More than 85% of these deaths occurred in low- and middle-income countries.

Cancer preferably occurs in the middle aged women in the age group of 40-50 years and mostly occurs in people with low socio economic status who are incapable to undergo regular health check up because of financial inadequacy, 80% of the new cervical cancer cases occur in developing countries, like India which contributes about one fourth cases of the globe every year. It is estimated that about 9 million new cancer cases are diagnosed every year and over 4.5 million people die from cancer each year in the world.

INDIA: The estimated number of new cancers in India per year is about 7 lakhs and over 3.5 lakhs people die of cancer each year. Out of these 7 lakhs new cancers about 2.3 lakhs (33%) cancers are tobacco related. There would be about 1.5 lakhs cancer cases at any given time in Karnataka and about 35,000 new cancer cases are added to this pool each year.

Many studies have highlighted that the main reason for poor coverage of screening campaign of cancer of cervix in India is due to lack of information, unavailability of resources even various preventive methods are available in India. The Study depicts that none of the woman have received HPV Vaccine and unaware of benefits of it. Almost eighty five percent of females and had poor knowledge and expressed community clinical outreach services helps in enhancing and active participation in such screening programmes.

Many advanced evidence based screening programmes are available for detecting precancerous lesions if these are treated effectively by simple treatment can prevent preceding into invasive cervical cancer. Periodical implementation of population based screening programmes in developed country has been reduced 85% of incidence and mortality related to Ca of cervix. Whereas only 5% of women were screened in developing countries annually with expenditure of 5% resources leading into diagnosing at 3rd or 4th stage with estimation of 60 to 80% of cases.

Revolution in lifestyle and socio-demographic characteristics are pleasuring variety of iceberg diseases among pupils located in middle income countries acquiring second most carcinoma of cervix among famines alone. Many of the research studies have highlighted lack in accessibility of material and badly structured health care units are important reason for elevation in occurrence of new cases. The popularized cancer center TATA Memorial uttered that alertness and utilization of simple screening methods of precancerous lesions of cervix at peripheral area by help of VIA or VILI might bring down incidence of cervical cancer.

A Study by Awasthy S et.al on awareness and practice of Screening related to CA of cervix among female residing in rural area of Kerala reveals that majority were unacquainted about risk factors of Cervical cancer. Even though 3/4th study participants were aware about screening test for early detection only around 7% have undergone pap test. Two studies of Tamilnadu and Maharashtra reveals that only 2.6% coverage of screening among women in age group of 18-69 at India.

Objectives Stated and objectives achieved

- To determine the prevalence of cervical precancerous lesion among healthy women
- To find out the association between the precancerous lesions with selected demographic lesions

Hypothesis

H_0: There is no significant association between the prevalence of precancerous lesion with selected demographic variables

H_1: There is significant association between the prevalence of precancerous lesion with selected demographic variables
Materials and Methods

Research Variable: Cervical Precancerous Lesions

Baseline Variables: Age, Occupation, Marital status, Age at Marriage, Number of pregnancy, last menstruation, Miscarriage, income of family, Nature of discomfort

Source of data: Data is collected from Healthy woman from selected rural area of Vijayapur District

Research design: Descriptive Research design

Setting: Study was conducted in selected Community health center of Vijayapur District

Sample: In this study the sample consist of Healthy women

Sampling Technique: In this Study the sampling Technique used was Purposive sampling Technique

Sample size: The sample size for the present study consist of 600 healthy women

It was clear that cervical Precancerous lesions were not associated with any of the selected demographic variables & does not have its influence on occurrence of cervical Precancerous lesions among healthy women. A Cervical visual inspection with acetic acid as an alternative screening test for cervical cancer detection VIA and Pap smear tests were performed on 468 women in Iran. The result shows that 43 patients had positive VIA and 23 patients had positive Pap smear results.
Sensitivity, specificity, positive predictive value and negative predictive value of VIA were 66.7%, 55.1%, 18.6% and 91.5%, respectively and for Pap smear test they were 75%, 82.1%, 39.1% and 95.5%, respectively. Test accuracy for VIA and Pap smear were 56.7 and 81.1, respectively. It concludes that VIA has high sensitivity but low positive predictive value. By considering the low price of this test and its availability, it can be proposed as a screening method in cervical cancer.7

The study conducted by Bhattacharyya et.al, reveals that the incidence of CIN is more[30%] in Poor economical condition with enhancement of cervical cancer upto 3% in the similar group with reason of lack of personal hygiene, low standard of living conditions, early age sexual contact, lack of education and multiple relationship.13

Table no 2, Reveals that prevalence of cervical Precancerous lesions was highly associated with visual examination findings such as cervicitis, white discharge, and abnormal findings. Although the Pap smear remains the most common screening test for cervical cancer, many less developed countries do not have adequate resources to implement cytology-based prevention programs. An alternative, low-cost test, visual inspection using acetic acid (VIA), has emerged for use in low-resource settings where it can be performed by auxiliary health professionals. VIA is similar to colposcopy in that acetic acid is applied and any acetowhite lesion is visualized9. By considering the low price of this test and its availability, it can be proposed as a screening method
in cervical cancer.

A study by A Omole–Ohonsi recommends that VIA can be adopted as alternative screening technique especially at poor resource setting with hopes for better services to needy women.

**Recommendations**

- In northern part of Karnataka the data related to prevalence of cervical cancer is not available. By considering the low price of VIA test, it can be proposed as a screening method in cervical Precancerous lesions.
- Screening helps for early treatment and prevents further complications. Hence it can be used as alternative screening modality for cervical cancer in low resource locations.
- A similar study can be conducted on a large sample may help to draw more definite conclusions and make generalization
- A similar study can be undertaken for sensitization of women to undergo screening of precancerous lesion

**Conclusion**

Presently cervical cancer has become most common among women dragging second position among mortality among females. Many evidence based low resource setting screening techniques are available still many of the health centers had delayed in implementation leading into severity of it among women this can be resolved by adopting simple low cost technique that is VIA

**Acknowledgement:** We acknowledge Rajiv Gandhi university of health sciences for the grant for conducting this research study and also extend gratitude to Principal, medical officer, ASHA worker and participants for providing conducive environment for successful completion of the study

**Conflict of Interest:** None Declared

**Ethical Clearance Certificate:** Ethical clearance certificate were obtained from institutional ethical clearance committee

Evaluate the Biological Activities of Biosynthesized ZnO- Nanoparticles Using Escherichia Coli

Suhad H¹, Neihaya HZ¹, Raghad AL¹
¹Scholar Researcher, Dep. of Biology, College of Science, Mustansiriyah University, Iraq

Abstract

About 50 isolates of E. coli were identified (83% from 60 stool sample, and 30 test bacteria which formed biofilm. ZnO- NPs synthesis by Escherichia coli and a white cluster pellet appeared, and absorption peak of UV-Vis. spectroscopy observed at 268 nm. XRD pattern showed the lattice planes of (100), (002), (101), (102), (110), (103) and (112) agreed to the 2θ values of 32.45°, 34.73°, 36.56°, 47.70°, 55.86°, 62.12° and 63.10° respectively, and the diffraction peaks are assigned with the hexagonal phase, while SEM images exhibited that size of the particles ranged between (31.55−45.9) nm. ZnO NPs displayed antibacterial potentiality against pathogenic bacteria, and inhibition zone around ZnO NPs as follows 5, 4, 2, 2, and 2mm for P.aeruginosa, S.aureus, A.baumannii, K.pneumoniae, and E. coli respectively. Also, ZnO NPs was able to decrease biofilm, and results showed that inhibition percentage were (18.6, 27.7, 39.4, and19.6) % against S.aureus, P. aeruginosa, A. baumannii, and K. pneumoniae, respectively after 48 hours of incubation. A549 cells viability was decreased with increasing the concentration of the ZnO NPs, and the IC₅₀ values of the A549 and WRL cells were 105.8 and 167.3 µg/mL respectively. In this study, the synthesized ZnO NPs using nonpathogenic E.coli showed antibacterial, antibiofilm and anticancer activities against studied pathogenic bacteria. So, these nanoparticles can be further used in biomedical, pharmaceutical and other applications as an effective antimicrobial and anti-cancerous agent.

Key words: Biosynthesized ZnO NPs, E.coli, Antibacterial, antibiofilm, Anticancer.

Introduction

Nanoparticles (NPs) is one of the roads to nanotechnology that is related with nanoscale materials through very small particles size ranging between 1 to 100 nm. NPs display distinctive properties due to their very small size also high surface area to volume ratio, which have attributed to the significant differences in the properties over their bulk counterparts (1). Zinc is an important nutrient in living organisms (2). In addition, ZnO has been registered as “Generally Recognized as Safe” (GRAS) by the US Food and Drug Administration (3) owing to its non-toxic properties (4). Researches showed that ZnO NPs possess a great possibility in biological applications, such as the antimicrobial agents (5). Moreover, many studies have been described on the efficacy of ZnO- NPs in preventing the growth of broad-spectrum of pathogens (6), which possibly could substitute the conventional antibiotic (7). The effect of zinc oxide on highly resistant biofilms, distinguishing degrees of operation for treatment depending on the bacteria used (8). ZnO- NPs also have been widely used in cancer therapy and have been reported to stimulate selective cytotoxic effects on cancer cell proliferation. Zinc oxide nanoparticles may be the most cytotoxic to cancer cells than adipocyte cells (9), these findings indicated that zinc oxide nanoparticles may selectively induce cancer cell apoptosis, which could be promising candidates for cancer care (8). This study aims to

biosynthesis ZnO-NPs from nonpathogenic *E.coli*, and used these nanoparticles as antibacterial, antibiofilm against multidrug resistant isolates, in-addition to that used as anticancer against human epithelial alveolar cells (A549).

**Materials and Methods**

**Collection of *E.coli***

Sixty stool samples were collected from non-infectious persons to obtain of *E.coli* bacteria, and ages ranged from (6-60) years old.

**Test bacterial isolates**

About 30 isolates of test bacteria (*P.aeroginosa, A.baumannii, K.pneumoniae, E.coli*, and *S.aureus*) were obtained from AL-Mustansiriyah university laboratories.

Detection of Biofilm production

Congo red test

Pathogenic bacteria were screened to detection their ability to biofilm production as in (10).

**Microtiter plate method**

To explore the susceptibility of bacteria to biofilm formation using the Microtiter plate method according to (11).

**Biological synthesis of ZnO- Nps**

Method of biosynthesis was according to (12), and the creation of a white precipitate at the bottom of the flask is an indication of the formation of nanoparticles (13).

**Characterization of biosynthesized ZnO nanoparticles**

Morphological study of ZnO NPs was identified using SEM (TESCAN-VEGA/USA). While, Optical properties were studied using UV-Vis. spectroscopy (Metertech sp. 8001) at (200-900) nm. Also, FTIR (4000-400) cm$^{-1}$ (Shimadzu/Japan) was used to determine the functional groups, and XRD (7000- Shimadzu Maxima) to determine the crystalline structure of ZnO NPs.

Determination of shelf life of biosynthesized ZnO-NPs

 Biosynthesized ZnO-NPs were stored at 4°C, 25°C, and 37°C for 7 months, then UV-Vis. spectrophotometer and FTIR were performed.

**Minimum inhibitory concentration of ZnO NPs**

MIC of the synthesized ZnO nanoparticles was evaluated by the microtiter plate dilution method according to (14) with modification.

**Effect of ZnO-Nps on Biofilm Formation**

**Congo red agar method**

ZnO NPs used in different concentration (100, 50, and 25 mg/ml) and the method as in (15) with modification.

**Microtiter plate method**

The procedure was used as described by (16) with modification, and the inhibition of biofilm formation was calculated as equation described by (17).

\[
\% \text{ Inhibition of biofilm formation} = \frac{OD \text{ control} - OD \text{ treatment}}{OD \text{ control}} \times 100
\]

Anticancer effect of ZnO NPs

Cancer cells (A549) and normal cells (WRL68) were used and the concentration ZnO NPs (25, 50, 100, 200, 400 µg/mL). Statistical analysis was performed to calculate the IC50 according to the following equation:

\[
\text{Viability (％)} = \frac{\text{optical density of sample}}{\text{optical density of control}} \times 100
\]

**Statistical analysis**

All statistical analysis were carried out using one way analysis of variance ANOVA(Duncan), and the statistical significance was fined as ≤ 0.05. The data was determined using Graph Pad Prism version 6 (Graph Pad Software Inc.,La Jolla, CA).
Results and Discussion

Isolation and Identification of *Escherichia coli*

About 50 isolates of *E. coli* were identified (83\%) from 60 stool sample, and documentation as described by (18). *Escherichia coli* under acidic environment eosin Y is precipitated and formed an amide bond among eosin Y and methylene blue in the medium (19).

Biofilm Formation

Result exhibited that biofilm formed by (3) isolates of *S. aureus*, while (2) isolates of *P. aeruginosa*, (3) isolates of *E. coli*, (4) isolates of *K. pneumoniae*, (4) isolates of *A. baumannii* by Congo red agar method.

Results of Microtiter plate method showed that 4 isolates of *P. aeruginosa*, *A. baumannii*, *E. coli* and *K. pneumoniae* produced strong biofilm, while 2 isolates produced moderate biofilm and 2 isolates weak biofilm production, and the 3 isolates of *S. aureus* produce strong biofilm.

Duarte *et al*, (20) observed that 74.7\% of *A. baumannii* isolates were capable to produce biofilm. Karigoudar *et al*., (21) showed 69\% of *E. coli* were able to produce biofilm, and Murugan *et al*., (22) reported that *P. aeruginosa* and *S. aureus* has a very high capacity for biofilm production. Nirwati *et al* (23) observed that 85.63 \% of *K. pneumoniae* isolates were able to produce biofilm.

Biosynthesis of ZnO Nanoparticles

ZnO- NPs synthesis by *Escherichia coli* as white cluster pellet, and the dry weight was evaluated. The biosynthesized of NPs regulated by general conditions such as metal ions are restriction in the microbial cells or on the microbial surface in the presence of enzymes, thereby reduced to form NPs (24).

ZnO-Nps Characterization

An absorption peak observed at 268 nm refer to the effective biosynthesis of ZnO NPs. Ifeanyichukwu *et al*., (25) reported that absorption peak of ZnO NPs synthesized from pomegranate leaf at 284 nm. While FTIR gave information about functional group related with the synthesized nanoparticles. XRD pattern observed lattice planes of (100), (002), (101), (102), (110), (103) and (112) agreed to the 2θ values of 32.45°, 34.73°, 36.56°, 47.70°, 55.86°, 62.12° and 63.10° respectively with the hexagonal phase of ZnO.

SEM images showed the size of ZnO NPs particles ranged between (31.55–45.9) nm, and aggregated as uneven round structure, which is similar to that reported by (26) (Figure 1).

![Image](image-url)
The Zinc Oxide nanoparticles stored for 7 months at different temperatures and remained stable without change in color. The results in Figure (2) illustrates the transmittance spectrum of the ZnO NPs as a wavelength (263 nm) and the band at 434 cm\(^{-1}\) is confirmed the stretching vibration of ZnO NPs.

![Figure (2) A- UV-visible transmittance spectrum, B- FTIR result of ZnO NPs](image)

Similar results were also reported by (27). The good stability of ZnO NPs because of the free amino and carboxylic groups and it is interacted with the surface of ZnO NPs, and the amide group obtained from the protein acted as capping agent of the ligands of the ZnO NPs (28).

**Minimal Inhibitory Concentration of ZnO nanoparticles**

Results showed that the MIC of biosynthesized ZnO NPs was found to be 12.5 mg/ml against each *E.coli*, *A.baumannii*, and *K.pneumoniae*. While the MIC against *P.aeruginosa* was 50 mg/ml, and 25mg/ml for *S.aureus*. The diameter of inhibition zones around the filter paper saturated with sub MIC ZnO NPs as flows (5, 4, 2, 2, and 2) mm for (*P. aeruginosa*, *S. aureus* *A.baumannii*, *K.pneumoniae*, and *E.coli*) respectively.

The variation in the antimicrobial activates of ZnO NPs as manifested by MIC of nanoparticles probably results from the differences in the tested genus and species (29). The mechanism of antimicrobial activity of ZnO NPs may include release of Zn\(^{2+}\) and generation of ROS and damage to cell membrane (30).

**Antibiofilm on Congo red method**

Pink colonies in the presence of Zinc oxide nanoparticles implied a loss of biofilm formation capability in all pathogenic bacterial isolates of the study (*A.baumannii*, *P.aeruginosa*, *K.pneumoniae*, and *S.aureus*), (Fig 3).

![Figure (3) Antibiofilm activity of ZnO NPs. A–control B–Antibiofilm of 25mg/ml ZnO NPs, C–Antibiofilm of 50mg/ml ZnO NPs D– Antibiofilm of 100mg/ml](image)
Antibiofilm on Microtiter plate method

ZnO NPs was able to decrease biofilm formation from MDR bacterial isolates. Results showed that inhibition percentage of biofilm were (18.6, 27.7, 39.4, and 19.6) % against *S.aureus*, *P. aeruginosa*, *A. baumannii*, and *K. pneumoniae*, respectively after 48 hours of incubation Table (1).

The resistant properties of biofilm, lead to eradication of biofilm related disease is challenging (31) ZnO nanoparticles have bioactivity properties like regulator of biofilms formation according to the concentration of this nanoparticles, as it has been as promising antibacterial agents than conventional antibiotics (31).

Cytotoxicity test of ZnO NPs:

The cells viability was decreased with increasing the concentration of the ZnO The IC$_{50}$ values of the A549 and WRL cells were 105.8, 167.3 µg ml$^{-1}$ respectively as shown in figure (4). The results showed that adding ZnO NPs decrease the cell viability of A 549 cells, and this decreasing related strongly with the concentrations significantly ($P < 0.05$). The percentage of decreasing viability was (42.3 ± 2.6, 54.1 ± 1.3, 68.2 ± 0.9, 81 ± 1.8 and 93 ± 2.3) in concentration (400, 200, 100, 50, 25) respectively, while adding the same concentration to the WRL 68 cells did not show significant effect of viability rate ranged between (62.6 ± 4.4, 71.3 ± 7.1, 88.3 ± 6.2, 87.6 ± 5.2 and 94.2 ± 1.7) as shown in table (2).

Values are expressed as mean ±SD of three experiments.

Reddy and Srividya (30) studied the cytotoxicity effect of ZnO NPs against (A549, HEK) human cell lines, and revealed the dose dependent cytotoxicity of zinc oxide nanoparticles using tested cell cultures. The biosynthesized ZnO NPs due to its semiconducting nature are reported to induce cytotoxicity in cancer cells by the generation of reactive oxygen species on the surface of the particle, the released Zn\(^{2+}\) ions are dissolved in culture media indicating direct interaction of NPs with a membrane of cancer cell resulting in oxidative stress thereby leading to the ultimate death of cancer cells (34).

**Conclusions**

From the results of this study, the biosynthesized ZnO NPs using nonpathogenic *E.coli* showed antibacterial, antibiofilm and anticancer activities against studied MDR bacteria. So, these nanoparticles can be further used in many biotechnological applications as an effective antimicrobial, biofilm disinfectant and anti-cancerous agent.

A Study on Patient Satisfaction in a Tertiary Care Teaching Hospital Mysore

Sujay Mugaloremutt Jayadeva, Harshith.N

1Assistant Professor, Department of Health System Management Studies, JSS Academy of Higher Education & Research, Sri Shivarahreshwara Nagara, Mysuru, Karnataka, India

Abstract

As it’s effortless to enumerate the physical values of the company’s products, as well as the services, even so the perceptions of the customerare something that really resolves a company’s brand appraisement in a marketplace. Patient satisfaction finds to be crucial for any hospital it not only brings good image to the hospital, but also gives a strong satisfaction and trust for the patient towards the hospital, this research was carried out mainly to assess the perceptions of healthcare satisfaction among the patients. 100 patients were taken as sample size in this study and the study was carried out. The data were obtained from the patients by collecting their reviews based on the questionnaire. Results suggested that a majority of the patients required customer services as their first preference and also there were only 6 patients who gave the scale of 10 for satisfaction. So the study concludes that there should be measures taken by the hospital in order to increase the patient satisfaction towards the hospital services.

Key Words: Patient satisfaction, perceptions, satisfaction, hospital, questionnaire

Introduction

As it’s effortless to enumerate the physical values of the company’s products, as well as the services, even so the perceptions of the customer are something that really resolves a company’s brand appraisement in a marketplace. Accordingly, the potentiality of the healthcare marketer’s in building the value of a brand and disseminate such value in a brand along with disseminating that built value towards target audience through numerous strategies of marketing and advertising, such activities are fundamental to achieve enduring achievements in his/her medical practices.

Patient’s Perceptions are about, deliberations of potential and existing patients on your medical practices. Such like the Perceptions results in a new patient acquisition, along with the potentiality to sustain the Quality Relationship with the existing and potential patients of your hospital.

The patients desire for quality healthcare practices, nevertheless the patients also desire to have the knowledge about whether they are acquiring the finest values. Such like values cannot be determined by just pricing of a company’s product/services, but it can be determined through the possibility & level of the care provided to the patient. Having brand awareness is just not sufficient. Patient this time additionally desires of having good senses on their healthcare providers.

Materials and Methods

The research methodology of this study is to investigate the relationship among hospital brand image,
service quality, patient satisfaction/perception and loyalty. The study begins with setting an objective to investigate the patient’s perceptions on the hospital’s brand equity and what all factors help in building up a better brand and what concepts, influences patient’s decision making towards selection of brand with meeting the needs of the patients.

**Data Collection Method**

A questionnaire study was conducted to assess the patient’s perception of selected corporate hospital’s brand equity. Responses have been collected from the 100 patients of Tertiary care teaching hospital for collecting the data required for the study. The data were obtained from the patients by collecting their reviews based on the questionnaire.

**Study Area**

The study was conducted in the tertiary care Teaching Hospital, Mysore

**Results and Discussion**

The present study indications depend on personal particulars of respondents’ perceptions on brand equity of a hospital for building up a better brand. Total 100 samples were obtained to get the satisfactory results for the study.

Figure 6: Satisfaction scale of patients
According to Table Number 6 and Figure Number 6. This study the patient’s reviews on “On a scale of 1-10, how satisfied the patients are with the services received” the respondents reveals 0% of respondents for a scale of 1, 1% respondents for the scale of 2, 2% respondents for scale of 3, 0% reacts on 4, 5% respondents on 5, 8% responds for 6, 25% responds for 7, 42% responds for 8, 11% responds for 9 and 6% of respondents reacts for 10. Majority of the respondents reacts for “8”, according the majority the patients ranks they rank the services at 8 on the of 1-10.

**Conclusion**

Recently there is some problem, including the changing of medical background, the intense competition, the increasing of the hospital choices of patient’s are based on the QUALITY and the REPUTATION of the hospitals. The marketing and Branding departments play vital roles in attracting the patients based on their satisfactions. As the study was conducted to know about the perceptions of the patients towards patient satisfaction. Healthcare management now a days should encounter not only best quality healthcare services, But also must meet the patient’s needs and satisfactions, which leads towards higher patient satisfaction and loyalty towards Brand and also helps in rapid increases in revenue

Success Rate of Intact Canal Wall Tympanoplasty in Safe Type of Chronic Suppurative Otitis Media’ Patients

Sukma Nisa Janitra1, Artono1

1 Senior Resident, 2 Teaching Staff, Department of Otorhinolaryngology Head and Neck Surgery, Faculty of Medicine, Universitas Airlangga – Dr. Soetomo General Academic Hospital, Surabaya, Indonesia

Abstract

Background: Surgical therapy for chronic suppurative otitis media (CSOM) is by tympanoplasty with or without mastoidectomy. The purpose of surgery is to eradicate the source of infection. Success indicators of tympanoplasty are achieving dry ears without recurrent otorrhea, myringoplasty, and an increase in the hearing threshold.

Objectives: is to know the success rate of intact canal wall tympanoplasty in safe type CSOM patients.

Methods: Retrospective descriptive was used in this study. All safe-type of CSOM patients undergoing intact canal wall tympanoplasty surgery from January to December 2018 at Dr. Soetomo General Hospital were used as the participant data.

Results: There were 32 participants, divided into a higher proportion of males than females (ratio 1.1:1). The characteristics of the participants included; the most age group were 21-30 years (37.50%), origin outside Surabaya (59.37%), and high school education level (62.50%). Most perforations were subtotal (40.63%) and hearing loss was conduction (62.50%). Apparently, 56.25% were patent Eustachian tubes, 90.63% were sclerotic mastoid Schuller photographs, and 62.50% were granulation tympanic cavity findings. Additionally, 78.13% were performed tympanoplasty type 1. The results of postoperative eradication showed dry ears (84.38%) and successful of myringoplasty (71.88%). The mean increase in the hearing threshold for AC, BC, and ABG after surgery was 15.98 dB, 4.57 dB, and 11.40 dB.

Conclusion: The results of eradication after intact canal wall tympanoplasty were mostly dry ears, successful myringoplasty, and an increase in the mean hearing threshold of AC, BC, and ABG.

Keywords: Chronic Suppurative Otitis Media, Safe Type, Intact Canal Wall Tympanoplasty, Intact Canal Wall Up Mastoidectomy

Introduction

Chronic suppurative otitis media (CSOM) is a chronic middle ear infection that lasts more than two months. It was characterized by a perforation of the tympanic membrane and continuous or intermittent discharge of secretions from the ear.1 Chronic suppurative otitis media (CSOM) is an ear disease inflammation commonly found in developing countries. The data from WHO (World Health Organization) shows that the prevalence of CSOM in developing countries such as Malaysia, the Philippines, and Thailand is still relatively high, namely 2-4% compared to developed countries in Europe such as Australia, England, Denmark and Finland which is around 0.4%.1,2 The survey conducted in seven provinces in Indonesia was obtained the prevalence of
CSOM was 3.6% of the Indonesian population. The low socio-economic life, slum environment, poor health, and nutritional status are risk factors that form the basis for the increasing prevalence of CSOM in developing countries.  

The management of the safe type of CSOM consists of non-surgery and surgery. The surgical option for safe type CSOM is tympanoplasty with or without mastoidectomy. The purpose of surgical therapy for tympanoplasty is to eradicate the infection from reaching dry ears, while another is to improve hearing process. A number of studies have reported the success factor of tympanoplasty influenced by age, perforation size, location of the perforation, ear condition before surgery, condition of the tympanic cavity during surgery, and Eustachian tube patency. Other factors are also influenced by operating technique, operator experience, previous surgery history, and smoking status. The success indicators of tympanoplasty surgery are achieving dry ears without recurring otorrhea, myringoplasty, and an increase in the hearing threshold. This study purpose is to determine the clinical characteristics of safe type CSOM patients undergoing intact canal wall tympanoplasty.

**Method**

A retrospective descriptive study was used with medical record data for January - December 2018 at out-patient care, Otology division of Dr. Soetomo General Hospital. The study inclusion criteria were patients with safe type CSOM who were undergoing intact canal wall tympanoplasty surgery. The study exclusion criteria included safe-type CSOM patients who underwent revision surgery, congenital anomalies, and incomplete medical record data. There were 136 patients with a diagnosis of safe type CSOM and 56 patients (41.18%) of whom underwent intact canal wall tympanoplasty surgery. The data that met the inclusion criteria were 32 patients. Participants were identified based on demographic data, clinical findings, plain Schuller mastoid radiograph, Eustachian tube patency test, operative findings, and type of tympanoplasty. The postoperative evaluation consisted of postoperative eradication results, myringoplasty, and pure tone audiometry 3 months postoperatively. The data distribution was analyzed by using the SPSS version 16.0 program.

This study has gone through a research protocol and received approval from the Health Research Ethics Committee of Dr. Soetomo General Hospital, Faculty of Medicine, Universitas Airlangga, Ref. No. 0131 / LOE / 301.4.2 / X / 2020.

Based on the table above, most types of perforation were subtotal type (40.63%), while most types of hearing loss were conduction deafness (62.50%). The tubal patency test of this study showed that the majority of patients (56.25%) and plain radiographs of Schuller mastoid were mostly sclerotic (90.63%) (Table 2).

The most pathology finding of the tympanic cavity during surgery was granulation tissue (62.50%), while the most type of tympanoplasty often performed was tympanoplasty type 1 (78.13%) (Table 3).
The results of postoperative eradication showed dry ear conditions (84.38%) and the success of myringoplasty was 71.88% (Table 4).

The mean preoperative Air Conduction (AC) hearing threshold increased from 56.09 dB to 40.12 dB postoperatively, so that the mean increase in AC hearing threshold was 15.98 dB. The mean result of preoperative Bone Conduction (BC) hearing threshold increased from 18.91 dB to 14.34 dB postoperatively, so that the mean increase in BC hearing threshold was 4.57 dB. The results of the preoperative mean Air Bone Gap (ABG) increased from 37.19 dB to 25.79 dB postoperatively, so that the mean increase in ABG was 11.40 dB (Table 5).

Research on hygiene categories showed females have higher hygiene standards than males. This psychological predisposition was related to the incidence of exposure to allergens, bacteria, and parasites.6

The population obtained in this study that most productive age was between 21-30 years (37.50%)
and the number decreased in the fourth to fifth decade. Research by Kumar, et al., found that the largest age group was 21-30 years and decreases in the age group over 60 years. The safe type of CSOM patients who come to an outpatient unit of Dr. Soetomo General Hospital was 59.38% came from outside Surabaya. The majority come from small cities to rural areas in East Java. As reported by Parmar, et al., the difference in the incidence of CSOM among elementary school students in the village (5.11%) was higher than elementary school students in the cities (2.32%). High incidence in small cities or rural areas is associated with a lack of education, education level, awareness of the disease, poor hygiene, and limited health services. Half of the participants were unemployed (50%) and the highest level of education was high school (59.26%). Kumara, et al., showed that CSOM is more common among people with lower socioeconomic status (39.4%). Sufferers of Chronic suppurative otitis media (CSOM) are often found in families with low socioeconomic status and income. Inadequate socioeconomic conditions, malnutrition, poor hygiene, recurrent respiratory infections, and inadequate health care centers were the factors in the occurrence of CSOM.6

The most perforation type in this study was the subtotal type (40.63%). Thakur, et al., obtained similar results (43.6%). The posterosuperior quadrant has more vascularization than other areas so if an inflammatory process occurs, it is susceptible to cell exposure. Repeated inflammation and negative intratympanic pressure effects tympanic membrane retraction until membrane rupture occurs, especially in areas with weaker structures. The most common type of hearing loss in this study was the conductive type (62.50%). Similar results were reported by Kumar, et al.,7 The results of chronic inflammation of the middle ear makes the formation of secretions, perforation of the tympanic membrane, and breaking the ossicular chain. This condition inhibits the transmission of sound waves from the middle ear to the inner ear causing conductive-type hearing loss.12

Mostly, Eustachian tube patency test showed a patent results (56.25%). Kumar, et al., reported that patent tubes in safe type of CSOM patients was 76%. Additionally, the inflammatory process of CSOM could change the pathology of tubal mucosa so it interferes with the function of the Eustachian tube. The inflammatory reaction causes mucosal epithelium hyperplasia, metaplasia, and edema to form granulations or polyps. The distribution of goblet cells and glandular increases in the bone and isthmus so it has an impact on tubal patency, especially the function of ventilation and drainage.11 The plain Schuller mastoid radiograph showed mostly the sclerotic features (90.63%). Roy, et al., obtained the same results with the largest picture being sclerotic (78.85%). The inflammatory process in CSOM affects mastoid pneumatization so the air cells mastoid tend to decrease. The duration is also believed to affect the degree of pneumatization of the mastoid air cells.13

The most common pathology of the tympanic cavity was granulation (62.50%). The same results were obtained in the study by Thakur, et al., which stated that Granulation is formed due to an inflammatory process in the middle ear and causes bone erosion in both the ossicular chain and the tympanic cavity wall. The tympanoplasty technique used in this study was based on the Wullstein classification. Most types of tympanoplasty were type 1 (78.13%). Similar research results were obtained by Antony, et al.,14 The purpose of tympanoplasty are to close the canal perforation, eradicate germs and improve hearing.10 Evaluation of the radiation results that carried out 3 months after the surgery was mostly dry ears (84.38%). The same result was reported by Puspitowati.15 The purpose of surgery for CSOM is to eradicate the source of infection and achieve dry ear conditions.4

Postoperative myringoplasty was mostly successful (71.88%). Yurtas, et al., showed myringoplasty were not much different (75%). Eustachian tube patency was one of the factors that play a significant role as a prognostic
for the success of safe type CSOM surgery because it is considered to provide an image of aeration in the middle ear. Patients with normal tubal function show a better ratio of myringoplasty growth outcomes than abnormal tubal function. Several studies reported that the success of tympanoplasty formation also influenced by age, perforation size, location of the perforation, preoperative ear conditions, and the condition of the tympanic cavity during surgery. Surgical technique, operator experience, previous surgical history, and smoking status are also factors in the success of tympanoplasty.

In this study, the means postoperative AC hearing threshold increased by 15.98 dB. The mean postoperative BC hearing threshold increased by 4.57 dB and ABG increased by 11.40 dB. Additionally, Similar results were reported by Dangol and Shrivastav with AC hearing threshold was an increase in postoperative by 11.45 dB and ABG by 8.9 dB. Post tympanoplasty hearing improvement can be affected by the degree of ocular bone damage. The increase in the hearing threshold appears to be more significant in good ossicle conditions.

**Conclusion**

The results of postoperative eradication were mostly obtained as a dry ear by 84.38%. The myringoplasty was successful by 71.88%. There was an increase in the mean postoperative hearing threshold of AC by 15.98 dB, BC hearing threshold by 4.57 dB, and ABG by 11.40 dB.

Estimation of Height from Foot Measurement in Kalaburagi District

Sunilkumar C.A 1, Santosh Garampalli 2

1 Assistant Professor Dept of Forensic Medicine KBNIMS Kalaburagi, Karnataka, 2 Associate Professor Dept of Forensic Medicine MRMC Kalaburagi, Karnataka

Abstract

Estimation of height of a person plays an important role in identification of a person which is necessary in criminal cases and as well as in mass disasters where only a portion or a part of body may be seen. The present study was carried out on the measurement of foot length and body height of 342 students (170 males and 172 females) of 05 to 30 years of age. Anthropometric measurements were taken by using anthropometric instruments in centimeter to the nearest millimeter. All the measurements were taken in a well lighted room. Obtained data was analysed for correlation coefficient and to derive a regression formula between foot length and height of an individual. A medium correlation of height was observed with foot length and it was statistically significant. The present study would be useful for anthropologists and forensic experts

Key words: Co-relation coefficient, Forensic Anthropology, Foot Length, Regression Equation, Stature

Introduction

The science of measuring the body parts constitutes Bertillon’s system or anthropometry.

Historical aspect of anthropometry as a means of establishing human identity is pretty interesting. It is also viewed as a traditional and basic tool of biological anthropology 1, but it has a long tradition of use in forensic sciences. Relationship that exists between different parts of the body and height has been of great interest to anthropologists, artists, scientists, anatomists, and medico-legalists for a long time. Height estimation by measurement of various long bones has been attempted by several workers with variable degree of success 2,3,4. Ossification and maturation in the foot occurs earlier than the long bones and therefore, during adolescence age, height could be more accurately predicted from foot measurement as compared to that from long bones 8. There are a lot of variations in estimating stature from limb measurements among people of different region and race. Hence there is a need to conduct more studies among people of different regions and group so that stature estimation becomes more reliable and identification of an individual is easily established. The aim of our study is to help in the identification of victims of mass deaths due to natural calamities or manmade disasters from fragmentary and dismembered human remains, identification of criminals from foot print & to find if there is any sex and racial differences of height when compared to foot length. The study also aims to find out any correlation of height with foot length among male and female population of kalaburagi district of

Karnataka state & to predict and estimate height from foot length by deriving a regression equation.

**Materials and Methods**

This observational cross sectional study using convenient sample technique was done over a period of 1 year from March 2019 to February 2020. The present study was carried out in the department of forensic medicine and toxicology at KBNIMS Kalaburagi. A total of 342 subjects were included in the study, out of which 170 males and 172 females within age group of 05 to 30 years. The subjects included in study were healthy individuals free from any apparent skeletal deformity. The left foot was taken for the measurement as per the recommendation of the International agreement for paired measurements at Geneva. Besides the above measurements, stature of each subject was also recorded. All measurements were taken in well lighted room. The measurements were taken using standard anthropometric instruments in centimeters to the nearest millimeter in following manner.

**Anthropometric Measurement**

**Foot length:** It is the distance from the most prominent part of the heel backward to the most distal part of the longest toe (2nd or 1st).

**Instrument:** Vernier Calliper.

**Technique:** The measurement was made on standing subject. The calliper was horizontally placed along the medial boarder of the foot. The fixed part of the outer jaw of the calliper was applied to the pternion and the mobile part of the outer was approximated to the acropodian and measurement were taken. In the same way measurement of the other side were taken.

**Stature:** It is the vertical distance between the point vertex and the heel touching the floor (ground surface).

**Technique:** The subject was made to stand in erect posture against the wall with the feet axis parallel or slightly divergent and the head balance on neck and the measurement was taken. The data was collected, analysed and subjected to statistical analysis using statistical package for social sciences (SPSS) to know the correlation of the stature with the length of feet and simple linear regression formulae were derived for various combinations. The reliability of estimation of stature from the lengths of feet was determined with the help of standard error of estimation (SEE).

The exclusion criteria were:

1. Major ailments in the past affecting foot.
3. Congenital or acquired deformity of foot, or spines.
4. Past histories of generalized disease affecting height like rickets, osteomyelitis, gigantism, dwarfism, achondroplasia, cretinism etc.

**Results and Analysis**

The mean age of males was 17.27 years with standard deviation (SD) of 5.424 whereas the mean age of females was 15.85 years with standard deviation (SD) of 6.069.

We have seen that mean height was found to be 159.21±18.64cm in male subjects and 145.22±18.02cm in female subjects. The mean foot length was found to be 24.62±2.75cm in male subjects and 22.24±2.46cm in female subjects. The mean foot breadth was found to be 9.92±1.07cm in male subjects and 8.99±0.90 cm in female subjects. The differential trends as assessed by mean of t-test reveal highly significant sex differences (p<0.000) for Stature, for foot length and for foot breadth. The following Regression formulæ were derived.
Regression formula from foot length for Males:
Stature (y) = 6.52 foot length - 1.30

Regression formula from foot length for
Females: Stature (y) = 6.82 foot length - 6.45

Regression formula from foot length for both
Genders: Stature (y) = 6.52 foot length + 0.78

Regression formula from foot breadth for
Males: Stature (y) = 14.75 foot breadth + 12.82

Regression formula from foot breadth for
Females: Stature (y) = 17.24 foot breadth - 9.76

Regression formula from foot breadth for both
Genders: Stature (y) = 15.66 foot breadth + 4.08

Discussion
Patel et al (2007)10 carried a study in Gujarat region and found the correlation coefficient between height and foot length as +0.65 in males and +0.80 in females; also derived regression equations to calculate the height from foot length as: H = 75.45 + 3.64FL for males and H=75.41 + 3.43 for females (H= Height, FL= Foot Length). Jaydip Sen et al (2008)11 conducted a study to estimate sex from foot length, foot breadth, and foot index among 350 living adult (age range: 18–50 years) Rajbanshi individuals (175 men and 175 women). They concluded that foot dimensions show significant sex differences and higher correlation between foot length and stature [correlation coefficient r=0.623 for males and 0.682 for females] than that between foot breadth and stature [correlation coefficient r=0.523 for males and 0.387 for females]. Mohanty & Agrawal12 studied a population of 300 students (M=206, F=94) aged 18—25 years of Odisha and developed a regression equation that could calculate the height of an individual from his foot length. They found that as height increases foot length of both male and female also increases. Krishnan (2008)13 examined the relationship of stature to foot size of 1040 adult male Gujjars of North India (age 18 to 30 years) and found that the highest correlation coefficient were shown by the toe length measurements (0.79 – 0.86). Agnihotri et al (2007)14 developed a relationship between the foot length and stature using linear and curvilinear regression analysis on a study group comprising of 250 medical students (125 males and 125 females) aged 18–30 years. It was concluded that general multiple linear regression model was highly significant (p<0.01) and validated with highest value for the coefficient of determination R2 = 0.769 and multiple correlation coefficient r = 0.877.

Conclusion
Simple regression equation derived from this study can be used to estimate height of individuals. This fact will definitely be useful in medicolegal investigations and in anthropological and archeological studies where total height of an individual can be calculated if foot dimension is known.

Phylogenetic Analysis Related to Hepatitis B Virus based on Region Surfaces in Tuban, East Java Province, Indonesia

Supiana Dian Nurtjahyani1, Retno Handajani2,3
1Faculty of Teaching and Education Science, University of PGRI Ronggolawe, Tuban, East Java, Indonesia, 2Faculty of Medicine, Universitas Airlangga, Surabaya, East Java, Indonesia, 3Institute of Tropical Disease, Universitas Airlangga, Surabaya, East Java, Indonesia

Abstract
Hepatitis B virus (HBV) is a virus cause liver disease. This virus could be transmitted through blood product, and it becomes the major problems in developing countries. Genotype distribution of HBV depends on geographical characteristics. Here, we reported HBV genotyping analysis of blood donors with positive Hepatitis Surface Antigen (HbsAg) at Indonesian Red Cross Foundation in Tuban, East Java. Total 150 sera were collected from blood donors at Indonesian Red Cross Foundation in Tuban, East Java. Enzyme-Linked Immunosorbent Assay (ELISA) was conducted by PRISM® HBsAg kit (ABBOTT) according to the manufacture’s instruction, to determine sample that has positive HbsAg. The genotyping analysis was done using polymerase chain reaction and sequencing method from 12 samples. Genetyx ver.10 software was used for identification of HBV type. Analysis of HBV genotype revealed three different types of HBV. HBV type B was the major HBV (50%). Interestingly, there was one unidentified HBV type suggested as a novel subtype of HBV. Further genotyping analysis is needed to confirm novelty of the unidentified HBV type. Analysis of HBV genotype revealed three different types of HBV. HBV type B was the major HBV (50%). Interestingly, there was one unidentified HBV type suggested as a novel subtype of HBV. Further genotyping analysis is needed to confirm novelty of the unidentified HBV type. This study was the first evidence of blood donor’s genotyping analysis in Tuban.

Keywords: blood donors, genotyping analysis, hepatitis B virus, region surface, Tuban.

Introduction
Hepatitis B virus (HBV) is a major virus causing both acute and chronic liver diseases that are spread widely in Indonesia. Chronic infection of HBV has a risk to develop become to carcinoma and liver cirrhosis. Indonesia is included in group of countries that have high prevalence of HBV with blood Hepatitis B surface antigen (HbsAg-emia) approximately 3-20%. Therefore, HBV infection still becomes the main health problem.

To date, there are 10 HBV genotypes already identified all over the world coded from A to J. These types are classified based on genomic properties of HBV. Classification is mainly observed from the genomic divergence, divergence with percentage >8% in nucleotide sequences from HBV whole genomes or >4% from region surface (S) genes.

Several regions in Indonesia have different prevalences of HBV infection. Lombok Island is a hyper endemic region in which about 10.6%-20.3% individuals in suburban area become a carrier of this infection. Infection transmitted through blood product remains high. It is reported that the highest evidence of blood donors with positive HBV is found in Papua province, about 10.5%. In addition, it also explained the evidence...
of blood donors with positive HBV at 11 big cities in Indonesia ranging from 2.1% to 9.5%.4

Tuban is one of the districts in East Java, Indonesia. This district is located near Central Java boundaries; therefore, it becomes one of the regions that connects East Java and Central Java. Based on data from Indonesian Ministry of Health in East Java region in 2007, Tuban has relatively high prevalence of hepatitis with frequency of 0.24% and ranked seventh among all 38 districts and cities in East Java province. That frequency might increase because from the recent data, the frequency of hepatitis prevalence increased significantly from 2007 to 2013 in East Java province2,3,4. Besides that, it has been suggested that the geographical position of Tuban could support the increased frequency of hepatitis prevalence. Here, we reported the first evidence of HBV genotyping analyses based on region surface gene from blood donors with positive HbsAg at Indonesian Red Cross Foundation in Tuban, East Java, Indonesia.

**Materials and Methods**

**Sample preparation**

Sample used in this study was 150 sera from blood donors at Indonesian Red Cross Foundation in Tuban, East Java. Enzyme-Linked Immunosorbent Assay (ELISA) was conducted by PRISM® HbsAg kit (ABBOTT) according to the manufacture’s instruction, to determine sample that has positive HbsAg. Genomic DNA was extracted from positive samples of human blood by Gentra Puregene Blood kit (QIAGEN) according to the manufacturer’s instructions prior to genotyping analysis.

**Genotyping Analysis**

Samples with positive HbsAg were continued for genotyping analysis. HBV genotyping analysis was performed using nested polymerase chain reaction (PCR) and DNA sequencing. Nested PCR was done using two different primers, external and internal primers. Sequences of external primers used in the first step are 5’- GTG GTG GAC TTC TCT CAA TTT TC – 3’ (P7) and 5’-CGG TAW[^A/T] AAA GGG ACT CAM[^A/C]GAT-3’ (P8). And sequences of internal primers used in the second step are 5’-CAA GGT ATG TTG CCC GTT TG-3’ (HBS1) and 5’-AAA GCC CTG CGA ACC ACT GA-3’ (HBS2).13,14

DNA fragment resulted from PCR was used for sequencing after purification step. Purification was performed by QIAquick Gel Extraction kit (QIAGEN) according to the manufacturer’s instruction. Purified DNA was then mixed with one of the primers and Big Dye Terminator kit reagent. Sequencing was conducted using ABI PRISM-310 Sequencer Machine (Applied Biosystems Inc.).

**Identification of HBV genotype**

The identification of HBV genotype was analysed by multiple alignments between sequencing results from sample and gen bank (NCBI) were performed using software Genetyx-Win Ver.10. Phylogenetic tree was made to determine the HBV genotype.

**Results and Discussion**

ELISA analyses from 150 samples of sera resulted in 13 samples that have positive HbsAg. DNA Sequence analysis was performed only in 12 samples. One sample failed to produce a good sequencing result. We used primers that amplified region surface gene in our study for genotyping analysis. The genotyping analysis showed that 12 samples could be included in two major groups. HBV type B was the be included in all groups of HBV type already identified.
Study conducted by Telenta et al. showed the usage of primers targeting the region of surface gene could showed genotype analysis results and analysis using whole genome of HBV. Multiple alignments were conducted between sequencing results from 12 samples and sequence from previous studies already described. Furthermore, phylogenetic tree was made from the alignment analysis. The genotyping analysis showed that 12 samples could be included in two major groups. HBV type B was the dominant type identified in six samples, thus frequency was 50%. This was followed by HBV type C identified in five samples, thus frequency was 41.7%. One sample with code VHB-Tbn-39 (frequency 8.3%) could not be included in all groups of HBV type already identified. HBV type C was considered prior to hepatocellular carcinomas and higher frequency of mutation at HBV core promoter region that related to susceptibility to chemical drugs, compared to HBV type B.

In general, our results showed a similarity with previous study conduct at other areas in Indonesia, whereas HBV types B and C are more dominant than other types. Although Lombok and Papua are well known as regions with the highest prevalence of Hepatitis, HBV type B and C are also dominant in both regions. But in Tuban, both types are almost equal in frequencies. Several Asian countries have similarities in dominant types of HBV such as China and Japan. Compared with other regions such as America and Africa, there were predominant other types of HBV such as types A, D, and E.
Several factors were related to distribution of HBV such as: 1) the effects of mutation prior to drug resistances and vaccination to patient with HBV; 2) individual sex behaviour in those regions\textsuperscript{18}; and 3) poor infection control at dental services\textsuperscript{19}. Basically, social life was closely related to the HBV evidence. Therefore, although there was similarity in predominant HBV types among Indonesian regions but it might be possible that the clinical characteristics among patients in different geographic regions were also different, as suggested in previous study by Orito \textit{et al.}\textsuperscript{20}. Thus, it is possible that the distributions of HBV are different worldwide.

**Conclusion**

In summary, since there is no clinical study related to genotyping analysis in Tuban, at least in part, the data resulted from this study seemed to be an important preliminary data. In our case, one sample was found to be significantly different from any HBV type already known. Further research with large numbers of sample, clinical feature observation, randomized, placebo-controlled study may be needed to confirm the predominant HBV type in Tuban, East Java, Indonesia. In addition, more sensitive genotype analysis should be carried out to reveal one sample that could not be identified.

Management of Patient With Caustic Ingestion Injury: A Case Report

Supriadi1, Budi Widodo2, Brinna Anindita3
1Senior Resident, Department of Internal Medicine, 2Gastroenterohepatologist, Division of Gastroentero-Hepatology, Department of Internal Medicine, 3Internist, Department of Internal Medicine, Faculty of Medicine, Airlangga University-Dr Soetomo General Hospital, Surabaya

Abstract

The ingestion of caustic substances, both accidental and voluntary, determines a complex syndrome, characterized by severe, often irreversible, visceral lesions, with still remarkable mortality in highly compromised patients. A 36-year-old woman came to Emergency-Room with the chief complaints of blackish vomiting about 4 times after drinking liquid to clean the bathroom floor. Patients with findings of grade 2B esophageal injury, pangastritis and gastric ulcer on endoscopy have high the risk of perforation and complications. Endoscopy done within 12 hours and no later than 24 hours following caustic ingestion to classify mucosal injury subsequent to caustic ingestion is useful to determine the severity of injury, particularly in suicidal cases, and thus helpful in predicting outcomes. Patient threat with rehydration with normal saline, total parenteral nutrition, pump omeprazole, injection of methylprednisolone, antibiotic, and sucralfate. Consultation with the Psychiatry department has been conducted psychoeducation and psychotherapy.

Keywords: caustic ingestion injury, endoscopy, suicidal cases.

Introduction

The ingestion of caustic substances, both accidental and voluntary, determines a complex syndrome, characterized by severe, often irreversible, visceral lesions, with still remarkable mortality in highly compromised patients. The most severe oesophageal and gastric damage is notoriously related to voluntary and pseudo-voluntary ingestion of high amount or concentration of strong acids or alkali compounds.1) Corrosive substances can be acidic or alkaline.

Mucosal damage caused by corrosive material can appear one to two months after the contact.2)

Ten-percent of patients sustaining caustic mucosal injury-(CMI) will experience immediate complication. The most common serious immediate complications after caustic material ingestion therefore include: perforation, bleeding, but late findings include fistula formation. Reported mortality approaches 10–20%. Among those sustaining caustic injury in a suicide attempt, mortality may approach 75%. The delayed complications include stricture formation leading to malnutrition and long term risk of developing malignant transformation.1)

We report a young adult woman with caustic ingestion injury. The aim of this case report is endoscopy following caustic ingestion to classify mucosal injury subsequent to caustic ingestion is useful to determine the severity of injury, particularly in suicidal cases, and thus helpful in predicting outcomes.

Case Description

A 36-year-old woman came to Emergency-Room with the chief complaints of blackish vomiting about 4 times after drinking liquid to clean the bathroom floor. When in the ER patient continued to vomit about 3 times. According to her husband, the patient did this to commit suicide due to their domestic problems. On physical examination general condition alert and weak.
Blood pressure 160/80mmHg, pulse 112x/minute, regular-rhythm, respiratory-rate 28x/minute, axillary-temperature 36.7°C. On abdominal examination, contour was flat, supple on palpation, no tenderness.

Laboratories tests showed Hb 13.5--g/dL, leucocyte--112210/mm3, thrombocyte 414000/mm3, Natrium 145--mmol/L, kalium 3.4-mmol/L, chloride 113-mmol/L, blood-glucose 89-mg/dl, AST 14-U/L, ALT 11-U/L, albumin 4.64-g/dL, urea 7-mg/dL, creatinine 0.64-mg/dL, HbsAg non-reactive. Chest-X-ray and BOF: within normal limit.

Based upon all finding we assessed the patient with intoxication of caustic substance and tentamen suicide, therapy with rehydration with normal saline, total parenteral nutrition, pump omeprazole 8mg/hour, injection of methylprednisolone 62.5mg/8hours intravenously, injection of ceftriaxone 1gram/12hours intravenously, orally sucralfate 10ml/8hours. Consultation with the Psychiatry department has been conducted psychoeducation and psychotherapy.

On 2nd day of treatment, cito endoscopy was performed on patients and grade IIB esophageal injury, pangastritis, and gastric ulcer were obtained. On 3rd day of treatment the patient feel better, she and her family refused further hospital care due to cost problems.

Fig.1 Multiple erythema appeared in the cavum oris, erythema and lacerations in the oropharynx and hypopharynx, Epiglottis looks edematous

Fig.2 The proximal to distal esophagus appeared hyperemetic and lacerations. Grade2B ulcers.

Fig.3 Gaster Mucousa appeared to be covered with blood clots, including multiple erythema, lacerations, and ulcers, with necrosis in the pre-pyloric region

Discussion

Ingestion of acid or alkaline caustic substances may cause serious injuries in the esophagus and stomach. The degree of injury is determined by the nature of the substance, the amount consumed or its concentration and state and the time of contact with the gastrointestinal mucosa.3) Mechanism of action of corrosive agents: Alkali ingestion: Causes liquefaction necrosis. This process includes protein dissolution, collagen destruction, fat saponification, cell membrane emulsification, submucosal vascular thrombosis and cell death. Acid ingestion: Causes coagulation necrosis. In this process, hydrogen (H+) ions desiccate epithelial cells producing an eschar. This process leads to edema, erythema, mucosal sloughing, ulceration and necrosis of tissues. Both acids and alkalis cause fibrosis and cicatrization (stricture formation).4)

Hemorrhage, thrombosis, and inflammation with oedema are the dominant processes during the first 24hours following ingestion. The clinical presentation
of caustic ingestion is diverse and do not always correlate with the degree of injury. Symptoms mainly depend on the location of damage. Hoarseness and stridor are signs that are highly suggestive of an upper respiratory tract involvement, particularly the epiglottis and larynx. Presence of these findings may signal a potentially life-threatening respiratory event. The upper gastrointestinal tract, on the other hand, may present as dysphagia or odynophagia for esophageal injury and hematemesis or epigastric pain for gastric involvement. The chief complaints of this patient is blackish vomiting about 4 times after drinking liquid to clean the bathroom floor.

Esophagogastroduodenoscopy is a sophisticated method for diagnostic evaluation of acute corrosive poisonings and injuries of the upper gastrointestinal tract. According to the latest controlled studies the most optimal timing for esophagogastroduodenoscopy is the first 12–24 hours following corrosive ingestion while according to other authors it may be safely performed within the first 96 hours following corrosive ingestion. Endoscopy, as part of the instrumental techniques usable in the acute phase, is the mainstay of diagnostic evaluation and staging, as it allows you to check: (a) the presence of lesions; (b) the severity of lesions; (c) the extent of the lesions by considered area (for example the esophagus); (d) the topographical distribution in the upper digestive tract (from the pharynx to the duodenum); (e) the presence of objective evidences correlated to the risk of perforation. Endoscopy should be always performed in all patients in whom the ingestion of caustic in large amount or strong concentration is sure or at least suspected, such as intentional or pseudovoluntary ones. About 20% of them could have visceral lesions without any oral pathological finding.

The findings on upper GI endoscopy are based on Zargar’s modified endoscopic-classification of burns due to corrosive ingestion into six grades: 0 (normal mucosa), 1 (erythema/hyperemia), 2a (superficial ulcer/erosion/friability/hemorrhage/exudates), 2b (findings in 2a deep discrete/circumferential ulcers), 3a (scattered necrosis, black/grey discoloration), 3b (extensive/circumferential necrosis of mucosa).

The results of this study confirm Zargar’s endoscopic-classification of mucosal injuries post caustic ingestion in relation to clinical outcome. The tensile strength of healing tissues in the first 3 weeks is low due to an absence of collagen. New collagen formation does not begin until the second-week after injury. Thus, it is advocated that endoscopy should be avoided from 5 to 15 days after caustic ingestion. Currently, EGD evaluation within 12 hours and no later than 24 hours after caustic ingestion is considered safe. EGD is not recommended from 2 to 3 days up to 2 weeks after caustic ingestion as a result of wound softening. On 2nd day of treatment, cito endoscopy was performed on patients and grade-2b esophageal injury, erosion of pangastritis, and gastric ulcer were obtained.

Short-term complications include perforation and death. Perforation of the esophagus or stomach can occur at any time during the first 2 to 3 weeks of ingestion. A sudden worsening of symptoms or an acute deterioration of a previously stable condition should warrant a thorough investigation to rule out the possibility of a perforated viscus. Chronic complications of caustic ingestion include stricture formation, gastric outlet obstruction and malignant transformation. Patients with esophageal strictures usually complain of dysphagia and substernal pressure, and ay become symptomatic 3 weeks or later after ingestion.

Management of caustic injury includes immediate resuscitation and evaluation of extent of damage. The cornerstone of all caustic ingestions is airway and hemodynamic stabilization. Since direct exposure of the upper respiratory-tract by the corrosive substance may occur, patients should be evaluated for the need to do immediate intubation or tracheostomy. Patient therapy with rehydration with normal saline, total parenteral nutrition, pump omeprazole 8mg/hour, injection of methylprednisolone 62.5mg/8hours intravenously, injection of ceftriaxone 1 gram/12 hours intravenously, orally sucralfate 10ml/8hours.
Neutralizing agents.

It has now been emphasized that these substances should not be administered due to the additional thermal injury and chemical destruction of tissues these reactions produce.9)

Nasogastric tube.

Routine nasogastric intubation for the purpose of evacuating any remaining caustic material is no longer warranted prior to endoscopic assessment of mucosal injury. This is due to the possibility of inducing retching or vomiting leading to further esophageal exposure by reflux of the remaining intragastric caustic material.10)

Gastric acid suppression and mucosal protection

Upon admission, the patient should be kept fasting. Gastric acid suppression with H2-blockers or intravenous protonpumpinhibitors are often initiated to allow faster mucosal healing and to prevent stress ulcers.5)

Antibiotics

A study in 1992 analyzed the utility of antibiotic together with systemic steroid administration in caustic ingestion. It was concluded that antibiotics with steroids may be useful in preventing strictures in patients with extensive burns.10)

Steroids

Methylprednisolone at a dose of 1 g/1.73-m2 per day for 3-days showed benefit in reducing stricture development. However, another study showed that prednisolone at a dose of 2g/kg intravenous did not provide any benefit in preventing stricture development.11,12)

Triamcinolone

Intralesional steroid such as triamcinolone (40-100mg/session) has long been known to augment the dilatation of caustic-induced esophageal strictures although results from most studies are still conflicting.5)

Conclusion

An 36-year-old woman with findings of grade-2B esophageal injury, pangastritis and gastric ulcer on endoscopy have high the risk of perforation and complications due to caustic ingestion injury. Endoscopy done within 12 hours and no later than 24 hours following caustic ingestion to classify mucosal injury subsequent to caustic ingestion is useful to determine the severity of injury, particularly in suicidal cases, and thus helpful in predicting outcomes.

Knowledge Regarding Prevention of Urinary Tract Infection In Patients with Indwelling Catheter among Staff Nurses: An Intervventional Study

Surinder Singh¹, Ruchi Kumari², Aarti Thakur³, Sakshi Tomar⁴, Mridul⁴

¹Assistant Professor, ²Nursing Tutor, Department of Medical Surgical Nursing, ³Nursing Tutor, Department of Obstetrics and Gynaecology Nursing, ⁴Clinical Instructor, Chitkara University College of Nursing, Chitkara University, Himachal Pradesh, India

Abstract

The study based on a broad framework with input, throughput, output and feedback first presented by Ludwig Von Bertalanffy. The investigation utilised an evaluative approach. Samples of 50 staff nurses were collected using random sampling by lottery. A structured questionnaire was used for data collection. The overall pre-test knowledge mean score was 14.14±1.629. After administration of the self-instructional module, the post-test mean score increased to 20.56±4.362. The hypothesis H1 expressed that there will be a considerable distinction between pre-test and post-test information scores of nursing officers regarding urinary tract infection. The ‘t ‘ test was discovered to be more prominent than the table worth. Acquired worth was (10.353), and table worth was (2.045). It showed the effectiveness of the SIM. The study was no significant relationship with demographic variables because the chi- square value was less than the table value. Thus, the H2 has been dismissed.

Key words: Effectiveness, urinary tract infections, knowledge, Self Instructional Module.

Introduction

The statement underlines the importance of kidneys to our lives. Satisfactory working of the renal system is essential for the support of a sound body.¹ These are the part of the urinary system, which precisely maintains the body’s chemical environment and performs various excretory and secretory functions of the body. The urinary bladder works as storage, whereas the ureters and urethra can be considered as waste channels for the urological system.² After shaped by the kidneys, when there is a decrease in the outflow of urine, it leads to UTI caused by pathogenic organisms in the urinary tract. It is one of the most common infections treated by primary care providers. The majority of urinary tract infections are brought about by catheterisation.

An indwelling catheter is embedded into the bladder to gather the urine from the bladder. A Foley’s catheter is a standard indwelling catheter. Its component is a balloon attachment toward one side. After addition to the catheter, the balloon is packed with sterile water. It keeps the catheter from leakage.³ Prevalence of urinary tract infections cystitis: 6.2 million grown-ups self-revealed having a bladder infection for every three months within the US 1988-1994.⁴ It is observed that 10-12% of patients hospitalised and 4% of patients in the community area have a urinary catheter in situ at some random time. Hospital-acquired UTIs create 5 percentage of urinary catheterised understandable – patients per day. With related bacteria in 4% and the 4% number of as 80% is an outcome of the urinary catheter. Health care providers play a vital role in the prevention of infection, except in particular circumstances. All the catheters should be administered in a sterile manner. Using non-sterile techniques lead to urinary tract infections.⁴
Need for the study

The kidney filters the body's liquid waste in the form of urine and sends it into the bladder to be stored. Urine contains salts, fluids and waste material; however, bacteria is not usually present in the urine. Microorganisms entering the bladder or kidney can regenerate quickly in the urine, causing a urinary tract infection. UTI are perhaps the most widely recognised hospital-acquired infection. Roughly 40% of all nosocomial infection and 80% of these are related to a urinary catheter's utilisation. The majority of deaths are due to the development of gram-negative bacteria. 33% of these infections are due to the bacteria formed inside the urinary system. 66% to 86% of the diseases happen chiefly due to urinary catheterization.

Nurses are a vital part of in-hospital treatment. They are responsible for taking care of the patients' basic needs throughout the day. It is their responsibility to give the best possible care to prevent any infection during the hospital stay, which is achieved by improving the quality of nursing care.

During the researcher's clinical posting, it was observed that the quality and standard of nursing care given by the staff for a patient with an indwelling catheter was inadequate. Due to that, many patients had developed catheter- associated urinary tract infection. The nursing personnel were consistently answerable for setting and keeping up the urinary catheter framework, including cleaning and different works.

Methodology

This pre-experimental study approved by the Institutional Ethical Committee (IEC-1988 A) was conducted from December 2014 to March 2015 in the hospital of Sri Guru Harkrishan Sahib College, Mohali. Formal permission was taken. Composed assent was sought from the subjects of the investigation.

Study design and setting

The study comprised a "Pre-Experimental One group Pre-test and Post-test Design" in SGHS hospital equipped with 300 beds and an intensive care unit with 60 beds.

Sample and Sample Size

The hospital had one hundred twenty staff nurses working in different units in shift duties. A sample of 50 nurses was selected by the non-replacement simple random sampling lottery method with the following inclusion and exclusion criterion.

Methods and tools of data collection

A questionnaire was used for accurately collecting data, followed by administering a self-instructional module. Based on the goals, the instrument was isolated into two segments.

Selection and development of a tool

A structured questionnaire was developed through reviewing of literature via pubmed, cinhal, experts, guides, co-guides is utilized as an apparatus for present investigation. Apparatus will be chosen in the wake of surveying the literature and after discussing with specialists.

Reviewing literature via pubmed, cinhal, experts, the guides developed a structured questionnaire, and co-guides used it for investigation

Description of tool

Segment I: Demographic variables

Segment II: Structured knowledge questionnaire. The tool consists of 30 items. Segment II: Structured questionnaire.

The questionnaire made in English, contained 30 multiple-choice questions with four options. Each correct response earned one mark. The incorrect response earned no marks.

The questionnaire covered different areas - introduction, definition and types, causes, risk factors,
sign and symptoms, prevention and management.

Procedure of Data Collection

Immediately after that, knowledge development tools were administered, and a pre-test was conducted after that SIM was introduced. After seven days, a post-test was conducted.

Results

Table 1: Frequency distribution of overall knowledge score among staff nurses regarding UTI

<table>

<td>19 (38%)</td>
<td>15 (30%)</td>
</tr>
<tr>
<td>Above average</td>
<td>0 (0%)</td>
<td>26 (52%)</td>
</tr>
</tbody>
</table>

Table 1 illustrates the frequency and percentage distribution of the staff nurses’ knowledge base in the pre and post-test scenarios. The pre-test outcome showed that 62% of participants had below-average knowledge, and 38% had average knowledge. No one qualified the above-average score.

The post-test score demonstrated a distinct improvement in their knowledge. 52% of the nurses had acquired better than expected information, while 30% had the required standard information. However, 18% of the nurses in the post-test continued to have below-average information.

Discussion

This study, based on a sample size of 50 nurses, demonstrated that 62% of the participants had low knowledge, 38% had average knowledge about the sensitivities/criticalities of catheter application. No participant possessed good knowledge in the pre-test scores.

The self-instructional module content on urinary tract infection included introduction, definition, types, risk factors, causes, sign and symptoms, prevention, and management. The self-instructional module was administered to the staff nurses soon after the pre-test. The post-test score was assessed by paired ‘t’ test. The mean of the post-test was 20.56 with SD of 4.362 and a paired value of 10.353, implying that the post-test score had better than the pre-test of staff nurses. The hypothesis (H1) that there was a difference between knowledge of pre-test and post-test scores was thus accepted. Overall, the pre-test mean score of staff nurses was 14.14 (SD+1.628), and the post-test mean score was 20.56 (4.362), implying that the improvement mean was 6.420. The determined ‘t’ test value was 5.79, which was more than the table value, which shows a considerable distinction between the pre-test and post-test scores of nurses concerning urinary tract infection. This also implied that the self-instructional module was practical. The determined chi-square values did not match exactly with the table values, implying no significant association between the demographic variables. Hence the hypothesis (H2) was rejected.

Conclusion

The findings showed that the teaching program effectively enhanced the work knowledge and reduced the occurrences urinary tract infections in patients with indwelling catheters. The study recommended the necessity of conducting regularly, in-service education programs for nursing personal regarding the prevention of urinary tract infections to enhance patient safety and quality of care in hospital.

Ethical Issues: informed written consent was taken No author had any conflict of interest to declare.

Funding

The study did not receive external funding.

Correlation Luteinizing Hormone (LH)/Follicle Stimulating Hormone (FSH) Ratio with Low Density Lipoprotein (LDL)/High Density Lipoprotein (HDL) Ratio in Polycystic Ovarium Syndrome (PCOS) Patients

Susi Oktaviani¹, Jusak Nugraha², Ashon Sa’adi³

¹Resident, ²Lecturer, Department of Clinical Pathology, ³Lecturer, Department of Gynecological Obstetrics, Faculty of Medicine, Airlangga University - Dr. Soetomo General Hospital, Surabaya, Indonesia

Abstract

The aim of this study is to analyze the correlation between the ratio of LH and FSH levels with LDL and HDL cholesterol in PCOS patients. This study is an observational cross-sectional study. The population in this study were women newly diagnosed with polycystic ovary syndrome who came to RSIA Ferina, RSIA Lombok 22, Elizabeth Clinic and RSIA Putri Surabaya and Clinical Pathology Laboratory of dr. Soetomo Surabaya. Examination of FSH, LH and LDL and HDL cholesterol levels on 27 specimens (stored frozen serum) using the ICT (Accurate Intan Madya®, VEDALAB) and enzymatic colorimetric (Dimension EXL®, Siemens) methods. Statistical analysis was performed using the Spearman and Pearson correlation test, with a significance level of p <0.05. The results showed that there was a moderate positive correlation between FSH and LDL cholesterol (r = 0.491, p = 0.009). Phenotype D of PCOS (non-hyperandrogenic type) had a moderate negative correlation between the LH / FSH ratio and the LDL/HDL cholesterol level ratio (r = -0.487, p <0.05). However, there was no relationship between the LH/FSH ratio and the ratio of LDL/HDL cholesterol levels in all SOPK patients in this study. This study showed that phenotype D PCOS patients (non-hyperandrogenic type) were less likely to have cardiovascular complications than other phenotypic PCOS patients. Insulin resistance has a role in the risk of dyslipidemia in non-hyperandrogenic PCOS patients.

Keywords: PCOS, LH, FSH, LDL, HDL

Introduction

Polycystic ovary syndrome (PCOS) is an endocrine disorder that is most often found in women of reproductive age, with an incidence of 4-18% worldwide. Santoso and Irawan conducted a study in Surabaya to get the prevalence of PCOS in women of reproductive age by 4.5% in 2007. The prevalence of this disease has increased to 8-10% due to changes in people’s lifestyles with a high calorie diet and sedentary life style.¹² The diagnosis of PCOS is determined by the presence of two of the three Rotterdam criteria, namely: oligomenorrhea or anovulation, clinical hyperandrogens, and polycystic ovary morphology on ultrasound evaluation. Many PCOS patients do not have clear clinical symptoms, and experience difficulty in diagnosis, especially in the Asian population. An increase in the ratio of LH/FSH was seen in PCOS patients. A disturbance in pulsatile GnRH causes an increase in LH levels but is not followed by an increase in FSH levels. However, other research states that only 30-90% of PCOS patients experience an increase in the LH/FSH ratio.³
PCOS patients often have a variety of endocrine and metabolic abnormalities. PCOS patients have increased levels of LDL cholesterol (LDL-C) and decreased levels of HDL cholesterol (HDL-C). The increase in LDL occurs due to insulin resistance and hyperinsulinemia which causes an increase in free fatty acids (FFA), and further induces the synthesis of very low-density lipoprotein (VLDL) and LDL-C. The decrease in HDL is caused by insulin resistance and the degradation of Apolipoprotein A1/HDL-C.³

Women with PCOS have a four times greater risk of developing metabolic syndrome than healthy population. According to NCEP (National Cholesterol Education Program) guidelines about 70% of women with PCOS have dyslipidemia. Rizzo’s research reports that women with polycystic ovaries are more likely to have stenotic coronary heart disease detected by angiography than women with normal ovaries. This study aims to determine the correlation between the LH/FSH ratio and the ratio of LDL/HDL cholesterol levels in PCOS patients.⁴,⁵

Materials and Methods

This research is an observational analytic study with a cross sectional study approach. The research specimens were taken from samples of PCOS patients who came to RSIA Ferina, RSIA Lombok 22, Elizabeth Clinic and RSIA Putri from March to July 2019. Inclusion criteria included: PCOS patients diagnosed with 2 of the 3 Rotterdam criteria, age 18-40 years. Exclusion criteria were using hormonal contraception, suffering from heart disease, hypertension, insulin resistance/hyperinsulinemia, and endometriosis, also on statin medication.

Venous blood serum was taken from a population that met the criteria for the main study. The stored serum is used for checking the levels of FSH, LH, LDL-C and HDL-C in 2020. Specimens were stored at -80°C while waiting for the running process. Examination of FSH, LH using the AIM tool (Accurate Intan Medika) with the ICT method. The LDL-C and HDL-C tests used the RXL dimension (Siemens Healthineers, Germany). The data normality test was performed using the Shapiro-Wilk test. Data that is normally distributed are expressed in mean values, while data that are not normally distributed are expressed in the mean value. The correlation of LH and FSH ratios with the ratio of LDL and HDL cholesterol levels in PCOS patients was analyzed by doing the Pearson correlation test (if the data were normally distributed) or the Spearman (if the data were not normally distributed).

Results and Discussion

The number of subjects who participated in this study were 27 patients PCOS. Data on the characteristics of research subjects included age, body mass index and phenotype (Table 1). The results of this study are in line with the research of Wahyuni et al, which shows that obesity is more likely to experience PCOS, namely 50.5%.⁶ Tavares and Barros state that the highest prevalence of patients with metabolic syndrome in each PCOS phenotype in Brazil has a BMI>30 kg/m² (obese). Obesity will cause chronic hyperinsulin or insulin resistance, and can aggravate hormonal and metabolic disorders in PCOS patients. This may be one reason obese patients sought treatment more frequently in this study.⁷

The Rotterdam criteria divides PCOS patients into 4 phenotypes. Phenotype A is PCOS patients with classic symptoms (hyperandrogen triad, anovulation, and polycystic ovary). Phenotype B has symptoms of hyperandrogens and polycystic ovaries. Phenotype C has symptoms of hyperandrogens and anovulation. Phenotype D had symptoms of anovulation and polycystic ovaries without symptoms of hyperandrogens. Wiweko’s research in Indonesia, Daan N, et al in the Netherlands, showed that phenotype A and D populations were the largest phenotypes. The Rotterdam criterion uses the Ferriman-Gallwey score, where a score of more than 8 is used to diagnose hyperandrogens. This score is probably lower in PCOS patients in Asia, so that the sensitivity decreases.⁸,⁹,¹⁰ The combination of the higher incidence of polycystic ovary morphology compared to European patients and the sensitivity of this low Ferriman-Gallwey
score could explain phenotypes A, B, C only slightly compared to phenotype D in this study.

Description: LH, Luteinizing Hormone; FSH, Follicle-Stimulating Hormone; LDL, Low Density Lipoprotein; HDL, High Density Lipoprotein; n, the number of cases.

The population of this study shows that there is an imbalance in LH and FSH production, as in table 2. Based on the mean of LH and FSH, it is found that LH / FSH > 2. In the past, this ratio served as the gold standard for clinical diagnosis of PCOS in addition to the Rotterdam criteria. However, LH / FSH levels have become controversial after a number of studies have reported a variable prevalence of this ratio (30-90%) among women with PCOS. A disturbance in pulsatile GnRH causes an increase in LH levels but is not followed by an increase in FSH levels. The hyperandrogenic state causes an increase in estrogen levels by the aromatase enzyme activity. Estrogen will inhibit FSH production from the anterior pituitary.

*aNormal distribution and Pearson correlation, bNon-Normal and spearman correlation, significant value <0.05* (P-value represents significance from Pearson and Spearman correlation statistical analysis). Description: LH, Luteinizing Hormone; FSH, Follicle-Stimulating Hormone; LDL, Low Density Lipoprotein; HDL, High Density Lipoprotein; n, the number of cases.

The results of the correlation test between FSH levels and LDL cholesterol levels showed a positive correlation 0.491, the strength of the relationship was moderate, which was significant (p = 0.009) (Table 3). This means that there is a significant relationship between FSH and LDL cholesterol (p < 0.05). The results of the correlation test between FSH levels and HDL cholesterol levels showed a negative correlation of -0.172, which was not significant (p = 0.390). This means that there is no significant relationship between FSH and HDL cholesterol (p > 0.05). These results are in accordance with the results of research by Arshad F, et al. (2019) in Pakistan which showed that FSH had a significant correlation with LDL (p = 0.01, r = 0.36) while FSH had no significant correlation with HDL (r = -0.152, p = 0.323).

*aNormal distribution and Pearson correlation, bNon-Normal and spearman correlation, significant value <0.05* (P-value represents significance from Pearson and Spearman correlation statistical analysis). Description: LH, Luteinizing Hormone; FSH, Follicle-Stimulating Hormone; LDL, Low Density Lipoprotein; HDL, High Density Lipoprotein; n, the number of cases.

The correlation of the LH and FSH ratios with the LDL and HDL cholesterol ratios in phenotype D (Table 4) is in accordance with the explanation of several previous studies. Women with hyperandrogenic PCOS differed significantly from women with non-hyperandrogenic PCOS regarding most of the endocrinological and cardiometabolic parameters. Women with hyperandrogenic PCOS have worse
cardiometabolic profiles, including higher BMI, higher LDL cholesterol and lower HDL cholesterol. Another study showed that the significantly lower prevalence of metabolic syndrome (6.5%) and hypertension (11.8%) in non-hyperandrogenic women was consistent with the prevalence previously reported in a population of normal (non-PCOS) women with age, BMI, and the same ethnic background. Overweight or obesity (28.5%) and lipid disorders (increased LDL-C, 52.2%) were relatively common among young women with PCOS phenotype D compared with non-PCOS.9,13

Based on the case finding in this study, it was found that phenotype D was the largest phenotype in the subjects of this study. The subjects of this study were taken consecutively, based on patients who came to several hospitals and clinics in Surabaya. This indirectly illustrates that phenotype D is the most common PCOS phenotype in the East Java region, which turns out to be consistent with research conducted in Asia. The correlation of LH and FSH ratios with the ratio of LDL and HDL cholesterol to phenotype D is in accordance with the explanation of several previous studies, indicating that insulin resistance has a role in the risk of dyslipidemia in non-hyperandrogenic PCOS patients. SOPK patients have impaired tissue insulin resistance. This will trigger the release of excess insulin as a form of compensation. This hyperinsulinemia condition will cause increased activation of the Insulin Growth Factor-1 (IGF-1) receptor. Ovarian theca cell abnormalities in SOPK patients also cause a decrease in aromatase so that estrogen decreases. This decrease in estrogen causes the synthesis of G protein coupled estrogen receptor to decrease, resulting in an increase in circulating LDL-C due to decreased LDL receptors. This imbalance of LDL-C and HDL-C cholesterol causes an increase in the ratio of circulating LDL-C to HDL-C. Lipids that accumulate in these blood vessels will cause atherosclerosis. 14

**Conclusion**

The negative correlation of the LH and FSH ratios with the LDL and HDL cholesterol ratios in phenotype D. Women with hyperandrogenic PCOS have worse cardiometabolic profiles, including higher BMI, higher LDL cholesterol and lower HDL cholesterol. Overweight or obesity and lipid disorders were relatively common among young women with PCOS phenotype D compared with non-PCOS. Insulin resistance still has a role in the risk of dyslipidemia in non-hyperandrogenic PCOS patients

The Medical and Psychological Effect of Hate Crimes and Hate Speech on Vulnerable Social Groups

Suvidutt M.S., Aditya Tomer

1PhD Scholar (Law), AIALS, Amity University, Noida; Advocate-on-Record, Supreme Court of India,
2Addl. Director, Amity Law School, Amity University, Noida

Abstract

The present study would be analyzing and interpreting the intricacies of hate speech in two-fold. Firstly, the authors would be meticulously analyzing the legal parlance of the term ‘hate speech’ in the present aeon and its repercussions, i.e., outline the constitutive and consequential harm faced by the people that goes beyond legal texts and judgments and beyond the legal notion of hate speech.

In furtherance, this research article would address the aftereffects of hate speech medically and how it takes a psychological toll on minority bigotry and pervasive gender or ethnic differences by using a plethora of well-known logical research approaches that are unique to analytic philosophy.

Hate speech cases have resulted in bans on campus, legal rulings, and national controversy. The term ‘Free Speech’ and ‘Hate Speech’ has been misconstrued and used misappropriately. The prime reason is the absence of precise clarification and the unbelievably wide usage of the term. The targeted communities experiencing hate speech are of paramount importance but are often overlooked due to the legitimacy of laws pertaining to hate speech.

Keywords: hate crime, hate speech, medical effect, psychological effect, social group

‘A public health approach to bigotry will not eliminate/ eradicate hatred, but may at least mitigate the damage hatred can inflict upon society.’

– Ronald Pies

Introduction

As everyone is aware that there is no standard definition of the term ‘Hate speech’, however, the same has/ is being used at persecuting people by denigrating their religious, ethnic or other racial identities. The term ‘Hate speech’ has always been used to mean violent, disrespectful, threatening, bullying or inciting abuse, hostility or bigotry against vulnerable groups characterized by characteristics such as ethnicity, faith, place of birth, residence, country, language, caste or community, sexual orientation or personal convictions. The balance of society is disrupted by these speeches, and it breaks the multifaceted structure of society.

While a single individual or small community may be the immediate target, through fostering bigotry and intolerance, the harm caused by hate speech can spread to whole populations. Although hate speech has been there for time immemorial, to date, there is no dearth of laws pertaining to the menace of hate speech.
The inclusion of Sections 153A and Section 505C in the Indian Penal Code, 1860 with respect to hate speech only make the substantive law more wholesome. The real need is to overhaul the prevailing laws with proper vigour and efficacy in order to devise ways to combat the injury caused due to hate speech. The authors would like to assert that on account of public order, incitement to violence and State protection, hate speech that has become a preeminent concern must be curtailed.

**Materials and Method**

This research paper is based on doctrinal study. The authors relied on several books and research papers by analyzing and interpreting them to bring a different point of view.

**Discussion**

How Far the Limitation on Free Speech Play a Role?

One among the most cherished rights of a civilized, democratic society is ‘Right to Freedom of Speech and Expression’ which has been enshrined and enunciated under Article 19 (1) (a) of the Indian Constitution. The prime objective of this provision is promoting a plurality of opinion. Per contra, it is of paramount importance to note that in an unjust society, this right will be in contrast with the doctrine of non-discrimination.

Equality of speech, including offensive speech many a time, berates the essence of equality. A question that arises is ‘Whether Freedom of Speech and Expression is absolute, or can there be any restrictions put on this right?’ Post the insertion of Article 19 (2) in the Indian Constitution by relying on the case of *Gitlow v. New York*, reasonable restrictions were imposed on this right. This provision act as a check to the provision that grants the freedom of speech and expression.

However, the authors deem that the same has not been imposed accordingly as the thin line to demarcate Free speech and Hate speech has been ignored that results in infringing the fundamental right of Freedom of speech and expression and misuse of the law. To demarcate a line between free speech and hate speech is a challenge that policy makers, law agencies, judiciary etc. are facing. It is a conundrum that need to be resolved. This is not only the scenario in India but also worldwide.

**An Analysis of Reported Hate Crimes**

Globally, hate crimes are under-reported, offering little details on the incidents. Based on the analysis, it was brought to light that in 2010 alone, there were 3,770 hate crimes reported in Germany, which included not only hate crimes but also incitement to hatred and propaganda offences. In 2014-2015, there were approximately 42,930 racially motivated public order offences in England and Wales. The FBI reported 7,145 hate crimes in 2017. It was found out that the reported hate crimes in 2017 were mainly motivated by hostility based on race/ethnicity (58.1 percent), religion (22 percent), sexual orientation (15.9 percent), gender identity (0.6 percent) and disability (1.6 percent).

To put an embargo on hate speeches and hate crimes, a bill was introduced in the U.S. House of Representatives known as ‘The National Opposition to Hate, Assault, and Threats to Equality Act, 2017,’ to collect more precise hate crime reports by training law enforcement to identify hate crimes and setting up monitoring hotlines. Apart from the introduction of the bill, there was no further action or measure taken on it.

In furtherance, the FBI’s Uniform Crime Reporting (UCR) while submitting the hate crime statistics elucidated that the hate crime information for 2019, submitted by 15,588 law enforcement authorities, offers information about the cases, suspects, perpetrators, and hate crime sites. There were 7,314 cases of hate crime incidents, including 8,559 offences among these organizations that sent incident reports.

The current study on hate crimes relied on hate crimes reported to the authorities, and thus rests not only on the desire of the victims to report but also on their capacity to supply the police officials with ample proof of the hate motivation. This leads to a shortage of knowledge that makes it impossible to measure the
nature of the issue and to take appropriate action to resolve it. Taking this into consideration, the European Commission against Racism and Intolerance (ECRI) proposes that States must offer practical assistance to hate speech and abuse targets. They should be made aware of their right to redress by institutional, civil and criminal action and advised to report the authorities and access legal and therapeutic support.

**Harms to Victims As Well As Perpetrators: A Medical/ Psychological Based Approach**

Based on research study by numerous psychiatrists, it has been noticed that people victimized by violent hate crimes are likely to suffer more psychological trauma than the victims of other violent crimes.\[19\] It takes a psychological toll on the victims, which leads to post-traumatic stress, safety concerns, depression, anxiety and frustration.\[20\]\[21\]

The first step in crime intervention and prevention is the awareness of the mindset of the hate crime perpetrator. Until thoroughly recognizing the reason for the offence, in the sense of social intolerance, bigotry, and discrimination, it is difficult to assess the far-reaching psychosocial impact for the victims or identify the mindset of the perpetrator. After a comprehensive analysis, it was found that most of the hate crimes/hate speeches are consummated by the youngsters. Regarding the diversity of youths, it is during puberty that the core signs of hate impulses become fully visible. To grasp the enormity of evil activities such as hate crimes, youngsters become ‘armed’ with the cognitive and moral apparatus and are thereby therefore motivated to commit them.\[22\]

Genetic theories have revealed that the genes of an individual may predispose the person to choose criminal activity under certain circumstances.\[23\] A genetic factor for illegal and aggressive activity has been proposed in both twin and adoption research.\[24\] It was found that the concept of hate crimes has not been discussed/addressed in any genetic testing.

The psychoanalytical approach of Young-Bruehl linked the lack of satisfaction of essential needs to the commission of hate crimes in many at-risk youths.\[25\] Without a welcoming atmosphere to express the typical anxiety, uncertainties and insecurity of adolescence, there is an incomplete sense of belonging and a fragile intensity of ego among young people. Due to these deficits, adolescents may use prejudices in their community because of these deficiencies to project unacceptable emotions, not to an individual nearby, but to an entire society, including a group outside personal familiarity. The consequence is intolerance of others and resentment at the shortcomings attributed to them. The average youth who acts on his hatred feels rejected and abandoned from friends and members of family and uses hate to make up for feelings of inadequacy. In their recruiting of youngsters, hate groups are effective because their beliefs have a kind of outward superego. The actions of the group offer gratification and an independent teenager may thus be persuaded to adhere to the group and disregard previous principles and convictions entirely.\[26\]

Aaron T. Beck, an American psychiatrist, views hate as a neurological challenge, a disease of thought. Thought drives conduct in this theoretical context, and the violence-prone person, including the perpetrator of hate crime, has a profound weakness in his understanding of social experiences.\[27\] He sees himself as righteous and moralistic, while the enemy is to blame for his troubles. Youths who commit hate crimes exhibit issues with impulse control, thrill-seeking conduct, problems with intimidation, behaviour or hostility, a desire to be professional, or feelings of betrayal and underlying harm.\[28\]

Data on convicted hate crime offenders have demonstrated that many of the most violent types of hate violence are perpetrated by persons with previous criminal backgrounds, those who are socially deprived and those who are susceptible to drug abuse. Furthermore, abusive offenders have displayed characteristics predicting antisocial and repetitive behaviour. In terms of psychological or demographic
status, including variables such as income level, religion, and national origin, the bulk of hate crime offenders are little identified.

It is of paramount importance that if hate speech continues to be unchallenged, over time bigotry towards already marginalized people is intensified, and their increased marginalization and alienation is promoted. Increased social tensions, clashes and, in some situations, armed confrontation will also occur.

Has the Government Taken Sufficient Steps to Combat Hate Speech?

Hate speech manifests itself in different forms to date, along with the rampant advancement of technology. The laws of various countries and international orders also respond to it in varied aspects. While several nations have regarded the malicious use of hate speech as a criminal act and have outlawed it, it is still widespread.

Some of the countries that consider hate speech as an offence and has enacted laws to prevent the same are Public Order Act, 1986 in U.K. has elucidated incitement to racial hatred as an offence; inciting abhorrence against any recognisable group has been considered as an indictable offence under the Canadian Criminal Code; Australia has formulated the Racial and Religious Tolerance Act 2001 that prohibits hatred against any race or religious beliefs etc.

In an article entitled, “Hatred-A Public Health Issue,” Public Health experts Izzeldin Abuelaish and Neil Arya claimed that “Hatred can be conceptualised as an infectious disease, leading to the scaling up of violence, fear, and ignorance. Hatred is contagious, it is capable of crossing hurdles and boundaries”.[29] It has been further enunciated that if hate and bigotry are both negative and contagious, how will this issue be approached by a public health approach? The professionals suggested numerous preventive strategies for the said question which includes promoting knowledge of the harmful health impacts of hatred; improving mental self-awareness and dispute solving skills; building ‘immunity’ against provocative hate speech, and fostering an understanding of mutual interest and human rights. Considering the strategies recommended by the public health professionals may not eradicate hate speech/ hatred, but can at least minimize the harm that hate will cause on society.

Although the hate speech laws are sufficiently broad, however, a greater degree of legal protection is in need in the present aeon that determines hate speech from the viewpoint of the vulnerable communities and also reflects the truly reprehensible nature of the offenders. In furtherance, it is not only that there must be stringent laws concerning hate speech but also must consider the strategies/ recommendations of medical professionals. The concept of hate speech must commence in early childhood. There is currently a lack of vertical and interdisciplinary training. Students, instructors, and administrators all need support to act correctly when they see violence happening in the classroom or on the playground. There is a need for comprehensive study and data collection on hate crime activities, with specific regard on youth offenders.

Conclusion

When we look into the fundamental right of Freedom of Speech and Expression along with the reasonable restrictions, it hasn’t been giving a huge impact on the society. Whatever amendments that have been enacted in the present legal framework with respect to hate speech by numerous countries, the authors believe that it is just to rationalize the existing provisions and an effective or adequate step hasn’t been taken by the government (s) to date to curb hate speech. Any further laws/ programs initiated towards prevention of hate speech/ hate crime must concentrate on fostering empathy and an awareness of diversity among school children.

In furtherance, the key reason for such a debate on hate speech/ hate crime is the lack of definition, which is of utmost importance. Many courts encounter this issue and often fail to provide a clear-cut definition for ‘hate speech’. Hate speech negates the entire possibility of social contact and avoids the continuation of never-ending debate of thoughts and feelings. Beyond the technical complexities in implementing applicable
statutory prohibitions, the difficulty in distinguishing between speech/ expression and actions emphasizes the need to punish varied forms of hate speech addressed to particular persons.

Despite the implementation of various educational programs and interventions, hate crimes are still persisting. Such proactive initiatives and strategies to deter hate before it is expressed in a criminal act can only minimize bias-motivated crimes. It is pertinent to note that as long as schools breed bigotry, hate crimes tend to happen. The authors would like to suggest that programs that encourage awareness for police and victim assistance providers to help hate crime victims coping with trauma are required across the globe. As elaborated earlier, a public health approach is the desideratum to prohibit hate speeches as it not only takes a psychological toll on the individual but on the society at large. In order to prevent such hate crimes against humanity, there needs to be narrowly tailored legislation banning the propagation of mis ethnic stereotypes designed to elicit crimes against outgroups should be implemented within a reasonable timeframe.

Abstract

Background: Hedgehog Interacting Protein (HHIP) gene polymorphisms have an association on COPD has been carried out in Europe and Asia but in Indonesia there is still very limited study on this type and the largest ethnic group in Indonesia is the Javanese. Objective: To analyze the association between the HHIP gene polymorphism and the incidence of COPD in male Javanese smokers in Lampung, Indonesia. Method: In a case-control study in Javanese male smokers, three single nucleotide polymorphism (SNPs) in the HHIP gene were analyzed by Sanger sequencing method. There were 110 participants in this study which were divided into 2 groups, such as COPD group (55 participants) and control group (55 participants). Three SNPs in the gene (rs13118928, rs1828591 and rs10519717) were selected for genotyping. Genotype distributions were compared between patients and controls. The statistical analysis was carried out with the SPSS program with a chi-square test. Result: The genotypic frequency of the HHIP gene sequence at the SNP position rs1828591, such as AA (52.72%), GG (3.63%) and AG (43.63%) in COPD group, while in the control group such as AA (38.18%), GG (9.09%) and GG (52.72%; p>0.05). The genotypic frequency of the HHIP gene sequence at the SNP position rs13118928 consisted of AA (47.27%) and AG (53.72%) in the control group, while the COPD group consisted of AA (52.72%), GG (1.81%) and AG (45.45%; p>0.05). The genotypic frequency of the HHIP gene sequence at the SNP position rs10519717 consisted of TT (34.54%), CC (14.56%) and CT (50.90%) in COPD group, while controls group consisted of TT (23.63%), CC (16.37%) and CT (60.00%; p>0.05). The genotypic analysis of Three SNPs in HHIP gene were observed but showed no significant difference between case and control groups. Conclusion: Single-nucleotide variants in the HHIP gene are not associated with COPD susceptibility in Javanese male smokers.

Keywords: HHIP, COPD, Javanese, Indonesia, male smokers

Introduction

Chronic obstructive pulmonary disease (COPD) is one of the major health problems that occur worldwide and in Indonesia. This disease is the fourth leading cause of death in the world, causing 3 million deaths of about 80 million people suffering from COPD in 2005. This disease is a major global health problem due to its high prevalence, which is about 10% of the adult population(1). The prevalence of COPD in Asia is estimated at 6.3% with the highest prevalence in Vietnam and the People’s Republic of China. The prevalence of COPD
in Indonesia is not certain. The results of a survey of non-communicable diseases by the Directorate General for the Control of Infectious Diseases & Environmental Health in 5 provincial hospitals in Indonesia (West Java, Central Java, East Java, Lampung, and South Sumatra) in 2004, showed that COPD was the first contributor to morbidity (35%), followed by bronchial asthma (33%), lung cancer (30%) and others (2%). COPD also ranks 6th of the Top 10 Non-Communicable Diseases Causes of Hospitalization in Indonesia in 2009 and 2010(2).

Hedgehog Interacting Protein (HHIP) is an inhibitor of the Hedgehog (HH) signaling pathway and a protein that plays a role in pulmonary tissue remodeling. HH protein is an important morphogen for various developmental processes, including the anteroposterior pattern of the limb and the regulation of left-right asymmetry in embryonic development. The HH signaling pathway plays an important role in pulmonary morphogenesis and cellular response to lung injury. The HH signaling pathway also has implications for cell development, cell repair, and cancer cell development(3). Several cell surface receptors are responsible for transmitting and/or regulating HH signals. HH protein is an important mediator for smoke-induced diseases such as lung cancer and COPD. HH signaling protein expression is regulated by HHIP. This HHIP protein is a highly conserved and specific HH signaling inhibitor in vertebrates(4). Expression of HHIP protects mice from cigarette smoke-induced emphysema by reducing the number and activation of lymphocytes in the lungs and reducing the number and size of lymphoid follicles(5).

The HHIP gene is found on chromosome 4 arm of the p locus 13. This gene is highly expressed in the lungs and brain. Several genomic regions that code for HHIP are associated with COPD susceptibility. Polymorphisms can cause changes in gene expression leading to functional changes and ultimately COPD. A significant reduction in HHIP gene expression on mRNA and protein was found in COPD patients compared to smokers with normal lung function(6). Haploinsufensing the HHIP gene in genetically engineered mice caused an increase in emphysema due to exposure to cigarette smoke. Mice with haploinsufficiency (HHIP<sup>−/−</sup>) are more prone to develop severe emphysema due to exposure to cigarette smoke than wild type mice (HHIP<sup>+/+</sup>)(5).

Study on the polymorphism of the HHIP gene and its association with COPD has been carried out by many researchers, especially in Europe and Asia. A European genome association study has shown that two single nucleotide polymorphisms (SNPs) near the HHIP gene, namely SNP rs1828591 and rs13118928, are associated with the risk of COPD. Both SNPs are significantly associated with the risk of COPD in Caucasians(7). The Asian study involved Han Chinese and Mongolian populations. The HHIP gene is involved in COPD susceptibility in the Han Chinese population. The polymorphism of the HHIP SNP gene rs10519717 is associated with the severity of COPD(8). Smokers with the HHIP variant rs7654947 were associated with the development of COPD and decreased lung function. Smoking and gene susceptibility have a cooperative effect on the risk of COPD and decreased lung function(9). HHIP gene polymorphisms on SNP rs10519717 are associated with COPD susceptibility in Mongolians(10).

The causal association between genetic factors and COPD is still a hot topic of study around the world with varying results. Based on the evidence currently available, it is possible that in the future the role of doctors will shift. Currently the role of doctors is primarily to recognize and manage disease, the main role of doctors in the future is to interpret and apply genetic and genomic information in prevention and therapy(11).

Study on the polymorphism of the HHIP gene and its relationship with the risk of COPD in Indonesia has not been reported. The largest ethnic group in Indonesia is the Javanese, which is estimated to be 41% of the entire population of Indonesia. A preliminary survey at the Harum Melati Respiratory Clinic, Pringsewu Regency, Lampung Province, obtained data on the number of COPD patients in 2019 as many as 161 people from a total of 1600 patients with lung disease. Most of the COPD patients (104 people / 64.5%) came from Javanese ethnicity. Based on the description above,
it is necessary to analyze the relationship between the Hedgehog Interacting Protein Gene Polymorphism and the Chronic Obstructive Pulmonary Incidence in the Javanese Tribe in Lampung, Indonesia.

**Method**

**Participant**

One hundred and ten male Javanese smokers were included in a case-control study. These subjects attended the Harum Melati Respiratory clinic, Pringsewu, Lampung. Case group of this study were patients diagnosed with COPD and were active smokers. The inclusion criteria for the group included being diagnosed with COPD (12) with a stable condition, having a history of smoking >10 pack years on the Brinkman index (13) and Javanese (both parents are Javanese). The COPD group exclusion criteria included COPD patients with comorbidities such as tuberculosis, diabetes mellitus, liver and kidney disorders acquired by history and physical examination, COPD patients in exacerbations, and patients not cooperating with spirometry. Meanwhile, The control group consisted of participants who had the following criteria: healthy male smokers, >40 years old, had a history of smoking >10 pack years on the Brinkman index (13), Javanese (both parents were Javanese), and had no history of smoking. COPD, bronchitis, bronchiectasis, bronchial asthma, pneumothorax, lung cancer, bronchopulmonary allergic disease, and no family history of COPD.

**Design Study**

This study was an observational study with a cross sectional comparative study design. In this study, the participants were divided into 2 groups which included COPD participants who were active smokers and participants who were healthy but active smokers. Sampling of patients was carried out at the Harum Melati Lung Specialist Clinic, Pringsewu Regency, Lampung Province, while the control group was obtained in Pringsewu and Tanggamus districts. Pulmonary function measurements and blood sampling were carried out at the Harum Melati Lung Specialist Clinic, Pringsewu Regency, Lampung Province. DNA extraction and PCR processes for the HHIP gene were carried out at Unit Pelaksana Teknis (UPT) Laboratorium Terpadu dan Sentra Inovasi Teknologi (LTSIT) Universitas Lampung. Sequencing is carried out by a gene sequencing service provider, namely Genetika Indonesia Ltd, Jakarta, Indonesia.

**Pulmonary Function Test Using Spirometry**

Lung function tests were measured by the spirometry method using a flow spirometer (CHESTGRAPH HI 101; Chest MI, Inc, Tokyo, Japan). Spirometry measures two volumes of air, namely the volume exhaled strongly during maximum inspiration or what is called forced vital capacity (FVC), and the volume of air exhaled in the first second of this breath or Forced expiratory volume in one second (FEV1). A comparison between FEV1 and FVC (FEV1/FVC ratio) is calculated. If the FEV1/FVC value after bronchodilator administration is less than 70%, the lung function test results are declared obstructive.

**Genetic analysis**

All of the participants’ blood was collected into Vacutainer ® tubes. Blood specimens were centrifuged with a special solution, namely Pancoll. This solution is in the form of a sugar solution that has a certain specific gravity, which when the blood is placed on top of this solution, then centrifuged will separate the blood into its component components. Initially 4 ml of Pancoll solution was put in a tube, then carefully 3 ml of blood was placed on top of the Pancoll solution with the help of a pipette. Then the tube rotates using a centrifugator with a speed of 5000 rpm for 10 minutes. Note the buffy coat/yellowish layer over the pancoll layer. With a single-use pipette, collect as much of the yellow layer as possible (generally in <0.5mL volume), avoiding taking significant amounts of plasma or RBCs. Transfer the buffy coat to a sterile pour-off tube.

The process of genomic DNA extraction was derived from 500 µL of buffy coat using a DNA extraction device brand Wizard® Genomic DNA Purification
Kit made by Promega in Madison, USA following the extraction protocol from the manufacturer. The quality and quantity of extracted DNA were analyzed using a nanophotometer made by IMPLEN, Munich, Germany.

In this study, three pairs of primers were designed. The primary source was taken from the sequence “Homo sapiens Hedgehog Interacting Protein (HHIP) gene, complete cds” with access code DQ995342.1. The first pair amplifies the SNP rs1828591, the forward sequence is TGAGGTTGAGTTTGGAG and the reverse sequence is 5’-AGAGGTGTTTCATGTTTCCA-3’. The second primary pair amplified SNP rs13118928, with a forward 5’-CCCTTCATACCTCCTTCTC-3’ sequence and a 5’-GGTGGGAAGAAACATTACA-3’ reverse sequence. The third primary pair amplified SNP rs10519717 with the forward sequence 5’-TACGTGATGTTTTGGGCT-3’ and the reverse sequence 5’-GGTGAACAGACTCCAAACTC-3’.

PCR multiplication was carried out with a total volume of 50 µL consisting of 10 nanograms of sample DNA, each 0.2 micromolar forward and reverse primer, 10 parts Taq Buffer, TaqGold, and 200 micromolar dNTP each.

The electrophoresis process aims to evaluate the PCR results. The PCR results were visualized using a digital electrophoresis device using Qiagen’s QIAxcel DNA High Resolution Kit following the electrophoresis procedure from the manufacturer. If there is amplification, a band will appear. Based on the source of the primary sequence taken, namely the sequence with the access code DQ995342.1, SNP amplifying primer rs1828591, will produce a single band of DNA with a size range of 491 bp, primers for rs13118928 will produce single bands of DNA 381 bp, and primers rs10519717 will produce bands single DNA 545 bp. The amplicons was then sent for sequencing. Sequencing was carried out by a gene sequencing service provider, namely Genetika Indonesia Ltd, Jakarta, Indonesia. SNPs analysis was carried out on the SNPs rs1828591, rs13118928, and rs10519717 with bioedit and chromaspro software in both forward and reverse sequences. In electroferogram analysis using bioedit software, the nitrogen base sequence is represented by peaked waves with various colors. Base C is yellow, base G is white, base T is green, base A is pink. Generally, one position has only one nitrogen base, but at one SNP position there can be 2 electroferogram peaks, for example bases A and G. This shows that the site is a heterozygous AG genotype.

Statistical Analysis

The DNA samples of 110 male Javanese smokers with and without COPD were genotyped, and three SNPs (rs13147759, rs1828591, and rs13118928) were evaluated. Genotype distributions were compared between patients and controls. The statistical analysis was carried out with the SPSS program with a chi-square test. Data analysis used IBM SPSS Statistics software version 22.0 (IBM Corp., Armonk, NY, USA).

Results

Participant characteristics

The characteristics of the participants can be seen in Table 1 which is described in detail regarding the differences between the COPD and control groups. There was no significant difference between the COPD group and the control group in each variable related to participant socio-demographic characteristics. There were a significant difference in the lung fuctions (\(p=0.000\)), history of respiratory tract infections at childhood (\(p=0.004\)) and body mass index (\(p=0.030\)).

The Association between HHIP gene polymorphisms in smokers with COPD and Control

The Genotype distributions were compared between patients and controls can be seen in table 2. There were 3 genotype of the HHIP gene sequences in the SNP rs1828591 position, namely AA, GG and AG. In COPD who were smokers, there were 29 cases of GG (52.72%), GG 2 cases (3.63%) and AG 24 cases (43.63%), while in control AA 21 (38.18%), GG 5 (9.09%) and GG 29 (52.72 %). Statistically, it was found that there was no \(p\) value < 0.05 in the genotype comparison of the HHIP gene at position rs1828591. This means that there were
no differences in the genotype frequency of the SNP rs1828591 of HHIP gene between COPD smokers and healthy smokers in Javanese in Lampung Province, Indonesia.

In table 2 it can be seen that in the control group there were only 2 genotype of the HHIP gene sequence in the SNP position rs13118928, namely AA and AG. In the control group obtained AA 26 (47.27%), and AG 29 (53.72%), while in COPD group, AA 29 (52.72%), GG 1 (1.81%) and AG 25 (45.45%) were obtained. Statistically, there was no p value <0.05 on the AA, GG and AG genotypes, meaning that there was no difference in the frequency of the SNP rs13118928 HHIP gene polymorphism between COPD smokers and healthy smokers in Javanese in Lampung Province, Indonesia.

In table 2 it can be seen that there are 3 genotype of the HHIP gene sequences in the SNP position rs10519717, namely CC, TT and CT. In COPD who were smokers, there were 19 cases (34.54%), CC 8 cases (14.56%) and CT 28 cases (50.90%), whereas in controls TT 13 (23.63%), CC 9 (16.37%) and CT 33 (60.00) %. Statistically, there was no p value <0.05 in the genotype comparison of the HHIP genotype at position rs1828591. This means that there is no difference in the frequency of the SNP rs10519717 genotype of the HHIP gene between COPD smokers and healthy smokers in the SNP rs10519717 genotype in Javanese in Lampung Province, Indonesia.

Discussion

COPD is defined as a disease state characterized by poor progressive and reversible airflow limitation that is usually associated with an abnormal pulmonary inflammatory response. Nearly 90% of COPD is caused by long-term smoking, however, only 25% of smokers end up being COPD patients. In addition, COPD tends to occur more frequently in smokers with a family history of obstructive airway disorders including asthma and COPD. All of this suggests that, apart from smoking, there are other genetic factors underlying the development of COPD(1).

Many factors can contribute to COPD. COPD can be influenced by racial, ethnic, gender and environmental factors as well as genetic factors. The variability found in lung function and the risk of COPD in people with a similar smoking history, together with family aggregation studies, supports the important role of genetics in the pathophysiology of COPD(14).

Genome association studies have identified several genomic regions that are clearly associated with COPD susceptibility. However, despite recent advances in the genetics of COPD, much of the heritability of COPD remains unexplained. To date AAT deficiency is the only well-identified genetic risk factor for COPD. It is strongly suspected that several other genes are involved in this disease process. Variants of several genes have been investigated and identified to have a close association with COPD, such as TLR-9, HHIP, IREB2, CHRNA3/5, and HHIP(7).

Pathophysiology COPD is a multifactorial process with a complex profile of inflammatory cells including eosinophils, macrophages, neutrophils, and lymphocytes. Levels of several cytokines, such as interleukin (IL) 8, interleukin (IL) -6, TNF-α, and VEGF are elevated in stable COPD patients, suggesting their key role in the pathogenesis of COPD. Therefore, COPD develops as a result of multiple steps involving inflammatory cells and mediators, of which local inflammation in the lungs is essential as it affects airway remodeling and parenchymal destruction(1).

The results of this study were the HHIP gene polymorphism had no effect on the incidence of COPD in Javanese. The HHIP protein is an inhibitor of the HH signaling pathway. HH protein is an important morphogen for various developmental processes, including the anteroposterior pattern of the limb and the regulation of left-right asymmetry in embryonic development(15). HH protein is also an important mediator for diseases caused by cigarette smoke such as lung cancer and COPD. HH protein activity is regulated by HHIP. This HHIP protein is an inhibitor of HH signaling, and it has been shown that HHIP expression protects mice from cigarette smoke-induced emphysema(5).

The HHIP gene is found on chromosome 4 arm of the p locus 13. This gene is highly expressed in the lungs and brain. Several genomic regions that code for HHIP are associated with COPD susceptibility. Polymorphisms can cause changes in gene expression leading to functional changes and ultimately COPD. A significant reduction in HHIP gene expression on mRNA and protein was found in COPD patients compared to smokers with normal lung function(6). Haploinsufficiency of the HHIP gene in genetically engineered mice caused an increase in emphysema due to exposure to cigarette smoke. Mice with haploinsufficiency (HHIP+/-) are more susceptible to developing severe emphysema due to exposure to cigarette smoke than wild type mice (HHIP+/-)(5). In this study, it was found that the presence of polymorphisms in the HHIP gene at positions rs13118928, rs1828591 and rs10519717 did not make Javanese smokers susceptible to COPD(16).

The results of this study differed from several studies in Europe and Asia. Study in Europe has shown that two single nucleotide polymorphisms (SNPs) of the HHIP gene, namely SNP rs1828591 and rs13118928, are associated with the risk of COPD. Study in Asia has concluded that the HHIP gene is involved in COPD susceptibility in Chinese Han populations(8, 9, 17) and in Mongolians(10).

This study is a preliminary finding in pioneering a road map for genetic susceptibility study against
COPD in Indonesia. There is only one publication of the relationship between gene polymorphisms and COPD in Indonesia, namely the study of Tarigan et al\textsuperscript{18}. Study on genetic susceptibility to a disease requires a lot of study with a homogeneous sample and needs to be carried out in various tribes. This is because Indonesia is a country with ethnic and ethnic diversity, which of course has a large genetic variation. This study will contribute to the successful prevention of COPD. This study could contribute to the initial screening of individuals who are susceptible to COPD, as well as play a role in early screening that will prevent smokers from developing COPD.

Groups at high risk of COPD could be screened using genetic screening in the future, although much effort must be made in this clinical area. We focus on pulmonary function and airway inflammation in patients with COPD. More comprehensive data should be obtained to reveal the mechanisms of COPD in further studies\textsuperscript{(11)}.

However, this study has drawbacks because it does not directly examine the levels of the HHIP protein to determine the genetic expression of the HHIP gene and this study also does not examine other downstream HHIP proteins, such as T lymphocyte activation and degradation of the pulmonary extracellular matrix (ECM) which increases the risk of COPD. This study is a cross-sectional study, so it is not possible to know how often there is a history of infection in COPD patients and how the development of nutritional status in COPD patients.

**Conclusion**

HHIP SNP gene polymorphisms including rs13118928, rs1828591 and rs10519717 were found in Javanese smokers in Lampung. There is no relationship between the HHIP SNP gene polymorphisms rs13118928, rs1828591 and rs10519717 and the incidence of COPD in Javanese in Lampung. Future studies can examine genes for other genes that may be associated with COPD in Javanese and it is necessary to carry out research on other ethnic groups in Indonesia.

**Ethical Approval:** Participants have expressed their consent to participate in this study and have signed informed consent. This research has been approved by the Health Research Ethics Committee of the Faculty of Medicine, University of Lampung, Bandar Lampung, Indonesia (2739/UN26/PP.05.02.00/2019).

**Funding:** Funding for this research was funded by Hibah Penelitian Unggulan grant from the University of Lampung in 2019.

Effect of Nano-Coating on Microleakage of Different Capsulated Glass Ionomer Restoration in Primary Teeth: An In Vitro Study

Sohaib Qais Alwan¹, Athraa Mustafa Al-Waheb²

¹B.D.S, College of Dentistry, Tikrit University, ²Professor, Department of Pedodontics and Preventive Dentistry, College of Dentistry, University of Baghdad, Iraq

Abstract

Aim: The aim of this in vitro study was to assess and compare the effect of the nano-coating on microleakage of different capsulated conventional glass ionomer cement (CGIC), resin-modified glass ionomer cement (RMGIC) and hybrid glass ionomer cement in primary molars.

Materials and Methods: A total of 36 primary molars samples were divided into three groups. Group 1 - teeth restored with capsulated RMGIC (Fuji II LC) without nano-coating. Group 2 - teeth restored with capsulated CGIC (Fuji IX) with nano-coating. Group 3 - teeth restored with capsulated hybrid glass ionomer (Equia Forte) with nano-coating. Microleakage was tested using immersed the teeth in 2% methylene blue dye penetration for 24 hours after the thermocycler and measured at x40 magnification under the stereomicroscope.

Results: The results of this in vitro study showed that coating with nano-coating showed a reduction in microleakage in hybrid glass ionomer (Equia Forte) and more microleakage in non-coating RMGIC (Fuji II LC) but also more microleakage in coating CGIC (Fuji IX), which was statistically significant. CGIC with nano-coating and RMGIC without coating showed highest microleakage followed by hybrid glass ionomer (Equia Forte) with coating.

Conclusion: Significant reduction in microleakage was seen in Equia Forte (hybrid glass ionomer) with nano-coating and the coating should use with all types glass ionomer.

Key word: Conventional glass ionomer cement, G-Coat Plus, microleakage, primary molars, resin-modified glass ionomer cement, thermocycling.

Introduction

Dental caries is the foremost common chronic disease in childhood. Around the world, the commitment of dental caries to the burden of oral infections is around ten times higher than that of periodontal infection and the other common oral condition. In dentistry, dental caries is the major reason for loss of the teeth, representing a major challenge for oral health. (¹). The work of a pediatric dental practitioner treating children is twofold, we must put quality work for our patients and we must be experts at managing our patient’s involvement. We must be able to work with speed and precision. This may only be possible in case we have materials that can hand easily and provide reliable results. One such restoration is glass ionomer cement capsule (GIC) (²). Glass ionomer has been utilized as a dental restoration since its presentation in 1972. With its presentation as a restorative material, there were a few restrictions to the material (³). Since their presentation, glass ionomers have advanced and have been progressed colossally. Today’s glass ionomers are simpler to handle by capsule, have superior wear resistance, and have superior esthetics than the first GIC (⁴). Glass ionomers have numerous
preferences as a restorative material. These incorporate, but are not constrained to the capacity to bond chemically to dentin and enamel, biocompatibility, favorable thermal extension, diminished dampness affectability, and the capacity to discharge fluoride, and after that act as a fluoride store. Resin-modified GIC (RMGIC) has resin monomers, like HEMA or Bis-GMA consolidated in its composition, making it a dual-cured cement having higher flexural, compressive, and pliable qualities than ordinary GICs (5).

EQUIA (GC, America) may be a new glass ionomer restorative framework. It may be a combination of a self-adhesive, chemically cured, exceedingly filled GIC (Fuji IX GP Additional, GC) and a self-adhesive, light cured, filled resin surface sealant (G Coat Furthermore, GC). The producers of EQUIA claim that the fabric has expanded break durability, flexural quality, and flexural weariness resistance which are required in Class V restorations (6).

As a result of these qualities, GIC is perfect for the uncooperative child as well as the “high caries risk” children (7). One of the most disadvantages of the filling materials is the microleakage around a tooth, which can be seen as recoloring around the edges of the filling, postoperative sensitivity, secondary caries, pulpal pathology or pulpal rot and the moment being decreased bond quality of the restorative cement driving to fractional or add up to disappointment of the filling itself. According to Nakabayashi and Pashley, in 1998 microleakage is characterized as the section of liquids and substances through minimal holes on the interface of the filling and teeth (8). Within the glass ionomer cements (GICs), water plays an vital part within the setting. Water is capable for the transport of calcium and aluminum cations, which can respond with the polyacid to make a polyacrylate framework. Joining of water with glass ionomers is related with increment within the translucency of the GIC. The freely bound water can be misplaced from the surface by drying up. This causes an unattractive chalky appearance as infinitesimal breaks create within the drying surface and leads to microleakage. Moreover, the nearness of moisture can lead to retention of water and hygroscopic setting extension. To avoid this, it is critical to secure the cement by covering it with an filling varnish or petroleum jelly (9). Another advantage of utilizing such surface defenders is that they fill little surface voids and absconds and may offer assistance to protect the first color of the restorations by diminishing the take-up of stains (10). The 21st century is the period of nanotechnology. Nanofillers make strides the wear resistance of coating operator, in this way giving more defensive coating over CGIGs. As of late, G-Coat Additionally and Equia coat a nanofilled, self-adhesive, light-cured defensive coating has been presented for ordinary GIC, RMGIC, composite resin, and compomer. Past studies have affirmed that when connected, the consistently scattered film thickness of G-Coat Additionally gives higher wear resistance, reinforces the rebuilding, and gives exceedingly gloss appearance (11). Therefore, the present study was undertaken to investigate the effect of G-Coat plus (nanofilled, self-adhesive, lightcured protective coating) on microleakage of conventional GIC and RMGIC in primary molars.

Materials and Methods

Sample’s selection & mounting:

Thirty-six extracted primary molar teeth for orthodontic purposes or because of still over time will select for the study collected for no more than 3 months inspected beneath magnifying lens to avoid any samples with (cracks, Hypoplastic or hypocalcified teeth), as well as the teeth with caries including more than one-fourth of the occlusal surface, will removed from the study. All the teeth were collected from dental specialized centers in Baghdad or from dental private clinics. The teeth belong to child patients.

The teeth were cleaned with hand-scaler then polished by pumice and rubber cups in handpiece low speed and stored at room temperature in distilled water (12).

Covered the roots of teeth by a layer of sheet wax short of the cervical line to work as the soft tissue and
act as a separating medium between the tooth and silicon. A base of silicon is mounted so that it covers the roots of the teeth short of the cemento-enamel junction and the mounting was in plastic molds.

**Samples distribution:**

The teeth were randomly distributed and numbered according to the filling materials used into three groups each contain twelfth samples as follows:

- **Group 1:** restored with non-coating Fuji II LC capsulated glass ionomer cement.
- **Group 2:** restored with coating Fuji IX capsulated glass ionomer cement.
- **Group 3:** restored with coating Equia forte capsulated glass ionomer cement.

**Cavity preparation and restoration:**

In order to standardize cavity preparations for all the teeth, used a modified dental surveyor. Turbine (high speed handpiece) attached to the movable arm of the surveyor in a way put the long axis of the bur in perpendicular to the long axis of the tooth during the preparation. Used diamonds depth cutter 2 mm-Crown Prepration bur was used and the bur was replaced after four teeth preparations.

The teeth received class V cavity width 4mm, length 2mm and depth 2mm prepared on the buccal surface of each tooth with no mechanical retention used diamonds depth cutter 2 mm-Crown Preparion bur under air-Water cooling perparation.

The depth and width of the cavity was checked by digital caliper and periodontal probe (12).

After cavity prepared the teeth were rinsed and dried, and moist cotton pellet was placed in the cavity to prevent complete dehydration of the tooth, cavity conditioning was carried out using 20% acrylic acid (GC, Tokyo-Japan) for 10 s by micro brushes and rubbing movements. Then, cavity was rinsed using water spray for 15 s, after that, a piece of cotton was placed in the cavity and gently dried for 5 s using air spray; then, the cotton was removed to prevent complete dehydration (13, 14).

After cavity preparation and cavity conditioner applied to the 36-primary molar.

...was restored with glass ionomer cement capsule powder and liquid in capsule according to manufacture, mixed in amalgamator 10 second and restore the cavity to full depth 2mm to cavosurface line angle of cavity after chemical setting take 6 min to group 2 (Fuji IX-GC, Tokyo -Japan) and group 3 (Equia forte-GC, Tokyo - Japan) but group 1 (Fuji II-GC, Tokyo -Japan) according to manufacture used curing with light cure 20 seconds, then finish and polish the filling with enhance polish bur during finish use internal water hand piece then applied layer of G-Goat plus (GC, Tokyo -Japan) it is Nano-fill protecting layer above the filling to group 2 (Fuji IX), and use Equia coat (GC, Tokyo -Japan) it is Nano-fill also to group 3 (Equia forte) then curing with light cure 20 seconds.

**Sample’s storage and thermocycling of the samples:**

All the specimens were then stored for 24 hours in normal saline, then use thermocycler device for thermocycling.

Thermocycling was carried out by soaking the teeth alternatively into (5-55 ±1~2°C) water bath chambers with 30 seconds immersion time in each bath and 10 seconds transition time (ISO/TS (E) 11405:2003; (15, 16, 17, 18). The thermocycling 500 cycle all the 12 specimens were thermocycled in the same time.

**Sample’s dye and microleakage measurement:**

All the teeth were dried and two layers of nail varnish were applied to the teeth to cover the complete tooth surface except for 1mm around the restoration edges. The root apices of the teeth were sealed with adhere wax and after that submerged in 2% methylene blue color for 24 hours. The teeth had been washed beneath running...
water and dried.

The samples were blocked with clear epoxy resin; this was done by fabrication of a mold using a specially fabricated plastic molds with dimensions (3-2-1) cm.

Cut longitudinally in the center of the teeth into two pieces using microtome by disk thickness of 0.01mm cutting at high speed and water coolant. The cut halved the tooth bucco-lingually. The cut was made parallel to the long axis of the samples.

The presence of microleakage was affirmed by the visualization of a blue line of the color at the tooth-restoration interface for the occlusal and the cervical dye entrance by visualization by two spectators utilizing stereomicroscope at magnification 40X (19).

The extent of microleakage was evaluated and recorded according to the depth of dye penetration scores given by two way:-

1-Each prepare section will investigation using a sterio microscope (Kruss-Germany) with video output device (20).

Use software (Optika Vision Lite) to measure dye penetration between Glass ionomer filling and tooth in millimeter.

2-The scoring was done as described by Khera and Chan (21).

0 = (No micro-leakage).

1 = Dye penetrating is to the lesser than and up to one half of the depth of the prepared cavity.

2 = Dye penetrating is to more than one-half of the depth of the prepared cavity but not up to the angle of the axial and occlusal or gingival wall.

3 = Dye penetrating up to the angle of the axial and occlusal or gingival wall but not have the axial wall.

4 = Dye penetration have the axial wall.

Pilot study:

After doing pilot study for 5 samples, intercalibration absolute agreement for microleakage (mmm) and its score using Intraclass correlation coefficient (ICC) and weighted Kappa is 0.8 and 0.85 respectively.

Statistical Analysis

Using Statistical Package for social Science (SPSS version 21, Chicago, IL, USA), Descriptive statistics is Frequencies and percentage for nominal variables, minimum, maximum, mean, and standard deviation (SD) for quantitative variable, while median and mean rank for qualitative variable and cluster chart bars. Inferential statistics are Weighted kappa, Intra Class Correlation Coefficient (ICC) Levene test, One Way Analysis of Variance (One Way ANOVA) with Dunnett’s T3 posthoc test and finally Kruskal-Wallis test with Multiple Wilcoxon Sum rank and Mann-Whitney U tests adjusted by Dunn-Bonferroni method.

Results

Test of Normality:

The table 1 indicates that micro leakage variable is normally distributed among groups by using Shapiro-Wilk test (p >0.05) so the parametric tests (One way Analysis of Variance “ANOVA”.

Measure of microleakage in millimeter penetration of dye:

Results in table 2 demonstrate that microleakage is higher in Capsulated FUJI IX followed by Capsulated FUJI II while the lowest is in the EQUIA FORTE with significant results among them further multiple pair wise comparisons using Dunnetts’s T3 post hoc test indicates that there is no significant finding between both capsulated of FUJI IX and FUJI II while each one of them is statistically significant with EQUIA FORTE (Figure 1).

Measure of microleakage in score for dye penetration:
Findings in table 3 show that microleakage score is higher in Capsulated FUJI IX followed by Capsulated FUJI II while the lowest is in the EQUIA FORTE with significant results among them further multiple pair wise comparisons using multiple wilcoxon sum rank test indicates that there is no significant finding between both capsulated of FUJI IX and FUJI II while each one of them is statistically significant with EQUIA FORTE (Figure 2).

### Distribution of scores among groups:

Results in table 4 shows that score 0 occurs in EQUIA FORTE only, score one mostly occurs in Caps. Fuji II followed by Caps. Fuji IX while lowest in EQUIA FORTE, score 2 finds in caps. FUJI IX followed by Caps.Fuji II, lastly score 3 finds only in Caps. Fuji IX (Figure 3).

Figure 1: Micro leakage among group.
Discussion

Enamel of deciduous teeth contains less calcium and phosphorus than permanent teeth; additionally, Deciduous teeth have more sensitive of enamel rods with more density. The Dentina tubule numbers in deciduous teeth are more than permanent teeth. All of these variables can cause higher microleakage score in deciduous compared with permanent teeth. (22).

Thermocycling has been utilized in this study to mimic oral conditions. This prepare may highlight the mismatch in thermal extension between the restoration and tooth structure, coming about in numerous volumetric changes amid temperature changes and causing weakness of the adhesive joint with consequent microleakage. This is often in understanding with other investigate, which expressed that, thermo-cycling as intra-oral temperature varieties and subjecting the restorations on the tooth to temperature extremes consistent with oral cavity (11).

Glass ionomers (GIC) have been used as a restorative material since of their capacity to chemically bond to tooth structure and discharge fluoride. They are broadly utilized in dentistry for restoration, as a luting and liner or base. GICs are most sensitive restorative materials to the moisture during the early stages to placement. (25).

Water plays a key part within the development of GIC. Drying out and water defilement amid the starting setting stages can compromise the physical properties of restoration (11).

According to Gemalmaz et al. (1998), when GIC restorations were contaminated with moisture, their mechanical quality diminished and the surface of the material disintegrated or wore quickly. The ability of (GIC) to minimize the degree of microleakage at the tooth or restoration interface is an important factor in clinical success. In the studies microleakage can happen due to disintegration of the tooth-restoration interface, contrasts between thermal expansion coefficients of the restorative material – tooth tissue or polymerization shrinkage, causing recoloring, recurrent caries, and restoration failure. (26).

To overcome the downsides of GIC from moisture defilement and drying up amid starting setting arrange, it has continuously been suggested that GICs must be covered quickly after put (GIC) with a water-proof
surface coating \(^{(9)}\).

Studies have suggested protection of the surface amid the starting setting of GIC with different surface coating agents such as cocoa butter, waterproof varnish, and also nail varnish \(^{(11)}\).

Earl \textit{et al}. (1989) have appeared that quick covering of immature (GIC) with a light-cured resin bonding is the foremost viable strategy of restricting movement of the water across to the surface \(^{(11)}\).

According to Tyagi., \textit{et al}, (2020)\(^{(26)}\) the amount of soluble framework is greatest amid the early stages of GIC formation and the foremost sensitive period is the primary six minutes after mixing. Any contamination by moisture amid this stage can cause the loss of soluble network and diminish its physical properties, thus the GIC ought to be ensured from extra water contamination amid the starting stages to avoid disintegration of particles though once it sets.

In this study found Fuji IX (conventional GIC) with coating and Fuji II (RMGIC) without coating have high microleakage and not significant different between them but equia fort with coating have not and less microleakage.

In previous studies founds Fuji II LC (resin modified glass ionomer) without coating less microleakage than Fuji IX (conventional glass ionomer) without coating because resin-modified GIC (RMGIC) has resin monomers, like HEMA or Bis-GMA incorporated in its composition, making it higher flexural, compressive, and tensile strengths than conventional GICs \(^{(27, 28, 29)}\) thus in this study the coating give improve to the Fuji IX become the same degree of microleakage to the Fuji II LC without coating.

According to Chuang, \textit{et al}. (2001)\(^{(30)}\), resin-modified glass ionomer cements (RMGIC) were developed to replace conventional GICs. RMGICs are materials that set concurrently via a dominant acid-base reaction and auxiliary photopolymerization. With the addition of resin monomer (2-hydroxyethyl methacrylate [HEMA]), and light-polymerized initiators, RMGICs are polymerized immediately after visible light irradiation. Compared with conventional analogs, RMGICs have been characterized as having a longer working time, a rapid set, improved appearance and translucency, and higher early strength. However, RMGICs retain some properties of their conventional counterparts. Additional resin monomer and supplementary photopolymerization have not significantly reduced the susceptibility of RMGICs to dehydration problems. Thus, the maintenance of water balance in the modified cements is important, resin-modified glass ionomers can be finished immediately, they remain moisture sensitive, the results suggest that resin adhesive should be used as a surface protection to reduce margin microleakage of resin-modified glass ionomer restorations. Their results indicated that RMGICs should be protected from water for at least 1 hour after cement mixing. In contrast, most manufacturers’ instructions indicate that RMGICs can be used with or without surface protection.

Whereas the most elevated scores were in Fuji II LC. This may well be come about from polymerization shrinkage that happens in light cured tar adjusted glass ionomer cements. Polymerization shrinkage creates inside 5 minutes after curing and proceeds for another 24 hours. This shrinkage brought about in withdrawal stress which can break the adhesive interface and make the gaps in the margin \(^{(12, 31)}\).

The display study shown that there was significant contrast in microleakage between three groups i.e. EQUIA specialty appeared lesser leakage. The advantage of GC EQUIA Strong point is an inventive restorative framework based on a new glass hybrid innovation, which has more voluminous glass fillers of EQUIA Specialty Fil were supplemented by smaller, exceedingly receptive fillers that reinforce the restoration. In combination with the EQUIA Strong point coat, a composite coating the flexural strength increments by 17\% and flexural energy by nearly 30\%. EQUIA Specialty Coat enters the surface porosities, hence increasing the quality of the generally EQUIA filling and diminishes the microleakage around the restoration \(^{(32)}\).
Conclusion

According to this study an in vitro study conclusion into:

1- Conventional glass ionomer (GC-Fuji ix) with nano-coating (GC G-Coat plus) have high microleakage equal to resin modified glass ionomer (GC-Fuji II LC) without coating.

2- Nano-Coating (GC-Equia coat) with resin modified glass ionomer (GC-EQUIA FORTE) have very low microleakage.

3- Maximum score in Fuji IX with coating then in Fuji II LC without coating but minimum score in Equia Forte with coating.

4- Thus, prefer use Nano-Coating with RMGIC to minimum microleakage.

5- Nano-Coating nanofilled resin-coating provides a high hydrophilicity combined with an extremely low viscosity, thus accounts for a perfect seal to GIC also provide color stability to cement and glossy appearance and bond chemically to tooth structure.

The Application Program of Smoking Free University Policy Campaign in Sisaket Rajabhat University

Tanaprat Thuksin¹, Chuthamat Nopparat², Tanapat Sriwarom³

¹Lecturer of Community Health Program, Faculty of Liberal Art and Science, Sisaket Rajabhat University, Sisaket, 33000, Thailand, ²Assistant Professor of Public Health. School of Public Health, Walailuk university, Nakhon Si Thammarat, 80160, Thailand, ³Lecturer of Local Politics and Governments Chalermkarnchana University, Sisaket, 33000, Thailand

Abstract

Background: These policy campaign were developed in law enforcement protection a non-smoking for smoking free university by students union president. Method: This quasi-experimental research aimed to evaluate the application program of smoking free university policy campaign. To study the effect of the student leadership development program in the management of the smoking free university, Sisaket Rajabhat University and study the level of participation of the student leaders in the management of the smoking free university towards the smoke-free zone in Sisaket Rajabhat University. by selecting the students union president population of 20 people, the samples were selected according to the inclusion criteria and the exclusion criteria, which the research pattern was used to conduct a comparative study within One Group Pretest - Posttest Design in 12 weeks with 4 activities. The data were collected by using questionnaires and using descriptive statistics presented in the form of a frequency distribution. The data distribution is normal. They were presented with the statistical values of frequency, percentage, mean and standard deviation. And translate the results into score values comparison of the mean, differences before and after the experiment. Within the experimental group using statistics : Paired Samples t-Test. Results: The results of the research were found that after the development of the experimental development program, the students’ leadership in the management of the non-smoking university, knowledge, skills, social roles, imagination or concept about oneself, motivation / mindset Participation in the development of student leadership potential in the management of the non-smoking university. Significantly better than before development (p <0.05). Conclusion: In conclusion of the study : Results of the Student Leadership Development Program in Management of Smoking Free Universities, Sisaket Rajabhat University. It can cause success factors in managing the non-smoking university. In organizing smoking free zones in Sisaket Rajabhat University. To bring about effective action and efficiency and developed as the non-smoking university model including campaigning activities establishing a banner that announces the non-smoking area that covers the entire university. To create participation of university students and the student leaders, The students union president have a clear understanding of roles and duties in their work operations and have an action plan. They realized the importance of organizing the non-smoking zone in the university. There are regulations / measures to prevent and control smoking in non-smoking zones jointly agreed by the leaders. Established a mechanism to support the construction of the non-smoking area in Sisaket Rajabhat University. The measures are followed up and monitored, and implement a participatory and sustainable non-smoking university.

Keywords: smoking free university, policy campaign, non-smoking area

Introduction

The tobacco control policy is an effective way to help people quit smoking and to assist and support smokers, which is an effective way to reduce the number of deaths. Smoking in Thailand has decreased, but there
are still 10.7 million smokers as reported by the Thai National Statistical Office in 2017.\\(^1\) For the purpose of reaching a prevalence of 15.75 percent or less, this goal is what Thailand agreed to achieve in the WHO’s Global Action Plan for the Prevention and Control of NCDs, 2013–2020, and the five-year National NCD Prevention and Control Strategy and Action Plan (2017–2021).\\(^2,3\)

The 2006 U.S. Surgeon General’s Report, The Health Consequences of Involuntary Exposure to Tobacco Smoke, has concluded that (1) second-hand smoke exposure causes disease and premature death in children and adults who do not smoke; (2) children exposed to secondhand smoke are at an increased risk for sudden infant death syndrome (SIDS), acute respiratory problems, ear infections, and asthma attacks, and that smoking by parents causes respiratory symptoms and slows lung growth in their children; (3) exposure of adults to second-hand smoke has immediate adverse effects on the cardiovascular system and causes coronary heart disease and lung cancer; (4) there is no risk-free level of exposure to second-hand smoke; (5) establishing smokefree workplaces is the only effective way to ensure that second-hand smoke exposure does not occur in the workplace, because ventilation and other air cleaning technologies cannot completely control for exposure of non-smokers to second-hand smoke; and (6) evidence from peer-reviewed studies shows that smokefree policies and laws do not have an adverse economic impact on the hospitality industry.\\(^4\)

Therefore, the researcher aimed to evaluate the application program of smoking free university policy campaign in Sisaket Rajabhat University. To compare before and after implementation of the program in subjects practicing smoking free university policy campaign by participation. This research also improved policy campaign were developed in law enforcement protection a non-smoking with a positivestudent leadership development program. In addition, there is also an increase in terms of knowledge, skills, social roles, imagination or concept about oneself, motivation / mindset Participation in the development of student leadership potential in the management of the smoking free university.

**Objective**

The objectives of the research were to evaluate the application program of smoking free university policy campaign in Sisaket Rajabhat University and to compare in terms of knowledge, skills, social roles, imagination or concept about oneself, motivation / mindset, management of the non-smoking university, Participation in the development of student leadership potential in the management of the smoking free university before and after implementation of the program within group.

**Material and Methods**

**Research Design**

This research was a total quasi-experimental research which aimed to evaluate the application program of smoking free university policy campaign in Sisaket Rajabhat University. The samples were total 20 student by selecting the students union president population, the samples were selected according to the inclusion criteria and the exclusion criteria.

The period of this research was 12 weeks and included 4 interventions. The research instruments of non-smoking university policy campaign in Sisaket Rajabhat University Program for the experimental groups.

- **Intervention 1** A competency and participation improving in smoking free university policy campaign.
- **Intervention 2** Set a smoking free area and notice for non-smoking area at all building in University. Let’s stage a campaign to stress the importance of the law enforcement protection a non-smoking Acts.
- **Intervention 3** The students union president MOU in managing the smoking free university. In organizing smoking free zones. To bring about effective action and efficiency and developed as the non-smoking university model Including campaigning activities establishing a banner that announces the non-smoking area that covers the entire university.
Intervention 4 The regulations/measures to prevent and control smoking in non-smoking zones jointly agreed by the leaders. Established a mechanism to support the construction of the non-smoking area in university. And assessment process and outcomes.

Population and Sample Characteristics Inclusion Criteria

The Population consisted of 20 students union president who had to students leader worker at them faculty are included 5 faculty in Sisaket Rajabhat University is Faculty of Liberal Arts and Sciences, Faculty of Education, Faculty of Humanities and Social Sciences, Faculty of Business Administration and Accountancy and College of Law and Government.

Research Period

The research has been undertaken in 3 phases; pre-research, research, and post-research. Data were collected from April 1, 2020 to August 30, 2020, obtained over a 12 week period.

Research Instruments

The evaluation form was provided for participants to answer questions by themselves, and the test of evaluation form consisted of 2 parts:

Instruments for collecting data

Instruments for collecting data consisted of Demographic data

Instruments of experimental

The instruments of quasi-experimental program had a guidebook of the experimental program for research assistants process for smoking free university campaign. The experimental program encouraged smoking free university policy campaign by using 4 interventions for the law enforcement protection a non-smoking Acts.

Data Collection

Before collecting data, ten registered public health students in who trained in the standard protocols and received a research assistance guidebook of the research program were assembled. The data were collected by the principal investigator and the other ten trained research assistants. The researcher and research assistants collected the data from 20 participants who were informed about this research and instructed in how to complete the evaluation form, including requesting consent by signing the research form. The data were corrected before and after the experimental phases. Afterward, collected assessment forms and questionnaires were checked for data accuracy then the results were put into a data entry in SPSS file format.

Data Analysis

Statistical method used to analyze the data was Statistical Package for the Social Sciences (SPSS) in the following aspects:

1. Descriptive statistics included the number, percentage, mean and standard deviation, to indicate the general information and smoking situation of the participants.

2. Statistical use paired samples T-test to compare within the group before and after the experiment to indicate in terms of knowledge, skills, social roles, imagination or concept about oneself, motivation / mindset and Participation.

Results

The application program of smoking free university policy campaign in Sisaket Rajabhat University, The results revealed that the program in terms of demographic data in this study showed that 20 student. They showed most were female, there were 11 (55.0%) and male, there were 9 (45.0%) and the most age range was 19 years, there were 9 people (45.0%), 21 years, there were 5 people (25.0%), 18 years, there were 2 people (10.0%) 20 years, there were 2 people (10.0%) and 22 years, there were 2 people (10.0%) respectively. Faculty studyingshowed that is Faculty of Liberal Arts and Sciences, there were 4 people (20.0%), Faculty of Humanities and Social Sciences, there were 4 people (20.0%), Faculty of Business Administration and
Accountancy, there were 4 people (20.0%), Faculty of Education, there were 4 people (20.0%), College of Law and Government, there were 4 people (20.0%). For College Years, They showed most were third-year, there were 7 people (35.0%), first-year, there were 6 people (30.0%), second-year, there were 6 people (30.0%) and fifth-year, there were 1 people (5.0%) respectively.

Table 1 described the results of the research were found that after the development of the experimental development program, the students’ leadership in the management of the smoking free university, knowledge, skills, social roles, imagination or concept about oneself, motivation / mindset and participation in the development of student leadership potential in the management of the smoking free university. Significantly better than before development (P-value < 0.05).

**Conclusion and Discussion**

The application program of smoking free university policy campaign in Sisaket Rajabhat University. The development of the experimental development program, the students’ leadership in the management of the smoking free university, knowledge, skills, social roles, imagination or concept about oneself, motivation / mindset and participation in the development of student leadership potential in the management of the smoking free university, the results were statistically significant at (p < 0.05). In conclusion of the study: Results of
the Student Leadership Development Program in Management of Smoking Free Universities, Sisaket Rajabhat University. It can cause success factors in managing the smoking free university. In organizing the non-smoking zone in Sisaket Rajabhat University. By using program included 4 interventions in 12 weeks. To bring about effective action and efficiency and developed as the smoking free university by organizing for the non-smoking zone. Including campaigning activities establishing a banner that announces the non-smoking area that covers the entire university and set a smoking free area and notice for non-smoking area. In a self-report survey, more than 75% and 50% of students reported being exposed to posters and public service announcements, respectively. Recognition of campaign theme was more than 80%. Almost half of respondents reported that the posters were interesting, one-third reported that the posters prevented them from smoking, and 10% reported that the posters encouraged them to cease smoking. Stock media posters had a significantly higher affective reaction than the customized media posters. To create participation of university students and the student leaders, The students union president have a clear understanding of roles and duties in their work operations and have an action plan. They realized the importance of organizing the non-smoking zone in the university. There are regulations / measures to prevent and control smoking in non-smoking zones jointly agreed by the leaders. Established a mechanism to support the construction of the non-smoking area in Sisaket Rajabhat University. The measures are followed up and monitored, and implement a participatory and sustainable non-smoking university. They were accorded to the research who found that the sample size had Perception in hazards of tobacco overall Ranking is good and perception is related behavior were statistically significant at p <0.05. with the finding of the research found that before the attitude test which related to cigarettes, there was no difference and after the attitude test related to cigarettes, there was statistically significant difference at p < 0.05. Overall, participants views about smoking on campus during the implementation of a smoke free policy suggest broad agreement but reflect concerns about enforcement, boundaries, non-smokers and designated areas. Consistent and systematic processes for implementation, maintenance and enforcement of policy goals, and cessation support, is needed to create a non-smoking culture on university campuses. They were accorded to the research this study adds to the existing literature by highlighting how clueless most college student smokers are about quitting, despite the availability of cessation programs and the fact that tobacco use is considered the single largest preventable cause of death and disease in the United States. Students experiment with various quit strategies in a random fashion with limited chances of success, given the addictiveness of the product.

However, it was found that the process of smoking free university policy campaign, the development of student leadership potential of the students union president in the management of the smoking free university. In addition, there is also an increased in terms of enforcement of policy goals.

**Ethical Clearance:** This research was approved for ethical certification by the Institutional Review Board of Faculty of Liberal Arts and Science. Sisaket Rajabhat University. (reference number: AF02-09 / COE 002/2563 Date.06 Feb 2020). Participants could refuse and/or leave this research at any time. The data in the evaluation forms was kept confidentially without specifying the participants’ names in the document. When the participants had completed their evaluation forms, they were sealed in the envelopes by themselves before returning to the researcher.

**Conflict of Interests:** This study has no conflicts of interest.

The Diagnostic Dilemma of the Most Common Yet the Most Complicated Malignancy Involving the Retromolar Region: A Case Report

Tanha Khan¹, M. K. Sunil², Megha Srivastava³, Arpan Manna¹, Chhavi Srivastava¹, Lakshay Vishnoi¹
¹PG Student, ²Professor and Head, Dept of Oral Medicine and Radiology, ³Senior Lecturer, Dept of Oral Medicine and Radiology, Teerthanker Mahaveer Dental College and Research Centre

Abstract

The most common type of oral malignant neoplasm is reported to be Oral Squamous Cell Carcinoma (OSCC), accounting for more than 90% of all malignant lesions in the oral cavity. The commonest site of OSCC are the tongue, oropharynx and the floor of the mouth. OSCC is more common in men as compared to women as men are often more associated with habits such as smoking and tobacco chewing. It is important to have proper knowledge of this disease so that early diagnosis can be done and mortality rate can be reduced.

Keywords: Oral Squamous Cell Carcinoma (OSCC), TNM Staging, Targeted therapy

Introduction

Oral Squamous Cell Carcinoma is the most commonly seen oral carcinoma with various types of clinical presentations¹. OSCC account for more than 90% of all malignant lesions usually occurring in the oral cavity². OSCC of mandibular region is reported to have lowest survival rate as compared to other carcinomas affecting the oral cavity³. Oscc can be seen clinically as ranging from a white plaque to an ulcerated lesion⁴. There can be delay in the proper treatment of oral carcinomas as they can often be misdiagnosed as other inflammatory lesions involving the oral cavity⁵. Thus, it is necessary for the dental practitioners to diagnose this disease as early as possible so as to deliver prompt treatment².

Case Report

A 35 year old male patient came to the department of Oral Medicine and Radiology with the chief complaint of swelling on right side of the face since 2 months. The patient mentioned that he noticed the swelling for the first time, 2 months back. But he didn’t consult any oral physician at that time. Suddenly 1 week before he reported, he started feeling pain in his right lower back tooth region. He also mentioned that he had a mobile tooth in his right lower back tooth region. So having thought of that tooth to be the root cause of the pain, he went to a local practitioner and got his mobile tooth extracted. After extraction, within 1 day, a small growth appeared on right lower back tooth region and the swelling of the right side of the face also started increasing. According to the patient, the size of the growth showed gradual increase from the day of extraction of the mobile tooth till the day he reported and has attained the present size.

The patient also gave history of analgesic medication for 4 days after extraction. The patient’s medical history and family history was not relevant. As per his statement, he had a habit of chewing smokeless tobacco (gutkha) since 15 years with a frequency of 10 packets/day. He used to...
keep the quid in his right lower buccal vestibular region.

General clinical examination revealed normal mouth opening. On extra-oral examination, a diffused swelling was present on right side of the face at the lower border of the mandible measuring approximately 3*4 cm. On palpation, the swelling was non-tender, non-fluctuant and hard in consistency. Multiple tender lymph nodes were noted on right side of the face and neck region. On palpation, submandibular and cervical lymph nodes were tender and palpable (approximately 4 cm in diameter) and were bony hard in consistency and fixed to the skin.

The intraoral examination revealed a large ulceroproliferative lesion measuring approximately 3*4 cm and was erythematous along with white keratotic appearance. Anteroposteriorly, the lesion was extending from the buccal vestibule of 46 region to the posterior aspect of the retromolar region and mediolaterally, it was extending from buccal vestibule to the lingual vestibular region of 45, 46, 47 region. The border of the lesion was everted (Fig.1).

For primary radiological investigation OPG was advised and it revealed ill-defined radiolucent area with ragged margin measuring 2*3 cm extending from distal aspect of 46 to the middle third of the ramus in right side (Fig.2).

After co-relating all the clinical findings, habit history and radiological findings, the provisional diagnosis was made as “Carcinoma of the Mandible”. Later exfoliative cytology was carried out followed by Incisional biopsy.

The final diagnosis of Oral Squamous Cell Carcinoma was confirmed based on the histopathological report. The TNM cancer staging of this case is Stage IVA and stage grouping T2 N2a M0 as the size of the tumor was approximately 3 cm and metastasis was seen in single ipsilateral lymph node approximately 4 cm in size, without any distant metastasis.

Later, the patient was referred to the department of Oral and Maxillofacial Surgery for the needful treatment.

---

Fig: 1: Intraorallylarge ulceroproliferative lesion measuring approximately 3*4 cm and was erythematous along with white keratotic appearance is present
Discussion

Squamous Cell Carcinoma is considered to be the most malignant neoplasm of the oral cavity in India. It is estimated that OSCC constitutes of about 90% of all oral neoplasms. The most common sites for OSCC are tongue, oropharynx and floor of the mouth and Squamous Cell Carcinoma of lips and gingiva are rarely seen. Men are more commonly affected by OSCC as compared to women as men are more exposed to high risk habits such as smoking and tobacco chewing. Additionally, OSCC is increasing nowadays in white people with age group of 18-44 years, particularly among white women.

Some OSCC tends to occur on apparently normal mucosa while others may preceded by some premalignant lesions, such as erythroplakia and leukoplakia. Usually, OSCC presents as an ulcer with raised irregular margins. It tends to show various clinical appearances such as a lump, as a red lesion, as a white lesion or mixed white or red lesion, a non-healing extraction socket or a cervical lymph node enlargement, characterized by hardness or fixation. It is important to note that OSCC should be considered when any of these above mentioned features exists for more than 2 weeks. In our present case, intraoral findings revealed similar features of OSCC which have been mentioned in literature, most commonly ulcero-proliferative growth of the lesion.

As mentioned above, the highest risk factor for OSCC in Western countries is the use of alcohol as well as tobacco. Although the risk factors were independent, it is seen that their actions are seen combinedly. The risk of OSCC increases fifteen folds in users as compared to non-users when combination of tobacco and alcohol is used. It is important to know that there are other risk factors such as betel quid chewing and is associated with increased risk of OSCC. As in our present case patient was chronic gutkah consumer and he used to place the quid in the affected side.

Regional lymph node metastasis is the other common feature of OSCC. In the literature, it is said that cervical lymph nodes of the submandibular triangle and upper jugular regions have more strong predilection of regional lymph node metastasis in most of the cases of OSCC involving lower alveolus. In this present case also, tender and palpable submandibular and cervical lymph nodes of about 4 cm were detected.
Prognosis of OSCC is mainly based on metastasis. Prognosis is better when it is well-differentiated and without metastasis. But most commonly, cases of OSCC are not diagnosed in early stage which ultimately leads to poor prognosis of the disease. Prognosis also varies on numerous other factors related to the tumor or treatment or to the patient.

Radiographically, the bony defects seen in OSCC can be classified as follows: (a) erosive-well defined margins of the absorbed bone and (b) moth eaten-irregular, ill-defined margins of absorbed bone. Further, the extent of the radiographically bone defects are described as follows: (a) grade 1- bone defects limited to the alveolar bone (b) grade 2- bone defect exceeded the alveolar bone but do not extend beyond mandibular canal and (c) grade 3- bone defects extending beyond the mandibular canal. This present case shows, ill defined radiolucency with ragged margin measuring 2*3 cm extending from distal aspect of 46 to the middle third of the ramus in right side extending up to the superior border of the mandibular canal indicative of grade 3-bone defect.

OSCC, being the most dreaded form of carcinoma is responsible for the loss of numerous lives. So, it must be diagnosed at an early stage and treated accordingly. OSCC is being treated traditionally by surgery, chemotherapy, radiotherapy and combination therapy depending on size, site, age, TNM staging.

Treatment modalities of OSCC includes primarily a surgical excision followed by radiation therapy and chemotherapy as an adjunct treatment modalities. In case where lymph node metastasis is present, Radical neck dissection is often required. When the bone defects do not show extension beyond the mandibular canal, marginal resection can be considered as a treatment option, whereas in cases when the bone defects extend beyond the mandibular canal, segmental resection is considered as a treatment option. Newer therapy technique called Targeted therapy have begun to emerge. This method tends to identify the mutated gene responsible for carcinoma and corrects the pathway through which these mutated genes act.

Early diagnosis can be done by other methods such as incisional biopsy, brush biopsy, the ViziLite (highlighting of keratin), oral autofluorescence, photodynamic detection, Optical Coherence Tomography (OCT).

**Conclusion**

As OSCC has various clinical presentations, dentists must be aware of all the characteristics of this disease. Various diagnostic investigations should be considered immediately after the provisional diagnosis in order to reduce the morbidity and mortality rate. Correct and timely diagnosis of the disease is of utmost importance so as to deliver proper treatment modalities to the patients.

Suicidal Deaths Amid COVID-19 Pandemic: A Cross-Sectional Autopsy-Based Study

Tanmay Sardar1, Ranjan Biswas2, Achintya Biswas3, Saptarshi Chatterjee1

1Associate Professor, Department of Forensic Medicine and Toxicology, 2Assistant Professor, Department of Psychiatry, Bankura Sammilani Medical College, Bankura, West Bengal, 3Associate Professor, Department of Forensic Medicine and Toxicology, Calcutta National Medical College, Kolkata, West Bengal

Abstract

Background: Suicide is a global issue, with an estimated 75.5% of the cases occurring in developing countries, and India alone accounting for 26.6% of all global suicidal deaths. With an advent of COVID-19 in the early months of 2020, India observed a rapid rise in suicidal deaths. Though, various media reports predicted loneliness, mental illness and economical instabilities as the major triggering factors, there is a lack of analytical or descriptive studies confirming this hypothesis. In this context, the present cross-sectional study was planned to determine the socio-demographic profiles of the victims and the triggering factors of the suicidal deaths during the COVID-19 phase, in context to the victims of suicide from 2017 to the Pre-COVID phase.

Methods: The present cross-sectional study was conducted by analyzing the suicidal deaths from 2017 to 30th June, 2020, interviewing the deceased family members during the COVID-19 phase and studying the Inquest reports, with the documents from the Institutional Medical Record Section.

Conclusion: The authors feel that suicide is an act of moment in mind, so any decision made under excitement or incitement is the real culprit. To curb the menace of suicide, state and society should ensure education, employment and socioeconomic well-being, along with strict law enforcement.

Keywords: Coronavirus, Mental illness, Pandemic, Suicide, Domestic violence

Introduction

Suicide, ranked among the leading causes of death in the world,1 is a global phenomenon, with an annual global suicide prevalence of 10.4 per 100,000 population.2 Suicide is the second leading cause of death in people aged 15-29 years and an estimated 75.5% of all global suicides occur in developing countries, with India alone accounting for 26.6% of all global suicide deaths. India’s contribution to the global suicidal deaths increased from 25.3% in 1990 to 36.6% in 2016 among women, and from 18.7% to 24.3% among men.3 Because of the large population size (18% of the global population), suicides and suicidality in India have global implications towards achieving a sustainable development goals (SDGs) by 2030, with suicide mortality rate as one of the key indicators.

The coronavirus disease (COVID-19) struck India in the early months of 2020. Concerning disease models led to historic and unprecedented public health actions to curb the spread of the virus. Remarkable social distancing interventions have been implemented to fundamentally reduce human contact. While these steps are expected to reduce the rate of new infections,
the potentiality for adverse outcomes on suicide risk is high. And in concordance to this, suicide became the leading cause for over 300 ‘non-coronavirus deaths’ reported in India due to distress triggered by nationwide lockdown in the months of April and May, 2020. There have been a staggering number of suicides, caused by fear of infection or being tested positive for the virus, loneliness, lack of freedom of movement, and alcohol withdrawal during the lockdown.

Suicide is a multi-faceted and complex event. So, the approach to understanding suicide must be multidisciplinary, involving psychiatrists, forensic experts and physicians. Hence, this study was planned with a purpose to know the magnitude and socio-cultural factors of the problem of suicides, the trend during the nation-wide lockdown and to assess the physical and psycho-social comorbidities associated with these suicidal deaths, so that a sound prevention program could be suggested, planned and implemented for flattening the ascending curve of suicidal deaths.

**Aims and Objectives**

1. To compare the proportion of suicidal deaths from January, 2017 to June, 2020

2. To study the socio-demographic profiles of the victims of suicidal death

3. To analyze the events that triggered the suicidal deaths

**Material and Methods**

a. Place of study: BS Medical College Police Mortuary, Bankura, West Bengal, India

b. Period of study: 1st March, 2020 to 30th June, 2020

c. Study population: All the patients sent for autopsy examination at BS Medical College Police Mortuary between 1st January, 2017 to 30th June, 2020

ii. Inclusion criteria: All the victims of suicidal deaths between 1st January, 2017 to 30th June, 2020, who attended to BS Medical College Police Mortuary for autopsy examination.

i. Exclusion criteria:

ii. Cases with incomplete or inadequate history

iii. Unknown cases

d. Sample size: All the victims of suicidal deaths, attended to BS Medical College Police Mortuary for autopsy examination between 1st January, 2017 to 30th June, 2020.

e. Study design: Cross-sectional descriptive study

f. Source of data:

i. Police or Magistrate inquests

ii. Statements of the family members of the deceased

iii. Postmortem register, Bankura Sammilani Medical College

g. Statistical analysis: All the data were manually checked and edited for completeness in a pre-determined format and were then coded for computer entry. Collected data was recorded and analyzed in Microsoft Excel worksheet and SPSS IBM 19.

**Results**

In the present study, the study population have been divided into five groups, namely subjects from the years 2017, 2018, 2019 and Pre-COVID Phase (1st January, 2020 – 29th February, 2020) with the COVID-19 Phase (1st March, 2020 – 30th June, 2020).

1. Proportion of suicidal deaths

**Table 1: Proportion of suicidal deaths**
2. Age-distribution

3. Gender distribution

The Male: Female ratios for the years 2017, 2018, 2019, Pre-COVID phase (January, 2020 - February, 2020) and COVID-19 phase (March, 2020 – June, 2020) were 1.6:1, 1.2:1, 1.4:1, 1.5:1 and 0.9:1 respectively.

6. Victims of COVID-19 Phase

6a. Occupation

42.5% victims of suicide were farmers, followed by the unemployed persons (23.7%) and homemakers (21.9%), and the rest of the population were students, retired person or salaried Government servants.

6b. Marital status

Majority of our subjects (55.5%) were married, followed by persons yet to marry (32.9%) and 10.1% of the subjects were either widow or widowers. 3 male subjects in the present study were divorced.

6c. Per Capita Income

![Figure 3 Distribution according to Per Capita Income (B.G. Prasad Scale)](image)

6d. Mental illness
13.04% of the victims were either suffering from mental illness or had a past history of mental illness, of which 37.03% of the subjects had a family history of mental illness. Considering all the victims of COVID-19 Phase, 23.67% of the victims had at least one member in their families with mental ill-health.

**Discussion**

The COVID-19 pandemic began in December 2019 at Wuhan, China, and has quickly spread globally affecting more than 16.5 million people. India reported her first confirmed case on 30th January 2020 in Kerala. However, with an affection of more than 1.4 million people and a death toll of 33,000, India is ranked third in the world in terms of infection, immediately next to the United States of America and Brazil. Understandably, medical professionals and public health specialists are focused on the treatment and containing the spread of the disease in the general population, with less attention to the psychological and social consequences of the Covid-19 crisis. New research warns that the rapid rise in unemployment, coupled to the prevailing mental health problems amid this pandemic can raise the suicide rates.

Though there is a paucity of literature on the trends of suicidal deaths amid COVID-19 crisis, multiple lines of evidence suggest that, this crisis may increase the prevalence of psychiatric disorders and suicide rates during and after the pandemic. This speculation is further amplified by the reports of 54 cases of suicidal deaths in the state of Punjab during the lockdown months of April and May in India. Reports from Nagpur claimed a decline in the suicidal deaths in the months of March and April, with an increase in incidence of suicidal deaths in May and a sudden spike in the month of June. The present study reflects a significant rise in the incidence of suicidal rates by more than 20%, as compared to the previous three years. Suicide, with an average prevalence rate of 25-30% among all the medicolegal autopsies, is uniformly distributed throughout the year in Bankura, West Bengal. However, a rise in the suicide rates is noticed from the early days of January 2020, with rapid developments from the months of March, reaching its peak by June. This explains the growing instabilities and uncertainties among the general people in a region, where more than one-third of the population is living below poverty lines.

Globally, suicide is a leading cause of death among teenagers and adults under 35 years of age, with a Male: Female ratio of 1.8 in age-standardized suicide rates, as per Global Health Observatory (GHO) data. Studies report that the age group of 20-63 years is most vulnerable, followed by the age group of 30-64 years. In our study, people of age group of 20-30 years were mostly affected, followed by the individuals of 30-40 years, with a gender distribution in continuity with the Global Health Observatory data from 2017 to 2019. But during March to June 2020, an altered ratio of 0.9:1 was seen, indicating more incidence of suicides in females, as compared to males. Women’s greater vulnerability to suicidal behaviour is likely to be due to gender related psychopathological and psychosocial stressors, coupled to the lower number of reasons for living during the COVID-19 days. The availability of specific means for suicide in one particular region depends upon various factors like age, sex, availability and access of methods, the socio-economic condition, as well as prevailing culture and religious customs. As the United States of America reports firearms as the most common method of suicide, China and South Korea, catering large rural populations, exhibits self-poisoning with pesticides as the usual method. However, in contrast, the National Crime Records Bureau in India reported that suicide by poisoning has gone down, with hanging becoming the preferred method. In concordance, our study reflects hanging as the most preferred method, followed by poisoning, with a fewer number of suicidal deaths attributable to self-immolation, drowning and railway runover. A systemic review on suicide in India found hanging as the most frequently reported method of suicide (10-72%), followed by self-poisoning (16-
49%), drowning (3-39%) and self-immolation (6-57%). Though poisoning and hanging are the two most preferred means of suicide over the decade in India, the gap between the two decreasing over time. 

Virtually all mental disorders carry an increased risk of suicidal ideation, suicidal attempt, and suicide. About 90% of individuals who attempt or commit suicide suffer from mood disorders, psychoses, and personality disorders. However, the prevalence of depression or other diagnostic mental disorders recorded by psychological autopsy for the suicidal victims in Asian countries is lower than non-Asian high-income countries. Depression is a public health issue in the South-East Asia region, with a prevalence ranging from 6.9% to 51.7%, among people who committed suicide. Identical results are reflected in the present study, which is also in concordance to a study in Indonesia, where major depressive episode was diagnosed in more than half of the people who died by suicide. And according to another report from the United States of America, suicide rates are largely unrelated to antecedent physical activity and alcohol consumption, and substantially higher among men reporting personality traits as insomnia, exhaustion, cyclothymia and self-consciousness.

The transition from suicidal ideation to actual suicide occurs impulsively as a reaction to acute psychosocial stressors. Numerous studies have examined the precipitating factors influencing suicidal behaviours, that include suicidal ideation, plan, attempts and completed suicides. Being unemployed, unmarried, low education and income were reported to be associated with suicidal behaviours. Additionally, family history of mental disorders, chronic debilitating diseases, depression, loneliness, and illicit drug use have been documented to predict suicidal behaviours. Contrastively, this study portrayed that the farmers and unemployed persons constituted majority of the victims, with married persons being more vulnerable to suicidal behaviours. This deviation in findings can be attributed to the COVID-19 pandemic, which struck India in the month of March 2020. The realization of the non-availability of vaccine and/or effective antiviral drug against SARS-CoV-2 virus, and understanding that social distancing and quarantine or self-isolation is the only available remedy, forced governments of most of the countries to declare the nationwide lockdown which had substantial effects on the global economy and the socio-cultural environment. Social isolation, anxiety, fear of contagion, uncertainty, chronic stress and economic difficulties may lead to the development or exacerbation of stress-related disorders and suicidality in vulnerable populations including individuals with pre-existing psychiatric disorders, low-resilient persons, individuals who reside in high COVID-19 prevalent areas and people who have a family member or friend who has died of COVID-19. Domestic violence alone accounted for almost 30% of all the cases in our study, followed by economic unrest. Fuelled by mandatory stay-at-home, physical distancing, economic uncertainties, and anxieties caused by the pandemic, domestic violence has increased globally. The National Commission of Women (NCW) noted a rise in the number domestic violence complaints in India. However, the number of cases reported are most likely not proportional to the actual rise in domestic violence, as most avenues to seek help or to physically remove themselves from their situations are impaired.

Conclusion

Suicide is a vast varied and intricate topic, yet our study is a tangible attempt of exploring the socio-demographic profiles of victims and the triggering events leading to suicides. Our study reported a suicidal incidence of 45.39% in the COVID-19 phase, as compared to a mean value of just over 26% from 2017 to Pre-COVID era. Majority of the victims belong to 20-30 years of age, with an overall male predominance, except during the COVID-19 phase, reflecting an unusual female dominance. Though the proportion of suicides is fairly distributed across the year, the months of pandemic reported a spike, with hanging and poisoning as the most preferred methods. Analysis during the pandemic revealed that farmers, unemployed and homemakers constituted the burden, with married persons from low-middle and low income groups. Victims with
low education and with a history of previous suicidal attempts were found to be most vulnerable. 13.04% of the victims were either suffering from mental illness or had a past history of mental illness, of which 37.03% of the subjects had a family history of mental illness. Considering all the victims of COVID-19 Phase, 23.67% of the victims had at least one member in their families with mental ill-health. However, domestic violence was depicted as the single most culprit behind these suicidal deaths.

To curb the menace of suicide, state and society should ensure education, employment and socioeconomic well-being, along with strict law enforcement. But authors feel that suicide is an act of moment in mind, so any decision made under excitement or incitement is the real culprit. Therefore, we would like to wrap up this by suggesting to improve the ability to think over any problem, with a balanced and reasonable tolerance.

Uncertainty-Based Critical Nursing Model on Family of Family Needs in Bangil General Hospital, Pasuruan, Indonesia

Tanty Wulan Dari1, Moch Bahrudin1

1Lecturer, Department of Nursing, Health Polytechnic Ministry of Health, Surabaya, Indonesia

Abstract

Holistic care in the intensive unit should be provided for patients and their families. The patient’s family waiting in the intensive care room may experience uncertainty. Not only because of the unfamiliar treatment rooms, but also because of the health workers who are strangers to them and speak with medical terms. The objective of this research is to develop the CCFN (Critical Care Family Need) Nursing Model towards the adaptation of the patient’s family in the Intensive Care Unit (ICU). The research was conducted with an explanatory design. The population in this study was patients’ most influential family member in making decisions (related to patients’ care and medication) at Bangil General Hospital in 2020. The sample size was 105 with consecutive sampling technique. Research variables included: factors related to the patient, family psychology, health services, family needs and family adaptation. PLS testing was performed, then FGD was done to strengthen the statistical model. Results showed a different finding compared to the initial concept, where there the families’ thinking capacity p showed no significant effect on the families’ coping factor. The families’ coping factor showed no significant effect on the critical care family need (CCFN). However, family coping factor showed a significant effect on family adaptation factor. In conclusion, there are two indicators that can explain the fulfilling of family needs factors, namely indicators of mental support from health workers and their closeness to patients. Calmness of family during discussion with health workers, as well as enthusiasm felt by the patient’s family, are things that must be noted, so that the family adaptation process occurs optimally.

Keywords: Patient’s family, CCFN, Uncertainty, Adaptation.

Introduction

Separation between patients and their family may cause stressful situations, especially for nuclear (main) families in Indonesia. People in Indonesia generally adhere to very close kinship, where if a family member is sick, all members would also feel the pain. When a patient undergoes treatment in the intensive care unit (ICU), the patient must be isolated and separated from their family. In Indonesia, a family can be seen as a system, where change in health or separation of a family member will impact other family members. Conditions like this are likely to create a situation where the family experiences stress or feelings of uncertainty1,2.

Other causes of the feeling of uncertainty in patients’ family is the lack or absence of supporting facilities to fulfill biological needs of the family in the waiting room, such as the waiting room itself, lighting, and bathroom/toilet facilities1,2.

A research revealed that the feeling of anxiety was experienced by 27 parents for 11 months whose child was treated in the ICU. Through this study, 5 (five) nursing diagnoses arose, including, uncertainty, conflict in the role of parents, high risk of ineffective nutrition for children, high risk of damage of relationship with children, high risk of lack of home care and high risk of tension in the role of service providers. Based on these
problems, nurses need to intervene with parents and other family members regarding to child care in the ICU to overcome problems that arise\textsuperscript{3,4}.

According to a preliminary study conducted by several researchers in February 2019 at Bangil Hospital, an interview was done to 10 families who were waiting outside of the ICU. Families stated that they almost never receive an explanation of the patient’s illness, prognosis, development, treatment and action. The family would only be called if needed to buy medicine or when the patient’s condition is in a nearly dying state. Other than that, every family that is called into the ICU always come out crying, which causes feelings of anxiety and uncertainty for the other families\textsuperscript{5,6}.

Families of patients in the ICU hope that nurses provide extra attention and care to patients. Around 90\% of the families want nurses to explain the patients’ situation, development and treatments using a language that is easily understood. Families also want to be able to be beside the patient. Efforts or research to solve the problems mentioned above has never been carried out before\textsuperscript{5,6}. The services provided so far are routines and researches previously carried out at Bangil Hospital.

Based on the results of several research journals, the effort of medical staffs increasing the intensity of communication with the patients’ family and showing affection towards them shows positive results. Often, patients’ family members feel uncertain, in need of help, guilty, fatigued, sad, scared and anxious. Effective use of communication by health workers, improving communication strategies, helping families relieve emotions and increasing family independence are goals that have been set\textsuperscript{7}.

Families who receive attentive care will be able to provide greater comfort for their illness, encourage improvements in care, and improve the skills assessment of health care providers. Leske categorizes five family principles that can be used to guide nursing interventions, which should be initiated at initial contact with family members\textsuperscript{4}. This would provide assurance and a calm and relaxed atmosphere that would support trust and empathetic relationships. Increased closeness means allowing family members to become closer to the patient by visiting the patient. The five family categories according to Leske: Assurance, Proximity, Information, Comfort, Support\textsuperscript{8}.

The need for information about the patients in the ICU is proven to be the top need of the patients’ family members. A study was initiated to determine the level of satisfaction of family members, and it was found that providing complete information of the patients in the ICU was associated with family members’ overall satisfaction\textsuperscript{5}. There are several ways to deliver information to the family: educational orientation programs, classes providing social support and information on disease management and recovery, and information packages. Learning the balance between too little and too much information and how to convey this information is an important skill for nurses in the ICU to learn\textsuperscript{6}.

The nurse must consider the nature of the information delivered to the family after deciding the best manner to deliver the information. In a study of 390 families of patients who passed away in the ICU, researchers found that the majority of respondents (82.6 percent) criticized the hospital, 17 percent felt the information received about the diagnosis was insufficient or unclear, and 30 percent expressed dissatisfaction regarding to the information received on the cause of death (particularly among family members who were notified of death by telephone and not in person)\textsuperscript{7}. Programs for family members to determine whether this program would increase family member’s satisfaction with treatments, meeting their need for better information, and reducing disruption to ICU care. The intervention consists of three components, namely: 1) discussion with the nurse approximately 24 hours after admission of the patient 2) an informational pamphlet given during the discussion 3) daily phone calls from nurses who treat the patients that day\textsuperscript{7,8}.

The number of incoming calls from family members was significantly lower in the experimental group than in
the control group. In the experimental group, satisfaction with patient treatment increased significantly compared to before. Family members’ perception is based on how well their information needs are met. The family goes through three stages of adaptation in response to news on a family member suffering from a fatal disease. Various emotional responses may arise during this phase, including disorganization/division, anxiety, and emotional instability. The first phase is the preparation phase. This phase begins when the first symptoms appear and continues through the initial diagnosis.

Nurses can help families by informing them that it is natural to go through these phases and that they can expect direction from complex problems in each phase of a fatal illness. Helping families accept their feelings and directing them to appropriate service resources, such as hospitals, family support groups, social workers, and family conferences, can be very useful.

**Method**

In this research, correlation analysis was performed and carried out in two stages. An explanatory design was used in the first stage and FGD was done in the second stage to reinforce the findings. Explanatory design was used to develop a Critical Care Family Need (CCFN) nursing model on family members of patients in the ICU. The approach used is cross sectional. This study examined the effect of patient, family psychology, service and family needs: CCFN factors on family adaptation. The research was carried out at Bangil General Hospital, Pasuruan, Indonesia in an integrated intensive care installation room which involved 265 respondents. Sampling was done in October-November 2020.

**Results and Discussion**

The majority of respondents’ answers are summarized as following: Disease indicator, the majority stated that the family knew about the patient’s illness, with 60% of respondent answers. Prognosis indicator, the majority said the family knew about the prognosis of the patient, with 55.1% of respondent answers. Disease history indicator, the majority of the patient’s families knew about the patient’s history, with 89.4% of respondent answers. Action indicator, the majority of the patient’s families knew enough about patient treatment that cause pain, with 70.2% of respondent answers.

The following is a summary of the majority of respondents’ answers related to family psychological factors: Communication indicator, the majority of the patient’s families do not have the communication skills to handle the uncertainties they experience, with 75.1% of respondent answers. Appreciation indicator, the majority said that there was no ability to appreciate things to overcome the uncertainty they experienced, with 86.4% of respondent answers. Togetherness indicator, the majority said that there was sufficient togetherness among family members to handle the uncertainty they experienced, with 72.1% of respondent answers. Health indicator, the majority of the patients’ family stated that they had sufficient health to handle the uncertainty they experienced, with 60.4% of respondent answers.

The following is a summary of the majority of respondents’ answers related to indicators on family coping factors: Regulatory indicator, the majority of the patient’s family had no opinion on regulatory regarding to a family member being treated in intensive care, with 54% of responses. Empathy indicator, the majority stated that there was no empathy service provided by intensive care officers to the patient’s family, with 85.3% of responses. Assurance indicator, the majority stated that there was no service assurance provided by the intensive care staff to the patient’s family, with 90.2% of responses. Tangible indicator, the majority stated that there was sufficient tangibility (real evidence) of the services provided by intensive care workers to the patient’s family, with 70.6% of responses.
Congenator indicator, the majority of the patient’s family had no opinions on congenator regarding to a family member being treated in the intensive care unit, with 70.9% of responses.

The following is a summary of respondents’ answers related indicators on family coping factors: Therapeutic communication indicator, the majority of the patient’s families were not given therapeutic communication between them and health workers, with 75.8% of responses. Involvement on family in treatment indicator, the majority of patients’ families were not involved in patient treatment, with 88.3% of responses. Mental support by health workers indicator, the majority of the patient’s family felt that they were not given mental support by health workers, with 88.7% of responses. Comfortableness with health facilities indicator, the majority of the patient’s family did not feel comfortable with existing health facilities, with 84.9% of responses. Closeness to patient indicator, the majority of the patient’s family was given the opportunity to be close to the patient, with 75.1% of responses.

The following is a summary of respondents’ answers related to indicators on family adaptation factors: Enthusiasm indicator, the majority of the patient’s family felt that they did not feel enthusiastic, with 91.3% of responses. Discussion indicator, the majority of the patient’s family felt uneasy discussing their experience, with 54.3% of responses. Decision making indicator, the majority of the patient’s family felt uneasy in making decisions related to their experience, with 95.8% of responses. Participation indicator, the majority of the patient’s family felt no sense of calmness in terms of participation in their experience, with 87.9% of responses.

The Family Needs on Family Adaptation factor has the highest value, namely 0.227. This indicates that when the needs of a family are increased by 1 unit, family adaptation value would increase by 0.227 times. Patient factor on family adaptation factor has a value of 0.042. This indicates that if the patient factor is increased by 1 unit, family adaptation value would increase by 0.042 times. The Service Provider Structure Factor on the Family Adaptation factor is -0.032 which indicates that these factors are inversely related. If the value of the service provider structure is increased by 1 unit, the value of family adaptation would decrease by 0.032 times.

**Conclusion**

Family coping factors affect family adaptation factors. The value of the effect is -0.126, meaning that if the family coping factor is given a value of 1 unit, the patient’s family adaptation value would decrease by 0.126 times. There is no effect of the Family Coping Factor on the Fulfillment of Family Needs Factor/CCFN. The family coping factor has no effect on the Fulfillment of family needs factor. Fulfillment of family needs factor affects the family adaptation factor. The effect has value of 0.227, meaning that if the family needs fulfillment factor is given a value of 1 unit, the patient’s family adaptation factor would increase by 0.227 times.

Findings in this study reveal that the factors required to fulfill the needs of families’ whose family member is treated in the ICU include: therapeutic communication, family involvement in treatment, mental support, comfort and closeness to patients. These factors directly affect the adaptation of the patient’s family. Meanwhile, indirect factors include the patient, psychology of family, services and family coping. In conclusion, the most effective factors that help patient’s family adapt to the situation are closeness to patient and mental support. Not all factors affected family adaptation. This may be related to the location of study, which was at Bangil General Hospital.

Abstract

Introduction: The present paper studied three lower organ linear disorders, including tibial rotation (rotating tibia bone around linear axis) (femoral anteversion), femoral normal rotation, and varus complications as possible risk factors of common sports injuries of knee.

Methods: In this comparative descriptive study, 60 men were divided into three meniscal injury, anterior cross ligament and healthy groups (n=20). All of the participants were current wrestlers at different clubs of Kermanshah province and towns who had at least four years of experience in various sports events. The samples of the injured groups were selected through questionnaire and referral to sports clubs and the healthy group sample was randomly selected. The healthy individuals had no record of knee injury.

Results: The results of the present study revealed that anteversion (internal rotation of femur) affected both common anterior cruciate ligament and meniscal impairments, and tibial rotation only significantly affected meniscal injury not anterior cruciate ligament. Also, increase of knee varus angle did not have any effect on meniscal and anterior cruciate ligament injuries.

Conclusion: The results of this study can be helpful to recognize the risk factors of sports injuries.

Key words: lower organ linear disorders, wrestlers, anteversion, knee varus angle

Introduction

Movement is an inseparable part of all living organisms. This vital factor is provided by the muscular-skeletal system of the living organism¹-⁴. Proper physical condition with no threatening motor diseases is one of the requirements of the living organism. Lower organ is the supporting surface, balance factor and motor element for the organism²,⁵-⁷. Thus, the disorders associated with this organ, in addition to changing the standing position, affect movements, too. As the largest joint of the body, knee is where most threatening factors and lower organ disorders occur³,⁴,⁷-⁹. Anatomical disorders and various distortions are seen in knee joints and rotation of lower organ as valgus, varus, hyperextension, anteversion
femur and tibia, which can be a reason for ligaments’ injury and stabilizing elements of knee joint\cite{10}. Increase in varus and valgus angles are associated with diseases like osteoarthritis and other types of arthritis. Nowadays, various studies are being conducted to investigate the effect of disorders such as knee joint disorders, rotation of lower organ, and incidence rate of injuries in this region. A lot of these studies have been conducted to prevent common sports injuries and to identify the possible risk factors of knee injury\cite{11-13}. Age, gender, body type, flexibility, joint laxity, muscular power, previous injuries, rehabilitation programs and anatomical disorders are the risk factors of lower organ injury\cite{14}, among which anatomical disorders are the most important causes. Based on the previous studies, knee joint includes most of the lower organ injuries so that 4.35% of the injuries, followed by the highest frequency, are associated with knee. According to the report by the orthopedics faculty of the United States, meniscal injury is the second most common knee injury and is often followed by 22- 86% anterior cruciate ligament injury. The annual cost of the injuries resulting from the sports around the world is estimated one billion dollars, a large sum of which is on knee injury treatment. Researchers have predicted remarkably lower costs for injury than treatment. In line with this, many researchers have been trying to find the risk factors causing common and costly traumas\cite{15-20}. Since dealing with injury is mainly focused on the preventive measures, identification of factors and predisposing risk factors of injuries are the most important issues to be taken into account to prevent injury\cite{21,22}. Previous research indicates that lower organ disorders are not known from the risk factors of common injuries in lower organ\cite{22-25}. The present study was aimed to study three lower organ linear disorders, including tibial rotation (rotating tibia bone around linear axis) (femoral anteversion), femoral normal rotation, and varus complications as possible risk factors of common sports injuries of knee. The results of this study can be helpful to recognize the risk factors of sports injuries.

**Material and Methods**

In this comparative descriptive study, 60 men were divided into three meniscal injury, anterior cross ligament and healthy groups (n=20). All of the participants were current wrestlers at different clubs of Kermanshah province and towns who had at least four years of experience in various sports events. The samples of the injured groups were selected through questionnaire and referral to sports clubs and the healthy group sample was randomly selected. The healthy individuals had no record of knee injury. Having signed the consent forms, the participants were informed about the study process and the orthopedics specialist explained the possible dangers of x-ray. Personal information, including height, weight, age, activity record, injury type, and time length after injury and time of inactivity due to injured foot, internal or external meniscal tear, time after surgery, superior leg and non-superior leg, body mass index (BMI) in both injured meniscus and anterior cruciate ligament was collected. Then, using 16-slide CT scan machine, the disorders of 100 people, including anteversion, rotation angle of tibia and varus angle were determined. Finally, the angles of disorders acquired for each person and each group were drawn and compared with the healthy group by the radiology specialist. In this study, 16-slide CT scan (Siemens, Germany) machine was used at Imam Hossein hospital in Kermanshah. To calculate the anteversion, intended cuts were taken from the pelvic region and distal part of femur. Then, in each region the best cut was chosen by the radiologist and by passing an imaginary transverse line through the same region, the tangent was drawn and the tangents on both distal and proximal parts of the femur were drawn to cross each other. The obtained angle from the crossed tangents was considered as anteversion angle. To calculate the rotation angle of tibia, taking the diagnosis of the radiologist into account, first the best cuts were selected from the proximal region of tibia and its distal region, respectively, then, the crossing lines and tangent on them were drawn and the obtained angle from the crossing lines was calculated as tibia rotation angle. Further, varus angle was calculated using the CT scan images and drawing the angle between the two imaginary transverse lines of the upper part and lower part of tibia. Finally, the angle of the acquired disorders in both groups of injured
Meniscus and anterior cruciate ligament were calculated by the radiologist and compared with the healthy group. Descriptive and inferential statistics were used to analyze the data. Also, Kolmogrov Smirnov was used to determine the normal distribution of the data. Then, independent t-test was used to determine the differences between healthy group and other groups. To analyze the data, SPSS (version 18) was used and Excel software was used to draw the graphs.

Findings

The findings indicated a significant difference between the tibial rotation of meniscal injury group (88.4±25.19) and healthy group (67.3±22.2) (p= 0.037), but there was no significant difference between rotation of tibia in anterior cruciate ligament injury group (58.3±85.21) and healthy group (88.4±25.19) (P=0.50).

In contrast, the anteversion level of the meniscal injury group and healthy group was statistically significant (p= 0.01), which was 73.1± 50.13 in the healthy group and 03.3± 65.15 in the meniscal injury group.

However, there was no significant difference between the anteversion level of anterior cruciate ligament injury group and healthy group (p=0.100), which was 73.1± 5.13 in the healthy group and 16.3± 85.16 in the anterior cruciate ligament injury group. Moreover, no significant differences were observed between the knee varus angles of the meniscal injury group (79.2±70.7), anterior cruciate ligament injury group (65.2± 75.7) and healthy group (59.3± 10.7) (p=0.50).

| Table 1 Personal data of the samples, including age, height, and weight |
|-------------------------------|----------------|---------------|
| Age (year) | Height (cm) | Weight (kg) |
| Healthy | 38.3± 88.28 | 62.7± 85.177 | 70.6± 9.76 |
| Injured meniscus | 38.5±65.26 | 69.4± 6.175 | 39.9± 3.77 |
| Injured ACL | 42.3± 57.26 | 35.5± 85.175 | 66.6± 55.77 |
| Total | 23.4± 37.27 | 20.6± 43.176 | 57.7± 25.77 |

| Table 2 Comparison of lower organ disorders between meniscal injury, ACL and healthy people |
|-------------------------------|---------------|----------------|
| Tibial rotation angle | Healthy | Meniscal injury | Anterior cruciate ligament injury |
| 88.4± 25.19 | 67.3± 2.22 | 58.3± 85.21 |
| Anteversion angle | 73.1± 50.13 | 03.3± 65.15 | 16.3± 85.16 |
| Knee drug angle | 59.3± 10.7 | 79.2± 70.7 | 65.2± 75.7 |
Discussion

The results of the present study revealed that anteversion (internal rotation of femur) affected both common anterior cruciate ligament and meniscal impairments, and tibial rotation only significantly affected meniscal injury not anterior cruciate ligament. Also, increase of knee varus angle did not have any effect on meniscal and anterior cruciate ligament injuries. However, increase of anteversion angle can be due to possible risk factors of common knee injuries. Therefore, based on the results of this study, it is necessary to identify the athletes with abovementioned disorders. Various studies have studied the effect of anatomical disorders on sports injuries and analyzed anatomical disorders as one of the predisposing risk factors.

Stanitski et al. in his study titled “anterior cruciate ligament tear in individuals with skeletal disorders” reported problems of skeletal disorders of lower organ as one of the most important causes of acute anterior cruciate ligament tear (about 6%). Scoville and Williams (2003) compared the injury rates and identified the risk factors associated with contact injury of anterior cruciate ligament between males and females on 859 people in a four-year period using a questionnaire. They reported that only 24 (16 male and 8 female) had noncontact injuries and other injuries were contact injuries. They also reported rotation of lower organ and dysfunctions of knee joint performance in them4. Alison Chang (2011) conducted a study on 90 people, divided into two groups, 46 with ACL injury and 44 healthy people. They analyzed the relationship between acute tear and inter condylar urethral stricture which is an anatomical disorder of the lower end of femur. Analysis of MRI for the knees of people with anterior cruciate ligament tear as well as the healthy people indicated a significant difference (p=0.001), and inter condylar urethral stricture was significantly associated with acute tear. chang (2011) investigated the rotation disorders of the lower organ on 50 people. The average time of anteversion for the right and left feet were 6.15° and 8.15°, respectively and the average time for tibial rotation in the right and left feet were 1.29° and 9.30°, respectively. Further, no significant difference was observed between rotation of different parts of right and left feet21.

Sung et al (2008) examined 53 people, 24 with tibial rotation and 29 healthy people. They showed more knee joint slipping and laxity in people with extra rotation of tibia than people with normal rotation. Thus, they suggested the extra rotation of tibia as an influential factor in knee injuries17. Braten et al. evaluated the anteversion angle in 50 male and female adults. They reported a significantly higher anteversion level in female than in male26.

Schmitz et al. (2008) investigated the internal and external rotations and increase of varus and valgus angles in men and women and reported more slipping and laxity of joints in people with higher varus and valgus angles. They also reported more possible injury for retaining and supporting ligaments of knee joint in people with internal and external rotation of knee than in other people. Further, they showed higher rotations and higher varus and valgus angles for females than in males7.

Conclusion

Based on the obtained results in this study regarding the significant effect of anteversion on common knee injuries as well as the effect of femur rotation on meniscal injury, it is recommended that incorrect sitting and sleeping habits of children be corrected. It is also suggested that exercises that cause an increase in disorders in athletes be avoided. Further studies are suggested to investigate the male and female athletes in other sports and compare them with non-athletes to analyze the effect of other disorders on common injuries in wrestlers and to examine the effect of disorders in terms of time duration after injury.

Risk Factors of Pre-Eclampsia of Women Birth From History of Eating Behavior During Pregnancy

Teta Puji Rahayu¹, Suparji¹, Nana Usnawati¹

¹Lecture, Jurusan Kebidanan, Politeknik Kesehatan Kementerian Kesehatan Surabaya, Indonesia

Abstract

Introduction: Pre-eclampsia is the second leading cause of maternal death, affecting 3% to 8% of pregnant women worldwide. Pregnant women preeclampsia in Magetan Regency in 2017 were 189 people, while in 2018 there were 270 people. The purpose of this study was to analyze the risk factors for preeclampsia from eating behavior factors in pregnant women. Methods: A case control study design with a retrospective approach. The research was conducted in the working area of the Community Health Center, Panekan District, Magetan Regency. The population of this study was data of all mothers giving birth in 2018 of 210 mothers. The sample size of the control group was 27 mothers giving birth without preeclampsia. The ratio between the case group and the control group was 1: 1, so the number of samples was 54 people. The sampling technique was simple random sampling. The independent variable was eating behavior and the dependent variable was the incidence of preeclampsia. Data collection tools in the form of questionnaires and study of medical record data documentation. The data analysis used was descriptive and logistic regression analysis. The error rate is set at α <0.05. Results: The results of the study using logistic regression of eating behavior obtained p value = 0.00 (p <0.05) and OR (Exp B) 35.714. Conclusion: The conclusion of the research results is that eating behavior affects the incidence of preeclampsia. Pregnant women who have unhealthy eating habits have a 35x greater risk of developing preeclampsia than pregnant women with healthy eating habits.

Keywords: Pre-eclampsia, eating behavior, women birth, pregnancy

Introduction

Pre-eclampsia is a condition in which an increase in blood pressure is accompanied by signs of hypertension and an increase in urinary protein that usually occurs in TM III pregnancy. If you don’t get early treatment, preeclampsia can progress to eclampsia¹. Preeclampsia (PE) is a contributor to maternal and infant mortality and morbidity. Preeclampsia is a health problem that often occurs in pregnancy.

Preeclampsia is the second largest cause of maternal death, affecting 3% to 8% of pregnant women worldwide. Nearly 18% of maternal deaths due to preeclampsia mostly occur in developing countries². In Indonesia, hypertension is the first cause of high maternal mortality. In 2015, the MMR was 305 / 100,000 KH. In 2024 it is targeted that the Maternal Mortality Rate (MMR) will decrease to 232 / 100,000 KH. The percentage of known causes of maternal death was 33.07% hypertension, 27.03% bleeding, 15.7% non-obstetric complications, 12.04% obstetric complications, 6.06% infections and 4.81% others SRS LITBANG³. The prevalence of preeclampsia in East Java in 2018 was 31% or as many as 163 people. This tends to increase compared to the incidence of preeclampsia in 2017 of 28.92% or as many as 153 people. Meanwhile, MMR in East Java in 2018 experienced a decline from the previous year, from 529
people to 522 people\textsuperscript{4,5}. Preeclampsia is the second contributor to maternal mortality. The percentage of causes of maternal death in East Java in 2018 is known to other causes, namely 32\% or 170 people. Pre-Eclampsia / Eclampsia, which is 31\% or as many as 163 people and bleeding, 23\% or as many as 119 people, heart 10\% or 51 people\textsuperscript{5}. While the smallest cause was infection by 4\% or as many as 19 people SRS LITBANG\textsuperscript{3}. Based on a preliminary study of LB3KIA data in Magetan Regency in 2017, the prevalence of preeclampsia in pregnant women was 189 people. Meanwhile, in 2018 there were 270 people. This shows that there has been an increase in the incidence of preeclampsia from 2017 to 2018, namely as many as 81 people. The highest incidence was in the area of the Panekan Community Health Center as many as 27 people. Preeclampsia is the second cause of death after bleeding, as many as 2 people died of preeclampsia or 15.38\% per 100,000 KH\textsuperscript{4,5,6}. AKI is an indicator of the success of maternal health efforts. This indicator is not only able to assess maternal health programs, but also able to assess the degree of public health, because of its sensitivity to improving health services, both in terms of accessibility and quality\textsuperscript{5}. The causes of preeclampsia are maternal health status, reproductive status, nutritional status, access to health services and health behavior\textsuperscript{7}. Health behavior is a response to stimuli. Health behavior consists of 3 aspects, one of which is nutritional behavior / eating behavior\textsuperscript{8}. According to Rahayu L.D and Suryandari A.E 2014 The habit of consuming foods high in fat and high in salt can cause pre-eclampsia to occur frequently in pregnant women so that adequate nutritional habits can prevent mothers from pre-eclampsia disorders\textsuperscript{8}. Research conducted by Rahayu L.D and Suryandari A.E 2014 with the title “Relationship between junk food consumption habits and the incidence of preeclampsia in pregnant women at Prof. Dr. Margono Soekarjo Hospital” concluded that the habit of consuming junk food can cause pre-eclampsia\textsuperscript{3,8}. There are 2 impacts that can be experienced by pregnant women with preeclampsia, namely the impact on the fetus and for the mother herself. For the fetus it can cause growth disorders (IUGR), fetal death in the womb (IUFD), LBW. Meanwhile, the impact on the mother is that the mother becomes unconscious (coma) until she dies\textsuperscript{1,2,3}.

The magnitude of the influence of preeclampsia on high maternal mortality and the risky impact of preeclampsia on maternal health, it is necessary to make efforts to prevent and handle preeclampsia cases. The government’s strategy in reducing the Maternal Mortality Rate in Indonesia based on RAKERNAS 2019 is through an intervention strategy consisting of four main things, namely increasing access to health services, improving the quality of health services, empowering communities and strengthening governance. The strategy includes quality ANC services according to the 10 T standard, pregnant women and giving birth in health facilities, quality ANC and PNC, early detection, an integrated referral system and a hospital for mothers and babies\textsuperscript{4,5,9}.

**Research purposes**

The purpose of this study was to analyze the risk factors for reaction of eating behavior factors in pregnant women.

**Materials and Methods**

The research design used was case control with a retrospective approach\textsuperscript{10}. The research was conducted in the area of the Community Health Center, Panekan District, Magetan Regency, East Java, Indonesia. The population of this study is data of all mothers giving birth at the Community Health Center, Panekan District, Magetan Regency, East Java, Indonesia. In 2018 there were 210 mothers. The sample of the case group was all women who gave birth with a history of preeclampsia and in the control group were some mothers who had no history of preeclampsia\textsuperscript{10,11}. The comparison between the case group and the control group was 1: 1, so the sample size was 54 people. The sampling technique used was simple random sampling technique\textsuperscript{12}. The independent variable in this study was eating behavior and the dependent variable was the incidence of preeclampsia. Data collection tools with questionnaires and study medical record data documentation. The data analysis was descriptive and analytical logistic regression.
error rate was set at $\alpha < 0.05$.\textsuperscript{11,12}

**Result**

The results of the study on a history of eating behavior during pregnancy with the incidence of pre-eclampsia in childbirth are

Based on the research data which can be seen in table 1, an overview of the characteristics of mothers who experience preeclampsia based on age groups shows that most respondents who experience preeclampsia, based on the 20-35 year age group, are as many as 20 people (74%), from the level of parity Multipara more 20 people (74%), based on the education level of the senior high school group as many as 11 people (40.8%) and based on the type of work, the highest incidence of pre-eclampsia in the IRT group was 11 people (40.8%).

</tbody>
</table>

The regression test results obtained p value = 0.00, (p < 0.05). These results indicate that eating behavior during pregnancy affects the incidence of preeclampsia in mothers during pregnancy and childbirth. The result of the odds ratio (Exp B) is 35.714, this shows that pregnant women who have unhealthy eating behavior have a 35x greater risk of experiencing preeclampsia compared to pregnant women who have healthy eating behavior. From the results of this study we can also conclude that 35.7% of preeclampsia is influenced by eating behavior, and as much as 64.3% is caused by other factors.

Discussion

The results showed that the incidence of preeclampsia in women who gave birth, the age group> 35 years showed a high number of cases compared to the age of mothers <35 years. The results of the research by Saifuddin2014, explained that the highest incidence of preeclampsia occurs in adolescence or early 20 years of age, but the prevalence increases in women over 35 years. Still according to Saifudin 2014 Age too young or too old is a factor in the occurrence of preeclampsia. Age less than 20 years is very risky because the reproductive organs are immature to get pregnant, and> 35 years of age the function of the reproductive organs also begins to decline so that they cannot work optimally. Mothers who are less than 20 years old and more than 35 years old have three times the potential to develop preeclampsia compared to pregnant women aged 20-35 years. But in fact, in the results of this study, the age of the mother who is not at risk also has a lot to contribute to the incidence of preeclampsia. Another study that explains the pre-eclampsia of pregnant and childbirth women is according to Transyah C.H 2018 in the Obstetrics room of Dr.M General Hospital. Djamil Padang 2016 shows that the age of pregnant women is mostly not at risk for preeclampsia and a small proportion of the age of pregnant women who are at risk for pre-eclampsia. The results of the study based on maternal parity showed that there were more mothers with a history of multipara who had pre-eclampsia during pregnancy and childbirth than primipara mothers. The results of research conducted by Pandiangan J.M and Kusnanto H (2017) stated that 25.23% of preeclampsia occurred in primipara, while the multipara group was 35.51%. Research shows that parity of mothers who experience preeclampsia occurs more in multipara than primipara. This is different from the opinion of Saifuddin 2014 which states that primipara is also a risk factor for preeclampsia both during pregnancy and during childbirth. Based on the research results, it can be concluded that preeclampsia can occur in Primipara and Multipara mothers. Primipara and Multipara mothers are both at risk of developing preeclampsia. Therefore, ANC services for mothers during pregnancy are very important so that they can detect any signs of preeclampsia.

The Effect of a History of Eating Behavior during Pregnancy on Preeclampsia

Based on the results of the regression test, it was found that pregnant women who have unhealthy eating behavior have a 35x greater risk of experiencing preeclampsia than pregnant women who have healthy eating behaviors. Research results that describe the same results as this study are the results of research by Retnawati and Suryanti 2017 that there is a relationship between the behavior of nutrient intake and the incidence of pre-eclampsia in pregnant women with a value of p = 0.000 (p <0.05). Rahayu and Suryandari’s research 2014 states that the habit of consuming foods high in fat
and high in salt can lead to pre-eclampsia. Food menu imbalances will form oxidative stress (Hyman Mark, 2006). Oxidative stress is said to be the result of an increase in free fatty acids and inflammation, this may be caused by low consumption of antioxidants or high consumption of foods rich in carbohydrates and fats. A diet like this is associated with an increase in free radicals in the body and then will cause pre-eclampsia. So that a pregnant woman will be better off if she consumes foods that are healthy and contain balanced nutrition. Another study conducted by Rahayu and Suryandari 2014 found that there was a relationship between junk food consumption habits and the incidence of pre-eclampsia in pregnant women (p-value = 0.012, 95% CI OR = 4.375). This shows that the habit of consuming junk food can lead to pre-eclampsia. According to Almadsier 2004 in Retnawati and Suryanti 2017 pregnant women need to eat foods that have complete nutrition, this is important, especially at 20 weeks of gestation, at this time pregnant women should not consume nutrients that are high in sodium and low in protein because they can cause pregnancy problems, such as pre-eclampsia. The impact of disruption of nursing patterns during pregnancy can result in an increasing number of pre-eclampsia which is characterized by symptoms of high blood pressure, excess protein levels in urine, leg edema, blurred vision, shortness of breath and decreased consciousness and seizures.

**Conclusion**

The conclusion of this study is the results of identification of the characteristics of pregnant women which show a description of the risk factors for eclampsia during childbirth, namely paretas, type of work and age group factors. The multipara group showed a greater incidence rate of preeclampsia than the primipara group. Based on the age group, the high incidence of preeclampsia during pregnancy and childbirth is the unhealthy age group, namely the age group <20 years and the age group> 35 years. The problem of eating behavior history during pregnancy in this study showed that a group of women with a history of unhealthy eating behavior during pregnancy contributed to the incidence of pre-eclampsia in childbirth. Based on the results of research on the history of eating behavior, that eating behavior during pregnancy affects the health status of the mother which will increase the morbidity rate of pregnant women, one of which is preeclampsia. Eating behavior during pregnancy affects the incidence of preeclampsia. Pregnant women with unhealthy eating habits have a 35x risk of experiencing preeclampsia compared to pregnant women with healthy eating behaviors.

Lp-PLA2 Selective Inhibitors (Darapladib) Effect in Lowering Serum and Aortic Lysophosphatidylcholine (LysoPC), NF-κB and Lp-PLA2 Levels on Dyslipidemic Rats Model

Teuku Heriansyah1, Indah Nur Chomsy2, Anwar Santoso3, Muhammad Ridwan1, Fitria Nugraha Aini4, Titin Andri Wihastuti5

1Department of Cardiology and Vascular Medicine, Medical Faculty, Universitas Syiah Kuala, Banda Aceh, Indonesia, 2Doctoral Program of Medical Science, Faculty of Medicine, University of Brawijaya, Malang, 3Department of Cardiology and Vascular Medicine, Medical Faculty, Universitas Indonesia, Jakarta, Indonesia, 4Faculty of Medicine, University of Islam Malang, Malang, Indonesia, 5Department Basic Nursing Science, Faculty of Medicine University of Brawijaya; Malang, Indonesia.

Abstract

Background: Atherosclerosis is a chronic inflammatory disease, and is associated with upregulation of Lipoprotein-associated phospholipase A2 (Lp-PLA2), the enzyme that hydrolyzes phosphatidylcholine, producing lysophosphatidylcholine (LysoPC) and free fatty acids. LysoPC is a lipid mediator with known pro-inflammatory and pro-atherogenic properties, and is believed to be a critical factor in cardiovascular diseases.

Methods: Thirty male Rattus norvegicus divided into three groups, those are Normal group: fed with rats food contained 3.44 kcal/g total calorie energy, Dyslipidemia group: fed with high-fat diet (HFD) contained 5.30 kcal/g total calorie energy and Dyslipidemia + Darapladib Group: fed with HFD and darapladib orally 20 mg/kg BW once a day. Each group consists of two serials treatment time: 8 weeks and 16 weeks. Expression of NF-κB, Lp-PLA2, and level of LysoPC aorta and serum was the variable that measured.

Results: Darapladib has decreased the expression of Nuclear Factor Kappa B (NF-κB) (p = 0.003) and Lp-PLA2 (p = 0.022). Darapladib also decreased the level of LysoPC Serum on 8 weeks of serial treatment time (p = 0.001) but increased the level of LysoPC Serum on 16 weeks of serial treatment time (p=0.040). Pearson correlation test showed that serum and aortic tissue LysoPC level correlation was strong (r = -0.584) for 8 weeks of serial time and less strong (r = -0.284) for 16 weeks serial time.

Conclusion: Darapladib decreased expression of NF-κB, Lp-PLA2, and level of LysoPC serum on 8 weeks of serial treatment time but increased on 16 weeks of serial treatment time. Pearson correlation test showed that serum and aortic tissue LysoPC level correlation was an inverse correlation.

Keywords: NF-κB, Dyslipidemia, LysoPC, Lp-PLA2

Introduction

Enzyme Lipoprotein-associated phospholipase A2 (Lp-PLA2) is a marker of arterial plaquedestabilization and can cause plaque rupture, myocardial ischemia, and the infarction(1-3). Enzyme Lp-PLA2 was also a marker of the lial dys function, which is the initial phase of atherosclerosis (4,5). Low-density lipoprotein (LDL) will oxidizing and become oxLDL(6,7). Receptor Lp-PLA2 was found in oxLDL. Lp-PLA2 will bind to its receptor and hydrolyze group of acyl short on position phospholipids sn-2 of oxLDL formed two mediators lipid bioactive, namely fatty acid oxidation (oxFA) lysophosphatidylcholine (LysoPC). LysoPC is a lipid mediator with known as proinflammatory and pro-atherogenic agent. It is believed to play an important role in atherosclerosis underlying cardiovascular diseases and several pathological conditions are associated with elevated LysoPC levels in the circulation(8).
The inhibitor enzyme Lp-PLA2 agent is considered capable of preventing atherosclerotic plaque formation\(^9\). There is more presence of active inflammatory cells and increased concentrations of Lp-PLA2 enzyme in unstable plaque, and that could be an important risk factor in the formation of atherosclerotic plaques and also in the process of the rupture\(^10\).

NF-κB has an important role in the early stages of atherogenesis. NF-κB modified the initial LDL lipids and the formation of inflammatory mediators, including secretory phospholipase A2, 5-lipoxygenase, 12-lipoxygenase, and COX-2. NF-κB also influences inflammation that occurs in atherosclerosis through the cytokines they produce, such as TNF, IL-1β, IL-6, IL-10, IL-12, and interferon-γ\(^11\).

Several studies prove that Lp-PLA2 is antiatherogenic and proatherogenic. In addition, it has developed preventive treatment of atherosclerosis through the Lp-PLA2 inhibitor. Based on the description above, it is very important to research to prove the provision of Darapladib as Lp-PLA2 inhibitor agents through the expression of Lp-PLA2, levels LysoPC tissue and serum, and the levels of the transcription factor NF-κB on dyslipidemia animal model divided in two serial times, that was 8 weeks and 16 weeks. The sample was sliced and stained in the Pathological Anatomy Laboratory, Faculty of Medicine, University of Brawijaya, Malang, Indonesia. Biochemical Parameters were measured at the Central Laboratory of Biological Sciences, Brawijaya University, Malang, Indonesia.

### Material and methods

#### Study Group

Thirty male Sprague-Dawley strain of *Rattus norvegicus*, two months of age, and weight around 150-200 g were obtained from Bogor Agricultural University, Bogor, Indonesia, and bred at Bioscience Central Laboratory of Brawijaya University, Malang, Indonesia. These rats were divided into three main groups. Those are Normal group: fed with rats food contained 3.44 kcal/g total calorie energy (67% carbohydrate, 21% protein, and 12% fat), Dyslipidemia group: fed with high-fat diet contained 5.30 kcal/g total calorie energy (58% fat, 17% carbohydrate, and 25% protein) and Dyslipidemia + Darapladib Group: fed with high-fat diet and given darapladib (purchased from GlaxoSmithKline) orally 20 mg/kg BW once a day. Each group consists of 2 serials treatment time: 8 weeks and 16 weeks. The sample was sliced and stained in the Pathological Anatomy Laboratory, Faculty of Medicine, University of Brawijaya, Malang, Indonesia. Biochemical Parameters were measured at the Central Laboratory of Biological Sciences, Brawijaya University, Malang, Indonesia.

#### Animal ethical approval

Ethical approval was obtained for the experimental animal processes in this study from the Animal Veterinary and had Committee Brawijaya University License Number 400/EC/KEPK/10/2016.

#### Lipid Profile Measurement

Measurement of total cholesterol concentration, HDL, and LDL / VLDL was done by the calorimetric method by using EnzyChrom AF HDL and LDL/VLDL Assay Kit (cat number: E2HL-100, Gentaur, Belgium)\(^12,13\).

#### Biochemical Test

The samples used were serum and aorta homogenates. Lp-PLA2 and NF-κB level were measured by immunofluorescence of aortic tissues that were previously fixated with PHEMO buffer and
were processed by immunofluorescence labeling with antirat antibody Lp-PLA2 using rhodamin secondary antibody and anti-rat antibody NF-κB using fluorescein isothiocyanate (FITC) secondary antibody (BIOS Inc., Boston, MA, USA). These parameters were observed with confocal laser scanning microscopy (Olympus Corporation, Tokyo, Japan) and were quantitatively analyzed using Olympus Fluov View software (version 1.7A; Olympus Corporation). LysoPC in serum level and aortic homogenate was measured with 1-palmitoyl-2-hydroxy-sn-glycero-3-phosphocholine (16:0) (Avanti Polar Lipids, Inc., 700 Industrial Park Drive, Alabaster, Alabama, USA).

**Statistical Analysis**

Statistical methods used in this study were Kolmogorov-Smirnov for normality test and Levene for homogeneity test. Whereas, for the significance test, we used One-way ANOVA to determine the effects of Lp-PLA2, LysoPC, and NF-κB expression in Sprague Dawley rats with dyslipidemia condition and treated by Darapladib. This analysis was continued by the *post hoc* test using the LSD method to detect the differences of parameters in each group. This study also used a correlation test to define the correlation of LysoPC aorta and Serum. Statistical analysis was performed with SPSS software version 20 (IBM Corporation, Armonk, NY, USA).

| P value | 0.043 | 0.000 | 0.001 | 0.010 | 0.040 | 0.000 | not significant |

Data were presented as mean ± standard deviation (range) values. All the values of the parameters have been corrected into the International Standard of Mathematics (decimals).

*p <0.05 indicates a statistically significant difference.

ANOVA = Analysis of Variance; HDL = High Density of Lipoprotein; LDL = Low Density of Lipoprotein; VLDL = Very Low Density of Lipoprotein; LysoPC = lysophosphatidylcholine; NF-κB = Nuclear Factor Kappa Beta; Lp-PLA2 = Lipoprotein-associated phospholipase A2; PAI-1 = Plasminogen Activating Inhibitor–1; aU = arbitrary Unit.

Table 1 and Table 2 showed that it is a significant difference in lipid profile (cholesterol total, HDL, and LDL) between normal, Dyslipidemia, and Dyslipidemia + Darapladib Group on both serial treatment time (p = 0.048). This table was also showed a significant increase in NF-κB and Lp-PLA2 expression in dyslipidemia group and a significant decrease in NF-κB and Lp-PLA2 expression in dyslipidemia + Darapladib group on both serial treatment time (p < 0.05).

Figure 1. Linear regression of LysoPC serum and LysoPC Aorta Level on both 8 weeks (A) and 16 weeks (B) serial treatment time.
Serum and aortic tissue LysoPC level correlation was an inverse correlation (Figure 1). The strength of serum and aortic tissue LysoPC level correlation was strong \((r = -0.651, r^2 = 0.424)\) for 8 weeks serial time and \((r = -0.83, r^2 = -0.689)\) for 16 weeks serial time.

There was a significant decreasing level of LysoPC Aorta \((p > 0.05)\) but an increasing level of LysoPC Serum \((p = 0.01)\) for 8 weeks of serial treatment time in Dyslipidemia Group. LysoPC Aorta and Serum levels were changed inversely at Dyslipidemia + Darapladib Group \((p < 0.05)\). However, for 16 weeks of serial treatment time, this study showed a different result than 8 weeks of serial treatment time. In the dyslipidemia group, there was a significantly increased level of both LysoPC Aorta and LysoPC Serum \((p < 0.05)\). On Dyslipidemia + Darapladib Group, LysoPC Aorta and Serum level were also changed inversely. Expression of NF-κB and Lp-PLA2, qualitatively observed using a confocal laser scanning microscope, can be seen in Figure 2.

![Figure 2](image-url)

Discussion

Lipid Fraction on High-Fat Diet Group

Lipid abnormalities fraction can be termed as dyslipidemia conditions. In the intestinal mucosal cells, free cholesterol is converted to cholesterol ester. Cholesterol ester joined to form VLDL triglycerides. VLDL then leave the heart and into the circulatory system. In the circulatory system, VLDL is converted to IDL by LPL and then into LDL. IDL and LDL are formed in the blood vessels can be entered into the endothelium of blood vessels or directly back to the liver. Ox-LDL phagocyted by macrophage cells. In macrophages, cholesterol esters hydrolyzed in to free cholesterol. Free cholesterol is brought to the surface of the cell membranes of macrophages and subsequently captured by HDL. Free cholesterol is converted into cholesterol esters and carried to the liver by HDL. This process will lead to the condition of Dyslipidemia.
There is a close relationship between the Lp-PLA2 enzyme and LDL, as well as a comparable and inverse relationship with HDL\(^{10}\). However, this study shows that the combination of Lp-PLA2 inhibitors and lowering hypercholesterolemia drugs gives better results to reduce dyslipidemia. This is because Lp-PLA2 inhibitors provide additional substances that can reduce LDL\(^{10}\).

Lp-PLA2 has a role in the pathogenesis of atherosclerosis and increases the risk of cardiovascular disease events\(^{16}\). Lp-PLA2 has been used as one of the early markers of atherosclerosis and as a therapeutic target\(^{17,18}\). Dyslipidemia conditions increase concentrations of LDL and VLDL in the plasma, thereby increasing the levels of Ox-LDL; fatty acids become oxidized fatty acids and will trigger an increase in free radicals. Increased Ox-LDL and oxidized fatty acids will stimulate an increase in Lp-PLA2 activity to convert it into LysoPC\(^{19,20}\). Receptor Lp-PLA2 was found in oxLDL, and Lp-PLA2 will bind to its receptor and hydrolyze the group of acyl short on position phospholipid sn-2 of oxLDL, formed two mediators lipid bioactive namely lysophosphatidylcholine (LysoPC) and fatty acid oxidation (Oxidized Fatty Acid/oxFA) which had an important role in the process of atherosclerosis\(^{21}\). Those products have proinflammatory effects that initiate and increase the progression of atheroma.

**Correlation Lysophosphatidylcholine (LysoPC) Level on aorta tissue and serum**

Lysophosphatidylcholine (LysoPC) is one of the Lp-PLA2 enzyme products which has the chemical formula \([(2R) -2-hydroxy-3 -[(9z,12z) -octadeca-9,12-dienoyl]oxypropyl]2- (trimethylazaniumyl) ethyl phosphate\ (National Center for Biotechnology Information. 2015). This study showed that in Dyslipidemia Group, there was a significant decreasing level of LysoPC Aorta (p > 0.05) but an increasing level of LysoPC Serum (p = 0.01) for 8 weeks of serial treatment time. And LysoPC Aorta and Serum level were changed inversely at Dyslipidemia + Darapladib Group (p < 0.05). However, for 16 weeks of serial treatment time, this study showed different results than 8 weeks of serial treatment time. In dyslipidemia group, there was a significant increasing level both of LysoPC Aorta and LysoPC Serum (p < 0.05). On Dyslipidemia + Darapladib Group, LysoPC Aorta and Serum level were also changed inversely.

**Serum and aortic tissue LysoPC level correlation** was an inverse correlation. The strength of Serum and aortic tissue LysoPC level correlation was strong (r = -0.651, r\(^2\) = 0.424) for 8 weeks serial time and (r = -0.83, r\(^2\) = -0.689) for 16 weeks serial time. That means the increase of the LysoPC serum level will decreasing the levels of LysoPC Aorta, and decreasing the LysoPC serum level will increase the levels of LysoPC Aorta. This correlation and linear regression pattern were shown in Figure 1A (for 8 weeks of serial treatment time) and 1B (for 16 weeks of serial treatment time). Lysophosphatidylcholine (LysoPC) is the main product of Lp-PLA2 activity, which can induce the synthesis of proteoglycans and play an important role in the thickening of the intimal layer of the endothelium\(^{22,23}\). In several studies, this LysoPC can stimulate proliferation apoptosis in endothelial and smooth muscle cells. LysoPC has also been instrumental in the recruitment of macrophages and differentiation of T cells into the arterial wall\(^{23,24}\). LysoPC is a chemotactic factor and led to the withdrawal of macrophages to the endothelium and induce the expression of adhesion molecules in endothelial cells mononuclear resulted in the initiation of lesions increased\(^{25}\). LysoPC performs its role in the pro-atherogenic process through this mechanism\(^{26,27}\).

**Nuclear Faktor Kappa Beta (NF-kB) expression and Lp-PLA2 on aorta tissue**

Table 1 and Table 2 were showed a significant increase (p < 0.05) in NF-kB expression in Dyslipidemia Group and a significant decrease in NF-kB expression in Dyslipidemia + Darapladib group on both 8 weeks and 16 weeks of serial treatment time. Excessive expression of NF-kB aorta is on the tissue will be very influential in the pathogenesis of atherosclerosis\(^{28}\). In the early
stages of atherogenesis, NF-kB plays a role in the modification of the initial LDL lipids and the formation of inflammatory mediators, including secretory phospholipase A2, 5-lipoxygenase, 12-lipoxygenase, and COX-2. NF-kB also plays a role in the expression of monocyte chemoattractant protein-1 (MCP-1), which plays an important role in the migration of macrophages into the extracellular matrix of the tunica intima.

Active NF-kB is also able to regulate some adhesion molecules, including P-selectin, E-selection, intercellular adhesion molecule-1 (ICAM-1), and vascular cell adhesion molecule-1 (VCAM-1)\(^ {11,29}\). After arriving in the extracellular matrix of the tunica intima, monocytes will soon turn into macrophages. This change involves a variety of macrophage colony-stimulating factor (CSF, M-CSF, or CSF-1). These factors are known to be regulated by NF-kB. This transcription factor also has a function in the regulation of matrix metalloproteinase-9 (MMP-9) were able to degrade the extracellular matrix that allows the migration of macrophages into the tissue. NF-kB also influences inflammation that occurs in atherosclerosis through the cytokines they produce, such as TNF, IL-1\(\beta\), IL-6, IL-10, IL-12, and interferon-\(\gamma\)\(^ {28,30}\). NF-kB is a protein complex that works as a DNA transcription controller. The protein is involved in cellular responses to external stimuli such as free radicals, ultraviolet radiation, oxidized LDL, stress, cytokines, and bacterial or viral antigens\(^ {31}\). Therapy with LpPLA2 inhibitor has succeeded in reducing the expression of NF-kB. NF-kB canonical pathway stimulated by reactive oxygen species (reactive oxygen species / ROS), lipopolysaccharide, and the signal from cytokine receptors such as TNF, IL-1, and Toll-like receptors. NF-kB pathway activated by specific proteins of the TNF family, such as lymphotoxin \(\beta\), factor B cell activation, and CD40 ligand. Stimulation of these proteins causes the translocation of NF-kB complex / RelB: p52 into the nucleus\(^ {32}\).

Table 1 (for 8 weeks) and Table 2 (for 16 weeks) were showed a significant increase (\(p < 0.05\)) in Lp-PLA2 expression in Dyslipidemia Group and significantly decreasing Lp-PLA2 expression in Dyslipidemia + Darapladib group on both 8 weeks and 16 weeks of serial treatment time.

Lp-PLA2 is a single chain glycoprotein member of the serine protease inhibitors (or serpins) family. Endothelial cells, smooth muscle cells, fibroblasts, monocytes/macrophages, adipocytes, endometrium, peritoneum, liver cells, mesothelial cells and cardiac myocytes could produce Lp-PLA2. Lp-PLA2 is a major stress-induced gene. Once synthesized, Lp-PLA2 is mainly stored in platelets and secreted to blood flow or deposited on the subendothelial matrix. The increased expression of Lp-PLA2 \textit{in vivo} suppresses fibrinolysis, consequently leading to the pathological fibrin deposition and then could cause tissue damage\(^ {33}\). Inflammatory cytokines (IL-6, IL-1, TNF-\(\alpha\)), growth factors, and hormones (insulin, glucocorticoids) also influence Lp-PLA2. Chronic inflammation, insulin resistance, and obesity influenced the expression of Lp-PLA2. Several studies had been demonstrated that fibrinolytic dysfunction (defined by Lp-PLA2 levels) mediates the increased risk of CVD in individuals with metabolic syndrome, and increased Lp-PLA2 concentrations have been found both in blood and in coronary plaques of metabolic syndrome patients\(^ {34}\).

**Conclusion**

Lp-PLA2 inhibitor (darapladib) has affected a fraction of lipids (LDL / VLDL and increase HDL) and decreased NF-kB and Lp-PLA2 expression on both 8 weeks and 16 weeks of serial treatment time. Lp-PLA2 inhibitor (darapladib) also decreased the level of LysoPC Serum on 8 weeks of serial treatment time but increased the level of LysoPC Serum on 16 weeks of serial treatment time. Serum and aortic tissue LysoPC level correlation was an inverse correlation. That means the increase of the LysoPC serum level will decreasing the levels of LysoPC Aorta, and decreasing the LysoPC Serum level will increase the levels of LysoPC Aorta. The strength of Serum and Aortic tissue LysoPC level correlation was strong for 8 weeks of serial treatment time and less strong for 16 weeks of serial treatment time.

Isolation and Selective Drug of Chose for Pseudomonas Aeruginosa as a Causative Agent in Suppurative Otitis Media

Thamer J Ghali1, Husam Oudah ALjwaid1, Ali A. Al-Hisnawi2-3, Kasim Sakran Abass4

1 Assistant Lecturer, 2 Lecturer, Department of Medical Laboratory Technique, College of Medical Technology, National University of Science and Technology, Thi-Qar, Iraq, 3 Assistant Professor, Department of Biology, College of Science, University of Kerbala, Kerbala, Iraq, 4 Professor, Department of Pharmacology and Toxicology, College of Pharmacy, University of Kirkuk, Kirkuk, Iraq

Abstract

Background: Chronic Suppurative otitis media (CSOM), is a chronic inflammation of the middle ear and mastoid cavity, which presents with recurrent (otorrhea) ear discharge through a perforated tympanic membrane. The bacterial cause for CSOM can include both aerobic and anaerobic bacteria, the most common microorganisms found in CSOM are Pseudomonas aeruginosa, Staphylococcus aureus, Proteus mirabilis, Klebseilla pneumonia, diphtheroid group, Citrobacter sp. and anaerobic bacteria and fungi like Candida sp as well as Aspergillus sp. P. aeruginosa was the most common iso (30500000) followed by S. aurease 27% (27 isolates), Proteus mirabilis 11% (11 isolates), E.Coli 11% (11 isolates), Klebseilla pneumonia 9% (9 isolates), respectively while other different species was 5% (5 isolates) and 2% (2 isolates) was fungi. Antimicrobial sensitivity for P. aeruginosa test by VITEK 2 System based on the main inhibitor concentration (MIC). The Piperacillin showed to be highly sensitive again P. aeruginosa 77.1% (27 isolation) followed by Meropenem, Imipenem, Levofloxacin and Amikacin 65.7% (23 isolation), 60% (21 isolation), 40% (14 isolation), 34.2% (12 isolation) respectively while Ciprofloxacin showed to be the less affected again P. aeruginosa 20% (7 isolation). Ceftazidime, Tobramycin and Ciprofloxacin were highly resistance 68.5% (24 isolation), 62.8% (22 isolation), 54.2% (19 isolation) respectively.

Keywords: Otitis media, P. aeruginosa, Antibiogram, Sensitive, Piperacillin

Introduction

Chronic Suppurative otitis media (CSOM), is a chronic inflammation of the middle ear and mastoid cavity, which presents with recurrent (otorrhea) ear discharge through a perforated tympanic membrane (1) depending on whether the disease process affects is classified into two types, tubotympanic the pars tensa and anticoanal or pars flaccida of the tympanic membrane (1,2) Incidence of the disease is higher in developing countries, especially among low socioeconomic societies because of malnutrition, overcrowding, poor hygiene, inadequate health care, and recurrent upper respiratory tract infections (2) The most important symptoms which make patients seek medical advice are hearing loss and suppurative drainage, reported in around 50% of the cases (3,4). CSOM is a persistent disease with high risk of irreversible complications which may range from persistent otorrhea, mastoiditis, labyrinthitis, and facial palsy to more serious intracranial
The bacterial cause for CSOM can include both aerobic and anaerobic bacteria, the most common microorganisms found in CSOM are *P. aeruginosa*, *Staphylococcus aureus*, *Proteus mirabilis*, *Klebsiella pneumonia*, diphtheroid group, Citrobacter sp., etc and anaerobic bacteria and fungi like Candida sp as well as Aspergillus sp. *P. aeruginosa* is one of the most predominant organisms to cause CSOM (10,11), with an incidence ranging from 21% to 52.94% (12).

The overall incidence of complications from otitis media is extremely low; infratemporal and intracranial complications occur in one in 100,000 children and in one in 300,000 adults per year (13,14). Patients with middle ear effusion may have persistent or fluctuating conductive hearing loss (14,15). Children with chronic middle ear effusion score lower on tests of speech, language, and cognitive abilities (15). Central perforation of the eardrum may cause chronic infection in the middle ear and mastoid cavity. Acute mastoiditis (i.e., pus in the mastoid air cells) may erode through the bone, forming a subcutaneous collection of pus (16). Contiguous spread or hematogenous seeding may infect the inner ear, petrous portion of the temporal bone, meninges, and the brain. Mastoiditis and intracranial complications of acute otitis media are more common in developing countries where persons have limited access to medical care (16,17).

**Material and Methods**

This study was carried out in the Department of Microbiology of Al-Haboby Hospital in Thi-Qar governorate. Total of 100 patients with bilateral and unilateral CSOM. All age and sex including in our study patient who had received antibiotics were excluded from the study.

**Sample collection**

Two sterile cotton swab was collated from patient ear discharge under aseptic precautions.

**Methods**

Case study and sample collected in Al-Haboby Hospital in Thi-Qar governorate. All age and sex including in our study patient who had received antibiotics were excluded from the study. Two sterile cotton swab was collated from patient ear discharge under aseptic precautions. One of swab was used for direct examination and gram staining and the second swab was used to culture onto Blood agar media, MacConkey agar media and nutrient agar media followed by incubation at 37 °C for 18-24 hrs Pseudomonas isolates and identified according to characteristic of colony morphology, pigment production and odor confirmed by VITEK 2 System for Identification and Antimicrobial Susceptibility Testing (bioMérieux).

**Procedure**

One of swab was used for direct examination and gram staining and the second swab was used to culture onto Blood agar media, MacConkey agar media and nutrient agar media followed by incubation at 37°C for 18-24 hrs Pseudomonas isolates and identified according to characteristic of colony morphology, pigment production and odor confirmed by VITEK 2 System for Identification and Antimicrobial Susceptibility Testing (bioMérieux) antibiotics tested were categorized into 6 classes.

Piperacillin (PRL), Meropenem (MEM), Imipenem (IM), Amikacin (AK), Gentamicin (G) Tobramycin (TOB), Levofloxacin (LVO), Ciprofloxacin (CIP), Cefoxitin (CEF), Cefazoline (CFA), Ceftriaxone (CRO), Cefazidime (CZM).

Discussion

Chronic Suppurative Otitis Media may lead to fatal intra-cranial and extra-cranial complications like facial palsy, brain abscess and meningitis if not adequately treated with (18,19). *P. aeruginosa* is the most common bacteria isolated from chronic supportive otitis media. This finding is in tandem with the observations by other studies (20). Our study was disagreement with other studies done by (21,22), that reported staphylococcus aureus was predominant causative agent in CSOM followed by *P. aeruginosa*.

Among the β-lactamase inhibitor antibiotics, Piperacillin was found to be the most effective antibiotic against *P. aeruginosa* this funding was agreement with (23) which recommended the use of combinations Piperacillin + Tazobactem were more effected against *P. aeruginosa* infections followed by Carbapenems Meropenem and Imipenem similar to the findings seen in studies done by (24,25). Among the Aminoglycosides, Sensitivity was seen with Amikacin (34.2%). This finding is in agreement with studies. Cephalosporins are common used in treatment of *P. aeruginosa* Ceftazidime and Ciprofloxacin were very high resistance against Chronic Suppurative
Otitis Media\textsuperscript{(26,27)}, Although Cefoxitin, Cefazoline, Ceftriaxone, and Ceftazidime were more effected in this family again \textit{P.aeruginosa} which is in contrast with study done be \textsuperscript{(28,29)}, which showed cephalosporins were highly sensitivity in Chronic Suppurative Otitis Media. Fluroquilonones, Levoflaxacin was (40\%) sensitive while Ciprofloxacin (20\%) was again \textit{P. aeruginosa} which is similar to the study done by \textsuperscript{(30,31)}.

**Conclusions**

In conclusion, this is the first paper that provided original data concerning a \textit{P. Aeruginosa} as a causative agent in suppurative otitis media. \textit{P.aeruginosa} is the most common bacteria isolated from chronic supportive otitis media. Among the \(\beta\)-lactamase inhibitor antibiotics Piperacillin was found to be the most effective antibiotic again \textit{P. aeruginosa}. Selective the correct antimicrobial will help in decreasing the complications of CSOM. \textit{P. aeruginosa} were found to be the common cause of CSOM in the present study. Furthermore, \textit{P. aeruginosa} was resistant to commonly used antimicrobials. piperacillin is a drug of chose in our study. Antibiogram of isolates is recommended in decreasing the complications of CSOM. Finally, in spite of this paper, further studies are required under different laboratories and different complement components compounds in order to improve and to increase our knowledge about this very interesting infection with \textit{P. aeruginosa}.

Abstract

Introduction: Present study is the study of epidemiology of poisoning cases brought for autopsy at tertiary health care centre in South-Western Maharashtra by finding out the incidence, pattern, sociodemographic factors, toxic agents, seasonal and other factors related to their deaths.

Material and Methods: Present study is a retrospective cross-sectional study done in mortuary of a tertiary health care centre in South-Western Maharashtra. Study included total 104 cases of death due to poisoning from Jan 2009 to Dec 2018 and the data collected from inquest papers, autopsy reports and regional forensic science laboratory reports was analysed using a structured proforma in Microsoft excel sheet.

Result: Out of 2570 medico legal autopsies conducted during the study period, deaths due to poisoning comprised 104 cases i.e. an incidence of 4.05%. Maximum deaths due to poisoning are found to be due to Intentional self-poisoning (suicides) and rural areas are more affected than the urban areas. Most commonly used toxic substance for poisoning is found to be pesticides and the maximum deaths occurred during the monsoon season. Gender-wise analysis shows that death due to poisoning is more common in males and majority of victims irrespective of their gender were married.

Conclusion: Study provides crucial information on various sociodemographic factors related to poisoning deaths in South Western Maharashtra which is relevant in understanding the causative factors behind the mortality due to poisoning and also helpful in devising preventive measure to reduce the loss of human life.

Keywords: Poisoning, Epidemiology, Autopsy, Suicide, Pesticides.

Introduction

Death by poisoning has been known since time immemorial. Some of the famous names and incidents such as Socrates, Meera Bai, Bhopal gas tragedy, Bradford sweet poisoning, Tokyo subway sarin attack and Punjab sweet poisoning, remind us of this dangerous threat to life. Death by poisoning whether intentional or unintentional is a significant global health concern as it is a major cause of worldwide mortality and morbidity. As per WHO estimates, in 2012 unintentional poisoning caused the loss of 193460 life’s and loss of 10.7 million years of healthy life all across the globe. Each year about 3.7 lac people lose their life by deliberate consumption

Email id – sandeep85w@gmail.com
of highly toxic pesticides and about 1 lac people become victim of fatal snake bite.\(^1\)

India is among the countries with high mortality due to poisoning and high incidence of suicide by farmers by pesticide consumption. About 50,000 people die in India every year due to poisoning as per the estimates.\(^2\) Mortality rate from poisoning in India varies from shocking 15 to 35%.\(^2\) The high incidence of farmer suicide has been plaguing the agricultural sector and is having a grave impact on our agriculture-based economy. Despite of being a highly debated issue and various measures like loan waivers for farmers, pesticide poisoning continues to be major contributor to the death by poisoning and much needs to be done to counter this menace.

Mortality due to poisoning varies from region to region and different regional studies have shown varying trends depending on multiple factors. Updated regional information on poisoning cases, availability of published data, regional poison information centers and robust surveillance system are must to significantly reduce the mortality and morbidity due to poisoning. Paucity of information on locally available toxic substances, population at risk, circumstances of poisoning is a hurdle in prevention of poisoning by targeted intervention programs and laws. Therefore, it is crucial to carry out region-based time to time review of poisoning patterns to help in reducing the mortality due to poisoning.

Present study aims at study of epidemiology of poisoning cases brought for autopsy at tertiary health care centre in South-Western Maharashtra by finding out the incidence, pattern, sociodemographic factors (i.e. age, gender, domicile and marital status), toxic agents, seasonal and other factors related to their deaths and to suggest preventive measures to avert loss of human lives due to poisoning.

**Material and methods**

This is a retrospective cross-sectional study done in mortuary of a tertiary health care centre in South-Western Maharashtra. All confirm cases of death due to poisoning from 1 Jan 2009 to 31 Dec 2018 were included in the study. Study included total 104 cases and data were collected from inquest papers, autopsy reports and regional forensic science laboratory reports. Ethical clearance was obtained from institutional ethical committee.

Data was entered in Microsoft excel sheet in a structured proforma consisting of age, gender, marital status, residence, type of substance causing poisoning, manner of poisoning, date, month and season of incidence and analysed. All the analysed data was presented in graphs, charts and tabular forms using the same software application.

**Results**

A total of 2570 medico legal autopsies were performed between Jan 2009 to Dec 2018 at the study centre. Deaths due to poisoning comprised 104 cases i.e. an incidence of 4.05% among the total autopsies conducted during the study period. Annual incidence rate of death due to poisoning was calculated for the study period and it showed a decreasing trend 2013 onwards. [Figure 1]
As per the manner of death, 93 (89.42%) cases were of suicidal poisoning, 8 (7.7%) cases were of accidental poisoning, 1 (0.96%) case of homicidal poisoning and in 2 (1.92%) cases, manner of poisoning was undetermined. [Figure 2]

Incidence of poisoning was found to be more common in rural areas (n=55, 52.88%) than in urban areas (n=49, 47.12%). [Figure 3]
The most common substances used for poisoning was found to be pesticides (n=79, 75.96%) and among them the commonest chemical used was organophosphates (n=54, 51.92%). [Figure 4]

The present study shows that maximum fatalities due to poisoning occurred during the Monsoon season (n= 49, 47.11%) and the month of March (n=14, 13.46%). [Figure 5]
FIGURE 5: DISTRIBUTION OF POISONING DEATHS ACCORDING TO SEASON AND MONTH

Study shows that death due to poisoning is more common among males (n=59, 56.73%) in comparison to females (n=45, 43.27%) with a male-female ratio of 1.3:1 and the most common age group affected is 21 to 30 years (n=34, 32.69%) irrespective of gender. [Table 1]

Most of the victims were married, both among the males (n=47, 79.66%) and females (n=35, 77.78%) constituting total 82 (78.85%) married cases. [Figure 6]
Discussion

Analysis of the data in the present study gives an incidence rate of 4.05\% for death due to poisoning out of total 2570 autopsies conducted during the study period. Review of literature shows that the incidence rate in the present study is less in comparison to other studies.\(^3\)\(^-\)\(^11\)

The decrease in annual incidence rate of death due to poisoning after 2013 reflects an optimistic trend encouraging both government and society to boost the ongoing efforts in countering this menace. However, the emerging trend of relinquishing agriculture related occupations among the people as a factor behind the decline in incidence rate cannot be ignored.

In present study maximum poisoning cases according to the manner of death are found to be suicidal (n=93, 89.42\%) followed by accidental (n=8, 7.7\%). Only 1 (0.96\%) case of homicidal poisoning death was reported during the study period and in 2 (1.92\%) cases manner of poisoning was undetermined. The results are similar to other studies in respect of manner of death.\(^3\)\(^-\)\(^13\)

Present study shows that incidence of poisoning is more common in rural areas (n=55, 52.88\%) than in urban areas (n=49, 47.12\%). The results are similar to findings of other studies\(^3\)\(^-\)\(^7\)\(^,\)\(^11\) except the study conducted in Kanpur\(^{[10]}\) where more poisoning deaths were found to occur in urban area. Rural population forms about 54.77\% of the total population of Maharashtra which explains the more occurrence of poisoning deaths in rural areas.\(^{14}\)

The most common substances found to be used for poisoning in the present study is pesticides (n=79, 75.96\%) and the results are in concurrence with findings of other studies.\(^3\)\(^,\)\(^6\)\(^-\)\(^12\)\(^,\)\(^15\) Among the pesticides the commonest chemical found to be used is organophosphates (n=54, 51.92\%) followed by herbicides (n=10, 9.6\%). Maharashtra’s economy is predominantly agrarian with agriculture as the mainstay which explains easy availability of pesticides in most of agriculture related households.\(^{16}\) Participation of community in implementation of preventive measures like central storage facility for pesticides at village level, regulation of sale by registered person and purchase by certified person, will help in reducing the incidence of death by poisoning. Seemingly small precaution
of storage of pesticides in locked cabinets under the supervision of responsible elder member of the family can be of great help in preventing death due to pesticide poisoning.

The study shows the occurrence of fatalities due to consumption of easily available household items like mosquito repellent (n=1, 0.96%), Lysol (n=1, 0.96%), carbolic acid (n=4, 3.85%), and antiseptic savlon (n=1, 0.96%). Review of literature shows that results are similar to other studies.10,11,12,15 These items are effortlessly available in most of the urban homes and are usually handled casually. Safe storage of these harmless appearing toxic chemicals can prevent tragic loss to the family.

Consumption of overdose of antipsychotic medicines led to death of 2 (1.96%) people in the present study. Review of literature shows similar results in study conducted at Thane 11 but the study conducted at Manipal 4 shows high number of deaths due to medicinal overdose. The variation is probably because of different socio-economic profile of victims.

Snake bite was responsible for death of 4 (3.85%) people in the present study and the results are similar to study conducted in Bangalore 12 but deaths due to snake bite were far more in study conducted in Jamnagar 3 and Berhampur 15. The reason for the difference is geographical variation of the regions. Use of innovative measure like wearing of knee length rubber boots in fields and solar powered snake repellent sticks could prove beneficial in preventing snake bite.

Study found that 2 (1.92%) people lost their lives due to exposure to toxic gases while working in the sewages. Review of literature reveals that past studies do not mention such poisoning deaths.3-13,15 Despite of the existence of laws prohibiting employment as manual scavengers in sewages, such incidents are still happening and are taking toll on human lives. Mandatory wearing of protective suits by sewage workers and strict legal action against defaulters is the need of the hour to prevent such mortalities.

Present study shows that maximum poisoning fatalities occurred during the monsoon season (n=49, 47.11%) followed by summers (n=31, 29.80%) which is different from the results of other studies carried out in different regions of the country where maximum poisoning deaths have occurred during the summers.6,7,9,10,12,15 The study region in the South western Maharashtra faces long but uneven rainy season from June to October. Damage to the Kharif crops caused by the unexpected floods due to excessive rainfall and hailstorms lashing the regions is one of the major factors impelling farmers to take the extreme step. Plight of the farmers is further compounded by the health expenses, children education expenses and mounting debts. The proactive preparation by the hospitals for the expected increase in poisoning cases during the monsoons and establishment of regional poison information centre will prove advantageous in reducing the mortality.

Gender-wise analysis shows that males died more due to poisoning in comparison to females constituting 59 (56.73%) and 45 (43.27%) cases respectively with a male-female ratio of 1.3:1. These results of the present study are in concurrence with other studies.5-11 Present study shows that most of the victims were married, both among the males (n=47, 79.66%) and females (n=35, 77.78%) constituting total 82 (78.85%) married cases and the results are in concurrence with other studies conducted.3-13 Study shows that married status of individual plays a significant role as the sought-after bliss of marital life brings along many responsibilities and unexpected problems requiring maturity, emotional and psychological support. Inability to cope up with the marital responsibilities and to resolve marital discord, are some of the factors impelling the individual to take the extreme step of ending his or her life. Pre-marital and post-marital counselling should be encouraged for couples which will be helpful in resolving marriage related problems.

Maximum deaths due to poisoning occurred in the age group of 21 to 30 years (n=34, 32.69%) followed by age group of 31 to 40 years (n=25, 24.03%). These findings are in concurrence with the results of other
studies but different to findings of study conducted at Bankura where the maximum deaths were found to occurred in age group of 40 to 49 years owing probably to socio-demographic variations. 21 to 30 years is the age group when the youth starts shouldering the various social and family responsibilities. The stresses created by the vagaries of life may push the individual towards committing suicide. Establishment of a suicide helpline by the government may prove to be an effective method in curtailing the mortality due suicidal poisoning.

Study shows that 11 [10.57%] seniors citizens lost their lives due to poisoning. Death by poisoning among the senior citizens is less in comparison to younger people and the findings are similar to other studies. Depression due to chronic illness and a sense of alienation among the senior citizens are the major factors driving them to take the extreme step of committing suicide. There is need of sensitization of society towards the emotional and psychological needs of the senior citizens.

Study highlights the age group of 11 to 20 years where death of 6 female teenagers outnumbers the death of 1 male adolescent due to poisoning. Death of the teenagers by intentional self-poisoning warrants serious concern by all parents. There is need of sensitization of parents to understand the teenage behaviour in this era of social media technology and address the issues with patience, open mind and compassion especially involving the females.

The least number of cases (n=3, 2.88%) were found to be in the age group below 10 years. Death of 2 children below the age of 10 years had occurred by accidental poisoning which could have been prevented by secure storage of toxicological chemicals at home. 1 male child below the age of 10 years had become the victim of homicidal poisoning by a female relative out of jealousy of not being able to conceive a male child. This reflects another disturbing aspect of our society necessitating introspection and change in the patriarchal mindset of people.

Conclusion

Present study shows the incidence rate of death by poisoning and provides important information about the sociodemographic profile of victims in South-Western Maharashtra covering the period from Jan 2009 to Dec 2018. Study also provides crucial information about the common toxic substances used for poisoning and seasonal variation in poisoning deaths in South-Western Maharashtra. The information obtained is not only valuable in understanding the causative factors behind the mortality due to poisoning in the region but also of paramount significance for devising of preventive measures which can be implemented by family members, panchayat, local community, hospitals and the government authorities in combating this grave health concern and averting the loss of human lives.

Abstract

Background: Prolonged QTc interval is one of the side effects of the short-regimen MDR-TB. QTc prolongation is a risk factor for Torsades de pointes and is influenced by many factors.

Case: 47-year-old woman who was diagnosed with MDR-TB through GeneXpert examination and received short-regimen MDR-TB. This patient experienced repeated QTc prolongation, with peak QTc interval 600 msec occurring at 4th month with mild hypokalemia without clinical symptoms. The patient completed 9 months of short-regimen therapy with improve chest x ray followed by negative sputum culture.

Conclusion: Short-regimen MDR-TB contains several drugs that cause QTc prolongation. Clinical evaluation is required in patients with QTc prolongation before changing the regimen.

Keywords: TB-MDR, QTc prolongation, Moxifloxacin

Introduction

Multidrug-resistant tuberculosis (MDR-TB) is still a world health problem and a threat to TB control globally. WHO estimates that there are about 3.3% new MDR TB cases and 20% MDR TB re-treatment cases. Several factors that contribute to the spread of MDR-TB, especially in endemic areas, include limited treatment options, high costs, ineffective and prolonged therapy. In 2016 WHO announced a short-term regimen for MDR-TB therapy that is expected to reduce costs, reduce costs and be effective for MDR-TB patients worldwide. This regimen consists of kanamicin, moxifloxacin, etionamide, clofazimin, pyrazinamide and high doses of INH for 4-6 months of the intensive phase and is followed by a follow-up phase consisting of moxifloxacin, clofazimin, pyrazinamide and ethambutol for 5 months (1, 2).

Although the short-term MDR-TB regimen brings new hope, this cannot be separated from the side effects caused by some MDR-TB drugs, one of which is the lengthening of the corrected QT (QTc) interval. QTc prolongation is a risk factor for the incidence of Torsades de Pointes (TdP) as well as arrhythmias that have the
potential to cause death. According to a review study the prevalence of sudden death due to TdP due to QTc prolongation due to MDR-TB drugs may be less than 1%. Electrocardiogram (ECG) monitoring is required in MDR-TB patients receiving short-term therapy, but in resource-limited areas this is neither a limitation nor a condition of using short-term MDR-TB regimens (2, 3).

The QT interval is the portion of the EKG that is calculated from the start of the QRS complex to the end of the T wave, it describes the time it takes for the ventricular myocardium to depolarize and repolarize or the time it takes the myocardium to replenish between heartbeats measured in seconds (s) or milliseconds (ms). The QT interval is influenced by heart rate, which can shorten at a fast heart rate and lengthen at a slow heart rate so the QT interval needs to be corrected. The QT or QTc correction formula is needed to estimate the QT interval at a heart rate of 60 times a minute. The normal value of QTc in men <450 ms and in women <470 ms (4, 5).

Fluoroquinolones (FQ) are one of the most effective mycobactericidal classes. FQ has also been noted to cause prolongation of QTc and TdP especially in the elderly population. All FQ can be used for MDR-TB treatment including Levofloxacin (Lfx) and Moxifloxacin (Mfx). Mfx was noted to be the FQ that caused more QTc lengthening than the other FQs (5, 6). Based on the above description we are interested in reporting a recurrent case of MDR TB and QTc prolongation interval in a woman.

**Case Presentation**

A 47-years-old woman with a previous history of failure to treat category 1 OAT was diagnosed with rifampicin-resistant pulmonary TB by geneXpert examination. The results of the x-ray examination obtained the results according to figure 1. Patients received MDR TB therapy including Kanamicin (Km) 750 mg, moxifloxacin (Mfx) 600 mg, clofazimine (Cfz) 100 mg, Ethionamid (Eto) 500 mg, isoniazid (H) 600 mg, pyrazinamide (Z) 1500 mg and ethambutol (E) 800 mg. Before starting therapy, the patient was previously carried out a baseline examination, including a complete laboratory examination, electrocardiogram (EKG), audiometry and psychology.

After receiving therapy for 1 week the patient experienced prolonged QTc interval 545 msec, without laboratory abnormalities or clinical symptoms. Mfx was stopped for 3 days and an EKG was evaluated every day. After the QTc interval returned to normal (411 msec), Mfx was started at a dose of 400 mg. A week later the QTc interval of 468 msec and Mfx was again given at a dose of 600 mg while evaluating the ECG (Figure 2 & Table 1).

When entering the advanced stage of therapy, the patient again experienced a prolonged QTc interval of 600 msec so that Mfx was temporarily stopped and a laboratory evaluation was carried out. The laboratory results at that time showed that the patient had mild hypokalemia with a potassium value of 3.2 mmol/l. After correction of hypokalemia the QTc interval returns to normal and Mfx is started again at a dose of 200 mg for 7 days, and then continued at a dose of 400 mg until the end of therapy.

Entering the 7th month of therapy, the patient again experienced a prolonged QTc interval of 539 msec, without clinical symptoms and laboratory abnormalities (potassium 3.7 mmol/l). Currently Mfx is still given at a dose of 400 mg but the Cfz dose is reduced to 50 mg/day. After a week of evaluation the QTc returned to normal and Cfz was again given at a dose of 100 mg/day until the end of treatment. The patient had conversion of Acid-fast bacilli at 4th month followed by negative sputum culture until the end of therapy. The patient experienced clinical and radiological improvement, at the seventh month the treatment was completed and the patient was declared cured.

Figure 1A. Chest X-Ray at baseline; B. Chest X-Ray after 6 month therapy; C. Chest X-Ray end of therapy
Discussion

Prolonged QTc interval greater than 500 msec is generally thought to increase the risk of developing TdP in the majority of the group with congenital long QT syndrome. The risk of TdP or sudden death is not always directly related to the length of the QT interval or the duration of QTc prolongation during therapy, but it can still be influenced by many factors. Drug-induced QTc prolongation has different properties from drug to drug. All FQs were noted to cause QTc prolongation, but according to case reports Mfx has the greatest risk of causing QTc prolongation\(^2,3\). The risk of QTc prolongation with FQ will be higher if there are electrolyte abnormalities and the use of other drugs that cause QTc prolongation\(^5,6\). In this case, when the patient experienced QTc lengthening of 600 msec, there was also mild hypokalemia (potassium 3.2 mmol/l). Apart from stopping Mfx we also provide potassium intake to the patient.

A 2018 Indian study involving 467 patients receiving the Mfx regimen after a 4-month evaluation did not show a significant increase in QTc. Although there were 5 patients who experienced prolonged QTc interval, Mfx had to be temporarily stopped and given again without experiencing a cardiac event. According to the study Mfx 400 mg daily given for 4 months did not cause prolonged QTc interval\(^7\).

In a South Korean study of 373 MDR-TB or NTM-TB patients receiving Mfx, Cfz and macrolide therapy, significant QTc prolongation occurred in 16.7% of patients with a maximum QTc value of 451 msec and a mean QTc lengthening of 33.6 msec from baseline.
This study concluded that drug combinations that cause QTc changes in MDR-TB or NTM therapy are generally safe to use\(^8\). Although Mfx significantly caused QTc prolongation it was of moderate duration with a mean increase of 4\% in the therapeutic dose of 400 mg. The effect of Mfx on ventricular repolarization occurs primarily at times of maximum plasma concentration, but QTc prolongation may be decreased with repeated administration, therefore the risk of TdP is small at 400 mg/day\(^9\). In this case, QTc prolongation still occurred in the advanced phase of therapy even though Mfx had been given at a dose of 400 mg/day, this might occur because the patient was still receiving other drugs that caused QTc interval lengthening, which is Cfx. After receiving low dose Cfx (50mg/day), QTc returned to normal. Although the evidence is limited, Cfx has been noted to increase QTc interval between 10-20 msec\(^10\).

Apart from FQ, there are several antibiotics used in MDR-TB therapy that are associated with prolongation of the QTc interval, such as bedaquiline, delamanid, and Cfx. The safety of using Mfx together with any of these drugs in MDR-TB therapy requires further clinical evaluation (Table 2). Until now, the incidence of TdP in clinical trials of TB patients is very rare, because the field conditions are difficult to evaluate for cardiotoxicity\(^10\). One study showed that the risk of Mfx-associated QTc prolongation was increased in individuals with certain genotypes\(^11\).

**Conclusion**

QTc prolongation is one of the side effects of the short-term MDR-TB regimen. This can be related to several factors, including the combination of several drugs that cause QTc prolongation, and certain clinical conditions, especially electrolyte disturbances. Although the incidence of TdP associated with QTc prolongation in MDR-TB therapy is rare, ECG evaluation in patients receiving short-term MDR-TB therapy is needed. Therefore a clinical evaluation should be carried out in patients experiencing QTc prolongation before stopping or changing their MDR-TB treatment regimen.

Abstract

Accidents in a workplace are caused by many human errors in form of unsafe behavior. One of the efforts to prevent work accidents is to improve safety performance in form of participation and obedience. Improvement of safety performance in workplace is affected by management and individual factors. Management factor is mainly associated with safety management practices while individual factor is associated with individual characteristics and occupational health and safety knowledge and training. This study aims to analyze the effect of individual factors and safety management practices on safety performance among workers at PT. Masmindo Dwi area. This research is a quantitative research using analytic observational and cross sectional design which was conducted in November-December 2020. Interviews were conducted on 72 workers out of 289 workers. The methods used in assessing safety management practices, individual factors and safety behavior are questionnaires, observation and interviews. The results showed that there is a direct (p=0,024) and indirect effect (p=0,001) of safety management practices on safety performance with safety knowledge as a mediating variable. Writer highly advise that in improving safety performance, the management have to be consistent, show commitments to safety rules and procedures that have been made, improve safety training programs, and increase the quantity and quality of training programs.

Keywords: safety performance, safety knowledge, safety management practices

Introduction

Indonesia has various industrial sectors, one of them is mining which included the mineral and coal mining industry. The mineral and coal mining industry in developed and developing countries has implemented sophisticated technology but the dangers and risks faced by this field of work are still there, as evidenced by the many accidents of work occurred in the mining sector.

Statistical Data of Mine Safety and Health Administration noted that injuries which occurred in US coal mines in 2007 reached 3,203 cases with the number of cases in open cut-mining reaching 733 cases or 23% of the total injuries¹. In Indonesia, the incidence of work accidents in the mining sector is also still experiencing a significant increase every year. Based on data from the Ministry of Energy and Mineral Resources (ESDM) on all mining companies in Indonesia as per September 30, 2019, it showed that the total mining accidents that occurred from 2012 to 2019 were 1,318 cases, consisting of 194 accidents resulting in death, 674 serious work accidents and 450 minor work accidents².

Heinrich et al. argued that generally work accidents might occur due to two main factors, namely unsafe working conditions and unsafe behaviour\(^3\). Research by Kamilah shows that there was a significant corelation between unsafe behaviour and the incidence of work injuries on construction workers\(^4\). The Ministry of Energy and Mineral Resources also conducted an analysis upon the results of investigation of mining accidents which resulted in death during 2012 – 2019\(^2\). The analysis showed that 19% the causes of the accidents were from unsafe behaviour factor, specifically due to not following applicable work procedures (SOP). Then the analysis continued on personal factors which became the leading causes, with 52%. Most of it were due to lack of knowledge related to safety. In addition, another 19% came from the occupational factors due to job hazards that had not been well identified and 18% due to insufficient leadership and supervision. According to Hughes and Ferret, a person’s behaviour can be influenced by factors from the individual himself, both the conditions and their own characteristics\(^5\).

The government has shown its commitment to reduce the number of work accidents and protect the safety and health of mining workers by issuing several policies related to occupational safety and health in mining sector. Ministry of Energy and Mineral Resources has obliged all mining companies to implement SMKP (Safety Management System for Mining) which is a derivative of the Occupational Safety and Health Management System (SMK3). The success of implementing occupational health and safety regulations in a company will never be separated from the personal compliance attitude of both employees and managerial parties in implementing OHS-related regulations and policies. The role of employees is of course very much needed to support the success of occupational health and safety management efforts, by displaying safety performance\(^6\).

Safety performance is a performance that is measured based on a person’s safety related behaviour. According to Neal & Griffin, safety performance is formed from Safety Compliance and Safety Participation\(^7\). Safety compliance is safety performance carried out by employees in maintaining safety, while safety participation is employee behaviour to participate in safety activities or safety behaviour.

PT. Masmindo Dwi Area (PT.MDA) is the only company holding a 7th Generation of Work Contract which engaged in gold mining with its working area in Latimojong District, Luwu Regency, South Sulawesi Province with area of 14,390 hectares square. The majority of PT MDA employees work on fields where the risk of accidents is very high due to the use of many heavy equipment, high-risk work locations (mountains and adjacent to ravines), several drilling activities that requires precision in carrying out the work and unsafe environmental conditions.

The results of previous observations by the author, there were still several work locations with unsafe conditions which pose risk of work accidents and even fatality. Likewise, the safety performance of workers was still low which could be seen from the poor compliance of workers in implementing company OHS-related rules and SOPs and also the lack of safety participation in reminding or reprimanding working colleagues who did not comply to safety.

Safety management practices are practices, roles and management functions designed by companies to improve employee safety, which consists of 6 dimensions, namely management commitment related to safety, safety training, employee involvement in solving safety problems, safety communication, safety regulations and procedures and safety promotion policies. Vinodkumar and Bhasi found that safety management practices had an effect on safety performance, through safety knowledge\(^8\). Based on the explanations above, this research aimed to determine the effect of safety management practices through safety knowledge as an intervening variable towards safety performance on workers of PT. Masmindo Dwi Area.

**Materials and Method**

This research was conducted at the Awak Mas Site, the Contract of Work area of PT. Masmindo Dwi Area.
(MDA), Luwu Regency. The type of this research was observational using a cross-sectional study design.

The population was all workers at Awak Mas site of PT. Masmindo Dwi Area. 72 people from several departments were then selected as samples by using proportional stratified random sampling who already stated their willingness to participate in this study by signing the informed consent that had been issued by the Ethics Committee of the Hasanuddin University Faculty of Public Health.

Data collection was carried out by researchers. Safety management practice data including management commitment, safety training, worker involvement in safety, safety communication and feedback, safety rules and procedures, safety promotion policies, safety knowledge and safety performance were measured by interview using a questionnaire.

Individual factor data and frequency distribution were processed using SPSS 21 for windows. To assess the effect of safety management practices towards safety performance, a multivariate “path analysis” was conducted using the smartPLS application.

Table 1 shows the distribution of respondents based on departments at PT. Masmindo Dwi Area. The most respondent came from Department of Geology with 12 people (16.7%). Then the most age group was in the old age (≥25 years), 62 people (86.1%), the most sex was male, 66 people (91.7%), the most work period was the oldone (≥ 1years), 43 people (59.7%). Then, based on the latest education, the most recent education was high school, 39 people (54.2%) and based on the health status category, the most respondents were in fit to work health status category, 39 people (54.2%).

Meanwhile, based on safety management practice indicators, management commitment variable was rated the most in good category by 65 respondents (90.3%), safety training was rated the most in good category by 64 respondents (88.9%), worker involvement was rated the most in good category by 70 respondents (97.2%), safety communication was rated the most in good category by 58 respondents (80.6%), safety rules and procedures were rated the most in good category by 49 respondents (68.1%), and safety promotion policies was rated the most in the good category by 38 respondents (52.8%).

The overall safety management practices were assessed by respondents to be in good category by 59 people (81.9%), safety knowledge was rated the most in good category by 58 people (80.6%) and safety performance was rated the most in good category by 56 people (77.8%).

Table 2 shows that out of 72 respondents, there were more workers who rated safety management practices in good category with good safety performance, 54 people (91.5%) compared to workers who rated safety management practices in poor category with poor safety performance, 11 people (84.6%). Furthermore, workers who have more safety knowledge tend to portrays good safety performance, 52 people (89.7%) compared to workers with poor safety knowledge who also tend to have poor safety performance, 10 people (71.4%).

![Figure 1 The Effect of Safety Management Practices Toward Safety Knowledge](image)

Figure 1 shows the research result model using path analysis. The analysis found that the effect of safety management practices towards safety knowledge has a value of $p = 0.011$ with an estimated contribution of 2.558, safety knowledge towards safety performance has a value of $p = 0.000$ with an estimated contribution of 4.397 and safety management practices towards safety performance has a value of $p = 0.024$ with an estimated contribution of 2.272. Then the results of simultaneous analysis of the safety management practices towards safety performance through safety knowledge have a value of $p = 0.001$ with an estimated contribution of 3.194.

**Discussion**

Work accidents generally can occur due to 2 main things, namely unsafe working conditions and unsafe behaviour. Safety Performance or safety behaviour can refer to safety related behaviour. In the occupational safety model at workplace by Christian et al. shows that safety performance antecedents are classified into individual factors and situational factors that are mediated by safety knowledge and safety motivation\(^9\). Situational factors are related to safety climate and safety leadership\(^10,11\).

The results explained before were in line with the statements of Vinodkumar and Bhasi who found that safety management practices had influence on safety performance\(^8\). Apart from being in line with the theory put forward by Vinodkumar & Bhasi, the results of this study were also in line with research by Froko et al. which found that there was a positive correlation between safety climate and safety performance that could predict compliance and safety participation\(^12\). Safety management practices had direct significant influence towards safety performance through its six indicators consisting of management commitment, safety training, worker involvement in solving safety problems, safety communication and feedback, safety rules and procedures, and safety promotion policies. Based on the results, most workers assessed that safety
management practices and safety performance were classified as good. This meant that management had maximized the implementation of safety management practices in order to improve worker safety performance so that work accidents could be avoided. However, even though it was dominated by workers with good safety performance, management also needs to pay attention to workers who had not been able to behave safely by assessing aspects of safety management practices which still could be improved.

Based on the observations result, the safety management practices at PT. Masmindo Dwi Area had been demonstrated properly based on safety management practice indicators. Management commitment indicators were shown through the application of the mining safety management system and the making of mining safety policies. Syamtinningrum suggests that OHS management in terms of commitment had a significant influence on unsafe behavior13. Safety training indicators were manifested through routine training for workers including refresher training. According to Saputra, workers who received training have a greater tendency to act and behave safely while working. Involvement of workers in safety at PT. MDA was demonstrated through the establishment of the Mining Safety Committee which was formed as a safety discussion forum for all workers through representatives of each department14. Safety communication and feedback at PT. MDA was demonstrated through the safety induction program, safety talk, pre shift meetings, and other safety programs. Geller states that one of the factors in behaviour that affects compliance in the safety triad theory is communication15. Based on this theory, it can be concluded that communication has an influence on the obedient behaviour of workers in the aspect of safety performance. Then the safety rules and procedures indicator were shown through making safety rules such as camp rules, standard operating procedures, working instructions, etc. However, even though management had maxed out the rules, there were workers who violate the rules and exhibit unsafe behaviour. The last indicator, namely the safety promotion policy. At PT.MDA, this indicator considered to be quite good but not optimal. This was because the safety reward and punishment program had not been implemented properly. Whereas Vredenburgh states that safety promotion policies which related to safety incentive programs could motivate employees to prioritize safety hence their safety performance might increase16. Maharja also said that reward system in the workplace affects the worker’s safety behaviour17.

Besides, Vinodkumar and Bhasi state that safety management practices affect safety performance through safety knowledge8. This study also shows results that were in line with Novi’s research and also research by Griffin and Neal which states that safety knowledge could mediate the correlation between safety climate and safety performance18,19. The significance in this study indicates that the good safety management practices at PT. MDA causes workers’ knowledge to improve where it led to a good safety performance. Safety knowledge was strongly related by employees’ knowledge of safety procedures that were applied in the company. With safety knowledge, workers would be more aware of unsafe environments. Having knowledge would tend came with the application of attitudes, and this plays an important role in reducing the rate of work accidents19.

The results showed that the majority of workers who rated safety management practices as good, also had good safety knowledge and had good safety performance. These results could conclude that if safety management practices were maximally implemented through the indicators such as management-made commitments then socialized to workers, safety trainings that were carried out routinely, involvement of workers in safety decisions making, good safety communication, rules and regulation and safety procedures were well made and enforced and also safety promotion policies through reward and punishment programs were also maximized, hence employees would possess and develop good safety knowledge and so in vice versa. In accordance with the results of the interview, worker’s knowledge about safety was in good category since PT. MDA had several OHS programs in improving safety knowledge which
was also closely related to safety management practices, namely safety training and safety communication.

**Conclusion**

As the result that had been presented previously, we could conclude that there was a direct and indirect effect of safety management practices towards safety performance through safety knowledge as an intervening variable. Researchers would like to suggest PT. Masmindo Dwi Area to increase and maintain workers to actively participate in the safety programs, management was also expected to increase the socialization of all programs related to safety management practices and to improve the quantity and quality of safety training for new workers as well as the refresher training.

Decreased Antioxidant Capacity in Corn Farmers Occupationally Exposed to the Mixture of Herbicides

Unchisa Intayoung1, Kanyapak Kohsuwan1, Klintean Wunnapuk2, Ratana Sapbamrer3, Supakit Khacha-Ananda4

1Graduate Student, 2Assistant Professor, Department of Forensic Medicine, Faculty of Medicine, 3Associate Professor, Department of Community Medicine, 4Instructor, Department of Forensic Medicine, Faculty of Medicine, Chiang Mai University, Chiang Mai, Thailand, 50200

Abstract

Background: The application of herbicides has been a common practice in worldwide agriculture, mainly with the goal to increase efficacy of weed control. So, most farmers faced a greater risk of herbicide exposure to develop adverse health effects from oxidative stress-induced herbicides. The aim of this study is to determine the urinary total antioxidant capacity (TAC) and 8-isoprostane levels in farmers using the mixture of herbicides in Long District, Phrae Province, Thailand.

Methods: Ninety-three participants were recruited. The spot urine samples (pre- and post-work) were collected. The urinary TAC was determined using ABTS radical scavenging assay. The urinary 8-isoprostane level was investigated by commercial ELISA kit.

Results: Most farmers worked on a farm during 1-5 h/day. Fifty-five percents of participants used the mixture of herbicide while working between glyphosate and paraquat as well as glyphosate and 2,4-D. The urinary TAC levels in pre-work urine sample of farmers applied combining herbicides were significantly higher than that level in their post-work urine sample. However, there was no significant difference between pre- and post-work urinary 8-isoprostane in farmers applied combining herbicides.

Conclusion: The results suggest that occupational exposure to mixture of glyphosate herbicides plus paraquat or 2,4-D could induce abnormal oxidative stress value especially antioxidant defense among agricultural workers.

Keywords: 8-isoprotane, Glyphosate, Paraquat, Total antioxidant capacity (TAC)

Introduction

Herbicides are being widely used for control the growing of weeds in agricultural activities1. Although herbicides are totally beneficial for agricultural activity, they are crucial sources of environmental pollution and exert irreversible adverse health outcomes both short- and long-term effects. The exposure of herbicides in workers generally caused from unintentional direct consumption, direct contact to skin due to improper application, inhalation of aerial sprays, or contaminated food consumption2. In the case of Thai farmers, there has been reported to have the high risk for herbicide exposure during occupation since most farmers practically apply high volume of the herbicide mixtures than recommended dosages for increase capability of weed control. As a result, these farmers faced greater risk of exposure to herbicides and development of adverse health effects3. The imbalance between oxidant and antioxidant defenses known as oxidative stress has been proposed as a key player in accounting for
herbicide toxic effect\(^4,5\). The overproduction of oxidants especially reactive oxygen species (ROS) caused adverse modifications to cell components such as lipids, proteins, and DNA damage. Lipid peroxidation is a one process of cell membrane-attacked ROS\(^6\). The by-products of this process such as malondialdehyde (MDA), propanal, hexanal, and 8-isoprostane were released and detected into various biological fluids\(^7\). In addition, the excess ROS was scavenged by effective protective mechanisms using antioxidant substances for preventing the attack of ROS on biomolecules and cells\(^8\).

Previous studies demonstrated that the increase of lipid peroxidation by-product (8-isoprostane) was induced in corn farmers exposed with mixtures of herbicide usage between atrazine and 2-(2,4-dichlorophenoxy) acetic acid (2,4-D)\(^9,10\). Available studies about antioxidant defense has been reported that superoxide dismutase (SOD), catalase (CAT), glutathione reductase (GR) level was significantly decreased in herbicide-exposed workers\(^11,12\). Hence, the investigation of oxidative stress status in farmers who occupationally exposed with mixture of herbicides need to be focused for health status evaluation. In the present study, we hypothesized that the imbalance between reactive substance in forms of 8-isoprostane and antioxidant activity could be induced by mixture of herbicides (glyphosate or paraquat or 2,4-D). The main objective of this study was to determine the urinary 8-isoprostane and TAC levels in farmers using of the group of herbicides during agricultural activities in Long District, Phrae Province.

**Material and Methods**

**Ethical approval**

This study was approved by the Ethics Committee of the Faculty of Medicine, Chiang Mai University, Thailand (Study code: FOR-2562-06349). All subjects were informed about the protocol of this study and signed the consent form according to the guidelines of the Faculty of Medicine ethical committee.

**Location and population**

This study was conducted in Long district, Phrae province, Thailand. Ninety-three participants were eligible for this study. The inclusion criteria consisted of 1) farmers aged between 30 to 60 years 2) have been using combination of glyphosate or paraquat or 2,4-D during the study period 3) have never been diagnosed with kidney disease, diabetes and gout. All individuals were interviewed face-to-face using a questionnaire documenting their sex, working hours on the farm, year of work, and type of herbicide usage. All participants were divided into two groups based on the type of herbicide use 1) single application; farmers who applied only glyphosate 2) combined application; farmers who applied the mixture of herbicides in the group of glyphosate or paraquat or 2,4-D.

**Urine sample collections**

The spot morning urine before work (pre-work) and next morning urine after working (post-work) were collected from each participant. All samples were stored at -20°C prior the quantification of urinary creatinine, 8-isoprostane, and total antioxidant capacity (TAC)\(^13\).

**Quantification of urinary creatinine levels**

The urinary creatinine level was determined by colorimetric assay of Jaffé method\(^14\). In brief, 50 µL of urine samples (dilution 1:50) was mixed with 200 µL of working solution (1:1 of 4.365 mM picric acid (Sigma-Aldrich, USA) and 0.25 M sodium hydroxide (Sigma-Aldrich, USA)). After 45 min of reaction times, the absorbance of the orange-red creatinine picrate reaction product was measured at a wavelength of 492 nm using microplate reader (Synergy™ H4, BioTek Instruments, Inc., USA). The level of urinary creatinine was calculated by comparing with creatinine standard curve and expressed as mg/dL.

**Quantification of urinary 8-isoprostane levels**

The urinary 8-isoprostane were measured using commercial ELISA kit (Abcam, UK) according to the manufacturer’s instructions. The assay is based on the competitive ELISA between 8-isoprostane in sample and reference for binding to the primary antibody. The level
of urinary 8-isoprostane was calculated by comparing with 8-isoprostane standard curve and expressed as ng/mg creatinine.

**Quantification of urinary total antioxidant capacity (TAC) levels**

The urinary TAC was determined using ABTS radical scavenging assay\(^\text{15}\). Fresh ABTS\(^\bullet+\) solution was prepared by the mixture between 1.0 mM of AAPH and 2.5 mM of ABTS dissolved in 100 mL of phosphate buffer solution (PBS), pH 7.4. The mixture was incubated at 70°C for 30 min. Five microliters of urine sample was mixed with 245 µL of ABTS\(^\bullet+\) solution and incubated at 37 °C for 10 min. The color reaction was measured at a wavelength of 734 nm by microplate reader (Synergy™ H4, BioTek Instruments, Inc., USA). The urinary TAC level was calculated by comparing with ascorbic acid (Biochemica, Scotland) standard curve and expressed as mg vitamin C equivalent/L (mg VCE/L).

**Statistical Analysis**

The statistical analysis was conducted using the SPSS for Windows (Version 16.0. Chicago, SPSS Inc; 2007) and the GraphPad Prism (version 8.3.0 for windows, GraphPad Software, San Diego, California USA, www.graphpad.com). All demographic data (gender, working hours in farm, year of work, and type of herbicide usage) were analyzed by descriptive statistics. The levels of 8-isoprostane and TAC were calculated by comparing between pre-work and post-work urine samples using the Wilcoxon signed-rank test.

**Results**

Ninety-three participants were randomly recruited from five villages in Thung Lang subdistrict, Long District, Phrae province. The characteristics of these participants are shown in Table 1. The majority of participants were male (62.36%). Sixty-two percent of farmers worked on a farm during 1-5 h/day. Most of the participants worked for at least 20-40 years (60.44). Approximately 55.91% of farmers used the single type of herbicides (glyphosate) and 44.09% of farmers used the mixture of glyphosate plus paraquat or 2,4-D.

To determine oxidative stress in subjects, the finding of urinary TAC in all participants is shown in Figure 1. The urinary TAC level in the pre-work and post-work urine samples of farmers who used single herbicide was ranged between 0.08 – 1.04 and 0.15 – 1.30 VCE/L, respectively. The urinary TAC level in the pre-work and post-work urine samples of farmers who used the mixture of herbicides was ranged between 0.10 – 1.42 and 0.10 – 1.28 VCE/L, respectively. The urinary TAC levels in pre-work urine sample of farmers used combination of herbicide were significantly higher than that level in the post-work urine sample. However, there were no significant differences of the urinary TAC levels between the pre-work and post-work sample in farmer who used single herbicide.

To determine the lipid peroxidation, the urinary 8-isoprostane was measured using commercial ELISA kit. The urinary 8-isoprostane level is shown in Figure 2. The urinary 8-isoprostane level in the pre-work and post-work urine samples of farmers who used single herbicide was ranged between 119.6 – 242508 and 80.02 – 249859 pg/mg creatinine, respectively. The urinary 8-isoprostane level in the pre-work and post-work urine samples of farmers who used the mixture of herbicides was ranged between 230.0 – 11164 and 168.6 – 4601 pg/mg creatinine, respectively. There was no significant difference between the urinary 8-isoprostane in pre-work and post-work sample of both groups (single and combination of herbicides use).

Figure 1 Box-plot demonstrating urinary TAC in herbicide-exposed farmers in the pre-work (open bar) and post-work (solid bar) urine sample. The line through the middle of the boxed represents the median of urinary TAC and the top and bottom of each box represents the first and third quartiles. The lower and upper error bars are computed as the lower and upper quartiles. *The TAC level was significantly different between the groups (P < 0.05).
Discussion

Occupational exposure of herbicides has been reported to induce several health outcomes. The mixing two or more herbicides together was practically applied in the farms rather than the single use of herbicide. Previous report revealed that glyphosate herbicide was mostly used in a mixture with other herbicides to enhance its potency for weed control\textsuperscript{16}. Therefore, it was probable that the farmers who applied the mixture of herbicides were at high risk of developing negative health effects resulting from oxidative stress-induced herbicides. The oxidative stress biomarker of lipid peroxidation, (8-isoprostane) and antioxidant defenses (TAC) indicating the imbalance of oxidative stress were determined this study. Our result found that the the urinary TAC levels in pre-work urine sample of farmers used combination of herbicides were significantly higher than that level in the post-work urine sample. The decrease of urinary TAC level could be indicative of oxidative stress or increased susceptibility to oxidative damage. Many classed of herbicides exerted the ability to generate reactive species, especially oxygen species molecules. Chronic oxidative stress could also reduce body antioxidant resources leading to lower antioxidant levels\textsuperscript{17}. Moreover, the level of two antioxidant substances; superoxide dismutase (SOD) and glutathione reductase (GR) was decreased in pesticide sprayers\textsuperscript{18}. Occupational exposure to pesticides among soybean farmers has been found to exert adverse effects at the biochemical level by observation of the alteration of antioxidant capacity in terms of ferric-reducing ability of plasma (FRAP) during exposure periods\textsuperscript{19}. According to the study of Ojha et al. 2011\textsuperscript{20} the level of antioxidant enzymes including catalase, superoxide dismutase, and glutathione peroxidase was decreased in dose-dependent in rats received the combined organophosphate pesticides.
Then, we aimed at assessing whether the decrease of antioxidant capacity from herbicide exposure may contribute to the elevation of oxidative stress marker. Previous studies reported that malondialdehyde (MDA) was the most popular marker for investigation of lipid peroxidation in vitro, however the level of MDA was a non-specific maker and depended on diet content\textsuperscript{21-23}. An alternative approach was to determine 8-isoprostanes since it was stable, unaffected by lipid contents in a diet, high specific, and sensitivity products of peroxidation\textsuperscript{7, 24}. The finding showed that there was no significant difference between the urinary 8-isoprostane in pre-work and post-work sample of both groups. There are two reasons for supporting our result. Firstly, the concentration of herbicides from occupational exposure may not be high sufficient to generate ROS, so the level of ROS may not be enough to disrupt lipid of cell membrane. Secondly, antioxidant defenses in the body can reduce ROS and maintain redox homeostasis resulting in unchange the level of 8-isoprostane\textsuperscript{25, 26}. Thirdly, working time of farmers was less than 5 h/day and they wore personal protective equipment (PPE) during their working, they could therefore be exposed to low level of herbicides\textsuperscript{27}. According to the study of Sapbamrer et al., 2019 the significant increase of SOD activity during the pesticide application season was associated with the number of working hours on the farm\textsuperscript{28}. Moreover, the oxidative stress markers including MDA and superoxide dismutase were reported to have the significant correlation with number of worked hours/day, hours of spraying pesticides/day in pesticide-exposed agricultural workers\textsuperscript{29}.

**Conclusion**

In the light of present findings, it can be concluded that occupational exposure to mixture of herbicides between glyphosate or paraquat or 2,4-D could induce abnormal oxidative stress index especially antioxidant defense among agricultural workers. Our findings could be applied for health surveillance in farmers who had a high risk to occupational herbicide exposure.

Mandibular Canine Index to Determine the Sex of the Individual- A Population based Study

Varsha A Shetty1, Vina Vaswani2, Suraj Shetty3, Mahabalesh Shetty4

1Assistant Professor, Department of Forensic Medicine and Toxicology, K S Hegde Medical Academy, Mangalore, 2Professor, Department of Forensic Medicine and Toxicology, Yenepoya Medical College, Mangalore, 3Associate Professor, 4Head of Department of Forensic Medicine and Toxicology, K S Hegde Medical Academy, Mangalore

Abstract

Introduction: The uniqueness of dental morphology plays an important role in Forensic Odontology, especially for human identifications. Mandibular canines may be considered vital for personal identification.

Objective: This study aims to establish the effectiveness of the Mandibular canine index in predicting the sex of an individual in a given population.

Materials and Methods: 400 participants (200Male, 200Female) were randomly selected from a given population between the age group 13 to 30 years. Using Digital Vernier calipers, the greatest mesio-distal crown width of both left and right Mandibular canines and Inter canine arch distance was measured.

Results: It show that canine dimensions and inter-canine distance were statistically larger in males compared to females and were statistically significant (p<0.001).

Conclusion: Canine dimensions can be considered as an adjunct for sex determination in our population

Keywords: Canine; Identification; Mandibular canines; Mandibular Canine Index; Odontology.

Introduction

Every human being has the right to protect their identity, whether living or dead. Forensic identification is the application of forensic science and technology to identify specific objects from the trace evidence often left at the scene. Establishment of the sex of an individual is a significant component of the identification process. Different odontometrical techniques are proven to be helpful in identification when the bodies are damaged beyond recognition.

Teeth are hard structures chemically stable and proven to be a good material for research and forensic identification. Role of teeth in the past dates back to centuries ago where teeth were used primarily for the identification or distinguishing a person from the rest based on their peculiarity. The identification of dental remains is of primary importance when the deceased person is skeletonized, decomposed, burned, or dismembered. Among all teeth, mandibular canines is known to exhibit good sexual dimorphism. Canine teeth are most likely to survive trauma. Hence, they can be considered as key teeth for personal identification.

Time and again, Forensic Odontology has proved that it has application with single identification or disasters with many people. The importance of forensic dentistry is increasing in the field of identification and solving crimes. The technique applied has started from the evolution beginning from the Garden of Eden to...
the present where all the identification of the accused of a rape trial in the state capital. It has an incredibly significant role, although the professional nature and its practices have evolved only in recent times and are still in progress.

This study aims to determine whether sex estimation is possible using mandibular canine tooth and investigate the reliability of canines in predicting sex in a given population.

**Materials and Methods**

This study group comprised of four hundred subjects (200 male, 200 female) from ages ranging from 13-30 years were randomly included from a given population. This age group was selected as all canine teeth would have erupted by this age, and intercanine distance would have been fixed. The attrition is expected to be minimal within this age group. All the participants included in the study had caries free teeth, normal overbite, absent spacing of teeth and no history of previous orthodontic treatment.

**Exclusion Criteria:**

- Absent canines or partially erupted or ectopically erupted teeth.
- Dental and occlusal abnormalities.
- Spacing in teeth.
- Physiological wear and tear (attrition, erosion, abrasion).
- Deleterious oral habits (bruxism).
- Bad/ poor oral hygiene.
- Previous orthodontic treatment.

**Ethical Clearance:** was taken from Yenepoya university ethics committee before starting the study. The participants who fit the criteria for this prospective study were randomly selected from a given population. The aims, objectives and procedure were clearly explained to each participant, and informed consent was obtained from the participant. All the measurements were taken intra-orally in a clean and well-illuminated room, keeping all the aseptic precautions in mind. A proforma filled with a detailed history including sex, age, address, date of birth, previous dental history, and the measurements of the teeth dimensions. Digital Vernier Calipers (Bruder Mannesmann, Germany), which is calibrated to 0.01mm, was used to take the teeth measurements.

**Mandibular canine width** was measured as the greatest mesiodistal dimension of mandibular canine on either side of the jaw using Digital Vernier calipers.

**The Intercanine distance** was measured as the linear distance between the cusp tips of the right and left mandibular canine using Digital Vernier calipers.

All these measurements were taken using the Hunter and Priest method. Two such measurements from both sides i.e., Right mandibular canine and Left mandibular canine are taken and then average of the two measurements is taken as the final value. This was done to rectify intra-observer error.

The measurement readings obtained were lay open to analysis to come to conclusions. The mandibular canine index was calculated using the formula:

\[
\text{MCI} = \frac{\text{Mesio-distal crown width of the mandibular canine}}{\text{Mandibular canine arch width}}
\]

Further the standard canine index was calculated for the mandibular canines using the formula derived by Rao et al.

\[
\text{Standard MCI} = (\text{Mean male MCI} - \text{SD}) + (\text{Mean female MCI} + \text{SD})
\]
According to Rao et al the calculated MCI was compared to standard MCI. The result obtained were both compared if the value was higher than the Standard MCI then it is considered a male canine tooth and lesser than standard MCI then it is considered a female canine tooth.11

All data were tabulated in the excel sheet and subjected to statistical analysis. SPSS software 16 was used and t test and multivariant discriminant analysis was applied and to develop a regression formula from this study.

**Results**

A total of 400 subjects participated in the study. The study included males and 200 females and 200 males. The parameters that were recorded were-

a) The Mesiodistal dimension of Left mandibular canine

b) The Mesiodistal dimension of Right mandibular canine

c) The Intercanine arch distance

Among the 400 participants, the mean value left mandibular canine was found to be 6.58 for males and 6.30 for females. The p value for this index is < 0.001 which is statistically highly significant as shown in Table No 1.

The mean value of the width of right mandibular canine was found to be 6.61 for males and 6.34 for females. The p value for this index is < 0.001 which is statistically as shown in Table No 1.

The intercanine distance of mandibular canines was measured for all subjects intra orally. The 400 participants the mean value of the intercanine distance of mandibular canines was found to be 27.51 for males and 26.31 for females. The p value for this index is < 0.001 which is statistically highly significant as depicted in Table No 1.

Multi variant Discriminant analysis was applied on the 400 samples from the participant to derive a formula for accurate of sex prediction.

The result is as follows: (Table 2)

1. In direct method, the percentage of accuracy using left mandibular canine, right mandibular canine and intercanine distance values the sex prediction is 63.60%.

Hence, the regression formula for direct method is,

\[ Y = 1.549 \times LMWidth + 0.704 \times RMwidth + 0.145 \times IC - 18.41 \]

2. In step wise method, it could be calculated only for left mandibular canine and intercanine distance because the right mandibular canine vales were insignificant. Hence using this method sex prediction for left mandibular canine and intercanine distance is 64.80%.

Hence, the regression formula for step wise method is,

\[ Y = 2.064 \times LMwidth + 0.177 \times IC - 18.05 \]

**Discussion**

In forensic cases teeth can be an important deciding factor in the identification of an individual. Canines are different from other teeth with respect to survival and sex dichotomy. Although canine survival and sex dichotomy are not related to each other still they are useful in the process of identification. In the present study 400 participants were randomly selected from a community between the age group 13-30 years. The mean age for eruption of canine tooth is 10.87 years and
according to literature is fully erupted by the age of 11 to 12 years and also inter canine distance is usually fixed by 12 years of age. Hence the age minimum limit in this study was taken to be 13 years. The age group maximum limit to avoid teeth which has gone for attrition and other age-related teeth queries is 25 years. Hence the age maximum limit in this study was taken to be 30 years. However, participants who had visible attrition of teeth were excluded from the study irrespective of their age. In studies conducted by Rao et al, Muller et al, the study participants consisted of students from a particular college rather than a targeted population. In this study 400 participants who were selected were from a targeted population who had similar ethnic, cultural, and behavioral backgrounds.

In a preliminary study conducted by Rao et al in 1989 on 766 participants randomly selected between age group 15 to 21 years, Multi variant discriminate statistical analysis showed 85.9% accuracy in sex determination which was highly significant however, in our study with sample size of 400 randomly selected from a given community between the age groups 13-30 years showed multivariant discriminant analysis of 64.80%. This difference in result could be attributed to the fact that Rao et al study was not a population-based study and the measurements of the teeth taken were using dividers which could lead to errors.

In another study conducted by Muller et al in France 2001 among 424 students at university of Nice Sofia Antipolis with 210 females and 214 male participants in the age group 20.4 ± 2.9 years. The aim of the study was to calculate mandibular canine index for sex determination as done by Rao et al but by taking occlusion into consideration. There was effort made by the author to find out the reliability of the method and its influence when there is lower anterior dental crowding. In cases of correct alignment, the values were higher for males compared to females however the study showed lower sex predictability value of 59.57% which coincides with our study with sex predictability of on 64.80% which is not significant.

In a study conducted by Vishwakarma and Guha in 2011 in Gwalior medical college among 180 participants (90 females and 90 males) between the age group 17-23 years using vernier calipers study comments on left mandibular canine being a better parameter to identify sex. In their study the mesiodistal width of mandibular canine of males and females were found to be statistically significant for left mandibular canine compared to the right. But in our study mean value of right mandibular canine is higher compared to the mean of left mandibular canine. However, when using step wise selection in multivariant discriminant analysis for right mandibular canines the data was invalid, and no accuracy or result could be obtained.

In a study conducted in 2014 by Bakkanavar S et al among 500 students (250 females and 250 males) randomly selected of age group 15 – 25 years of South India using a digital calipers to take measurements of both maxillary and mandibular canine to see if this could be used as a tool for sex determination. The results showed that the mesio-distal crown width of both right and left mandibular canines in males were more than the females. The sex predictability according to the study was poor for mandibular canine index which was 74.8%. In comparison to our study where the value was 64.80% the value of Bakkanavar S et al seems higher. This can be attributed to the fact that unlike our study which is based on a particular population Bakkanavar S et al study participants were students from diverse and from different backgrounds which could have contributed to the higher values. However, Bakkanavar S et al study shows that results obtained show poor sex predictability which is similar to our study.

**Conclusion**

The developing field of forensic dentistry in India relies a lot on easy and inexpensive methods for identification. Forensic dentistry helps in investigation when other means fail to do so. A dentist can be asked upon to render on their expertise in the field of forensics, when in need during investigation. A data base could be created with morphometric measurements
with the purpose to determine if there is significance among larger population. This data may be beneficial for anthropological, genetic, legal, and forensic applications. It is recognized that canines among other teeth exhibit sexual dimorphism. This study measured linear dimensions of teeth. However more accuracy can be obtained by using sophisticated equipments and also the use of more standardized and complex mathematical equation. This might increase the accuracy of the prediction. However, one must not forget that only when more parameters are considered the more accurate the determination of sex will be. For this reason, clues from dentition must be correlated with other clues.

Application of Machine Learning and Deep Learning Technology in the Field of Dentistry among Top Five Gross Domestic Product (GDP) Countries - A Scientometric Analysis

Varshini Rajendran¹, V.V.Bharathwaj², P.Suganya³, D.Prabu⁴, Rajmohan⁵, M.R.Prashanthy³

¹Undergraduate Student, ²Lecturer, ³Postgraduate, ⁴Professor, ⁵Reader, Department of Public Health Dentistry, Chennai, Tamilnadu, India

Abstract

Background: The Scientometric analysis of the articles helps to provide more useful information about the field of research.

Aim: This study aims to evaluate the articles based on the application of deep learning and machine learning in the field of Dentistry among top five Gross domestic product (GDP) countries.

Materials and Method: The articles related to Deep learning (DL) and Machine learning (ML) in the field of Dentistry among top five GDP countries were retrieved from electronic databases such as Google Scholar, Scopus and PubMed using keywords and MeSH terms. The parameters such as author name, number of authorships, number of citations, year, place of the study, journal, type of article, field of dentistry, outcome and implementation of deep learning and machine learning in dentistry were evaluated. The collected data were analyzed and tabulated using descriptive analysis.

Results: Totally thirty seven number of articles regarding deep learning and machine learning in the field of dentistry among top five GDP Countries were obtained. The maximum number of studies was published in United States of America and minimum studies in Japan. The articles were published between the years 2001 and 2020 in different fields of Dentistry.

Conclusion: The Scientometric analysis of articles related to the use of deep learning and machine learning in the field of Dentistry helps the researchers and dentists to have an idea about the trends and improvement for better analysis and treatment in the future for greater benefit of patients.

Keywords: Deep learning, machine learning, research, Gross domestic product, dentistry.

Introduction

Artificial intelligence is a branch of computer science demonstrated by machine, contrary to natural intelligence laid out by living beings. Artificial intelligence plays a crucial role in the recent advancements of dentistry [1].

The ideas of machine learning have been applied in various fields including medicine and dentistry for decades. Machine learning is an application of artificial intelligence which provides the ability to automatically learn and improve from experience without being programmed. This mainly focuses the development of computer program to access data and learns automatically. It is used to assess the pattern in data and make better decision for the future. The main aim is to allow the computer to learn automatically without human intervention or assistance and use of instructions [2].
Deep learning is a subset of machine learning in artificial intelligence (AI) that has network capable of learning unsupervised from data. It is also known as deep neural learning or deep neural network. Deep learning methods have dramatically improved advances in speech recognition, vision, hearing, genomic and in the field of dentistry [3].

In the recent years, machine learning and deep learning have been implemented in dentistry and made a huge impact for better treatment decisions. This technology is very advantageous and beneficial for dental professionals as they play a convenient role in precise teeth detection and classification [4], dental diseases diagnosis [5], interpretation of dental images automatically [6], highly accurate automatic teeth type classification on CT image for forensic identification [7], assessment of Tooth morphology on radiograph [8], detection of Periodontal Bone Loss [9], detection of apical lesions [10], in orthodontic and Prosthodontic treatments [11], malocclusion assessment [12] dental Age Estimation, 3D prosthesis [13] etc.

Scientometric analysis is the field of study which concerns itself with analyzing and measuring the scientific literature. It helps to measure the impact of scientific articles and journals and use of measurements in management contexts and policy [14]. Gross domestic product (GDP) is the monetary value of all finished goods and service made within the country during a specific period [15] based on that the country with highest GDP are United States of America followed by China, Japan, Germany, India and so on [16].

This article helps to determine the scientific articles that were published about machine learning and deep learning in dentistry among top five GDP countries, i.e. United States of America, China, Japan, Germany, India, so that researchers can have knowledge about the expansion of technology.

Materials and Methods

This study was performed to evaluate the Scientometric analysis of articles related to machine learning and deep learning in the field of Dentistry among top five Gross domestic product (GDP) countries. The articles were obtained from electronic databases such as PubMed, Scopus, Google Scholar as ‘deep learning in dentistry’ and ‘machine learning in dentistry’. The data were collected using MeSH term and keywords such as deep learning, machine learning and dentistry.

The articles published among top five GDP countries were evaluated and the parameters like author name, number of authorships, number of citations, field of Dentistry, type of article, name of the journal, year of publication, outcome of the study and implementation in dentistry was included.

The inclusion criteria of this study includes only articles related to machine learning or deep learning in dentistry, only original and review articles were included. Only articles from the top five GDP countries are considered. The exclusion criteria of this study are the articles with no open access and articles published in other than English language were excluded.

Results and Discussion

A total number of articles related to the application of deep learning and machine learning in the field of dentistry among top five GDP countries were thirty seven. The articles were published from the year January 2001 to April 2020. Most of the studies are conducted in United States of America whereas the least number of articles are published in Japan with the lowest number of articles.

**Figure 2:** Implementation of machine learning and deep learning in different fields of dentistry among top five GDP countries

Figure 2 shows the implementation of articles related to deep learning and machine learning in various fields of dentistry among top five GDP countries. 1
Figure 3: Year wise distribution of articles related to application of deep learning and machine learning in dentistry

Figure 3 shows the number of articles published on application of machine learning and deep learning in dentistry among top five GDP countries. They were published between the years 2001 and 2020. The number of articles was found to be gradually increases from the year 2017. The maximum number of articles was published in the year 2019.

The study conducted by Suganya et al in the year 2020 had discussed about the bibliometric analysis of top cited artificial intelligence articles in the field of dentistry [44]. Gross domestic product (GDP) is the total monetary or market value of all the finished goods and service provided within the country’s border in a specific time period. The top five countries with highest GDP are United States of America, followed by China, Japan, Germany and India. There are articles published from these counties on the application of deep learning and machine learning in the field of dentistry. Information like author, number of authorships, journal, year, number of citations, field of dentistry, outcome of the study, were tabulated for each article.

Totally eleven articles were published from 2001 to 2020. One article had single authorship. Out of eleven articles, eight of them are original articles and three are review articles. The deep learning and machine learning were implemented in different fields of dentistry like orthodontics, Prosthodontic treatment, oncology, diagnosis and public health care. The articles with highest number of citations in United States of America were twenty four and there were four articles with nil citation.

Totally nine articles were published in China; all of them were original articles. Deep learning and machine learning methods were implemented in different fields of dentistry including radiology, orthodontics, forensics etc. They were published between the years 2013 and 2019. The articles with highest number of citations in an article published in China were nineteen and three articles had the lowest number with one citation.

Deep learning and machine learning methods were used for tooth identification and diagnosis. Implementing these methods gave better and accurate results. The
highest number of citations in an article published in Japan was eighty two and lowest number of citation was one.

Totally five articles were published in Germany; all of them were original articles. These articles were published between the years 2019 and 2020. Deep learning and machine learning techniques were implemented in endodontic periodontal diagnosis and in forensics. The highest number of citations in an article published in Germany was eight and two articles had nil citation.

Totally 8 articles were published in India, out of which 1 article had Single authorship. These articles were published from 2017 to 2020 and were applied in different fields. Table 10 shows the outcome and the implementation of the studies published in India based on the deep learning and machine learning in dentistry. Accordingly, machine learning and deep learning methods were used in dentistry for accurate and better diagnostic purpose. Highest number of citations in an article published in India was twenty and the six number articles had nil citation.

The highest number of citations in an article was eighty two which was published in Japan in 2016. There are twelve articles among all the five countries with no citation. According to figure 1, a total of thirty seven articles were published related to application of machine learning and deep learning in dentistry, among which eleven articles were published in the United states of America, nine articles in China, eight articles in India, five articles in Germany and four articles in Japan. All these articles have open access, and all were in English language.

Accordingly, China, Japan, and Germany had no review article, they were all original articles. In India, four articles were published on machine learning and deep learning was review article and four were original. In the United States of America, eight articles were original and three were review articles.

The number of articles with implementation of machine learning and deep learning in different fields of dentistry like namely Prosthodontics, Endodontics, Periodontics, Pedodontics, oral oncology, forensic dentistry and public health.

In the year 2020, till the month of April four number of articles was published regarding machine learning and deep learning in dentistry among top five GDP countries. From the figure it is evident that the number articles published in a year gradually increases than the previous year. Before the end of 2020 more articles might be conducted. Considering all the data, more number of researches may be conducted in the future, following a trend.

The limitation of this study includes only articles with full text and open assess. The articles published in other than English language were not taken into an account. Other databases should also be considered to get more relevant data. The data was obtained from only countries with highest GDP. Further studies should be conducted throughout the world to get more information and knowledge.

**Conclusion**

This article concludes that based on the previously published articles related to the application of machine learning and deep learning in dentistry, we can predict that more number of articles will be published in the future. This Scientometric analysis helps researchers to gain more knowledge about the advancements in dental treatment and diagnosis. Totally thirty seven number of articles were published among top five GDP countries, of which America has the highest number of articles. The application of deep learning and machine learning have progressively improved treatment plan by getting accurate results and less time consuming. It was useful to dental professionals as well as to public by providing self assessment of their oral health which prevents and reduce the further progression of diseases at an earlier stage.
Future Scope:

This article will be more useful for dental professionals and public regarding the recent advancements and treatment modalities of dental health. This paves a pathway for the scientists to be more updated on recent advancements in dentistry and also motivates them to conduct more researches to obtain maximum benefits for the people.

Abstract

The genotyping of red-and-white cattle for the genes of kappa-casein and beta-lactoglobulin in the farm has revealed the presence of three genotypes, namely AA, AB and BB. In first-calf heifers, the frequency of the AA genotype of the kappa-casein gene was 33.10%, AB was 56.69%, BB was 10.21%. A allele frequency was 0.61%, B - 0.39%. In first-calf heifers, the frequency of the AA genotype of the beta-lactoglobulin gene was 16.20%, AB was 53.52%, BB was 30.28%. A allele frequency was 0.43%, B - 0.57%. The AB AB genotype prevailed in the population of red-and-white cows (29.23%) according to the frequency of occurrence of complex genotypes of kappa-casein and beta-lactoglobulin. In terms of milk yield, cows with genotype BB of the kappa-casein gene surpassed cows of the same age with genotypes AB and AA by 153-644 kg. In terms of the content of fat and protein mass fraction, the superiority was 0.06-0.19% (P≥0.95; 0.99), and protein by 0.13-0.22% (P≥0.99; 0.999). In terms of milk yield, the superiority of cows with the AA genotype of the beta-lactoglobulin gene over cows of the same age with the AB and BB genotypes was 208-413 kg (P≥0.95). According to the mass fraction of fat and protein in milk, preference is given to cows with the BB genotype, whose milk contains 0.06-0.09% more fat and 0.08-0.17% protein (P≥0.95; 0.99) compared with cows with AB and AA genotypes. The yield of milk fat in first-calf heifers with genotype BB of kappa-casein was also higher by 14.3 kg and 43.5 kg (P <0.05) than that in animals of the same age with genotypes AB and BB. Heifers with the AA genotype of the beta-lactoglobulin gene had the highest milk fat yield of 328.36 kg. This is 13.87 kg (P <0.05) more compared to the BB genotype. In terms of milk protein yield, the difference in kappa-casein genotypes was: BB to AA 36.9 kg (P <0.01), BB to AB 14.3 kg.

Key words: breed, type, gene, kappa-casein, beta-lactoglobulin, milk production, fat, protein

Introduction

The use of genetic markers, which are responsible for the quality indicators of milk productivity in animal husbandry, will improve the economically useful characteristics of cattle. Kappa-casein and beta-lactoglobulin genes are some of these markers [1,2,3,4,5,6,7,8,9].

Kappa-casein is one of the genes that is directly related to indicators of milk protein content and technological properties of milk. It is believed that when breeding cattle, it is preferable to increase the frequency of the B allele of kappa-casein in the population. This allele allows to increase the protein content in milk, and also to improve the technological properties of milk in cheese production [10,11,12]. Many scientists are not yet able to determine exactly which of the A or B alleles of the beta-lactoglobulin gene will improve the biochemical and technological characteristics of milk [13,14,15,16].
Purpose of the study. The aim of this work is to study the polymorphism of kappa-casein and beta-lactoglobulin genes in the genomes of red-and-white cows of the being created Volga type and their influence on animals’ milk productivity.

Materials and Methods

The research was carried out with the red-and-white cows in the Federal State Unitary Enterprise “The 1st of May” at State Scientific Institution “Mordovian Research Institute of Agriculture”. The polymorphism of the beta-lactoglobulin and kappa-casein genes was assessed on the basis of polymerase chain reaction (PCR). For further research, based on analogues principle [17], according to the results of genotyping for the gene of beta-lactoglobulin and kappa-casein, 3 groups of red-and-white cows were formed. The first group included heifers with the genotype of beta-lactoglobulin and kappa-casein AA (control group), the second consisted of cows with the AB genotype, and the third involved animals with the BB genotype.

Blood obtained from the tail vein of animals was added to tubes with 100 mM EDTA to a final concentration of 10 mM.

Analysis of the beta-lactoglobulin gene locus

PCR was carried out by a programmable thermal cycler “Tertsik” (Russia) in a volume of 20 μL with primers Forward: 5’- GTCTTTGTGGCTGACACCCGACTACA-3’ and Reverse: 5’- CAGGACACCCGCCGTATATGAC-3’ designed by J.F. Medrano and E. Aguilar-Cordova, [1990] to amplify a 350 bp beta-lactoglobulin gene fragment.

To determine the allelic polymorphism of the kappa-casein gene, 20 μl of PCR samples were treated with 10 units restriction endonucleases Hfni I in 1 x buffer “O” and 1 x buffer “W” (made by SibEnzyme (Russia) at 37°C overnight.

The frequency of occurrence of the kappa-casein and beta-lactoglobulin genotypes was determined by the formula:

\[ p = \frac{n}{N} \]

p is the frequency of the genotype,

n is the number of individuals with a certain genotype,

N is the number of individuals.

The frequency of individual alleles was determined by the formula:

\[ p_A = \frac{n_{AA} + n_{AB}}{2N} \quad \text{and} \quad q_B = \frac{n_{BB} + n_{AB}}{2N}, \]

where

\[ p_A \] is frequency of A allele,

\[ q_B \] is frequency of B allele,

N is the total number of alleles.

Having conducted scientific and production experiments, the following indicators were studied:

- milk productivity of cows was determined by monthly control milking during the entire first lactation;
- fat and protein content was determined with “Klever-1M” device in farm dairy laboratory once a month.
The research results were processed by the method of biometric statistics \[18,19\] on a personal computer.

**Results**

Carried out genotyping of red-and-white cattle for kappa-casein and beta-lactoglobulin genes revealed the presence of three AA, AB and BB genotypes. In first-calf heifers, the frequency of the AA genotype of the kappa-casein gene was 33.10%, AB type was 56.69%, and BB type was 10.21%. A allele frequency was 0.61%, and B allele one was 0.39%. In first-calf heifers, the frequency of the AA genotype of the beta-lactoglobulin gene was 16.20%, AB type was 53.52%, and BB type was 30.28%. A allele frequency was 0.43%, and B allele one was 0.57%. The AB AB genotype prevailed in the population of red-and-white cows (29.23%) according to the frequency of occurrence of complex genotypes of kappa-casein and beta-lactoglobulin. Milk productivity study of cows with different genotypes of kappa-casein showed (Table 1).

Note: * P<0.05; ** P<0.01; *** P<0.001

Milk yield of first-calf heifers with genotype BB was higher than milk yield in animals with genotypes AA by 644 kg (P <0.01) and with genotype AB by 153 kg. Heifers with the BB kappa-casein genotype had higher levels of fat in milk than first-calf heifers with the AA and AB kappa-casein genotypes. The difference was 0.19% (P<0.001) and 0.06% (P<0.05) respectively. The milk fat yield in first-calf heifers with the BB genotype was 340.2 kg, which exceeds the same indicator in first-calf heifers with a homozygous AA genotype by 43.5 kg (P <0.001) and with a heterozygous AB genotype by 14.3 kg. In animals with genotype BB, the protein content in milk was 3.57%, which is 0.22% higher (P <0.001) than in animals with genotype AA and higher than in heifers with genotype AB by 0, 13% (P <0.01). In terms of the yield of milk protein, animals with the BB genotype also had a superiority. The difference in kappa-casein genotypes was: BB to AA 36.9 kg (P <0.01), BB to AB 14.3 kg.

Note: * P<0.05; ** P<0.01; *** P<0.001

Milk yield per lactation in the group of first-calf heifers with the beta-lactoglobulin BB genotype was 6471 kg, AB genotype was 6679 kg and AA genotype was 6884 kg. Cows with the BB genotype were inferior to the same age animals with the AB genotype by 208 kg, with AA genotype by 413 kg (P <0.05) milk.

The highest fat content in milk (4.86%) was observed in heifers with the BB genotype of the beta-lactoglobulin gene, which is significantly higher in comparison with the AB genotype by 0.06% (P <0.05) and AA genotype by 0.09% (P <0.05). In terms of mass fat content, animals with A allele of the beta-lactoglobulin gene in their genome showed superiority (320.60-328.36 kg). They exceeded the same age animals by 6.11 and 13.87 kg (P <0.05), respectively. Animals with the A allele of the beta-lactoglobulin gene in their genome had significantly higher protein content in milk than the same age animals with the homozygous BB genotype by 0.08% -0.17% or by 12.36-25.62 kg.

The data in Table 3 show the effect of different combinations of kapp-casein and beta-lactoglobulin genes on cows’ milk production.

Studies have shown that red-and-white cows have a clear tendency for the influence of the beta-lactoglobulin genotype on milk yield. Thus, in the group of cows with the AB AA genotype of the kappa-casein and beta-lactoglobulin genes, the milk yield was 322.36 kg higher (P≤0.05) compared to animals with the AB BB genotype (Table 3).

The studies carried out made it possible to assess the productive capabilities of animals of the creating Volga type red-and-white dairy cattle with different genotypes of kappa-casein and beta-lactoglobulin.

Analysis of animals’ milk productivity found out a significant difference in fat content in groups with genotypes AAAA < AABB (P≤0.05) and AAAA < ABBB (P≤0.05), as well as in the amount of milk protein AABB < ABAA (P≤0.05).

**Discussion**

Carried out genotyping of red-and-white cattle for the genes of kappa-casein and beta-lactoglobulin revealed the presence of three genotypes AA, AB and BB. In first-calf heifers, the frequency of the AA genotype of the kappa-casein gene was 33.10%, AB genotype was 56.69%, BB genotype was 10.21%. A allele frequency was 0.61%, B - 0.39%. In first-calf heifers, the frequency of the AA genotype of the beta-lactoglobulin gene was 16.20%, AB was 53.52%, BB was 30.28%. A allele frequency was 0.43%, B - 0.57%. The AB AB genotype prevailed in the population of red-and-white cows (29.23%) according to the frequency of occurrence of complex genotypes of kappa-casein and beta-lactoglobulin.

The following table shows the reliability of the difference in the ratio of the genotypes of kappa-casein and beta-lactoglobulin in terms of milk productivity.

fat in cows with BB of kappa-casein was also higher than that of the same age animals with genotypes AB (by 14.3 kg) and BB (43.5 kg) (P <0.05). Heifers with the AA genotype of the beta-lactoglobulin gene had the highest milk fat yield of 328.36 kg. This is 13.87 kg (P <0.05) more compared to the BB genotype.

Studies of the effect of complex genotypes of kappa-casein and beta-lactoglobulin on milk productivity have shown that in red-and-white cows there is a clear trend in the influence of the genotype of beta-lactoglobulin on milk yield.

Conclusion

The studies carried out made it possible to assess the productive capabilities of animals of the created Volga type red-and-white dairy cattle with different genotypes of kappa-casein and beta-lactoglobulin.

Determination of the genotypes of kappa-casein and beta-lactoglobulin in young animals will improve selection, which will favorably affect the milk productivity and milk quality of red-and-white animals.

Radiology - A Specific Tool in Identification: A Review

Vinoth Kumar S1, Monisha B. M2

1Associate Professor, Department of Radio Diagnosis, 2Assistant Professor, Skin and Std. Department, Vinayaka Missions Kirupananda Variyar Medical College and Hospitals, Salem – 636456, Tamilnadu

Abstract

Nowadays in Forensics, Radiology or Imaging plays a major role in identification of criminal and civil proceedings. Why Radiology here means, it is making bit sensible that to analyze the bony structures like skeletal remains and other body parts. The main aim of the manuscript is to unite the two disciplines in one part majorly “Radiology and Forensics”. The forensic application of diagnostic medical radiology can be applied in many fields; the prime target of evaluation is the osseous skeleton, but soft tissues which may offer several key findings. Essential methods consist of radiological methods such as conventional radiography, computed tomography, and magnetic resonance imaging, but other techniques such as 2D and 3D surface scanning along with printing are also employed.

Key Words: Radiology, Forensics, Investigations, Identification

Introduction

Forensic science deals with the identification of the dead using numerous techniques. Forensic odontology has a lot of scope in human identification. Methods like Rugoscopy, Bite marks, Photographs, Lip prints, Age Estimation and Sex Determination etc. are used for identifying the individuals.[1] Due to the increased use of imaging for forensic purposes as well as the establishment of specific research projects, the number of published studies in this field has increased rapidly in recent years. This new domain of research is interesting to radiologists as well as to forensic pathologists; radiologists have been involved in most forensic imaging projects from the beginning, underscoring the field’s integration of two distinct medical specialties. While radiologists read the obtained images, forensic pathologists focus on findings important for medico-legal reconstructions, which are not necessarily important from a clinical point of view. Pathologists are also able to explain certain phenomena visible on images due to their knowledge of thanatology. There was much speculation about the role of these methods and their relationship to forensic autopsy. Unclear study designs and unscientific terms were often used, leading to unsupported conclusions that were questioned. Confusion was further increased by the use of undefined or unclear terms such as “necro-radiology”, “forensic radiology”, “virtual autopsy”, and “minimally invasive autopsy”, which were rarely explained in the articles.[2]

Recent Methods of Radiology Imaging:

1) Intra Oral Periapical Radiography (IOPA)
2) Extra – Oral Radiography
3) Computed Tomography (CT)
4) Magnetic Resonance Imaging (MRI)
5) Postmortem Computed Tomography (PMCT)

6) Multi-detector Computed Tomography (MDCT)

**Anatomical and Forensic Identification:**

Medico-legal cases, Natural disasters like tsunamis, earthquakes, explosions, etc. For confirming death in monetary issues, Septum deviations, Upper and Lower skeletal bone readings, Head and Neck bony remains identification, Teeth related identifications, etc., Digital radiography when used along with dental matching software fastens the forensic victim’s identification. Also, digital radiography reduces the exposure times by requiring 90% less radiation than that required to expose a standard type D film radiograph and 50% less radiation than that required in exposure of type E film radiographs.[3]

**MRI**

More recently, MRI has been used to increase forensic investigations, particularly in musculoskeletal, cardiovascular and angiographic fields and in forensic imaging of the living (such as cases of child abuse), survived strangulation and age estimation. Virtual Autopsy is one new technique that offers several advantages over the traditional approach and helps connect radiology with forensic medicine. The most important advantage is its non-invasive approach that doesn’t harm the body or tamper with forensic evidence. MRI involves no ionizing radiation; it is based on the principle of nuclear magnetic resonance. When a patient is placed in a magnetic field, the hydrogen protons in the body align with the field. A radiofrequency pulse is emitted from the scanner, exciting specific atomic nuclei and rotating the protons to a 180° position. As the energy from the pulse decreases, the protons return to their initial state within the magnetic field and generate an MRI signal that is digitally transformed into images. The interval between arrival in the initial state and signal emission is called the relaxation time. Contrast between anatomical structures is possible due to the specific relaxation time of atoms within each tissue. MRI offers high spatial resolution as well as excellent soft-tissue contrast, as it distinguishes muscles, fat, parenchyma, and neurological structures. [4-5]

**Conventional Radiography:**

Conventional radiography is the oldest radiological imaging method used in forensic medicine. In this technique, the body is investigated via direct exposure to X-rays; structures exposed to the beam are projected onto a radiographic image. The image is composed of different tonalities of black and white, corresponding to the number of X-rays that reach the detector. Contrast is possible due to the distinct absorption properties of body structures (bone is associated with high absorption and soft tissues display less attenuation). Conventional radiography employs two types of devices available in medical institutions: 1) analog equipment that uses radiological film for the impression of images, and 2) newer equipment that is completely digitized. In digital and digitized analog equipment, images are acquired in digital DICOM format, which is currently used for all imaging modalities. [2]

Conventional radiography is one of the most common imaging modalities in forensic medicine worldwide. Most forensic institutions possess their own X-ray devices, which are often used to evaluate the osseous system in cases of trauma or to characterize the presence of a foreign body. Radiography is advantageous, as it is simple to perform, rapid, and cost-efficient. Radiography is often implemented for infant corpses, for highly putrefied, charred, or otherwise altered bodies, and for bodies of unknown identity. Conventional radiography can also provide important information that is integrated with other complementary exams for age determination (Figure 1), not only of deceased but also of living persons. [6-7]
PMCT:

Currently, one of the most-used radiological modalities in modern forensic imaging is MDCT. This extensive use means that the term PMCT often refers to MDCT. Unlike conventional radiography, MDCT uses a computer to generate images that are saved in DICOM format. MDCT is based on the principle that the density of each tissue can be measured by calculating the attenuation coefficient of an X-ray beam passing through it. The body is examined through direct exposure to X-rays via a rotating tube. The attenuation values of the X-rays are expressed in Hounsfield units; these units are characteristic of various tissues and body fluids. Radiographic data are interpreted through the evaluation of various cross-sectional images. While 3D reconstructions are very clear and intuitive, enabling better understanding of the images for a medical layman, radiological assessment and diagnosis should always be based on axial views. Three-dimensional models are always at risk of artifacts, and the assessment of 3D models alone may cause discrete findings to be overlooked. [8]

CT:

CT is the ideal method for detecting radio-opaque foreign bodies. For example, it visualizes medical implants, projectiles and/or their fragments, and swallowed or aspirated foreign bodies. CT makes the discovery of small or fragmented objects much easier than does classic autopsy and allows rapid orientation for targeted extraction during autopsy. [9-11]
3D scanning:

Three-dimensional surface scanning is a technique that was developed for the car industry; it is extensively used for forensic investigations in Switzerland by police and medico-legal institutions. Its main fields of application are the reconstruction of traffic accidents, the correlation of a lesion and the presumed injuring-causing instrument, and the comparison of bite marks with dental models of the supposed perpetrator. [12-14]

Radiology in Age and Sex Determination:

Estimating age is the most important prerequisite for identification of the dead. Age estimation can be done by various factors like: Jaw bones, Tooth germs, Process of mineralization, Stages of crown development, Completion and their eruption into oral cavity, Volume of pulp chamber, Third molar development and eruption pattern, Root morphology, Maxillary Sinus height and width, Nasal Septum area, Pulp Tooth Area Ratio (PTR), Height and Width of the crown, Estimation of sutural closure, (Figure 2) etc.,[3]

Conclusion

Forensic radiology has modest and early origins. Previous evidence shows that medical principles have been applied to medico legal issues for thousands of years. It was not long after Roentgen discovered “a new kind of ray” that advanced forensic scientists established its value in forensic science. Radiologic imaging is better defined as the practice that lies at the many interfaces of medicine and law. Radiologic imaging plays a vital role at many of those connections, from the identification of dead to the confirmation and validation of precious sculptures.

Abstract
Cluster of pneumonia infection emerged in Wuhan, China due to severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). Additionally, more than 190 countries have confirmed 82 million cases of SARS-CoV-2 infection. Currently, there is a SARS-CoV-2 epidemic, and no effective prophylactic methods are available. A vaccine is considered as an effective method to restrict an epidemic. Several vaccine designing techniques have been established, which is enabling researchers from various institutes for developing vaccine towards SARS-CoV-2 infections. In this review, we condense the development of vaccine research against SARS-CoV-2.

Keywords: COVID-19, SARS-CoV-2, Vaccine Design.

Introduction
A cluster of pneumonia infections emerged in Wuhan Hospital, China which started from December 2019 up to now. The infection was reported to be caused due to a type of beta-coronavirus, which named by World Health Organization (WHO) as severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2)\textsuperscript{1,2}. As per reports till March 26\textsuperscript{th} 2021, the pathogen had infected more than 120 million individuals and caused 2.7 million deaths worldwide\textsuperscript{1}.

SARS-CoV-2 had a material genetic of positive-stranded RNA and belongs to Betacoronavirus genera. Studies have revealed that SARS-CoV-2 genome consists of 29,700 nucleotides, and shares approximately 79.5% similarity to the genome of SARS-CoV\textsuperscript{3,4}. Furthermore, SARS-CoV-2 is known to have an ORF1ab polyprotein at the 5′-end which had a role in coding for viral non-structural proteins. Genes at 3′-end had been known to encode the structural proteins such as spike (S), nucleocapsid (N), membrane (M), and envelope (E)\textsuperscript{5,6}. Several studies have reported that SARS-CoV-2 binds to angiotensin converting enzyme 2 (ACE2) receptor on the host cell. The receptor played a key role in viral entry mechanism and related pathogenesis\textsuperscript{7,8} (Figure 1).

A vaccine is considered as an effective method which had high economic significance to restrict an infectious disease outbreak\textsuperscript{3,9}. The use of vaccines inducing neutralizing antibodies is the best option to increase the number of populations that are immune to SARS-CoV-2\textsuperscript{10}. Thus, the development of SARS-CoV-2 vaccine became an essential need. As per few reports, about 40 pharmaceutical companies and academic institutions in the world have currently assigned the
A program for developing vaccines towards SARS-CoV-2. Therefore, we summarize the ongoing advance research in development of SARS-CoV-2 vaccine.

**Figure 1. Structural part of SARS-CoV-2. The virion consists of spike glycoprotein (S), membrane protein (M), envelope protein (E), and nucleocapsid protein (N).**

**Antigenic Retrieval and Selection from SARS-CoV-2 Structural Protein**

Various nonsrtructural protein is common to be utilized for vaccine development. However, spike protein (S protein) is widely being investigated to be used for developing a vaccine against SARS-CoV-2. Studies have revealed that it is a viral surface protein, which is directly recognized by the host immune system. Subsequently, it has been reported that S protein acts as a mediator for interaction between virus and host cell by binding to ACE2 receptor, and cause consequent pathogenicity. The homologous structure of S protein is being used for vaccine development, which has proven to be effective in overcoming the previous outbreaks including SARS-CoV and Middle East respiratory syndrome coronavirus (MERS-CoV). The S protein monomer consists of 1273 amino acids in length and molecular weight about 140 kDa. Furthermore, it has ability to undergo the self-association mechanism and formed a homotrimer structure as a special feature of class I viral fusion protein. Structural studies showed that S protein is composed of two subunits, termed as S1 and S2 part. The S1 subunit can be organized into two domains, such as N-terminal domain (NTD) and C-terminal domain (CTD). In brief, the CTD is reported as receptor-binding domain (RBD). On the other hand, the S2 subunit had an essential part for membrane fusion which consist of internal membrane fusion peptide (FP), two heptad repeats (HR), membrane proximal external region (MPER), and transmembrane domain (TM). Recently, the S trimer structure of SARS-CoV-2 within the pre-fusion stage, and the RBD structure in convolution with ACE2 had been successfully determined.
Figure 2. Brief structure of SARS-CoV-2 spike glycoprotein.

The S trimer protein structure had been reported to act as an epitope and had ability to induce a high immunogenicity. Coleman et al. showed that the S trimer protein could be produced within baculovirus insect cells, and it could be transformed into nanoparticles\textsuperscript{16}. Furthermore, it was formulated with an adjuvant (alum) and injected into the mice. Moreover, the immunized mice were observed to obtain the data about titers level of specific antibodies after the nanoparticle administration\textsuperscript{16,17}. Recently, the Clover Biopharmaceutical has announced that they have designed SARS-CoV-2 S-trimer based-vaccine which processed into the preclinical testing stage\textsuperscript{9}.

RBD has been known to interact directly with ACE2 receptors of the host cells. Thus, many studies have suggested RBD for immunization to investigate the antibody formation. It estimated for having ability to inhibit the viral recognition of ACE2 receptor, and prevent the subsequent pathogenesis\textsuperscript{18,19}. Accordingly, many RBD-antigens based SARS-CoV-2 subunit vaccines are currently being developed. A study showed that the recombinant RBD, which was isolated from different types of virus serotypes, could trigger the multi-conformational by neutralizing antibodies towards SARS-CoV-2. This might be due to the presence of multiple epitopes that are recognized by specific immune systems\textsuperscript{20}.

As previously reported, S1 subunit has RBD as well as NTD, which suggests its role in binding S protein to the host receptor\textsuperscript{21}. Subsequently, these domains can be widely utilized for vaccine development. As comparison, previous studies showed that MERS-CoV S1 subunit with MF59 adjuvant could protect the human dipeptidyl peptidase 4 transgenic (hDPP4-Tg) mice against infections\textsuperscript{22}. Furthermore, FP in S2 subunit has been reported to be involved in membrane fusion which is essential step for viral pathogenicity\textsuperscript{23,24}. At present, Tianjin University is constructing RBD-FB-based vaccines and producing high titers of neutralizing antibodies in mice\textsuperscript{9}.

In other hand, N protein is abundantly expressed by the coronavirus and it has molecular weight about 50 kDa. It has been reported for promoting several functions such as nucleocapsid formation, initiation of viral budding transduction signal, RNA replication, and mRNA transcription\textsuperscript{25,26}. Furthermore, N protein
has been suggested to have high antigenicity as about 80% of patients with COVID-19 have been observed to produce antibodies specific to SARS-CoV N protein.27

Moreover, they have been observed to significantly reduce the viral load of vaccinia virus.28 In addition, previous studies reported that bronchitis virus-related N protein could induce the activation of cytotoxic T lymphocytes (CTLs) by attenuating infection and thereby, protecting lungs from viral pathogenicity.29,30

Moreover, M protein is a glycoprotein located in the transmembrane of virus and it has molecular weight about 25 kDa. In brief, it has a crucial role for viral assembly. Furthermore, previous report exhibited that it abundantly expressed on the viral surface.31,32 Full length M protein has been previously evaluated as a vaccine, which is reported could be neutralizing antibodies in patients with SARS. M proteins also consisted T cell epitope clusters and it was evaluated to be immunogenic33,34. In addition, it also identified for having high conserved domain.32,35

E protein has been reported to have about 76-109 amino acids from studies in different types of coronaviruses. Moreover, it has been demonstrated to have limited immunogenicity compared to S, N, and M proteins. Thus, E protein is not predicted as an immunogen. However, E protein knockout models have been observed to significantly reduce secretion of inflammatory cytokine such as interleukin 1β (IL-1β), tumor necrosis factor (TNF), and IL-6.36

Recent Developments in SARS-CoV-2 Vaccine Technology

Studies have shown that whole-cell killed or live-attenuated vaccine exhibit all antigenic components to the host and it could potentially trigger different immunological responses to fight the pathogen.37,38 Traditional vaccines could be developed using advanced technology to design the foremost SARS-CoV-2 vaccine that may have prompt applications in healthcare. Wuhan Institute of Virology, Chinese Academy of Sciences, Zhejiang University, and other companies have successfully isolated SARS-CoV-2 and they have started developing vaccines. Recently, Codagenix Inc. collaborated with Serum Institute of India Ltd. developed live-attenuated SARS-CoV-2 vaccine.9

Vaccine subunits that comprise of more than one antigen with high immunogenicity could trigger the host immune response. Good quality of vaccines should be safe and easy to produce; however, it commonly requires adjuvants to exhibit the strong immune response.39 Several companies have established programs to develop SARS-CoV-2 subunit-based vaccine, and most of them have been reported utilizing protein S as an antigen. The utilization of “molecular clamp” technology by University of Queensland and “Trimer-Tag” technology by Clover Biopharmaceuticals Inc. are several examples of subunit vaccines. Recently, Novavax Inc. announced nanotechnology-based vaccine candidates that have been evaluated in animal models while further testing in humans is needed. Furthermore, Pasteur Institute has collaborated with Chongqing Zhifei Biology Co. Ltd. and started developing SARS-CoV-2 subunit-based vaccine.9,40

Advanced technology in the synthesis, modification, and delivery of mRNA vaccines has been developed for past two decades. The mRNA vaccine is a notable alternative for conventional vaccine since it known for remarkable efficiency, fast production, low cost, and safe consumption.41,42 In general, the mRNA vaccine development consists of several steps, including antigen selection, sequence optimization, nucleotide modification, delivery system, evaluation of immune response, and evaluating vaccine safety.43 Recently, the mRNA vaccine against SARS-CoV-2 had been developed by Moderna and it is qualified for further analysis. Similarly, the mRNA vaccine based on protein S and RBD is being assessed into in vivo study under the collaboration of Fudan University, Shanghai Jiaotong University, and Bluebird Biopharmaceutical.9

Heterologous antigen expression is the principal action for live vector vaccines. It commonly produces stronger immunogenicity and trigger higher cellular
immunity. Houston-based Greffex Inc. has been successful in developing live vector-based SARS-CoV-2 vaccine using adenovirus vectors, and it is evaluated in animals. Moreover, Tonix Pharmaceuticals has recently announced the development of SARS-CoV-2 vaccine using Horsepox Virus (TNX-1800).

Another kind of vaccine, such as synthetic peptide-based vaccines are also developed. It generated from small fragments or peptides which synthesized through chemically process. However, it has been reported that it exhibited a low immunogenicity effect due to the low molecular weight and complex structure. As a result, synthetic peptide vaccines require a few modifications, such as structural modification, presence of a delivery system, and adjuvants formulation. Currently, researchers from Hong Kong University of Science and Technology are developing a peptide vaccine based on B and T cell epitopes from S and N proteins of SARS-CoV.

Conclusion

We hope that several vaccines that have been developed could be used as an effective treatment for COVID-19 outbreak. Different methodology of vaccine development had both advantages and disadvantages. Furthermore, current advancements in technology may assist researchers to contribute in development of SARS-CoV-2 vaccine.

How Do Patient Satisfaction in Dental Polyclinic? - Patient Characteristics and Quality of Dental Health Services

Vitri Nurilawaty¹, Ngatemi¹, Dwi Priharti¹, Tedi Purnama¹, Ruth Lasma Milan²
¹Lecturer, Departemen of Dental Health Ministry of Health Polytechnic Jakarta I, Indonesia,
²Dental Therapist of Bukit Duri Health Center, South Jakarta, Indonesia

Abstract

Excellent service is the demand of the community. Aspects of the quality of services provided will affect patient satisfaction, where patients will compare between dental treatment at dental health service facilities. In improving the quality of service, the management of complaints from patients is needed. This study aims to determine the relationship between patient characteristics and the quality of dental health services on patient satisfaction. Method: this type of analytic observational study with cross sectional design. The research was conducted on patients with dental polyclinic at the Health Center of Bukit Duri Village, Tebet District, South Jakarta. Data collection using a questionnaire. Data analysis using Chi-Square. Results: showed that the variable age had a p value of 0.691, gender with a p value of 0.013, a source of funding with a p value of 0.921 and the quality of dental health services with a p value of 0.001 on patient satisfaction. Conclusion: There is a significant relationship between gender and the quality of dental health services on patient satisfaction at the dental clinic.

Keywords: Patient satisfaction; service quality; dental polyclinic

Introduction

The health sector is the main service sector in various countries because it plays a vital role in maintaining and improving public health to achieve the goals of a country. Currently the service industry in the health sector is one of the promising business opportunities with high competition and fast growth.¹,²

The quality of health services is a factor that can increase patient satisfaction. Excellent service is the demand of society, in line with the increasing needs and awareness in state life as a result of technological advances. High quality is a requirement, not only in business activities but also in health activities.³,⁴

Aspects of the quality of service provided will affect patient satisfaction. Patients will compare or ask other people’s recommendations for dental treatment instructions. The aspects seen from the quality of service include the physical appearance of the dental clinic (tangible), reliability aspects, responsiveness, assurance, and empathy aspects.⁵,⁶

In improving the quality of service, the management of complaints from patients is needed. Many complaints from patients are received by the health center management either directly or through the suggestion box that has been provided as a channel to measure patient satisfaction.⁷,⁸

Oral and dental health services are professional health services aimed at the community, family and individuals, both sick and healthy. Dental health services are carried out to maintain and improve the degree of public health in the form of improving dental health, prevention of dental disease, treatment of dental diseases.
and restoration of dental health by the government which is carried out in an integrated, integrated and sustainable manner.9,10

Public health center is a functional organization that organizes health efforts that are comprehensive, integrated, equitable, acceptable and affordable to the community and uses appropriate technology and focuses on services for the wider community, in order to achieve an optimal health degree. Many Public health center still do not have adequate facilities for public health services. There are still a lot of dental equipment that is still not owned by the Public health center, because Public health center usually only provide basic / minor treatments, so that many cases are referred or handled minimally.11,12

Bukit Duri Health Centre is one of the Public Health Center in South Jakarta which is visited by many people because of its strategic location and adequate health personnel. In an effort to improve health services, including dental health services, the Bukit Duri Health Center has implemented an ISO 9001-2008 quality management system. It is proven that the data on patient visits at the dental polyclinic at the Bukit Duri Health Center showed that the number of patients at the dental polyclinic in 2018 was 2214 patients.

**Method**

This research is an analytic observational study with a cross-sectional design. The research was conducted at the Bukit Duri Health Centre, Tebet district, South Jakarta from March to April 2019. The sampling technique used purposive sampling. The number of samples in this study using a minimum sample of 30 respondents.13 With inclusion criteria: new patients who went to a dental polyclinic; The age of the respondent is at least 20 years old and willing to be the respondent.

The collection of service quality data using a questionnaire has been tested for its validity and reliability and patient satisfaction is measured by providing a smile card / pin.

The stages of the activity include: before conducting a questionnaire, the respondent is given an informed consent first as an agreement that he is willing to be a research respondent. Then give a service quality questionnaire and then give an assessment card / pin to enter it into the patient satisfaction box. Data analysis was performed using the SPSS statistical program for univariate analysis and presented in the form of a frequency distribution after bivariate analysis with chi-square.

Table 4 shows the relationship between respondent characteristics and the quality of dental health services and patient satisfaction. The table indicates that there is a significant difference in the patient satisfaction level among different age groups and genders. The chi-square test results show that the age group (p = 0.691) and gender (p = 0.013) do not have a significant relationship with patient satisfaction. However, the gender has a significant relationship with patient satisfaction.
Cont... Table 4. Results of the chi-square analysis of respondent characteristics and quality of dental health services on patient satisfaction

| Sources of financing |  
|---------------------|------------------|-----------------|-----------------|-----------------|-----------------|-----------------|
| BPJS                | 12   | 46.2 | 13   | 50  | 1   | 3.8 | 26  | 100 |
| General             | 2    | 50   | 2    | 50  | 0   | 0   | 4   | 100 |
| Total               | 14   | 46.7 | 15   | 50  | 1   | 3.3 | 30  | 100 |

| Quality of dental health services |  
|-----------------------------------|------------------|-----------------|-----------------|-----------------|-----------------|
| Satisfied                        | 6    | 50   | 6    | 50  | 0   | 0   | 12  | 100 |
| Very satisfied                   | 8    | 47.1 | 9    | 52.9| 0   | 0   | 17  | 100 |
| Not satisfied                    | 0    | 0    | 0    | 0   | 1   | 100 |
| Total                            | 14   | 46.7 | 15   | 50  | 1   | 3.3 | 30  | 100 |

Table 4 shows that what has a significant relationship with patient satisfaction is the variable quality of dental health services with a p value of 0.001 and gender with a p value of 0.013, while other variables, namely age and funding sources, do not have a significant relationship with patient satisfaction because p value > 0.05.

**Discussion**

Patient satisfaction is the state when the patient’s wants, hopes and needs can be met. Respondent characteristics obtained respondents indicated that the majority were 20-40 years old as many as 15 people (50%), female gender as many as 19 people (63.3%), BPJS financing as many as 26 people (86.7%).

The results of research on the quality of dental polyclinic services found that most of the respondents stated that the service quality was very satisfied as many as 17 people (56.7%). Meanwhile, regarding the satisfaction of dental polyclinic patients, it was found that the majority of respondents who stated that they were very satisfied were 15 people (50%).

The results of the study on the relationship between respondent characteristics and patient satisfaction showed a p value of 0.013, meaning that it had a significant relationship between gender and service quality.

This is in accordance with Suhamiartici. Sembelet al stated that men are easily satisfied with dental and oral care so that they do more dental and oral care. Budiman et al. stated that gender is related to patient satisfaction with Jamkesmas services at Public helath center. Gender affects satisfaction, where men have greater demands so they tend to be dissatisfied than women. In addition, gender is a predisposing factor that affects behavior.

The results of the study on the relationship between the quality of dental health services on patient satisfaction showed a p value of 0.001, meaning that there was a significant relationship between the quality of dental health services and patient satisfaction. This is due to the professionalism of dentists and dental nurses in providing services and having complete facilities and infrastructure. Ability, knowledge, skills of staff in handling every service provided so as to foster trust and a sense of security for customers.

The results of this study are in line with the results of Rizal research, there is a relationship between the quality of health services as seen from the guarantee and the level of patient satisfaction. Sembel et al. research which was conducted at the Shoulder Health Center in Manado, showed that medical services showed 89.1% of patients were very satisfied. Research Dahyanto et al. in the patient at Hospital, proved the level of satisfaction in the very satisfied category.
Conclusion

Based on the results of the study, it can be concluded that there is a significant relationship between gender and the quality of dental health services on patient satisfaction at the dental clinic.

A Study Survey of Awareness of Jordanian Chemists about Chemical Hazards

Waed R Alahmad, Tala H. Sasa, Nawal H Bahtiti, Ahmed Abu-Rayyan

Abstract

This study is an attempt to identify the level of awareness of safety measures practiced in the survey was conducted between September and December 2020 among chemists graduated in Jordan in several working sectors (teaching, Laboratory work and in manufactures). A total of 245 eligible subjects were asked to participate in the study. The majority were females (71.0%), their ages ranged from 18 to 40 years, and most of them were between 18-22 (62.9%). As for educational qualifications, 65% were students. 77.1% of them had a good knowledge of chemistry. Most of the accidents were in the laboratory by females (68%), 78% of the accidents were by females in the household. The age of 18-22 (58.9%) caused most of the accidents in the laboratory. Also, the age of 18-22 (69.9%) caused most of the accidents in the household. 55.5% of laboratory accidents were from students. As result females and students were the major reason for chemical accidents. There is no significant difference in the average attitude towards chemical safety by age. There is no significant difference in the average attitude towards chemical safety as per education.

Keywords— Awareness, chemical safety; safety perceptions; laboratory safety.

Introduction

The amount and variety of chemicals used in workplaces, households, and others have led to an increase in chemical accidents. Chemical accidents include fires, explosions, or leaks that can cause illness, injury, disability, or death. These accidents affect the environment, disrupt societies, and the economic burden in many countries. Hazardous chemicals are controlled and managed through relevant laws and regulations to prevent chemical accidents.

A chemical incident is defined as the uncontrolled emission of a toxic material, which results in harming the health and the environment surrounding it. Chemical incidents can occur because of natural activities, or because of accidental or intentional activities. These incidents can be rapid and severe or have a slow onset when there is a ‘silent’ release of a chemical. Also, they can also range from slight releases to full-scale main crises (1). The term “chemical incident” might refer to anthropogenic or technological events, including:

- an explosion at a place of work that stores or uses chemicals.
- contamination of a chemical with food or water supply.
- an oil spills.
- a leak during transportation from a storage unit.
- deliberate release of chemicals in conflict or terrorism.
- an outbreak of disease that is associated with chemical exposure.

Chemists are dealing with dangerous materials that
can be irritant, explosive, flammable, radioactive, or a health hazard. Accidents in industrial factories, chemical laboratories & chemical storages, or even in houses have been reported worldwide for several reasons, such as an absence of personal protective equipment (PPE), limited experience, mishandling of chemicals, and lack of knowledge about the proper actions to be taken in emergency cases \(^{(1)}\). A list of chemical incidents illustrated in table 1.

</tr>
</tbody>
</table>
The likelihood of these events can be minimized if chemicals are used and stored properly and under strict safety regulations and rules. As a result, regulations and laws have been developed by different organizations for using chemicals with potential hazards, through Safety Data Sheets (SDS) or labels. Labels are assigned to each chemical according to the potential hazard it may cause, and chemists should be familiar with the meaning of each label to know how it should be handled. Crucially, the United Nations Conference on the Environment and Development (UNCED) has recognized that a Globally Harmonized System (GHS) of classification and labeling of chemicals was needed.

Proper comprehension and interpretation of the dangerous chemicals & chemical labels is a very important factor for preventing accidents anywhere. Most of the studies that were conducted were aimed at students of chemistry and related branches of work in chemistry laboratories, chemical laboratory safety among college students in Trinidad and Tobago.

Regulatory standards - such as the Process Safety Management (PSM), the Risk Management Plan Rule Standard in the USA, and the Seveso III Directive in Europe - require locations where hazardous chemical products are stored and used to comply with their requirements. These regulatory standards should prompt a process safety protocol for any chemical-physical laboratory in industry and academia.

In academic physical and chemical laboratories, where toxic and flammable chemical products are handled, there should be qualified personnel. However, according to Olewski and Snakard (2017), student and research staff turnover is an important reason why compliance with these regulations is difficult in short-term experiments in academic research laboratories. Also, process safety information should be available when performing the routine analysis. However, when research is conducted, process safety information is usually part of the research. This creates a difficult problem from a safety standpoint if poor process safety information procedures are in place during the research. Ultimately, poor information on process safety for short-term experiments can occur due to the high turnover of students and postdoctoral researchers.

It is recommendations to the creation of the Chemical Hygiene Plan, involving: i) lab planning and inspections, ii) the creation of safety policies, and iii) training for students and staff.

To ensure safety and security in scientific laboratories, the following requirements must be met:

1) Risk management: It is the preventive aspect of laboratory work and aims to prevent or reduce risks to individuals and facilities, reduce losses and avoid recurring accidents.

2) Laboratory practices: It is the practical aspect that includes all practical activities related to the science course. It is imperative that these activities are sound and properly performed according to the instructions regulating them. Failure to perform tasks due to lack of knowledge, carelessness, or haste may cause accidents.

3) First aid: It represents the therapeutic aspect that is no less important than the preventive and practical side of safety procedures in the laboratory. In many cases, good behavior in an emergency and providing first aid to injured people in the laboratory can be critical.

The aim of this work was to evaluate chemist knowledge in workplaces regarding the safe use of chemicals and chemicals products in Jordan.

Methods

Study design

The survey was conducted between September and December 2020 among chemists graduated in Jordan in several working sectors (teaching, Laboratory work and in manufactures). A total of 245 questionnaire were conducted.

It is divided into the following secondary questions:

1) What is the level of awareness of safety measures (i.e., laboratory risk management, appropriate laboratory
practices, and first aid for laboratory injuries).

2) Are there statistically significant differences in the degree of awareness of safety procedures used by the participants due to practical experience at (α ≤ 0.05)?

3) Are there statistically significant differences in the degree of awareness of the safety procedures used by the participants due to the educational level at (α ≤ 0.05)?

**Survey instruments**

The questionnaire was developed based on the literature reviews of comparable studies. The questionnaire consisted of 20 items distributed into the following five sections: Personal Information, Knowledge of Chemicals, Attitude towards Chemical Laboratory Safety, Chemical Laboratory Safety Practices, Emergency Equipment and Procedures.

**Statistical analysis**

Statistical analysis was developed using STATA software program, version 16 (Stata Corporation. College Station, Tx).

**Results**

**Subjects characteristics**

A total of 245 eligible subjects were asked to participate in the study. The majority were females (71.0%), their ages ranged from 18 to 40 years, and most of them were between 18-22 (62.9%). As for educational qualifications, 65% were students. 77.1% of them had a good knowledge of chemistry. 65.0% had good knowledge of hazardous chemicals, for an issue (how many chemical accidents have you been involved in), most of the answers were between 1 to 3 accidents (89.8%).

The frequency and the percent are illustrated in Table 2.

</table>

Three questions 7, 8 and 9 were asked, then linked to basic information (age, gender, and education), and a chi-square test was administered to these questions.

Q7-where was most of these accidents?
Q8-what was the type of accident?
Q9-What is the major reason for the chemical accident?

The result shows that:

Most of the accidents were in the laboratory by females (68%), 78% of the accidents were by females in the household. The age of 18-22 (58.9%) caused most of the accidents in the laboratory. Also, the age of 18-22 (69.9%) caused most of the accidents in the household. 55.5% of laboratory accidents were from students. As result females and students were the major reason for chemical accidents. 60% of instructor masters or doctors saw that absence of protection as the main cause for the chemical accident. The persons whose age 18-22 saw that the limited experience as the main cause reason for the chemical accident.

The second part concerns the types of situations that are considered chemical accidents. For them, the answer was agreed or disagree, or neutral, Cronbach’s alpha was applied, and it gives a score of 0.671 for these questions.

T-tests and analysis of variance were performed on these questions to answer whether there were statistically significant differences in the levels of study structures that could be attributed to age, gender, and education. Table 3 shows the mean, standard deviation, and position of the position elements of chemical safety.

A t-test was performed for independent samples to test that there were no differences in the levels of the study structures that could be attributed to gender, and there was a significant difference in the mean attitude towards chemical safety of males (2.7981) and females (2.3046) $PV = 0.000 < \alpha = 0.05$. An analysis of variance was performed to explore the effect of age on levels of study constructs, Sig. $> 0.05$ no sig difference. There is no significant difference in the average attitude towards chemical safety by age. There is no significant difference in the average attitude towards chemical safety as per education. Table 3 shows Mean, standard deviation and attitude for items of Attitude Toward Chemical Safety.

It is well known that preventing or reducing accidents in laboratories is a collective responsibility that requires efforts on the part of staff and users. That is, everyone is responsible for reducing the occurrence of the accident, especially those who conducted the experiment. Accidents usually occur due to negligence, lack of common sense, failure to implement instructions, or errors in conducting experiments.

Prevention of laboratory accidents requires a range of measures including the application of safety awareness requirements after appropriate training, the use of personal safety tools such as wearing glasses and a lab coat during the laboratory period, the use of the least amount of chemicals possible, and experimentation with non-hazardous or less hazardous materials. Whenever possible, anticipate the sequence of events in action. Sources of safety awareness include university courses, faculty, laboratory safety guides, and websites (4).

Correct laboratory practices were significantly more likely in researchers who recognized that their exposure to chemicals was low, but who had significant exposure to biological hazards, who agreed with the statement that colleagues handled chemicals by following safety procedures, and who recognized that they had received adequate training in accident management and first aid. Our results showed large gaps in knowledge and a paucity of preparedness in adhering to safety processes to prevent and contain risks related to the use of chemical compounds in research laboratories (5).

Residents’ awareness of Personal Protective Equipment (PPE) against chemical accidents. Overall, 88% of the population indicated that they need to be prepared to use PPE for chemical accidents, while only a small portion (9%) of respondents answered otherwise, which means that PPE is absolutely necessary for chemical accidents (6).

The online safety training available is usually not standardized or accredited courses and is a general limitation. Conversely, similar scores across all demographic workshop groups that have received cross-curricular training indicate chemical laboratory safety, or have attended a bachelor’s degree, indicate that these resources are effective in improving students’ attitude toward chemical laboratory safety (1).

**Conclusion**

This result can be explained by the fact that strict rules apply to students enrolled in chemistry laboratories. Students are not allowed to enter chemistry labs without wearing personal protective equipment. Chemicals are kept in fume hoods, so students are not allowed to take them to their seats.

Services of Specialist Doctor at Type C Regional General Hospital based on Regulation of the Minister of Health No. 3 of 2020 on Hospital Classification and License

Wahyudi¹, Irma Indra Wahyuni¹, Muhammad Firdan Resaldi¹, Mokhamad Khoirul Huda²

¹Master of Law Students at Hang Tuah University, Surabaya, Indonesia, ²Professor Faculty of Law, Hang Tuah University, Surabaya Indonesia

Abstract

The problem occurs when the number of human resources for health workers, mainly the number of specialist doctors, is not comparable to the number of hospitals in Indonesia, particularly in type C regional general hospitals. Currently, many private hospitals are competing to provide better and quality services. When they are sick, many people choose a hospital with a much better and modern service. It becomes a concern for the government to meet its citizens’ basic needs in the health sector. The problem that lies behind the researchers to write is Regulation of the Minister of Health No.3 of 2020 on Hospital Classification and License to find out a legal review of specialist doctor services at type C regional general hospital. Based on the analysis of the Regulation of the MinisterNo. 3 of 2020 on hospital classification and license, the regulation does not regulate the minimum requirements for specialist doctors in each hospital classification. It causes an unequal distribution of specialist doctors in type C regional general hospital and results in the unequal quality of health services throughout Indonesia.

Keywords: Regional General Hospital, Law, Specialist Doctor, Type C Hospital Classification

Background of Study

Based on Regulation of the Minister of Health No. 3 of 2020 on Hospital Classification and License, it is necessary to carry out a legal analysis of the need for specialist doctors in every hospital, especially in type C hospitals. The legal analysis is to improve the degree of equitable public health in distributing specialized healthcare services and improving regional healthcare services. As quoted from kompas.com, specialist doctors’ ratio to a population is 14.6 per 100,000 population where this ratio exceeds the target ratio set. Still, the distribution of specialist doctors is not evenly distributed.¹ This condition raises many problems, and it becomes worse when it is in an emergency. There is no standby-specialist doctor at the hospital, so the patient must wait for doctors from other hospitals. The lack of concern for health services has resulted in unfulfilled health services standards and rampant lawsuits by the public.

On the other hand, hospitals are obliged to improve quality and service by especially presenting specialist doctors to make the public believe hospital services’ quality.² However, the problem occurs when the number of human resources, especially medical specialist doctors, is not comparable to the number of hospitals throughout Indonesia. The specialist doctors are located in major provinces in Indonesia and are piled up in type A and B hospitals. The unequal distribution of specialist doctors results in the quality of health services throughout Indonesia. Based on the Regulation of Minister of Health No. 23 of 2019 on the criteria for
determining the needs and selecting candidates for civil servants in 2019, regional governments must submit the number of civil servants to the central government. However, as stated in article 31 paragraph (2) of Law No. 23 of 2014 on Regional Government, the government has the autonomous right to handle the health sector to accelerate public welfare improvement. It is an increase in the human development index marked by an increase in health, education, and community income, even though type C and D hospitals require specialist doctors. The four basic specialist doctors needed are pediatrician, surgeon, internist, obstetricians and gynecologists, and an anesthetist as the supporting specialist doctors.

Hospital as one of the health service facilities is part of health indispensable resources in supporting the health efforts. Essentially, the hospital functions as a place to cure diseases must carry out health service efforts, including promotive, preventive, curative, and rehabilitative, and health restoration, as the government’s responsibility in increasing the level of community welfare. The right to get healthcare services in government hospitals must be protected to ensure health financing for the poor and emergency financing in hospitals because of disasters and extraordinary incidents.

According to Law No.36 of 2009 on Health Article 1 paragraph (1) (from now on referred to as the Health Law), health is a healthy state of physical, mental, spiritual, and social, enabling everyone to have productive life socially and economically. Health is a prerequisite for good economic growth because unhealthy people cannot work correctly, effectively, and productively, and they will spend their finance on their health treatments. The problem of healthcare and the importance of health maintaining is an integral part of the safety of productive human life as a fundamental right for every person guaranteed by the 1945 Constitution, as stated by article 28H, that everyone has the right to healthcare services. Based on article 34 paragraph (3), the state is responsible for providing proper health service and public service facilities.

Nowadays, medical science and technology are developing rapidly; hence, in this case, medical personnel and health workers must work harder also to improve their capacity by providing optimal, humane, and quality services. Nevertheless, the power of technology must be utilized carefully and responsibly to ensure its application is carried out efficiently and humanely. Satisfying and quality service, the friendliness of experienced senior doctors in handling health cases becomes a consideration for prospective patients to choose a particular hospital. According to Mosadeghrad (2013), the excellent quality of health services is indicated by appropriate service methods, good communication, joint decision making, and cultural sensitivity. Based on the description above, the researchers aim to outline the main issues on the general description of the distribution of specialist doctors, a legal review of the needs for specialist doctor services based on Regulation of the Minister of Health No. 3 of 2020 on Hospital Classification and License, and service quality and distribution of specialist doctors in type C regional general hospital (RSUD).

Discussion

Hospital

The hospital definition is clearly stated in Article 1 of Law No. 44 of 2009 on Hospital and Article 1 of Regulation of the Minister of Health No. 3 of 2020 on Hospital Classification and License. It is stated as follows, “Hospitals are health service institutions organizing comprehensive individual health services that provide inpatient, outpatient and emergency services.” Meanwhile, the Hospital in several references is explained as something with some elements, including physical buildings and other infrastructures, patients and doctors; the existence of services; the presence of sick people; the existence of treatment and medical action as professional practice.

To achieve its objectives, functions, and roles requires a transparent form of regulation; the hospital requires adequate legal instruments. Based on Law No. 44 of 2009 on Hospitals, article 1 paragraph (2), government, local government, or the private sector
can establish hospitals. Meanwhile, the Regulation of the Minister of Health on Hospital Classification and License, article 16 paragraph (1), stated the distinction of hospital classification. General hospitals’ classification is divided into type A general hospital, type B general hospital, type C general hospital, and type D general hospital. Furthermore, in Article 17, it is explained in detail about the difference in hospital classification as follows:

1. Type A general hospital, as referred to in Article 16 paragraph (1) letter (a) is a general hospital that has many beds of at least 250 (two hundred and fifty) units.

2. Type B general hospital, as referred to in Article 16 paragraph (1) letter (b), is a general hospital that has many beds at least 200 (two hundred) units.

3. Type C general hospital, as referred to in Article 16 paragraph (1) letter (c), is a general hospital that has many beds at least 100 (one hundred) units.

4. Type D general hospital, as referred to in Article 16 paragraph (1) letter (d), is a general hospital that has many beds at least 50 (fifty) units.

Hospital classification is further explained again in the Draft of Government Regulation of the Republic of Indonesia in implementing Law No. 11 of 2020 on Job Creation of Health Sector in Hospitals. The government determines hospitals’ classification based on health service facilities, supporting facilities, and human resources. As stated in article 16 of the Draft of Government Regulation, hospital classification arrangement remains only based on the number of beds. It is still the same as the previous regulation in Article 17 of the Regulation of the Minister of Health No. 3 of 2020. However, it is still in the discussion stage, which has not yet been passed into a Government Regulation.

Articles 18 and 19 of Law No. 44 of 2009 on Hospitals explained that hospitals are different based on the type of service and management. Based on the types of services provided, hospitals are categorized into general hospitals and specialized hospitals. The general hospital provides health services in all fields and types of disease, while a specialized hospital only provides primary services in one particular field or type of disease based on scientific discipline, age group, organ, or other specificities.10

**Type C Regional General Hospital**

Regional General Hospital belongs to local, district/city, or provincial government. It provides health services and must have clearly defined standard services following the public’s expectations and needs.11 The process of service delivery strongly influences the quality of health services in hospitals. Therefore, the improvement of quality factors such as physical facilities, available human resources, medicines, and medical devices, including professionalism, becomes the critical factor in quality health services and results in equitable distribution of health services to the whole community.12

Type C Regional General Hospitals is commonly facing a fact on the lack of specialist doctors. According to the Board for Development and Empowerment Human Resources of Health, at the end of 2019, there were 350 Type C Regional General Hospitals in Indonesia. In performing its functions, the Type C Regional General Hospitals requires at least basic specialist doctors (internist, obstetricians and gynecologists, surgeons, and pediatrician) and supporting specialists (radiology specialists, anesthetists, and clinical pathologists).13 The evaluation of the Board for Development and Empowerment Human Resources of Health of the Ministry of Health showed as many as 216 hospitals had met the needs for specialists, while the other 134 hospitals have not met the need yet either basic specialists or supporting specialist doctors. The non-fulfillment of specialist doctors in 134 related regional general hospitals can cause sub-optimal service for type C regional general hospitals.

The Need for Specialist Doctor Services at Type C Regional General Hospital
The need for specialist doctor services in Type C Hospitals was once regulated in several Regulations of the Minister of Health, initially regulated in the Regulation of the Minister of Health No. 56 of 2014 on Hospital Classification License. As stated in article 43, the medical workers at the type C regional hospitals consist of at least 9 (nine) general practitioners for basic medical services; 2 (two) general dentists for oral dental, medical services; 2 (two) specialist doctors for each type of basic specialist medical service; 1 (one) specialist doctor for each supporting specialist medical service; and 1 (one) specialist dentist for each type of oral dental specialist medical service.

Regulation of the Minister of Health No. 56 of 2014 subsequently changes to the Regulation of the Minister of Health No. 30 of 2019. In Article 19, it is emphasized that class C general hospital is a general hospital that has facilities and medical service capability of at least 4 (four) basic specialists and 4 (four) specialist medical support. The last amendment of Regulation of the Minister of Health on Hospital Classification and License issued in early 2020 is the Regulation of the Minister of Health No. 3 of 2020 on Hospital Classification and License. Based on this amendment, the medical services provided in Type C Hospital are divided into 3; general medical services, specialist medical services, and subspecialty medical services.14

The difference between the Regulation of the Minister of Health No. 3 of 2020 from the previous one is the removed part or ambiguity on what types of subspecialists are included in the basic subspecialty category, what is included in other subspecialty groups. The specialist doctors for basic medical services, specialist doctors for medical support services, and specialist doctors for medical services other than basic specialists and subspecialists are no longer mentioned in detail also. The operating license for determining the type of hospitals no longer requires based on the assessment results of the fulfillment of the Hospital classification criteria such as buildings and infrastructure, service capability, human resources, and equipment, but only based on assessing the number of beds. In this case, it becomes a challenge, an opportunity, or even a threat for type C regional general hospitals. There will be disadvantaged parties and vice versa by enacting the Regulation of the Minister of Health No. 3 of 2020.

Quality of Service of Specialist Doctors at Type C Regional General Hospital

According to Parasuraman et al., there are five aspects to view the service quality of specialist doctors in type C regional general hospital: reliability, responsiveness, assurance, empathy, and tangibility. Reliability is the ability to provide services reliably and accurately. Responsiveness is the willingness to help service users and provide services on time. Assurance is the knowledge and friendliness of service providers and their ability to inspire service users’ trust and comfort. Empathy is a complex cognitive and affective response to the emotional distress of others. Tangibility is the physical facilities, equipment and appearance of service personnel.15 Government must realize public service to the community as one of the community’s rights, including the right to Empathetic services. Health is a right and an investment. Every citizen has the right to health, including the poor, therefore, there must be a system to regulate its implementation to fulfill citizens’ rights to stay healthy. Health services are the rights of everyone guaranteed by the 1945 Constitution of the Republic of Indonesia, and it must be placed as the primary effort to improve the highest public heal16,17

Based on several studies, specialist doctor services at type C regional general hospital were not optimal since many people do not experience excellent service. The quality of fast and precise service at the type C regional general hospital has not been achieved. There are still many convoluted service procedures, and the community is still having difficulty getting the information services needed.18 The unequal distribution of specialist doctors in various type C regional general hospital type C, then the amendment to the Regulation of the Minister of Health No. 3 of 2020 from the previous regulation is a challenge, opportunity, and threat for type C regional general hospital. It becomes a consideration.
in improving the quality of health services for type C regional general hospital.\textsuperscript{19} Accordingly, the Specialist Doctor Utilization Program can be a solution to the need for equal distribution of specialist doctors in type C regional general hospital to optimize the quality of health services for the community.

The regional government’s role should be further improved in the health sector to maintain the distribution of specialist doctors. Based on article 9 paragraph (3) of Law No. 23 of 2014 on Regional Government, concurrent government affairs are government affairs shared between the Central Government and Provincial and Regional Governments. Concurrent government affairs submitted to the Regions are the basis for the implementation of Regional Autonomy.\textsuperscript{20} The health sector is a compulsory concurrent government affair related to basic services that fall under the region’s authority.

\textbf{Conclusion}

Regulation of the Minister of Health No. 3 of 2020 only determines the classification of hospitals based on the number of beds, while the number and qualifications of specialist doctors are only adjusted to the results of the analysis of the workload, needs, and capacity of hospital services. It is no longer specific to determine the distribution of specialist doctors, especially in the type C regional general hospital, where usually it is a lack of specialist doctors. It results in health services that are not optimal for specialist doctors at type C regional general hospital. The quality of service is a crucial thing to get attention more. Hence, Regulation of the Minister of Health No. 3 of 2020 should not eliminate the minimum requirements for basic specialist doctors owned by hospitals, and the Draft of Government Regulation on Job Creation in the Health Sector in the Hospital should restate the details of the number and specifications of specialist doctors in each hospital. It is expected to be a solution to the need for equal distribution of specialist doctors in type C regional general hospital to optimize the community’s quality of health services.

The Effects of Telehealth During Pregnancy on Maternal Knowledge and Postpartum Mental Health in the Covid-19 Pandemic

Wahyul Anis¹, Rize Budi Amalia¹

¹Lecturer Staff at School of Midwifery, Faculty of Medicine, Universitas Airlangga, Surabaya

Abstract

Background: The Covid-19 pandemic caused changes in health services, especially Antenatal Care (ANC) because pregnant women are at risk of contracting Covid-19 so telehealth is one of the methods developed to make ANC more effective and efficient. This study aimed to analyze the relationship between telehealth during pregnancy on knowledge and mental health of postpartum mothers.

Methods: The research method uses a case-control where there are two groups of samples. The case group consisted of 30 postpartum mothers who received telehealth (routine online monitoring and counseling) during pregnancy, while the control group consisted of 27 postpartum mothers who did not receive telehealth during pregnancy. Samples were taken using a random sampling technique with inclusion criteria are postpartum mothers who received online monitoring and counseling during pregnancy routinely by volunteer mothers. The exclusion criteria were postpartum mothers who did not routinely receive online monitoring and counselling. Statistical analysis used Wilcoxon Mann Whitney, Chi-Square, and Fisher Exact tests.

Conclusions: The telehealth has influenced the maternal knowledge but it will necessary to develop a telehealth strategy that contribute to the mental health of mother during the postpartum period.

Key-words: telehealth, knowledge, mental health, postpartum

Introduction

The first Covid-19 case was discovered in Indonesia on March 2, 2020. During this pandemic, it was reported that health services at the community level stopped, more than 75% of integrated service post (Posyandu) were closed, more than 41% of home visits and less than 10% of facilities primary health care (Puskesmas), antenatal care (ANC) services have also stopped. Services were stopped because of public health worker was concern about Covid-19 transmission because they face it directly¹. Telehealth is one of the innovative methods in health care that aims to monitor a person’s health because it does not allow direct examination and counseling. Telehealth for pregnant women is very important during the Covid-19 pandemic to minimize pregnant women contracting Covid 19 during direct visits to health facilities. During pregnancy, support is needed not only from the family, the community but also from health providers, this monitoring and support can be done via telehealth.

The technical guidelines for maternal and newborn health services during the Covid-19 pandemic issued by the Ministry of Health, have explained several things about telehealth, including that the District / City Health Office is expected to facilitate the use of technology to replace routine direct services. The communication technology used can be a special call center for...
Mother and Children Health, Short Message Service (SMS), Whatsapp messenger, or telemedicine/telehealth applications.

Mental health is very important, especially for postpartum mothers. The decrease in hormones during childbirth can cause postpartum mothers to be susceptible to psychological and emotional problems such as postpartum blues, depression to psychosis. Prevention of this problem is by having a good support system from families, society, and health providers. Knowledge is very important to evaluate the effectiveness of counseling by health providers. It is hoped that good knowledge can make a mother more empowered and improve their health degree. Therefore, we are interested in further researching the effects of telehealth during pregnancy on the knowledge and mental health of postpartum mothers at Krembangan Selatan dan Tenggilis Public Health Center Surabaya, Indonesia.

Materials and Methods

An observational case-control study was undertaken at Krembangan Selatan and Tenggilis Public Health Center, Surabaya, Indonesia. Ethical approval was obtained from the Faculty of Public Health, Universitas Airlangga Surabaya, Indonesia number 02/EA/KEPK/2020.

The study population was postpartum mothers in the target areas of Krembangan Selatan and Tenggilis Public Health Center. The sample in the case group was postpartum mothers who received telehealth (online monitoring and counseling) during pregnancy, while the control group was postpartum mothers who did not receive telehealth during pregnancy. Inclusion criteria are postpartum mothers who were recorded at the Krembangan Selatan and Tenggilis Public Health Centers and received online monitoring and counseling (telehealth) during pregnancy. The exclusion criteria were postpartum mothers who did not routinely receive online monitoring and counseling (telehealth) during pregnancy. The sample size was 30 postpartum mothers in the case group and 27 postpartum mothers in the control group.

This study used an online questionnaire form. The questionnaire contains questions that examine the level of knowledge and mental health of postpartum mothers. The knowledge component was questioned about pregnancy, childbirth, and postpartum that the mother should know, while the mental health questionnaire uses the Edin Burgh Scale. Data were analyzed descriptively with frequency distribution and statistical tests Wilcoxon Mann Whitney, Chi-Square, and Fisher Exact tests.

Results and Discussion

Telehealth is a method of communication in the health sector that aims to monitor a person’s health because it does not allow for direct examination and counseling. Telemedicine has proven to be a method that can be used to provide sustainable care and can increase maternal satisfaction when receiving services.

Telehealth is an important service, especially in the care of pregnant women during the Covid-19 pandemic because it can minimize pregnant women contracting Covid-19 when making direct visits to health facilities. Pregnant women are a vulnerable group to contracting the Covid-19 virus, so many recommendations aim to explain the importance of social distancing and self-isolation for this group. Telehealth will facilitate pregnant women to continue monitoring and management through online communication.

The digital era greatly facilitates health workers in providing health services through telehealth, for example by telephone, virtual communication media, and other applications that provide for online health services. Telehealth carried out in this research is a monitoring and counseling which have done by mother’s companion volunteer. They were midwifery students who have graduated from a midwifery diploma school and currently continuing their education to the professional level. Assistance activities carried out starting from early pregnancy until the postpartum period is complete.

It can be explained that most of the postpartum mothers in both groups were between 20-30 years old and were mostly not working or as housewives.

The Canadian Community Health Survey results show that a mother between 35-39 years old has a lower risk of developing postpartum depression and mothers between 40-44 years old have a greater risk of postpartum depression⁴. A study from Gebregziabher explained that housewives had 0.24 times less incidence of postpartum depression than working mothers, but mothers with low economic status had a 13 times greater risk of developing postpartum depression than the good one⁵. Occupation is a part of the demographic that related to the level of knowledge on postpartum mothers. Maternal age has a significant relationship to maternal knowledge and ability to carry out beneficial practices during the puerperium⁶.

More than half (56.67%) of the respondents in the case group had a good level of knowledge, while 48.15% of respondents in the control group had sufficient knowledge. Analysis results using the Wilcoxon Mann Whitney statistical test obtained a P-value of 0.037 so that it can be explained that there are different levels of knowledge between the case and control groups.

Table 2 explains that the knowledge level of postpartum mothers in the case group is better than the control group. In the case group, the information given is according to the mother’s need especially about pregnancy, childbirth, and postpartum. This information has given via WhatsApp message, telephone, and video call. The questionnaire used to measure the mother’s knowledge contain what pregnant women should know about pregnancy, childbirth, and postpartum.

α : 0.05

In the case group, only a small proportion (26.67%) of postpartum mothers were at risk for depression during the puerperium, while in the control group nearly half (44.44%) of respondents were at risk of experiencing depression during the puerperium. Chi-Square test obtained a P-value = 0.26, it can be explained that there is no difference in the mental health of postpartum mothers both those who get telehealth during pregnancy.

The risk of mental health disorders of postpartum mothers is great influenced by hormonal changes during childbirth and the lack of support from people around them, especially husbands and families. Health providers, especially midwives, assist women during the life cycle of women so that midwives have an important role in preventing mental health problems in women during pregnancy until the postpartum period.

Chi-square test results that there is no relationship between telehealth during pregnancy and the mental health of postpartum mothers. Postpartum mothers feel more comfortable when monitoring and counseling have given directly through home visits. Most mothers are not used to getting online or telehealth counseling. The insignificant results could also be due to the insignificant sample size because many studies are explained the importance of telehealth in mental health. Some of the factors that influence the occurrence of postpartum depression are marital status, unwanted pregnancy, infant disease, and low social support so the importance of good communication and health counseling during postpartum care.
Home-based telehealth is believed to provide effective care for mothers at high risk because it provides psychological and social comfort for pregnant women, but to achieve this requires good communication and information technology systems. The main activity of telehealth by monitoring high-risk pregnant women is an innovative way to provide a better experience for mothers. The mother is in a comfortable and private environment, it can help reduce anxiety and consider the efficiency of costs incurred. The results of experimental studies to analyze the importance of telehealth through telemonitoring in cases of metabolic syndrome explain that telemonitoring can help reduce the risk of disease, improve mental health and physical abilities so that they are more productive. Telehealth with the aim of monitoring has been applied to pregnant women who are at high risk of developing hypertension during pregnancy. Telemonitoring in pregnant women requires careful planning and it is important to collaborate with multidisciplinary knowledge by midwives, obstetricians, psychologists, nutritionists, and others to achieve the expected goals. Telemonitoring has been shown to prevent preterm labor.

Midwives and mother’s companion volunteers are very important to consider planning and strategies when implementing telehealth so that it is expected to have an impact on reducing the incidence of postpartum depression in mothers. Interprofessional collaboration is needed so that the care provided is more comprehensive.

α : 0.05

It can be explained that almost half (46.67%) of postpartum mothers who are well informed also have normal health during the postpartum period. Fisher Exact test obtained a P-value of 0.212, it can be concluded that there is no relationship between knowledge and the mental health of postpartum mothers after receiving telehealth during pregnancy.

Table 4 explains that postpartum mothers in the case group with good knowledge have good mental health during the postpartum period, but the statistical analysis is not significant. This could be because other factors affect the mental health of postpartum mothers. Several studies have shown that family support is a major factor in reducing the incidence of depression in postpartum mothers, but there is still low public awareness about the problems and impacts of mental health in pregnancy and childbirth, that efforts are needed to increase public awareness through knowledge of mental health.

α : 0.05

The results of statistical analysis using the Fisher Exact test obtained a P-value = 0.009, it can be concluded that there is a relationship between knowledge and the mental health of postpartum mothers who do not get telehealth during pregnancy.

Table 5 explains that in the control group, it was found that mothers with less knowledge were at risk of depression than mothers with sufficient and good knowledge. The results of statistical analysis using chi-square are significant, it can be explain that there is a relationship between knowledge and the mental health of postpartum mothers. Research on knowledge and mental health during a pandemic also suggests that good knowledge can be useful in reducing anxiety and depression.\(^1\)

This study results explained that providing online care through telehealth at Krembangan Selatan and Tenggilis Public Health Center shows the relationship between telehealth during pregnancy with knowledge and mental health in postpartum mothers. It still needs to do further research about strategies used in implementing telehealth because mothers in this work area are not familiar with telehealth. Factors that influence maternal satisfaction during telehealth are very important to studied, so that telehealth will provide an optimal contribution to maternal health both physically, mentally, and socially.

Research in Poland explains that midwives are not ready to accept new tasks in perinatal care, such as assessing and treating mothers who experience mental health problems during pregnancy and childbirth. Special training is needed to increase knowledge and skills related to screening and management of depression in mothers.\(^1\) Currently, there have been many studies on mental health during pregnancy and childbirth, but there have not been many implementations and efforts to reduce mental health problems. It is very important to pay attention to the mental health of mothers. Increasing maternal knowledge is an effort to reduce mental health problems in postpartum mothers.

**Conclusion and Acknowledgement**

The telehealth contributes to increasing maternal knowledge especially when there are restrictions on offline pregnancy visits because of the Covid-19 pandemic but it is necessary to develop strategies so that telehealth can more effective to improve the mental health of mothers during pregnancy and postpartum.

Discharge Plan for Parents having Children Suffering from Head Trauma

Walaa Abd Allah El-Tayar¹, Eman Amin Mohammed¹, Salma El Sayed Hassan¹, Hyam Refaat Tantawi¹

¹Department of Pediatric Nursing, Faculty of Nursing, Ain Shams University, Cairo, Egypt

Abstract

Background: Effective discharge planning is a vital component to maintain care continuity for head trauma pediatric patient. Despite this, there is a critical gap in the process and quality of discharge planning in Egypt.

Aim of this study was to assess the effect of discharge plan on parents having children suffering from head trauma.

Design: A quasi-experimental design was used.

Settings: This study was conducted in Emergency Department, Pediatric Intensive Care Unit (PICU) and Neurological Department at children Hospital affiliated to Ain Shams University and El-Menshawy Hospital in Tanta affiliated to Ministry of Health.

Subject: A convenient sample consist of 40 parents accompanied their children suffering from head trauma who attended in the previously mentioned settings.

Tools: 1)- Pre-designed questionnaire sheet which included two parts: part I: concerned with characteristics of studied parents and characteristics of the studied children, Part II: knowledge of the parents regarding caring of their children suffering from head trauma, 2)- Observational check list and 3)- Child Medical Record.

Results: All of studied parents reported that no one gave them any information about head trauma. There was a marked improvement in parents’ knowledge and reported practices post implementation of discharge plan. There were strong positive correlations between studied parents’ total knowledge and their total reported practices related to care of children after head trauma pre/post discharge plan. There was highly statistical significance difference between parents’ total knowledge regarding care of head trauma in children and their level of education post implementation of discharge plan. There was statistical significance difference between parents’ total reported practices regarding care of head trauma in children and their level of education post implementation of discharge plan.

Conclusion: All of research hypothesis were accepted and implementation of discharge plan led to significant improvements in parents’ knowledge and reported practices regarding care of their children suffering from head trauma.

Recommendations: Discharge plan for all parents having children suffering from head trauma must begin with parents at their first day of admission.

Key words: Head trauma, Discharge plan, Parents, Pediatric Patient

Introduction

Traumatic head injury is recognized as a significant public health issue that needs urgent intervention due to its role in high pediatrics’ mortality and long-term disabilities, which involve impaired physical, psychological, cognitive, emotional, and social functions, resulting in complete reliance on parents for all everyday activities.¹ & ²
Management of pediatric patients with mild head trauma targets to concentrate on early detection of intracranial injuries. These intracranial injuries lead to bad neurological outcomes if not readily detected. Clinical management of moderate to severe head trauma targets to maintain physiological state of the pediatric patient to prevent secondary brain injury, following identifying of intracranial injuries that can profit from neurological intervention and neurosurgical strategies.3

Pediatric patient return home immediately after being medically stable. This doesn’t imply that the child is recovered completely. Instead, it intelligibly means that, a specialist has concluded that the child’s condition is stable and the hospital-level treatment is no longer needed. A discharge plan is a series of actions and activities carried out by hospital clinicians to ensure that patients move smoothly and safely from acute care to subsequent care or home environments.4

After the child returns home, parents have to continue engaging in the care scenario as continuity of care and rehabilitation becomes their responsibility since the post-release period is a highly vulnerable period for pediatric head trauma patients. Intensive steps to enhance pediatric patients’ and parents’ hospital discharge planning are being considered to avoid poor discharge behaviors and treatment discontinuity and reduce the likelihood of poor health outcomes, readmission, and other adverse outcomes.5, 6

**Aim of the Study**

This study aims to assess the effect of discharge plan on parents having children suffering from head trauma. This will be achieved through:

- Assessing knowledge and reported practice of parents related to care of their children suffering from head trauma.
- Designing and implementing discharge plan for parents related to care of their children suffering from head trauma.
- Evaluating the effect of discharge plan for parents related to care of their children suffering from head trauma

**Research hypothesis:**

The current study hypothesized that there is a positive relation between discharge plan for parents having children suffering from head trauma and knowledge and reported practice related to head trauma.

**Research Design:**

A quasi-experimental design was utilized in carrying out the study.

**Technical design**

Technical design includes the research design, setting, subjects, and tools for data collection.

**Research Setting:**

The study was conducted in emergency department, pediatric intensive care unit (PICU) and neurological department at children Hospital affiliated to Ain Shams University and El-Menshawy Hospital in Tanta affiliated to Ministry of Health.

**Research Subjects:**

A convenient sample consist of 40 parents accompanied their children suffering from head trauma who attended in the previously mentioned settings, regardless their characteristics.

**Tools for data collection:**

Data was executed using the following Tools:

**I-Pre- Designed Questionnaire Sheet (Before and After):**

This sheet was developed by researcher after reviewing the related literatures in a simple Arabic language to suit all parent’s knowledge related to their awareness about care of their children suffering from head trauma. It was consisted of two parts:
Part 1: It was concerned with characteristics of studied subjects:

- Characteristics of studied parents include name, age, gender, educational level, and occupation.

- Characteristics of the studied children include name, age, gender, ranking, date of the trauma, causes of the trauma, and imaging studies include CT.

Part 2: It was concerned with knowledge of the parents regarding caring of their children suffering from head trauma which include definition, causes, types, signs and symptoms, diagnosis, management, preventive and safety measures.

II- Observational Check List:

It was used to assess parents reported practice regarding care of their children suffering from head trauma which include:

Care of child with posttraumatic seizure, consisted of 7 items according to checklist adapted from Hockenberry & Wilson, 7.

Administer of oral medication, consisted of 23 items according to checklist adapted from Leifer, 8.

Administer of ear drops, consisted of 10 items according to checklist adapted from Leifer, 9.

Administer of topical medication (Ointments and creams), consisted of 8 items according to checklist adapted from Pope, 10.

Administer of nose drops, consisted of 7 items and nasal sprays consisted of 7 items according to checklist adapted from Perry et al., 11.

Applying eye ointments and eye drops, consisted of 12 items according to checklist adapted from Mason & Stevens, 12.

Measuring axillary temperature, consisted of 11 items according to checklist adapted from McKinney et al., 13.

Apply tape water compression, consisted of 15 items according to checklist adapted from McKinney et al., 14.

Perform scalp wound care at home, consisted of 17 items according to checklist adapted from Schmitt, 15.

Perform cast care at home, consisted of 20 items according to checklist adapted from James et al., 16.

Maintain skin integrity at home, consisted of 17 items according to checklist adapted from The Royal Children’s Hospital Melbourne, 17.

Perform eye care at home, consisted of 8 items according to checklist adapted from Macqueen et al., 18.

Perform oral care, consisted of 17 items according to checklist adapted from Beatty, 19.

Preventing of falling for child from (0 to 2 years), consisted of 20 items according to checklist adapted from McWilliams, 20.

III- Child Medical Record.

Medical record used to assess child history, diagnosis, growth and development, investigations, consultation, treatment, and prognosis.

Operational design:

Field Work

The actual field work was implemented over a period of 6 months from the first of September 2019 up to the end of February 2020. The researcher was attending in the agreed study setting during morning shift 4 days/week (Saturday to Tuesday) from 8.00 am to 2.00 pm. and actual field work was divided into four phases:

1-Assessment phase

2-Planning phase

3-Implementing phase

4-Evaluating phase
Validity and Reliability:

Assessment and certainty of the tools of the study were performed by pool of five experts in pediatric nursing to enable validating of format, layout, consistency, accuracy and relevance of the tools. The reliability was conducted for the developed tools. Cronbach’s Alpha for questionnaire was 0.921 and for reported practices was 0.968.

Exploratory phase:

A pilot study was proceed on 10% of the parents of the study sample (four parents) to test the validity and feasibility of the tools, time consumed to fill in the tools. The parents involved in the pilot study were banned from the study sample.

Administrative design:

An official sanctioned permission to carry out the study was obtained through an issued letter from Dean of faculty of nursing, Ain Shams University to hospital directors of the previously mentioned settings.

Statistical Design:

The obtained data was organized, tabulated, categorized and statistically analyzed by using statistical package for social sciences (SPSS). The significance of the results was considered as follows: When \( P > 0.05 \) there is no statistical significance difference and \( P \leq 0.001 \) there is a statistical significance difference.

Ethical considerations:

The ethical considerations in the study included the following:

All the gathered data was used for research purpose only. The study sample was edified about the purpose and intended results of the study and they was assured that the study is free of hazards, they uncoerced for participation and they have the right to withdraw from the study at any time and without given any reason. They were assertive also that anonymity and confidentiality were guaranteed. Informed consent was obtained from parents preceding data collection.

Results

This study was designed to assess the effect of discharge plan on parents having children suffering from head trauma.

** Highly statistical significant difference

This table illustrated that, there was statistical significance difference between parents’ total reported practices regarding care of head trauma in children and their age, gender and job post implementation of discharge plan ($P\ value = 0.417, 0.563 & 0.662$ respectively).

Discussion

Head trauma is a critical public health problem which has a relatively high rate of emergency department
visits worldwide. It is one of the most frequent causes of pediatric death and acquired disabilities. Long-term disabilities can transpire across many areas of child functioning including: cognitive abilities, psychomotor skills, language, executive functioning, emotional and behavioral functioning, social competences, academic and occupational performance and quality-of-life, resulting to a high burden for pediatric patients and their families.\(^\text{21}\)

The findings of the current study revealed that, more than two fifths of the studied parents aged from \(30 < 40\) years. This finding was in agreement with the study of Halawa et al.,\(^\text{22}\) who study entitled “Epidemiology of Non-Fatal Injuries Among Egyptian Children: A Community-Based Cross-Sectional Survey” found that, about one third of the studied mothers were in the age group \(30 < 40\) years.

As regards characteristics of parents under study, results revealed that, more than three quarters of studied parents were females. This finding was consistent with O’Brien et al.,\(^\text{23}\) who conducted a study entitled “A Comparison of Student and Parent Knowledge and Perceived Confidence about Brain Injury and Concussion” and reported that, females parents proportion were more than two thirds, while males parents proportion were more than one third.

Concerning to parents’ level of education, the finding of the present study showed that, more than half of the studied parents held secondary education. This finding was not in accordance with Black et al.,\(^\text{24}\) who carried out a study entitled “Parental Report of Significant Head Injuries in Children Aged 3–17 Years: United States, 2016” reported that, the percentage of children suffered from head injury whose parents had high school education were higher compared with those whose parents had secondary education or less. These results might be due to the differences in the study settings.

This study showed that, more than two thirds of studied parents were not working. This finding was incongruent with Foster et al.,\(^\text{25}\) who performed a study entitled “Parent Perspectives and Psychosocial Needs 2 years Following Child Critical Injury: A qualitative Inquiry”, observed that, proportion of paid employment was the majority of the studied sample.

Regarding the characteristics of the studied children, the present study clarified that, the most affected age group was \(5 < 10\) years. This finding was contrasting with Amram et al.,\(^\text{26}\) who found in a study entitled “Socio Economic Status and Traumatic Brain Injury amongst Pediatric Populations: A Spatial Analysis in Greater Vancouver”, that, the majority of injuries occurred in children between 15 and 18 years of age.

The findings of the present study revealed that male children were more affected than female children. This was parallel to study done by Egbohou et al.,\(^\text{27}\) who carried out a study entitled “Epidemiology of Pediatric Traumatic Brain Injury at Sylvanus Olympio University Hospital of Lomé in Togo” described that, males have a higher risk of head injury than females. This result might be due to males and females are different in growing environment, neurodevelopment, and sociological attributes.

Considering parents’ source of knowledge about head trauma, all of studied parents’ reported that, no one give them any information about head trauma in hospital. From the researcher point of view, this could be due to low awareness of health care providers on importance of discharge plan in addition to, some job obstacles include but not limited to, lack of staff, and poor communication among different healthcare professionals. This finding was supported by that of Sarsfield et al.,\(^\text{28}\) who performed a study entitled “Evaluation of Emergency Medicine Discharge Instructions in Pediatric Head Injury” reported that, children sustaining head injury were inadequately instructed to restrict athletic activities upon discharge. In the same context, Camp et al.,\(^\text{29}\) who carried a study entitled “Emergency department visits for children with acute asthma: discharge instructions, parental plans, and follow-through of care--a prospective study” mentioned that, parents not obtained any specified asthma strategies to demote the repercussion of upper respiratory tract infections. Also
Kirk et al.,30 studied “Supporting Parents following Childhood Traumatic Brain Injury: A Qualitative Study to Examine Information and Emotional Support Needs across Key Care Transitions.” clarified that, parents had disappointed information and emotional support needs across the care pathway from the time of the accident up to their child’s return to home. They lacked information related to the consequences of the traumatic brain injury on their child, existing and future treatment/rehabilitation plans, helping their child and managing their behavior, and accessing services/support.

According to the studied parents’ total knowledge and total reported practices, the current study clarified that, there were an improvement post discharge plan compared to its implementation. These findings were corresponding to those of Mohamed et al.,31 who conducted a study entitled “Effect of Discharge Plan for Children Undergoing Chemotherapy and their Caregivers on Improving Practice and Coping Pattern” affirmed that, caregivers who take receipt of discharge plan instructions showed improving in knowledge and practice with regard to care of their children. In the same context Rashad et al.,32 very recently carried out a study entitled “Effectiveness of Maternal Training Program on Improvement of Care Provided to Their Children with Cerebral Palsy at Zagazig University Hospitals” reported that, slightly less than on quarter of the studied mothers had satisfactory reported practice score before implementation of the educational module compared to half of them after implementation of educational module. On the other hand, these findings were not in accordance with Thomas et al.,33 who carried out an observational study entitled “Parental Knowledge and Recall of Concussion Discharge Instructions” reported that, nearly fifth of parents who received verbal instructions were muddled about when to return to the emergency department after evaluation for head injury, moreover one quarter of parents misremembered discharge advice related to concussion.

As regards the correlation between the studied parents’ total knowledge of and their total reported practices regarding care of head trauma in children, the result of the current studied clarified that, there were a strong positive correlations between studied parents’ total knowledge and their total reported practices post implementation of discharge plan. This result indicated that the improvement in parents’ knowledge about head trauma led to improve parents’ reported practices. Previously, Hassan et al.,34 carried out a study entitled “Discharge Plan for Mothers to Cope with their Children Suffering from Bronchial Asthma” mentioned that, there were a strong positive correlations between total knowledge of the studied parents and their total reported practices post implementation of discharge plan. Additionally, Mahmoud & Sabea,35 recently conducted a study entitled “Dietary Counseling Program for Mothers of Children with Cerebral Palsy” mentioned that, mothers’ knowledge and reported practices toward their children with cerebral palsy improved significantly post implementation of the dietary educational program.

As regards the correlation between the characteristics of the studied parents and their total knowledge and total reported practices regarding care of head trauma in children, the result of the current studied indicated that, there were a positive correlations between parents’ level of education and their total knowledge and total reported practices post implementation of the discharge plan. Meanwhile, there were no correlations between parents’ age and job. These findings were close resemblance to those of Megahed et al.,36 who carried out a study entitled “Knowledge, Attitude and Practice of Rural Mothers towards Home Injuries among Children Under 5 years of age in Menouf District- Menouf Governorate, Egypt” reported that, there was a statistically significantly higher percent of satisfactory knowledge amidst mothers who held high education. There was a significant positive correlation between mothers’ practice and either their education.

**Conclusion**

All of research hypothesis were accepted and the implementation of the discharge plan led to significant improvements in parents’ knowledge and reported practices regarding care of their children suffering from head trauma.
head trauma.

**Recommendations:**
- Discharge plan for parents having children suffering from head trauma must begin with parents at their first day of admission.
- Reinforce effective discharge plan through planning, educational programs for health care providers, performance review, and standardized and policy-driven protocol.
- Periodical educational training program for all parents in safety measures should be conducted to decrease incidence of head trauma among pediatric population.

Pap Smear in A Sample of Iraqi Women with Positive Visual Inspection by Acetic Acid

Wasan Fawzi Sanad1, Halah Abdulwahhab Mohammed2, Bothayna Ahmed Alwan3
1Specialist Obstetrics and Gynecology, Fallujah Teaching Hospital, Ministry of Health, AlAnbar, Iraq, 2Specialist Obstetrics and Gynecology, Ministry of Health, Baghdad, Iraq, 3Specialist Obstetrics and Gynecology, Abu Garib Hospital, Ministry of Health, Baghdad, Iraq

Abstract

Background: Organized cervical cytology screening program are not feasible in many developing countries where cervical carcinoma is important cause of mortality among adult women. This study compared visual in section of the cervix after application of 3-4% acetic acid (Visual inspection by acetic acid, or colposcopy) with cytology as methods for the detection of cervical carcinoma and its precursors.

Method: Prospective study was done in Baghdad city. 547 patients all of them had Visual inspection by acetic acid those with positive Visual inspection by acetic acid send for Pap smear and those with positive Pap smear send for Histopathology to see the sensitivity and specificity of Visual inspection by acetic acid by 3-4% acetic acid.

Result: Visual inspection by acetic acid was positive 35.5% and Negative 64.5%, Pap smear was positive 32.0% and Negative 68.0%.

Visual inspection by acetic acid:

Sensitivity → 92.6%.
Specificity → 46.5%.
Positive predictive → 44.8%.
Negative predictive value → 93.0%.
Accuracy rate → 61.2%.

This result mean Visual inspection by acetic acid is significant and sensitive test for detection of premalignant change of carcinoma of cervix.

Conclusion: There was no significant demographic change in pap smear in Iraqi general VIA can be used in screening of cervical cancer for premalignant and malignant condition Because of high negative predictive value this will be reassure the patients probably they don’t have CIN or cancer.

Keywords: Positive Visual Inspection, Acetic Acid,

Introduction

In countries that do not have access to cervical cancer screening and prevention programs, cervical cancer remains the second most common type of cancer (17.8 per 100,000 women) and cause of cancer deaths (9.8 per 100,000) among all types of cancer in women.

Human papillomavirus (HPV) is central to the development of cervical neoplastic and can be detected...
in 99.7% of cervical cancers. The most common histologic types of cervical cancer are squamous cell (69% of cervical cancers) and adenocarcinoma (25%) (1).

Cervical cancer can be prevented by A. Visual inspection of the cervix & pap smear, in countries where Pap smear screening is routine, it is recommended that females who have had sex seek regular Pap smear testing. Guidelines on frequency vary from every three to five years. If results are abnormal, and depending on the nature of abnormality, the test may need to be repeated in sex to twelve months. If the abnormality requires closer scrutiny, the patient may be referred for detailed inspection of the cervix by colposcopy. The patient may also be referred for HPV DNA testing, which can serve as an adjunct to Pap testing. Additional biomarkers which may be applied as ancillary test with Pap test are evolving (2).

Many health care providers are under the false impression that only sterile water, or no lubricant at all, should be used to lubricate the speculum. This may result in unnecessary discomfort. A number of studies have shown that using a small amount of water-based gel lubricant does not interfere with, obscure, or distort the pap smear. Further, cytology is not affected nor some STD test (3).

B: Vaccination

HPV vaccines are typically given to women age 9 to 26 as the vaccine is only effective if given before infection occurs. The vaccines have been shown to be effective for at least 4-6 years (4).

C: Condom

One study suggests that prostaglandin in semen may fuel the growth of cervical and uterine tumors and that affected women may benefit from the use of condoms (5).

Pre-cancerous lesion

It classifies mild dysplasia as CIN1, moderate dysplasia as CIN2, and severe dysplasia and CIS as CIN3, more recently, CIN2 and CIN3 have been combined into CIN2/3. These results are what a pathologist might report from a biopsy (6).

Cervical cancer

Is a severe and potentially life-threatening illness with adverse effects on the physical and psychological well-being of patients (7). The development of abnormal cells in the cervix (uterine neck) is cervical cancer. More than 92,000 deaths in the female population due to cervical cancer were reported in agreement with WHO. The number of cervical cancer deaths is 10.3 percent in total (8). 158,000 new cervical cancer cases have been reported, and 95,766 have been reported in Southeast Asia. Cervical cancer is the most prevalent disease in Indonesia among women 0.8% (9).

Aim of Study

The aim of this study is to compare between naked eye visual inspection with acetic acid and cervical cytology as a screening test for cervical intraepithelial neoplasia.

Materials and Methods

Statistical prospectivestudy was carried out in Baghdad city (one hospital) and six health centers and oncology teaching center during the period from the 1st of May 2019 to the 1st of June 2020. The study included 547 women ages 20-55 years, who were attending the outpatient department for different gynecological problems.

Exclusion criteria for the study:

1. Virgin.
2. Pregnant woman.
3. Previous total hysterectomy.
4. Women with severe cervicitis until they had completed treatment.
5. Moderate to severe vaginal bleeding at time of examination.
6. During menstruation.
The patients included in the study were given information about the study, and agreed to participate. Questions asked to the patients are listed in paper.

Freshly prepared 5% acetic acid solution (5ml of glacial acetic acid with 95 ml of distilled water). The woman is asked to lie in a modified lithotomy position on to the examination table after she has emptied her bladder.

Cusco’s speculum was carefully inserted in the vagina, and avoids use antiseptic solution for Sterilization of genetilia. Inspection of the cervix. Then screening by VIAdone for all patient and those who had abnormal changes by visual inspection and the cervix looks unhealthy then we did tests Pap smear sampling was performed. A Pap smear sample was done for 294 patients using conventional or liquid based by Bruch.

The patient should avoid douching or using vaginal medicines, spermicidal foams, creams, or gels pessaries. The patient should not have sexual intercourse for 1 to 2 days before Pap test, because these may hide abnormal cells and cause unclear results. After completing the Pap smear, on the same day and it involve gentle application of 5% acetic acid using cotton swab to avoid bleeding. The woman is informed that she might feel a slight stinging sensation. After 1–2 minutes a naked eye evaluation was performed under 100- watt illumination. The transformation zone is carefully checked for any dense non movable acetowhite areas in the mucosa. If acetowhite areas are identified on the cervix after 1-2 minute, the test is positive. Criteria for categorization

Results

VIA test outcome Criteria

- Negative (-)
- Positive (+).
- Quire 100 randomly selected patients with negative acetowhite area but complain of IMB or PCB or having unhealthy cervix during examination.
- No aceto white lesions.
- Acetowhitening on endocervical polyps, nabothisan cysts.
- Prominent white line like acetowhitening of the squamo columnar junction.
- Faint, translucent, ill defined, irregular acetowhite lesions on the cervix.
- Definite, angular, geographic acetowhite lesions far away from the squamo columnar junction.
- Opaque, dense, dull, definite, well-defined acetowhite lesions touching the squamo columnar junction or close to the external os.
- Large, circumferential, well-defined, thick, dense acetowhite lesions.
- Growth on the cervix turns acetowhite.
- Those with negative result reassured and returned back to the program of screening by Pap smear every three year.
- Those with quireor positiveresult we did for her pap smear and then we do comparison between both results of pap and VIA.

We did colposcopy for those with abnormal finding either by pap or by VIAThen a punch biopsy was taken from transformation zone of the cervix of 94 patients with positive aceto white areas and pap smear with positive result. These samples were kept in container with 10% formaldehyde, and sent for histopathological examination to the pathologist specificity, predictive values) with their 95% confidence interval. Finding with p value <0.05 were considered significant and our P value =0.0001 tables (1-5).

Result of Pap smear: Normal LSIL HSIL Cancer

Result of VIA: Negative, positive, quire

Result of Histopathology: Normal, N.S.C CIN1 CIN2 CIN3 Cancer.

*Significant positivity using Pearson Chi-square test at 0.05 level.

Discussion

VIA sensitivity 92.6%, specificity 46.5%, VIA positivity for hormonal contraception user 22.4% & Pap smear positivity for hormonal contraception users 16.3% & for smoker VIA positivity is 33.3% & Pap smear positivity is 24.2%. And this mean that smoking and hormonal contraception is not significant risk factor for cervical cancer in our community, the most striking thing in our study is significant VIA & Pap smear positivity for patient complaining of (post coital & intermenestrual bleeding) is 78.9% & 51.5% respectively.

Hormonal contraception is implicated on cervical cancer development. Appleby et al, in analyzing 24 studies worldwide that included 16,573 women with cervical cancer and 35,509 without cervical cancer, concluded that the relative risk of cervical cancer is increased in current users of oral contraceptives, and that increased risk is higher in current smokers’ women (10).
Male Muslim circumcision and circumcision decrease incidence of HPV infection, also Muslim population have the same culture and same sexual habit, many studies show that notably orthodox and Jewesses are almost immune to cervical cancer, the strict avoidance of coitus during and after menstruation when cervical epithelium might become vulnerable,

While in Washington Pap smear is a robust test among HIV-positive women regardless of immune status. Results should be cautiously interpreted when using HPV among those younger, immunosuppressed, or on HRT <2 years, and when using VIA among those ≥40 years, of 500 enrolled, 498 samples were collected. On histology, there were 172 (35%) normal, 186 (37%) CIN1, 66 (13%) CIN2, 47 (9%) CIN3, and 27 (5%) indeterminate. Pap (ASCUS+) was the most sensitive screening method (92.7%), combination of both Pap (HSIL+) and VIA positive was the most specific (99.1%), and Pap (HSIL+) had the highest AUC (0.85). In multivariate analyses, (10)

Xi et al. in 2009 reported an analysis of 1,050 women HPV16 and/or HPV18 positives for viral DNA load, enrolled into the ASCUS-LSIL Triage Study. The authors concluded that higher HPV16 and HPV18 DNA load was associated with status of current, but not former, smoker. Among current smokers, the viral load did not appear to vary appreciably by the intensity and duration of cigarette smoking, in accordance, (11) with previous study of Gunnell et al. in 2006, that in testing for HPV16 DNA presence in first archival cervical smears from 375 cases of in situ cervical squamous carcinoma (CIS) and in 363 controls, it was found that current smokers with a high HPV16 viral load at time of first smear were at a particularly increased risk (27-fold) compared with current smokers without HPV-infection(12).

Many developing countries do not have ample resources to implement cytology-based prevention programs, which necessitates well-organized laboratories to collects material and specialized personnel apt to render a diagnosis(13).

in India, Goel in 2003 -2005 (16.27%) had a positive Pap, VIA was positive in patients (13.81%), In India Cancer cervix has been considered preventable but not prevented because it has a long preinvasive state and availability of screening programs and treatment of preinvasive lesions is effective. It has been well established that well-organized screening by cytology has substantially reduced the incidence of morbidity and mortality from cervical cancer in developed countries(14).

In Iran, Ghaemmaghami 2004 VIA test sensitivity and specificity were 95.7% and 44.0% respectively, while they were 10% and 92% for cytology tests. The results of this study indicate that although VIA is a sensitive screening test for detection of cervical dysplasia, it cannot be used by itself. Applying VIA along with Pap smears helps to detect a higher number of cases with cancer precursor lesions, which is very comparable to our research result sensitivity by VIA 92.6%, and specificity 46.5(15)

In Lahore the sensitivity of VIA was 93% and of Pap smear was 83%. Corresponding specificities were 90% and 97%. VIA was more sensitive than Pap smear which was statistically significant (P value < 0.05). The PPV of VIA was 62.5% versus 83% for Pap smear in our result PPV of VIA was 44.8% which is statistically significant (P value < 0.001) The NPV of VIA was 98% versus 97% for cytology in our result NPV 93% Accuracy rate 61.2%, our P =0.0001(significant) There was no significant difference between the negative 81 predictive values (NPV) of both tests (P value equals 1). Overall, VIA demonstrated an accuracy of 90% as compared to 96% for cytology, these results indicate that VIA is more sensitive as compared to Pap smear. The detection rate of early lesions of cervix using VIA is comparable to Pap smear in validity and usefulness. (16)

In Bangladesh However, the specificity of VIA was slightly lower (97.87%) than that of cytology (98.58%). The PPV of VIA was 73.91% versus 71.42 % for Pap smear82. Also, by Rana et al (2010), the sensitivity for VIA was 93% which is significantly higher than that for Pap. Smear (83%). There was no statistically significant
difference between the sensitivity of low and high threshold VIA, high threshold VIA were the same 80% and for pap smear was 77.5%\(^{(17)}\).

**Conclusion**

There was no significant demographic change in pap smear in Iraq. In general VIA can be used in screening of cervical cancer for premalignant and malignant condition. Because of high negative predictive value this will be reassure the patients probably they don’t have CIN or cancer. thors declare that there are no potential conflicts of interest related to the study.

Percetakan Negara 29, Jakarta, Indonesia 10560

Abstract

Data in the world states that 462 million are underweight, 47 million children under the age of 5 are wasting, 14.3 million are very thin, and 144 million are stunting. Previous study reports about 45% of child deaths <5 years are related to malnutrition—the study aim to analyzing the relationship between poverty and nutritional status of the toddler in Indonesia ecologically. The study used secondary data from the official report of the Indonesia Ministry of Health. The study takes all provinces as samples. Moreover, the study used the percentage of poor people as an independent variable. On the other hand, the researchers analyzed three other variables as dependent variables: the proportion of underweight toddlers, the proportion of stunting toddlers, and the proportion of wasting toddlers. The study examined the data using a scatter plot to determine the relationship. The results show that the greater the percentage of an underweight toddler in a country, the higher the proportion of underweight toddler in that region. Meanwhile, the more significant the proportion of the deprived population in an area, the more considerable proportion of stunting in that area. Moreover, the higher the poor people in the province, the higher the proportion of wasting in that province. The study concluded that poverty has a relationship with nutrition status of the toddler in Indonesia.

Keywords: poverty, underweight, stunting, wasting, ecological analysis, public health.

Introduction

Malnutrition can include wasting, stunting, and underweight. Data in the world states that 462 million are underweight, 47 million children under the age of 5 are wasting, 14.3 million are very thin, and 144 million are stunting. About 45% of child deaths <5 years are related to malnutrition1. Therefore, reducing child stunting is the first goal in the global nutrition target by 20252. Despite social and economic developments, the worldwide burden of malnutrition remains too high. There is an important relationship between nutritional status, human resources, and financial status. Poor nutrition causes a decrease in individuals’ physiological, mental capacities, hinders productivity levels, and is vulnerable to poverty. There is a two-way relationship between malnutrition and poverty. Malnutrition results in conditions of poverty by reducing the economic potential of the population3. Discussion on nutritional status is crucial because it is an indicator of the growth of children under five.

We can measure toddler growth through body weight, height, and body mass index. Impaired growth of children under five is a sign of an obstacle to nutritional status. Malnutrition can cause various losses, including...
developmental delays in children aged 3-6 years, quality of life of children, physical function, emotional function, social function, communication, fine motor skills, and problem-solving. The overall prevalence of developmental delay was 35.4\%.\(^4\)-\(^7\)

The prevalence of child stunting in Indonesia has remained high over the last decade. At the national level, child stunting is around 37\%.\(^2\). Another study states that the prevalence of stunting, wasting, and very thin is 9.1; 3.8; and 3.8\%.\(^6\). The prevalence of stunting was 39.4\%, while the percentage of households consuming foods high in protein and calcium was 41\%.\(^8\). This phenomenon shows that nutritional status is still a significant problem in achieving the global nutrition target in 2025. Several factors supporting stunting and wasting rates in Indonesia require a deeper study.

Previous studies have suggested that the percentage of poor people is positively related to the prevalence of stunting\(^9\). Households that occupy a livable house and have completed basic education negatively correlate with the prevalence of stunting in Indonesia. The situation means that this variable is a protective factor for a province to have short children under five. Meanwhile, non-exclusive breastfeeding for the first 6 months, low socioeconomic status of the family, premature birth, short birth length, short mothers, low maternal education are the determining factors for child stunting in Indonesia\(^2\). Education and income reduce the likelihood of being underweight by 10-30\%\(^{10}\). It is estimated that 90 percent of children, especially girls and young women, experience some form of poverty\(^{11}\). Physical, economic, demographic, social, and environmental factors are the main contributors to food insecurity\(^{12}\).

In contrast to other studies, it is stated that there is no correlation between short-term changes between measures of income and overall height\(^{13}\). Similarly, a study was found that found positive deviations of feeding with the nutritional status of children under five in low-income families \(^{14}\). Overall, the factors that represent the ecology of internal and external nutrition need to be considered to reduce stunting rates\(^{12}\)—the study aim to analyzing the relationship between poverty and the nutritional status of the toddler in Indonesia ecologically.

Materials and Methods

Study Design

The author used an ecological interpretation method in the research. Environmental research relies on collective comparisons rather than human comparisons. The data examined in the ecological analysis is aggregate data at a given community or level; in this case, it is at the provincial level. Aggregate measures, environmental measurements, and global measures should also be used as factors in an ecological survey. In epidemiology, ecological research aims to make biological inferences about individual risk effects or ecological inferences about group effects\(^{15,16}\).

Data Source

Secondary data from the 2018 Indonesia Basic Health Survey and the 2018 Indonesia Health Profile report were included in this analysis. Both papers are official documents of the Republic of Indonesia’s Ministry of Health. The province is the study’s unit of research. The thesis looked at every part of Indonesia (34 provinces).

Data Analysis

The dependent variable in this study is the nutrition status of the toddler. The nutritional status of a toddler consists of underweight, stunting, and wasting. Underweight is a classification of toddler nutritional status based on body weight index for age (Z-score < -2.0). Meanwhile, stunting is a classification of the nutritional status of children under five based on indicators of length/height per age (Z-score < -2.0). Moreover, wasting is a classification of the nutritional status of toddlers based on indicators of body weight per length/height (Z-score < -2.0)\(^{17}\).

In this analysis, poverty was used as an independent variable. The percentage of a province’s impoverished
population was used to define poverty (September 2018). The data was evaluated bivariate using a scatter plot in the analysis. The linear fit line was used in the analysis to assess the association between toddler poverty and nutrition status. The author carried out the research with the assistance of the IBM SPSS 21.

Source: The 2018 Indonesia Basic Health Survey and the 2018 Indonesia Health Profile

Figure 1 depicts a scatter plot of the number of impoverished citizens and the proportion of underweight toddlers by Indonesian province. The graph displays the two variables’ penchant for a positive relationship. The more significant the poor people proportion in a region, the higher the underweight toddler percentage.
Figure 2. Scatter plot of the percentage of the poor people and the proportion of stunting by the province in Indonesia, 2018

Source: The 2018 Indonesia Basic Health Survey and The 2018 Indonesia Health Profile

Figure 2 depicts a scatter plot of the number of disadvantaged people and the proportion of stunting in Indonesia by region. Figure 2 illustrates the two variables’ propensity for a favorable interaction; as a result of the condition, the more significant the deprived population proportion of the region, the greater the stunting toddlers proportion in that region.

Figure 3. Scatter plot of the percentage of the poor people and the proportion of wasting by the province in Indonesia, 2018

Source: The 2018 Indonesia Basic Health Survey and The 2018 Indonesia Health Profile
Source: The 2018 Indonesia Basic Health Survey and The 2018 Indonesia Health Profile

Figure 3 shows the scatter plot of the percentage of poor people and the wasting of toddlers in Indonesia’s province. The scatter plot shows the tendency for a positive relationship between the two variables. The situation means that the higher the poor population in the province, the higher the wasting toddlers proportion in that province.

Discussion

Several previous studies have informed that socioeconomic status is related to the nutritional status of children under five, both underweight, stunting, and wasting. Previous studies have found that poverty is closely related to the nutritional status of children under five\(^1\). Poverty is known to be closely associated with the ability of families to provide food needs in the family. Families with poor conditions for a long time will significantly affect the nutritional status of children under five to become worse\(^1,2\). In general, better socioeconomics is a strong determinant of better health output\(^2\).–2\)

Meanwhile, poverty in the family is also known to be related to the low level of education of family members, especially their parents’ education\(^2\). The intense maternal education situation makes them less aware of the nutritional status of children, both because of limited knowledge and because of financial limitations\(^2\)–26.

On the other hand, poverty is also closely related to poor sanitation, especially in urban slum settlements. This situation worsens the low nutritional status of children under five due to the risk of infection and disease caused by poor sanitation. The low-income family lives, including diarrhea and worms\(^27,28\).

Intervention by the government in this poor group of people is needed. This intervention ensures that there is no deterioration in the nutritional status of children under five due to food availability in inadequate families. In Indonesia, the government has issued several policies to strengthen food security for low-income families. Among them is distributing rice to the poor and providing direct cash assistance, including subsidizing contribution assistance for National Health Insurance\(^29\).

Study Limitation

Since the data used is statistical data at the regional level, this study, undertaken using the ecological analysis method, has drawbacks in its use as a policy basis. More research at the personal level is needed to collect more reliable knowledge before deciding on an intervention strategy\(^30\).

Conclusion

The study concluded that poverty has a relationship with the nutritional status of the toddler in Indonesia. The higher the poor population in the province, the higher the proportion of underweight, stunting, and wasting in that province.

Abstract
Diabetes is a social health problem that is large with special attention in the community and among individuals. Nevertheless, the efforts to spread paradigm of health society to inputsocial determinant of health including analysis and contextual of social factors that are considered out of the scope of the health research is seldom conducted. As a result, the conceptualization of dynamic health inequality of diabetes is superficial. By using a holistic anthropologist lens has the potency to offer insight intothe character of social determinant which is wider. The individual factor that is traditionally focused on the health of society and qualitative exploration structural, deeply local context, social environment, and culture, and their interaction and intersexuality, as the key factors, while considering how to reach alterations. The systematic study aims to describe that culture, ethnicity, and lifestyle have much impact on the patients of diabetes mellitus. The method of the systematic study is the article’s investigations which are listed by PubMed with the keywords “culture, ethnic, lifestyle, and diabetes”. Twenty-nine articles are got from the result of an investigation and after a selection has been done and got five articles to be analyzed furthermore. The result of the review of the literature study shows that culture, ethnicity, and lifestyle are able to influence the case of diabetes illness to the individual or group. On a certain ethnic group besides economic problem, the characteristic of certain body starts from size and shape of the body make someone can suffer from diabetes, in addition, the motoric activity of the body and physical activity can influence the case of diabetes.

Keywords: Culture, Ethnic, Life Style, and Diabetes.

Introduction
Health paradigm as a national movement in the context of health development toward Indonesia Sehat 2015 is an effort to increase national health which is pro-active. The goal of the effort is to push society to be independent to keep in their health and realize how important health service that is promotive and preventive without ignoring curative and rehabilitative efforts is.(1) The lifestyle change which affects the change of the eat behavior pattern can cause degenerative illness. Diabetes Mellitus is one of the degenerative illness. It is a group of metabolic illness which is marked by increasing of blood sugar levels. The increase can occur because of the abnormality of the secretion of insulin, insulin work, or both of them.(2,3)

among them undergo routine treatments. Environment factors and unhealthy lifestyles, such as eating too much, overweight, lack of activities, and stress have an enormous role as the cause of Diabetes Mellitus. Besides that, Diabetes Mellitus can occur because of genetic factors (Mahendra, et al, 2008).

Around 60% of the number of diabetes patients are in Asia. (4) Indonesia is in the fourth position and has the most cases of Diabetes Mellitus in the world. (5) In 2000 in Indonesia there are 8.4 million Diabetes Mellitus Patients and it is estimated to get 21.3 million in 2030. (6) In diabetes map InternationalDiabetes Federation list Indonesian over 20 years old is 125 million and by the assumption of Diabetes Mellitus prevalence 4.6%. Based on the pattern of current population growth, it is estimated that in 2020 there will be 178 million of the population over twenty-year-old within assumption prevalence of Diabetes Mellitus 4.6% will be 8.2 million Diabetes Mellitus patients. (7)

Diabetes Mellitus become the highest cause of death in a certain age group. It makes Indonesia is on the fourth world position as a country that has the most diabetes Mellitus cases. In Jawa Timur, is got that the highest prevalence is in Surabaya where is 6.2%. (6) The result is predicted that it will increase in 2030 and become 21.3 million people. Diabetes Mellitus is on top five of the biggest illness that spreads in PuskesmasPutat Jaya with 3.555 cases (6.37%).

In ancient times, Diabetes Mellitus is considered an “old illness” because more cases are found over forty-year-old, but now there has been a shift in disease. The illness transitions show that Diabetes Mellitus does not only attack elderly age but also attacks children and adolescents. The research conducted by the Child Endocrinology Coordination Work Unit throughout Indonesia in 2012 showed that the number of patients with diabetes in children and adolescents under 20 years-old was 731 people. Diabetes Mellitus in children and adolescents can be caused by some factors, one of them is the genetic factor in which children and adolescents with Diabetes Mellitus parents are at risk of developing Diabetes Mellitus.

The effort of preventions can be done to adolescents, especially those who are at risk in order to for them to not suffer from Diabetes Mellitus in the future, so the prevalence of Diabetes Mellitus cases can be brought down. Nutritional needs during adolescence are relatively bigger than other periods because adolescence is a period of growth and development. Nutritional needs in adolescence need attention because changes in lifestyle and eating habits at this time have an impact on the need for and intake of nutrients. (9)

Diabetes Mellitus (DM) is a disease, in which the condition of glucose levels in the blood exceeds normal limits. This is because the body is unable to release or use insulin adequately. Insulin is a hormone released by the pancreas and is the main substance responsible for maintaining blood sugar levels in the body to keep it in balance. Insulin functions as a tool that helps sugar move into cells so that it can produce energy or be stored as an energy reserve. (10)

Diabetes mellitus is characterized by chronic hyperglycemia. The patients with Diabetes Mellitus will be found by various symptoms, such as polyuria (lots of urination), polydipsia (lots of drinking), and polyphagia (lots of eating) with weight loss. Hyperglycaemia cannot be detected because Diabetes Mellitus does not show symptoms (asymptomatic) and often referred to as the “Silent Killer” of human beings and cause vascular damage before the disease is detected. Diabetes Mellitus can cause metabolic disorders that cause macrovascular and microvascular pathological disorders in the long-term. (11)

So far, diabetes has focused on diet only, but there are important things that have not been noticed, namely culture, ethnicity, and lifestyle, apart from genetic factors. Culture, ethnicity, and lifestyle can affect food consumption patterns which can result in overweight conditions and can trigger of arising of Diabetes. The original culture of ethnicity as well as the cultural changes experienced due to modernization can play an important role in the prevalence of diabetes in a certain
ethnic group. Therefore, the aim of the literature study is to provide an overview of how culture, ethnicity, and lifestyle can have no small effect on the occurrence of Diabetes.

**Method**

In this literature review, was conducted an in-depth study of articles published in various journals indexed by Pubmed. The keywords used in the article search were “culture, ethnicity, lifestyle, and diabetes”. In choosing articles, flow charts are used. The articles selected for analysis (inclusion criteria) were (1) articles containing descriptions of how a culture, ethnicity, and lifestyle can affect diabetics; (2) articles containing the location of diabetics; and (3) articles containing data on diabetics. Meanwhile, the exclusion criteria were articles written other than in English or Indonesian. Data taken from each research article includes information about diabetes, the location of diabetics, and data on diabetics.

![Article selection diagram](image)

**The Result**

A total of 29 articles in the form of titles and abstracts were found in the search, as shown in Picture 1. The articles were checked, then were chosen 17 articles to be selected furthermore based on the inclusion and exclusion criteria. After eliminating the unsuitable articles, there were 5 articles published from 2013 to 2015 for further analysis (Table 1).
In this systematic study, the following data were collected on the relationship between energy value and nutritional intake with body shape and size parameters (weight, height, waist, and hip line) which were carried out in 2014 and 2016 on 148 female volunteers aged 57-88 from Mazovian and Lublin Province (Poland). The sample selection targeted elderly age with different body types. The exclusion criteria were: multi-organ failure, cancer, and disability. Then among the subjects, a survey was conducted, which included demographic data, lifestyle, health status, and vitamin and mineral supplement intake. WHR and BMI index, total protein intake, animal protein intake, vitamin E intake (p ≤ 0.05), and fat, phosphorus and thiamine intake (p ≤ 0.1). The results showed that the place of residence, physical activity, chronic disease, diet use, fluctuations in body weight, BMI, and WHR differed depending on the somatotype in female groups. Endomorphic subjects had a significantly bigger waist and hip line and diastolic blood pressure compared to other somatotypes. The somatotypes only have a significant effect on total protein, animal protein, and vitamin E intake, and ectomorphic elderly women may be particularly susceptible to nutritional deficiencies. Due to the risk of macronutrients, vitamin and mineral deficiencies in the diets of the women examined, the mean age of the subjects was 68 years. Most of the subject’s education is high school. The majority of women surveyed live in cities of more than 100,000 residents. Significant differences were found between somatotypes and residence (p < 0.001). Ectomorphic females are most prevalent in cities with under 100,000 population. Mesomorphic and endomorphic subjects live mainly in cities with a population of over 100,000. Among the villages, the most dominant are endomorphic. Statistically significant relations between somatotype and physical activity, chronic disease, and application of a special diet were observed. All women with ectomorphic physiques engage in regular physical activity such as recreational activities. The majority of mesomorphic women are active, unlike the endomorphic ones who rarely do physical activity. The chronic disease most often occurs in an endomorphic physique. The application of a special diet is most popular among endomorphic women, less popular with mesomorphic subjects, and least popular among ectomorphic subjects.
Endomorphic women were more likely to experience fluctuations in body weight than those in other groups. All are ectomorphic and mostly mesomorphic are thin. Conversely, the highest number of women who were overweight or obese was found in the endomorphic group. They also had significantly more frequent WHRs above 0.8 (the tendency for ectomorphic abdominal obsession ($p < 0.001$)). Diastolic blood pressure differed significantly in somatotypes and was significantly higher in endomorphic women than in ectomorphic ones ($p = 0.046$). Average daily energy intake, total protein, animal and vegetable protein, fat, saturated fatty acids, monounsaturated and unsaturated fatty acids, cholesterol, sucrose, and fiber were estimated based on a 3-day diet. Statistically significant higher total protein intake was found in endomorphic subjects, than lower in mesomorphic ones, and low in ectomorphic women ($p \leq 0.05$). There was a statistically significant effect on the somatotype of animal protein intake. Ectomorphic and mesomorphic consume less than endomorphic.

In the study group, the tendency to increase total fat intake among endomorphs was also higher compared to other types ($p \leq 0.1$). There are no other statistically significant differences in macronutrient intake between the somatotypes. The highest propensity for higher intakes of amines ($p \leq 0.1$) and phosphorus ($p \leq 0.1$) was observed in women with endomorphs compared to the other groups. Intakes of other vitamins and minerals are similar in all subjects regardless of somatotype.\textsuperscript{(12)}

Ethnic society was stripped from their land and forcibly resettled and reserved, which currently have the highest unemployment rates in the United States. For years, diabetes rates have been very low among Native Americans. In the 1950s, the Cornell University Medical Team provided and performed physical examinations for most members of the Many Farms Navajo community and found several cases of type 2 diabetes. In 1998, Hall, Hickey, and Young \textsuperscript{11} revisited many farms and collected the comparison data. They found that members are now 10 times more likely to have diabetes than they were 30 years ago. The main changes in society included dependence on subsidized food, consisting mainly of refined flour, cheese, lard, and refined sugar. These factors coupled with the dramatic reduction in physical activity resulted from changes to traditional work patterns and greater access to fast food. Healing rituals restore body, mind, and spirit to a state of balance for a balanced and harmonious life between food, activity, prayer, sleep, and social relationships. Widely in the Southwest and Mexico, they are known to be hypoglycemic to nopal (prickly pear cactus), garlic, onions, and hintonia (copalquin). Some of these ingredients also contain toxins. Hintonia, for example, contains alkaloid pyrrolizidine which can cause severe liver damage. \textsuperscript{29,30} Other ethnic groups have followed suit. Rural South Africa Americans may believe that “blood sugar” is caused by an imbalance in eating (lots of sugar and starchy foods) and is exacerbated by stress. Common treatments include prayer, trusting in God, and the use of bitter foods and herbs (lemon juice, garlic, juniper berries) to neutralize the blood. Older African Americans may reverse the typical pattern of older ethnic members using more traditional therapies, including prayer, belief in God, and the use of bitter foods and herbs (lemon juice, garlic, juniper berries) to neutralize blood. Older African Americans with diabetes were found to use popular remedies less often. Chinese Americans may have incorporated diabetes into the traditional Chinese medical system. Diabetes may be considered a “hot” or yang illness that can be neutralized by “cold” or yin remedies. Ginseng is one of the cooling herbs believed to restore energy and cure diabetes. Mexican-American and Puerto Rican patients may believe that diabetes results from their consuming too much sugar or as God’s will or punishment. This population reports the following symptoms indicating increased blood glucose: weakness, headache, nervousness, leg pain, joy, and anger. In one study of elderly Puerto Ricans with diabetes, more than half used herbs and prayer to treat diabetes, reporting that the latter provided a peacefulness that improved their diabetes.\textsuperscript{(13)}

Culture and family challenges to diabetes management within foreign-born Chinese American families are identified as “participant” statements.
The family’s symptoms challenged family harmony. Increased irritability as a diabetes symptom was frequently described as a challenge to family harmony. Participants noted that patients “get angry easily” particularly when their blood glucose was high. Emotional variability held particular resonance for Chinese immigrants because social ease, avoidance of overt expression of strong negative emotions, and accommodation of family members’ expressed and unexpressed needs were culturally valued. Emotional fluctuations were most often attributed to the disease.

The meaning of rice in the Chinese family diet was a culturally multifaceted and historically nuanced story about sustaining holistic health and well-being and partaking of symbolically vital food. Patients and families were challenged by being asked to restrict rice and change from familiar white “fragrant” rice to foreign “chewy” and “tasteless” brown, red, or black rice. These challenges were persistently noted by participants who felt called upon to cope with this change in communal meals. The importance of rice was taken for granted in group discussions. Participants agreed that the amount of rice provided in institutional meals - such as airplanes or hospitals is very small, “If you don’t eat rice can you sustain your daily living?” Additionally, participants expressed significant suffering because of restrictions on rice, a symbolically comforting food. Many found that disease-related food restrictions disregarded cultural concerns for balancing foods (e.g., “hot” and “cold”) understood to have specific medicinal properties according to traditional Chinese medicine (TCM). Even for those who did not specifically incorporate TCM in their diet management, the metaphor of balance was powerfully invoked. Participants additionally feared that diabetic food restrictions, if strictly followed, might lead to emotional imbalance and depression. Pleasurable food was generally appreciated as crucial to mental health and balance: “If I say every time, ‘This and that you can’t eat’ some people would develop negative feelings and say, ‘There’s no meaning to life now.’” Patients’ difficulties in following an appropriate diet at Chinese restaurants led some to withdraw from socializing over meals. Spouse: “Now when I asked her to go to dim sum, she would say, ‘I am not going. You can go. I don’t want to go alone, right? (Why?) It’s meaningless to go by myself.”

For many Chinese participants, social interaction was an integral part of a meal. Attending dim sum or Chinese breakfast alone was meaningless because meals were sustaining only if shared. Difficulties in managing the social elements of meals were intensified in ritual meals. Birthdays, weddings, or Chinese New Year’s banquets, with multiple courses and desserts, were unavoidable, yet socially fraught: “Gee, I couldn’t even eat a bowl of sweet dessert soup! How miserable.” The social context of ritual meals provided layered concerns for patients and families. The presence of family reminded patients of their responsibility to observe diabetes restrictions, as a duty to family. “Since they tell you, you don’t dare do it. You are well aware that the bowl of sweet dessert soup may do you a lot of harm.” Reciprocally, family members felt obliged to care for patients’ disease and yet at the same time to create social ease and pleasure. It’s better to die. You restrict me like this and don’t let me eat.” Disagreements arose about whether all family members should observe the patient’s dietary restrictions. A few participants argued in favor of family restraint because the diabetic diet supported general health and observing restrictions demonstrated camaraderie with the patient. Participants also argued against such family restraint as unnecessarily restrictive. He agreed to his wife’s strict restrictions on family dinners but would not relinquish his breakfast pork buns. Families were additionally challenged when patients and spouses held differing expectations about what family members should learn about the disease. Some patients felt neglected because spouses were “not very aware” of the risks and demands of the disease. (14)

These results suggesting that beliefs about diabetes held by low-education African Americans and American Indians differ from all other groups is also consistent with Kawachi and colleagues’ contention that the combination of educational attainment and ethnic minority status has the potential to create distinct contexts for health disparities. Our results, when combined with the broader literature, suggest that
educational attainment and ethnicity both require careful consideration when developing and implementing culturally-appropriate diabetes education (and possibly broader health education) programs. Our multi-ethnic sample did not include individuals from other ethnic groups, like Latinos, that experience elevated rates of diabetes. The sample consisted of adults aged 60 years and older. Previous research suggests that age is associated with different EMs of diabetes among African Americans, presumably capturing either period or cohort effects. Consequently, the generalizability of the findings to young adults is unknown. Theoretically informed to ensure comprehensive coverage of diabetes-related beliefs. The comparative sample design with similar adults from three distinct ethnic groups provides a solid foundation for examining cultural differences in diabetes beliefs. The structure and content of diabetes beliefs held by Whites, African Americans, and American Indian older adults in rural North Carolina are very similar. Similarity across ethnic groups is particularly evident in the Symptoms and Consequence domains of diabetes beliefs. Where ethnic differences do exist, they appear to be driven primarily by socioeconomic factors rather than “ethnicity”.

71 percent of American Samoa females were obese and another 19 percent were overweight, leaving fewer than 10 percent of American Samoa females within the range of normal BMI. The reductions of physical activities that come with a transition away from an agricultural economy, other factors are directly connected to these increases in obesity and its related disease such as diabetes. Food choices have changed from a traditional plant and fish-based diet to one with a heavy reliance on highly processed imported foods, resulting in higher consumption of calories, protein, simple carbohydrates, cholesterol, sodium, and saturated fat. Fast-food consumption has also increased and as of this writing, the main American Samoan island of Tutuila has several fast-food outlets, including two MC Donald’s. in 2011 the local franchises began advertising Samoan burger: a big mac sandwich to which a fried egg is added.

Discussion

Somatotype can be defined as the present morphological state of the individual. The ectomorphic body type is characterized by a slim physique, weak bones and muscles, sloping arms, relatively short torso, and long limbs. The chest is narrow and flat, arms rounded, thighs and shoulders weak, fingers long and delicate and skin is dry. This body type is characterized by rapid energy expenditure, low-fat cell count, and as well as slow muscle growth. The ectomorphic physique requires less intensive training, longer interruptions, higher protein intake, and an adequate resting period. Ectomorphs are considered introverted, ill-tempered, irritable, with a tendency to schizophrenia. A mesomorphic physique is a muscular body type with a strong skeleton, broad shoulders and chest, firm limbs, massive pelvis, and very fast muscle growth. A mesomorphic person is regarded to be energetic, active, dynamic, and aggressive. In contrast, the endomorphic type is characterized by a rounded physique, a large number of fat cells, a larger waist circumference than the chest, a large head, a broad face, and a short neck. Besides endomorphs have rounded shoulders, relatively short and weak limbs and fingers, small feet and hands, and strong bones. Results are presented in a three-digit form. An individual who has only endomorphic features has the assigned symbol 7-1-1, while a person with only mesomorphic characteristics 1-7-1 and ectomorphic one 1-1-7. This means that there are 343 possible combinations.

Because females have a higher total fat mass, there are more females in an endomorphic state. The change happens as at both sexes except mesomorphic somatotype group increased until 50-year-old at the females and thereafter decreased, and Male endomorphy remained almost unchanged at the somatotype components. dried after age 30. The largest difference of all somatotype components was between the age groups 18–40 years. The mesomorphy continued to increase until the 6th decade and then decreased. The number of ectomorphy decreased until age 50 years and then there is no more
change to be observed.\(^{(18)}\)

Somatotype, diet, and female’s nutrient status 395 of endomorphic components, stability in one mesomorphy, and a little increase in ectomorphic components. It is believed that somatotype may be important in age studies like diabetes type 2 and Alzheimer’s disease where the differentiation of the big body is observed. The somatotype technic can be equipped to observe and study the change of physic in this case illness.\(^{(19)}\)

For reasons which are mentioned above and the relation between body composition and energy and the order of nutrition in this research between somatotype and diet and nutrient status of females, age 57-88 has been checked. Subjects and method of the design of the study and the research which was conducted in 2014 and 2008 2016 about 148 females 57-88-year-old from Mazovian and Lubin Province (Polandia). The result of the study in this paper is the first in Poland to show the effect of somatotype to indicators which are chosen from the health status, diet behavior, and national status nutrition of elderly females. The relations between somatotype and blood pressure has been shown in this research. Found that female endomorphy have diastolic blood pressure which is higher than mesomorphic and ectomorphic. The same correlation has been shown where the endomorphic subjects are characterized by higher blood pressure than another type.\(^{(18)}\)

The government of California State, for example, has the competency of established culture orientation to have contractor medical plans. 9 culture competencies include awareness and sensitivity of different cultures: knowledge of cultural values, beliefs, behaviors; and skill to work with a culturally diverse population. Cultural competency needs both at the practitioner level and agency. Contents and instruments have been available to evaluate practitioners and agency of cultural competency and to create service of cultural competence.\(^{(20)}\)

A cultural assessment is a focused and systematic appraisal of beliefs, values, and practices conducted to determine the context and substance of client needs and then to best adapt (or construct) and evaluate health interventions. Unlike physical assessments, cultural assessments are necessary for each of the three phases of professional practice: problem identification, intervention, and evaluation. Cultural assessments are not exhaustive of all aspects of culture, but rather are focused on those elements relevant to the presenting problem, necessary intervention, and participatory evaluation.

Needs to consider cultural factors in the treatment of diabetes patients has been identified for several decades. However, it is not close to problem-solving effectively. The main reason is that patient’s culture is often seen as a problem, the cause-obstacle to care. Our problematize are patients and culture. Next, by thinking that culture is what another has, we mind that culture can keep away from ethnic patients.\(^{(21)}\)

However franchise of fast food is a new phenomenon, Samoa non-high fat food has been part of the island diet since the early 20s century, while canned meat imported by the US army become a precious class that used in food exchange - an important golden rule for many cultural events.\(^{(22)}\) The level of practice decreases because of the movement of agricultural and sub-system when giving birth lose the source of core physical activity regularly.\(^{(23)}\) Although epidemiology research is in progress and perhaps gives the evidence of the impact of new genetic, modernization, American culture, and the change of another lifestyle in the last thirty-forty years all of them contribute to the levels of epidemic of obesity and diabetes.\(^{(23)}\)

Samoan Concepts of Health, Body Image and Individuals Previous body image studies among Samoan adults have demonstrated the acceptability of large body size. Traditionally as well as in the past, larger body size was seen as beautiful and correlated with social prestige.\(^{(24)}\)

**Conclusion**

The general data of respondents on the five articles above show that most female respondents have a higher risk to have diabetes than males. It is caused by stress levels of psycho-social and people with colored skin had higher diabetes prevalence than white people because of
socioeconomic problems. Until now, we have assumed that when we exercise self-control and strict dietary regulation of what enters the body according to our knowledge, we will avoid diabetes and based on the writer’s opinion that while someone’s knowledge of disease is pretty good then they will avoid the disease, but in the five articles above, there are not so many factors that influence, namely culture, ethnicity, and lifestyle. Therefore, in-depth research is needed in Indonesia to find out whether culture, ethnicity, and lifestyle really influence the prevalence of diabetes considering there are so many tribes in Indonesia.

Assessment of Cardiovascular Risk in a Patient with Rheumatoid Arthritis

Xamrayev Xamza1, Goyibov Salim2, Tagaeva Dilnoza2

1Assistant Professor 2Researcher, Department of Internal Medicine Samarkand State Medical Institute, Samarkand, Amir Temur Street 18, Uzbekistan

Abstract

Purpose: to study cardiovascular risk on the mSCORE scale in patients with rheumatoid arthritis (RA).

Methods: We examined 140 RA patients aged 35 to 60 years. The diagnosis of rheumatoid arthritis was made on the basis of the ACR (1987) and ACR / EULAR (2010) criteria. The mSCORE scale (SCORE / EULAR) was used for early detection and prediction of cardiovascular risk.

Results: In patients with RA, hereditary risk factors (RF) for cardiovascular diseases were detected in 31.4%, abdominal obesity in 35%, arterial hypertension (AH) in 63.6%, hypercholesterolemia in 25.7%, and hypodynamia in 37.9% of patients. Smoking accounted for 10.8% of patients in the study, as the majority (82%) of the surveyed were women. At the same time, AH was observed 1.5 times, hypercholesterolemia 2.1 times more often in men than in women. According to the results of the study on the mSCORE scale, 52 (37.1%) had low risk, 64 (45.7%), a high risk was in 14 (10%), and a very high risk was in 10 (7.2%) patients.

Conclusion: In RA patients, the use of the mSCORE scale enables early diagnosis of cardiovascular risk and timely correction of risk factors.

Keywords: rheumatoid arthritis, cardiovascular risk, mSCORE scale

Introduction

The risk of cardiovascular disease (CVD) in rheumatoid arthritis (RA) is an important problem in modern medicine. RA occupies one of the leading places among rheumatic diseases and belongs to diseases of high medical and social significance, due to the significant prevalence and progressive nature of the course, leading to early disability in patients of working age. According to multicenter studies, cardiovascular morbidity and mortality in patients with rheumatoid arthritis is higher than in the general population[Myasoedova et al. 2010; Zulfiqar et al. 2018]. The immediate cause of death in RA patients is diseases associated with atherosclerotic vascular lesions, namely: coronary heart disease (CHD), cerebrovascular accident (CVA), congestive heart failure[Liao2017; Mackey et al. 2018]. Arterial hypertension (AH) is the most important risk factor for cardiovascular complications; however, in patients with RA, there is a wide scatter in the prevalence of AH (from 16% to 76%), which is associated with an underestimation of the clinical characteristics of patients and the characteristics of antirheumatic therapy[Crowson et al. 2018; Khanna et al. 2019].

The development of cardiovascular complications in RA patients is associated with the influence of traditional risk factors, systemic inflammation, and side effects of non-steroidal anti-inflammatory drugs taken[Magda et al. 2016; Metsios et al. 2020]. In the pathogenesis of these diseases, NSAIDs, by suppressing the activity of cyclooxygenase (COX), can lead to a decrease in the systemic and renal synthesis of vasodilator prostaglandins, which causes an increase in vascular
tone and fluid retention, accompanied by an increase in blood pressure (BP) and decompensation of chronic heart failure (CHF) [Castañeda et al. 2016; Krüger 2019]. The association of RA and cardiovascular risk is the subject of close attention of rheumatologists and cardiologists. Studies have shown that the prevalence of RA is about 0.5–1% of the population and cardiovascular disease is the leading cause of mortality in these patients. In a recently published meta-analysis, the authors found that the risk of mortality from cardiovascular disease (ischemic heart disease and stroke) is 50% higher in RA patients compared to the general population [England et al. 2018; Saidova et al. 2018]. However, it is clear that early atherosclerosis observed in this group of patients cannot be explained only by traditional cardiovascular risk factors. The solution to this problem involves the assessment of the prevalence of CVD, cardiovascular risk factors and metabolic disorders; identification of groups of patients predisposed to the development of cardiovascular complications (CVC); study of the effect of antirheumatic drugs on the cardiovascular system; development of a set of preventive and therapeutic measures aimed at reducing the risk of CVC; creation of a system of dynamic control and monitoring of the development of cardiovascular pathology in this category of patients [Zegkos et al. 2016; Gómez-Vaquero et al. 2018; Saidova et al. 2018].

Material and Methods

We examined 140 RA patients aged 35 to 60 years. The diagnosis of rheumatoid arthritis was made on the basis of the ACR (1987) and ACR / EULAR (2010) criteria. When determining the frequency of cardiovascular risk factors in patients with rheumatoid arthritis, heredity, smoking, rheumatoid factor, hypercholesterolemia, abdominal obesity, C-reactive protein, as well as the incidence of arterial hypertension (AH), coronary heart disease and diabetes mellitus were assessed. The mSCORE scale (SCORE / EULAR) was used for early detection and prediction of cardiovascular risk. SCORE chart: 10-year risk of fatal cardiovascular disease (CVD) in countries at low CVD risk based on the following risk factors: age, sex, smoking, systolic blood pressure, and total cholesterol. To calculate the mSCORE risk index, the value initially collected from the SCORE risk index was multiplied by a factor of 1.5 for RA patients that met two out of the following three criteria: a disease lasting more than 10 years, RF and/or anti-CCP positivity, and finally, patients with extra-articular manifestations. The study did not include patients with coronary heart disease and diabetes mellitus.

Results

According to the results of the study, 90 (64.3%) of 140 patients with RA were women, whose average age was 51.21 ± 5.63 years, and 50 (35.7%) were men, whose average age was 52.89 ± 5.56. It was determined that 46 patients were 35–49 years old, and 94 patients were 50–60 years old. The results showed that 101 (72.1%) patients were seropositive and 39 (27.9%) were seronegative RA.

The clinical course of the disease in patients was assessed using the pain syndrome scale - VAS and the DAS-28 activity index. On the VAS scale, 25 (17.8%) patients had moderate pain, 73 (52.1%) had severe pain, and 42 (30%) had very severe pain. According to the DAS-28 index, 61 (43.6%) patients had II - moderate activity, and 79 (56.4%) - III - high activity.

In patients with RA, hereditary risk factors (RF) for cardiovascular diseases were detected in 31.4%, abdominal obesity in 35%, AH in 63.6%, hypercholesterolemia in 25.7%, and hypodynamia in 37.9% of patients. Smoking accounted for 18.5% of patients in the study, as the majority (64.3%) of the surveyed were women. At the same time, AH was observed 1.5 times, HCS 2.1 times more often in men than in women.

When analyzing the incidence of risk factors in one patient, 113 (80.7%) patients had a risk factor, of which 1 risk factor was detected in 21.4%, 2 risk factors were detected in 25%, and patients with 3 or more risk factors were 34.2%. No risk factors were observed in 19.3% of patients. When risk factors were analyzed by age,
patients aged 50-60 had higher rates than patients aged 35-49. It was noted that AH is 2.3 times more common in patients aged 50-60 years than in patients aged 35-49 years.

Cardiovascular risk scores in patients with rheumatoid arthritis were determined using the mSCORE scale. On the basis of performance criteria, patients were considered to have “low risk” less than 1%, “moderate risk” from 1 to 5% (1% ≤ 5%) and “high risk” from 5 to 10% (5% ≤ 10%), ≥ 10% are in the “very high risk” group. According to the results, 52 (37.1%) had a low risk, 64 (45.7%) had a medium risk, 14 (10%) had a high risk, and 10 (7.2%) had a very high risk. patients (Table 1).

The increased risk of death from cardiovascular disease is associated with the age of the patient and the presence of additional risk factors. Coronary atherosclerosis and the associated complications largely determine the clinical course and outcome of some rheumatic diseases [19]. In this context, it is important to reduce CVD by assessing RF, overall cardiovascular risk and changing all available RFs [Zulfiqare et al. 2018]. Of the examined patients, 64 were 35-49 years old, 76 patients were 50-60 years old. When these rates were analyzed by age, a low risk of cardiovascular disease was found in 53.1% aged 35-49 years, 23.7% aged 50-60 years old, the intermediate risk aged 35-49 years old was 40.6% and 50% at the age of 50-60. In the group of patients aged 50-60 years, the risk <10% was 2 times higher than in patients aged 35-49 years, and a very high risk >10% was found only in patients aged 50-60 years (tab. 2).

Discussion

According to international guidelines, every patient with a SCORE risk of >1% should be informed of the presence of risk factors and should work with a physician to address these factors as well as complications from cardiovascular disease [Weijers et al. 2018]. The risk factors can occur in humans over a number of years, and this condition is often the result of non-compliance with healthy birth principles [Kamilova et al. 2019]. It is therefore difficult to change the lifestyle that has been practiced over the years and it often requires an individual approach [Targocski-Stepniak et al. 2018].

Early detection and assessment of risk factors for cardiovascular diseases in patients with RA using the mSSORE scale increases the effectiveness of the principles of prevention of cardiovascular diseases by raising public awareness, eliminating risk factors, and promoting a healthy lifestyle [Ozen et al. 2016; Kamilova et al. 2019].

The results obtained showed that 10-year CVD risk indicators depend on arterial hypertension and its level, and risk factors. Assessment of CVD risk using the SCORE scale allows for the timely identification and monitoring of people with high and very high risk of cardiovascular diseases, and also increases the effectiveness of therapeutic and preventive measures [Van der Heijde et al. 2013; Turdiev et al. 2019].

Conclusion.

Thus, determination of CVD risk factors in patients with RA, the use of the mSCORE scale makes it possible to early diagnosis of cardiovascular risk, development of preventive measures and timely correction of risk factors.

The Effect of Chemical Weapon Exposure on Semen Fluid Analysis and the Determination of SOD and MDA Levels in Peshmerga against ISIS War

Yasin Kareem Amin
Assist. Prof. Hawler Medical University, General Directorate of the Institute of Forensic Medicine, Kurdistan Region-Iraq

Abstract

The identification of chemical weapons as “weapons of mass destruction” highlights their possible damaging consequences on many civilians’ health. The effect of chemical weapon agents has been documented to cause reproductive toxicity and have adverse effects on semen, leading to infertility in those exposed to those chemical agents. This study analyses the semen fluid and follows up the exposed Peshmerga forces to the chemical weapon during the ISIS war. A prospective cohort study in which 58 exposed Peshmerga in three chemical attacks, compared with the same number of the non-exposed Peshmerga. Semen fluid analysis was performed for all, following up after one year. The serum level of both MDA and SOD was measured. An individual’s BMI was calculated. The participants’ mean age in this study is (32.5) years in the case group while (35.5) years in the control group, with a standard deviation of 5 years in both groups. All participants are male, and no gender effect be seen. All chronic illnesses have been excluded from the study. The mean body mass index is 22.4, with a standard deviation of about 3.1 kg/m. Hypospermia developed in 18% of the exposed group (20% of the total participants), oligospermia (20% overall, only 3% of these in the non-exposed), and decreased motility in 19% of all participants, but 16 of this 19% where the exposed group with significant relative risk results, while morphology not changed in both groups, also the findings showed that significant elevation in MDA level and SOD activity. Chemical weapons can significantly affect semen fluid analysis and interpretation through quantitative disturbances in the volume and account of sperm, while the percentage of abnormal sperm counts has been increased considerably in peoples exposed to chemical weapons. However, the morphology of semen fluid sperms has not changed to the same degree, and its function cannot be estimated. Even when functioning, the genetic errors on future generations may need further testing.

Keywords: Exposure, Peshmerga, semen fluid analysis, MDA, and SOD.

Introduction

Infertility has been identified as the failure to function to attain pregnancy one year after regular, unprotected intercourse. In recent years, reproductive medicine and specifically male infertility have developed unexpectedly in the domain of appropriate evaluation, etiological factors such as anatomy, genetic, environmental aspects. Semen analysis is very important for evaluating male infertility. Samples can be collected by masturbation after a period of abstinence of two to three days. Semen volumes and sperm concentrations might be considerably different among fertile men. Several samples might be required before it is possible to conclude that the results are abnormal. Semen fluid volume greater than two ml is generally accepted as a reference value for any semen analysis, the sperm concentration is more than 20 million/ml, total count...
more than 40 million/ejaculate, motility of more than 50% motile, with 25% rapid progressively motile, and morphology to be more than 15% normal, vitality (live) more than 75% of the collected sample, and the leukocytes must be less than one cell in each million/ml. A normal sperm concentration is greater than 20 million per milliliter as a result; however, men with low sperm counts may be fertile. The accessory sex glands’ ability to dilute the concentrated epididymal spermatozoa during ejaculation with fluids. Sperm concentration is affected by other reproductive organs’ functioning, so it is not a quick indicator of testicular sperm product. Nevertheless, multiplying sperm concentration by semen volume yields the total number of sperm ejaculated. In the absence of ejaculation, spermatozoa accumulate young and older adults’ sperm concentrations in semen fluid, for example, maybe similar. Still, their total sperm counts may vary; as people get older, both the volume of seminal fluid and total sperm production decrease, as a minimum, in some populations. The time since the last sexual activity. The epididymis is then flushed out in the urine after running into the urethra. The increased length of abstinence and penultimate abstinence period does not affect sperm vitality or chromatin. Semen is formed during ejaculation from a concentrated suspension of spermatozoa held in the paired epididymis, fluid secretions from the accessory sex organs mix with and dilute, containing two main quantifiable attributes. The total number of spermatozoa is the first attribute, and it underlines sperm production by the testes and the post-testicular duct systems potential. The total fluid volume, which reflects secrecy activity of the glands, is the second attributed by all the accessory glands; the sperm (its vigor, motility, and morphology) is therefore of particular importance, and the composition of seminal fluid for sperm usages purposes. This social problem became very easy to be solved in medicine with the help of new technology even though these slightly new techniques assisted various infertile men to be a father, the long-standing dream that they had, several other males who were fertile and lost their probable fertility as a result of numerous causes for example exposure to chemical, physical, biological and additional ecological risk agents. Some men with low sperm counts are still fertile. Different types of sperm function tests can be performed in specialized laboratories. However, they do not add much to the treatment options. Etiology: toxic materials harm the testes as well, such as insecticides, fungicides, heavy metals, cottonseed oil, and chemical agents used during wars, which may create negatively affected the germ cells. Leydig cells are also less susceptible than Sertoli or germ cells to the majority of chemotherapeutic medication. However, serum testosterone stages are usually used in exposed men despite their infertility. However, exposure to these agents is not the only aspect that affects fertility. Suppose it is at work and to chemical agents. In that case, it will cause continuous exposure more likely; even people who live in contaminated zones could have infertility because the protection of humankind is a serious environmental crisis that can disturb this process (fertility). Such a problem cannot be terminated unless international cooperation and interference regarding this problem will be planned. Chemical Conflict Agents, used in wars between Iraq and Iran (S/16433, United Nations, 1986). For example, Sulfur Mustard is a lipophilic alkylating chemical agent used as a primary chemical warfare weapon. Most of the patients have been exposed to the chemical warfare agents, which existing a single contact with Sulfur - mustard gas. Nonetheless, both concentration and duration of the breath of mustard diverse. As long as we were investigating the effects of chemical warfare agents and organization over the histories of people who had been exposed, we comprised people with a single exposure. Terrorists could find agents problematic to employ as weapons of mass destruction for several similar reasons that apply to choking agents. The effects can enter the body in various ways like breath or interaction with the eyes or the skin. Some agents can infiltrate by regular clothing materials, triggering blisters even in parts with a cloth covering. Whereas agents that cause blisters can respond rapidly through contact with the skin, their symptoms could be overdue. In the agent mustard, impairment happens within 1 to 2 minutes during the exposure time, choking agents are mostly gases, have noticeable smells, and the color
maysurround the air. Investigation detecting chemical agents after chemical weapon exposure is the part of the concern for soldierly developers, although some of these agents need detection proficiencies at first responders qualified to handle risky materials, whereas, some of the armed units have suitable equipment for chemical weapon detection, civilian people who are the first responders, they use a diversity of profitable equipment to spot and recognize an inclusive variety of chemicals, mostly in a dangerous material background.12,13

**Material and Methods**

**Patient and sampling**

A descriptive cohort study is performed. In this study, we examined 63 exposed Peshmerga, 58 of them included and taken as a sample group. In contrast, 22 participants were taken from the same military unit as the control group (who are not exposed). During the study, initial abnormal results from both groups are excluded (exclusion criteria). The data collected difficulty, and it is not far from the examiner’s exposure to the remnant of chemical weapon products carried by the participants. However, data collection and analysis were performed in the forensic medical institute in Arbil city from 2016 till May 2018. All victims were transferred to the local military health care unit and then transferred to the emergency hospital at the Erbil west emergency hospital. They have both signs and symptoms of dyspnea, lacrimation, cough, skin sores, pruritus, and erythema. Samples were transferred to the forensic medicine institute, then to a specific international laboratory and exposed confirmed through examples taken from clothes blood, urine, hair, saliva, and semen fluid sample-exposed documented by international labs and through the help of some humanitarian organization. Inclusion criteria detailed chemical exposure. A single exposure to a different chemical agent is defined that can cause acute signs and symptoms exclusion (criteria 1) none exposed and non-documented exposure (criteria 2) history of primary infertility. All patients had the same clinical severity; that is why no categorization was performed for dividing exposed military units. However, the sample was taken as the case group, and an equal number of military units taken as the control group concerning age and location. Both groups are examined periodically by re-taking history and re-examination with repeating semen fluid analysis (with three-day abstinence from sex before examination) semen fluid analysis performed in labs of the forensic medical Institute of Arbil city and patient-guided by expert nurses with analysis of the sample according to international guideline and standard laboratory instruments and equipment. After the case group was exposed to the chemical warfare agent, the study group and the control group were followed up on during the study. The members of the control group had never been exposed to somewhat of chemical war agents. Both groups were nominated from a similar military service location and were told similar conditions apart from the chemical agent.

**Procedure**

After 30 minutes as the time of liquefaction, the sample (ejaculated semen) collected in a container-specific sterile tube, immediately taken to the lab, with labeled data, date, and time besides the name of the patient recorded on both container and visitors of the lab, for analysis, quantitative and qualitative study for semen fluid performed by an expert analyzer. Then all results were recorded and saved on the lab system for further evaluation. The method of Estimating the activity of the Superoxide Dismutase (SOD) enzyme depends on the SOD’s ability to prevent epinephrine from being autooxidized into adrenochrome, the reaction occurs at 30 °C, pH = 10.2, and SOD measured at wavelength 480nm, absorbance was measured using Spectrophotometer (G10S UV-VIS, Thermo scientific, USA). Thiobarbituric acid (TBA) reacts with Malondialdehyde (MDA), the lipid peroxidation process’s end product, at 100 °C and acidic medium produce a pinkish complex product. The product is measured at 532nm. Absorbance was measured using Spectrophotometer (G10S UV-VIS, Thermo scientific, USA).
**Statistical Analysis**

New WHO guidelines have been regarded in all aspects of the infertility questionnaire for data collection from the case and control group during the study period. All data were entered into a computer by using Excel program. All statistics analyzed using SPSS (Version 21) and a significant P-value of less than \( (P \leq 0.05) \) with 95 % confidence intervals.

**Results**

The average age in this study of the participants is 32.5 in the case group while 35.5 in the control group, with a standard deviation of 5 years in both groups. All participants are male, and no gender effect be seen. All chronic illnesses have been excluded from the study. The mean body mass index is 22.4, with a standard deviation of about 3.1 kg/m; nearly all exposed peoples are smokers, and all are married. Table 1 shows the effect of chemical exposure on semen fluid volume (semen volume of fewer than 2 ml is regarded as hypospernia), the incidence of hypospernia compared in both groups compared (relative risk). Hypospermia is increased in the exposed group by about 3.2 times than in the non-exposed group. The lower limit range of hypospermia recorded is 0.5 in three participants in the exposed group, with an average semen volume of about one milliliter in the exposed group with hypospermia. In contrast, the lower limit of hypospermia is 1 milliliter in the non-exposed group.

</table>

Table 2 shows the effect of chemical exposure on sperm count, a prominent decrease in sperm count in the exposed group on with relative increase risk of oligospermia by about 2.6 times than in the non-exposed group. The minimum sperm count is 1 million seen in two participants in the exposed group, with an average sperm count of about 6 million and a standard deviation of about 3 million.

</table>
On further evaluation, the motility also decreased in the exposed group by 2.1 times than those not exposed (Table 3). On further analysis of the exposed group of sperm motility, the effect ranges from sluggish to extreme immobility, with nearly 70% of immobility in more than half of the exposed participants. However, the ratio is more extreme, reaching 90% of immobility in the exposed group but only reaches 65% in the non-exposed group with significantly fewer immortality cases.

On the other hand, no effect of chemical exposure is seen according to this study on sperm morphology. The relative risk between the incidence of exposure to the non-exposed group is about equal (relative risk =1) (Table 4). The accepted lower limit of 5% normal morphology apparent in nearly all participants in both groups. Even those with abnormal morphology are a total of three participants, and one of them in the non-exposed group and has an abnormal morphology of about 4.5 %. The exposed group, on the other hand, displayed normal morphology in only two participants.

Discussion

Ghanei and Allameh, from Iran study, chemical warfare agents' effect on fertility in the case-control pattern through a questionnaire-based method to detect infertility in the exposed group versus the non-exposed group. This is in comparison to our study. We concentrate on the result of semen fluid analysis only; the comparison of each survey is to single exposure to chemical weapons with follow up in one year. The chemical materials used in the war on Iraq-Iran were archived in the United Nations S/16433, 1986. While our article is not documented by the United Nations but supported by several humanitarian organizations, Ghanei and Allameh, 2500 male study has participated, but in our research, there are 58 males, which is a relatively smaller sample. In both mentioned studies, the presence of a prior history of infertility is an absolute criterion for excluding the exposed person or participant in the control group. The research group's average age was 28.5 +/- 4 in the Ghanei, and Allameh, study versus 32.5 +/- 3 in our study, when compared to the control group, the mean age of participants was 35.4 +/- 5, while 38.5 +/- 3 in the current study, which indicates no so much difference in the age groups in both studies, making an age effect of being not significant. At the end of the study of Ghanei and Allameh, concluded no impact of a chemical weapon on male fertility while the results on semen fluid analysis were not declared. Still, in our research, it is finely analyzed the effects on semen fluid analysis, making a question for future study and the possibility of gene error detection as a plan for a prospective study. On the other hand, and in a study performed in Iran in 2005, there was no infertility registry available among the soldiers who had been exposed to chemical war agent throughout the first Gulf War. Male infertility was not proven, and there was no noticeable significant difference between the exposed and non-exposed soldiers. In these two contrary studies, we can cross to an idea in which the functional assessment may give the exact explanation for semen fluid. However, none of these studies, including the current research, did perform this step in his article during his phases of medical works. Many chemicals in use in industry and are over the earth and within the water of use, seems to be reaching the semen fluid of the infertile men, reports by a Queen's university research scientist, which may make the isolated effect of these chemical weapons of concomitant harm in both control and patient's groups, that is to say, the environmental impact of these chemicals to be of note. In patients with normal semen fluid parameters besides blood count and 24-hour urine analysis of most sensitive biologic index to think about psychiatric complain in the exposed group, and may which may give an excuse for further functional testing in current and future study. In this study also, a significant increase in MDA levels was detected in the patients; this elevation in MDA levels as a result of an overabundance of reactive oxygen species (ROS) contributing to an excess of oxidative damage in these patients. In turn, these oxygen types can oxidize various other vital biomolecules, including the membrane of lipids. This rise in MDA levels corresponds to a study that found an increase in MDA levels in patients suffering from reproductive problems.
in SOD activity stages may be due to excessive ROS generated through oxidative stress (OS). Also, the increase in SOD activity levels could be due to the rise in OS patients with dismutation of superoxide results in the development of \( \text{H}_2\text{O}_2 \). A study indicated that the levels of SOD activity were observed to be higher in the blood serum of male patients with reproductive problems.\(^{18}\)

**Conclusion**

In the current study, we can conclude that chemical weapons can significantly affect semen fluid analysis and interpretation through quantitative disturbances in the volume and account of sperm. In contrast, the percentage of abnormal sperm count has markedly increased in people exposed to chemical weapons. However, the morphology of semen fluid did not change to the same degree, and its function cannot be estimated. Even when functioning, the genetic errors on future generations may need further testing.

A Comparison Study of Adding Magnesium Sulfate to Local Anesthetics During Spinal Anesthesia for Cesarean Section

Yasir Fadhil Alkhazraji¹, Haitham AbdulSattar Sahib², Mukhallad Mahdi Saleh³

¹Lecturer, MBChB, FICMS-A & IC. Iraqi fellowship of interventional pain Management IBMS/IFIPM. College of Medicine/Al-Nahrain University, ²Researcher. MBChB, FICMS/CABA&IC. Baghdad Teaching Hospital, ³Researcher. MBChB, FICMS. Ghazi Al Harreri Hospital

Abstract

Background: Regional anesthesia is frequently used in obstetric, orthopedic, and urological procedures, commonly intrathecal and epidural local anesthetics are combined with opioids to prolong analgesia; however, these do not prolong the motor block time and can attenuate the response to surgical stress, in addition to being associated with side effects such as respiratory depression, urinary retention, pruritus, hemodynamic instability, nausea, and emesis. Objective: to investigate the effect of adding 75 mg of magnesium sulfate on the duration of sensory block and duration of motor block

Patients and Methods: In a prospective randomized study, ASA I or II, 128 (64 control and 64 experimental groups) pregnant women (at term) who were candidate for cesarean section with spinal anesthesia, were recruited in this study. They were collected from “Baghdad Teaching Hospital” at the period from (September 2020 to Feb 2021).

Each experimental woman received 12.5 mg (2.5 ml) of hyperbaric bupivacaine (0.5%) and 0.5 ml (75 mg) magnesium sulfate (15%), while controls received same does of hyperbaric bupivacaine and 0.5 ml of distilled water.

Results: The duration of analgesia (sensory blockade) and the duration of motor blockade manifested a statistically significant increase in experimental as compared to their controls (control = 116.41 ± 12.47, experimental = 159.75 ± 10.56, control = 180.76 ± 11.83, experimental = 240 ± 9.46 minutes respectively).

Conclusion: Significantly increased the duration of postoperative analgesia and prolonged the sensory and motor blockade without significant apparent maternal or fetal side effects.

Key words: Spinal anesthesia, Bupivacaine, Magnesium sulfate, Cesarean

Introduction

Regional anesthesia is frequently used in obstetric, orthopedic, and urological procedures, commonly intrathecal and epidural local anesthetics are combined with opioids to prolong analgesia; however, these do not prolong the motor block time and can attenuate the response to surgical stress, in addition to being associated with side effects such as respiratory depression, urinary retention, pruritus, hemodynamic instability, nausea, and emesis. There are other drugs that can enhance antinociception, including epinephrine, clonidine, ketamine, and neostigmine.

Spinal anesthesia, is a form of regional anesthesia involving injection of a local anesthetic into the
subarachnoid space, generally via a fine needle through intervertebral foramen (L4 –L5).\(^{(1)}\)

Cesarean section is one of the most frequent surgeries in the world, and surely the most frequent obstetric surgery, with an incidence that varies between countries, hospitals and even between obstetric groups 1 out of 23 \(\%\) and more than 50\(\%\) of pregnancies.\(^{2}\)

The type of anesthesia used depends on multiple factors, among others: availability of anesthesiologist, urgency of the procedure, maternal preoperative status, indication for cesarean section, personal preference, etc.

Currently, the type of anesthesia most used for this type of procedure is neuraxial regional anesthesia (epidural and / or subarachnoid), which offers the advantages of keeping the mother awake, allowing early contact with the newborn; minimize the potential risk of gastric content aspiration; avoid neonatal depression due to general anesthesia drugs 2 and be associated with a 16 times lower risk of maternal mortality due to anesthetic causes, when compared to that of general anesthesia \(^{3}\).\(^{\(\text{6}\)}\)

Magnesium sulfate was added to local anesthetics too for the same purpose. In experimental studies, spinal injection of magnesium sulfate reduces the response to painful stimulus in rats.\(^{(7)}\) On the other hand, magnesium sulfate potentiates morphine anti-nociception at the spinal level.\(^{(8)}\)

### Complications of Spinal Anesthesia

The real incidence of neurological complications after neuroaxis blockade is difficult to obtain due to its low frequency, its lack of registration and communication, and the legal implications that its declaration entails. Furthermore, the different definitions of complication and the heterogeneity of the groups studied make their measurement even more difficult. Overall, we can say that the incidence of neurological complications related to central blocks is less than 4 / 10,000 patients, with 0-4.2 / 10,000 and 0-7.6 / 10,000 being permanent after spinal and epidural anesthesia, respectively.\(^{(7)}\)

The incidence of post-dural puncture headache (CPPD) has now decreased greatly due to the use of small gauge “pencil point” needles (25G and 27G) (0.002-1.2\%) \(^{8},\ ^{9}\), designed to minimize the loss of cerebrospinal fluid when puncturing the dura mater.

### Aim of the Study

To investigate the effect of adding 75 mg of magnesium sulfate (to hyperbaric bupivacaine) on the duration of sensory and motor blockade.

### Patients and Methods

This study was performed after the approval of the Iraqi Council for Medical Specialization in anesthesia and intensive care, and after obtaining them consents from the patients.

In a prospective randomized study, ASA I or II, 128 (64 control and 64 experimental groups) pregnant women (at term) who were candidate for cesarean section with spinal anesthesia, were recruited in this study. They were collected from “Baghdad Teaching Hospital” at the period from (September 2020 to Feb 2021).

Each experimental woman received 12.5 mg (2.5 ml) of hyperbaric bupivacaine (0.5\%) and 0.5 ml (75 mg) magnesium sulfate (15\%), while controls received same does of hyperbaric bupivacaine and 0.5 ml of distilled water.

Patients were randomly chosen and divided into two groups: control group (64 patients) and experimental group (64 patients).

The inclusion criteria were:

1. Age (17-40) years
2. Height (151 - 170) cm
3. Weight (57 - 78) kg
4. ASA class I or II.

The exclusion criteria were:

1. Regional anesthesia refusal
2. Absolute contraindication of spinal anesthesia

3. Complicated pregnancy

Dosing:

After obtaining their consent and explaining the full details of the study.

Each experimental woman received 12.5 mg (2.5 ml) of hyperbaric bupivacaine (0.5%) and 0.5 ml (75 mg) magnesium sulfate (15%), while controls received same does of bupivacaine and 0.5 ml of distilled water.

Each patient, from control and experimental groups, were monitored by recording:

1. The time of onset of anesthesia (TO)
2. The time of end of surgery (TES)
3. The time of analgesia requirement (TAR)
4. The time of complete recovery (CR)

Statistical Analysis:

Data were analyzed using SPSS version 25. Descriptive statistics as mean ± standard deviation.

Student – T – test was employed for comparison between control and experimental groups.

All statistical analysis level of significance was set at P value equal or less than 0.05 to be considered as significant difference.

Results

General Notes

The side effects during anesthesia and in recovery, such as nausea, vomiting, headache and dyspnea and side effects during surgery such as hypotension were relatively lower in experimental group than controls although not statistically significant.

Age, height and weight:

The age, height and weight of control and experimental patients (the 128 patients who were included in this study) are summarized in table (1), (2) and (3) respectively.

No significant difference was found in the studied groups regarding to age, height and weight.

Discussion

Duration of analgesia (Duration of sensory block)

Few trials were done to increase the time of analgesia and anesthesia by adding different doses of magnesium sulfate to the local anesthetics. Shoeibi and his coworkers, recorded an increase in duration of analgesia after adding 50 mg magnesium sulfate to lidocaine spinal anesthesia. Moreover, Manjula and colleagues disclosed that addition of 50mg of magnesium sulfate to 2.4 ml of 0.75% of isobaric rupivacaine spinal anesthesia prolongs the duration of sensory and motor blockade. Furthermore, Buvanendran and colleagues found that intrathecal magnesium prolonged (20 µ) fentanyl analgesia. However, Mitra and Sayed found that adding 100mg of magnesium sulfate to hyperbaric bupivacaine prolongs the duration of analgesia, while 50 mg of magnesium sulfate didn’t do it. On the
other hand, Khalili and his coworkers arrayed that in patients undergoing lower extremity surgery with spinal anesthesia, the addition of 100 mg magnesium sulfate to 15 mg bupivacaione without opioid supplement, prolonged the duration of the sensory block, decreased postoperative analgesic consumption, and significantly prolonged the onset of spinal anesthesia. (13) All the above mentioned investigations agreed that magnesium sulfate revealed a statistically significant increase in the duration of anesthesia, and this coincides with the outcome of this study. However, the dose of magnesium sulfate that causes this statistically significant prolongation of the analgesia was controversial. All agreed that adding 100 mg of magnesium sulfate leads to a significant prolongation of sensory blockade (12,13), yet 75 mg and 50 mg disclosed significant and nonsignificant outcomes.(9,10,12)

Duration of anesthesia (duration of motorblock)

The significant prolongation of motor blockade that is elicited in this investigation coincides with previous studies. (10,12) However, other studies found that adding magnesium sulfate to bupivacaine and fentanyl was not effective. (14,15)

Conclusions and Recommendations

The addition of 75 mg of magnesium sulfate to hyperbaric bupivacaine in spinal anesthesia for cesarean section had significantly increased the duration of postoperative analgesia and prolonged the sensory and motor blockade without significant apparent maternal or fetal side effects.

Acute Pyrethroids Insecticide Ingestion in An Elderly Patient

Yhan Batista1, Novira Widajanti2
1Senior Resident, 2Geriatrician, Division of Geriatric Medicine, Department of Internal Medicine, Universitas Airlangga – Dr. Soetomo General Hospital Surabaya, Indonesia

Abstract

Insecticide ingestion is not an uncommon phenomenon found in daily practices. An elderly woman, 69-year-old, was rushed to emergency room due to household cleaning liquid ingestion. There was a history of previous suicide attempt and severe depressive episode before. Since there was no sign of severe intoxication, patient received symptomatic treatment. Patient was discharged with symptomatic treatment and antidepressants.

Keywords: pyrethroids, elderly, chemical ingestion, intoxication, depression

Introduction

Chemicals and chemical products stored in homes are the source of many accidental or intentional exposures that can be found in different ages. Elderly people are vulnerable to intoxication since they are more fragile than younger age groups so poisoning leads to severe complications.1 Pyrethroids have been developed for the control of household and agricultural insects, and human lice. Pyrethroids have extremely high selective toxicity for insects compared to mammals, due to higher insect nerve sensitivity, lower mammalian skin absorption and more efficient mammalian hepatic metabolism.2

Patients with significant pyrethroid ingestion can present with severe symptoms and signs, from nausea, headache to seizure and coma which would constitute a medical emergency and should be immediately referred to hospital for proper medical management.2

Case Illustration

Mrs. L, 69-year-old, a widow, was brought by her son to emergency room after ingesting household insecticide liquid 12 hours prior to admission. She complained nausea and vomiting after she ingested approximately 250 milliliters of the liquid 12 hours prior to admission. She vomited 3 – 4 times with food contents and accompanied with abdominal pain and soft stool defecation once. There was no trouble in swallowing meal or liquid. Excessive salivation, cough, lightheadedness, and seizure were denied. There was no problem in urinating. She intentionally ingested the household cleaning liquid to end her life. There was decreasing appetite in a month and weight loss 3 kilograms in one month. There was a history of diabetes mellitus for one year, controlled with metformin 500 milligram three times daily. She had controlled hypertension for two years with amlodipine 10 milligram daily. There was a history of being admitted in Psychiatric ward one month ago for four days, diagnosed with severe depression episode and suicide attempt. She received clobazam 5 milligram twice daily and sertraline 25 milligram once daily. History of recreational drugs abuse was denied. There is no psychosis history in her family. She is a

widow with four children.

From physical examination, it was found weak condition with GCS 456. Blood pressure was 130/80 mmHg, respiratory rate was 20 times per minute, heart rate was 88 beats per minute and axillary temperature 36.8° Celsius. From head and neck examination, no miosis pupils and no hypersalivation were found. No abnormality found in chest examination. From abdominal examination, epigastric tenderness was found. No abnormality found in extremities examination.

Laboratory results showed hemoglobin level 13.1 g/dL, hematocrit level 38.3%, leucocyte 11300/ mm³, platelet 387000 mm³, serum glutamic oxaloacetic transferase level 27 IU/L, serum glutamic pyruvate transfease level 34.4 IU/L, blood urea nitrogen 15 mg/dL, creatinine level 1.01mg/ dL, serum sodium level 141 mmol/L, serum potassium level 3.9 mmol/L, serum chloride level 98 mmol/L, random blood sugar level 132 mg/dL, Blood gas analysis showed pH 7.38, pCO2 43 mmHg, pO2 69 mmHg, BE 0.3 mmol/L, HCO3 25.4 mmol/L and SpO2 98% in room oxygen level. Chest x ray showed no abnormality with cardiothoracic ratio 54% and electrocardiography showed normal sinus rhythm with 92 beats per minute. Patient was consulted to Psychiatry Department in Emergency Room and assessed severe depressive episode without psychotic symptoms. Advises were delaying psycho-pharmacy with tight observation on organic conditions, placing at near nurse station, putting away dangerous substances or tools that patient could use as suicide media and psychotherapy intervention for patients and family.

Based on history taking, physical examination and laboratory findings, patient was assessed chemical ingestion, suicide attempt, severe depressive episode without psychotic symptoms, diabetes mellitus and hypertension. Diagnostic plans were fasting blood glucose, 2-hour post prandial glucose and HbA1c. Early management was intravenous line insertion with Ringer Dextrose 5% 1000 milliliters per day and intravenous omeprazole 40 milligram twice daily. Monitor plans were vital signs, complains and suicidal ideation.

On second day of admission, patient felt nauseous decreased, vomiting decreased and abdominal pain decreased. Vital signs were stable. No abnormalities were found in the physical examination.

On third day of admission, patient felt no nausea, no vomiting, and no abdominal pain. She could sleep soundly in the night. She still felt regret of what her doing. Vital signs were stable. Fasting blood glucose was 95 mg/dL, 2-hour post-prandial glucose was 123 mg/dL and HbA1c 6.2%. Therapy continued as previous day. On fourth day of admission, patient had no complains. Vital signs were stable. Patient was discharged with amlodipine 5 milligram peroral daily omeprazole 20 milligram peroral daily, sertraline 25 milligram peroral daily, clobazam 5 milligram peroral daily, and aripiprazole 5 milligram daily.

**Discussion**

HIT 0.26 AE mosquito repellent spray contains active ingredients of prallethrin 0.120%, cypermethrin 0.100%, and dimefluthrin 0.040%. Prallethrin, cypermethrin, and dimefluthrin are classified into pyrethroid group. Pyrethroids are ion channel toxins which interfere with nervous system function. They modify the gating characteristics of neuronal voltage-sensitive sodium channels by delaying the closure, thereby extending neuronal excitation. The toxic effects of pyrethroids result from this neuronal excitation, including a wide spectrum of signs and symptoms from mild to severe. Allergic reactions, including contact dermatitis or asthma, are rarely reported.

Pyrethroids are ion channel toxins which interfere with nervous system function. They modify the gating characteristics of neuronal voltage-sensitive sodium channels by delaying the closure, thereby extending neuronal excitation. The toxic effects of pyrethroids result from this neuronal excitation, including a wide spectrum of signs and symptoms from mild to severe. Type I pyrethroids (allethrin, permethrin) have a basic cyclopropane carboxylic ester structure and produce reflex hyperexcitability and fine tremor (T syndrome). Type II pyrethroids (cypermethrin, deltamethrin, fenvalerate) have a cyano-group and they cause salivation, hyperexcitability, choreoathetosis and
seizures (CS syndrome). Both types produce sympathetic activation. Dermal exposure causes paresthesia of the exposed skin while ingestion results in gastrointestinal irritation. Life threatening toxicities could be resulted from pyrethroid poisoning.6,7

The symptoms of acute pyrethroid poisoning in humans are supposed to be subdivided into two classes. However, since most of the reports on human poisoning are related to type II pyrethroids, it is not yet known whether the T-Syndrome applies also to humans.4,5,7

Acute pyrethroid poisoning may be confused with organophosphorus intoxication. There may be difficulty in making the diagnosis of pyrethroid poisoning since similar features are also found in severe organophosphorus pesticide poisoning. Pyrethroid ingestion causes sore throat, nausea, vomiting and abdominal pain within minutes. As systemic toxicity due to pyrethroid exposure is rare, most patients exposed to pyrethroids require only skin or eye decontamination and symptomatic and supportive measures. Measurement of the red cell cholinesterase activity which is reduced in acute organophosphorus poisoning but not in pyrethroid intoxication allows clarification.6,8

Following ingestion, gastric lavage is probably best avoided since solvents present in many formulations may increase the risk of aspiration pneumonia. Alternatively, although there is only limited experimental evidence that pyrethroid insecticides are adsorbed to charcoal, the administration of active charcoal 50 – 100 grams to an adult may be considered if a potentially toxic amount has been ingested within 1 hour. Isolated brief convulsions do not require treatment but intravenous diazepam 5–10 milligram should be given if seizures are prolonged. Rarely, it may be necessary to paralyze and ventilate the patient. Hypersalivation and pulmonary oedema are known to develop in cases of severe pyrethroid poisoning. Intravenous atropine 0.6 – 1.2 milligram may be useful in controlling excess salivation.8,9

Most patients with pyrethroid poisoning recover within 6 days and fatality is rare. There were seven fatalities among 573 cases in one series and one among 48 in another. Out of the 573 cases of acute pyrethroid poisoning reported by He et al., four of seven fatalities were due to convulsions and one was due to pulmonary edema.10,11

Although pyrethroids are considered less toxic than organophosphates, poisoning with large doses could be life threatening. Since its presentation mimics organophosphates, thorough history taking, and examinations are needed to manage the intoxication properly.6

**Conclusion**

Pyrethroids ingestion could be found in daily practice case since pyrethroids products are easy to access. We reported a mild case of intoxication which successfully treated symptomatically. Predisposing factors of ingestion such as depression should be investigated and treated to prevent repeated incidence.

The Development of a Community-Based Model as an Assisting Approach in the Prevention of Pregnancy and Labor Complications in Pandeglang Regency, Banten, Indonesia

Yudhia Fratidhina¹, Nina Herlina², Hamidahs¹, Sri Mulyati¹

¹Lecturer, Department of Health Science, Faculty of Midwifery, Politeknik Kesehatan Kementrian Kesehatan Jakarta III. Address: Jl. Melati 2 No.15, RT.001/RW.009, Jatiwarna, Kec. Pd. Melati, Kota Bks, Jawa Barat 17415, ²Head of the Midwifery Undergraduate Program, Faculty of Public Health, Gunadarma University, Jakarta. Address: Jl. Margonda N.100 Pondok Cina Depok, Jawa Barat

Abstract

Most of the direct causes of maternal death is obstetrical complications. Some programs have been done to reduce the incidence of complications on pregnancy and childbirth complications unfortunately the implementation of the program has not been maximized. Community empowerment is required to ensure the sustainability of the program. This research was conducted to develop community-based Model in preventing pregnancy and labor complications based on asset and community participatory. This research was conducted with a mixed method approach. On the stage of model development is conducted qualitatively through Focus Group Discussion and in-depth interview with 4 key informants and 13 support informants. Furthermore, model is developed quantitatively by using cross sectional study design on 80 respondents. The analysis that used in this research is SEM PLS. Once the model is formed, the evaluation was conducted on 83 respondents by using pre and post-test design. Application of community-based Model in the society is done by mentoring models using Module of asset and participatory-based prevention of pregnancy and labor complication through community-based Model. The results show that community-based model can be achieved through community participation, community assets development, knowledge, attitudes and behavior. The results also reveal that the community-based model is statistically proven to increase knowledge (p 0.000), attitude (p 0.000) and the behavior of expectant mother (p. 0.000). Community-based Model consists of five variables and it was proved to be effective in improving the knowledge, attitude and behavior of expecting mothers on the prevention of pregnancy complication and childbirth.

Keywords: Community-based Model, Pregnancy Complications, Community’s participation, Labor Complication, Maternal Mortality.

Introduction

Maternal Mortality Rate (MMR) is one of the important indicators of public health in Indonesia. The maternal mortality rate describes the number of women who die from a cause of death related to pregnancy disorders or their handling, excluding accident or incidental cases, during pregnancy, childbirth and postpartum 42 days after delivery, regardless of the length of pregnancy per 100,000 live births. Maternal mortality rates can be used in monitoring deaths related to pregnancy. This indicator is influenced by health status in general, education and services during pregnancy and childbirth. Based on the 2012 Indonesian Demographic and Health Survey (IDHS), MMR in Indonesia is still lower than the expected value.
high at 359 per 100,000 live births. This figure increased compared to AKI in 2007 which was equal to 228. Meanwhile, the fifth global Millennium Development Goals target was to reduce MMR to 102 per 100,000 live births in 2015.

The biggest cause of maternal mortality during the period 2010-2013 was bleeding, which was consecutively from 2010 amounting to 35.1%, in 2011 amounting to 31.9%, in 2012 amounting to 30.1% and in 2013 amounting to 30.3%. While prolonged delivery is a contributor to the lowest maternal mortality. While other causes also play a significant role in causing maternal deaths. Other causes are indirect causes of maternal death, such as cancer, kidney, heart disease, tuberculosis or other illnesses suffered by the mother. The direct cause of maternal mortality of more than 90% is a result of obstetric complications, especially labor complications. Complication is a complication, a condition that aggravates an illness. Pregnancy complications are obstetric emergencies that can cause death in the mother and foetus. Pregnancy complications include hypertension and preeclampsia, anaemia, placenta previa, and diabetes. While complications of labor are difficult labor (dystocia) that causes a disease. Complications of labor include premature rupture of membranes, preterm labor, foetal position abnormalities, and others.

Other factors that determine the regularity of pregnant women in their pregnancy checks by health workers, early detection of high risks and complications of pregnancy and childbirth, and family support in obtaining services for pregnancy and childbirth and emergency referrals. Early detection of high risks and complications of pregnancy and childbirth needs to be done as an effort to reduce the risk of maternal death. The introduction or socialization of the causes of pregnancy complications must be early and handled with the right standards. Every pregnancy hazard if not found early and handled to the correct standard will cause further pregnancy complications and will have an impact on maternal and infant mortality. These deaths are the effects of pregnancy complications, namely bleeding, infection, hypertension. Antenatal care plays an important role to be able to recognize risk factors in pregnancy as soon as possible so that deaths or unnecessary diseases in the mother and baby can be avoided. There are still many mothers who are less aware of the importance of prenatal care, which does not detect high risk factors that may be experienced by them. Antenatal examinations are related to the availability of health care facilities. There is a relationship between the distance of the house to the health service place and antenatal use.

The Government has carried out the Program for Maternity Planning and Complication Prevention (MPCP) as one of the efforts to accelerate the reduction of MMR. Maternity Planning and Complication Prevention is an activity facilitated by midwives in the village in the context of the active role of husbands, families and communities in planning safe deliveries and preparation for complications for pregnant women, including planning for the use of postpartum birth control, using stickers as a media notification target in order to improve coverage and quality of health services for mothers and new-borns. The program has been launched by the government since 2007. Through MPCP, it is expected that every pregnant woman will be properly recorded and monitored. The technical form of MPCP is that every pregnant woman gets stickers so that this sticker can be attached to every home that has a pregnant woman.

The target to be achieved in MPCP begins with monitoring of targets with high, medium, low risk directly in the hope that complications can be prevented and addressed early. In fact, the MPCP has not been implemented optimally, only around 55%. This is due to the lack of understanding of pregnant women to carry out high-risk early detection, lack of participation of cadres and health workers (midwives) in disseminating MPCP and unclear information delivery to pregnant women so that they do not understand the benefits and objectives of MPCP get support from husband and family. Based on the explanation by Prasetyawati (2012), it was stated that the health problems of
pregnant women and infants were not only focused on health workers but also needed community-based partnerships. MPCP is a program whose sustainability is highly dependent on government policies and budgets. Given the efforts to prevent these complications are important. So the sustainability of these efforts requires the active role of the community.

One strategic step is to increase the knowledge, awareness and motivation of pregnant women, husbands, families and communities towards improving behavior towards efforts to prevent complications of pregnancy and childbirth. This can be done through empowering and participating families or communities. Participation is the voluntary involvement of the community in self-determined changes, can also be interpreted as community involvement in the development of themselves, their lives and their environment. Community empowerment is intended so that the community can determine practices/actions to solve problems faced and manage planned activities, both individual capacity building, increased efforts to control, institutional improvement and environmental improvement. The purpose of empowerment is to increase community capacity and capability so that able to recognize the problem at hand, able to explore and utilize available resources, and be able to express themselves clearly.

This community empowerment approach has become the government’s concern. This can be seen from the formation of government programs that empower the community. One example is the Smart Healthy Generation Program, which is part of the government’s efforts to improve the quality of basic social services, especially in the fields of basic education and maternal and child health through a community empowerment approach, especially rural communities. Empowering rural communities in reducing maternal mortality is one of the important things, considering that maternal mortality rates are more prevalent in rural areas. These efforts are in line with the mandate of Law No. 6/2014 on villages, that villages have authority, based on village-based origin and local authority, to realize village independence as a strong foundation in implementing governance and development towards a just, prosperous society and prosperous. The development paradigm in the health sector as stated in Law No. 36/2009 on Health aims to increase awareness, willingness and ability to live a healthy life for everyone in order to realize the highest degree of public health as an investment for the development of human resources. This is in line with one of the strategic programs in the health sector, which is the development of Healthy Village Houses (HVH) mandated by the enactment of Law No. 6/2014 on villages that strengthens village autonomy in determining its development priorities and strategies.

A healthy village house is a facilitation to accelerate the improvement of the quality of basic health services in the village community which was initiated and facilitated by the government and implemented and managed by the village community in order to reduce the maternal mortality rate. Empowerment of village communities is used to increase public awareness and participation so that the potential/assets of the community in its implementation can be in accordance with the principle of village sovereignty. One approach is to increase community participation through the Participatory Action Research (PAR) approach. Research on the development and application of the mentoring model which is a combination of the theory of PAR and ABCD by including variables of knowledge, attitudes and behavior, such as those used in the community-based model has never been reported. The successful implementation of the community-based model as a mentoring approach to prevention of complications of pregnancy and asset-based childbirth and community participation in Banten Province is expected to be developed to be applied in other regions that have problems with high maternal mortality rates.

The concept of assistance in the community-based model that combines community empowerment with the use of community assets in order to reduce the complication rate of pregnancy and childbirth in line with the village development program as stated in Law No. 6/2014 on Villages. Village development, especially health development, is realized in the program of
Healthy Village Houses and Healthy Smart Generation (HSG). One of the implications of HVH’s achievements in achieving indicators of changes in community behavior includes the prevention of complications of pregnancy and childbirth through public health education, information communication and education and community-based health efforts. Meanwhile HSG put forward the basics of community development and mentoring that combined aspects of critical awareness, capacity building and strengthening of local institutions towards the integration of village development (health). With the existence of HSG, it is expected to facilitate access to maternal and child health services, especially for the First 1000 Days of Life intervention, especially for the poor and marginalized groups.

This study resulted in a community-based model that is a participatory mentoring model which is a model of assistance to prevent pregnancy-based complications of asset-based labor and community participation developed based on a comprehensive approach, namely community participation approaches, asset development approaches and behavioral change theories where communities utilize the potential that exists in society to solve problems, namely the incidence of complications of pregnancy and childbirth. This model is a new approach used in dealing with the problem of complications of pregnancy and childbirth. The use of this model approach involves developing assets that exist in the community with community participation. The dimensions of each variable were obtained from the development of the theory which was constructed and tested statistically. The results obtained are that in a homogeneous population, social dimensions can be excluded from community assets. The approach to participation and development of community assets, simultaneously able to increase knowledge, attitudes and ultimately behavior related to prevention of complications of pregnancy and childbirth. This community-based model can be adaptively used integrated in supporting and achieving existing programs such as MPCP, Desa Siaga, Healthy Indonesia Program with Family Approach and Healthy Village House Program.

Research Method

The study approach used in this study is mixed method with a sequential exploratory approach strategy. The strategy of this approach is the collection and analysis of qualitative data carried out in the first stage then followed by the collection and analysis of quantitative data in the second stage which is built on the initial qualitative results. More weight / priority is given to qualitative. This sequential exploratory design is usually used to prove the findings of the first (qualitative) results with the results of the next (quantitative) analysis. So that with this approach the direction of theory formation is inductive. Qualitative data were collected through focused group discussion, In-depth Interviews and observations. To guarantee the validation of qualitative results, triangulation is carried out, so as to increase confidence in the answers given. This research was carried out in all villages in the District of Cimanuk, Pandeglang Regency. Cimanuk District consists of 11 villages. Based on the preliminary study conducted by the author, it is known that of the 35 sub-districts in Pandeglang Regency, the highest proportion of groups of pregnant women at high risk in the District of Cimanuk. Research groups were built from the grass root level. The groups built consisted of groups of mothers and cadres, husbands, paraji. The aim of building this group is to increase knowledge and insight along with efforts to strengthen resilience, self-confidence, and community responsibility. The total population in this study was as many as 800 pregnant women who lived in the working area of the Cimanuk District Health Center. The minimum number of samples taken by researchers directly through the object as many as 80 respondents with the following criteria:

a. Inclusion Criteria: Second and third trimester pregnant women with healthy conditions, domiciled in the working area of Cimanuk Sub-District Health Center, high-risk pregnant women, mothers and husbands agree to become respondents.

b. Exclusion Criteria: Pregnant women who have experienced complications, abnormal pregnancies,
respondents moved to domicile.

Samples were taken in accordance with the rules of the number of samples in the PLS (Partial Least Squares) guideline where the sample size is 5 to 10 multiples of the number of indicators to be examined. In this study there were 16 indicators used to observe five variables, so in this case the sample size taken ideally was between 80 and 150. Sampling was done by simple random sampling (SRS). SRS is a sampling technique where each individual has the same opportunity to be selected as a sample. Since the population in this study is pregnant women, each pregnant mother who is in accordance with the inclusion and exclusion criteria has the same opportunity to become a sample.

Results and Discussion

Complications of pregnancy/Labor

Complications of pregnancy/Labor are estimated to occur in 15-20% of pregnant women, not all of which have been detected early. While those detected, not all have been handled in a timely and adequate manner. Delay in the detection and management of labor complications can threaten the mother and foetus. Labor complications include bleeding (25%), infection (14%), abnormalities of hypertension in pregnancy (13%), complications of unsafe abortion (13%) and the consequences of prolonged labor (7%). Bleeding is the main cause of death, which is largely due to retention of the placenta. As a result of the infection caused is an indicator that shows the poor efforts to prevent and treat infections in pregnancy and childbirth.

Research from the Ministry of Health of the Republic of Indonesia in 2013 mentions factors related to complications of prolonged labor delivery (15.4%), 27.5% of respondents aged <20 years and ≥ 35 years experienced labor complications, 27.8% of respondents lived in rural areas, 23.9% parity ≥ 4 and 16.7% were never ANC (antenatal care), and 17.4% never received Fe tablets, 24.6% had no time to deliver at health facilities, 35.6% experienced complications during pregnancy. Analysis of the factors causing pregnancy and childbirth complications is caused by distant determinants and determinants between. Both of these determinants have the opportunity to cause complications for pregnant women and childbirth which can ultimately lead to maternal death. Determinant variable factors include health status of pregnant women, reproductive status, access to health services and behavior / use of health services, while far determinants include maternal status in family and society, family status in society and community status.

Labor complications are difficult to predict and difficult to diagnose, so the treatment is difficult to be applied with certainty. Several factors can cause high-risk labor including maternal age, maternal education level, maternal occupation, family income, knowledge of ANC examination, maternal attitudes toward ANC examination, practice of mothers in ANC examination, parity, pregnancy distance, medical history, obstetric history and quality of ANC services.

Citizens’ Participation

The Focus Group Discussion results indicate community participation in efforts to prevent complications of pregnancy and childbirth is in the form of mutual cooperation, regular meetings of pregnant women and socialization of pregnancy myths. According to Laksana (2013) the participation of the community in Cimanuk Village was included in the form of ideas and social participation. Community empowerment and community involvement in reducing maternal mortality are also carried out by many other studies. A study conducted in Malawi in 2007 involved 729 women assisted by 81 voluntary facilitators to mobilize communities related to maternal and child health. Two years later, half of the group received a maternal and child health development program (part of the maternal and child health task force) which had a main focus to increase the coverage of ANC examinations, knowledge of maternal and child health and delivery in health services. In addition the group also identified high-risk pregnant women, promoted delivery in health services, ANC and PNC services, and conducted health education.
Community involvement in improving health status is a contribution of the community to the health of community members through giving responsibilities related to certain issues. Of course, this responsibility is also flexible in accordance with the characteristics of the community and region. In some conditions, sometimes communities only carry out social responsibility, such as making conditioning in the community that is able to support the implementation of health programs. But in other conditions, in addition to carrying out social responsibility, the community also carries out technical responsibilities. In general, the realization of the responsibilities carried out by the community towards the condition of public health can be through:

a. The adoption of behaviors to prevent health problems;

b. Effective participation in disease control activities;

c. Contribute to the design, implementation and monitoring of health programs;

d. Providing health resources.

In an effort to reduce the risk of complications that can cause maternal mortality, community participation can increase the coverage of the program. Participation can be in the form of community involvement and presence during health promotion, so that when participation increases, the information/knowledge delivered in the program is conveyed to more targets. As was done in Bangladesh\(^{[19]}\) that communities form groups that actively hold meetings every month that discuss maternal, infant, and toddler health. The result is that there are significant differences related to maternal mortality in areas that have active community participation compared to areas that do not have community participation. Community participation also means that people get additional learning about issues that are being worked on and at the same time take concrete actions. By attending the monthly meeting, the community will gain knowledge about ways to recognize pregnancy complications, ANC examinations and access to health facilities in the face of labor complications.

Impact of the Community-Based Model

Community-based model is carried out by involving health workers (midwives), families, cadres, and the community. All elements that play a role need to get training to better understand the concepts and roles in implementing this model. In addition, training is also given to equalize common goals, namely the formation of preventive behaviors for complications of pregnancy and childbirth which can ultimately prevent complications of pregnancy and childbirth. The involvement of cadres and communities in this model is very appropriate. Based on the results of a systematic review, cadres were proven to be able to convey a message of intervention to prevent maternal and child health problems in developing and poor countries. Because cadres are able to convey messages directly to the target, namely the mother, by using cultural and customary approaches that apply in the community\(^{[20]}\).

The success of the community-based model in increasing knowledge, attitudes, and behaviors about preventing complications of pregnancy and childbirth is a very good outcome in the effort to prevent complications of pregnancy and childbirth in particular, as well as increasing village health development in general. Substantially, the researchers have confidence that the community-based model can be applied and generalized to other villages. This is due to the relatively similar characteristics of villages in Indonesia, which are mostly self-help villages. The community-based model can be applied to support the Healthy Village and Healthy Smart Generation program launched by the Ministry of Village, Development of Disadvantaged Villages and Transmigration. This model comprehensively involves community participation and the development of community assets as carried out by the two programs. Healthy village houses are focused on the development and utilization of health assets, while the healthy smart generation focuses on community empowerment to raise awareness about health issues, one of which is the issue of maternal and child health. In addition, this model also
emphasizes community participation. This is consistent with the findings of Sulaeman (2012) suggesting that community participation has a contribution of 51.69% to solve health problems.\cite{21} This is implemented by participating in village meetings that determine village development plans. Communities can participate in the form of conveying problems around them for later analysis and problem solving solutions. This is in line with what is applied in the community-based model.

The effectiveness of the community-based model in increasing the knowledge, attitudes and behaviors of prevention of pregnancy and childbirth complications at the time of this study needs to be maintained. Maintaining the sustainability of this program is a challenge in itself. One possible way to do this is to integrate this model into established programs in the community such as alert villages, MPCP, HVH and HSG and through family empowerment and women’s empowerment. However, considering the issues that are of concern in the community-based model are specific issues related to complications of pregnancy and childbirth, it is necessary to refresh the material for the community-based model. Refreshing this material can be done every six months or once a year in a special activity, or also in a routine annual meeting of cadres in Cimanuk District. The results of this study indicate that there are assets that play a major role in preventing complications of pregnancy and childbirth. These assets need to be mapped in detail to continue to maintain their function in preventing complications of pregnancy and childbirth. With the complete asset mapping, even though there has been a change in leadership in the village, the focus on the use of assets remains unchanged, and may even develop. Community-based model significantly changes the level of knowledge of mothers about complications of pregnancy and childbirth. Knowledge. This result is in line with studies conducted in the United Kingdom, that significantly increased midwife knowledge in midwives who received obstetric emergency training.\cite{22}

When the pre-test was conducted, the respondents’ average knowledge score was only 41.01. This score falls into the category of low knowledge, meaning that less than 50% of knowledge about complications of pregnancy and childbirth is known by respondents. Knowledge about bleeding is the thing that most respondents know. The study conducted in Uganda showed results that were not much different. Only one third of respondents knew at least three danger signs during the pregnancy, childbirth and postpartum phases. Among them most of the respondents answered that bleeding during pregnancy and swelling of the hands and face were danger signs during pregnancy.\cite{23} Knowing the signs and symptoms of pregnancy and childbirth complications will make respondents anticipate and prevent more to mitigate the impact of complications of pregnancy and childbirth by reducing the first three late and late third if the health facility is ready to deal with complications.\cite{23}

The introduction of obstetric danger signs is the main key in finding health services for obstetric emergencies and in seeking prevention or promotion efforts during pregnancy and childbirth. So that the lack of awareness of danger signs will be related to the lack of preparation for normal delivery and preparedness in the face of complications.\cite{24} Assuming that all pregnancies are at risk, the mother must be aware of the danger signs of complications of pregnancy, childbirth and postpartum. Efforts to increase this knowledge can be done through health promotion, both verbally, written and audio. One of the most recent approaches to increasing knowledge and delivery outcomes is Centering Parenting.\cite{25} Centering Parenting is a model that involves groups of 6-7 mothers and babies together to get care for the first year. Through nine sessions, medical staff provide care and also provide information about health, infant development and issues of maternal and infant safety. This program integrates three main components of care, namely health, education and support in groups.\cite{26}

**Conclusion**

The construction results of the community-based model state that variables of community participation, community assets, knowledge, attitudes and behaviors to prevent pregnancy and childbirth complications
are issues / discourses obtained based on qualitative findings. This result is in line with the basic concept of this research. The variable forming construct on the model is in accordance with the theory that applies to the present. The construction of the community-based model consists of community participation which consists of knowledge about prevention of complications of pregnancy and childbirth, attitudes about prevention of complications of pregnancy and childbirth, and behaviors about preventing complications of pregnancy and childbirth. The results of the development of the community-based model show that all variables have a significant relationship with the prevention behavior of complications of pregnancy and childbirth. At the time of validity testing, it is known that social assets are invalid in forming community assets. Likewise for the right construct is invalid in forming behavioral variables preventing complications of pregnancy and childbirth. The community-based model is applied through the process of mentoring pregnant women by cadres. This assistance is carried out starting from the second or third trimester of pregnancy until the mother gives birth. As a tool to assist pregnant women, cadres are equipped with a mentoring module to prevent the complications of asset-based pregnancy and childbirth and community participation with the community-based model approach. The community-based model was significantly able to increase the score of knowledge, attitude and behavior to prevent complications of pregnancy and childbirth. This model is the novelty obtained from this study.

Abstract

**Background:** Severe septicemia can result in impaired oxygen perfusion to the tissues. The PaO$_2$/FiO$_2$ ratio (P/F ratio) is one of the measurement parameters for hypoxemia. This study aims to evaluate the P/F ratio as a risk factor for hypoxemia against septicemia mortality in children.

**Method:** An observational with a prospective cohort design was conducted. Thirty-six patients with septicemia, consisting of 18 patients who living (survivor) and 18 patients who died (non-survivor). The P/F ratio is obtained based on blood gas analysis carried out in the first 24 hours of treatment recorded on medical records and calculated manually. The P/F ratio has an area under the curve (AUC) of 0.83 (95% CI 0.71–0.95) with a cut-off of 226. Septicemia children with P/F ratio < 226 who have a mortality risk of up to 6.9 times (RR 6.9; 95% CI 1.719-27.957; $p=0.005$) with sensitivity 72.70%; specificity 72.20%; PPV 76.19%; NPV 68.42%. The mean P/F ratio in the non-survivor group was significantly lower than the survivor group 161.60 (95% CI 1.05) compared to 391.09 (95% CI 2.13); $p=0.005$).

**Conclusion:** The P/F ratio can be a risk factor for hypoxemia on septicemia mortality.

**Keywords:** Septicemia; P/F ratio; children; hypoxemia

Introduction

Septicemia is a complex and multifactorial syndrome that occurs due to the body’s response to infections that tend to be harmful, dangerous, or destructive. Untreated septicemia will progress to severe septicemia.$^1$ Currently, septicemia is associated with high morbidity, mortality, and care costs, and is the leading cause of infant and child mortality worldwide.$^2$ The high mortality in septicemia, often caused by delay in diagnosis and treatment.$^3$ In severe septicemia or septic shock, there is impaired oxygen perfusion to the tissues. The result of hypoxemia will affect outcomes such as length of stay, mortality, and morbidity. Based on the medical records at the Dr. Soetomo General Hospital (2015), septicemia in children was recorded as 124 cases, while in 2016 and 2017 there were 52 and 109 cases.$^4$ The number of deaths in PICU Dr. Soetomo General Hospital in 2018 with 23 cases of severe septicemia (35%) and 16 cases of septic shock (25%).$^5$ Therefore, it is necessary to recognize signs of hypoxemia both clinically and in laboratories examination. The diagnostic criteria for acute respiratory failure in children are varied and inconsistent. The PaO$_2$/FiO$_2$ ratio (P/F ratio) is one of the measurement parameters for hypoxemia.$^6$ This study has validated the cut-off value for the P/F ratio which can be
used as a predictor of septicemia mortality. Until now, research on the P/F ratio as a risk factor for hypoxemia on septicemia mortality has not been widely used. The examination of the P/F ratio is considered to be more accurate and easily available, allowing the application of appropriate therapy. This study was conducted to evaluate the P/F ratio as a risk factor for hypoxemia against septicemia mortality in children.

**Materials and Methods**

This study was an analytical observational study with a prospective cohort study design to analyze the role of the PaO2/FiO2 ratio (P/F ratio), as a risk factor for hypoxemia on septicemia mortality in children treated at Dr. Soetomo General Hospital, Surabaya. The sample of the study were pediatric patients with septicemia who were treated in the pediatric intensive care unit (PICU), emergency department, and pediatric ward at Dr. Soetomo General Hospital Surabaya in the period time from March 1st – September 30th 2020. Thirty-six patients met the inclusion and exclusion criteria with living (survivor) septicemia and 18 patients have died (non-survivor). We used a primary data based on the supporting examinations carried out during the treatment at Dr. Soetomo General Hospital Surabaya. The data collection instrument used in this study was the data collection sheet (DCS). The data from each examination result is confirmed to be complete and relevant first before further processing. The examination was carried out on incomplete and less relevant data. The demographic characteristics of participants were analyzed using T independent test. The correlation test between variables presented in cross-tabulation was analyzed using the Chi-Square test. The cut-off value is obtained using the receiver operating characteristic (ROC) curve. Statistical analysis using Chi-Square test, the significance value \( p < 0.05 \). The collected data were analyzed using the IBM SPSS Statistic program.

**Results and Discussion**

The basic characteristics of the participants were presented based on the basic characteristics of gender, age, Pelod II score. Meanwhile, for laboratory characteristics, various parameters were assessed from the results of blood gas analysis and complete blood counts such as PCO2, PaO2, SO2, FiO2, AaDO2, Hb, and leukocytes. The basic characteristics of the groups are listed in Table 1 and Table 2.

*a p-value < 0.05 was statistically significant.

The highest gender in the survivor and non-survivor septicemia group was male. The mean age in the survival septicemia group was 58.5 months while in the non-survivor group was 87.4 months. The mean Pelod II score was higher in the non-survivor group with p-value < 0.05. The number of AaDO2 and FiO2 in septicemia patients who non-survivor was significantly higher than in survivors with p-value < 0.05. The number of FiO2 (41.91 vs 26.00) had a relevant and significantly higher increase found in the septicemia patients who non-survivor with a p-value of 0.020. Meanwhile, for the values of PaO2, PaCO2, SO2, Hb, and leukocytes, there were no significant differences were found in non-survivor and survivor. A total of 36 patients with septicemia divided into 18 survivors and 18 non-survivors with the P/F ratio was calculated as shown in Table 3.

*a p-value < 0.05 was statistically significant.

The results of this study showed a significant difference in the value of the P/F ratio (161.60 ± 1.05 vs. 391.09 ± 2.13; p = 0.001) between survivor and non-survivor septicemia patients as shown in Table 3. In patients with septicemia, a low P/F ratio value is significant for the occurrence of death, meaning that the lower the P/F ratio value, the risk of death is 6.9 times higher than those with a high P/F ratio value as shown in Table 3.
P/F ratio in septicemia has an area under the curve (area under curve / AUC) of 0.83 (95% CI 0.71-0.95). The cut-off reference value P/F ratio of 226 has a sensitivity of 72.70%, specificity of 72.20%, a positive predictive value of 76.19%, and a negative predictive value of 68.42% (Figure 1 and Figure 2).

Figure 1. Area under curve P/F ratio to mortality in septicemia patients

Figure 2. The cut off P/F ratio in septicemia
It was found that the number of males (52.5%) was greater than that of females (47.5%) in both the survivor and non-survivor septicemia group. Following the study of Zhou J et al. (2014) in China regarding the features and prognosis of severe septicemia and septic shock in the ICU saying that 60.4% of the study subjects were male. This is influenced by the female hormone estrogen which has a protective effect against infection, septicemia, and trauma. A study in Bandung found that in the case group, 50 (51%) subjects were male and 48 (49%) female subjects. Meanwhile, in the control group, 66 (66.7%) were male and 34 (33.3%) were female. There was no significant difference between the two sex groups.8

Many studies show that gender has a role in infectious diseases and septicemia. The female sex has shown to be protective against septicemia, whereas the male sex, on the other hand, interferes with cell-mediated immune responses and cardiovascular function. Male sex hormones, namely androgens, have been shown to suppress cell-mediated immunity. In contrast, female sex hormones exhibit a protective effect that may contribute to naturally benefiting women in septic conditions. The hormone estrogen affects increasing the immune system by increasing the production of IL-4 and IL-10 so that antibodies increase.9

A study in China on 461 children reported that the age of less than 1 year had the greatest percentage of 50.5% who were admitted to the PICU.10 This occurs because the responses of macrophages and other innate immune systems such as mucosal cells, skin cells, cilia, and acute-phase protein formation have decreased and the number of T lymphocytes is decreased due to thymus reabsorption. The median ages of cases and controls were 12 and 24 months.11

The number of AaDO2 and FiO2 in septic patients who died was significantly higher than in living septicemia patients with p-value <0.05. The number of FiO2 (41.91 vs 26.00) had a relevant and significantly higher increase found in the septic patients who died with a p-value of 0.020. Meanwhile, for the values of PaO2, PaCO2, SO2, Hb, and leukocytes, there were no significant differences were found in non-survivor and survivor septicemia patients.

The results of this study indicate a decrease in the P/F ratio value in patients with non-survivor septicemia compared to living septicemia. The mean PaO2/FiO2 ratio in this study was 161.60 in non-survivor septicemia and 391.09 in survivor septicemia. The decrease in the P/F ratio occurs due to a mechanism of impaired oxygen perfusion to the tissue. Hypoxia tissue condition will cause metabolism to be ineffective due to anaerobic metabolism and accumulation of lactate resulting in cell dysfunction and destruction which leads to multi-organ failure and death.12,13

The above studies show that the excessive release of proinflammatory cytokines triggers the release of vasoactive amines and chemokines as well as activation of the complement system, coagulation, and release of reactive oxygen species (ROS). These mediators are responsible for increased vascular permeability, hypotension, and septic shock. In an advanced stage, the release of a mediator such as high protein group box 1 (HMGB1), which allows the inflammatory reaction to being continued. Since O2 is the final receptor for electrons in the electron transport chain, measuring oxygen consumption is a good choice for assessing mitochondrial function. The peripheral blood of septic patients shows normal PO2 levels although the oxygen consumption by the cells may be reduced, which can lead to tissue hypoxemia followed by tissue damage and ultimately organ system failure. Multi-organ damage is the cause of death.14,15

P/F ratio is the partial pressure of arterial oxygen (PaO2 in mmHg) to fractional inspired oxygen (FiO2 is expressed as a fraction, not %) so that PaO2/FiO2 is commonly known by the abbreviation P/F Ratio. P/F Ratio is used to determine hypoxemia, although there are still several things that need to be reviewed regarding its function as a basis for diagnosis.16 The PaO2/FiO2 ratio (P/F ratio) is a commonly used oxygenation measurement tool. The normal P/F ratio is 300-500
mmHg, with values less than 300 mmHg indicating abnormal gas exchange and values less than 200 mmHg indicating severe hypoxemia.\textsuperscript{17}

The severity of hypoxemia classified according to the Berlin criteria was associated with an increase in mortality in adult patients, namely 27\% (95\% CI 24-30\%) in mild hypoxemia, 32\% (95\% CI 29-34\%) in moderate hypoxemia and 45\% (95\% CI 42-48\%) for severe hypoxemia with \textit{p}-value <0.001. The severity of hypoxemia was also associated with an increase in the mean duration of mechanical ventilation in the survivor group, namely 5 days (interquartile range/ IQR 2-11) in mild hypoxemia, 7 days (IQR 4-14) in moderate hypoxemia, and 9 days (IQR 5-17) in severe hypoxemia with \textit{p}-value <0.001. The value of the PaO$_{2}$/FiO$_{2}$ ratio has an area under the curve (area under curve/ AUC) of 0.577 (95\% CI 0.561-0.593) as a predictor of mortality.\textsuperscript{18,19}

A study by Rice et al in patients with acute respiratory distress syndrome (ARDS) has the most common causes of being septicemia, pneumonia, and trauma, found a mortality rate of 53.0\% at a PaO$_{2}$/FiO$_{2}$ ratio <100, a mortality rate of 39.8\% at 100<PaO$_{2}$ <200, the mortality rate was 39.8\% at 200<PaO$_{2}$/FiO$_{2}$<300, and the mortality rate was 16.75\% at PaO$_{2}$/FiO$_{2}$ >300 \textit{(p = 0.064)}. The results of the insignificant relationship between the PaO$_{2}$/FiO$_{2}$ ratio and the incidence of death can be due to the PaO$_{2}$/FiO$_{2}$ ratio data obtained from this study all above 100 mmHg /%, while according to Viviani et al, the PaO$_{2}$/FiO$_{2}$ ratio can only be used as a predictor of mortality if it is below that 100 mmHg /%.\textsuperscript{7,20}

Hypoxemia is defined as a decrease in the partial pressure of oxygen in the blood. Hypoxemia does not necessarily indicate tissue hypoxia. This can be caused by hypoventilation, ventilation-perfusion mismatch, right-to-left shunt, diffusion disturbance, or reduced inspired oxygen pressure.\textsuperscript{21} Arterial (PaCO) and alveolar (PACO) carbon dioxide pressure increase during hypoventilation, which causes alveolar oxygen pressure (PAO) to decrease. As a result, the diffusion of oxygen from the alveoli to the pulmonary capillaries is decreased, resulting in hypoxemia and hypercapnia. The results of the P/F ratio prognostic test in this study also showed that the cut-off P/F Ratio reference value of 226 had a sensitivity of 72.70\%, a specificity of 72.20\%, a positive predictive value of 76.19\%, and a negative predictive value of 68.42\%. In this study, the increase in mortality rate was inversely proportional to the degree of hypoxemia based on the PaO$_{2}$/FiO$_{2}$ ratio in this study, namely the lower the PaO$_{2}$/FiO$_{2}$ ratio, the higher the mortality rate.\textsuperscript{22}

Rice et al reported the cut-off ratio of PaO$_{2}$/FiO$_{2}$ 300 AUC 0.878 with a specificity of 56% with positive predictive value and negative predictive value were 2.06 (95\% CI 1.64-2.76) and 0.16 (95\% CI 0.12-0.21). PaO$_{2}$/FiO$_{2}$ ratio of 200 specificity 85\% with positive predictive value and negative predictive value of 5.64 (95\% CI 4.69-7.08) and 0.17 (95\% CI 0.15-0.20).\textsuperscript{7}

This study has validated the cut-off point for the SaO$_{2}$/FiO$_{2}$ ratio which can be used as a substitute for a prognostic predictor of severe septicemia when the PaO$_{2}$/FiO$_{2}$ ratio is not available.\textsuperscript{7} Perez et al investigated that the S/F ratio can be used in the assessment of respiratory distress and as a predictor of mortality in patients with septicemia in the ICU and has a correlation with the P/F ratio.\textsuperscript{6} Laila et al found that a low S/F ratio is associated with mortality and has a good correlation with the P/F ratio. The cut-off of S/F ratio <300 indicates high specificity of mortality prognosis.\textsuperscript{23}

Data on the first-day in septicemia patients who are non-survivor showed a low P/F ratio. Meanwhile, survivor septicemia patients showed a higher P/F ratio, but we still need further study, because the patient’s condition is certainly supported by many factors. In this study, the relationship between comorbid patients and the changes in the value of P/F ratio was not examined. However, the data showed that comorbid patients compared to a lower P/F ratio than non-comorbid patients, so indirectly there is a possibility that the patient’s comorbidities can influence the decrease in P/F ratio.

This study is the first study to investigate the P/F ratio as a risk factor for hypoxemia to septicemia.
mortality in children at Dr. Soetomo General Hospital. While the weakness of this study is the blood test. The blood gas analysis was done once when the patient was first diagnosed with septicemia (blood retrieval was only one observation). In this study, first-day data in septicemia patients who died showed a low P/F ratio. While in septicemia life shows a higher P/F ratio value, but still needs further evaluation, because of the patient’s condition is certainly supported by many factors. Many things can affect the level of P/F ratio in a person, be it heart, lung, and other abnormalities. We are aware that this study did not assess some aspects regarding the relationship between the comorbidity of the patient and the changes in the value of the P/F ratio. But, we believe that this study provides valuable information which help the health personnel treating the septicemia in children.

Conclusion

The cut-off value of the PaO₂/FiO₂ (P/F ratio) as a risk factor for hypoxemia on mortality in children with septicemia was 226. The lower the P/F ratio, the relative risk of death in children with sepsis is 6.9 times higher than children with sepsis who have higher P/F ratio.

Acknowledgment: We would like to thank our teacher Prof. I Dewa Gede Ugrasena with his permission we were able to carry out this research properly. We also appreciate the help of nurses and residents who give the support and warm welcome to the authors.

Ethical Clearance: We obtained an approval of whole project from Ethical Committee Review Board of Dr. Soetomo General Hospital Surabaya. The Ethical Clearance has issued by the Clinical Research Unit of Dr. Soetomo General Hospital Surabaya, Indonesia number 1852/KEPK/III/2020.

Tuberculous Pneumonia as a Primary Cause of Acute Respiratory Distress Syndrome: A Case Report

Yuliza¹, Helmia Hasan²

¹Resident, ²Lecturer, Department of Pulmonology and Respiratory Medicine, Faculty of Medicine, Universitas Airlangga – Dr. Soetomo General Academic Hospital, Surabaya, Indonesia

Abstract

Background: Tuberculosis is an uncommon and very rare cause of Acute Respiratory Distress Syndrome. Moreover, it has been associated with poor outcomes with a very high mortality rate (40-80%). The clinical symptoms and radiological findings of tuberculous pneumonia that resemble bacterial pneumonia result in difficulties to decide definitive diagnosis. Case Presentation: A 35-year-old male patient was admitted to hospital with shortness of breath, fever, cough without expectoration. The patient had history of asthma since childhood. Chest physical examination showed rhonchi and wheezing on both lungs. Initial laboratory findings were leucocytosis, granulocytosis, eosinopenia, increased ALT and ALP levels, blood gas analysis revealed acute respiratory failure. PaO2/FiO2 was 49 mmHg. ECG showed sinus tachycardia and chest X-ray showed consolidation on both lungs. The patient was initially managed for asthma exacerbation and bilateral pneumonia with ARDS. The result of microbiological findings showed acid fast bacilli (AFB) positive. He had been treated with anti-TB first category. Clinical improvement was achieved after 1 week of anti-TB treatment. Summary: Tuberculous pneumonia with ARDS is a rare case of pulmonary tuberculosis. The diagnosis is established by a prompt and complete examination that lead to optimal treatment with appropriate anti-TB.

Keywords: tuberculous pneumonia, tuberculosis with acute respiratory failure, tuberculosis with ARDS

Introduction

Tuberculosis (TB) is one of the major health problems in the world, especially in developing countries¹. The disease usually has a slow onset and progression. Tuberculosis patients usually experience coughing, weight loss, anorexia, night sweats, and malaise, which occur for several weeks before getting sick. Tuberculosis with pneumonia and acute respiratory distress syndrome (ARDS) is very rare². Data on TB patients with pneumonia was 10% of community-acquired pneumonia (CAP) cases in Asia³. Meanwhile, TB with ARDS was reported to account for 1.5-5% of all pulmonary TB cases⁴. Based on the description above, we would like to report a case of a 35-year-old man who was diagnosed with TB with symptoms of pneumonia and ARDS.

Case Presentation

A 35-year-old man with main complaint of shortness of breath for the past 3 days before being admitted to hospital. Shortness of breath occurred in the early hours of the morning and decreased slightly after using fenoterol and salbutamol sprays. The patient also complained of fever for the past 1 day and cough
with phlegm since 1 week before being admitted to the hospital. There was no weight loss and night sweats. The patient had a history of asthma since the age of 10 and he had never received TB treatment before.

The results of physical examination showed 124 pulse per minute, the respiratory rate was 34 beats per minute, the oxygen saturation was 92% using a non-rebreathing mask of 10 lpm oxygen, and an axillary temperature of 39.1°C. Chest physical examination showed vocal fremitus increased on 2/3 upper of both lung, percussion was dull in 2/3 upper of both lung, bronchovesicular sound in 2/3 upper of both lung, rhonchi in 1/3 lower of right lung and 2/3 lower of left lung, and wheezing in 1/3 upper of both lung. The laboratory examination results showed leukocytosis (14.11/mm³), Granulocytosis (94.3%), decreased lymphocytes (3.7%), decreased eosinophils (0.4%), increased SGOT (181 U/L), increased SGPT (155 U/L), hypoalbuminemia. (3.02 g/dL), negative HIV test. The results of blood gas analysis showed respiratory failure with PaO2/FiO2 49 mmHg. Echocardiography results showed neither volume overload nor acute heart failure. Chest X-ray revealed extensive consolidation in both lung fields (Figure 1A).

The patient was diagnosed with severe pneumonia, severe attacks acute exacerbation of moderate persistent bronchial asthma with ARDS with a differential diagnosis of Allergic Bronchopulmonary Aspergillosis (ABPA) and planned to install a ventilator but the care giver refused. The patient was given nebulized therapy for asthma and empiric antibiotics in the form of Ceftazidine 1000 mg intravenously every 8 hours and Levofoxacine 750 mg intravenously every 24 hours. The day-6 evaluation showed leukocytosis (16.06/mm³), granulocytosis (90.7%), lymphocytopenia (5.4%), eosinopenia (0.4%), anemia (9.0 gr/dL), procalcitonin 4.49 ng/mL. The results of blood gas analysis showed respiratory failure with PaO2/FiO2 49 mmHg. Echocardiography results showed neither volume overload nor acute heart failure. Chest X-ray revealed extensive consolidation in both lung fields (Figure 1A).

The patient was subjected to a chest CT scan with contrast on the 7th day of treatment. The results showed a tree in bud pattern accompanied by consolidation with air bronchogram in the right and left lung. These findings suggested a picture of pulmonary tuberculosis that was still possibly accompanied by secondary infection with multiple bullae in the superior lobe of the left lung and the superior lobe of the right lung. Multiple nodules in the inferior lobe of the right and left lung, with the largest size of +/- 0.9 cm in the posterobasal of the inferior lobe of the right lung, could represent a tuberculoma (Figure 2). On the 8th day, the patient’s clinical condition had not improved. The results of the blood gas analysis still showed respiratory failure with PaO2/FiO2 139 mmHg. Antibiotic therapy was changed to Meropenem 1000 mg intravenously every 8 hours and Levofoxacine 750 mg intravenously every 24 hours. The patient was also given adjuvant therapy of methylprednisolone 62.5 mg through intravenous injection every 8 hours. Sputum induction was conducted on the 9th day, with Gram stain examination, BTA examination and Xpert MTB/RIF sputum. On the 13th day, the results of morning scanty sputum BTA, with the result of Xpert MTB/RIF MTB detected very low Rifampin resistant not detected. The patient was then treated with a special liver anti-TB regimen Streptomycin 750 mg through intramuscular injection, Levofoxacine 750 mg through intravenous injection, and Etambutol 1000 mg orally on day 13 of treatment because there was still an increase in ALP (115 U/L) and ALT (230 U/L). On the 20th day of treatment, the patient began to show clinical improvement with a significantly reduced breathlessness. The patient was given 3 lpm nasal cannula oxygen therapy, showing moderate hypoxemic blood gas analysis results. The results of chest X-ray on the day 24 (day 11 using OAT
therapy) (Figure 3) showed improvement in the patient’s condition.

The patient was then subjected to a bronchoscopy to take sample of Broncho Alveolar Lavage (BAL) on the 29th day of treatment, with the result of M. tuberculosis. The patient was discharged from the hospital on the 31st day with 100 mg of INH-sensitized therapy, 750 mg of Levofloxacine and 1000 mg of Etambutol orally.

Figure 1. (a) Chest x-ray on the first day and (b) the third day

Figure 2. Thoracic CT-scan on day 7
Discussion

Several cases of tuberculous pneumonia reported that cough with phlegm occurred prior to respiration and other systemic complaints. The resulting acute respiratory failure also confuses the likelihood of TB because the incidence is very low among hospitalized pulmonary TB patients\(^\text{(5)}\). The diagnosis of tuberculous pneumonia can be made should the patient has a high fever with signs of severe toxicity, thoracic physical examination showing signs of consolidation, the presence of consolidation of a minimum area in one lobe, and microbiological examination of sputum revealing tuberculous puncture\(^\text{(6)}\). ARDS in TB patients is an extremely rare occurrence\(^\text{(7)}\). ARDS criteria include onset within 1 week of known clinical insult, or deteriorating or recent respiratory system, SpO\(_2\)/FiO\(_2\) ≤315 with SpO\(_2\) ≤97\%, features of bilateral opacity evaluated by ultrasonography or chest X-ray should available, respiratory failure unrelated to heart failure or fluid overload, the need of objective assessment such as echocardiography to rule out hydrostatic edema in the absence of risk factors\(^\text{(8, 9)}\).

Anti-TB drugs are therapy given to TB patients with a combination of at least 4 types of drugs at a dose in accordance with the patient’s body weight. Treatment requires a minimum of 6 months in category 1, given in 2 stages, namely the intensive stage (2 months HRZE) and the advanced stage (4 months HR) to prevent recurrence and resistance\(^\text{(10)}\). Patients with a threefold increase in liver enzymes before starting anti-TB therapy can be given a special liver regimen according to WHO guidelines (2HRES/6HR or 2SHE/10HE). Tuberculosis is rarely considered a diagnosis should the patient has features of acute pneumonia and respiratory failure. This can lead to the use of antibiotics that have anti-TB therapeutic effects such as fluoroquinolones which temporarily improve clinical conditions, increase the resistance of fluoroquinolones used as monotherapy, thereby accelerating the occurrence of XDR and pre-XDR cases\(^\text{(2)}\).

Tuberculous pneumonia therapy is similar to TB therapy in general. Corticosteroids are used as adjuvant therapy in TB treatment to overcome this inflammatory reaction \(^\text{(11)}\). Corticosteroids work by inhibiting the release of cytokines that play a role in constitutional symptoms and tissue damage. In addition, corticosteroids make it easier for anti-TB drugs to enter the granuloma and destroy mycobacterium tuberculosis. The use of corticosteroids can make patients more susceptible to

![Figure 3. Chest x-rays on day 24 and day 11 using anti-TB drugs show improvement.](image)
other infections\(^{(3, 11, 12)}\). The benefits of corticosteroids in tuberculous pneumonia with acute respiratory failure have been reported in several studies. Tuberculous pneumonia patients with acute respiratory failure who received corticosteroid therapy showed lower mortality than those who did not receive corticosteroid therapy (56.7% vs 77.8%)\(^{(9)}\). The prognosis of tuberculous pneumonia patients has improved with the use of corticosteroids, in which corticosteroids are a favorable prognostic factor for tuberculous pneumonia patients\(^{(10, 13)}\). Corticosteroids play a role in improving the clinical situation in TB patients when used as adjunctive therapy\(^{(14, 15)}\).

In conclusion, a 35-year-old man was reported having symptoms of acute pneumonia with ARDS. The 2-week pneumonia therapy showed no improvement. Moreover, the results of chest CT scan with contrast and Xpert MTB/RIF examination of sputum induction detected MTB. The patient was given anti-TB therapy and experienced improvement both clinically and radiologically.

A Comprehensive Study on Homicidal Deaths in a Tertiary
Health Care Institution in Nellore, Andhra Pradesh

Z. Sashikanth
Associate Professor, Department of Forensic Medicine, ACSR Medical College

Abstract

Homicide is a serious crime committed against humans and its detection and solution is important to the entire society. Homicide may be the result of accidental, reckless or negligent acts even if there is no intent to cause harm. The present study was taken up to know the incidence of homicides in the city of Nellore and to determine the trends in committing homicides.

Aim: To study the pattern of homicides and to elucidate the different aspects of homicidal deaths.

Methodology: This was a retrospective study done on alleged homicide cases autopsies done in Forensic Department of ACSR Medical College from March 2019 to February 2020 (1 year). Data was collected from 39 reports with an alleged history of homicide. All the homicide cases for which autopsies were done except for homicide cases which involved death due to rash negligent act. Data was collected from the Postmortem reports of victims of homicide, police inquest reports, medical records and relevant history collected from family members, relatives and friends was studied. Data was entered into MS excel and expressed as frequencies and percentages.

Results: Total autopsies done during the study period from March 2019 to February 2020 (1 year) were 902, of which 39 were alleged homicide autopsies. Majority of the victims belonged to 21-30 age group. Majority of the homicide cases were males. Majority of the deaths were caused by blunt objects (48%). In about 67% of the cases the assailant was a known person. Most of the homicides were family centered and due to quarrels. Early detection and prevention is the need of the hour.

Key Words: Homicide, Autopsy, Blunt and Sharp weapon, negligent act

Introduction

Homicide is the act of one human killing another. A homicide requires only a volitional act by another person that results in death, and thus a homicide may result from accidental, reckless, or negligent acts even if there is no intent to cause harm.

“Homicide is defined as the killing of one human being by the act, procurement or omission of another and the term applies to all such killings whether criminal or not.”

Homicide is prevalent widely almost all over the world. Murder of an opponent for various reasons is one of the oldest tools of power struggles from Stone Age.

Homicide is a large killer globally – in some countries it’s one of the leading cause of death. According to the Global Burden of Disease study, just over 400,000 (405,000) people died from homicide in 2017. The scale of homicide is even more pronounced among younger adults aged 15 to 49 years old.

We see that homicide ranks within the top ten causes of death globally. Globally, 0.7% deaths in 2017 were the result of homicide. Homicide rate is measured as the number of homicide deaths per 100,000 people. It was estimated that around 3.9 deaths occur/100,000 South east Asia according to 2017 statistics. These statistics vary from country to country and region to region.
consistent uptrend both in absolute number of homicides and in homicide rates reflects the general increase in all crimes of violence i.e., homicide, rape, armed robbery, aggravated assault etc.\textsuperscript{7} Explanations for increase in the Incidence of homicides probably due to rapid rise in population, industrialization, internationalization, growing unemployment, stressful life, depression in day-to-day life, lack of harmony in family members, drug addiction and socio-political factors.

The grave implications of homicide make its detection, solution and adjudication, a matter of vital importance to the entire society. The perpetrators’ of a homicide should be promptly identified and apprehended for the good of the society and for doing justice.

Sometimes it may not be possible to find the perpetrators due to complexity of the circumstances & motives surrounding the fatal incident. Unlike other serious criminal offences, homicide is to a large extent an intimate, personal crime where the crime is committed by relatives, friends or enemies. A minor number of homicides are “felony – homicides”.\textsuperscript{8} Therefore, homicide should be taken as a public health issue and emphasis has to be laid on reliable data and surveillance mechanisms, so that we can bring a practical and simple approach to homicide prevention. The pattern of homicide may be a useful indicator of the social stresses in a community and may also provide useful information for the law enforcement agencies. Several workers have tried to elucidate the different aspects of homicidal deaths in various parts of the world and in India also. As there is no previous literature or study on the mortality profile of homicidal cases from this region, the present study was undertaken to study these aspects.

Aim: To study the pattern of homicides and to elucidate the different aspects of homicidal deaths.

Material and Methods

Study design: Retrospective study done for a period of 1 year from March 2019 to February 2020 based on records.

Study setting: Department of Forensic Medicine, ACSR Medical College, Nellore.

Sample size: Data was collected from 39 reports with an alleged history of homicide

Inclusion Criteria: All alleged case of homicides irrespective of age and both genders among whom autopsies were done from March 2019 to February 2020 (1 year).

Exclusion criteria: deaths occurred due to rash and negligent act were excluded.

Data Collection: Postmortem reports of victims of homicide, police inquest reports, medical records if available, crime scene photographs and history collected from family members, relatives and friends were studied to analyze the factors such as Age and Sex of victims, Method of homicide, Weapons used, Motive for such acts, Place of occurrence, Time of occurrence, etc. involved with the homicide. All the homicide cases for which autopsies were done for a period of 1 year from March 2019 to December 2019.B.G. Prasad Socio-economic status classification 2020 was used.

Statistical Analysis

Data was collected from the Postmortem reports of victims of homicide, police inquest reports, medical records. Data was entered into MS excel and expressed as frequencies and percentages.

Permissions were obtained from the Institutional Head (Principal, ACSR Medical College, Nellore) and Institutional Ethics Committee, ACSR Medical College, Nellore for the conduct of the study.

Results: Of the total autopsies done from March 2019 to February 2020 were 902, of which 39 were alleged homicide autopsies (4.3%).

Sex of the Victim: Of the total 39 alleged homicide cases, in 23 (58.9%) cases were males and rest of the cases were female 16(41.1%),(Table 1)

Male-to-female ratio was 1.4:1.
IDENTITY OF VICTIM: The identity of homicide victims was known in 36(92.3%) of cases and in 3(7.7%) of cases the identity was not known. All the 3(100%) unidentified or unknown homicide victims were male.

SOCIOECONOMIC STATUS: With regard to socioeconomic status, majority of homicide victims were from lower and lower middle socioeconomic strata 21(53.8%) followed by middle class 8(20.5%). Only few belongs to upper and upper middle class 7(18%). (Table 1)

MARITAL STATUS: Majority of homicide victims were married 25(64.1%) and 11 (28.2%) were unmarried. In 3(7.7%) of cases the marital status was not known. Among 25 married, 13 were males and 12 were females. Among 11 unmarried victims, 7 were males while 4 were females.

LITERACY: Majority 23(59%) of homicide victims were illiterate whereas 13(33.3%) were literates and in 3(7.7%) the literacy status was not known. Around 10(77) % of literates were males and the rest3(23%) were females. (TABLE: 1)

PLACE OF CRIME: in the present study the most common places of occurrences of crime were deserted and secluded places like roadside, bridge underpass, agricultural fields (43.5%) followed by at house of the victim in 30% of the cases. About 25.8% of the victims were attacked their work place. Majority of the females are victims of homicides occurring at house.

TIME OF CRIME: Most of the crimes took place during the night time 28(71.8%) while 11(28.2%) of the crimes happened at morning time.

IDENTITY OF THE ASSAILANT :(Table 1) In about 29(74.3%) of the total homicides, the assailant was a family member of victim. In 7(18%) of cases, the assailant was a known person/neighbour/friend. In 3(7.7%) of cases the assailant was not related to victim. (Table 1)

DEATH ON SPOT OR HOSPITAL: most of the victims 28(71.8%) died on the spot of the incident due to fatal injuries while rest 11(28.2%) dies while receiving treatment at a hospital.

MOTIVE OF CRIME: The motive of crime was revenge in 2(5.1%), extramarital affairs 5(12.8%), love affair 1(2.5%), financial issues 4(10.2%), property dispute 7(18%), quarrels 14(35.8%) and 3 (7.8%) of crimes were related to dowry in which victims were only females. In 3(7.8%) of cases the motive of crime was not known.

In majority cases 14(35.8%) quarrel was found to be the reason for homicide. Among homicides committed because of quarrel 10 (71.5%) were males and 4 (28.5%) were females. (TABLE:1)

WEAPON USED FOR CRIME:In majority of homicides, the inflicting injuries were caused by blunt weapons 11(28.2%), followed by sharp weapon 9(23.1%).

INJURIES: In majority of homicide victims, the cause of death was found to be head injury 11(28.2%) followed by stab injuries 9(23.1%). Poisoning as cause of homicide death was found in only 6(15.4%) victims and 7(18%) burns and 6(15.4%) are strangulation. (TABLE:1)

AGE OF THE VICTIM: Majority of the homicide victims belonged to 21-30 age group 15(38.5%) followed by 31-40 years 13(33.3%). Figure 1 shows 82% of homicides victims were less than 40 years of age.

Discussion

In the present study, out of 902 medico-legal cases autopsied at ACSR Medical College, Nellore 39 cases (4.3%) were reported to be alleged homicidal deaths. Whereas in a study done by PrashanthMada et al.9 the percentage of alleged homicide autopsies was 3.24.

The incidence of homicide in the present study was lower when compared to those observed by Murthy et al10 15.1%, Gupta et al.11 7.5%, Sinha et al12 5.9%, Dhaval13 9.13% and B.C. Shiva Kumar et al. (14) 4.76%, whereas it was consistent with studies of Prajapati et al.15 4.12% and O. Gambhir16 2.89%.

In the present study 58.9% of the cases are males and 41.1% are females. In the present study, M:F ratio was 1.4:1. Almost similar findings were also observed in various other studies like Murthy et al10, Prajapati et al15. This is because males are more aggressive, rash and earning members, they have more opportunity for interpersonal interactions. Generally, women and children are spared off even in case of revenge, whereas males are the main target.

In the present study out of 39 victims, 64.1% were married and marital status was not known in 7.7%. The findings are consistent with the studies done by Dhaval13 (69.62%) and O. Gambhir16. In the present study homicides were commonly seen in 21-30 years age group 38.5% followed by 31-40 years of age (33.3%) 41-50 years age group (12.8%). This observation goes in favour that homicides involve the age group, which is in most active and productive period of life. People of 21-30 years age group are violent and more vulnerable to fast changing social trends, ending up in misunderstanding, frustration, hatred, etc. Studies done by Rekhi et al17 and Wahlsten et al.18 reported 31-40 years as the most commonly involved age group.

In this study personal quarrels, extramarital affairs and love affairs, property disputes came out as the major motives behind the act which indicates that the victims were mostly married well into the lives or were getting into the love affairs because of this age. Family disputes, financial burdens, lack of understanding between the spouses and other family members having extramarital affairs are the reasons for very high incidence of homicide among married people when compared to unmarried persons. In the present study majority of the cases (71.8%) occurred during night time. These findings were consistent with those of Dhaval13, CT and Sinha et al.12, whereas Bhupinder S et al.19 and B.C. Shiva Kumar.14 reported the incidence to be more between 6 AM-12 PM. As darkness of night provides favourable conditions and easy execution and escape for the accused, it is more preferred.

Quarrels were the main reason behind majority the homicidal act (35.8%) followed by property disputes (18%), extramarital affairs (12.8%), financial matters (10.2%), Dowry related issues (7.8%) and revenge (5.1%). In 7.8% cases motive was not known.

Contrary to our findings, revenge as a major reason for homicide by Dhaval. CT13 (29.4%), B. C. Shiva Kumar et al.14 (32.5%). In the present study financial matters contributed to only 10.2% of cases whereas financial matters were reported as a major reason for homicide by Sinha et al.12. In the present study, majority of homicides, the inflicting injuries were caused by blunt weapons 11(28.2%), followed by sharp weapon 9(23.1%). The findings are consistent with the studies of Dhaval13 (32.5%) and Prajapati et al15 where blunt weapon was commonest but contradict with the studies of B. C. Shiva Kumar et al14 (50%) and Vij et al20 (49.4%), where sharp weapon was commonest. Easy availability of hard and blunt objects.

In the present study place of occurrence of crime was at deserted and secluded places like roadsides, bridge underpass, agricultural fields, (43.5%) followed by at house in 30% cases. About 25.8% of the victims were attacked at their work place. Similar findings were observed in studies done by Dhaval13 and B. C. Shiva Kumar14 where outdoors was the major site of homicidal act. In the present study most of the victims died on the spot (71.8%). While 28.2% died while receiving treatment at hospital. Higher rate of death on the spot
could be due to occurrence of crime during night time and delay in approaching hospital as most of the crimes happened in secluded places and help was not readily available.

**Conclusion**

Out of 39 homicidal death cases, age group of 21-40 years was mostly affected with a male-to-female ratio of 1.4:1. About 64.1% of the victims were married and most cases of homicide took place during night hours. Quarrel was the most common reason for committing homicide, followed by extramarital affair in second place. Blunt weapon was the commonest weapon used with most of the homicides occurring at places other than the house of victim. Homicide is one of the worst forms of crime as no one has the right to take the life of an individual. Socioeconomic wellbeing, removal of poverty and enhanced employment opportunities will help to check the incidence of homicides. Importance of ethical and moral values should be taught to the children in schools itself, which will help in strengthening of human relationships. Overall, law and order of the state has to be strong quick and rigorous punishment will deter people from committing heinous crimes in future.

Aadhar Arogya: Integrated Electronic Health Record as an Aid in Bridging the Gap between Individual Health and Public Health in India – A Review

Haritha R.K1, Jagannatha G.V2, Nagaland T3, Cyril Benedict3

1Dentist, 2Head of the Department, 3Senior Lecturer, Department of Public Health Dentistry, Chettinad Dental College and Research Institute, Kelambakkam, Tamilnadu

Abstract

Aadhar card is an Indian Government ID card that is issued to all Indian residents. It is one of the largest biometric databases in the world with over 1.28 billion enrollments thereby constituting the most ubiquitous ID card in India. With the additional features of QR code and biometric scanning, it forms an ideal database to be linked with the electronic health record. The health records of an individual currently in India is being maintained by the individuals. But most often they are misplaced, disorganized, incomplete or lost. This would force the clinician to assume or ascertain the current medical status by subjecting the individual to tests. Improving the quality of the medical and dental services rendered paves way for an integrated electronic health record. The common concerns arising from such a linkage is data management and data security. Big data management provides a systematic approach to maintaining such large data. The data security concerns can be addressed by employing a data controller in every hospital and a cell to inform the security breach, who can further take up legal penalties. Pseudonymisation, cryptography, audit trial, firewall, antivirus software, and cloud computing are some techniques that can be incorporated.

Keywords: Electronic health record, Aadhar card, Data security

Introduction

Patients seeking dental care often visit a clinic with a disorganized or incomplete set of medical records and sometimes without any past records. Most often the dental clinicians rely on patients’ recall to reveal their past medical illness, which often incomplete. This could result in the clinician taking one of the two possible approaches. Firstly, he/she could assume the medical history given by the patient as complete and true and initiate treatment. Secondly, the clinician could subject the patient to the required tests to ascertain the existing medical condition, which sometimes could be repetition as the patient could not produce the recent reports of the tests, he/she underwent. Moreover, most often these conditions are misreported and this significantly increases with an increase in age [1] and some individuals who don’t deem their medical history important either due to a lack of awareness or just negligence might not report accurately.

Migrant workers and people from low socioeconomic backgrounds face practical difficulty in maintaining such records. Most often they do not seek treatment and if they do seek treatment it is for acute health issues.
Integrated medical and dental records can help close these misreporting gaps and improve the quality of dental services rendered especially to individuals with underlying medical conditions minimize the duplication of resources. The word ‘Aadhar’ means foundation or base while ‘Arogya’ means health. Why the concept of ‘Aadhar Arogya’ could be a one-stop solution to finally bridging the gap between public health and individual health is the objective of this review.

Why the Aadhar Card?

Aadhar card is the Indian Government-issued ID and is fast becoming the Central and State Government’s base for public welfare and citizen services. It assigns a unique 12 digit number to all the Indian residents. It is invariable i.e., it doesn’t change in the lifetime of the individual. It is one of the largest biometric databases in the world with over 1.28 billion enrollments. Linking the medical records with the Aadhar card could improve the quality, accuracy, efficiency of diagnosis & treatment planning and reduce ambiguity in the process. Unique patient identification is a technique for linking patients to their electronic medical records that exist globally in a domain.

1. UNIQUE PATIENT IDENTIFIER (UPI)

The American Society for Testing and Materials (ASTM, 2000) Standard Guide lists desirable attributes of a UPI: unique, non-disclosing, invariable, canonical, and ubiquitous. Unique i.e., one UPI for one individual which cannot be shared, non-disclosing such that it maintains the confidentiality of the individual, and the number does not indicate aspects like name, address or phone number. Invariable as it doesn’t change in the lifetime of the individual; Canonical i.e., an individual is entitled to only one UPI; Ubiquitous i.e., all the individuals have one. Out of all the Indian government-issued IDs, a passport complies with all the desirable attributes except being ubiquitous, since it is voluntary. The other government-issued ID cards like Driver’s license, Voter’s ID require the individual to have a certain set of skills or be of a certain age. The Aadhar card additionally also has biometric and QR scanning options making it an ideal option for linking with the electronic health record.

PAST EXPERIENCES

Since 2013, Aadhar has been linked to several health-related schemes like Janani Suraksha Yojna wherein pregnant women are encouraged to undergo institutional deliveries for a direct cash transfer benefit. Linking of Aadhar card ensures that the right person is benefited from it.

Revised National Tuberculosis Control Programme mandated those who are eligible for financial benefits under the scheme to get their Aadhar authenticated or furnish proof of Aadhar. This is done to ensure validated services via Aadhar enabled direct benefit transfer and improve the scope of surveillance. However, the remaining elements of the scheme like free diagnosis and treatment would continue without interruption. Aadhar linked smart cards are assigned to all the tuberculosis patients undergoing treatment. It acts as a single unique identifier for the patients availing various public & private sector services, social, state & central services to which the patient is entitled during treatment.

Other National health programs, such as the National AIDS Control Program, have started linking their databases with Aadhar as a pilot project in Delhi Reference. This would allow people living with HIV (PLHIV) to have access to various state, central and social schemes ensuing financial benefits transferred to their accounts obviating the need to produce life certificates periodically. However, the intended benefit wasn’t realized as the patients quit the treatment program fearing privacy issues. Recently, the CoWIN app for COVID-19 vaccine registration has started linking the Aadhar card for its registration process. Beneficiary registration, beneficiary verification, Aadhar authentication, vaccination status and reporting of adverse events following vaccination can be carried out with the aid of the app, which helps to keep track without concerns of duplication.
WHAT CAN BE EXPECTED FROM LINKING THE HEALTH RECORD WITH THE AADHAR CARD

It aids in easier delivery & monitoring of primary health care services. Once a patient visits a PHC or any screening camps his/her Aadhar no. can be noted and relevant medical and dental history could be uploaded to the database. The patient can then be counselled & monitored to see if he/she has undergone treatments further - which provides a valuable tool to assess the patient’s health-seeking behaviour and serves as reliable feedback for the services rendered. Hence it bridges the gap between public health & individual health. It can aid in fulfilling the three core functions of public health that is the assessment, policy development and assurance. Public health surveillance is the data collection, analysis and dissemination of data at the appropriate time for preventing and controlling the disease or condition. Establishing public health surveillance classically involves 6 steps that are to establish goals, develop case definition, select appropriate personnel, acquire tools and clearances for collection, analysis and dissemination, implement surveillance system, and evaluate surveillance activities. It can also aid in the development of evidence-based medicine and dentistry which is the intersection of individual clinical expertise, external evidence and value to the patient.

CLINICAL IMPLICATIONS

During times like road traffic accidents & other emergencies wherein the patient is not in a position to relay the medical history, the clinician can gain access to unambiguous & reliable information by scanning the patient’s retina or fingerprint. Inter department coordination could be strengthened, for example, cleft palate surgery in childhood requiring further orthodontic treatment. Tailored diagnosis & treatment planning based on the treatment outcomes, existing health conditions etc. and lifelong monitoring could be made possible.

India is a diverse country with an internal migration of 450 million as per the 2011 census. There is a lack of continuity of treatment, repetition of treatment to be sure, higher recurrence rate due to missed appointments, language & literacy level barriers. All this hinder the migrant population’s wellbeing, who form a significant portion of the population who are often overlooked by state government schemes.

HOW CAN THIS BE ACHIEVED?

1. PILOT QUESTIONNAIRE SURVEY

A pilot questionnaire survey in the maintenance of health record showed that 80% of people have misplaced some or all of their records previously and 70% of people have been asked to repeat a test which was taken elsewhere. This clearly shows that there is a fragmentation of manual health record and an array of scope for Aadhar Arogya to bloom. Furthermore, the questionnaire was framed to assess the willingness to accept a digitalized health record. It showed that only 40% of people were willing to link their medical record to the Aadhar card and the common concerns expressed were issues of security.

2. BIG DATA MANAGEMENT

In India, health data are not digitalized and when digitalized they are not standardized. Big data management offers a systematic approach to this. Big data analysis challenges include capturing data, data storage, data analysis search, sharing, transfer, visualization, querying, updating, information privacy & data source. The data lifecycle involves – plan, collect, assure, describe, preserve, discover, integrate, analyze. It is used in healthcare to deal effectively with a large volume of data both from internal and external sources i.e., from the providers, payers, researchers, consumers & marketers, government and developers. Big data management tools and technologies are either available as open-source or commercial products. Some of the open-source products are the Apache Hadoop framework, NoSQL databases etc. The commercial products include the Hadoop distributed file system.
simultaneously. This is known as parallel processing. [21]

Big data analytics in healthcare are of three types, they are predictive, descriptive and prescriptive. Predictive analytics is used to predict treatment outcomes, descriptive analytics deals with current and past data to make evidence-based decisions. Prescriptive analytics is used to showcase to the policymakers the things to be acted upon. [17]

3. DATA SECURITY

To address the data security concerns of the general public the centralized electronic health record maintenance security regulations of developed nations were considered. Based on these and other electronic health record maintenance suggests that - proper informed consent be taken explaining in simple language regarding the whereabouts of the data shared and for what purpose. [24] A data controller should be assigned to every 250 bedded institutions, who are governed by a data supervisor. Whenever there is a data breach it needs to be informed by the data controller to the supervisor and/ or the legal panel within 72 hours. Based on the scale of breach legal penalties are sentenced. Access to all the sensitive information should be on a need to know basis.

Pseudonymisation or partial anonymization can be done so that with the data as a sole reference one cannot be able to identify a patient. It can be achieved in two ways i.e., encryption and tokenization. Encryption involves the need for a decryption key to access the information. While tokenization is the replacement of sensitive information with non-sensitive substitutes. [22] The GDPR also keeps track of the records of processing activities.

The Health Insurance Portability and Accountability Act 1996 (HIPAA) suggests the use of access control to the patients like passwords and PINs. An individual can ask for an audit trail at any point in time, wherein who, when and what information is accessed can be checked. [25]

The Personal Information Protection and Electronic Documents Act (PIPEDA) uses technological tools which are constantly changed to be up to date like firewalls and security patches. Organizational controls like security clearances, limiting access, staff training and agreements are ensured. Sensitive information can only be accessed on a need to know basis. [23]

Cryptography involves techniques like passwords and digital signature. Other simple techniques involve cloud computing and antivirus software. It is cheap and effective, additionally, cloud computing reduces the burden of maintenance.

Conclusion

The current review suggests that linking the Aadhar card with an electronic health record has the potential to improve the quality and continuity of the treatment. The potential of the Aadhar card has been realized in the recent past and has been linked with various National-level health-related schemes. To expand this comprehensively to cover all the health data under one roof, the current review suggests the need to emphasize data safety laws and regulation before they can be implemented on a large scale. A brief look at the data safety regulation in developed nations suggests many techniques like pseudonymisation, cryptography, audit trial, firewalls, cloud computing, antivirus software and legal penalties. Further research on the implementation in the Indian scenario and addressing problems therein are suggested.

COVID war or KARMA war: Who Deserves Homecoming??
Are We Taught Anonymously the Forgotten Lesson of Bhagavad Gita?

Ashok Kumar Jena¹, Venkatachalapathy Anusuya², Jitendra Sharan³
¹Additional Professor, ²Senior Resident, ³Assistant Professor, Department of Dentistry, All India Institute of Medical Sciences, Sijua, Dumduma, Bhubaneswar, Odisha, India

Abstract

History repeats itself until you learn and correct the mistakes. We all tend to create the future with the same past experiences. Nothing new than the forgotten old. The great Kurukshetra war of Indian Hindu epic the Mahabharata and the Lord’s unsung song Bhagavad Gita from it remind us the same. Although centuries had crossed, the lessons to be learned, and learning from the Gita are the same. Amidst the COVID-19 pandemic, the entire world is battling against the unseen enemy. We are fighting physically, mentally, economically, and socially. Each and everyone is contributing to the maximum to win the battle. But, the invisible enemy, coronavirus is seemingly stronger than the advanced technologies and growth of humanity. This short write up is in search of the true etiology of COVID-19 that came up in the curious mind of a medical researcher who is amazed in the bizarre situation and uncontrolled fight against this unseen enemy.

Key words: Death, COVID-19, KARMA, SARS-CoV-2 virus

Introduction

Only one person had known the “truth”, the truth of actual scenarios in the greatest Kurukshetrawar of Indian Hindu epic the Mahabharata. He was the only one who was given the chance to see the complete incidences of eighteen days war with unbiased eyes; was the one who told very clearly that who killed whom during the entire war; how Pandavasarose to the victory with a homecoming to the golden land (Hastinapur). It was none another but the Barbarika.¹ ²

The battle was between the dharma and adharma i.e. righteous and iniquity. The war was getting ready between the loved ones Pandavas and Kauravas. Even the incredible minds were oscillating to choose the side to fight against, as it was within the family and each one was equally important. Barbarika was not an exception, the grandson of Bhima (second of the Pandava brothers) choose to join the weaker side if need urges. He was famously known as “bearer of three arrows”, as he was blessed with three infallible arrows in a boon.²

Krishna, the descendant of Lord Vishnu stood the side of Pandavas charioting for Arjuna(third of the Pandava brothers). Before the beginning of the war, Krishna asked the warriors that how long will take for them to complete the war individually and Barbarika told that he could finish the entire war in a minute. As he had three arrows, he would use the first arrow to fix whom to be destroyed, the second one to fix whom to be saved, and then third to destroy all the objects marked by

the first arrow or destroy all the objects not marked by the second arrow. And at the end of this, all the arrows would return to the quiver.1,2

The Krishna was astonished by the infallible power of three arrows. Hence, he asked the Barbarika’s head as a charity, so that the strongest Kshatriya warrior’s sacrifice would help in beginning the war. By doing so, Krishna did not allow the Barbarika to participate in the war; Accepted Barbarika asked Krishna that his last wish was to watch the great battle, so Krishna let his head to watch the whole battle from a mountain top nearby the battleground.2

At the end of the battle, Pandavas won and the time came to dedicate the victory to the responsible person. Each warrior was justifying their points and chaos started. When Barbarika was asked about his view regarding the victory of Pandavas, he explained that it was neither Kaurava’s weakness nor Pandava’s strength. All he could saw in the whole war was that the divine invisible chakra of Krishna, which was spinning all around the battlefield and killed all those who were not on the side of dharma.1,2

Amidst the COVID-19 pandemic, the entire world is battling against a known enemy with an unknown trait. The initial days of COVID-19 were like a bio-war with the highest threat to humanity.3 In Italy, healthcare workers were considered as God who decides who would survive and who would not. Geriatric populations were thought to have a poor prognosis and were triaged under the least preference category for intensive treatment.4 As days moving on, the entire world was infected and different countries came up with different traits of coronavirus.5 The virulence of the virus was changing in terms of mortality rate, and more asymptomatic cases were increased.

In many countries, aged geriatric patients were started to survive by winning the coronavirus infection but many healthy young patients and health care workers have succumbed to the same despite intensive treatment. Aged men were suggested to have high risk but adolescents have also lost their lives. Despite immunity, sex, age, co-morbidity, and many other factors as suggested, no peculiar factor was defined as a predictive factor for mortality, but, we all are losing precious lives. The so-called God, health care workers started failing to hold the lives back. Day by day, this bizarre scenario is moving towards the hype of uncertainty. Thus, the time calls to analyze what factor is responsible for this mortality in the COVID-19 pandemic. Though multifactorial, the uncertainty in the individual risk poses it very difficult for health care workers to predict the outcome.6 Thus; it was not the health care workers who are deciding the lives. It was not the pre-determined co-morbid, risk factors that are choosing the lives. If not them, then what is responsible to win or lose the COVID-19 battle???

Like in Bhagavad Gita, though the Pandavas won the battle, it was not them, who were responsible for the victory. They were mere instruments for the execution of Lord Vishnu’s actions. Pandavas were thinking that they killed the Kauravas. Like we think that the coronavirus is killing the lives. But the Barbarika who had watched the war from outside only knew the truth that it was the divine chakra of Krishna, not those who were participating in the battle. Likewise, being health care workers, government sectors, society, and victims of coronavirus infection, all are battling against COVID-19 selflessly and staying detached from personal emotions and attachments7, we all have succumbed to the thought that the coronavirus is killing the lives and threatening humanity. But who knows, this myth could just be the unproven scientific phenomenon and the karma of individuals that are risking their own lives in the form of COVID-19 infection. The good and bad deeds of individuals are called karma. Like the divine chakra of God, the individual’s karma might be spinning all around this COVID-19 battle choosing whom to survive and whom to leave this earth. The SARS-CoV-2 virus may just be a mere invisible instrument, masking the deeply lying truth. The time will unfold the answers; like the eyes of Barbarika, the eyes of researchers could only tell the truth in the future.

Important of Morphological Examination of Bone Marrow for a Hematological and Non-Hematological Disorder

Safaa Jassim Mohammed
Researcher, Department of Hematology, Ibn Sina Teaching Hospital, Directorate of Ninava Health, Ministry of Health/Environment, Ninava, Iraq

Abstract

Background: The bone marrow examination is important for the investigation, diagnosis, and management of the blood, bone marrow and many systemic disorders. Morphological Bone marrow examination alone is sufficient to diagnose nutritional anemias and most acute leukemia.

This study aimed to determine the importance of morphological examination of bone marrow to diagnose hematological and non-hematological disorders like various systemic illnesses that affect the bone marrow.

Methods: A prospective study carried out for one year at the Hematology lab, Ninava Ibn Sena Teaching Hospital, A total of 201 cases were investigated. The bone marrow examination was taken from the posterior superior iliac spine.

Results: The age range was (15-87) years. The male-to-female ratio was 1:1.2. The most common disorder finding was acute leukemia 17% (include AML & ALL) and AML is more common than ALL, whereas lymphoproliferative disorders was second bone marrow finding fallowed by Megaloblastic anemia of Myeloid dysplasia syndrome (MDS) and Essential thrombocythemia (ET).

Conclusion: Morphological bone marrow examination is a useful procedure in ascertaining the diagnosis of several hematological and non-hematological disorders.

Keywords: AML (acute myeloid leukemia), ALL( acute lymphoid leukemia), MDS(Myeloid dysplasia syndrome), Essential thrombocythemia (ET).

Introduction

Diagnosis and management of many hematologic diseases depend on bone marrow evaluation. Bone marrow examination usually involves two separate, but interrelated, specimens. The first is a cytologic preparation of bone marrow cells. The second specimen is a needle biopsy of the bone and associated marrow (1). Marrow biopsy is useful for diagnosing and following the course of disorders such as megakaryoblastic leukemia, hairy cell leukemia, and chronic myeloproliferative neoplasms. In myelodysplastic syndromes, marrow biopsy is useful for evaluating abnormal localization of immature precursor cells and abnormal megakaryocytes (2, 3). Satisfactory samples of bone marrow can usually be aspirated from the sternum, iliac crest, or anterior or posterior iliac spines. In most circumstances, the posterior superior iliac spine is the preferred biopsy site and selection of this site has the advantage that, if no material is aspirated, a trephine biopsy can be performed immediately (4).

**Methods**

A cross-sectional study was conducted in the Hematology lab, Ninava Ibn-Sena Teaching Hospital, from January 2019 to December 2019. Clinical data concerning age, sex, dietary habits, mode of onset, history of drug intake or exposure to toxic chemical agents, H/O bone pains, hepatosplenomegaly, and lymphadenopathy respectively, were recorded. This study excluded patients who are present for assessment response of bone marrow to the treatment of previous diagnosis patients. Amongst all the subjects, peripheral smears, reticulocyte counts, and bone marrow aspiration and biopsy were obtained.

The procedure of BMA was done after giving local anesthesia from the posterior iliac spine. Bone marrow trephine biopsy was performed. Bone marrow examination was done on Leishman stained for smears and Hematoxylin-eosin-stained for trephine biopsy sections.

**Results**

The age group ranged from 15 years to 87 years. Most of the patients are belonged to the 51-60 years old group. 89 of 201 cases were male and 112 cases were female, and male-female-ratio is 1:1.2 (Table 1). The commonest mode of presentation was anemia; other main symptoms were pancytopenia, organomegaly, whereas fever was the rare presentation (Figure 1). Finding of Bone marrow aspiration normal active bone marrow was (29.3%) cases, AML (9%) cases, Megaloblastic anemia (7.4%) cases, Multiple myeloma (7%) cases, CML (5.4%) cases, secondary metastasis (4.4%) cases, erythroid hyperplasia (4%) cases, were plasma cell leukemia, ET and MDS (0.5%) cases for each of them (Table 2).

Hematological disorders include a wide range of diseases ranging from reactive hyperplasia to hematological malignancies.

Male to female ratio was 1:1.2 which similar to the study done by Sreedevi et al (5) and Chand et al (6). The majority of the patients in the study belonged to (51-60) years old which similar to the studies done by Joshi et al (7) and Saeed et al (8). The commonest indication in our study was anemia (42%). Similar findings, anemia was the commonest indication in a studies done by Sreedevi et al (5), Saeed et al (8), Kumar et al (9), Timothy et al (10).

Bone marrow examination showed (29.3%) of patients with normal findings, which similar to the study done by Saeed et al (8), which reporting normal bone marrow 29.05% of biopsy. About (70.7%) of bone marrow was pathological and largest hematological malignancy is acute leukemia 17% (included AML, ALL, M3 and M3V) and AML is more common than ALL similar result reported by other studies (11-14).

Lymphoproliferative disorders are the second pathological bone marrow finding followed by Megaloblastic anemia which different from the percentage report by other studies (6, 8, 15), this difference may be due to the difference in sample sizes.

The lowest percentage (only one case) of myeloid dysplasia syndrome and Essential thrombocythemia was diagnosed in similar reported by the study done by Shah et al (8, 16, 17).

**Conclusion**

Morphological examination of bone marrow aspirate is important for the diagnosis of many diseases hematological disorders like leukemia, lymphoma, multiple myeloma, and myeloproliferative neoplasm, and non-hematological diseases like the cause of anemia, thrombocytopenia, and pancytopenia.

Statistic Assessment of Spreading Cases (Total Confirmed, Recovered, Death) From Different Areas Contain Novel Coronavirus (2019-nCov)

Huda Sahib Abdul Mohammed Al-Rawazq

Assistant Professor, Department of Anatomy-Biology Section, College of Medicine, University of Baghdad, Baghdad, Iraq

Abstract

Background: In Wuhan, Hubei Province, China 31, December 2019 were discovered several cases of pneumonia of unknown causation and correlated to Wholesale Market Huanan Seafood. And caused acute viral respiratory diseases called Coronavirus Disease 2019 (COVID-19).

Aim: The aim of this study is statistic assessment of cases (total confirmed, recovered, death) from different areas in world, Arab nation and in Iraq contain 2019-nCoV.

Methods: The first study include collected data from Center for System Science and Engineering (CSSE) at John’s Hopkins University and Iraqi Ministry of Health website daily reports from 29th February to 31th December 2020 of people infected with 2019-nCoV.

Results: From this statistics the prevalence of 2019-nCoV the spreading cases (83,561,252 total confirmed, 47,136,188 global recovered and 1,820,668 global death) from 191 countries in the world. The most distribution confirmed cases represent in (19,975,250 US, 10,286,709 India, 7,675,973 Brazil, 3,153,960 Russia, 2,677,806 France, 2,496,231 United Kingdom, 2,208,652 Turkey, 2,107,166 Italy). Also, global recovered represent in (9,883,461 India, 6,848,844 Brazil, 2,553,467 Russia, 2,100,650 Turkey, 1,508,419 Colombia, 1,463,111 Italy, 1,426,676 Argentina, 1,355,384 Germany). And global death represent in (345,844 US, 194,949 Brazil, 148,994 India, 125,807 Mexico, 74,159 Italy, 73,622 United Kingdom, 64,760 France, 56,798 Russia). From this result the Arab nation including 3,139,205 total confirmed cases, 2,783,448 recovered cases and 55,326 death cases from 21 countries infected with 2019-nCoV between this result the Iraqi infected patients represent 595,291 total confirmed cases, 537,841 recovered cases and 12,813 death cases.

Conclusions: In concluded, the percentage of 2010-nCoV increase in all the global confirmed cases in different areas of the world and become pandemic. In Iraq show the infection is mild to moderate in spite of no special antiviral and vaccine is present.

Key Word: 2019 Novel Coronavirus (2019 n-CoV), Cases (infection, recovered, death), different countries, Pandemic.

Introduction

In Wuhan, Hubei Province, China 31, December 2019 were discovered several cases of pneumonia of unknown causation and correlated to Wholesale Market Huanan Seafood1. And caused acute viral respiratory diseases called Coronavirus Disease 2019 (COVID-19)2. Began, in Wuhan and rapidly diffused into different area of China, many factors were accountable for this fast diffuse of the virus to various groups like; different route of infection, virulence of virus and peoples capability3. World health organization (WHO) were pronounced as a universal public health emergency because, the type of pneumonia caused by the COVID-19 is continued
outbreak and a highly contagious. Declared on March 11, 2020 as a cosmopolitan pandemic. In the past two decades that has emerged the third coronavirus causing multinational outbreaks and transferring substantial mortality and morbidity. The severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) was named by International Committee on Taxonomy of Viruses (ICTV), which is a novel strain of human coronaviruses. Coronaviruses belong to the subfamily Coronavirinae, stranded RNA viruses are single positive, enveloped, the length of genome ranging from 26 to 32 kilo-bases, possibly known the largest viral RNA. The four genera of subfamily Coronavirinae consists of: Alphacoronavirus, Betacoronavirus, Gammacoronavirus and Deltacoronavirus. The infectious only to mammals are Alphacoronaviruses and Betacoronaviruses genera while infectious to birds are Gammacoronaviruses and Deltacoronaviruses, but also some of them can infect mammals.

Also have been known in many avian hosts. Coronaviruses in various animals may cause infections in multiple systems, and in humans cause mainly respiratory tract infections. Even though most coronavirus infections in human are mild, the two betacoronaviruses epidemics, Middle East respiratory syndrome coronavirus (MERS-CoV), and severe acute respiratory syndrome coronavirus (SARS-CoV), have caused in the past two decades accumulative cases more than 10,000, with 37% mortality ranges for MERS-CoV and 10% for SARS-CoV. At the same time, the transmission human-to-human was confirmed and staff caring for patients were reported infections with 2019-nCoV in hospital. And mainly spread through respiratory droplets or close contact, latest suggest possibility of oral-fecal route transmission. Transmission of droplet may occur out of tears, close contact and fomites around the infected person by immediate environment. The range of incubation period was 1 to 14 days with average five days and experience signs within 11 to 12 days approximately 95% of contact patients. During the incubation period when patients show without symptoms is believed the novel coronavirus may be infectious. The potential sources of SARS-CoV-2 infection is asymptomatic transporters. The most popular symptoms of the COVID-19 which are like to that of MERS-CoV and SARS-CoV infection: fever, dry cough, fatigue, lethargy and muscle pain. The clinical presentation range from mild to severe, but the high case-fatality rate show in elder patients or comorbidities patients, such as diabetes, hypertension, chronic renal failure, cardiomyopathy, decreased immunity and chronic obstructive pulmonary disease. WHO enabled various laboratories to produce reverse-transcription diagnostic polymerase chain reaction (RT-PCR) test especially for revelation of viral RNA, due to the genetic sequence of the 2019-nCoV was obtainable. CT findings mainly in the lower lung lobes consist of bilateral multipolar ground-glass obscurities, with marginal posterior distribution. When the RT-PCR screening test is negative, chest CT may prove to be a precious savings because it may display distinctive features of the disease. The own immune status becoming the majority definitive agents affecting disease progression and predication, due to the absence of vaccine and specific antiviral drugs. Clinically researched to discovery any thinkable treatment for COVID-19, by many antiviral complex that are applied to treat other infections.

Methods

The first study include collected data from Center for System Science and Engineering (CSSE) at John’s Hopkins University and Iraqi Ministry of Health website daily reports from 29th February to 31th December 2020 of people infected with 2019-nCoV.

Statistical Analysis

The next step of this study analyze the data calculated using (IBM SPSS statistics 20) they include the following:

Descriptive statistics: Statistical tables including observed frequencies with their percentages. Inferential statistics: for statistical hypotheses which maybe accept or reject, Persons Chi-Square test ($\chi^2$) at level of...
Result

From this statistics the prevalence of 2019-nCoV the spreading cases (83,561,252 total confirmed, 47,136,188 global recovered and 1,820,668 global death) from 191 countries in the world show in Figure (1). The most distribution confirmed cases represent in (19,975,250 US, 10,286,709 India, 7,675,973 Brazil, 3,153,960 Russia, 2,677,806 France, 2,496,231 United Kingdom, 2,208,652 Turkey, 2,107,166 Italy). Also global recovered represent in (9,883,461 India, 6,848,844 Brazil, 2,553,467 Russia, 2,100,650 Turkey, 1,508,419 Colombia, 1,463,111 Italy, 1,426,676 Argentina, 1,355,384 Germany). And global death represent in (345,844 US, 194,949 Brazil, 148,994 India, 125,807 Mexico, 74,159 Italy, 73,622 United Kingdom, 64,760 France, 56,798 Russia). From this result the Arab nation including 3,139,205 total confirmed cases, 2,783,448 recovered cases and 55,326 death cases from 21 countries infected with 2019-nCoV show in Figure (2) between this result the Iraqi infected patients represent 595,291 total confirmed cases, 537,841 recovered cases and 12,813 death cases show in Figure (3).

P-Value 0.000
In December 2019 were examined in Wuhan, China, to this moment I was writing the research, the numeral of confirmed cases raising dramatically in all the world and reach to (83,561,252 total confirmed, 47,136,188 global recovered and 1,820,668 global death) this spreading cases show in Figure (1). And refers for the most cases only [(19,975,250 US, 10,286,709 India, 7,675,973 Brazil) most global recovered is (9,883,461 India, 6,848,844 Brazil, 2,553,467 Russia) and the most global death is (345,844 US, 194,949 Brazil, 148,994 India)]. Due to the existing of infectious disease the characteristic of COVID-19 outbreak and control cannot
be used to observed the data and describe directly. The survey is making similar to other studies from 80 to 90% carrying out performed during the COVID-19 outbreak in China. Including the application of extraordinary public health measures throughout the world on traditional strategies of social distancing, quarantine, isolation and community containment. Also, took some aggressive measurement inclusive the shutdown of workplaces, schools, cancellation of public gatherings, roads and transit systems, compulsory quarantine of uninfected people without known disclosure to COVID-19. In Figure (2) show spreading cases (total confirmed 139,205, recovered 2,783,448, death 55,326) in the Arab Nation. The most cases show in Table (1) [Infection in Iraq 595,291 (51.9), Morocco 439,193 (51.4), Saudi Arabia 362,741 (50.2), Jordan 294,494 (51.8), most recovered in Iraq 537,841 (46.9), Morocco 407,504 (47.7), Saudi Arabia 353,853 (49.0), Jordan 270,551 (47.6) and most death in Iraq 12,813 (1.1), Egypt 76,31 (3.0), Morocco 73,888 (0.9), Saudi Arabia 62,223 (0.9)]. The p-value 0.000 in 2-sided represent non-significant result. Spreading cases (total confirmed 595,291, recovered 537,841, death 12,812) in the Iraq show in Figure (3). On 24 February 2020, the first assured case of COVID-19 has been recorded in Iraq from Najaf province to Iranian student came from Iran, followed on 25 February, in Kirkuk province from one family by four cases, they have as well travel date to Iran. On 27 February, An additional case was registered in Baghdad, for a patient who visited Iran lately. The distribution of cases (infection, recovered, death) in Iraq from different Months show in Table (2) which began the first weeks in 24th February to 31st December 2020 the p-value 0.000 in 2-sided represent non-significant result. During this time the infection is increase due to some people is close contact being within the room of a novel coronavirus case for a long period of time while not wearing bespoke personal covering equipment, living with, visiting, or input a health care suspense area or room with a novel coronavirus case or having direct contact with contagious excretion of a novel coronavirus case while not wearing counseled personal preservative tools. In Iraq the percentage of mild to moderate in severity until todays represent 80% and the percentage of chronic represent 20% in elder patients or comorbidities patients, such as diabetes, hypertension, chronic renal failure, cardiomyopathy, decreased immunity and chronic obstructive pulmonary disease this led to death.

Conclusion

In concluded, the percentage of 2010-n CoV increase in all the global confirmed cases in different areas of the world and become pandemic. In Iraq show the infection is mild to moderate in spite of no special antiviral and vaccine is present.

Selective Caries Removal- A New Improvised Technique for Caries Management

Megha J Nair, Arathi Rao, Suprabha BS

Post Graduate Student, Professor, Professor & Head, Department of Pediatric and Preventive Dentistry, Manipal College of Dental Sciences, Mangalore, Manipal Academy of Higher Education (MAHE) Manipal

Abstract

The strategies to manage deep caries are constantly evolving as evidence heaps for the use of minimal conservative techniques which would prevent pulpal exposure leading to preservation of pulp vitality, remineralisation of the carious dentin and arrest the progression of caries and offer a predictable success of the restoration. Changes in our understanding about the caries process, advent of new adhesive restorative materials and the possibilities of remineralization of demineralized dental tissues helps us to explore different techniques in caries management. Selective caries removal is now considered an efficient and evidence based approach in deep caries management and focuses on maximum retention of tooth material thus avoiding the probability of pulp exposure to provide a sound peripheral bondable surface for restoration and creating excellent hermetic seal.

Key Words: Caries, caries removal, pulp protection

Introduction

Dental caries result from an ecological shift in the dental biofilm from a healthy balanced state of microbial population to an unbalanced population of microbials dominated by acidogenic and aciduric bacteria, developed and maintained by the frequent consumption of fermentable carbohydrates, eventually leading to further imbalances in demineralization- remineralization cycle manifesting the carious lesion. This understanding of caries has changed the treatment strategies from a traditional “drill and fill” approach to a minimal invasive approach aiming at the control of biofilm activity.

Great many options are available for such a biofilm activity control in non cavitated lesions. Strategies for noncavitated lesions include diet control to manipulate the composition of biofilm, inactivation or removal of biofilm by mechanical and chemical means as well as use of fluoride agents to minimize the susceptibility of demineralization. Micro invasive methods like resin infiltration is recommended for early caries. Cavitated lesions warrants an conservative operative technique facilitating effective restoration of form and function.

With the changing of our understanding about the caries process, advent of new adhesive restorative materials and the possibilities of remineralization of demineralized dental tissues emphasis is on the selective removal of carious tissue to create a favorable surface for bonding as well as for supporting a restoration with good resistance and hermetic coronal seal.

This review explores this concept of selective caries removal, detailing the different techniques involved and the materials used for restoration following selective caries removal.

Evolution

More than a century ago, G V Black in his bookmentioned that an ideal cavity preparation needed removal of all the carious lesion. He believed that it was better to expose the pulp than leave it covered...
with a layer of soft dentin.\textsuperscript{7} There was a change from this belief when Fusyama et al\textsuperscript{8,9} identified two layers of carious dentin namely, inner demineralized dentin & outer microbial contaminated dentin and recommended that only the contaminated dentin needed to be removed and the inner layer (firm) would be remineralized. This marked the beginning of a minimally invasive treatment in cavity preparation and was termed as selective caries removal.

Massler et al coined the terms infected (previously termed outer contaminated) and affected (previously termed inner demineralized) dentin. Little was known that these terms would have a huge impact on the current concepts of caries management and how caries should be removed.\textsuperscript{10}

The techniques mentioned above have approximately 40\% (in permanent) and 53\% (in primary) risk of pulpal damage or exposure in cavitated moderate-deep lesions. In such a case, treatment modalities would include direct pulp capping, pulpotomy, pulpectomy/Root Canal Treatment or extraction of teeth. The success rate of pulp therapy in mechanical exposure of pulp is reported to be high especially in young permanent teeth with an open apex. However, a carious exposure significantly brings down the success rate to 33-37\% after 3 years to as low as 13\% after 10 years.\textsuperscript{11}

In International Caries Consensus Collaboration meeting in 2015, participated by 21 experts in Cariology from 12 countries assessed a compilation of evidences from various studies and discussed on different treatment strategies for caries management. This consensus elaborated on various methods and techniques of caries tissue removal and management with special focus of teeth that could be retained and with pulp with a potential to respond positively to pulp testing as well as with reversible pulpitis.\textsuperscript{6}

Objectives

The objectives of selective caries removal are to avoid exposure of the pulp during cavity preparation in an attempt to preserve the pulp vitality, manipulate the microbial population, provide a sound peripheral bondable surface for restoration creating excellent hermetic seal thereby cutting off the residual microbes of substrate/carbohydrates for survival subsequently preventing the progress of the carious lesion.\textsuperscript{6}

A shallow lesion which is not extending into the inner 1/3\textsuperscript{rd} to 1/4\textsuperscript{th} of the total dentin thickness, is at low risk of pulpal damage and therefore priority has to be given for restoration success than pulpal health. But, in deep carious lesions extending into the inner 1/3\textsuperscript{rd} to 1/4\textsuperscript{th} of dentin, priority should be for preservation of pulp vitality and reducing risk of pulpal damage which may lead to pulpal necrosis demanding invasive painful procedures later.\textsuperscript{10}

Procedure

Selective caries removal in shallow to moderate cavities:

This technique is employed in primary & permanent dentition with shallow and moderately deep cavities (radiographically extending less than the pulpal 1/3\textsuperscript{rd} or 1/4\textsuperscript{th} of dentin).\textsuperscript{2} The carious tissues are removed with the help of a spoon excavator from the base of the cavity until a resistance is felt. At this point, firm dentin is reached which is more often not discolored. The carious tissue from the walls of the cavity is excavated completely up to hard dentin which is “scratchy” when felt with a probe.\textsuperscript{10}

Selective caries removal in deep cavities:

Attempt is made to avoid the chances of pulpal exposure and preserve pulp vitality. A layer of ‘soft to touch’, ‘wet and moist’ dentin is left deliberately at the base of the cavity over the pulp. But a complete caries excavation on the walls is done to ensure a good coronal seal and a durable restoration.\textsuperscript{2} A provisional restoration which is durable up to a year is given keeping in mind the patient may not return to complete the treatment. This would also give time for dentinal changes to take place. During second visit, cavity is reentered, the formation of tertiary dentin confirmed by visual and tactile criteria and caries removal is continued up to leathery dentin after which a durable restoration is given. The reasoning for this method is that after the initial visit, the microbial diversity significantly reduces, remineralization of demineralized dentin and formation of tertiary dentin take place.\textsuperscript{12}

Methods of carious tissue removal

There is a wide array of criteria useful for evaluation of caries removal including tactile (hardness) and visual evaluation (dryness & color) of dentin, use of caries detector dyes.\textsuperscript{5}
Although there is no strong recommendations, hardness of dentin may be used as a primary criterion for assessing the effectiveness of carious dentin.  

Polymer burs work on the principle of differential hardness of the tooth tissues. The Knoop Hardness of a sound dentin is 66-80 while that of carious dentin is around 30. A polymer bur of Knoop Hardness Number 50 removes caries selectively.  

The erbium laser at 2940 nm is absorbed by water and hydroxyapatite crystals. This absorbed energy causes vaporization of the water making the area dry and results in micro-explosions and expulsion of the target material. This helps to remove the tooth structure rapidly especially having higher water content. This is of importance in cavity preparation since the carious tissue has more water content than healthy tissue which facilitates its easy and rapid removal. However, lasers are comparatively slow in the removal of carious lesions as compared to using a dental handpiece. 

Air abrasion makes use of the kinetic energy of aluminium oxide particle stream to remove carious lesion. They abrade the lesions without any vibration, sounds or heat production. Since the particles exist at the end of the tip, it is an end cutting instrument. There is evidence that the tooth preparation done using this technology results in rounder internal angles as compared to conventional cavity preparation, thus resulting in restorations with more longevity. 

Cavity disinfection following selective caries removal

Cavity disinfection following selective caries removal is a debated topic. It is said that microbial numbers play a limited role in the success of this treatment provided, a tight and good hermetic seal is achieved. Cavity disinfection with anti-microbial agents like 0.12% chlorhexidine with 35% phosphoric has been found to reduce the bacterial penetration into the dentinal tubules after selective caries removal. Phosphoric acid removed the smear layer which opens up the dentinal tubules and facilitates effective penetration of chlorhexidine. 

Use of Cavity liners

Cavity liners are routinely used in deep caries management in an attempt to keep the pulp viable, reducing the bacterial numbers, promote reactionary dentin formation, remineralization of demineralized dentin and to isolate the pulp from noxious stimuli. Cavity liners are beneficial while using resin-based cements as the final restoration after selective caries removal as it prevents the seeping of the monomers through the dentinal tubules. Also, the caries affected dentin has a low elastic modulus and poorly withstand the tensile forces which may lead to fracture lines in dentin during the polymerization shrinkage of resin-based cements due to which cavity liners are beneficial. 

Calcium hydroxide, used as a liner material reduces the number of microorganisms, promotes remineralization and aids in the formation of dentin bridge formation. However, its use as cavity liners following partially excavation of caries has shown unsatisfactory results. The high solubility of calcium hydroxide over time, tendency to cause internal resorption, tunnel defects in the dentin bridge formed makes it unfavorable for cavity lining after selective caries removal. 

Other bioactive materials that induce deposition of minerals in the dentin leading to the formation of apatite-like material protecting the underlying pulp are MTA, Biodentine, light cured calcium silicate base materials (TheraCal LC) . MTA is considered the most validated material for use as lining the base of the cavity. 

There is a lack of consensus in the literature about the ideal cavity liners to be used after selective caries removal. While some argue that liners don’t contribute to the success of selective caries removal if a good hermetic seal is achieved, some studies show that MTA be preferably used because of their high biocompatibility, osteoconductive properties as well as superior dentin bridge formation. It has been shown that MTA produces less pulpal inflammation and a thicker dentinal bridge with an odontoblastic layer formation. It maintains the vitality of the pulp and ensures a normal physiological pulpal function. A randomized clinical trial compared calcium hydroxide and MTA after selective caries removal in primary molars and reported no statistical differences after a 6 month and 1 year follow up. 

The key factors to be considered is the bond between the cavity liners and the residual dentin as well as the bond between the cavity liner and the final restoration. Even though its proved time and again that MTA and Biodentine may be used as reliable pulp capping agents, evidence suggest that MTA continues to mature a year after placement beyond the setting time. This would impact its mechanical integrity and bond strength.
Likewise, studies show that Biodentine matures up to 2 weeks after its placement.\textsuperscript{23}

Restorative materials used following selective caries removal

The primary objective of a restorative material is to promote the remineralization of carious left out dentin to restore the original mechanical properties and the choice is made based on the remaining coronal tooth structure, size of restoration, occlusal forces, caries risk of the patient, location of the carious lesion, esthetic needs of the patient and other related factors.\textsuperscript{24}

Amalgam and composite resin are globally accepted permanent restorations. Recent meta-analysis indicates that amalgam has better longevity as compared to composite restorations.\textsuperscript{25,26} In spite of good mechanical properties of amalgam, the poor esthetics and limitations of use of mercury containing materials and procedures,\textsuperscript{27} its use as a restorative material has drastically reduced globally.

Composite restorations form a tight micromechanical bond at the cavity margins by forming resin tags. But this bond with the carious dentin is very poor.\textsuperscript{28,29} Among the various systems, etch and rinse adhesive system yield a better bond to carious dentin as compared to self-etch systems.\textsuperscript{29} Some clinical available techniques to improve the bond strength is the pretreatment of cavity with chlorhexidine and use of Quaternary Ammonium Methacrylate containing products like 12-Methacryloyloxy-odecylpyridinium bromide (MDPB). They are polymerizable anti-microbial agents which inhibit collagenolytic enzymes that degrade the adhesive collagen, preventing cohesive failure.\textsuperscript{30}

Conventional Glass Ionomer Cements (GIC), Resin Modified Glass Ionomer Cements (RMGIC), comomers are cariostatic restorative materials due to their fluoride releasing properties and may be used as alternatives to composites. High viscosity GICs (HV GIC) are gaining increasing popularity as a restorative material after selective caries removal. Unlike the adhesive systems, HV GIC has similar bond strengths to both sound dentin and carious dentin. (31) In a study carried out in head and neck irradiated xerostomia patients providing ideal conditions for study of restorative material over a short period of time, HV GIC has been shown to have good longevity. Also further studies have proven that both Low Viscosity GIC (LV GIC) and HV GIC completely prevented the development of secondary caries even after the restoration was lost and in low fluoride compliant patients. Most notably, deteriorated restorations could be transformed into sandwich restorations.\textsuperscript{31-33}

Follow up

Any deep caries management places the patient under medium and high risk category which warrants the requirement of a follow up at 6 months. A positive pulpal response may be ensured by assessing the dentin beneath the restoration and non-progression of carious lesion compared to baseline.\textsuperscript{34}

Conclusion

The strategies to manage deep caries are constantly evolving as evidence heaps for the use of minimal conservative techniques which would prevent pulpal exposure leading to preservation of pulp vitality, remineralisation of the carious dentin and arrest the progression of caries and offer a predictable success of the restoration. Selective caries removal is now considered an efficient and evidence based approach in deep caries management. The decision to use cavity liners should be based on the need for additional pulp protection. The choice of final restoration should be based on clinical factors like size of cavity, type of carious dentin left behind, location of the cavity.

Effectiveness of Educational Package Regarding Knowledge of Somatic Symptom Disorders among Adolescent Girls- A Pre-Experimental Study

Vishakha Rani¹, Raman Deep², Poonam Ahlawat¹

¹MSc Nursing, ²MSc Nursing & Associate Professor, SGT University, Gurugram, Haryana

Abstract

Objective: This study was undertaken to assess the effectiveness of educational package regarding knowledge of Somatic symptom disorders among adolescent girls.

Methods: 75 adolescent girls were selected by using non probability convenient sampling technique. The data was collected by using a reliable and validated tool to assess the knowledge regarding Somatic symptom disorders.

Results: The quantitative assessment of knowledge regarding Somatic Symptom Disorders revealed that after administration of educational package, 56 (74.67%) adolescent girls had average knowledge and 19 (25.33%) adolescent girls had adequate level of knowledge. There was significant difference between knowledge in pre test and post test after administration of educational package. Also, the post test knowledge was statistically associated with educational level of father of adolescent girls (0.043), educational level of mother of adolescent girls (0.046) and occupation of mother of adolescent girls (0.003). The study revealed that, the pretest mean score value of knowledge was 9.52 with standard deviation (SD) of 2.21 and the post-test mean score value of knowledge was 17.00 with SD of 4.01 with a mean difference of 7.48. The calculated-t value was 13.87. This indicated that there was a high statistical significant difference in the pre and post test knowledge level regarding Somatic symptom disorders among adolescent girls, p value 0.05.

Conclusion: Results of this research generates evidence that educational package regarding knowledge of Somatic symptom disorders among adolescent girls was effective.

Keywords: Assess, effectiveness, educational package, knowledge, Somatic symptom disorders and adolescent girls.

Introduction

“All emotions, even those that are spoken and unspoken, have physical effects. Primarily unspoken emotions tend to stay inside the body like tiny ticking time bombs, them are unit sicknesses in incubation.”

Marilyn Van M. Derbur, Miss America by Day

In today’s world of excellence, almost everyone experiences various degrees of stress in their daily lives. Even children aren’t an exception there too as they’re experiencing greater stress on account of rising expectations at both school and residential to perform beyond their aptitude. India accounts for 21% of adolescent population worldwide.

Literature shows that academic pressure causes various mental and behavioral disorders like depression, frustration, anxiety, helplessness, and suicidal behavior; these are more common emotional disorders in adolescents. [1]
Somatic symptom disorder Somatic comes from soma, the Greek word for body. Somatic symptom disorders are characterized by physical symptoms suggesting medical disease, but without demonstrable organic pathology or known pathophysiological mechanism to account for them.

The Somatic symptom related disorders include Somatic symptom disorder, factitious disorder, Hypochondriasis, conversion disorders, and psychological factors affecting other medical conditions. Additionally, DSM-5 has added new severity ratings for Somatic symptoms.

Invasive and costly diagnostic procedures are also done repeatedly in these cases. Hence, it’s vital to know the emotional factors that contribute to the event and maintenance of the functional Somatic symptoms and supply proper management at the earliest.

Somatic symptoms disorders, is characterized by 6 months of a general and non-delusional preoccupation with fears of getting, or the thought that one has, a significant disease supported the person’s misinterpretation of bodily symptoms. This preoccupation causes significant distress and impairment in one’s life; it’s not accounted for by another psychiatric or medical disorder; and a subset of people with Somatic symptoms disorder have poor insight about the presence of this disorder.

In many psychiatric disorders, including anxiety and depressive disorders, headache is usually prominently symptomatic. Children who undergo stress may present with complaints of nausea, vomiting, diarrhea, palpitation, headache, abdominal pain, limb pain, and pain over multiple sites, difficulty in breathing, hyperventilation, aphonia, giddiness, fatigue, weakness, non-epileptic seizures, tremors, abnormalities of gait and problems associated with micturition.

Sometimes psychological factors can cause unhealthiness without actually causing a disease. As results of unhappiness, anxiety or stress because of personal problems, physical symptoms may develop. We are all conversant in the headache that develops as a result of stress. Similarly, other physical symptoms can develop. These include nausea, abdominal pain and pain, breathlessness, diarrhea and giddiness and muscle pains.

Very few studies are conducted during this context, in India. Among these studies, varying prevalence of psychological state problems has been reported, from 9.5/1000 to 370/1000 population in India.

Somatic symptoms in adolescence are predicted as a severe adult mental disease as measured by hospital-based care also when controlled for important confounders. Adolescents with Somatic symptoms need early treatment and extended follow-up to treat these specific symptoms, no matter co-occurring depression and anxiety.

In general medical clinic populations, reported 6-month prevalence of Somatic symptom disorders are 4 to 6 percent, but it may be as high as 15 percent. It is more common in women than in men, in rural areas and less educated person (Black & Andresen). The disorder is chronic, with symptoms starting before age 30. Some evidence indicates that this diagnosis is more common among blacks than among whites.

Lifetime prevalence rate of conversion disorder vary widely. Statistics within the general population ranged from 5-30 percent. Somatic symptom disorders are more common in women than men and more frequently in adolescents and young adults than old age groups.

In India, the number of cases reported due to mental illness are 1-2% neurosis, somatic diseases 2-3%, mental retardation 0.5-1%, psychiatric disorders in children 1-2%, outpatient department attended in government hospital 3.63 million/year, outpatient department attended in private hospitals 2.63 million/year, 15 to 20% of all help seekers in general health services in both developed and developing countries.

Richa, Ghildiyal RG, Subramanyam A, Sharma P (2018) conducted a study which highlights the need for a joint effort by parents, pediatricians, psychiatrists
and teachers to help our children cope with the stress of today’s fast paced competitive world.\textsuperscript{[15]}

Somatic symptoms occur more commonly in females than males. Girls are reporting more symptoms as puberty and adolescence progresses (LeResche et al, 2005). In the majority of studies, girls have been found to report symptoms at increasing rates during adolescence, whereas reporting levels by boys of some Somatic symptoms (e.g., abdominal pain) fall during this time (LeResche et al, 2005).\textsuperscript{[16]} Worldwide, 20% of youngsters and adolescents suffer from a disabling mental disease. Therefore, knowledge of the prevalence of these disorders can be used to design intervention strategies.\textsuperscript{[17]}

The most common complaints are abdominal pain, headaches, and muscular or joint pains. Recurrent and troublesome Somatic symptoms occur in fewer than 10% of children and adolescents (Garralda, 2005; Rask et al, 2018).\textsuperscript{[18]}

Somatic symptom disorders are most common psychiatric disorder found in general practice. Somatic symptom disorders are very prevalent mental health problem among adolescents and they have lack of knowledge regarding Somatic symptom disorders. Somatic symptom disorders are more common among adolescent girls. That’s why researcher took this study to improve the knowledge regarding Somatic symptom disorders among adolescent girls with the help of educational package.

In the present study the investigator adopted a modified conceptual framework based on Ludwig Von Bertalanffy’s (1968) General System theory.

Ludwig general system theory model focuses on three areas, i.e., Input, throughput and output.

Beutel ME, Wiltink J, Kerahrodi JG, Tibubos AN, Brahler E, Schulz A, et. al (2019) conducted a study to assess the (1) prevalence of Somatic symptoms in men and women in the general population and (2) to identify the contributions of psychosocial factors and Somatic disease on symptom reporting. A total of 7,925 participants aged 40 to 80 years underwent medical and psychological assessments, based on the PHQ-15 (Patient Health Questionnaire). Pain complaints (arms, legs, joints, back pain) affected the majority of men and women, and Somatic symptom reporting increased with age. Findings highlight the complex psychosocial and Somatic contributions to Somatic symptom reporting.\textsuperscript{[19]}

Acheampong K, Baffour-Awuah D, Ganu D, Appiah S, Pan X, Kaminga A, et al. (2019) conducted a study to assess the predictors of dysmenorrhea, its impact, and methods for dealing with stress among adolescents in Shai Osudoku District, Ghana. Method: self-controlled survey to get information from adolescents elected to take an interest with in study. Conclusion: This examination uncovered that dysmenorrhea is high among young people in Shai Osudoku District which adversely influences the day by day action of greater part of them.\textsuperscript{[20]}

Richa, Ghildiyal RG, Subramanyam A, Sharma P (2018) conducted a study to evaluate the clinical profile of patients presenting with Somatic symptom and related issues. An open labeled, unidirectional and prospective study was conducted at a tertiary care hospital on 60 children in 5 to 16-year age group over a period of 18 months. The overall prevalence of Somatic symptom and related disorders was 60. The most common presenting symptom reported was generalized pain by 30 (50.0%) among Somatic symptoms and Pseudo seizures (33.3%) among conversion symptoms. Family issues (most common stressor) was found in 38 (63.3%) subjects. 30 (50.0%) patients had authoritarian parents. 46.7% of those counseled did not require any further intervention. In the present study, the most important areas in which stress was apparent were in school and family. So study highlights the need for a joint effort by parents, pediatricians, psychiatrists and teachers to help our children cope with the stress of today’s fast paced competitive world\textsuperscript{[15]}
Cerutti R, Spensieri V, Valastro C, Presaghi F, Canitano R, Guidetti V (2017) conducted a study to evaluate the pervasiveness and recurrence of Somatic symptoms additionally on explore the useful inability in children with high number of self-detailed substantial manifestations versus those with less Somatic symptoms. Also, the parental sentiment of their children’s Somatic symptoms and working was investigated. At long last, we assess the legitimately and by implication impacts of challenges in distinguishing sentiments in foreseeing Somatic symptoms and useful inability among school-aged children. Method: 356 Italian school-aged children and their moms partook during this examination. Results among children 66.3% didn’t pronounce physical manifestations and 33.7% detailed at least one Somatic symptom inside the most recent fourteen days. A positive connection rose among kids and moms. Determinations Findings uncovered that a more recurrence of substantial indications is related to useful inabilities and alexithymic features in school-matured kids. \[21\]

**Materials and Methods**

A pre-experimental research design was adopted for conducting the present study by using only manipulation. The research design selected for the present study is one group pre-test & post-test design.

**Table-1**

The variables under study are: The independent variable of the study was educational package on Somatic symptom disorders. The dependent variable of this study was Knowledge regarding Somatic symptom disorders among adolescent girls. The extraneous variables of this study were age, educational level of adolescent girls, educational level of parents, occupation of parents, monthly income of family, type of family and exposure to knowledge regarding Somatic symptom disorders.

In the present study, the research setting was Govt. Senior Secondary School, Village Chhara, Jhajjar, Haryana, 75 adolescent girl students (age group 13-17 years) were selected. Sampling technique adopted for the study was non probability convenient sampling technique.

**Inclusion criteria:**

The study includes:

1. Adolescent girl students of age group 13-17 years.
2. Girl students who were present /available at time of data collection.
3. Girl students those who were willing to participate in the research study.

**Exclusion criteria:**

The study excludes:

1. Girl students who were below 13 year or more
than 17 years.

2. Girl students who were not willing to participate in the study.

3. Girls who were not available at the time of data collection.

The tool was constructed after extensive review of literature and discussion with experts, to collect the data. The tool to measures the knowledge of adolescent girls was self-structured questionnaire. A structured questionnaire was developed and the same tool was used for pre-test and post-test for collecting the data. It consists of two parts namely Section-1 and Section-2.

Minimum score: 0    Maximum score: 25

Interventional Tool: Educational Package

Educational package aimed to improve knowledge of Somatic symptom disorder among adolescent girls. The educational package included

1. Video on Somatic symptom disorders

2. Lecture cum discussion on Somatic symptom disorders, power point presentation for a period of 45 min.

3. Blackboard, chart, flashcards and handouts were used for effective teaching and learning experience.

The reliability of the tool was assessed by doing pilot study. The reliability was assessed by using test retest method.

\[
r = \frac{\text{n} \text{ΣXY} - \text{(Σx)(Σy)}}{\sqrt{\text{n} \text{Σx}^2 - (\text{Σx})^2 } \text{n} \text{Σy}^2 - (\text{Σy})^2}}
\]

The reliability score obtained was 0.881 by test retest method. The r-value indicated positive correlation, which showed that the tool was reliable for the researcher for conducting the main study.

Ethical Considerations

The pilot study and main study was conducted after the approval from Departmental Research Committee (DRC) & Institutional Ethical Committee. Permission was obtained from concern head. After that the
researcher explained the study to the participants. An informed consent was obtained and assurance was given regarding maintenance of confidentiality and anonymity of the data collected.

**Pilot Study**

Pilot study was conducted for a period of one week from 7 February to 14 February, 2020, at Govt. Senior Secondary School, at Village Talao, Jhajjar, Haryana, after taking formal permission from Principal. After pre-test, interventions which include educational package regarding Somatic symptom disorders given to adolescent girls for a period of one hour. After 7 days the Post-test was conducted by using structured knowledge questionnaire devised by investigator.

Analysis of the findings depicts that the educational package had a significant effect on enhancing the level of knowledge regarding Somatic symptom disorder among adolescent girls. The result of the pilot study revealed the feasibility and practicability of the study.

**Procedure For Data Collection**

The pilot study and main study was conducted after the approval from department of research committee (DRC) & Ethical committee. Permission was obtained from concern head. Data collection procedure was done at Govt. Girl Sr. Sec. School, Jhajjar, Haryana. Formal administrative approval was obtained from the Dean, Faculty of nursing, SGT University, Gurugram, Haryana and the Principal, Government senior secondary schools. Data collection was carried out for a period of two weeks.

During the first week the researcher selected the adolescent girls based on sample selection criteria. There were totally 75 adolescent girls selected as samples. Samples were obtained by non-probability convenient sampling technique. A brief introduction about self and purpose of the study was given; consent was obtained from the adolescent girls. Confidentiality regarding the data was assured so as to get co-operation during the procedure of data collection. The school authority provided well ventilated separate class room for data collection. Data was collected by using structured questionnaire based on demographic variables and knowledge questions devised by the investigator.

After pre-test, intervention which included educational package regarding Somatic symptom disorders given to adolescent girls for a period of one hour. After 7 days (26 Feb. 2020) the post-test was conducted by using structured knowledge questionnaire devised by investigator.

The data analysis was done under the following headings by using both descriptive and inferential statistics.

- Frequency and percentage distribution were used to analyze the demographic variables of adolescent girls.
- Mean and standard deviation was used to analyze the pre and post-test level of knowledge regarding Somatic symptom disorder among adolescent girls.
- Paired ‘t’ test was used to compare the pre and post-test level of knowledge regarding Somatic symptom disorder among adolescent girls.
- Chi-square test was used to find out the association of Post-test knowledge level regarding Somatic symptom disorders with selected demographical variables of adolescent girls.

Assessment of pre-test and post-test level of knowledge regarding Somatic symptom disorders  N=75
Fig. 1  Bar graph showing frequency and percentage of pre-test and post-test level of knowledge regarding Somatic symptom disorders among adolescent girls

The data presented in figure: 12 depicts that in pre-test 26 (34.67%) adolescent girls had poor knowledge and 49 (65.33%) adolescent girls had average level of knowledge regarding Somatic symptom disorders, and out of 75 no adolescent girls had adequate knowledge regarding Somatic symptom disorders. After administration of educational package, the post-test findings revealed that 56 (74.67%) adolescent girls had average knowledge and 19 (25.33%) adolescent girls had adequate level of knowledge, and out of 75 no adolescent girls had poor knowledge regarding Somatic symptom disorders.

The data presented in figure 13 reveals that pre-test mean score value and standard deviation score was 9.52 ± 2.21 and the post-test mean score value and standard deviation was 17.00 ± 4.01 and the calculated t-value was 13.87 which was statistically significant at p= 0.001. The above result reveal that there was a significant difference between pre-test and post-test knowledge levels among school going adolescent girls after implementation of educational package regarding Somatic symptom disorders.

*Significant at 0.05 level of significance

DF (74) = 1.98 Significant at 0.05 level of significance

The data presented in table 5 explains that the pre-test mean score value and standard deviation score was 9.52 ± 2.21 and the post-test mean score value and standard deviation was 17.00 ± 4.01 and the calculated t-value was 13.87. Which was statistically significant at p= 0.001. Hence, it can be inferred that obtained mean difference 7.48 is not by chance but it is a true difference, thus research hypothesis was accepted. So, it can be concluded that there was a significant difference between pre-test and post-test knowledge levels among school going adolescent girls after implementation of educational package regarding Somatic symptom disorders.

Significant at the level of p<0.05 - significance

*S -Significant NS- Not Significant

[** values were calculated by Fisher’s exact test]

Table 5 depict that chi-square value obtained to find out the association between post-test knowledge level with demographic variables.

The data presented in table 6 reveals that there was statistically significant association between post-test knowledge and educational level of father of adolescent girls (0.043), educational level of mother of adolescent girls (0.046) and occupation of mother of adolescent girls (0.003). No significant association was found with post-test knowledge level and other demographic variables, such as age (0.375), educational level of adolescent girls (0.186), occupation of father (0.179), monthly income of family (in rupees/month) (0.724), type of family (0.506), and exposure to knowledge regarding Somatic symptom disorders (0.508)
Discussion

The pre-test knowledge level regarding Somatic symptom disorders among adolescent girls, out of 75 adolescent girls 26 were in poor knowledge category, 49 adolescent girls were in average knowledge category and 0 (no) adolescent girls were in adequate knowledge category. The study reveals that, the pretest mean score value of knowledge was 9.52 with standard deviation (SD) of 2.21. Mean difference was 7.48 the calculated-t value was 13.87.

There was a significant association to develop and administer educational package to enhance knowledge regarding Somatic symptom disorders. The findings of study were similar to the findings reported by Rota E, Evangelista A, Ciccone G, Ferrero L, Ugolini A, Milani C, et al (2011) in their study to assess the effectiveness of an educational and physical program in reducing accompanying symptoms in subjects with head and neck pain in 384 employees. The study findings shows that educational and physical program were effective in reducing the burden of behavioral or somatic symptoms along with headache, neck and shoulder pain in a working community.

The study reveals that, the pretest mean score value of knowledge was 9.52 with standard deviation (SD) of 2.21 and the post-test mean score value of knowledge was 17.00 with SD of 4.01. Mean difference was 7.48 the calculated-t value was 13.87. This indicated that there was a high statistically significant difference in the pre and post-test knowledge level regarding Somatic symptom disorders among adolescent girls, p value 0.05.

The effectiveness of educational package was analyzed using unpaired ‘t’ test. The calculated unpaired ‘t’ test value for knowledge was 13.87 which was greater than the table value and this indicated that there was statistically high significant difference in Post-test level of knowledge regarding Somatic symptom disorders among adolescent girls. It indicated that educational package was significantly effective in improvement of knowledge regarding Somatic symptom disorders among adolescent girls.

Hence, the null hypothesis $H_0$ stated earlier that “There is no significant difference between the mean pre-test and Post-test knowledge level regarding Somatic symptom disorders among adolescent girls at $p<0.05$ level of significance is rejected and $H_1$ is accepted.

There was a significant association between effectiveness of educational package on knowledge regarding Somatic symptom disorders which was found consistent with the study conducted by Manonmani C (2011) conducted a pre experimental study to determine the effectiveness of Information, education, communication package on knowledge and expressed practice regarding management of primary dysmenorrhea among adolescent girls at Girls Higher Secondary School in Srirangam. The study showed that IEC was effective in increasing the knowledge and expressed practice of adolescent girls regarding primary dysmenorrhea management.

The association of post-test knowledge regarding Somatic symptom disorders of adolescent girls with selected demographic variables (age, educational level of adolescent girls, educational level of father and mother, occupation of father and mother, monthly income of family, type of family, exposure to knowledge regarding Somatic symptom disorders) were analyzed by using chi-square & fisher’s exact test and found that there were statistically significant association between post-test knowledge and educational level of father of adolescent girls (0.043), educational level of mother of adolescent girls (0.046) and occupation of mother of adolescent girls (0.003). No significant association was found with Post-test knowledge level and other demographic variables, such as age (0.375), educational level of adolescent girls (0.186), occupation of father (0.179), monthly income of family (in rupees/month) (0.724), type of family (0.506), and exposure to knowledge regarding Somatic symptom disorders (0.508).

There was a significant association between Somatic symptoms and some of the selected socio demographic variables. The findings of study were in line with
the findings reported by Aswathy Raj, Saleem TK; Varsha Vidyadharan (2019). They conducted a study to assess the Somatic complaints and depressive symptoms of 250 adolescent girls and to identify the relationship between these variables. Association between Somatic complaints/depressive symptoms and selected socio personal variables was also analysed. The study found a significant positive correlation between Somatic complaints and depressive symptoms.

Conclusion

The study concluded that there is a significant difference between knowledge level before and after implementation of educational package regarding Somatic symptom disorders among adolescent girls at selected Govt. Sr. Sec. School, Jhajjar, Haryana. There is significant association between post-test knowledge level and selected demographic variables such as educational level of father and mother, and occupation of mother. The present study aimed at assessing the effectiveness of educational package on knowledge regarding Somatic symptom disorders among adolescent girls and the findings of the study showed that That the pre-test means value and standard deviation score was 9.52 ± 2.21 and the post-test mean value and standard deviation was 17.00 ± 4.01, and mean difference value was 7.48. The calculated t-value was 13.87. Which indicated that educational package was an effective intervention to improve the level of knowledge regarding Somatic symptom disorders among adolescent girls.

Recommendations

A study can be done to assess effectiveness of educational package on Somatic symptom disorders among adolescence including both boys and girls. A comparative study can be done to assess the prevalence of Somatic symptom disorders in different age groups. A descriptive study can be done to assess the prevalence and knowledge regarding Somatic symptom disorders with a large number of sample sizes. An experimental study can be done to assess the effect of cognitive behavior therapy and meditation, yoga on Somatic symptom disorders. An experimental study can be done to assess the prevalence, knowledge and attitude regarding Somatic symptom disorders.

Changes in the Cancer Antigen Markers in the Pleural Liquid During Chemotherapy among Ovarian Cancer Patients

Abbas Abdulmueed Mustafa Alani¹, Ihab Q. Ali², Yasir Khaleel Almusawi³

¹Lectural Doctor, Medical Laboratory Department, Pharmacy College, Uruk University, Iraq, ²Lecturer, ³Assistant Lecturer, Medical Laboratory Techniques Department, Al-Esraa University College, Iraq

Abstract

The silent killer or ovarian cancer (OC) is one of the major causes of cancer deaths among women in the modern age. In view of the therapeutic roles of platinum based chemotherapy among the ovarian cancer patients, objective of this report was to assess the effects of the first round of chemotherapy among women with ovarian cancer. Here, the levels of the pleural markers for cancer bio markers, before and after the chemotherapy were tested among ovarian cancer patients. The biochemical indices may be of use in deciphering the relation between cancer relapse and platinum retrieval. The pleural analyses pre and post platinum chemotherapy session demonstrated wide range of biochemical and protein marker changes among ovarian cancer patients. The various cancer antigens were variedly reduced post chemotherapy. Hence, it is proposed that biochemical markers in pleural liquid may serve as better indicators and early diagnostic tools for ovarian cancer.

Keywords: Ovarian cancer, chemotherapy, pleural liquid, cancer antigens.

Introduction

One of the major cancer deaths among women is caused by ovarian cancer (OC). There has been an immense development in the field of cancer therapy, the majority of patients experience disease recurrence and receive second-line and sometimes several lines of treatment (¹⁴). The progression-free survival among OC patients is fairly constant at about 1.5 years with respect to the modern diagnostic tools and treatment patterns. As high as 80 percent women with advanced stages of OC report tumor progression or recurrence. As high as 70% cases of OC are diagnosed at advanced stages leading to bad prognosis. Generally late-stage ovarian cancer is incurable in the majority of cases. The recent developments in surgical technology and contemporary regimes of systemic treatment, as well as some new drugs have turned the late-stage OC as a chronic condition by extending the survival days (³). The “silent killer” synonym for ovarian cancer is because the majority of patients are diagnosed in late stage, and that in early stages of the disease symptoms are not evident.

Pleural effusion is a common feature among women with OC and breast cancer. Pleural effusion is an abnormal accumulation of fluid in the pleural cavity which is the space between lungs and chest wall (⁴). The liquid starts accumulating the between the layers of the pleura. When pleural effusion is related to cancer or there are cancer cells in the fluid, it may be called malignant pleural effusion.

Approximately 20% of women with advanced-stage ovarian cancer survive beyond 12 years after treatment and are effectively cured. Initial therapy for ovarian cancer comprises surgery and chemotherapy, and is given with the goal of eradicating as many cancer cells as possible. Indeed, the three phases of therapy are as follows: debulking surgery to remove as much of the cancer as possible, preferably to a state of no visible residual disease; chemotherapy to eradicate any microscopic disease that remains present after surgery; and second-line or maintenance therapy, which is given
to delay disease progression among patients with tumour recurrence (2). Epithelial ovarian cancer has the highest mortality rate of all gynaecological malignancies. Most women present with advanced disease and develop a recurrence after radical surgery and chemotherapy. Improving the results of first- or subsequent-line chemotherapy has been slow, and novel approaches to systemic treatment are needed. Ovarian cancer is a heterogeneous disease with complex molecular and genetic changes. Understanding these better will provide information on the mechanisms of resistance and opportunities to target therapy more rationally, exploiting specific changes in the tumour (4,5).

Primary debulking surgery followed by platinum-based chemotherapy remains the standard treatment of patients with stage III-IV epithelial ovarian cancer. Neoadjuvant chemotherapy is an alternative treatment regimen that can be considered in selected patients. Complete cytoreduction, both through primary debulking surgery and interval debulking surgery, has a major positive effect on survival and should be the goal, even if this requires extensive surgery. When thorough assessment of tumor spread and performance status of the patient indicates that complete primary cytoreduction is not feasible without unacceptable morbidity, then alternative therapeutic strategies, such as neoadjuvant chemotherapy, must be considered (5,6,7).

Malignant pleural effusion is the most common site of stage IV ovarian cancer. A positive cytology is required for a stage IVA diagnosis. Unfortunately, the accuracy rate of pleural cytology remains low. A number of factors have been identified as prognostic for clinical outcomes in patients with epithelial ovarian cancer (7,8,9). The pleural cavity constitutes the most frequent extra-abdominal metastatic site in ovarian carcinoma (OC). In patients with OC and pleural effusions, a positive fluid cytology is required for a stage IV diagnosis. Unfortunately, about 30% of malignant pleural effusions exhibit false-negative cytological pleural fluid results. In those circumstances, exploratory video-assisted thoracoscopic surgery (VATS) serves as a diagnostic, staging and even therapeutic modality (8,9).

We hypothesize that the pleural liquid markers could serve as significant markers of disease progression and response to therapy among OC patients before and after one cycle of chemotherapy.

Materials and Methods

Participants: All participants (patients) were enrolled as part of clinical trial going on according to the IP and GCP/GLP guidelines at a reputed hospital. Patient/immediate relative consents were obtained for using the serum/plasma for research and data management.

Drug and dosage: PEGylated liposomal cis-platini is a formulation of cis-platini in polyethyleneglycol-coated liposomes with a prolonged circulation time. Cisplatin intercalates between base pairs in the DNA helix, thereby preventing DNA replication and ultimately inhibiting protein synthesis. Dosage is calculated by estimating Body Surface Area (BSA) and at 50mg/m² BSA is infused intravenously (2mg/ml).

\[
\text{BSA (m}^2) = \sqrt{\frac{\text{height (cm)} \times \text{weight (kg)}}{3600}}
\]

Collection of Pleural liquid: Patients having ovarian cancer were selected by the Medical Practitioner and suggested for the study (n=31). The pleural samples were collected before the initiation of chemotherapy (PEGylated cis-platin liposomes) and after three weeks of first chemotherapy session (PEG= poly ethylene glycol). The Pleural liquid of the patient was collected by the nursing professional and immediately introduced into collection bottles. Approximately 100ml aliquot from each patient was collected and immediately used for all the biomarkers and stored at -20°C.

Estimation of the biomarkers: Level of pleural markers were estimated by using ELISA kits according to manufacturer’s instructions.

Statistical Analysis

The data expressed as mean ± SE were analyzed by one-way ANOVA followed by a post hoc Tukey’s test to compare the control and treatment groups as well as
among the groups (p ≤ 0.05) using GraphPad Prism 5.0 software. Different alphabet letters indicate significance difference among the respective groups. In some assays, * indicates significance difference from control (p≤0.05).

**Results and Discussion**

Among the ovarian cancer patient volunteers who belonged to an age range of 43 to 65 years, nearly 45% of them complained of pain in the abdominal area while 35% of them presented nausea as their main symptom. In my previous report I demonstrated that the pleural thickening was significantly reduced among the ovarian cancer patients after first round of Platinum-based chemotherapy. The reduction in the pleural thickness is observed in most of the clinical trials. However, in this study, the reduction was not to a marked extent but significant change was recorded. The hexose levels were unaffected while the cholesterol was markedly increased among the patients. Anti-inflammatory markers also elevated among chemotherapy patients which was duly reported in my previous publication. As a proof of principle, the chemotherapy resulted in biochemical changes in the pleural liquid among ovarian cancer patients.

![Figure 1](image.png)

*Figure 1. Effect of chemotherapy on the Lactic dehydrogenase activity in the pleural liquid among patients of ovarian cancer before and after one cycle of chemotherapy (n=31). Different letters indicate significant difference between groups (p≤0.05).*

The enzymic levels of Lactic Dehydrogenase were decreased among post chemotherapy samples (Figure 1).
The cancer Biomarker: Carcinoembryonic antigen (CEA) levels were significantly reduced among post chemotherapeutic samples, however, the levels were not reaching the safe diagnosis (Figure 2).

The cancer Biomarker: Cancer antigen (CA 125) levels were significantly reduced among post chemotherapeutic samples (Figure 3). However, the levels were not reaching the safe diagnosis levels.
The cancer Biomarker: Cancer antigen (CA 27.29) levels were very marginally but significantly reduced among post chemotherapeutic samples, however, this data is suggestive that multiple sessions of chemotherapy could bring down the cancer marker levels (Figure 4).

**Conclusion**

Analysis of the pleural samples from ovarian cancer patients before and after one round of chemotherapy revealed that there were varied biochemical changes. In lines with my previous report, here additional data about cancer antigen markers are presented. There was a significant change among cancer antigens in pleural liquid after chemotherapy. Hence, it is proposed that biochemical markers in pleural liquid may serve as better indicators and early diagnostic tools for ovarian cancer.

**Conflict of Interest:** There are no conflicts of interests.

**Acknowledgement:** The author thanks the patients who were willing to participate in the study.

**Ethical Clearance:** This study regimen was approved by and followed the guidelines of the institutional ethical committee.

**Source of Funding:** This research work was conducted as a part of project work of the author Mr. Alimuneer Abdul Rahman with self-financing. No other government or private funding were used for the study.

An Analysis of the Implementation of Diversion in Efforts to Settle Medical Disputes in Indonesia

Arista Candra Irawati¹, Sarsintorini Putra², Retno Mawarini Sukmariningsih², Adhi Putra Satria³

¹Lecturer at the Faculty of Law of Ngudi Waluyo University and a Law Faculty Student of University of 17 Agustus 1945 Semarang, ²Lecturer at the Faculty of Law of University of 17 Agustus 1945 Semarang, ³Law Faculty Student of University of 17 Agustus 1945 Semarang

Abstract

Based on the legal construction contained in Article 29 of Law Number 36 the Year 2009 concerning Health, it has ordered that health workers suspected of neglecting in carrying out their profession. There is a need for a settlement preceded by the mediation stage or what is known as the settlement of disputes out of the court. The facts in the field show that the handling of medical disputes, especially for doctors who commit negligence, has not been fully implemented according to the provisions of Article 29 of the Health Law, meaning that the handling is not carried out through the first mediation stage, as in the case experienced by dr. Ayu et al. They had to be brought to court accused of committing medical malpractice because they failed to save the patient during a cito-cesarean operation. Dr. Ayu et al. at that time did not fulfill their rights to get mediation. This is because there has been no further regulation governing the procedures, procedures, and rules for implementing mediation, especially health services. Due to this fact, it becomes an obstacle to the consistency of mediation efforts as a necessity in solving medical disputes. Law No. 29 of 2004 concerning Medical Practice and Regulation of the Medical Council Number 32 of 2015 concerning procedures for handling suspected disciplinary violations of Doctors and Dentists do not regulate mediation efforts, so the implementation of mediation efforts in health services is not optimal.

Kata Kunci: Diversion; Mediation; Medical Disputes;

Introduction

Conflicts in the health care profession that culminate in the court for health professionals are indeed a lot related to ethical problems that have the potential to cause medical disputes by placing everyone entitled to claim compensation for health workers and/or health providers who cause losses due to errors or negligence in the health services they receive.[1] This is due to the characteristics of the legal relationship between patient and doctor in health care, based on a therapeutic contract and the relationship due to laws and regulations.[2] In the first relationship, it begins with an agreement (unwritten) so that the will of the two parties is assumed to be accommodated when the agreement is reached. The reached agreement, among others, is in the form of approval of medical action or even rejection of a medical action plan.[3] While the second relates to relationships because laws and regulations usually arise because of the obligations imposed on doctors because of their profession without the need for patient consent.

These two relationships give birth to legal responsibility, professional responsibility, and ethical responsibility. Violation of doctor or dentist discipline can be prosecuted in several courts. For example, there are civil courts, criminal courts, and administrative courts in the legal field.[4] In addition, doctors or dentists can also be brought before the Ethics Court in professional organizations and the Professional Discipline Court by (MKDKI). The basis for a doctor’s obligation is a professional contractual relationship between medical personnel and their patients, which creates general obligations and professional obligations for the medical
personnel. Professional commitments are described in the professional oath, ethical rules, various service standards, and various operational procedures.

The enactment of Law Number 36 of 2009 concerning Health is considered flexible because it can keep up with developments in science and technology in the medical field. This is based on the consideration that there are 5 (five) reasons for considering why it is necessary to establish a health law quo. The five primary considerations as intended include: first; health is a fundamental right and an element of well-being. Second; principles of non-discriminatory, participatory, and sustainable health activities. Third; health is an investment. Fourth; health development is the responsibility of the government and society, and fifth is that Health Law No. 23/1992 is no longer in line with developments, demands, and legal needs in society.[5]

A step forward in the provisions of Article 29 of Law Number 36 the Year 2009 concerning Health states that “If a health worker is suspected of negligence in carrying out his profession, the negligence must first be resolved through mediation”. Referring to the article in question, the necessity to take mediation efforts is highly expected/recommended or even obligatory if a medical dispute occurs between a patient or his family and a health worker or between a patient and a hospital/health facility in Indonesia.[6]

However, the obligation to exercise discretion as mandated in Article 29 of the Health Law has never been achieved in practice. This is following the case that happened to dr. Ayu, which occurred in April 2010. Dr. Ayu and her colleagues, namely dr. Hendry Simanjuntak, and dr. Hendy Siagian are working with Puskesmas referral patients in the Manado area. Due to the urgent situation, dr. Ayu performed a cito-cesarean surgery. But those measures failed to save the patient. The patient’s family reported having operated without permission. At the Manado District Court (PN) trial, dr. Ayu et al. were demanded 10 (ten) months in prison. At the level of Appeal, it is decided to be Free. The Public Prosecutor (JPU) who handled the case filed a cassation, and the Supreme Court granted a decision issued on November 18, 2012. In a legal reconsideration effort through a decision in February 2014, dr. Ayu et al. were acquitted because they were not proven to have committed malpractice. The basis for the consideration of granting the PK was that the convicts did not violate the SOP in the handling of the Sesco Ciceasria operation so that the judex facti considerations at the Manado District Court were correct.

Medical dispute complaints to the police at Polsek, Polres, and Polda levels are received and processed like a criminal case. Shifting civil cases to the realm of crime, inconsistent use of articles, difficulties in proving legal facts, and limited understanding of medical insights by law enforcers at almost every level make medical disputes threatened with criminal disparities.

**Aims and Objective**

With the regulation of the necessity of mediation in medical disputes over the services of health workers, especially the doctors and dentists, it becomes the basis for the authors to examine this matter more deeply. This paper aims to know and analyze how the implementation and efforts of mediation as medical dispute resolution in Indonesia.

**Observation and Results**

1. Health Services in the Implementation of Medical Practices

Health is a human right and one of the elements of welfare that must be realized following the ideals of the Indonesian people as referred to in Pancasila and the 1945 Constitution of the Republic of Indonesia.[7] Provisions of Law No. 36 of 2009 concerning Health, there are forms of health services, namely promotive health services, preventive health services, rehabilitative health services, curative health services, and traditional health services.[8] As one of the main components of providing health services to the community, medical services for doctors and dentists are vital because they are directly related to providing health services and the quality of services provided.
The principles and objectives of the implementation of medical practice are the foundation based on scientific values, benefits, justice, humanity, balance as well as protection, and patient safety.\[9\] In terms of health services, the profession of health workers, this case, doctors, has a lot to do with ethical problems that can potentially lead to medical disputes. Law No. 36 of 2009 concerning Health brings changes by providing more protection and legal certainty for both service providers as health workers (as stated in Article 21 to Article 29) and recipients of health services (as stated in Article 56 to Article 58), because in practice medical disputes often arise as a result of unsatisfactory results from the health service, due to lack of information from doctors or negligence arising from medical personnel themselves.\[10\] This is in line with the provisions of Article 66 of Law No. 29 of 2004 concerning Medical Practice, which affirms that “patients can complain to doctors or hospitals for alleged violations to the Indonesian Indonesian Medical Disciplinary Board (MKDKI)”.

2. Mediation of Out of Court Dispute Resolution

Disputes in health worker services provide space for parties who feel aggrieved (patients) to take the path of settlement in court both in civil, criminal charges, and administration.\[11\] This is reflected in Article 66 paragraph (3) of Law no. 29 of 2004 concerning Medical Practice, namely “Complaints do not diminish the right of everyone to report suspected criminal acts to the competent authority and/or sue for civil damages to the Court”.

In suspected disciplinary violations in health services, to uphold the principle of faster, cheaper, effective, and efficient dispute resolution by patients or patients’ families with solutions through means outside the court, it has not been used widely. Furthermore, with the increasing number of patients filing lawsuits in court, it will reduce public confidence in medical practice as the main component of health service providers to the community.

Etymologically, the term mediation comes from the Latin “mediare,” which means being in the middle.\[12\] This meaning refers to the role played by a third party as a mediator in carrying out its duties to mediate and resolve disputes between the parties. “Being in the middle” also means that the mediator must be in a neutral position and not take sides in resolving disputes. He must be able to protect the interests of the disputing parties fairly and equally, thus fostering the trust of the disputing parties.\[13\] Settlement of disputes over suspected violations of doctor’s discipline outside the court or known as non-litigation through mediation, as one of how the effectiveness of reaching an agreement on disputes arising is based on good intention.

Several provisions of laws and regulations that regulate and implement Mediation as a dispute settlement, namely:

a. Mediation Based on Law No. 30 of 1999 concerning Arbitration and Alternative Dispute Resolution

Based on Law No. 30 of 1999 concerning Arbitration and Alternative Dispute Resolution, there are several provisions, namely:

a) The provisions of Article 1 point 1 state that: “Arbitration is a way of resolving a civil dispute outside the general court based on an arbitration agreement made in writing by the disputing parties.”

b) Article 1 point 10 states that:

“Alternative Dispute Resolution is a dispute resolution institution or difference of opinion through a procedure agreed upon by the parties, namely settlement outside the court through consultation, negotiation, mediation, conciliation, or expert judgment.”

The provisions above, arbitration is a way of resolving disputes chosen by the parties to help resolve the dispute and provide an opinion on a specific legal relationship. The result of the agreement is a form of agreement agreed upon by the parties on the result of a binding win-win solution. Disputes that have been settled to be resolved through arbitration will not proceed to the judiciary.\[14\] The existence of Arbitration institutions in Indonesia,
known as BANI (BANI Arbitration Center), BAPMI (The Indonesian Capital Market Arbitration Board), and BASYARNAS (The Indonesian National Sharia Arbitration Board). In its application, the Arbitrator can be selected by each of the disputing parties. However, if the parties do not appoint the arbitrator themselves, they can request court assistance to appoint the arbitrator as examiner and decision-maker of the dispute case.

In line with Arbitration, Article 6 of Law No. 30 of 1999 concerning Arbitration and Alternative Dispute Resolution, several matters are regulated regarding alternative dispute resolution procedures, namely:

(1) The parties can resolve disputes or civil differences of opinion through alternative dispute resolution based on the good intention by overriding the settlement by litigation in the District Court;

(2) Settlement of disputes or differences of opinion through alternative dispute resolution as referred to in paragraph (1) shall be settled in a direct meeting by the parties within a maximum period of 14 (fourteen) days. The results are stated in a written agreement;

(3) If the dispute or difference of opinion as referred to in paragraph (2) cannot be resolved, then with the written agreement of the parties, the dispute or difference of opinion is resolved through the assistance of one or more expert advisors or through a mediator;

(4) If the parties within 14 (fourteen) days with the help of one or more expert advisors or through a mediator fail to reach an agreement, or the mediator fails to bring together the two parties, the parties can contact an arbitration institution or alternative dispute resolution institution to appoint a mediator;

(5) After the appointment of a mediator by an arbitration institution or an alternative dispute resolution institution, within 7 (seven) days, the mediation effort must be initiated;

(6) Efforts to resolve disputes or differences of opinion through a mediator as referred to in paragraph (5) by upholding confidentiality, within 30 (thirty) days an agreement must be reached in writing signed by all parties concerned;

(7) A written dispute settlement agreement or difference of opinion is final and binds the parties to be implemented in good intention and must be registered at the District Court within a maximum period of 30 (thirty) days from the signing;

(8) As referred to in paragraph (7), both parties must complete the dispute settlement agreement or difference of opinion within 30 (thirty) days from registration;

(9) Suppose both parties cannot achieve the peace effort, as mentioned in paragraph (1) to paragraph (6). In that case, the parties based on a written agreement can submit a settlement effort through an arbitration institution or ad-hoc arbitration.

b. Mediation Based on Supreme Court Regulation No. 1 of 2016 concerning Mediation Procedures in Courts

The preamble provisions of the Supreme Court Regulation No. 01 of 2016 concerning Mediation Procedures in Court, letter a states that: “Mediation is a process of dispute resolution that is faster and cheaper, and can provide greater access to the parties to find a satisfactory solution and fulfill a sense of justice”. And in letter b, it is stated: “that in the framework of reforming the bureaucracy of the Supreme Court of the Republic of Indonesia, which is oriented towards the vision of realizing a great Indonesian judicial body, one of the supporting elements is Mediation as an instrument to increase public access to justice as well as the implementation of the principles of simple, fast, and low-cost judicial administration”.

Furthermore, according to Article 1 point 1 in this Supreme Court Regulation, what is meant by mediation, namely: “Mediation is a way of resolving disputes through the negotiation process to obtain agreement from the Parties with the assistance of a Mediator”.

The process of the mediation procedure period in the Supreme Court Regulation No. 01 of 2016 with the
following conditions:

1) The mediation process lasts no later than 30 days from the stipulation of the order to mediate.

2) Based on the Parties’ agreement, the mediation period may be extended by a maximum of 30 days.

3) The mediator shall request an extension of the mediation period with reasons.

Supreme Court Regulation No. 1 of 2016 Article 7 regulates the obligation to carry out mediation with good intention. The parties involved in the mediation process must have good intentions to be carried out and run well with good intentions. Indicators stating that the parties did not have good intentions in carrying out the mediation, namely:

1) Not attending the mediation process even though he has been summoned twice in a row;

2) Present at the first mediation meeting, but subsequently not attending even though they have been summoned twice in a row;

3) Do not attend over and over again so that it interferes with the mediation schedule;

4) Not filing or not responding to the case resume;

5) Not signing a peace agreement.

The implementation of mediation when the parties do not have good intentions has a legal impact on the case examination process. In this case, it can be seen that the legal consequences of the parties who are not in good faith regarding the Plaintiff who does not have good intentions will declare that the lawsuit is not accepted (NO). Furthermore, the legal consequence of Defendant’s not having good intentions resulted in the payment of mediation fees.[15]

c. Mediation Based on the provisions of Law No. 36 of 2009 concerning Health

Mediation in the Health Law is stated in Article 29 of the Health Law, namely, “If a health worker is suspected of negligence in carrying out his profession, the negligence must first be resolved through mediation”. It is further stated in the elucidation of Article 29, “Mediation is carried out when a dispute arises between a health service provider and a patient as a health service recipient. Mediation is carried out to resolve disputes outside the court by a mediator agreed upon by the parties”.

Based on the provisions of the phrase “must” based on The Great Dictionary of the Indonesian Language of the Language Center, it means that 1/ha•rus/adv 1. appropriate; 2. mandatory; must (cannot or may not): Assign mediation steps first “must”, “mandatory”, taken as an effort to resolve disputes determined out of court by the mediator agreed upon by the parties.

d. Mediation Based on the Law of the Republic of Indonesia Law No. 36 of 2009 concerning Health in the Perspective of Legal Politics The New Normal

The order of community life in Indonesia is inseparable from legal provisions to create order, peace, tranquility, happiness, and prosperity, as created in the objectives of the Indonesian state are definitively stated in the fourth paragraph of the preamble to the 1945 Constitution.[17]

The role of law as a tool to achieve the goals of the state must also function and always be based on the four basic principles of legal ideals (rechtsidee), namely: [18]

1. Protecting all elements of the nation for the sake of integrity (integration)

2. Realizing social justice in the economic and
social fields

3. Acknowledging the sovereignty of the people (democracy) and state law (nomocracy)

4. Creating tolerance based on humanity and civility in religious life.

The four principles of legal ideals will guide the realization of the ideals and goals of the state because legal ideals are normative and constitutive belief frameworks. The ideal of law is normative. After all, it functions as an ideal base and prerequisite that underlies every positive law and is constitutive because it directs the law to the state’s goals. In achieving the country’s goals, as a whole, it cannot be separated from Indonesia’s national legal politics. The 1945 Constitution is the basis of Indonesia’s national politics. The existence of national law politics as a legal policy that has been or will be implemented nationally includes: first, legal development consisting of making and updating legal materials to suit current needs; second, implementation of existing legal provisions including affirming institutional functions and fostering law enforcers. [19]

Emphasizing the nature of legal politics, according to Satjipto Rahardjo, is the activity of choosing and the means to be used to achieve specific social and legal goals in society. The politics of law cannot be separated from the ideals of the Welfare State in the constitution. [20] Furthermore, according to Mochtar Kusumaatmadja, political law is a legal and statutory policy in legal reform with legal, political instruments carried out through law. The essence of legal, political thought put forward by Mochtar Kusumaatmadja is related to which laws need to be formed (renewed, changed, or replaced) and which laws need to be maintained so that gradually the goals of the state can be realized. [21]

Based on the political nature of law in the opinion of Satjipto and Rahardjo Mochtar Kusumaatmadja about Law no. 36 of 2009 concerning Health in Article 29 regarding mediation arrangements as mandatory, because it is not further followed by implementing regulations under it. Regulations of the Minister of Health, Regulations of the Medical Council make it challenging to apply them to the settlement of disputes that have the core of deliberation (Indonesian Medical Council Regulation No. 12 of 2015 concerning Procedures for Handling Cases of Suspected Discipline of Doctors and Dentists).

Furthermore, in the absence of any mediation procedural rules and procedures in line with Article 29 of Law No. 36 of 2009 concerning Health brings weaknesses that result in not running optimally as mandated by the Health Law, so the steps of the government to choose and the methods to be used to achieve specific social and legal goals in society through mediation efforts bring about weaknesses that arise, namely:

a) Mediation is mandatory but is not explicitly regulated in other regulations regarding the process and procedures for the mediation to be pursued;

b) The obligation to mediate for suspected health workers of negligence in carrying out their profession is not in line with Article 66 paragraph (3) of the Medical Practice Law. Will the process of mediation efforts delay the process of prosecution or claim for compensation? Considering that the processes and procedures are not regulated, are they based on Law No. 30 of 1999 concerning Arbitration and Alternative Dispute Resolution or based on the Regulation of the Supreme Court of the Republic of Indonesia No. 1 of 2016 concerning Mediation Procedures in Courts?

3. Inconsistency of Indonesian Medical Council Regulation No. 12 of 2015 for Not Regulating Mediation Efforts

Indonesian Medical Council Regulation No. 12 of 2015 concerning Procedures for Handling Cases of Alleged Disciplinary Violation of Doctors and Dentists was set on March 25, 2015. The stipulation of the council’s regulations was long after Law No. 36 of 2009 concerning Health. The basis for consideration of the Indonesian Medical Council Regulation No. 12 of 2015 as stated in the preamble:
a. That the enforcement of Doctor and Dentist discipline is part of the effort to provide protection for Doctors and Dentists and the public;

b. Whereas the procedures for enforcing the discipline of Doctors and Dentists are regulated in the Regulation of the Indonesian Medical Council No. 20 of 2014 concerning Procedures for Handling Cases of Alleged Discipline Violation of Doctors and Dentists need to be adjusted to the application of effectiveness;

c. That is based on the considerations as referred to in letters a and b and to implement Article 70 of Law No. 29 of 2004 concerning Medical Practice. It is necessary to stipulate a Regulation of the Indonesian Medical Council concerning Procedures for Handling Cases of Alleged Disciplinary Violation of Doctors and Dentists.

Referring to the above considerations about the procedure for complaints of cases of suspected disciplinary violations by doctors and dentists, several weaknesses were found, namely:

a. Indonesian Medical Council Regulation No. 12 of 2015 concerning Procedures for Handling Cases of Alleged Disciplinary Violation of Doctors and Dentists does not refer to Law No. 36 of 2009 concerning Health has regulated Mediation (Vide Article 29), only referring to Law No. 29 of 2004 concerning Medical Practice (Vide Article 70);

b. Mediation has no legal force, is challenging to achieve, is not an effective measure in resolving suspected violations by doctors and dentists because it is not strictly regulated how the process and procedures are. This can be compared to how the process and procedures for mediation settlement as described in Law No. 30 of 1999 concerning Arbitration and Alternative Dispute Resolution and Supreme Court Regulation No. 01 of 2016 concerning Mediation Procedures in Courts.

c. Law No. 36 of 2009 concerning Health has provided an opportunity for the necessity of resolving health service disputes through Mediation. Still, these opportunities have not been accommodated, and there is no precise regulation, specifically a reference for complainants as stated in the Regulation of the Indonesian Medical Council Number 32 of 2015.

Conclusion

Based on all the descriptions above, it can be concluded that health services run by doctors and dentists for patients are very susceptible to medical disputes. Health Law No. 36 of 2009 has covered the legal basis for health. Conceptually, it reflects the existence of a health law principle that rests on the right to health care as a social basis (the right to health care) which is supported by 2 (two) individual fundamental rights consisting of the right to information (the right to information) and the right to determine the right of self-determination to achieve safety for patients in an optimal health degree according to the principle “Agroti Salus Lex Suprema” - Patient safety is the highest law.

The legal incident that befell Dr. Setyaningrum, and Dr. Ayu et al. will not happen again to maintain the honor of the medical and dentistry professions. They have been allowed to handle suspected disciplinary violations by doctors and dentists using mediation as mandated in Article 29 of Law No. 36 of 2009 concerning Health. With no concrete implementing regulations regarding procedures and processes of mediation in the Regulation of the Indonesian Medical Council No. 12 of 2015 concerning Procedures for Handling Cases of Alleged Disciplinary Violation of Doctors and Dentists is set on March 25, 2015, so mediation in medical dispute resolution has not run optimally.

Suggestion

The Regulation of the Indonesian Medical Council in the procedure for handling cases of suspected disciplinary violations by doctors and dentists includes a clause in the Mediation process as an obligation that must be followed as in the application of civil procedural law in force in the Court.

To realize the objectives of the Government’s Political Law through legal reform, the provisions of
Article 29 of Law No. 36 of 2009 concerning Health do not only cover disciplinary violations of doctors and dentists but other health workers, hospital services. Mediation should be implemented by making Mediation guidelines to achieve effectiveness in resolving health service disputes and upholding dignity in human rights.

Evaluation of the Social Wellbeing Status and Associated Factors in Students of Dezful University of Medical Sciences (Iran): A Cross-sectional Study

Fereshteh Sohrabivafa¹, Kamal Azam², Malihe Sohrabivafa³
¹Assistant Professor of Health Education and Promotion, Department of Community Medicine, School of Medicine, Dezful University of Medical Sciences, Dezful, Iran, ²Associate Professor of Biostatistics, Department of Epidemiology and Biostatistics, School of Public Health Tehran University of Medical Sciences, Tehran, Iran, ³PhD Student, Department of Health Education and Promotion, School of Public Health, Tehran University of Medical Sciences, Tehran, Iran

Abstract

Objectives: The aim of this study was to determine the social wellbeing status and related factors in students of Dezful University of Medical Sciences in 2016. Materials and Methods: The present study was a cross-sectional study that was conducted on 248 students of Dezful University of Medical Sciences in 2016. Students from different disciplines were selected by quota sampling method. The data collection tool was a questionnaire in two areas. The first part consisted of demographic and background characteristics and the second part was social well-being questionnaire of Keyes which was used for the assessment of social wellbeing and its various dimensions. Statistical analysis was conducted using SPSS 24 (multiple linear regression model, independent t-test, Analysis of Variance (ANOVA)) and P-value<0.05 was considered statistically significant. Results: The number of male and female were 114 (46%) and 134 (56%); respectively. The mean of age was 22.81 ± 3.09 years and the majority of students were in the age group of 21-25 years. The mean scores of well-being, social actualization, social integration, social coherence, social acceptance and social contribution were 67.24, 14.14, 9.91, 12.04, 13.42 and 17.70; respectively. The multiple linear regression model showed that age (β=0.59), sex (β=1.13), medical field (β=2.87) and student’s place of residence (β=1.07) were the most important predictors of social wellbeing (P-Value<0.05). Conclusions: Age, sex, medical field and student’s place of residence were the most important predictors of social wellbeing in the students, therefore, it is necessary to pay attention to these factors to promote social wellbeing of students.

Key words: Social Wellbeing, Students, A Cross-sectional Study, Dezful, Iran

Introduction

Health is the most fundamental issue in all cultures and an indicator of the well-being of today’s societies. Usually, more physical dimension is considered in health, while in addition to the dimension, health also depends on social factors (¹). Today, social wellbeing has gained a wide role and importance as one of the important dimensions of health along with physical, mental and spiritual health. In other words, health is not just being free from physical and mental illness and human performance in social relations and his thinking about society are also considered as criteria for assessing individual health at the macro level of society (²). Social
wellbeing is the ability to perform social roles effectively and efficiently, evaluation and reorganization the individual’s performance in society and the quality of his relationships with other people, relatives and social groups (3-6). According to Keyes theory, social wellbeing consists of five dimensions: 1- social actualization (believing in the gradual evolution of society and the existence of potential capabilities for positive change), 2- social coherence (belief in understanding, rationality and predictability of society), 3- Social acceptance (individual interpretation of society and characteristics of others), 4- social integration (assessment of the quality of mutual relations in society and social groups) and 5- social contribution (assessment of the individual of his social value and the importance of what he does in society (7-10).

Studies have shown that people with high social wellbeing can more successfully cope with the problems of playing key social roles (11). On the other hand, the active participation of young people in social and civic behaviors is considered as one of the indicators of youth development and promoting their health is one of the main goals in general health policies in different countries (12). Among the strata of society, the students of any society are the future makers of the country and paying attention to their physical, mental, social and cultural health will provide the necessary ground for a dynamic and healthy life in society for years to come (13). Due to the effective role of social wellbeing on other aspects of health and also on the educational status of students, not paying attention to the social dimension of health can increase or exacerbate mental problems such as depression, suicide, substance abuse, decreased quality of life, increased social harm, physical problems and decline in their academic performance (14-16).

Studying at university, which is associated with entering a larger society, different educational, social and cultural environment and economic problems can make many changes in a person’s life in various individual and social dimensions, such as changes in social and human relationships. These changes have a significant impact on students’ health, quality of life and educational status due to their level of skills and social performance (17). Medical students, while having the problems of other students, are also involved with certain problems such as psychological stress caused by the hospital environment and dealing with patients’ problems (18). Therefore, considering that medical students will play an important role in providing, maintaining and promoting community health in the future, and in order to play this important role properly, they themselves must have a desirable level of social health, the aim of this study was to determine the social wellbeing status and related factors in students of Dezful University of Medical Sciences in 2016.

Material and Methods

Study Design and Subjects

The present study was a cross-sectional study to evaluate the social wellbeing of students in Dezful University of Medical Sciences in 2016. Inclusion criteria consisted of student studying at Dezful University of Medical Sciences and informed consent to participate in the research. Exclusion criteria consisted of guest students from other universities and students with a history of less than one semester of study at the Dezful University of Medical Science.

Sample Size and Sampling Method

\[ N = 698 \] (Total number of students)
\[ \alpha = 0.05 \]
\[ Z^2 \times \frac{\alpha}{1-\alpha} = 1.96 \]
\[ d = 1.420 \]
\[ \sigma = 14.20 \]

The study of Farzi H. et al. (19) was used to estimate the sample size. Taking into account the 95% confidence interval and 80% power, the maximum sample size was estimated 248 students based on the following formula:

\[ n = \frac{N \times \sigma^2 \times Z^2}{(N-1) \times d^2 + \sigma^2 \times Z^2 \times 1-\alpha} \]

For sampling, we first took a list of students by gender and field of study, then using the quota sampling
method in proportion to the percentage of students in each field of study according to gender, the samples were selected (proportion to size).

**Data collection**

The data collection tool was a questionnaire in two areas. The first part was related to demographic and background characteristics including age, gender, marital status, field and level of education, household size, parents’ education level and student’s place of residence. The second part of the questionnaire was related to the assessment of social health and its various dimensions, which The Keyes Social Health Questionnaire was used for this purpose. This questionnaire has 20 questions in different dimensions, including social actualization dimension (4 question), social integration dimension (3 question), social coherence dimension (3 question), social acceptance dimension (5 question) and social contribution dimension (5 question). The questionnaire scoring method was the 5-point Likert scale (completely disagree = 1, disagree = 2, have no idea = 3, agree = 4 and completely agree = 5). Of course, this scoring method was inverse for questions 3, 5, 6, 7, 13, 14, 15, 16, 17, 18, 19, 20 (completely disagree = 5, disagree = 4, have no idea = 3, agree = 2 and completely agree = 1). In order to calculate the score related to each dimension and the total score of the questionnaire, the total scores of the questions related to that dimension and the total scores of all questions were used, respectively. The higher scores indicated higher social health. It should be noted that the validity and reliability of this questionnaire to assess the social wellbeing of students in a study in Iran has been confirmed (16, 20).

**Statistical Analysis**

For the descriptive analysis, mean (standard deviation) and frequency (%) were used. Then, to examine the relationship between demographic and background variables with social wellbeing and its various dimensions depending on the assumption of non-normality (according to Kolmogorov-Smirnov test), the Independent-Samples T-test or Mann–Whitney U test and Analysis of Variance (ANOVA) or Kruskal-Wallis test were used. Finally, multiple linear regression model was used to predict the effective factors on the students’ social wellbeing. It should be noted that the SPSS24 software was used to data analysis and P-Value <0.05 was considered as a significant level.

**Ethics Consideration**

First, the objectives of the research were fully explained to the students, and then informed consent was obtained from them. This study was done according to the principles expressed in the Declaration of Helsinki and was approved by the Deputy of Research and Ethics Committee of Dezful University of Medical Sciences.

**Results**

The aim of this study was to evaluate the social wellbeing of students in Dezful University of Medical Sciences in 2016. A total of 248 students were examined. The number of male and female were 114 (46%) and 134 (56%); respectively. The mean of age was 22.81 ± 3.09 years and the majority of students were in the age group of 21-25 years. The majority of participants were studying in the Bachelor of Science (B.Sc. course). Also, 86.60% of these students were single. In terms of field of study, the highest and lowest were related to nursing and operating room with 25.4 and 10.10%, respectively. In addition, the most of the students’ parents had non-academic education and the majority lived in student dormitories (Table 1).

The multiple linear regression model was used to determine the effective factors on mean of the students’ social wellbeing (Table 3). The results of this model showed that age, sex, field of study and student’s place of residence were the most important predictors of social wellbeing. As can be seen, the value of β for the sex was 1.13 which means that the social wellbeing score was 1.13 unit higher in male than female students. Also, the value of β for the age was 0.59, this means that for every 1 unit increase in the mean of age, the mean of social wellbeing is increased an average of 0.59 units. In addition, the social wellbeing score of students who lived with his parents was 1.07 unit higher compared to those who were in the university dormitory. Finally, the results of multiple linear regression model showed that the independent variables included in the model explained about 0.49 of the variance of social wellbeing score. Other details can be seen in Table 3.

Coefficient of determination (R2) for the model : 0.49

**Discussion**

The aim of this study was to evaluate the social wellbeing of students in Dezful University of Medical Sciences in 2016. A total of 248 students were examined. The number of male and female were 114 (46%) and 134 (56%); respectively. The mean of age was 22.81 ± 3.09 years and the majority of students were in the age group of 21-25 years. The mean scores of well-being, social actualization, social integration, social coherence, social acceptance and social contribution were 67.24, 14.14, 9.91, 12.04, 13.42 and 17.70; respectively. Also, the field of study showed a statistically significant association with all dimensions of social wellbeing except social contribution. In addition, age showed a statistically significant relationship with social coherence and social acceptance. Sex and marital status only with social acceptance showed a statistically significant association. As well as, there was statistically significant association between mother’s education and degree’s student with social coherence. Finally, the multiple linear regression model showed that age (β=0.59), sex (β=1.13), medical field (β=2.87) and student’s place of residence (β=1.07) were the most important predictors of social wellbeing (P-Value<0.05).

This study showed that with increasing age, social wellbeing of students increases (β=0.59), this finding was consistent with the results of studies by Javadi et al. (20) and Mazloomy et al. (21), which were conducted to assess the social health of students and related factors in students of Guilan and Hormozgan Universities of Medical Sciences. In addition, our results were in line with the findings of Fathi et al. (11), and Mozaffari et al. (22), who showed that with increasing age among Iranian teachers and nurses, their social wellbeing increases significantly. Generally, aging and its positive effect on students’ social wellbeing indicate that older students have more reasonable behaviors and more social adjustment in the face of problems.
In the present study, the social wellbeing of male students was higher than female students ($\beta=1.13$). This finding is also consistent with the studies of Abdelah Tabar et al. (23) and Fathi et al. (11), these studies attributed the difference to the higher prevalence of physical and mental disorders in girls than in boys. However, some other studies do not agree with our results (20, 21). These studies have mentioned that women are more likely than men to seek information about diseases prevention and also more than men, they feel responsible for their health and are concerned about their health. Also, the prevalence of smoking, alcohol and drugs and other high-risk behaviors that are dangerous to health in men is higher than women (24).

Regarding marital status, the results of the present study showed that the mean score of social wellbeing of married people, although higher than singles, however, the difference was statistically significant. This lack of significance was not consistent with most studies in this field. Studies have shown that being married has always been associated with health and promoting social health, and reduces risky behaviors, especially for men. In addition, marriage also provides emotional and moral support in stressful situations, which ultimately improves people’s social health (22, 23, 25). The inconsistency of this finding with the other studies may be due to the different effects of demographic and environmental factors on health and requires further investigation of these factors.

In the present study, also, social wellbeing in students living with family was more than students living in dormitories ($\beta=1.13$). This finding is in line with similar studies in this field. Students living in dormitories, due to being away from their families and lack of support, may be experience emotional and psychological crises and do not have adequate social skills and performance and reach lower levels of social wellbeing which this reflects the positive effect of family support on social health of students because family support for students at home helps them acquire good social skills and social functions (21, 26).

In addition, our study showed demonstrated that there is a statistically significant relationship between fields of study with field of study with social wellbeing in students under study so that the highest score was related to doctor of medicine and medical emergency with 68.38 and 70.67; respectively. It seems that the reason of different levels of social wellbeing the different disciplines under study is due to the difference in the type and nature of specialized units offered to students during the course of study because passing these units is a factor that can affect student behavior (20, 23). Perhaps one of the reasons for the high level of social wellbeing in medical students compared to other fields is due to the more opportunity faced with challenges and gain the necessary experience to solve various problems from the first year of entering the university. In contrast, a limited number of studies have found low social wellbeing score in emergency medical students. The reason is the low level of education (associate) in this field compared to other fields, because this problem may create a sense of low self-esteem and affect their social health (20).

This study, like other studies, has limitations. Perhaps the most important limitation is the nature of the study, in other words, due to the cross-sectional design of the present study and the measurement of all variables simultaneously, the possibility of examining the causal relationships between the studied variables and the level of social health is limited (27), therefore, the design of longitudinal and prospective researches with higher sample size is proposed.

**Conclusion**

The results of this study showed that age, sex, medical field and student’s place of residence were the most important predictors of social wellbeing in the students, therefore, it is necessary to pay attention to these factors to promote social wellbeing in medical students.

Age Estimation from Radiological Study of Epiphyseal Fusion Around Wrist Joint in Male Population of North East Madhya Pradesh

Harshwardhan Khushalrao Khartade¹, Rahul Mishra², Priyanka Kumarsen Meshram³, Vidya Garg⁴, Prateesh Shukla⁵, Shashidhar Prasad Garg⁶

¹Associate Professor and Head, Dept. of Forensic Medicine, Shyam Shah Medical College, Rewa, Madhya Pradesh, ²Associate Professor and Head, Dept. of Radiodiagnosis, Shyam Shah Medical College and Associated Sanjay Gandhi Memorial Hospital, Rewa, Madhya Pradesh, ³Nodal Officer, COVID-19 Immunization, District Immunization Centre, Rewa, ⁴Associate Professor (Designated) Dept. of Physiology, ⁵Resident, Dept. of Forensic Medicine, ⁶Professor, Dept. of Forensic Medicine, Shyam Shah Medical College, Rewa, Madhya Pradesh

Abstract

Apart from identification, determination of age is required in various civil and criminal cases. Age estimation by observing appearance and fusion of ossification centres is most accurate and reliable method which is implemented universally. However, it is not possible to establish a uniform standard for age estimation from appearance and fusion of ossification centres for whole India as there is disparity in the timing of appearance and fusion of ossification centres in Indian population due to various factors. Hence, this descriptive observational study was conducted to estimate average age of fusion of ossification centres at lower end of radius and ulna in male population of North East Madhya Pradesh. Total 80 cases in the age group of 12 to 20 years attending the OPD of this tertiary care centre were included in the study. X-rays of both wrists were taken in anteroposterior view at Dept. of Radiology after taking written informed witnessed consent from parents and legal guardians of patients and examined in Dept. of Forensic Medicine.

Age of fusion of lower end of radius and ulna is found to be 17-18 years in males of North East Madhya Pradesh.

Keywords- Age estimation, X-rays, Ossification, Radius, Ulna

Introduction

Identification is the determination of individuality of person based on certain physical characteristics.¹ Age determination is one of the essential factor in establishing exact identity of a living individual. Apart from identification, determination of age is required for civil purposes like employment, consent for marriage, immigration, attainment of majority, competitive sports law suit and criminal purposes like rape, kidnapping, criminal responsibility, prostitution and judicial punishment.² Age estimation in the living becomes more important in developing countries where birth records are often not well maintained. Age estimation by observing appearance and fusion of ossification centres is most accurate and reliable method which is implemented universally.³ Ossification is a continuous process. Some of the bones are cartilaginous and some are membranous in origin. Ossification imparts terminal
shape and texture to them. Changes in ossification of bones occur in predictable order and hence, they are taken into account while estimating the age of a person.

There is disparity in the timing of appearance and fusion of ossification centres of the bones in Indian population. This disparity is mainly due to various factors like racial, hereditary, climatic, and nutritional. Due to these variations, it is not possible to establish a uniform standard for age estimation from appearance and fusion of ossification centres for whole India. Hence, this study was conducted to formulate references in future to estimate the age of males from radiological examination of wrist joint in North east Madhya Pradesh which will be helpful in civil and criminal cases.

Aims and Objectives

To estimate average age of fusion of ossification centres at lower end of radius and ulna in male population of North East Madhya Pradesh.

Material and Methods

This descriptive observational study was conducted in Dept. of Forensic Medicine of this tertiary care centre from October 2019 to October 2020 after obtaining approval from Institutional Ethics Committee. Total 80 males in the age group of 12 to 20 years attending the OPD of this tertiary care centre were included in the study. Cases were equally divided into 8 groups as 12-13, 13-14, 14-15,15-16,16-17,17-18,18-19 and 19-20 according to their age in years where upper limit indicates the completed age and lower limit indicates non completed age. Cases with nutritional, endocrinal and developmental disorders affecting skeletal maturity, cases showing physical deformities and fractures of radius and ulna and those in which birth date is not known or date of birth is not supported by valid proof like birth certificate etc. were excluded from the study. Written informed consent was taken from parents or legal guardians of participants. X-rays of both wrists were taken in anteroposterior view at Dept. of Radiology of this tertiary care centre and examined in Dept. of Forensic Medicine. Process of fusion of epiphysis with metaphysis was divided in five stages based on classification by Sangma W et al

Stage 1: Non union–When the epiphysial cartilage does not begin to decrease in thickness. (Figure No.1)

Stage 2: Commence of union – when the thickness of epiphysial cartilage is found to be reduced appreciably (1/4th united). (Figure No.2)

Stage 3: Incomplete union – when the epiphysis has begun to fuse with shaft and complete union is well underway (1/2 united). (Figure No.3)

Stage 4: Complete union – when the epiphysial cartilage is bony in architecture and its density indistinguishable from the epiphysis and diaphysis in its neighbourhood but an epiphysial line called epiphysial scar can still be distinguished. (3/4 united)(Figure No.4)

Stage 5: Complete union – with absence of epiphysial scar. (Figure No.5)

The youngest age group where there is complete fusion of epiphysis and diaphysis at distal end of radius in 100% cases is taken as criteria for generalization.

Data analysis was done in computer using SPSS software.

It is evident from table no.2 that complete fusion at distal end of radius is seen in 30% of cases in age group 16-17 years and 100% of cases in age group 17-18 years, 18-19 and 19-20 years. The youngest age group where there is complete fusion of epiphysis and diaphysis at distal end of radius in 100% cases is taken as criteria for generalization. Hence, it can be interpreted as distal end of radius fuses completely at 17-18 years in males of North East Madhya Pradesh.

Figure 1- X-ray AP view of wrist of 12 years male showing stage 1 of ossification of radius (Non-union)

Figure 2- X-ray AP view of wrist of 13 years male showing stag 2 of ossification of radius (Commence of union)
Figure 3- X-ray AP view of wrist of 15 years male showing stage 3 of ossification of radius (Incomplete union)

Figure 4- X-ray AP view of wrist of 17 years male showing stage 4 of ossification of radius (Complete union with epiphyseal scar)
Discussion

The cardinal principle of age estimation techniques in juveniles is that the skeleton is continuously growing slowly until the adult age is reached. Fusion of centres of ossification occur during age periods which are remarkably persistent for a particular bone. As per recommendations of the study group on Forensic Age Diagnostics, procedure for estimation of age should consist of a physical examination including measurements of height and weight, determining degree of sexual maturation by Tanner staging, dental examination and radiological examination. Ideally, a longitudinal study assessing the fusion of epiphysis with diaphysis will predict more accurately the age of epiphyseal union. However, this is not ethically possible owing to the health risks to participants caused by repeated radiological examinations. A cross-sectional study involving large number of individuals in each age group will resolve this problem. Typical long bones develop by primary and secondary centres. Initially, the centre is small, round and pinhead sized. It grows peripherally and gradually takes up the osteological details of bony part. This is possible due to complex but dependable system by which the osseous framework of the body develops, grows and matures. Radiologically, primary and secondary centres become apparent as white spots. As bone grows, this white area increase in size and only black plate remains between primary and secondary centres termed as growth plate. It is a layer of hyaline cartilage that remains between epiphysis and diaphysis. Complete disappearance of the epiphyseal plate is termed as fusion. Fusion is not an event but it...
is a process. Epiphyseal scar is a radiopaque line visible at the junction of epiphysis and metaphysis which represents union. It was interpreted as complete fusion in present study. Union of epiphysis is seen about 6 months earlier radiologically than anatomically. In present study, we observed various stages of fusion of epiphysis with diaphysis giving particular importance to last two stages that is stage 4 and 5 as they are having higher practical utility forensically.

We observed fusion of lower end of radius in 17-18 years. Similar to our findings, Pillai MJ14, Gaulstaun15, Prasad RS et al22, Bhise et al25, Vaishnawa et al29, Shanmugasundaram et al30, and Wankhade et al28 also observed fusion of lower end of radius in the same age group. Hapeworth12 observed fusion of lower end of radius in earlier age group i.e.16-17 years in a study conducted on Punjabi population. Lall R and Nat BS13, Loomba16, Mehta17, Das et al18, Saksena and Vyas19, Gupta SMD et al20, Kothari21, Banerjee and Agrawal22, Nemade et al24, Patel et al26, Kadam and Vishwanathan27, Hassan et al2, Krishnamoorthy et al31, Leena et al32, and Dere et al33 noted fusion of lower end of radius in higher age groups. Also, all studies conducted on American population by Pryor34 and Greulich and Pyle41, European population by Brash39, Breathnach40 and Gray42, Australian population by Flecker38, English population by Paterson35, Jordanian population by Al-Qtaita43, Egyptian population by Sidhom and Derry36 and Pakistani population by Ledger and Wassom37 showed that fusion of lower end of ulna occurred in higher age groups than present study.

Differences in fusion of lower end of radius and ulna may be due to climatic, hereditary, racial, and nutritional factors.

**Conclusion**

Age of fusion of lower end of radius and ulna is found to be 17-18 years in males of North East Madhya Pradesh. It can also be concluded that age of fusion of lower end of radius and ulna is highly variable in populations of different countries and population of different regions of same country. Hence, standard data for one population may not be applicable to other population and every region must have their own standard set of data for comparison for accurate age estimation. Small sample size in each age group is a limitation of present study and authors recommend that further studies should be conducted by taking larger sample size for each group for more reliable results and higher applicability of results to population of North East Madhya Pradesh.

Complex Training and its Effect on the Speed Force and Quantities of Strength for Specific Distances and the Achievement of 400 Meters Freestyle Under the Age of 20 Years

Ali Hussein Sabri¹, Rafid Saad Hadi², Nadia Shaker Jawad³
¹M.Sc. Student, ²Asst. Prof. Dr., ³Prof. Dr., Faculty of Physical Education and Sports Sciences / University of Kerbala, Iraq

Abstract
Athletics in general, and in particular the 400-meter freestyle event, requires special physical preparation for the parts of the body that greatly participate in the skillful performance so that the running process can be performed in the correct manner and with minimal effort by matching the muscles of the legs, distributing the exerted force during the run and increasing its quantities, from this basis, we must focus on the strength component, because strength has a good effect in the final achievement of the 400-meter freestyle, as modern training methods must be used here to improve the strength component, and among these methods is the complex training whose basis is the mixing of weight exercises with plyometric exercises where weight exercises are stimulated muscles well and with plyometric exercises, allowing contractions moving in a circle (lengthening - shortening), therefore, the importance of the research lies in providing data and information within the complex training to know its effect on the force distinguished by speed and the quantities of strength for specific distances and the achievement of 400 free meters, by applying these double exercises together and because they have an effect on the development of the most important types of muscle capacity, either the problem of research and through the follow-up of the researcher for many training units for 400-meter freestyle runners in Kerbala, the researchers noted the lack of trainers’ use of modern training methods that would raise the level of the muscular capabilities of runners and their reliance on traditional training methods, and the importance of research is to perform exercises in a complex training method and to identify the effect of temporary training on strength distinguished by speed and strength quantities for specific distances and to achieve 400 free meters.

Keywords: complex training, strength distinguished by speed, strength quantities.

Introduction
Athletics is one of the sports spread throughout the world, as it consists of several activities and this is what makes it distinct from the rest of the games, this sport consists of short sprint races, hurdle races, throwing events, medium and long distance races. Each activity has its own rules and laws, as well as records, and these numbers came through the contribution of modern science and studies to the development of achievement and thus benefit from these sciences and studies in the development of various athletics activities.

The 400-meter freestyle race is one of the short distance races, and it is the third of the short sprint competitions after 100 meters and 200 meters, the 400-meter freestyle race takes place on the track, that is, in the open air. This race is characterized by the strength of numbers, and this is due to the strength of competition and the strength of achievement that
runners aspire to and the best evidence; the world record is 43.03 seconds.

New methods have appeared that are used in the development of physical abilities, especially components of muscular ability, and one of these methods is complex training, as this training method depends on the interaction between weight training and playmaking exercises, and this method supports another activation of the nervous-muscular system by increasing muscle contraction associated with the previous discipline and deals with muscular capabilities within the training unit and thus the development of physical capabilities (strength characterized by speed).

The quantities of strength (the force exerted on the ground by the runner) is an important indicator in the 400-meter race, as these quantities differ from one runner to another and according to the distances divided for the race, and this requires good preparation and structured training of the muscular strength represented by the distinctive forces with speed, which is determined by the force of striking the ground and the organized step also, the force of characteristic speed is a positive role in the stages of the 400-meter race, as the force characterized by speed is an important role at the beginning and middle of the stages of the race through the performance of muscle contractions mixed with speed during the sprint and all of this will be developed that will greatly affect the achievement of a 400-meter freestyle sprint.

Therefore, when preparing for training programs for runners, the training goal must be based on the development of the components of muscle strength and focus on the development of the strength component, as this leads to an increase in strength quantities at specific distances from the 400-meter freestyle race and thus to the development of the achievement time by taking advantage of the strength component and must it takes into account the recovery process, where the influential training process is effective in achieving the goal that was previously set, and the most important one of these exercises is the complex training.

The research problem crystallized, through the researcher’s follow-up of many training units for the 400-meter freestyle runners in Kerbala, the researcher noticed the lack of trainers’ use of modern training methods that would raise the level of physical capabilities of runners and their reliance on traditional training methods as these traditional training methods raise the level of capabilities the physical fitness of the runners, but not of the required level, which in the end simulates the good achievement of the 400-meter freestyle.

This is why the importance of the research lies in providing data, statistics and information within the complex training to know its impact on the development of strength distinguished by speed and quantities of force for specific distances and the achievement of 400-meter freestyle runners under the age of 20 years.

Research objective:

- Preparing complex training exercises in developing the force characterized by speed and quantities of strength for specific distances and the achievement of 400 free meters under the age of 20 years.
- Identify to effect of exercises with complex training in developing the force characterized by speed and quantities of force for specific distances and the achievement of 400 freestyle meters under the age of 20 years.
- Identify the effect preference between the experimental and control groups.

Research methodology and field procedures:

Research Methodology

The researcher used the (experimental method) in the manner of the two equivalent groups (control and experimental) with two tests (pre and post), in order
to fit this approach into the nature and problem of the research.

**Community and sample research:**

The researcher identified a society, the research with hostile clubs, Kerbala governorate under 20 years of age for the 400-meter freestyle race, of which (8 clubs) (in front of Al-Mutqeen, Al-Hindiya, Al-Hussainia, Iraq, Al-Ghadriyah, Al-Hur, Al-Mass, Al-Khairat), and who participated officially in the tournaments held by the Central Federation for Athletics and adults. their number (18 runners), and chose the researcher his research sample by random way. The simple (lottery) and by (12 runners) and divided into two groups (control and experimental) and also by the simple random method. (Draw), and the researcher conducted parity between the two research groups in the pre-test for the research variables that were adopted, as shown in table (1).

</table>
From table (1) it becomes clear to us that the level of significance of the test is greater than the value of the level of significance (0.05), and for all the variables under study, this indicates the lack of significance of the test between the two research groups and that the two groups are equal.

Means, devices and tools used by the researcher:

Methods of data collection:
- Observation.
- Test and measurement.
- The questionnaire.
- Sources and references.

Tools and devices used in the research:
- Force sensor (Dyna Foot).
- Dell laptop (1) of Korean origin.
- Two cameras video with speed (500 p / s), a Korean-made (Casio), and accessories.
- Manual stopwatches, number (3) type Kislo 610 of Chinese origin.
- Sharp hand-held electronic calculator, number (1) of Chinese origin.
- Different weights.
- Boxes of different heights.
- (15) barriers.
- tape measure.
- Two whistles.

Field research procedures:

Determine the search tests:

- The strength speed of the legs: To determine the tests, the researchers looked at a number of scientific sources, and through them, they nominated a group of tests and put them in a questionnaire that was presented to a group of experts and specialists in the science of sports training and strength games of (12) experts. After collecting the forms and unpacking the data, they were treated statistically with the (Ki ²) law, and table (2) shows that.

- Distances to measure the strength applied on the ground: For the purpose of determining the distances for measuring the amounts of force imposed on the ground while running 400 free meters for the research sample, the researcher prepared a questionnaire and presented it to a group of experts and specialists in the science of sports training and strength games and the number of experts and specialists was (12), and after collecting these forms and downloading the data, they were processed. Statistically, by the (Ki ²) and table (2) shows that.
Table (2) shows the statistical treatment ($Ki^2$) of approval and non-acceptance of the opinions of experts and specialists in determining the strength speed test characteristic.

Determine the tests:

The partridge test for a distance of 36 meters (18 m for the right leg and 18 m for the left leg); (1)

**Purpose of the test:** To measure the strength speed characteristic of the legs.

**Test requirements:** Timer, recorder, stopwatch, tape measure, whistle.

**Test description:** The tester stands behind the starting line, and upon hearing the whistle, it sets off to roll on the right leg to the finish line, then turn to partridge on the left leg and return to the starting line as shown in figure (1).

**Register distance:** The distance is measured to the nearest tenth per second.

Figure (1) The partridge shows a distance of 18 m on the right leg and 18 m on the left leg.

Test run of 400 meters from low start: (2)

**Purpose of the test:** Measuring the time achieved to travel a distance of 400 meters and measuring the force exerted during specific stages by means of a force sensor (Dina foot).

**Test requirements:** Legal stadium, stopwatches

**Test description:** A runner stops behind the starting line with a low starting position after installing a force sensor device on it, and after hearing the signal, start as quickly as possible to the finish line

**Register:** Distance travel time is measured to the nearest tenth of a second. With the preparation of a means of transmission that ensures that the sensor signal remains within the sensing area, to ensure that the changes in force values are read during the run for the distances that have been determined.

**Exploratory experience:**

The researchers conducted an exploratory experiment on Tuesday (1/12/2020) on six runners (400 free meters) from the research community and from outside the research sample and applied the tests listed on them. The purpose of the exploratory experiment was as follows:

- Determine the difficulties and obstacles that will arise during the implementation of the tests and measurements.
- Identify on when to take tests and measurements and how long to take.
- Identify the possibility of measuring the force using a DYNA FOOT sensor.
- Identify the necessary equipment and tools to be available and test their validity.
Pre-test:

The researchers conducted pre-tests and measurements of the research variables (strength distinguished by speed, quantities of strength and achievement) on Sunday (13/12/2020) in order to confirm the degree of measurement and identify the level and work in light of these levels when preparing exercises.

Main experience:

The researcher prepared complex training exercises and implemented them on the experimental group to develop the variables of the research under study, relying on the analysis and review of a large number of scientific sources and references, and the researcher took into account the training level, the age stage and the physical ability of the research sample. Likewise, he took care of training the sample members for the rest of the week, so that the goal of training was one. The exercises were distinguished by the following:

- The exercises were carried out in the special numbers stage.
- The implementation of the training units began on Saturday (19/12/2020).
- The training modules included in the training program continued for a period of (8 weeks).
- The number of training units (Appendix No. 6) during one week was (3 training units) and thus the total number of units prepared was (24 training units).
- The days of the training units were: Saturday, Monday, Wednesday.
- The time for performing the exercises differed in the main section of the training unit, and the time ranged between (48-76) minutes.
- The intensity used in the implementation of the exercises ranged between (80% - 89%) from the maximum repetition of one runner (1RM) and in light of the pre-tests that were applied to the research sample.
- The rest was between repetitions (1 minute) and between groups (3 minutes), and the researcher used the high intensity interval training method.

Post-test:

The post-tests were conducted under the same conditions as those conducted in the pre-tests, on Saturday (2/13/2021).

Statistical means:

The researcher used the SPSS to compare the results in the tests for the two research groups.

Presentation and discussion of results:

Discussing the results of the pre and post tests for the control and experimental groups for force characterized by speed and strength quantities for specific distances and achievement:

By observing table (3) which shows the results of the pre and post tests for the control group for the research variables, as it was found from the table that there are significant differences between the pre and post tests and in favor of the post-test with respect to the variables (characteristic strength in speed, the end of the first 50 meters, the end of the fourth 50 meters and the achievement of 400 Meter), and it appears from the table as well that there are no significant differences between the pre-test and the post test for variables (end of the sixth of 50 meters and the end of the seventh 50 meters).

The researchers attribute the moral development that took place to the variables (strength, characteristic speed, end of the first 50 meters, end of the seventh 50 meters, and achievement) to the exercises that were given by the trainer and their commitment to it as it was purposeful and effective in relation to the above variables, and it was ineffective for the variables (the end of the sixth is 50 meters and the end of the seventh 50 meters) and this is what appeared in the table in the absence of significance between the pre and post- test for this group.

As for Table (4), which shows the results of the pre and post tests for the experimental group of the research variables, if it appears from the table that there are significant differences between the pre and post tests and in favor of the post tests and for all research variables.

The researchers attribute this moral development to the group’s use of complex training exercises, which depended on a combination of weight exercises with plyometric exercises, which rely on these exercises on the rapid character of muscle fibers through resistance training with weights, jumping and jumping exercises, and the variety of exercises and targeted movements and the ability to rapid responses through these exercises. Which confirms (Ahmed Amin Fawaz, 2008) (3), “The diversity of tools and exercises, all of this will stimulate the players and increase the motivation towards progress and upgrading the athletic level”.

As for the variable strength characteristic of speed, the researcher attributes its development through the use of complex exercises with weight and play, which was of a fast nature and high movement through its exercises, which was represented in frequent and fast movements, and the researcher relied on his viewpoint (Karl Heinz, Kibo Schdotter, 1987) (4), “The force of characteristic velocity has a great correlation in skill performance”.

On the other hand, the exercises used by the researcher, the plyometric exercises that depend on the circuit (development and shortening), which in turn worked to improve the compatibility between the nerves feeding the muscle groups that lead the movement in terms of the increase in the frequency and speed of nerve signals, and this was confirmed (Abu Al-Ola Ahmad Abdel-Fattah, 1997) (5) “The neuromuscular compatibility is one of the most important factors that lead to the development of rapid force”.

The researcher focused on weight training to be strong, quickly and with high intensity, ranging between (80% -9%), and by the method of high-intensity interval training, and this was given a positive impact to achieve the best level in the rapid strength of the material muscles for the two men and this is what we noticed in increasing the quantities of strength for the specified distances for the 400-meter freestyle race, he asserts (Stein H, 1999) (6), “There is a need to increase the intensity to develop muscle capacity, with an emphasis on the importance of the size of the exercises and the amount of muscle contraction”, the development of the characteristic strength with speed and the increase in the strength of the runners helped the development of the achievement time in the 400-meter freestyle race through neuromuscular compatibility and rapid muscle contractions.

Significance level (0.05) and degree of freedom (n = 10)
Discussing the results of the post-tests of the experimental and control groups for force characterized by speed and quantities of force for specific distances and achievement:

Through Table (5), which shows the statistical indicators of the results of the post-tests for the experimental and control groups, the table shows that there are significant differences between the experimental and control groups and in favor of the experimental group in the post-tests.

The researchers attribute this development to the exercises used according to the complex training method, through which the muscular capacity developed (strength characterized by speed and strength quantities to aggregate specific distances), as weight training and plyometric exercises contributed significantly and clearly to the above variables.

The development of the characteristic strength with speed came due to the adaptation of the working muscles due to the added weights in addition to the plyometric exercises, which in turn led to an increase in the capacity of the neuromuscular systems, and this is consistent with what was stated by (Sarih Abdul Karim, 2003) (7), “Muscle fibers have the ability to produce strength Large through the change of resistance, and thus the working motor units will increase and increase accordingly their ability to produce energy”.

In its training units, the researchers took into account the gradient in loads and privacy with the change in the intensity used as well as the repetitions, (Jamal Sabry Faraj, 2012) (8) asserts, “The nervous-muscular system responds better when it is excited in a variable manner all the time, and this system needs to be surprised in order to be forced to adapt to weight training and playmaking exercises, and this is what was taken into account in the training units”.

The exercises used were in different proportions in the complex training, which led to the occurrence of adaptation in the fast fibers and this gave a major role in the production of strength during jogging and this was reflected in the increase in strength amounts and for the specified distances, as weight training gives strength to runners by defining a special muscle They are greatly stimulated, and in return comes the work of the (lengthening and shortening) circuit in the plyometric exercises, and the plyometric exercises are complementary to the work of the strength of runners, and this is in agreement with (Burger, 2000) (9) “Weight training exercises with plyometric left in training based on scientific foundations has a positive effect, on other physical abilities”.

The researchers also find weight training exercises not sufficient for the performance of the runner, as they must be completed with the playmate exercises, and that the fact that the plyometric exercises are a reinforcing factor for strength training and able to improve the level of neuromuscular compatibility, and this is what was confirmed (Jamal Sabri Faraj, 2010) (10) “The weight training does not it alone suffices to give elasticity to the muscles, but hinders muscular capacity and joint mobility, on the contrary, we find that plyometric exercises give multiple movements to the joints and occur at the same time”.

The development of muscle capacity (strength distinguished by speed) and the development of strength quantities have helped the development of the time of achievement, as he (Amer Fakher Shagati et al., 2006) (11) points to the development of ability and the enemy: “The use of vehicle exercises for the 400-meter race is free to use the means (weights and exercises) And with fixed devices, climbing stadiums, jumping exercises, partridges to the front or the top, plyometric exercises, push-ups using crates, use of stadium seats and barriers”.

Conclusions and recommendations:

Conclusions:

- The complex training had a positive effect
on the force distinguished by strength speed and for specific distances of the 400-meter freestyle runners.

- That the development of force characterized by speed and magnitudes of strength for specific distances was positively reflected in the development of the time of achievement of the members of the experimental group.

**Recommendations:**

- The use of complex training because of its positive effect on the development of muscular capacity (strength characterized by speed) and strength quantities of runners.

- Conducting similar research and studies, for other events, and for different training categories.

Febrile Seizures in Thalassemic Patients in Babylon Teaching Hospital for Maternity and Children

Yahya A. Altufaily1, Hakim Yosif Radhi2, Laith Jasim khejani2

1Prof. Dr., University of Babylon, Faculty of Medicine, Iraq. 2Ph.D., Dr., Babylon Teaching Hospital for Maternity and Children, Iraq.

Abstract

Febrile seizures are the most common seizures in children. Their incidence is (2-5 %). To date, the pathophysiology of febrile seizures is unknown. But several hypotheses have been supposed that it may relate with plasma iron level. Such low risk in thalassemic patients whose plasma iron level is high could give some clues to this hypothesis.

Aim of the Study: Determine the risk of febrile seizure in thalassemic patients in comparison with the corresponding control group.

Patients and Methods: This case–control study was conducted on one hundred fifty patients with thalassemia major between six month and six years of age who were visit Babylon center for inherited blood diseases in the Teaching hospital for maternity and children from April 2019 to January 2020. All medical records of thalassemic patients were thoroughly reviewed and the occurrence of febrile seizures are interviewed and compared with the control group. The children in the control group are neither thalassemic nor has iron deficiency anemia.

Results: Febrile seizure was detected in one case of the thalassemic group (0.66%) versus six cases (4%) of the control group. The risk of febrile seizure in the control group was 6 times more than that in the thalassemia group, which was statistically significant (P =0.036).

Conclusion: The risk of febrile seizures in thalassemic patients was (0.16) that of the general children population. Thus, iron overload may be a major factor involving the brain metabolism that prevents febrile seizures.

Keywords: Patients, Children, Maternity, Thalassemic, Febrile Seizures

Introduction

Febrile seizures are seizures that occur between the age of 6 and 60 mo with a temperature of (38oC) or higher, that are not the result of central nervous system infection or any metabolic imbalance, and that occur in the absence of a history of prior afebrile seizures (1). Febrile seizures are the most common cause of convulsions in children and a frequent cause of emergency hospital admissions (2). Between 2% and 5% of neurologically healthy infants and children experience at least one, usually simple febrile convolution (1). Febrile seizures are typically divided into two types: ‘simple’ and ‘complex.’ A simple FS is a generalized seizure (without focal features) which lasts less than (15) minutes and occurs only once during a 24-hour period of fever in a neurologically normal child (3). The pathophysiology of febrile seizures remains unclear. It is generally believed that FS is an age-dependent response of the immature brain to fever (4). This postulation is supported by the fact that most (80-85%) of febrile seizures occur between (6) months and (3) years of age, with the peak incidence at
(18) months (7,8). A positive family history for febrile seizures can be elicited in (25-40)% of children with febrile seizures. Familial clustering studies indicate a doubling of risk in children when both parents, rather than one parent, had febrile seizures (5). Studies show a higher concordance rate in monozygotic as compared to dizygotic twins. Although there is clear evidence for a genetic basis, the precise mode of inheritance is unclear. Most studies suggest that the mode of inheritance of susceptibility to febrile seizures is mostly polygenic and rarely autosomal dominant (6). Certain ion channels in the brain are temperature sensitive and may generate fever-associated synchronized neuronal activity (7). There is also evidence to suggest that hyperthermia-induced hyperventilation and alkalois may play a role (8). Children with febrile seizures have been reported to have significantly low levels of plasma ferritin, suggesting a possible role of iron insufficiency (9). Also low ferritin level or low serum iron, was associated with increased risk of febrile seizures (10). Iron also plays specific roles in the central nervous system (CNS). It is involved in myelin formation, as well as in the production of several neurotransmitters such as dopamine, norepinephrine and serotonin, and generation of GABA activity. In addition, iron overload is implicated as a cause of neuronal death (11). The incidence of febrile seizures in thalassemic children is significantly lower, and iron overload may be a major factor that prevents their occurrence (12,13).

**Aim of the Study**

To determine the risk factors of febrile seizure in thalassemic patients in comparison with the corresponding control group, to prove that high iron storage is a protective factor against febrile seizure.

**Patients and Method**

This case-control study was conducted on one hundred fifty patients with thalassemia major between six months to six years of age, who were attending the center for inherited blood diseases in Babylon Teaching hospital for maternity and children from the first of April 2019 to the end of January 2020. To avoid bias, just one child from each family was selected & interviewed about. All medical records of thalassemic patients were thoroughly reviewed. The children who were diagnosed as thalassemic patients on the basis of clinical manifestations, complete blood count and hemoglobin electrophoresis were studied. We summarized data regarding percentage of hemoglobin, MCV, MCH, MCHC, RDW, type of thalassemia, and serum ferritin level. The control group consisted of one hundred fifty non-thalassemic patients selected at the same hospital with similar sex and age distribution as the cases. Exclusion criteria for both groups were history of any brain lesion, mental retardation, cerebral palsy, family history of epilepsy and history of afebrile seizure. Another exclusion for control group if there CBCs and blood films show a hypochromic microcytic anemia with a high RDW, and reduced RBC it means they have a presumptive diagnosis of iron deficiency anemia.

This exclusion made because of many researches that found iron deficiency anemia is a risk factor for febrile seizure to guarantee better comparism. Questionnaires containing demographic data and past history of febrile seizure, onset of febrile seizure, hospitalization, number of episodes, family history of febrile seizure, history of afebrile seizure and its etiology were included. More information to differentiate febrile seizure from shivering, temper tantrums, breath holding spells, and other types of seizures has been taken if parents reports history of seizure like activity. We exclude (38) controls from the study because they have a presumptive diagnosis of iron deficiency anemia, two others have family history of epilepsy and one case has history of afebrile seizure.

**Data Analysis**

Statistical analysis was carried out using SPSS version 18. Categorical variable were presented as frequency and percentages. The Pearson's, Chi-square test (X2) test was used to determine the
associations between two groups. A P-value of <0.05 was considered as statistically significant. Logistic regression analysis was also done for the analysis by using Fishers exact test.

**Results**

One Hundred fifty thalassemic patients range from six months to six years old, and one Hundred fifty non thalassemic children as a control group were evaluated in this study. Table (1) shows seventy eight thalassemic patients (52%) were male, and seventy two (48%) were female, the sex distribution was comparable with control group in which eighty one (54%) were males and sixty nine (46%) were females and the small differences are statistically not significant.

**Discussion**

In accordance with the present study, the risk of febrile seizures in thalassemic patients is lower than that of control group.

The results of this study are consistent with the results of a previous study performed by Auvicha in Thailand\(^{(13)}\). They reviewed (430) patients with β-thalassemia. Three of them had febrile seizure and the rate of febrile seizure was 4.4 times less than the normal population.

In another study by Dauod, (Department of Pediatrics, Jordan University of Science and Technology) it was shown that serum ferritin was significantly lower in cases with febrile seizure compared to individuals in the control group\(^{(14)}\), but in another study, Hartfiel (Department of Pediatrics, University of Alberta, Canada) showed that the rate of Iron deficiency anemia in patients with febrile seizure was two times less than its rate in febrile patients without seizure\(^{(15)}\).

The explanations to support the conclusion that said “high iron storage might probably act as a protective factor against febrile seizure” illustrated below.

It has been known that the complex balance between glutamate-GABA systems plays a crucial role in controlling convulsions. Hyperthermia was reported to reduce the activity of the GABA system while increasing the activity of glutamate via the decrease in glutamate reuptake and therefore inducing the up-regulation of glutamate receptor and resulting in a convulsion.

Iron has been reported to correlate with various functions of the nervous system especially neurons for a long time\(^{(16,17)}\). Iron deficiency was also reported to reduce the GABA metabolism via the alteration of glutamate decarboxylase and GABA transaminase enzymes\(^{(18,19)}\).
Therefore, the effect of iron on febrile seizures could possibly be due to iron overload increasing the activity of GABA system which is the main inhibitory neurotransmitters in the brain. This system is particularly important in suppressing seizures. In the case of febrile seizure in the thalassemic group, there were no data on the serum ferritin level at the time of febrile seizure but the nearer levels of serum ferritin before and after the event are (1420) nanogram/ml and (1575) nanogram/ml respectively. Taking into account the prevalence of iron deficiency anemia in children and the relationship between febrile seizure and the serum ferritin level, as shown in the present and similar previously study, it could be suggested that iron supplement and treatment of iron deficiency anemia could reduce the corresponding risk of febrile seizure\(^1\)\(^{,}10\).

### Conclusions

1. The risk of febrile seizures in thalassemic patients was less than that of the controls.

2. Iron overload may be a factor involving the brain metabolism that prevents febrile seizures.

### Recommendation:

1. Further similar studies are recommended, better to be a multicenter studies which will include larger sample size about the risk of febrile seizure in thalassemic patients and the effect of iron overload in prevention of febrile seizure.

2. Therapy for those with iron deficiency anemia could decrease the risk of seizure recurrence and will prevent other sequelae of iron deficiency in the young children.

3. Special attention for thalassemic patients presented with fever and convulsion to exclude CNS infection and other potential causes as the frequency of FS are very low in those patients.

Scout Culture and its Relationship with Scout Curricula According to the Perspective of the Sustainable Development Goals among Scout Leaders in Iraq

Magda Abbas Muhammad Ali¹, Mahmood Dawood Salman², Amna Fadel Mahmoud³

¹Lecturer, University of Babylon - Faculty of Physical Education and Sports Sciences / Iraq, ²Prof. Dr., Al-Mustaqbal University - Physical Education and Sport Sciences Department, College, 51001 Hillah, Babil, Iraq, ³Prof. Dr., University of Babylon - Faculty of Physical Education and Sports Sciences / Iraq

Abstract

The Scout movement is considered a tool for upbringing and building for generations in a way that reflects positively on the civilized, scientific and social development of society, for it is no longer just a means to occupy the leisure time of youth, but rather has become a contribution to developing their abilities and behaviour by developing their social skills, instilling sound values and ethics for them, and enriching their knowledge with movements and information that it can contribute to providing them with experiences that qualify them physically, mentally and socially as individuals who are good citizens in their societies to build a generation capable of serving their homeland. Values have a great and direct influence on the work that the mobile performs in terms of controlling his behavior and defining his goals and taking decisions related to its work, and the extent of the relationship of scouting curricula according to the perspective of the sustainable development goals with the application of scout culture in the behavior of scouts, the research objectives. The research community was identified with leaders and scout leaders in the education directorates in the governorates of Iraq except for the Kurdistan region for the academic year 2019-2020, and the researchers identified the research sample in a random way, Whereas, (10) leaders and female leaders were selected for the reconnaissance experiment, (40) leaders and female leaders for the construction sample.

Keywords: Scouting culture, Scouting curricula according to the sustainable development goals perspective.

Introduction

The Scout movement plays multiple roles and functions within the social system, as it is considered a form of general culture and is a practical application of moral ideals, and its fields are full of attitudes through which its practitioners acquire the good qualities that motivate our youth to assume full responsibility for increasing production and investing their energies to double national income in addition to preparing them to assume positions Leadership in different areas of life and their pride in belonging to the group and the homeland (¹)

The Scout movement is considered a tool for upbringing and building for generations in a way that reflects positively on the civilized, scientific and social development of society, for it is no longer just a means to occupy the leisure time of youth, but rather has become a contribution to developing their abilities and behaviour by developing their social skills, instilling sound values and ethics for them, and enriching their knowledge with movements and information that it can contribute to providing them with experiences that qualify them physically, mentally and socially as individuals who are good citizens in their societies to
build a generation capable of serving their homeland. The problem of research The Scout movement did not get much attention in our beloved country, Iraq, and the diversity in its curricula, knowing that the Scout movement in Iraq had started in The year (1918 AD) and its curricula are schools for group work and self-reliance in the time of technology and difficult living conditions, knowing that it was previously receiving attention for all its scouting stages, especially the (wandering) stage because of this stage of great importance in the life of society because it includes the group of university youth who The culture is acquired through education and experience from together. Values have a great and direct influence on the work that the mobile performs in terms of controlling his behaviour and defining his goals And taking decisions related to its work, and the extent of the relationship of scouting curricula according to the perspective of the sustainable development goals and the application of scout culture in the behaviour of scouts, the research objectives The research aims to identify the reality of scouting culture and scouting curricula by the goals of sustainable development and to identify the relationship between scouting curricula by the goals of sustainable development And between the scouting culture of scout leaders in Iraq.

The practical side:

The researchers used the descriptive approach in the survey method, due to its blame and the nature of the research, and the research community was identified with leaders and scout leaders in the education directorates in the governorates of Iraq except for the Kurdistan region for the academic year 2019-2020, and the researchers randomly identified the research sample, as (10) leaders and leaders were selected. For the pilot experiment, (40) leaders and leaders of the construction sample.

Field research procedures:

First: Measuring Scout Culture.

The researchers adopted the Scout Culture Scale for the researcher (Wathiq Hadoud Shuailah), where the researcher relied on applying the Scout Culture Scale to theoretical definitions, which focus that scout culture is the outcome of information that scouts have, through which he can be an idea about the scouting movement to help him develop his personality, and improve His social relations and the development of his cognitive, educational, health and moral aspects, the scale consists of (54) paragraphs and each paragraph has five responses and each response represents a specific situation, and there are five alternatives to the answer in front of each paragraph, which are (always, often, sometimes, rarely, never), positive weights of them (5-4-3-2-1) respectively, and the negative weights are (1-2-3-4-5).

Second: Measuring the Scout curricula according to the sustainable development goals perspective.

The researchers adopted the Scout Curriculum Scale according to the sustainable development goals perspective of the researcher (Magda Abbas Muhammad), where the researchers adopted the application of the scale on the sustainable development goals used in the Scouting curricula, the scale consists of (71) paragraphs and each paragraph has five responses, and each response represents a specific situation. In front of each paragraph there are five alternatives to the answer, which are (always, often, sometimes, rarely, never), the positive weights of which are (4-3-2-1-0) respectively, and the negative weights are (0-1-2-3-4) The highest score obtained by the subject is (284), and the lowest score is (0). The hypothetical mean of the scale (142), and whenever the score obtained by the subject is equal to or higher than the hypothetical mean, indicates the prevalence of the scout curricula according to the perspective of the sustainable development goals among scout leaders.

Psychometric properties of the Scout Culture Scale:

Honesty:
The validity of the Scout Culture Scale and Scouting Curricula was verified according to the sustainable development goals perspective, by presenting their paragraphs to a group of experts and specialists to ensure the validity and suitability of their paragraphs for measurement.

**Stability:**

To verify the stability of the Scout Culture Scale and the Scout Curriculum Scale by the sustainable development goals perspective,

**Halftone segmentation:**

The half-segmentation was calculated by isolating the individual paragraphs from the marital paragraphs and to find out the homogeneity between the individual and marital paragraphs, and then calculate the correlation coefficient between them, so the value of the correlation coefficient between the two halves was (0.767) for the Scout Culture scale and (0.744) for the Scout Curriculum Scale according to the development goals perspective. Since this indicator is concerned with half of the vocabulary, it is necessary to use the (Spearman-Brown) equation to identify the amount of the stability coefficient for all vocabulary. After the statistical procedure for this equation, the stability value of the entire scale was (0.868) for the Scout Culture scale and (0.849) for the Scout Curriculum Scale the scale. According to the perspective of the sustainable development goals, which is a high value, which indicates that the scale is constant.

**Statistical methods:** The Statistical Package for Social Sciences (SPSS) was used.

**Results**

Presenting, analyzing and discussing the results of Scouting culture and Scouting curricula according to the perspective of the Sustainable Development Goals of the Scout leaders, to verify this goal, the researchers used the T-test for one sample t-test to compare the sample mean of (100.144) with a standard deviation of (33.84) with the average hypothesis for the scale was (150), so the calculated T value was (-23.62), which is a function of the level of significance (0.05) and the degree of freedom (250) of (± 1.96). They have psychological security and statistically significant. Table (1) illustrates this.

**Table (1):** It shows the results of the T-test for one sample to indicate the difference in the scouting culture of students of the College of Physical Education and Sports Sciences.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>
This result can be interpreted as naturally expected, as the Scouting curricula, which depend on the perspective of sustainable development, are those that meet the needs of the present without compromising the ability of future generations and helping them meet their own needs.

The relationship of the Scout curricula according to the perspective of the sustainable development goals in Scout culture:

Table (2): It shows the relationship of the Scout curricula according to the perspective of the sustainable development goals in Scout culture:

</table>

We conclude from Table (2) that there is a relationship between the Scouting curricula, which is based on a sustainable development perspective, and the Scouting culture adopted by the Scout Leader, scouting curricula being a group of diverse programs that meet the needs of Scouts according to their age, to achieve the principles of the Scout Movement that seeks to educate the individual from all ways. It is also the group of experiences and activities that the Scout Movement provides under its supervision to Scouts with the intention of their contact with these experiences and their interaction with them, and the results of these frictions are the interaction that takes place learning or modification in their behaviour that leads to achieving comprehensive integrated growth. (5) It is a comprehensive general plan for the subjects that the student should study. In school in order to obtain an academic degree or a certificate qualifying to work in a specific profession, “Scout programs” is all the activities that boys and youth do in terms of activities that suit their needs by using the Scout method to achieve the educational goal of the movement, and it includes the various activities on which the activities of the stages depend “is the development that works to achieve A better life for the individual than he is by working to improve the social, economic, cultural and political aspect, especially the health and environmental aspect, as it has a very great impact on the life and health of the individual, sustainable development has become a major issue for many international organizations included in the United Nations, such as the United Nations Development Program (UNDP) and the Organization for Economic Cooperation (OECD), the Sustainable Development Committee emanating from the Earth Summit issued a book that includes four main dimensions of development. Sustainability represented in the economic, social, environmental and technological dimension, and these dimensions give his view on the most important indicators related
to each dimension. (6)

First - the economic dimension:

Several indicators are reflected in the environment in which a person lives, namely:

1- The rate of per capita consumption of natural resources: the rate of per capita consumption must be commensurate with the available resources and in a way that ensures their survival for future generations. It is known that developed countries are more consumers of natural resources than developing countries.

2- Eradication of poverty: Developing countries seek to fight poverty through their indication that poverty does not mean prosperity and the exploitation of all environmental potentials, but rather taking people to their needs and directing resources properly so that an individual can fulfil the requirements of his life and that development is inclusive of the sufficiency of individuals.

3- Equitable Income Distribution: Sustainable development aims at distributing income among all individuals in an equitable manner, and not building social disparities between the rich and the poor, and this requires developing countries to distribute equitably in the resources available to them. (7)

Second - the social dimension:

The social dimension is of prominent importance in achieving sustainable development and there are a set of indicators that define the role of this dimension, namely:

1- Good governance: It is represented in the use of democracy and participation in decision-making, which will be positively reflected in society.

2- Providing health and education: Providing health and education at all school levels is important, and sustainable development has had a prominent role through concern for human development and human building, which will ensure the continuity of development and lasting awareness.

3- Population growth and population distribution:

Sustainable development means determining the population and not overly increasing the capacity of societies, which will negatively affect the environmental depletion as well as the population distribution between rural and urban areas in a thoughtful manner, to reduce the prejudice to green areas and reduce the emitted environmental pollution.

Third - the environmental dimension:

“The environmental dimension represents natural resources (water, energy, agriculture and biodiversity), which is the backbone of sustainable development. It is defined as the interest in managing natural resources by focusing on the quantity and quality of resources on the globe. The concept of environmental development is related to environmental pollution or the overuse of resources that leads to depletion. Natural resources and their collapse, on the other hand, it is related to the concepts of waste recycling and safe disposal of waste.

Fourth - The technological dimension

“The technological dimension and its uses have positive results in raising the income of countries and individuals and improving living conditions. Among its most important indicators, which should be taken into account:

1- The use of clean technology in industry: as technology may result in a pollution tax, therefore it is necessary to choose technology with a clean use that does not cause environmental pollution, and many industrialized countries have passed laws for the use of technology, and financial penalties for those who commit such violations.

2- Adopting advanced technology: it is the process of selecting technology with high quality and appropriate efficiency, as well as using tools and machines with a clean use. (8)
Conclusions

In light of the results reached by the researchers, a set of conclusions were reached:

The members of the research sample, the Scout leaders, enjoy a good level of Scouting culture, as well as there is a moral correlation between the Scout curricula according to the sustainable development goals perspective and the scouting leader’s scout culture.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

The Effect of Feedback at Different Times by Using Multimedia in Learning the Performance of Some Basic Skills in Handball For Students

Hamida Obaid Abdulamir¹, Nisreen Hassan Naji², Naseer Ahmad Kamil³
¹Assistant Prof., University of Kufa/Faculty of Education for Girls / Department of Physical Education and Sports Sciences / IRAQ, ²Assistant Prof., University of Kufa/Faculty of Education for Girls / Department of Physical Education and Sports Sciences / Iraq, ³Lecturer, Al-Furat Al-Awsatt Echnical University/ Iraq

Abstract

The handball game has taken to keep pace with the development and progress in the world, where many changes have occurred in the methods of learning and training in various aspects, including in particular changes in the methods of playing teams in terms of applying defensive and offensive plans in order to surprise the competitor, and the use of feedback in the process of learning and developing basic skills By varying the time it is given in order to make the learner have the ability to absorb the skill and the process of choosing the appropriate motor program to solve the motor duty in the best way and according to the requirements of the situation facing him. Conclusions: The use of times (10, 20, 30 seconds) to provide feedback of all kinds has an impact. Positively in learning basic handball skills and for the three groups, the use of multimedia (visual display device “Data show”, video cameras, color papers for the movement sequence of skills, display of the live model) has a great role in developing basic skills of handball through increasing motivation In competition between players, a time of (10, 30) seconds in providing feedback is more influential in learning basic handball skills.

Keywords: Feedback at different times, basic handball skills

Introduction

The handball game has taken to keep pace with the development and progress in the world, where many changes have occurred in the methods of learning and training in various aspects, especially changes in the methods of playing teams in terms of applying defensive and offensive plans to surprise the competitor, and the use of feedback in the learning process and the development of basic skills By diversifying the time it is given to make the learner have the ability to absorb the skill and the process of choosing the appropriate motor program to solve the motor duty in the best way and according to the requirements of the situation he faces. (¹)

The importance of the research lies in providing feedback at different times using multimedia in developing the basic skills of female students with handball, to be an expressive method used by coaches to achieve the best results. (²)

Practical Part:

Research Methodology:

The researchers used the experimental approach to suit the nature of the research problem.

Research community and sample:

The research community was identified by the students of the Department of Physical Education and Sports Sciences in the College of Education for Girls at the University of Kufa, whose number is (40) students. The sample is (75%) of the size of the community, with (10) female students for each group.
Determine search variables:

Identify some basic skills and shape them with a hand reel:

The researchers prepared a questionnaire to present the basic skills and form them to the experts and specialists in handball to determine the most important of these skills and their shapes, as in Table (1).

Table (1). Questionnaire to present the basic skills and form them to the experts and specialists in handball to determine the most important of these skills and their shapes.

**Exploratory experience:**

The exploratory experiment is one of the most important necessary procedures that the researcher undertakes before performing his final experiment to test research methods and tools and indicate the requirements of accurate and correct work free of difficulties. Conducting exploratory experiments on a sample of (10) female students for basic handball skills tests, the aim of which was:

1. Ensure the efficiency of devices and tools
2. Knowing the time spent for each test as well as the time for the total exams
3. Efficiency of auxiliary work team
4. The level of difficulty of the tests for the research sample
5. Knowing the difficulties facing the researcher to avoid them in the future
6. Finding scientific transactions for tests (stability and objectivity).

**Scientific foundations of basic skills tests:**

**Test validation:**

Honesty is one of the important qualities that a good test should possess. A test that does not have a good percentage of honesty cannot perform its function. To extract the validity of the candidate tests for basic skills, the researcher will present the contents of the tests to a group of experts and specialists. Often it is “by logical judgment about the existence of the characteristic, characteristic, or capacity in question, to investigate whether the proposed method of measurement measures it or not.”

**Stability test:**

To extract the stability factor for basic skills tests, the principle of the static test must be applied, which gives similar results or the same results if applied more than once in similar conditions. The test reliability is also the value expressed on the extent of the test’s accuracy in extracting fixed results if the test is repeated More than once on the same sample to give close results.

**Objectivity:**

Objectivity is defined as “the extent to which the judge or examiner is free from subjective factors. That is, the test is not subject to self-assessments. To extract objective values, the objectivity of the test must be
used, which indicates that the assessors do not differ in judging something or on a particular topic.

**Pre-tests:**

The researcher conducted the pre-tests for the research sample (the first experimental, the second experimental and the third experimental) before starting the main experiment with controlling all the variables.

**Equivalence of the sample:**

To equalize the research groups among themselves, the researcher will work by relying on the results of the pre-test for basic skills and by applying a (t-test) for the results of the pre-tests. Table (4)

**Table (4). The equivalence of the three research groups in the tests under investigation.**

**Competition style tutorial:**

The researchers reviewed the educational curriculum followed, after which they provided feedback at various times using multimedia on the vocabulary of this program after reviewing the relevant sources and references. The researchers also conducted personal interviews with many experts in the field of motor learning and training to develop appropriate exercises and special duties And how to give feedback and how to apply multimedia during the main experience in line with the capabilities of the handball players.

* The researchers also adopted multimedia during the educational units, which are as follows.

* Displaying a live model via the laptop for the basic skill being applied.
* Illustrations of the skills in question.

The two researchers prepared coloured papers showing the kinematic sequence of the studied skills to take advantage of them in the player’s knowledge of her mistakes during the motor performance of the skills under study. This helps the player to overcome these errors at the same time.

* Live model display, the researchers performed studied skills in front of the players to identify the correct typical performance.

* Provide the feedback in the form of written text.

Post test:

The researchers conducted the post-tests after completing the educational program, taking into account the same conditions in the pre-tests.

Statistical means:

The researcher used the statistical bag (SPSS) to process the data.

Results

View and analyze the results of the first experimental group tests.

Discussion

It was evident from the previous tables that the three experimental research groups had developed in a different and different way in the basic skills tests under study, but it is noticed that the group that has the most influence in learning these skills is the first and third group, as the results showed significant differences in favor of these two groups. The researchers attribute the reason for these differences...
to the use of the appropriate time for the feedback that these two groups worked with, which is a time (10, 30) seconds, (8) as the first group that used the time (10) seconds has an immediate feedback. This helped the learner to know his mistakes quickly and try to correct his path through Looking at the colored papers hanging on the stadium wall and the coach’s directions. The second group that used time (30) had the opportunity to look at the clips that the coach had previously filmed and watched to find out the correct performance and try to repeat as seen in the video and through it the learner has knowledge of his wrong performance He corrects the error if it occurs, as this is the learner’s self-evaluation by being an “appropriate” time that allows the learner to recognize weaknesses in performance and correct his mistakes, if any, thus generating a complete perception of his performance in an attempt to improve and develop it, which made this group outperform groups The remaining search. (9)

**Conclusions**

1- The use of times (10, 20, 30 seconds) to provide feedback of all kinds has a positive effect on learning basic handball skills and for the three groups.

2- The use of multimedia (visual display “data show”, video cameras, colour sheets for the movement sequence of skills, display of the live model) has a great role in developing basic handball skills by increasing motivation in competition between players.

3- The time (10, 30) seconds in providing feedback is more influential in learning basic hand reel skills

Abstract

Aim: to note the views of Iraqi lecturers towards e-Learning. Did they approve of E-learning? What are the principal conflicts of E-examinations?

Methods: This descriptive, observational, prospective study. It involved 78 haphazardly collected Iraqi lecturers from various colleges and institutes of Al- Anbar. The data gathered by a combination of learners from the higher health institute of Al-Anbar. The research began from 1st February 2021 to 1st March 2021. The survey form about the lecturers’ views towards E-learning by implementing three points agreement Likert scale. Microsoft Excel software used for data analysis. The institute gave the Ethical permission. The dismissed lecturers were those who did not reply.

Results: There were seventy-eight lecturers, aged (25-55) years old. Thirty-three females (43 %) and 45 (57 %) males lecturers. Forty-eight (61.5 %) lecturers had two modules. Forty-nine (62.6 %) lecturers had more than 100 students per a lecturer. Sixty-four (82.2 %) lecturers dislike E-learning. Fifty-five (70.7 %) lecturers did not support E-learning nor E-written examinations.

Keywords: Attitudes, Iraqi, lecturers, Electronic, learning.

Introduction

During COVID-19 lockdown, there was an emerging type of Learning started in the world. This type of learning is called online learning or E-learning.¹ E-learning or online learning is a type of learning gained by electronic tools and media. E-learning passes from the teacher by the net, to the students. Students get the learning syllabus online at far distant places. E-learning is a developed learning method in Europe, the USA, and Japan. There are good Infrastructures to send these learning types like online degrees, courses. (Singh V, 2019).

E-learning has many kinds:

1. Synchronous type: in this kind, the lecturer must be present online with the students at the same time.

2. Asynchronous learning: it allows the lecturer to participates with extra students like webinars.

3. Blended learning: it is a mixed kind of traditional and eLearning-like workshop. (Khalid A, 2012)

E-Learning strategies embrace many plans for data transfer. So it aids the students to get the learning aims.

1. E-lectures:

2. E-discussion

3. E-problem-solving

4. E-simulation

Each of these strategies had its own characteristics and indications.⁴
There were 169 papers on E-learning topics in the Iraqi scientific journals. The oldest paper was published on this topic was in 1986. This indicates that Iraq is the first country in the middle east that E-learning.

Iraqi researchers developed well-designed strategies and programs of E-learning. Iraqi scientists understand who needs E-learning and when to apply. Although, there were simple computer technologies and primitive use of E-learning measures. In 2005 there was a paper about E-learning use in Iraq. Since 2005, many Iraqi studies have deliberated the E-learning views in different aspects. Iraq developed adjusted methods of E-learning. But, E-learning continued in primitive ways. It was not applied until the COVID-19 lockdown. Newton’s platform started in February 2020. The higher institute of Nursing in Al-Anbar started E-learning at the same time. During the COVID-19 pandemic, the academic teachers commenced Google classroom as a platform. Electronic lessons, and examinations completed in the expected time.

E-Learning platforms:

There are many popular e-learning platforms:

The electronic platform gives comfortable entrance to online learning. So, these platforms enable students to interact and motivate their Lecturers. These platforms permit classes and examinations by linking the educational data. The various kinds of electronic platforms are important learning tools. (Ajaj IE, 2020)

1. Google classroom:

Google Classroom is a popular learning platform. It is free and extended in a brief time to many countries, incorporating Iraq. Google Classroom is a popular learning platform. It is free and extended in a brief time to many countries, incorporating Iraq. 10

2. Moodle:

Moodle is another well-known e-learning platform. Many colleges allow Moodle usage. It is as effective as google classroom, because of its comfortable uses. Some universities choose Moodle platform to enable more learning effects. 11

Importance of study:

1. E-learning is a modern type of learning in Iraq.

2. E-learning had many challenges to the Iraqi lecturers.

3. There are few articles in the Al-Anbar government about this topic.

4. This study allows lecturers to improve this method.

5. This study had good addition to the Iraqi and Al-Anbar libraries.

Statement of the problem:

In 2020, there was a COVID-19 pandemic that causes a universal lockdown. This lockdown obligates Iraqi students to be at home. The Iraqi lecturers started E-learning learning to overcome the COVID-19 lockdown. This important topic made this group of students explore the lecturers’ attitudes toward e-learning. Also, this article shows how the Iraqi lecturers change their strategies in learning.

The purposes of the Cross Sectional study are:

1. to show the attitudes of the Iraqi lecturers towards e-Learning.

2. How did the lecturers believed about e-learning?

3. What are the lecturers struggles of E-learning?

4. How can the Iraqi lecturers develop e-learning in the institute?

Methods

This descriptive, observational, prospective study. It involved 78 haphazardly collected Iraqi lecturers from various colleges and institutes of Al-Anbar. The
data gathered by a combination of learners from the higher Health institute of Al-Anbar. The research began from 1st February 2021 to 1st March 2021. The survey form about the lecturers’ views towards E-learning by implementing three points agreement Likert scale.

Microsoft Excel software used for data analysis. The institute gave the Ethical .

**Limitation of the study:**

It is a small sample size & not represents the whole community.

Conflict of interest: none

Ethical committee: vague names, oral consent
Plagiarism: none
Bias risk is low

**Results of the Study**

There were seventy-eight lecturers, aged (25-55) years old. Thirty-three females (43 %) and 45 (57 %) males lecturers. Forty-eight (61.5 %) lecturers had two modules.

Forty-nine (62.6 %) lecturers had more than 100 students per a lecturer. Sixty-four (82.2 %) lecturers dislike E-learning. Fifty-five (70.7 %) lecturers did not support E-learning nor E-written examinations.

Discussion

In COVID-19 lockdown, there was an emerging type of Learning started in the world. This new type is called an E-learning type. \(^1\)

It is gained by electronic tools and media, passed from the lecturer by the net, to the students. All the Iraqi lecturers used E-learning. In this study, a group of Iraqi lecturers expressed their attitudes towards E-learning.

In this study, there were seventy-eight Iraqi lecturers. This study covered a group of a haphazard collection of diverse lecturers from different colleges and various specialties.

This diversity of elections gives the study its originality and unique character.
Thirty-three female’s lecturers (43 %) participated in this study. Female selection is not biased. But, the selection of a group depends on who wants to take part. Some of the females felt shy or did not want to take part.

Table 1 and fig. 1 show the numbers and percentages of modules per a lecturer.

There were 45 (57 %) males lecturers. Male dominance is not intended. The researchers called for lecturers’ participation in different ways and optional ways.

Forty-eight (61.5 %) lecturers held two modules. These lecturers express the majority of the lecturers. Twenty-seven (34.8 %) of them were males, while females were 21 (26.7 %). Twenty-seven lecturers (34.8 %) possessed one module. This group received the practice module or had more than 100 students. Fifteen (19.7 %) of them were males, and twelve (15.8 %) were females. However, the male lecturers were more than females. Three (0.3 %) of lecturers who received three modules, were males only. This means that males were more tolerant of the extra work than females.

This result is similar to many previous researches like 12 Table 2 and fig. 3 show the numbers of students per a lecturer.

Forty-nine lecturers (62.6 %) had more than 100 students per a lecturer. This means more stress and extra effort of learning. This task in E-learning needs satisfactory net and stable electricity for the lecturer and the student. Google classroom; is the main platform could not tolerate more than fifty students. Some lecturers used Moodle platform or divide the students into two groups. In both solutions, there was extra work in lesson explanation and attendance registration.

Some lecturers dislike E-learning for this matter. The other lecturers find E-learning is the easiest type in electronic written examinations for a class of more than 100 students. Student crowding is one of the reason to state E-Learning during Covid-19 crisis. This result is parallel to the universal studies like 13

Twenty-four lecturers (31 %) held module/s of (50-99) students. Those lecturers also had many difficulties in lesson explanation and attendance registration. However, there were fewer struggles in electronic written examinations.

Five lecturers (6.8 %) held a class of fewer than fifty students. Those lecturers felt more comfortable with the lesson explanation and attendance registration. But, they felt that electronic oral and written examinations are troublesome. These finding went with many articles like 14

Table 3 and fig. 3 show the opinions of the lecturers.

Sixty-four (82.2 %) lecturers dislike E-learning, while seven lecturers (8.9 %) prefer it. This result may be due to the earlier trials of E-Learning in Iraq. There were many difficulties due to the weak infrastructure of E-Learning in Iraq. This finding went with the established Iraqi papers like 15

Forty-four lecturers (56 %) believed that E-Learning is harder than the traditional model. This result may be due to the structure of the E-Learning, the weak net, or the fluctuating Electricity. It could be the fewer skills in E-Learning or the usual practice of the traditional Type. This result is parallel to the reported studies, like (Jabir AC, 2020)

Forty-eight lecturers (62 %) rejected the modules demonstration is better in E-learning. This event could be interpreted as the little experience of lecturers in their computer skills. While the thirteen lecturers (16.5 %) agreed to the module’s demonstration is better in E-learning. This debate may be due to their sufficient computer skills. 17

Fifty-three lecturers (67.5 %) disapprove of module preparation in E-learning.
This result might be due to lecturers’ proficiency in electronic skills. Yet, twelve lecturers (16%) prefer modules preparation in E-learning. This finding went with previous studies, like (Timothy M, 2018)

Forty-six lecturers (59%) accepted that Electronic examinations are more difficult in E-learning due to their primitive expertise. This challenge arose from the type of questions, and to prevent fraud. The use of some kinds of questions leads to exam cheats. The nature of questions that reduces cheats was the essay questions and multiple-choice tests.

This result is the same as the mentioned articles, like 19

Forty-two lecturers (53.8%) think that the score evaluation is harder in the electronic exam due to their trials to stop cheats among the students. Cheats could be the principal barrier against the reliability of the electronic exam. Nevertheless, there were 24 lecturers (30.2%) who did not agree by using tricky multiple-choice questions or adjustments of essay questions. This result went well with the mentioned reports, like 20

Table 4 and fig. 4 show the attitudes of the Lecturer towards E-learning.

Fifty-five (70.7%) did not support E-learning. This is because of the primitive experiences of this type. The lecturers may change their opinions in the future because of the increased experiences and skills practices. This upshot is parallel to the reported work of literature like (Qianzhou AH, 2021)

Forty-seven lecturers (60.3%) discourage Electronic oral examinations. This is the result of the lecturers’ struggles in E-learning. The lecturers felt that their sufferings affect the student’s level of training and downgrades learning as a whole. However, there were twenty lecturers (25.6%) who encourage E-oral examinations. Those lecturers asked the student to open the camera and answer the oral exam. Some lecturers use educational pictures, tools, or models and asked their students to answer. These exams need a stable net and stable electricity to perform. The lecturers who dislike electronic exams felt unhappy with the security of the electronic exams. Cheats and fraud are the main struggles.

This result is parallel to the documented studies like (Konishi K, 1998)

Fifty-four lecturers (69.4%) did not boost E-written examinations. The lecturers believed that the electronic tools had insufficient security to prevent cheats and fraud. The simple expertise and the lack of time control in the Google Classroom were the principal barriers. This outcome went in parallel with the mentioned reports like (Villarroel V, 2020)

Conclusions

Electronic Learning is a challenging style of learning. It demands progressive development and configuration to prevent cheats and fraud. The infrastructure of electronic learning is the chief obstacle. The Webinars, conferences, and workshops improve the control of E-examinations and enhance E-learning in Iraq.

Recommendations:

1. E-learning necessitates reliable infrastructure to achieve.

2. Webinars, conferences, and workshops improve the control of E-examinations and learning in Iraq.

3. The lecturers’ good experiences drive good E-learning.

4. The lecturers’ skills in electronic tools create excellent E-learning outcomes.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.
Ethical Clearance: “All experimental protocols were approved under the Community Health Nursing and carried out in accordance with approved guidelines”.

Master Degree in Medical Laboratory Technology

Abstract

Matrix metalloproteinases (MMPs) are key enzymes responsible for matrix degradation, derived from polymorphonuclear leukocytes, during the early stages of periodontitis. There is plenty of evidence for the role of matrix metalloproteinases in the destructive processes of periodontal disease as a viable target in early diagnosis and chemotherapeutic approach. The aim of this study was to determine the levels of salivary matrix metalloproteinase-9 (MMP-9) in patients with periodontitis and healthy controls and the role of gene polymorphisms in the aetiology of the disease. Levels of MMP-9 in saliva was determined by enzyme linked immune sorbent assay (ELISA) technique in healthy subjects without any periodontal disease (n = 45) and in the patients with diagnosed periodontitis (n = 45). Gene Amplification, gel electrophoresis and genotyping were also carried out on MMP-9 gene. The MMP-9-1562C/T appeared in three genotypes: CC, CT and TT, allele specific gene polymorphism was amplified by PCR technique. The distribution of different genotypes in patients and controls for each of MMP-9-1562C/T polymorphism was in a good accordance with Hardy-Weinberg equilibrium (HWE). Genotypes in both dominant and recessive models were non-significantly associated with periodontitis. Significantly higher salivary MMP-9 was observed in cases of periodontitis compared to healthy adults (p = 0.043). Salivary MMP-9 may serve as a biomarker of periodontal disease monitoring and aid in the early detection of periodontitis.

Key words: Polymorphism, matrix metalloprotinase-9, chronic periodontitis, ELISA, saliva, promoter −1562 C/T.

Introduction

Chronic periodontitis (CP), the most commonly occurring and slowly progressive form of periodontal disease, can lead to continual inflammatory host response, which may finally result in periodontal attachment loss and bone resorption (¹,²). The CP is a highly prevalent disease and has shown to affect 90% of the worldwide individuals (³). Even though the key etiological factor that results in progression of CP is the formation of complex biofilm on the surfaces of teeth adjacent to their periodontal tissues, determinants like demographic, social, environmental, behavioural, systemic and genetic factors have also been coupled with the epidemiology of this disease (⁴).

Matrix metalloproteinase-9 (MMP-9) is a member of a family of proteolytic enzymes that
regulate cell matrix composition by requiring zinc for their proteolytic activities. The MMP-9 cleaves denatured collagen (gelatin), in particular, type IV collagen, which constitutes the major component of the basement membranes \(^5,^6\). This cleavage helps lymphocytes and other leukocytes like dendritic cells (DCs) to enter and leave the blood and lymph circulations. The MMP-9 also cleaves myelin compounds such as myelin basic protein (MBP) and type 2 gelatin, which leads to remnant epitopes that can generate autoimmunity \(^5,^6,^7\). Expression and secretion of MMP-9 by activated lymphocytes and monocytes is tightly regulated by cytokines, chemokines, eicosanoids and peptidoglycans \(^7\). In most cell types, gene transcription of MMP-9 is inducible by cytokines and cellular interactions. The MMP-9 is secreted as a zymogen (proenzyme), which remains inactive unless it is activated by the removal of the propeptide domain by proteolytic enzymes like stromelysin-1, MMP-2 and other MMPs \(^6\).

The aim of this study was to determine the role of gene polymorphisms in matrix metalloproteinase-9 gene in chronic periodontitis and investigate the association of gene polymorphism in this gene using the saliva MMP-9 concentration.

**Methods**

This study included 45 patients with chronic periodontitis and 45 healthy controls. Blood and saliva samples were taken from all participants, DNA was extracted from whole blood for all participants, the Matrix metalloproteinase-9 (MMP-9) gene fragment corresponding the MMP-9-1562C/T SNP was amplified with specific primers using conventional PCR technique. Genotyping was achieved through restriction fragment length polymorphism (RFLP)-PCR. Enzyme linked immune sorbent assay (ELISA) technique was used to measure the saliva concentration of MMP-9.

**Results**

A specific pair of primary was used to amplify Matrix metalloproteinase-9 (MMP-9) gene fragment corresponding the MMP-9-1562C/T polymorphism using PCR, as shown in figure (1).

![Figure (1): Gel electrophoresis of MMP-9-1562C/T gene polymorphism amplified with specific pair of primers using conventional PCR. The PCR product was stained with ethidium bromide. The fragment length was 435 base pair (bp).](image-url)
Genotyping was achieved through RFLP-PCR. According to the cutting pattern, the MMP-9-1562C/T appeared in three genotypes: CC, CT and TT (Figure 2).

Figure (2): Sph I restriction endonuclease restriction fragment length polymorphism analysis of the MMP-9-1562C/T biallelic polymorphism, M, DNA ladder; lanes 1, 3, 5, 8 and 9: GG genotype; lanes 2 and 10: TT genotype; lanes 4, 6, 7, and 11: GT genotype.

bp: base pair.

Table (1) shows that the frequency of CC, CT and TT genotype in patient with periodontitis was 53.33 %, 40 % and 6.67 % respectively which did not differ significantly from that of the healthy controls (68.69 %, 28.89 % and 2.22 %, respectively). Moreover, genotypes in both dominant and recessive models were non-significantly associated with periodontitis. Although the frequency of T allele was higher in the patients than that of the controls (26.67 % versus 16.67 %), the difference did not reach the significant level (OR= 1.82, 95 % CI= 0.88-3.75, p= 0.106).

Table (1): The frequency of different genotypes and alleles of MMP-9-1562C/T polymorphism in both patients and controls.

The concentration of MMP-9 in saliva in the patient group (the mean ± Standard deviation) was (10.27 ± 4.07) ng/mL while in the control group, it was (7.67 ± 3.35) ng/ml. There is a significant increase in patient in comparison to the control group (p= 0.043).

![Figure (3): Mean concentration of Matrix metalloproteinase-9 (MMP-9) in saliva of both patients and controls. We note significant increase at P value <0.05.](image)

**Discussion**

Our results show that there was no statistically significant difference in the frequency of the MMP-9-1562C/T genotypes between the periodontitis patient and the control persons, with no association between MMP-9-1562C/T polymorphism and the occurrence of periodontitis. Furthermore, genotypes in both dominant and recessive models were not significantly associated with periodontitis. The meta-analysis study of (Song et al., 2013) (8) demonstrates that a lack of association between the MMP-9-1562C/T polymorphisms and periodontitis. However, (Pan et al., 2013) study (9) found that the MMP-9-1562C/T polymorphism was associated with modified risk of periodontitis among Caucasian population, which population that differ from middle east population such as Iraq. While (Emingil et al., 2014) study (10) suggested that the other MMPs polymorphism such as MMP-8 might be associated with the susceptibility to periodontitis in Turkish population that also differ from Iraq population.

In this present study, the salivary MMP-9 levels (mean ± Standard deviation) in the periodontitis patient group was (10.27 ± 4.07) ng/mL while in the control group, it was (7.67 ± 3.35) ng/ml with a significant increase in patients comparison to the control group (p = 0.043). Our results were in agreement with many studies such as (Rai et al., 2008) (11), (Wan et al., 2014) (12) and (Baeza et al., 2016) (13) studies. Other studies, such as (Wang et al., 2013) (14) and (Cheng et al., 2014) (15) studies, proved that the MMP-9 levels could also predict the prognosis and progression of many disorders in nasopharyngeal region including chronic inflammation and carcinoma, e.g. squamous cell carcinoma.

However, (Franco et al., 2017) meta-analysis study (16) established that the other genotype of MMP-9 such as MMP-9-753 C/T polymorphism reduced the risk of chronic periodontitis but not mentioned the relationship between the MMP-9-1562C/T
polymorphism and chronic periodontitis, also the same study mentioned that the MMP-9 is the most abundant MMPs in periodontal tissues reflecting periodontal disease severity, progression, and treatment response.

**Conclusion**

Our study concludes that the salivary Matrix metalloproteinases (MMPs) determination can definitely be used as a biomarker for the diagnosis and progression of periodontal diseases. It may also facilitate the better treatment of periodontal disease and the assessment of periodontal conditions in medical and research settings.

The Anthropometric and Biochemical Parameters in Normal Weight-Central Obesity Females

Sanaa Jameel Thamer  
Department of Biology, College of Science, University of Basrah, Iraq

Abstract

Central obesity is abdominal fat that accumulates and affects the health status. The present study aims to estimate some blood biomarkers among normal-weight females with central obesity and determine the prevalence of central obesity. The method: healthy females with normal body weight and age group of (33-44 y) have participated and their body anthropometric parameters were determined. The Navy formula detected the body composition. Serum glucose, lipid profile, insulin, and cortisol hormone were tested. The results: a high prevalence has been found of the central obesity among females with normal weight (71.098%). Central obesity is characterized by increasing WC, WHR, and WHtR with high-fat percentage and fat mass (40.55%, 25.6 kg) than females without central obesity (31.5%, 19.4 kg, respectively). The central obesity females showed significant elevation in serum glucose 8.937 mmol/L, insulin 177.884 pmol/L, and HOMI 10.216 with dyslipidemia than the ones with the non-central obesity. A high significant cortisol level (29.126 µg/dl) was observed in the normal weight central obesity group. Conclusions: the incidence of central obesity among normal-weight females has been associated with changes in some blood profiles, which may contribute to increasing adiposity-related risk factors and health outcomes and the effect on body shape.

Keywords: Biochemical parameters , anthropometric, females , obesity

Introduction

The local body fat distribution revealed an important role in initiating health problems [1]. The distribution of body fat is identified as the android shape (central) and ganoid shape (peripheral) [2]. Central obesity is one of the regional fat accumulations that contribute mainly to metabolic abnormalities like hypertension, diabetes type2, and cardiovascular diseases [3] by promoting mediating factors including inflammations, insulin resistance, and dyslipidemia [4].

Central (abdominal) obesity was observed in subjects with normal body weight (BMI < 25 Kg/m²) [5], which resulted from many factors, mainly diet type and lifestyle modifications [6]. The central fat is characterized by excessive abdominal fat deposit even among the subjects with normal weight [7]. The abdominal fat has been considered as the optimal criterion for the prediction of the fitness and for the metabolic syndrome incidence, especially visceral fat type [8, 9].

Abdominal obesity is gender-specific obesity [10] that is affected by the age [11]; in the females, abdominal obesity showed a specific android pattern (apple shape) with increasing WC [11, 12].

The modern direct measurement for abdominal obesity is magnetic resonance imaging or computer tomography scan [13]. Since they are expensive, not available, and limited in use, the simple alternative is using the anthropometric indicators including WC, WHR, and WHtR [7, 14]. These indicators were
suggested by many epidemiological studies and health organizations [15, 16].

The most widely used obesity index measurement is the BMI method. Still, with some limitations, represented in the fact that it does not provide the pattern of body fat distribution, therefore the combination between abdominal measurements with BMI was recommended [17]. In general, the regional fat depots were assessed among overweight and obese people and not considered in normal-weight subjects, which is an important indicator for the health condition. This study aims to determine the prevalence of central obesity among females with normal body weight, assess the risk factors associated with abdominal fat deposits through blood biomarkers, and detect the correlation between WC and some blood parameters.

**Materials and Methods**

The population sample of the study consists of healthy females (n=173) with normal body weight (BMI≥25 kg/m²) and age (33-44) years. The subjects were divided according to age into two age groups, the first age group: (33- 38 years) and the second age group (39- 44 years). The data has been collected from the participants according to the protocol of the ethical committee of Biology Department-Science College-Basrah University. The data has been collected firstly by questioner forms and then the anthropometric parameters and blood samples have been taken. Questioner forms asked all participants about social status, diet type, lifestyle, physical activity, smoking, drugs, hormonal therapy, allergy condition, and polycystic ovaries syndrome. The exclusion criteria were pregnancy, athletic females, hormonal therapy, females with diseases, and medications. The study was carried out from July 2019 to February 2021.

**The anthropometric measurements:**

The body mass index (BMI) is measured by weight kg/height m² [18]. Waist circumference (WC) was measured at the umbilicus region (cm), hip circumference (HC) was measured at iliac ridge over the buttocks (cm), the neck circumference at the neck place. All measurements were done by plastic strip [19]. The WHR ratio by WC/HC, the WHtR by WC/height. The central obesity was determined according to WC, WHR and WHtR: WC ≥ 80 cm, WHR ≥ 0.85, and WHtR > 0.50 [20]. Basing on questioners and medical history, all participants have been considered in good health. The participants were classified to normal body weight with central obesity and normal body weight without central obesity. The percentage of body fat (%BF) has been measured according to the formula of American Navy: females= 163.205 × log10 (waist + hip - neck) - 97.684 ×log10 (height) - 78.387 [21]. Using a digital scale to measure the weight. The blood pressure was taken in a sitting position.

**The Blood Sample**

The venous blood sample (5ml) from all participants was drawn after overnight fasting (at 8-10 Am). Serum specimens were collected in a gel tube after blood clotting for 15 minutes at room temperature and then centrifuged at 3000 rpm for 10 minutes. The serum was stored at deep freeze -70 °C [22].

**The serum assays:**

Serum glucose and lipid profiles (triglycerides TG, total cholesterol T-ch, and high-density lipoprotein HDL) were measured by using the commercial kits (Biolab, France). According to the formula, low-density lipoprotein (LDL) is Tch- HDL- TG/5 [23]. The insulin has been measured by Elisa kit (Abcam, USA) and cortisol by Elisa Kit (Crystal Chem, USA). The homeostatic index of insulin resistance (HOMI) by the formula: [glucose (mmol/L) × insulin (pmol/L)] ÷ 155 [24].

**The Statistical Analysis**

The data were analyzed by ANOVA test by SPSS version 22. T-Test was used for the two groups, Chi-square was used for obtaining values of percentage, and a general linear model was used for groups with many factors. The correlation by bivariate analysis.
The data has been expressed by mean ± standard deviation SD.

Results

The female participants of this study had a normal body mass index (23-24 kg/m²) (Table 1). A group of females revealed a significant (p ≤ 0.05) increase in WC (94.189 cm), WHR (0.908), and WHtR (0.579) than other female participants, therefore, they have been divided to normal BMI with central obesity and normal BMI without central obesity. The female group without central obesity showed normal ranges in WC (78.419 cm), WHR (0.778), and WHtR (0.479) values.

According to anthropometric parameters, the healthy females with normal body weight showed a high prevalence of central obesity 123 (71.098 %), while the females without central obesity reveal less occurrence 50 (28.901%), table (2).

The Navy formula (table 1) revealed that the females with normal weight and central obesity are considered obese as they showed higher body fat percentage (% BF) and higher fat mass 40.55%, 25.6 kg, respectively with significantly (p ≤ 0.05) compared to the non-central obesity females group (31.5%, 19.4 kg respectively). The lean body mass that has been displayed by this formula showed that the non-central obesity females had more lean mass, 42.1 kg, than the females with central obesity 37.4 kg.

The systolic and diastolic pressure were significantly (p ≤ 0.05) elevated in normal weight-central obesity group 123.927 mmHg and 80.893 mmHg respectively compared to normal weight without central obesity 119.371 mmHg and 77.440 mmHg.

According to age groups (table 3), in the central obesity group, the second age group, 39-44y of central obesity displayed a higher WC (95.588), WHR (0.917), WHtR (0.585) with significantly (p ≤ 0.05) than the first age group (33-38 y). The Navy formula also displays insignificant differences in the percentage of body fat, fat and lean mass between the two age groups. There were significant differences (p ≤ 0.05) between the systolic and diastolic pressure between the two age groups.

In normal weight without central obesity, the second age group showed higher significance (p ≤ 0.05) values in the ratio of WC, WHR, and WHtR than the first age group. According to the Navy formula, the second age group considers obese by high significant body fat percentage and fat mass values than the first age group, which have been considered with average body fat. No significance was observed in lean mass between the two age groups. The systolic and diastolic pressure showed insignificant differences.

The biochemical parameter between the two main groups (table 4) showed significant (P≤0.005) elevation in serum lipid profiles of central obese females TG, T-ch, LDL: 163.420 mg/dl, 177.656 mg/dl, 112.7 mg/dl, and a decrease in the HDL 47.233 mg/dl compared to non-central obesity.

There was a significant (p ≤ 0.05) increase in serum glucose and insulin levels in females with normal weight and central obesity group 8.937 mmol/L, 177.884 pmol/L respectively compared to normal weight without central obesity 8.079, 171.464. Therefore, the homeostatic index of insulin resistance was significantly higher in the central obesity group 10.216 than the non-central obesity group 8.937.

The results observed an increased level of serum cortisol in normal weight-central obesity females 29.126 µg/dl with significant difference (p ≤ 0.05) than the non-central obesity females 21.621 µg/dl.

From table (5), according to age groups, in normal weight-central obesity females, it was observed that the second age group (39-44 y) showed significant (p ≤ 0.05) elevation in glucose, TG, T-ch, and LDL levels compared with the second age group. Also, there was an increase in the insulin level 179.629 pmol/L and HOMI (10.316) with significant differences compared to the first age group 176.140 pmol/L and 10.116,
respectively. The serum cortisol level displayed significant elevation in the second age group 30.531 µg/dl compared to the first age group 27.721 µg/dl.

There were significant differences in normal weight without central obesity (p ≤ 0.05) in the levels of glucose, TG, insulin, and HOMIR between the two age groups. A significant elevation in these parameters characterizes the second age group. No significant differences were observed in the levels of T-ch, HDL, LDL, and cortisol between the two age groups.

The results of the bivariate correlation analysis (table 6) showed that BMI had a positive correlation with fat mass percentage. The WC displayed a positive correlation with WHR and serum cortisol level. There was a positive correlation between WHR and HOMIR and between serum fasting glucose and TG level.

Discussion

The general anthropometric parameter to diagnose obesity in the population uses the body mass index BMI [18]. In this study, we found that the healthy females with normal body weight showed central obesity by increasing WC, WHR, and WHtR despite lowering their BMI (18.5-24.9 kg/m\(^2\)). The high prevalence of central obesity among the study participants suggests the importance of detecting the WC, WHR, and WHtR in normal-weight subjects to determine regional obesity as critical measurements for body fat distributions [25].

In this study, we compared the results of the Navy formula with the WC, WHR, and WHtR and found that the normal weight females with central obesity showed more fat percentage in both age groups. Simultaneously, the normal weight females without central obesity also showed a fat ratio and were considered obese in older age (39-43y). These results indicate that the Navy formula was adequate to determine body fitness by including all body anthropometric parameters in addition to sex and age. Also, this formula was effective in expressing fat accumulation in the normal body weight. The Navy formula is an adequate and certain formula for the detection of the body composition with similar results as using the bioelectrical analysis [26, 27], and suitable for use any time even after the physical activity [28], it has also been considered as a screening tool for body fitness and obesity complications [29].

The normal-weight females without central obesity showed high-fat percentage, especially in the second age, this may related that the Navy formula reflect the fitness degree of these participants. In our study, all participants showed a sedentary lifestyle. In the central obesity females, the formula showed a higher fat percentage as expected with increasing the abdominal fat deposit in this group.

The total body mass, including the fat and non-fat mass, was expressed by BMI. In contrast, the WC expressed only the fat accumulation in the abdominal region and HC revealed the fat tissue in peripheral body parts [20]. In normal BMI with central obesity, the increase in WC and decrease in the HC may decrease fat deposits in hips and legs [6].

In this study, the females with central obesity showed elevation in lipid profile, glucose, insulin, and HOMI, indicating that the central fat accumulation causes a disturbance in lipid and glucose metabolism and developing the risk factors leading to glucose intolerance, dyslipidemia, hypertriglyceridemia, insulin resistance, and then systematic inflammation [7].

The lipolytic activity resulting from lipids disturbance, causing high TG production and transferring to the liver, which in turn increases VLDL synthesis and TG elevation in the blood circulation, enhances the exchange of the cholesterol esters and TG hydrolyzing, leading to lower HDL levels [30]. High TG production in liver during hyperglycemia decreases the insulin clearance and causes hyperinsulinemia [31].

Some previous studies revealed the importance of determining the central obesity among people with normal weight [7, 32] as it is pointed to developed morbidities like that in obese people with central obesity [7, 33]. These because of a strong association between the central obesity and CVD, regardless of BMI [34]; also, the WC and WHR are more correlated with the risk factors of metabolic problems beyond the BMI [34, 35].

The excessive visceral fat depots in the abdominal region may cause metabolic alternations, including dyslipidemia and hyperinsulimia that elevated risk factors of cardiovascular diseases CVD [36, 37, 38]. The presence of hypertension and diabetes type 2 in normal-weight central obese individuals leading to develop cardiovascular diseases (CVD) was more than the individuals without the central obesity [39, 40].

In this study, the elevated systolic and diastolic blood pressure in normal–weight–central obesity females may be explained by the fact that the ratio of body adiposity was an independent risk factor for hypertension [41]. The risk factor of hypertension was 63% in normal-weight Malaysian women [42]. The normal weight subjects with high-fat percentages showed elevated blood pressure and were more expected to develop CVD [43].

The study results showed that the normal BMI with central obesity has high serum cortisol compared to female without central obesity, this may be related to increased visceral fat accumulation [44], or the elevated cortisol in blood circulation that caused abdominal obesity [45]. The visceral adipose tissues are supplied with more blood vessels than the peripheral adipose tissues and with more glucocorticoid receptors; therefore, the visceral fat was more sensitive to TG and glucocorticoids. The glucocorticoids, like cortisol stimulate proliferation and differentiation of human adipose tissue that causes a redistribution of fat cells from peripheral to central accumulation [46].

Conclusions

Inclusion of central adiposity measurements and body fat percentage with BMI are important parameters for
detecting body fat deposition and body fitness even in the absence of whole-body obesity. It is important to consider the metabolic alternations associated with central obesity in normal BMI to avoid the risk factors of metabolic complications. Considering normal weight subjects as a control in clinical studies based only on BMI and regardless the abdominal obesity will lead to misclassification and underestimation of blood metabolites like lipid profile and hormones that will affect the study results.

Morphological Study of the Esophagus in the Domestic Fowl

*Gallus Gallus Domesticus* (Linnaeus 1758)

Wijdan Basheer Abed¹, Hanan Raad Dheyaa Hussain², Dalia H. Al-Hamawandy³

¹Assistant Prof. Dr., Department of Biology, College of Education for pure Science (Ibn Al-Haitham), University of Baghdad, ²Assistant Lecturer, Directorate General of Education Al-Karkh First, Ministry of Education, ³Lecturer, Directorate General of Education Al-Karkh First, Ministry of Education

Abstract

The esophageal morphology of domestic fowl (*Gallus gallus domesticus*) was investigated to fill the dearth of information on the morphology of esophagus from available literature and help in understanding its digestive tract biology. The esophagus is under study as musculomembranous tubular shape, it began from oropharyngeal cavity and terminated on the proventriculus. The esophagus was divided into three regions are represented by cervical part, crop, and Thoracic part. Internal lining of the esophagus consisted of un-branched straight longitudinal folds The length of the cervical part, crop and thoracic part were 11.5 cm, 3.5 cm, 6 cm respectively.

**Key words:** Avian, chicken, esophagus, *Gallus gallus domesticus*.

Introduction

The avian digestive tract is a continuous tube that opens at either end (beak and vent) to the outside world and consists of a mouth, esophagus, crop, proventriculus, ventriculus or gizzard, intestine, ceca, rectum, and cloaca. As food progresses The esophagus is a narrow, muscular, highly-distensible tube extends from the pharynx and joins with the stomach¹. Sisson et al (1986)² observed that the avian esophagus is on the right side of neck (mammal present it was on left side) and it was placed between the pharynx and stomach glandular portion, it was thin and dilatable walls with a diameter relatively larger than of mammals. According to³ the avian esophagus consist of two parts, cervical and thoracic, while in mammals through these organs, a specific sequence of digestive events occurs, including grinding, acidifying, hydrolyzing, emulsifying and transporting of the end products⁴.

There was three parts, cervical, thoracic and abdominal. At the thoratical part of the avian alimentary tract, oesophagus enlarge to form the crop, so that, the cervical part functionally acts to lubricate the food and contact it into the thoratical part in which the food is stored and released into the other parts of the alimentary tract¹. The distensibility of the avian oesophagus, however, comes from the longitudinal folds in the inner layer of it. Unlike mammals, the avian oesophagus don’t have any sphincter in both upper and lower regions of it⁵. Crop structure and function vary according to the species and the diet, the crop is absent in the gulls and penguin so food passe directly or it is stored in the tubular esophagus⁶. The crop in duck and goose as in most birds is merely a fusiform enlargement of the esophagus⁷, crop takes a simple spindle shape while in pigeon as an herbivorous, it took a more complicated structure, whereas some granivorous species have no true crop and can store their food in a very distensible oesophagus⁸. Crop may provide a type of protection for birds by its storage function that allows the ingestion of the stored food in the evening providing the overnight energy needs, in the other hand, it also allows the birds to ingest their...
food rapidly and softly by swallow the water giving
the important security for them\textsuperscript{9}. The digestive system
of birds has adaptations to facilitate flight. Many birds
operate on a thin margin of metabolic safety and may
require a constant source of feed to sustain activity.
Birds cannot afford to store heavy food materials
for long periods and digest their food rather quickly
relative to mammals\textsuperscript{10}.

Materials and Method

Twenty adult specimens of species domestic
fowl (\textit{Gallus gallus domesticus}) were obtained from
different localities at Baghdad city, Iraq. They were
collected during December 2020 until February
2021, the animals were brought to the laboratory
alive the animals were anesthetized and decapitated
according to the international protocol for biomedical
investigation with human being and animals, then
dissected carefully by making at longitudinal incision
at the middle line of skin from ventral surface starts
from first cervical vertebrae access to pelvic region,
then the skin separated from muscles, which under it.
The thoracic region mad transverse incision, then the
skin was drawn from muscles. The peripheral muscles
were removed within ventral wall, then to cut right
part of ventral wall, followed by cut left part of ventral
wall and to complete incision across to thoracic
girdle. The gastrointestinal tract was extirpated and
esophagus was remove and measurement related
to formation study were taken which are length of
cervical crop thoracic parts.

Results

The esophagus of domestic fowl (\textit{Gallus gallus
domesticus}) (Fig. 1) was muscular membranous,
tubular shape, which began from oropharyngeal cavity
and terminated on the proventerculus (Fig. 2). The
esophagus divided into the three regions represented
by cervical part, crop and thoracic part (Fig. 3). The
cervical part of esophagus was located in the right
side of neck and began with the end of the oropharynx
and intertwined on the trachea, the length of cervical
part of the esophagus was 11.5 cm. The crop was sac-
like structure protruded in the upper part of the body
of birds began before the entering of the thoratical
cavity, it had a thin wall and very low inner folds
(Fig.4), crop length was 3 cm and thoracic part where
the crop returned to narrow was length 6 cm . The
lining of esophagus in chicken seems white color in
three part (cervical, crop, thoracic), and cervical part
of esophagus was composed of about 5 un- branched
high straight longitudinal fold, but the thoracic part
have contains about 7 un-branched straight lower
longitudinal folds (Fig.4).

![Figure 1: Class: Aves Order: Galliformes Family:
Phasianidae Genus: Gallus Species: gallus.](image)

![Figure 2: Ventral view of thoracoabdominal cavity.
L, liver; H, heart; G, gizzard; Du, duodenum; TR, trachea.](image)
Results of the present study showed that the oesophagus in the domestic fowl under investigation was an organ located on the right side of the neck and situated between the pharynx and stomach glandular. This result agrees with 2, 11.

Peristaltic contraction of inner circular and outer longitudinal muscles in the tunica muscularis propels food posteriorly through the esophagus. Esophagus was divided into three anatomical regions: cervical oesophagus, crop, and thoracic oesophagus as it was found by 12. Cervical part longer than thoraces. This result in agreement with Samuelson (2007) who study the esophagus in party Rhynchotus rufescens, also in similar with Das et al. (1967) during his study on goose esophagus. To aid in swallowing large food items, the esophagus is expandable as a result of a series of longitudinal folds. This accordion-like arrangement is enriched with mucous glands to provide lubrication that results agree with Rasha et al. (2015) in wood pigeon (Columba palumbus) and The barn owl Tyto alba, also agree with Al Kinany (2017) in Breasted Kingfisher (Halcyon symamensis).

The esophagus widens into a crop just before entering the thoracic cavity, It appears primarily in the esophagus Grain- eating birds (Granivorous) Where is a place To store and hydrate food (Parachami and Dehkordi, 2011) while being lost in Others, such as gulls (Larus melanoccephalus) (Ali, 2014) and Bustards( Bailey et al., 1997).

The crop is a sac-like enlargement on the esophagus. This description similar with Rasha et al. (2015) who studied esophagous of wood pigeon and Shehan (2012) but different with Al Kinany (2017) and Al-Jumaily and Al-Borznge (2016) who studied Esophagus in White Breasted Kingfisher (Halcyon symamensis) (Piscivorous) who founded that the bird don’t had crop, Similar with Rodrigues et al. (2012) and Bailey et al. (1997) on his study on in rheas and captive bustards respectively. Some granivorous species (eg. Cardueline Finches) do not have a true crop, but they usually have a very expandable esophageal pouch that can store food items 4. The presence of large folds of mucosa in crop allows considerable expansion and shrinkage, depending on the amount of contents. Immediately cranial to the thoracic inlet, the crop narrows to reform an esophageal tube and passes between the coracoid bones to the right of the syrinx and dorsal to the heart (Evans, 1996). Within the crop, food softens as a result of hydration by saliva added to food during

Discussion

Results of the present study showed that the oesophagus in the domestic fowl under investigation was an organ located in right side of neck and situated between the pharynx and stomach glandular this result agree with 2,11.

Figure 3: Forms, location of esophagus in Gallus gallus domesticus. CER, cervical part; C, crop; THO, thoracic part; L, liver; GB, gall bladder; G, gizzard; DU, duodenum; CO, Colon; CL, cloaca; P, pancreas ; SI , small intestine.

Figure 4: Inner view of esophagus showing LF, Longitudinal folds; CER, cervical part; THO, thoracic part; C, crop.
swallowing, mucus secreted into the crop, and water consumed after a meal. More significant digestion may occur because of the presence of enzymes in the food itself or from microbial action in the warm moist environment of the crop, the crop also provides a temporary storage area that permits a bird to rapidly forage for large amounts of food and then fly off to digest the meal in safe cover. A crop also permits “tanking up” in the evening, so that food can be slowly released to supply nutrients during the nighttime (Soedarmo et al., 1961 and Hainsworth et al., 1972). The crop and the esophagus play an important role in nourishing the young by permitting the storage and softening of food, which is later regurgitated into the beak of the nestlings. The nutritional and immunologic contribution of the hen to the regurgitated food is not known for most species, but is important in pigeons. The crop represents the first major defence against poultry pathogens and zoonotic organisms with well-established adaptive and innate immune function, and a lactobacilli dominated microbiota capable of reducing the passage of these organisms further along the digestive tract (Classen et al., 2016).

Mothers’ Knowledge toward Home Care for Children with Wilms Tumors at Pediatric Hospitals in Bagdad City

Rehab A. Ali¹, Zaid W. Ajil²
¹M.Sc., Student, Department of Nursing, Ministry of Health, Baghdad, Iraq, ²Lecturer, Dr., Department of Nursing, College of Nursing, University of Baghdad - Iraq

Abstract

Objectives: To find out relationships between mothers’ knowledge and their demographic characteristics that includes (age, marital status, level of education, family income, home location, number of family members.

Methods: A descriptive research was performed from October 1, 2020, to June 1, 2021, Non - probability (purposive) sample. In which the sample was objectively chosen from (100) mothers who participated in the study and were obtained from three Baghdad hospitals. It included 47 mothers at the Child welfare Teaching Hospital and 28 at the Central Child Teaching Hospital and 25 in the city of Miamian al-Kadhimin (peace be upon them both) in Baghdad.

Results: Mothers’ knowledge towards homecare for “Children with Wilms Tumours” at pediatric hospital’s items was not assigned at the established level in which that achieving the goal of this study.

Conclusion: Mothers’ knowledge towards homecare for “Children with Wilms Tumours” at pediatric hospital’s items was not assigned at the established level in which that achieving the goal of this study.

Keywords: Mothers’, knowledge, homecare, Wilms Tumours.

Introduction

Wilms tumour or nephroblastoma is a type of cancer that occurs in the kidneys, and this type is considered one of the most common forms in children. This type of cancer was named after the germen doctor Max Wilms, who was the first to write about the disease in 1899 [2]. Around the world about 90% children’s’ cancers suffer from this type of tumours. However, nephroblastoma often affects one side (unilateral) or two sides (both), every 100 children 7% affects both kidneys [11]. The cause of childhood cancer is unknown, although there are causative factors, including chemotherapy, radiation, smoking and congenital anomalies that have a major role in the occurrence of childhood cancer and are associated with cancer [9]. Among the causative factors of this disease are genetic or environmental factors, as well as congenital anomalies that have an effective role in this disease, as it has been proven that about 20% of children who suffer from solid tumours are infected with congenital abnormalities in the kidney where they have a defect of chromosome 11. In some cases, the tumour can progress to other tissue, such as the liver, bones, and brain, in the solution of not being diagnosed and treated early [6].

Importance of Study

The World Health Organization states that health is “a complete physical condition, social and mental well-being and not merely the absence of disease and disability [12]. This means that a disease is “a disease or a period of illness affecting the body and mind ⁵. The disease can be classified into many categories and these groups are associated with the disease: acute (it starts in the beginning and lasts a month) long-term (this type lasts about more than 6 months (chronic)
lasts for a long time and dangerous for the patient’s life \cite{7}. Wilms’ tumour is one of paediatric cancers that affect the kidneys and its present in children. Around the world about 90\% children’s cancers suffer from this type of tumour. It often affects one side (unilateral) or two sides (both), every 100 children 7\% affects both kidneys \cite{11}.

**Method and Material**

Descriptive Design that applies a methodology to achieve the study objectives to assess mothers ‘knowledge in home care of children with Wilms’ tumour in children’s hospitals in Baghdad during the period from October 28, 2020 to June 1, 2021. The research was carried out in the city of Baghdad, at three hospitals. The total sample number of children with Wilms’ tumour was (100) mothers. In the city of Baghdad, including the regions of Baghdad on both sides of al-Karkh and al-Rusafa. The sample was purposive selected which included three hospitals in Baghdad and a sample size of 100 mothers. It was divided into three categories and distributed to hospitals, including (47) samples in the Child welfare Teaching Hospital in the Medical city (28) samples in the Central Teaching Hospital, and (25) samples in the city of Al-Kadhimin, peace be upon them, in the city of Al-Kadhimiya in Baghdad.

Data were collected during the period /1December/2020 to 1/March/2021. For this study to collect data, the researcher collected data from mothers, what is their knowledge towards home care for their children with Wilms ’tumour. Data were collected randomy from three hospitals in Baghdad.

Ethical considerations were concerned throughout study process, and the Research Ethical Committee at College of Nursing was approved the questionnaire format.

Results shows that a highly significant differences are accounted at $P<0.01$ between observed distribution with their expected outcomes in each variable. Regarding of “Age Groups” most of studied respondents were focused at the third and fourth age groups (i.e. $\geq 30$) yrs., since they accounted (72.0%), “Marital Status” showed that (97%) are accounted married status, and only two of them has divorced status, and only one has recorded widowed, “Educational Levels” showed that studied women are characterized by a low educational level, as the levels of education were distributed at the highest level at the intermediate graduate school achievement , “Income”, showed that about half of the studied respondents has recorded a sufficient income, and accounted (48%) , “Residency” showed that most of studied respondents has recorded urban residence, and they are accounted (73%), and finally “Occupation” showed that all studied respondents has recorded housekeeper.

**Discussion**

The results showed that the age groups of third and fourth mothers (i.e. $\geq 30$) years are the respondents, where the percentage of them reached about 72%. According to a report by Kamal, A. (2017) on the characteristics of a thoughtful caregiver, the vast majority of caregivers are mothers. Almost two-thirds of them were between the ages of 30 and 40, with the remainder being under 40. Caregivers did not exist, and more than half of them did. They can read and write, and their parents can as well they were not related to the majority of the people. The
educational level was found to be low for educated mothers. In a related survey, it was discovered that 97 % of mothers with education had adequate awareness and activities for their children when it came to the steps of chemotherapy for children with leukemia [1]. As for the monthly income, it reached about half of the studied sample, and they recorded that they had sufficient income at about 48%. As for residency, the results indicated that most of the mothers who participated in the study were urban residence by 73%, and the occupation made it clear the results are that all mothers are housekeepers. The findings of this study were close to those of [8] who conducted research on childhood cancer in the United States cases from the pediatric cooperative clinical trials were analyzed geographically. Several organizations have stated that mother’s work allows them to spend more time with their children, her to devote more time to studying and caring for their offspring. Following statistical analysis of the results, the research sample discovered that mothers’ awareness of the direction of home care for children with Wilms’ tumor in Baghdad children’s hospitals was not at the necessary level to achieve the study’s objective. As most of the responses relevant to the field were observed in the majority of the results the “disease definition” sub-field received a moderate rating and was assigned four (80%) objects, while the remaining portion was given a high rating. The second sub-field “causes, signs, and symptoms” follows after that. The assessment was moderate for three (60%) objects, while the remaining elements received high ratings. The third sub-domain, “disease spreading phases,” received a low rating for two (66.67%) components, while the remaining component received a medium rating. Following that, the fourth sub-domain of “treatment process” was evaluated. The remaining portion received a moderate rating, followed by a fifth sub-domain of ‘Multiples,’ which received a low rating for 3 (100%) objects. In a recent Conducted by [1] it was discovered that knowing the gender of the parents makes a major difference in the treatment of children, and that knowledge among mothers differed significantly from that of fathers, despite the fact that mothers were less educated. Most caregivers lacked information about sickness, diet, home treatment, and preventive steps, according to [3]. Illiteracy and a low socioeconomic status are the causes of this lack of education. Of this study showed that there is a significant gap in these mothers’ awareness about cancer, complications, and risk factors, as well as symptoms and different aspects of chemotherapy. This lack of information may jeopardize their ability to help. Similar but less information gaps were found by [10] in their analysis. In order to encourage parents’ and inspire their children to engage in frequent follow-up, the writers stressed the importance of improving parents’ awareness about cancer, care, possible late effects, and the importance of regular follow-up.

**Conclusion**

Mothers’ knowledge towards homecare for “Children with Wilms Tumours” at pediatric hospital’s items was not assigned at the established level in which that achieving the goal of this study.

**Recommendation**

Providing a permanent program in hospitals for mothers who have children with Wilms’ tumours to keep them informed of health education about the care of their children.

**Financial Disclosure:** There is no financial disclosure.

**Conflict of Interest:** None to declare.

**Ethical Clearance:** “All experimental protocols were approved and carried out in accordance with approved guidelines”.

Morphological Description of the Esophagus in the Mallard Duck (*Anas platyrhynchos*)

Hanan Raad Dheyaa Hussain¹, Wijdan Basheer Abed², Dalia H. Al-Hamawandy³

¹Assistant Lecturer, Directorate General of Education Al-Karkh first, Ministry of Education, ²Assistant Prof. Dr., Department of Biology, College of Education for pure Science (Ibn Al-Haitham), University of Baghdad, ³Lecturer, Directorate General of Education Al-Karkh first, Ministry of Education

Abstract

The esophageal morphology of Mallard Duck (*Anas platyrhynchos*) was investigated to fill the dearth of information on the morphology of esophagus from available literature and help in understanding its digestive tract biology. The esophagus is long and highly distensible, musculomembranous tubular shape, it began from oropharyngeal cavity and terminated on the proventriculus. The esophagus was divided into two regions are represented by cervical part and Thoracic part, the crop was absent. Internal lining of the esophagus consisted of un-branched straight longitudinal folds the mean length of esophagus was about 25 cm; it was wider in the anterior part than the posterior part.

Key words: Avian, Mallard duck, esophagus, Anas platyrhynchos.

Introduction

Domesticated forms of ducks descend from two different species, i.e. from Cairina moschata and *Anasplatyrhynchos*. The mallard, *Anasplatyrhynchos*, originated in the northern hemisphere and gave rise to many duck breeds and varieties. The Mallard is widely distributed across the Northern Hemisphere, North America from southern and central Alaska to Mexico, the Hawaian Islands, and across Eurasia, from Iceland and southern Greenland and parts of Morocco (North Africa) in the west, Scandinavia to the north, and to Siberia, Japan, and China in the east. The distinctive anatomy and physiology of the avian gastrointestinal tract reflects the constraints of flight, in that most of the tract’s weight is centralized within the body cavity to optimize aerial maneuverability. The avian gastrointestinal tract has a larger number of organs, which have greater interorgan cooperation than their mammalian counterparts. The precise anatomic plan of the digestive tract of companion birds varies somewhat, depending on their typical diet.

Mallards is omnivorous and very flexible in its foods choice. Its diet may vary based on several factors, including the stage of the breeding cycle, short term variations in available food, nutrient availability, and inter- and intraspecific competition.

Birds have relatively long necks because their beak must serve the function of hands or paws in food gathering. Their esophagus is, therefore, also relatively long. It has numerous mucous glands to help lubricate the passage of food. The crop is an enlargement of the esophagus and it serves to store food for subsequent passage to the stomach. (This is analogous to the cardia in the mammalian stomach) The size and shape of crops vary between species.

Materials and Methods

The animals under investigation were collected from Babylon Governarate. Five birds were used to study the different aspects of the present study. The studied pigeons have two large lateral pouches, gallinaceous birds have a single pouch, hawks have a spindle-shaped enlargement of the esophagus and...
owls have no crop. Birds were anesthetized using chloroform. the length of esophagus and its different parts were measured.

**Results**

The esophagus of Mallard Duck (*Anas platyrhynchos*) (Fig. 1) was muscular membranous, tubular shape, which began from oropharyngeal cavity and terminated on the proventerculus, the esophagus divided into two regions represented by cervical part and thoracic part, the crop was absent (Fig. 2). The cervical part of esophagus was located in the right side of neck and began with the end of the oropharynx and intertwined on the trachea, the mean length of esophagus was about 25 cm, the mean width of esophagus was about 2.5 cm in cervical part and about 1.5 cm in the thoracic part. The lining of esophagus in Mallard Duck seems white color, the mucous membrane contain longitudinal folds varies in depth (height) and number, between them folds less tall, the cervical part of esophagus was composed of about 13 un-branched straight longitudinal folds, the thoracic part has contained about 7 un-branched straight longitudinal folds and the region in between contains about 10 folds (Fig. 3). There was a cardiac sphincter separating the esophagus and proventriculus (Fig. 4).
Figure 4: Inner view of esophagus showing ES, Esophagus; PV, proventriculus; SPh, cardiac Sphincter.

Discussion

Mallard (Anas platyrhynchos) anatomy was extensively studied in Iraq, studied anatomical and histological features of the kidney, studied Histomorphological and Histochemical structure of the stomach, studied Morpho-histological comparative study of the liver and studied Histomorphological and histochemical study of the small intestine of the mallard (Anas platyrhynchos) in south Iraq. The digestive tract of birds shows a great diversity according to their respective feeding and dietary habits, results of the present study showed that the esophagus in the mallard duck under investigation was an organ located in right side of neck and situated between the pharynx and stomach glandular this result agrees with Sisson et al. (1986). Esophagus was divided into two anatomical regions these are cervical oesophagus and thoracic oesophagus, the crop was absent this description agree with AL-Jumaily and Al-Borznge (2016) in their study of esophagus in white breasted kingfisher (Halcyon smyrnensis) (Piscivorous); Rajabi and Nabipour (2009) in Passeriformes birds and Bailey et al. (1997) in captive bustards (opportunistic omnivores) and disagree with Rasha et al. (2015); Ivey et al. (2005) and Shehan (2012) they found that esophagus was divided into three anatomical regions, cervical part, crop and thoracic part.

The results of the current study showed the presence of longitudinal folds in the mucous membrane varies in depth (height) and number, it turns out that the cervical part form longitudinal folds between them folds less tall and alternately, the diameter of the esophagus and number of folds gradually narrows towards the thoracic part this result agree with Al-Jumaily and Al-Borznge (2016).

The reason for the variation in numbers and lengths of folds maybe back to the feeding pattern as the esophagus in this study has many folds that increase widening when swallowing prey as well as narrowing of the lumen of the posterior part of the esophagus allows it to store food between its folds for a time because the crop was absent in this bird (Nickle, 1977), Although food may be stored throughout the length of the esophagus of avian species which have no crop (Ziswiler and Farner, 1972; McLelland, 1979a), In ratites, the crop is also absent and the large proventriculus and ventriculus of these birds is considered to help with food storage (Angel et al., 1996). Birds eating high-protein diets generally have less complicated digestive systems than those eating complex carbohydrates. In mallard, there was a strong sphincter between esophagus and proventriculus while it was absent in pigeon (Hassan and Moussa, 2012).

Effect of Nanoparticles and Ionization Radiation on Same Oxidant and Antioxidant Enzymes

Rafal Dawood Ali¹, Baydaa T. Sih², Dakhel Ghani Omran³

¹M.Sc., Student, ²Assistance Prof. Ph. D / Department of Physics / College of Science / University of Baghdad, Iraq., ³Prof. D / Department of Biology / College of Science for Women / Babylon University / Iraq

Abstract

Ionizing radiation effect on atoms and molecules of living organisms by formation of free radicals because it has high energy radiation which causes gain or loss one electron or more. In last year’s there are a biggest interest for using nanoparticles in medicine as a drag delivers or cancer treatments , as its will knew. The present research was focused to evaluate the effects of X- ray and nanoparticles (alone or together) on level of Malondialdehyde (MDA), it is the final product of oxidative reactions, and, on the other hand, alleviate these effects by addition of vitamin – E (as anti-oxidant) in blood samples in-vitro. Results which were yield from this research indicated that level of MDA had been significantly increased when blood samples exposed to X-rays but its values were significantly dropped in the presence of nanoparticles of titanium dioxide (TiO₂) in a comparison with those non-treated blood samples (control samples). It was well found that levels of MDA were markedly decrease in the samples treated with V-E after exposure them with both X-ray and nanoparticles. From those observations, it appear that exposure of living tissues to X-rays and nanoparticles causing production of free radicles (oxidative stress) and these adverse effects can be limited and ameliorated by treatment with antioxidant vitamins.

Keywords: TiO₂NPS (titanium dioxide nanoparticles), ROS (Reaction Oxygen Spaces), MDA (Malondialdialdehyde enzyme)

Introduction

Free radicals are naturally considered to be intracellular interactions from the metabolic processes of the cell to produce energy after Glucose or Cholesterol oxidation reactions, rapid free radicals enable to form other compounds mostly toxins or they interact with particles in cells. Free radicals are unstable atoms or molecules with free outer electrons. This makes them highly reactive because free electrons always strive to form a stable bond. This stabilization involves gaining an electron from another molecule, triggering a chain reaction. Such reactions are omnipresent in the human body, but under certain circumstances can damage biomolecules. There are many different sources of free radicals within cells and the environment. In aerobic organisms, free radicals are produced during and through normal metabolic processes. Various in vitro and in vivo studies show that free radical formation can be triggered by nanoparticles (fullerenes, carbon nanotubes, quantum dots, emission particles). Nanoparticles can be taken up actively (phagocytosis) by certain cells (macrophages) and initiate ROS formation. Passive cellular uptake of particles has also been documented. X-Ray is one of the most common electromagnetic radiation that characterised with high frequency and short wavelength, these radiation are employed to be applicator in wide range of science fields such as medicine, biology and industries. Radiotherapy has been used in treatment of many disease in particular cancerous diseases and oxidative
stress (OS) [2]. The Oxidative stress is an imbalance between production of reactive oxygen spaces (ROS) and antioxidant components within living cell that can mediate the damage of biological macromolecules including lipids, proteins and nucleic acids [3,4]. ROS are commonly called oxidants that are harmful for living tissues, among of the ROS are superoxide anion (O$_2^-$), hydrogen peroxide (H$_2$O$_2$) and the hydrogen radical (OH$^-$) as well as nitrogen reactive spaces (NRS) [5]. Reactive oxygen species can be removed and inhibited by antioxidant that are enzymatic and non-enzymatic, such as catalase and vitamins [6], such as hypertension, hypercholesterolemia, and diabetes, are associated with oxidative stress. These observations and further data derived from a plethora of investigations provided accumulating evidence that oxidative stress is decisively involved in the pathogenesis of endothelial dysfunction and atherosclerosis. Several enzymes expressed in vascular tissue contribute to production and efficient degradation of reactive oxygen species, and enhanced activity of oxidant enzymes and/or reduced activity of antioxidant enzymes may cause oxidative stress. Various agonists, pathological conditions, and therapeutic interventions lead to modulated expression and function of oxidant and antioxidant enzymes, including NAD(P Molondialdialdehyde (MDA) is the most common product of lipid peroxidation because of ROS reaction [7]. Nanoparticles were synthesized and employed in different fields of since, such as medical, biological and clean energy, these nanoparticles have been documented to induce oxidative stress because the production reactive oxygen species. [8]

**Materials and Methods**

Method of preparing and adding nanoparticles (Tio$_2$):

1. Titanium dioxide particles Tio$_2$ in a synthesized as in [9]

2. Normal Saline with concentration 20 micrograms per 10 ml (it is dissolved and placed in a water bath for 15 seconds to ensure that the nanoparticles in normal saline are distributed correctly)

**Sampling and addition method:**

1. Collecting 20-30 venous blood samples from healthy donors, with an amount of 15 ml of blood per person

2. Samples are placed in tubes containing anticoagulant

3. Blood samples are placed in the centrifugation apparatus to separate the plasma from the blood for a of 15 minutes at 3000 cycles per minutes

4. Blood plasma samples sprated to 7 test tubes (1 ml each tube), the samples classified as follows:

   a. The first sample is considered control sample (without any addition).

   b. The second sample we add 40 μl of NPSTio2 in plasma of blood to study the effect of NPSTio2

   c. The third part is left without additives for irradiation, but it is also treated like the rest of the samples

   d. the fourth part, put NP$_3$Tio$_2$ of 40 μl and radiate it to study the effect of NPSTio2 and irradiation together

   e. The fifth part, added 20 μl of therapeutic vitamin E to be used as antioxidant, not pure vitamin E

   f. The sixth part, add 20 μg of vitamin E and 40 microliters of NPSTio2 to study the effect of vitamin and nano together.

   g. The seventh part, add 20μl of the NPSTio2 and 40μg of Vitamin.E and left it around 24h to rest and after that irradiated with X-rays about 10 Gy to study the effect of radiation and the vitamin together

A chemical solution is applied to all parts of the samples except for the control sample, and this chemical solution works as a kit to measure
molondialdialdehyde, as it has been manually prepared in a chemical manner as described in [10] hydrogen peroxide (H2O2) and this kit is placed in studied and appropriate quantities for the purpose of the tests and measurements that are made on all the samples above.

* After the process of preparing the samples and left for 24 hours in appropriate conditions, away from moisture and kept at 4° C and far from the sun’s rays. The samples were examined by using a UV-visible spectroscopy device to found the absorbance for each one separately and study the differences between the different sample treatments described for the purpose applying absorbance value to the (MDA) equation and measurement.

Results and Discussion

MDA is considered to be a measure of free radicals in living cells as the time period for formation and dissolution of free radicals is very short, MDA is used as a measure of the percentage of free radicals in the body in the following research. MDA and increased enzyme measurements are the result of an increase in free radicals resulting from metabolic processes in the living cells of the human body.

Note that ionizing X-ray works to greatly increase Malondialdehyde (MDA) activity and that the MDA enzyme is responsible for creating a free radicals in the human body, which means that the radiation increases free radicals. Also noted that the samples are reduced by the presence of Tio2NPS, but by the presence of Tio2NPS and ionizing X-rays together, we notice that there is a slight increase in the value of enzyme activity.

Table (1) the activity of Malondialdehyde at (control) and Measurement the effect of NPs-Tio2, vitamin and x-ray each one at time and both to together.

Note that the MDA enzyme decreased in the presence of nanoparticles.
Fig1 (change of control)

Fig2: Average of changes
But it increased a lot when it was irradiated with 10Gy of x-rays because the x-rays increase the rate of production of free radicals, meaning that (MDA is an enzyme that results from the increase of free radicals). A slight increase in the presence of titanium dioxide and X-ray particles. We note that it decreased in the presence of vitamin E because vitamin E works to soothe and reduce free radicals. And it decreased slightly with the presence of nano-dioxide titanium + vitamin E (because the presence of nanoparticles reduces the effect of vitamin E). It also increased with the presence of (vitamin E and X-rays). Significant increase in (Nano-dioxide titanium, vitamin E and x-ray), in the cells of the human body, the use of ionization radiation (IR) was witnessed a wide applications in different fields of science such as medicine, diagnostic, methods and therapeutic options [11]. Recent studies was conducted by [12] confirmed that decrease or minimize the adverse stress by addition of vitamin D and melatonin hormone whose functions are ameliorating of oxidative stress and they have protective effect to minimize side effects of ionizing radiation. It is well documented the deterioration effects of (IR) are induce oxidative stress when attack living tissue, since, the (IR) causes ionization chemical structures including organic and non-organic structures of living cells [13]. Previous experimental study was conducted on rat animal in this study 1000 GY does of ionization radiation was exposed to head of animals the obtaining results inducted results of lipid peroxidation which manifest itself by increment of carbonyl and methylene group of lipid component as well as decrease member fluidity, strength of hydrogen bonds located in phosphate groups [14].

In addition, another previous experimental research investigate the effects of X-rays of antioxidant system of rabbits, the study involved in poseur of exposure of animals to 550-rad- X-rays with administration

Antioxidant vitamin (E and C) and antioxidant minerals (Manganese, Zinc, and copper) the results of this study showed increase of Malondialdehyde (MDA) and decrease of glutathione peroxidase in irradiated group without antioxidant (vitamin and minerals) but those group which administered with antioxidants do not affected with oxidative stress after irradiation because reinforcement of antioxidant system [15]. In conclusion, the results which are recorded above, it obviously appear that ionizing radiation and nanoparticles, alone or combined, can increase levels of free radicals but the application of synthetic antioxidant vitamins have ability to ameliorating and alleviate these effects

Abstract

Five types of grain available in local markets have been selected, viz: Barleys, Oat, Sorghum millet and wheat bran. They were milled in the form whole grain and replaced with proportions 5, 10, 15, and 20% of wheat flour extraction 72% with the control mixture 100% Wheat flour stored at laboratory temperature and Cooling for 24-72 hours and studied the effect of dietary fiber on the changes that occur during storage and Staling. It was found that the moisture of the crust increase when storing at laboratory temperature for a period of 24 hours and the increase continued after 72 hours until the equilibrium state was reached. As for the Crumb moisture, sediment value, Swelling Power, pH, Electrical conductivity and turbidity decreased rapidly after 24 hours at both temperature and continued to decrease slowly after 72 hour. This is due to the occurrence of starch retrogradation, the transformation of the starch from the amorphous state to the Crystalline state with loss of moisture in the bread crumb accompany by increase in the moisture content of the crust.

Keywords: Effect, Dietary fiber, storage properties, bread.

Introduction

Bread is one of the staple and important foods in developed and developing countries. Because it is an important component of the human diets a sources of Carbohydrate, Proteins, minerals and vitamins, bread is an important staple food made of wheat flour, salt and Yeasts. Bread Contains a wide range of important nutritional components which provide a positive effect on human health. The most important factor that was considered by researchers and manufactures was Producing bread high quality and long shelf life. Bread quality may undergo physical and chemical changes which called Staling. These changes caused decrease of bread firmens, flavor losses, and resulting in product determination. This phenomenon is frequently attributed to starch retrogradation, a tern used denot partial recrystallization. These changes differ from those that can occur to bread by the action of microorganisms.

Whole grain are used in the bakery industry to add dietary fiber which is important in reducing the risk of developing some chronic diseases such as diabetes and stroke (Wetlon et al., 2005; Montonen et al., 2003) Colon Cancer, Obesity.

Dietary fiber increases the absorption of the bread dough with water, which in turn helps preserve the thirst of bread for a long period of time during storage and reduce the occurrence of Staling.

Materials and Method

The whole grain was ground into five types of available in the local market have been selected viz: Barley, oat, sorghum millet and wheat bran, replaced by the ratio, 15, 10, 5 and 20% from wheat flour 72% extraction. It is used to make four types of bread:

First mixture: 80% Wheat flour, 10% Wheat bran and 10% Barley flour (WWbB).
Second mixture: 75 % Wheat flour, 5% Wheat bran, 5% Barley, and 15 % Oat flour. (WWbBO).

Third mixture: 80% Wheat flour, 5% Wheat bran, 10 % Oat flour and 5 % Sorghum. (WWbOS).

Fourth mixture: 75% Wheat flour, 5% Wheat bran, 5% Barley, 5% Oat, 5% Sorghum, and 5% Millet, (WWbBOSM).

Storage Test

Staling tests

Moisture in the crumb and crust

Moisture in the crumb and crust estimated according to the method mentioned in ACCC (2000).

Estimation the Swelling Power in the crumbs

The swelling power in bread crumb was determined to the method mentioned by AACC (1998) (20-50) with a weight of 2 gram in 50 ml centrifuge tubes, added 20 ml distilled water, mix the contents well for 30 minutes, centrifuged the tube with sediment and determined this swelling Power from the equation:

\[
\text{Swelling Power} = \frac{(A + B) - D}{B}
\]

A: weight centrifuge tube.

B: weight of the sample.

D: weight the sediment with the tube.

Determinations of pH

pH values of the Crumb was measured according the method of AOAC (2007).

Electrical conductivity

Electrical conductivity according to the methods described in Bales et al. (2011). Weight 10 gm of the selected backed and added 75ml of distilled water, mix well for 15 minutes and left 60 minutes, The filtrate was drained in to a glass cylinder and electrode of the apparatus was immersed in the solution the reading was recorded in mili Moz, The final was taken from the product of the device reading in the correction factor in special tables.

Turbidity

Turbidity according to the method described in Sobolewska and Fortuna (2010), added 75 distilled water to 10 gm from backed Crumb, Mix well for 15 minutes, left for one hour, the filtrate was drained into glass cylinder, take 5 ml from filtrate and put in tube for the device with the additions of 5 ml of distilled water, the tubes were closed tightly, the device reading recorded after the tubes were placed in NTU unite.

Statistical Analysis

The experiments were performed in a completely randomized design. All experiments were conducted in triplicates and the mean values and standard deviations were reported. Analysis of variance) ANOVA) was performed and results were Separated using the Multiple Ranger Duncan’s test (p > 0.05) using Statistical Software of Statistical Package for the Social Science (SPSS), Version 16 (SPSS Inc. New Jersey, USA).

Results and Discussions

The effect of adding dietary fiber on the bread staling

staling tests

The effect of adding dietary fiber on the moisture content of the crust and Crumb of bread stored at different temperatures and time periods

The tables (1) (2) showed the moisture of the crust and the crumb stored for a period of 24 and 72 hours at a room temperature and in a refrigerator at 5°C. Table (4-15) shows that there was significant differences (p < 0.05) in the percentage of moisture between the baked crust and control treatment. The results revealed an increase in the percentage of crumb moisture in the bakery products (WWbB, WWbBO, WWbOS, and WWbBOSM). The
The percentage of crumb moisture was 17.1 - 20.3 and 18.7 - 21.5% for WWbB, WWbBO, WWbOS and WWbBOSM respectively for a period of 24-72 hours at a room temperature and in a refrigerator at 5°C. The results also found an increase in the percentage of control sample compare to the bakery products. The moisture of the crust in in the bakery products increased faster within 24 hours of storage due to the migration of moisture from the crumb to the crust. In Contrast, the increase in the moisture became slower after 72 hours of storage.

Control : 100% Wheat flour.

1-: 80% Wheat flour, 10 % Wheat bran and 10 % Barley flour. (WWbB).

2- 75 % Wheat flour, 5% Wheat bran, 5% Barley, and 15 % Oat flour. (WWbBO).

3- 80% Wheat flour, 5% Wheat bran, 10 % Oat flour and 5 % Sorghum. (WWbOS).

4- 75% Wheat flour, 5%Wheat bran, 5% Barley, 5% Oat, 5% Sorghum, and 5% Millet, (WWbBOSM).

Table (1-2) shows significant differences in the moisture of the crumb of the bakery products stored for a period of 24 and 72 hours at a room temperature and in a refrigerator at 5°C. The results noticed that the percentage of moisture of the crumb in the bakery products was decreased after 24-72 hours at a room temperature and in a refrigerator at 5°. The highest value of moisture was in the first sample 24.8%, which decreased to the 23.6 % after 24 hours at a room temperature. It continued to decline from 23.3% to 23.1% after 72 hours in a refrigerator at 5°C. It was also noticed that all the bakery products was better than the control sample of 23.5 and 22.1% after 24 hours at the room temperature to reach 21.6 and 21.2% in a refrigerator at 5°C after 72 hours of storage. The results also exhibited that the water content of the stored bakery products was decreased faster at room temperature for a period of 24 hours than the products stored in refrigeration after 72 hours.

The Tables (1) and (2) show an increase in the percentage of crust water content in the manufactured bakery products in the laboratory. Thereafter, the water content was decreased during the storage due to the addition of dietary fiber in different proportions that contain groups of hydroxyl that have the ability to The connection of water by forming the hydrogen bonds between the food fiber and the starch. This leads to a delay in the starch retrogradation, thus the bread retains its freshness for a longer period of time.
The process of amylopectin retrogradation in the starch is mainly responsible for the hardening of the bread crumb.

The phenomenon of staling is a major cause of spoilage of bread during storage, due to the transfer of moisture content from the crumb of bakery products to its crust until reaching a state of equilibrium in the moisture of the crust and crumb during the storage. Then, the transfer of moisture content stopped, which leads to a decrease in the moisture content of the baked crumb.

Effect of adding dietary fiber on the sediment volume and the pH to mixtures stored at different temperatures and for different time periods

The results in Table (1-3) showed that there were significant differences in the sediment volume of the water crumb for the manufactured bakery products. The values of the sediment volume in the watery crumb for all manufactured bakery products decreased after 24-72 hours at a room temperature and in a refrigerator at 5°C. The bakery products of the first mixture significantly better than the rest of the bakery mixes regarding the sediment volume after 24-72 hours at a room temperature and in a refrigerator at 5°C, followed by the bakery products of the second mixture. The results also indicated that the bakery products of all mixtures were significantly better that the control mixture after 24-72 hours at a room temperature and in a refrigerator at 5°C. Whereas, the results showed no significant differences between the bakery products of the first mixture and second mixture at room temperature for a 24 hours due to the high volume of the water crumb sediment. The decrease in the storage capacity to retain the moisture content during the storage period led to the possibility of the phenomenon of starch retrogradation and the shift from the amorphous state to the crystalline state with the possibility of water migration from the bread crumb to its crust.

The results of Table (1-4) show that there were significant differences in the pH values of the manufactured bakery products in the laboratory. These products showed a slight decrease in the pH values after 24-72 hours at a room temperature and in a refrigerator at 5°C. The pH of the bakery products of the first mixture was significantly higher among all mixtures. The values of all the bakery products increased compared to the control mixture. The results also were found that the pH of the bakery products mixtures was decline after storage for 72 hours. The pH was used to know what happens during the occurrence of the phenomenon of starch retrogradation and the shift from the amorphous state to the crystallized state. The phenomenon of bread flaking can be followed, as it is possible to follow up on the changes that occur in the starch by studying the effect of acidity on the properties of gels in starch.

The effect adding dietary fiber on electrical conductivity and turbidity of mixture stored at different temperatures and time periods

Table (5) shows significant differences in the electrical conductivity of the manufactured bakery products in the laboratory. The electrical conductivity of the manufactured bakery products was decreased after 24-72 hours at a room temperature and in a refrigerator at 5°C. The results showed that the highest electrical conductivity was the bakery products of the first mixture of 3.81 dS/cm, which then decreased to reach 3.73 dS/cm after 24 hours of storage at room temperature, while the electrical conductivity of the bakery products of the first mixture was declined from 3.64 dS/cm to 3.61 dS/cm in a refrigerator at 5°C for a period of 72 hours. In contrast, the value of electrical conductivity of bakery products for all mixtures was higher than the control sample at the same storage conditions. It is also noted that the electrical conductivity of bakery products for all mixtures decreased significantly after 24 hours at a room temperature and in a refrigerator at 5°C, while the decrease was slow after 72 hours. The electrical conductivity test is one of the main modern tests used to monitor the occurrence of the Staling of bread, as the electrical conductivity is a measure of the material’s ability to pass the electric current. This test was used often to know the moisture content in the materials. Therefore, measuring the electrical conductivity in the crumb of the bread is an accurate measure of the shelf life of the bread (Saleh et al., 2016). This result was in agreement with Bales et al. (2011) who found a clear decrease in the electrical conductivity in bagged and unpacked of bread during storage. Chintan and Nagaraju (2010) mentioned that the electrical conductivity decrease was greater during a 24-hour due to the moisture content and its movement between the crumb and the crust until reaching equilibrium.

Table (6) shows the significant differences in the percentage of crumb swelling power in the manufactured bakery products in the laboratory. The results observed that swelling power decreased with increasing the time of storage at a room temperature and in a refrigerator at 5°C. It also found that the swelling power of all bakery products at the room temperature for a period of 24 was 2.32 - 2.65%, which decreased to reach 2.24 - 1.38 after 24 hours at the same temperature. Whereas, the swelling power of the crumb after 72 hours in a refrigerator at 5°C reached 2.20 - 2.41 and 2.18 - 2.38%, respectively. The results showed that all mixtures of the bakery products had higher values compared to the control sample. The results were consistent with 8 who studied the swelling power of crumb in bakery products after storage for four days. They stated that the swelling power was decreased by 13.3% on the second day, while it decreases by 7% on the fourth day due to the occurrence of the staling of starch retrogradation and the shift from the amorphous state to the crystalline state.

Control : 100% Wheat flour.
1. 80% Wheat flour, 10% Wheat bran and 10% Barley flour. (WWbB).

2. 75% Wheat flour, 5% Wheat bran, 5% Barley, and 15% Oat flour. (WWbBO).

3. 80% Wheat flour, 5% Wheat bran, 10% Oat flour and 5% Sorghum. (WWbOS).

4. 75% Wheat flour, 5% Wheat bran, 5% Barley, 5% Oat, 5% Sorghum, and 5% Millet. (WWbBOSM).

Table (1-7) shows the significant differences in the average values of turbidity of the solution of the crumb of the manufactured bakery products in the laboratory. The results showed that the manufactured bakery products for mixtures were significantly superior to the control sample. The turbidity values for manufactured bakery products were 293-794 NTU and 234-701 NTU at a room temperature and in a refrigerator at 5°C after 24-72 hours. The results also found that manufactured bakery products for all prepared mixtures had higher values than the control sample of 307, 277, 246 and 227 NTU respectively at the same storage conditions. A significant decrease in the turbidity value of all bakery products was observed in the first 24 hours of storage, while the decline was slower after 72 hours of storage. The turbidity test can give an idea of the qualitative description of the Staling of retrogradation in the bread, and this test can also be used to know the effects of storage on this Staling and the extent of the effect of the Staling bread on stored bakery products, and this test was also used to find out the effect of adding Maltodextrins on the Staling of starch retrogradation.

Conclusion

In conclusion, the results were consistent with those of Abdul Aziz N, Bhat R, Azahari B. Storage studies of bread prepared by incorporation of the banana pseudo-stem flour and the composite breads containing hydrocolloids. CyTA-Journal of Food. 2014; 12(2): 141-149. who confirmed an increase in the percentage of moisture in the crust after 72 hours of storage, whereas the percentage of crumb moisture, the volume of the watery crumb sediment, swelling power, pH, electrical conductivity, and turbidity were gradually decreased during the storage period. The reason for the decrease in the ability of the crumb to retain water was due to the occurrence of the staling of starch retrogradation from the amorphous state to the crystallized state and the transfer of water from the crumb of the bread to its crust, therefore, the occurrence of the Staling of bread increases when the swelling power, the size of the sediment in the crumb, pH, electrical conductivity, and turbidity decreases.

The Level of Anxiety and Depression in Patients with Lung Cancer in Al-Diwaniyah Teaching Hospital

Mortada Abdel Reda Eajal1, Kareem R. Sachit2
1M.Sc., Student, 2 Assist. Prof. Dr., Department of Psychiatric and Mental Health Nursing, College of Nursing, University of Baghdad

Abstract

Objectives: To assess level of anxiety and depression among Patients with lung cancer. To find out the relationship between level of anxiety and depression with age, gender, educational level, occupation, residence, frequency of admission, marital status, and monthly income.

Methodology: Descriptive analysis designs are used to conduct the study. The study period started from March 1th, 2021 to April 15th 2021 at the Department of Oncology in Al-Diwaniyah Teaching Hospital. Total of (110) patients selected from oncology department in Al-Diwaniyah Teaching Hospital. ten patients were excluded from the study for the pilot study. So the total number of patients participating in the study was (100) patients. The depression and anxiety Scale are consisting from 14 items self-rated questionnaire that involves two dimensions. These are depression (7 items) and anxiety (7 items). These items are measured on a (4) point Likert-type scale of 1 (Not applicable), 2 (Somewhat applicable), 3 (Often remarkable) and 4 (Very often applicable). The total score is computed by summing scores of all items. The score of each dimension is calculated by summing the scores of the items and dividing by the number of items.

Results: The demographic and clinical characteristics of the samples the vast majority of the patients were (73%) were all males, (85%) are married couple, the participants (48%) were housewives and unemployed, (62%) from lung cancer patients are urban, (46.8%). Monthly income, Concerning the significant differences between depression and anxiety with patients’ age, the study showed that there is high significant difference in depression symptoms with regard to older age patients at p-value= 0.001 respectively.

Key words : lung cancer, anxiety, depression.

Introduction

Lung cancer is a serious disease that puts people’s lives in jeopardy. Lung cancer in charge of more than a quarter (27%) both cancer-related deaths. The diagnosis and treatment of cancer will bring up a wide range of negative emotions, including anxiety and depression. Patients with malignant diseases, especially lung cancer, suffer from a high rate of depression and anxiety. Anxiety, depression, and other forms of emotional distress have been shown in studies to have a detrimental impact on lung cancer patients’ standard of life and even survival 1. Small cell lung cancer (SCLC) and non–small cell lung cancer (NSCLC) are two of the most common forms of lung cancer. The most prevalent form of lung cancer is non-small cell lung cancer (NSCLC), which accounts for 85 to 90 percent of all cases. Squamous cell carcinoma, adenocarcinoma, and large cell carcinoma are the three subtypes of NSCLC, which account for 85 to 90 percent of all cases. Adenocarcinoma and squamous
cell carcinoma are the most prevalent histologic subtypes; NSCLC cases account for 50% and 30% of all cancer cases, respectively. Small cell lung cancer affects ten to twenty percent of lung cancer patients. Its aggressive genetics, proclivity for early metastatic disease, and poor prognosis set it apart from other forms of cancer. In addition, Lung cancer is the most common cancer-related death in the world. Despite advancements in treatment effectiveness, affected patients also suffer from debilitating disease-linked signs and symptoms such as dyspnea, cough, nausea, anxiety, depression, insomnia, and pain. Lung cancer patients can suffer a wide range of health problems, including psychological distress as a consequence of cancer or its therapy unfavorable impact. Physical activity and exercise can help to reduce these symptoms. Comorbid depression and other psychological disorders are common in lung cancer patients, also a wide range of physical symptoms. For example, Progressive illness, pulmonary venothrombosis is a complication of lung cancer, or until therapy lung cancer may cause anemia and anorexia. Progression of disability exacerbates distress, anxiety, and depression in people with metastatic lung cancer, a lack of autonomy, unrelenting physical symptoms like pain, or underlying mechanistic triggers like systemic inflammation are all possible causes. Anxiety and depression are both severe and chronic mental illnesses. Anxiety is described as an uncomfortable feeling of danger or possible harm that lasts for a long time, which is frequently accompanied by fear, discreet, lack of concentration, Muscle pain, palpitations, and Mood swings, lack of enjoyment or interest in hobbies and sports, reduced motivation, difficulty focusing or making choices, Depression manifests itself in a variety of ways, including disturbed appetite and sleep, psychomotor like irritable bowel syndrome, insomnia, psychomotor agitation, and attempted suicide. Patients’ capacity to withstand the disease burden and aggressive treatment regimens can be harmed by anxiety and depression, this lengthens hospital stays, lowers quality of life, and raises mortality rates.

Methodology

Design of the Study: Descriptive analysis designs are used to conduct the study. The study period started from February 14th, 2021 to April 15th 2021.

Setting of the Study: at the Department of Oncology in Al- Diwaniyah Teaching Hospital.

A Sample of the Study: Total of (110) patients selected from oncology department in Al-Diwaniyah Teaching Hospital. ten patients were excluded from the study for the pilot study. So the total number of patients participating in the study was (100) patients.

Instrument: The study instrument includes the patients’ socio-demographic sheet and the Depression, Anxiety and Stress Scales

Reliability of the practice Items: The reliability of the instrument was determined through the computation of Alpha Cronbach’s test (Alpha Correlation Coefficient); internal consistency method was used for determining the reliability. The Alpha Correlation Coefficient was applied to determine the reliability of the present study instrument by application of Statistical Package for Social Science Program (IBM SPSS) version 24.0.

Statistical Methods: The data were analyzed using SPSS (Statistical Package for Social Sciences) version 25 application of statistical analysis system. The following statistical data analysis approaches were used for analyzing and assessing the results of the study.
## Result

</table>
This table shows that more of patients are males (73%) and remaining are females (27%). The variable of age refers that they are older patients in which the highest percentage is 58% for those with age 59 years or more. Regarding residency, 62% of them are resident in urban areas and 38% are resident in rural areas. The level of education among patients refers to “read and write” as recorded with high percentage of 44% among them. The marital status indicates that more than half of patients are married (52%) and 14% are still unmarried.

The occupational status refers that 48% of them are jobless or housewife and 22% of them are retired while only 14% are still working as employee.

The patients are perceived insufficient monthly income as reported among 68% while 23% are perceived barely sufficient monthly income. 51% of them are having their own house while 36% are live in rented houses.

This table exhibits that patients are associated with moderate to high anxiety level; in which 54% are associated with moderate level and 43% are associated with severe level of anxiety.

This chapter presents a systematically designed interpretation and reasonably derived discussion of the results with the support of the available related studies.

**Part I: The Discussion of the patients’ Demographic Characteristics and clinical characteristics of the Study Sample, as Shown in Table (4.1) and Figure (4.1) and (4.2):**

According to the findings of the study, the vast majority of the patients were (73%) were all males, as showed in (Table 4-1). This finding supported by Khue et al. (2019) and Hu et al. (2018) who discovered that the vast majority of the study participants were men.

Concerning educational levels, the majority of the sample patients (44%) was read and writes, as showed in (Table 4-1). Patient’s level of education could control detecting of the symptoms in the earlier stages of the cancer, and decreasing the effect of the...
risk factors as well as the complications by enhancing their awareness toward the disease and also treatment modalities. So, most of persons who suffer from is poor of education have higher risks of cancer. The educational level gives an indicate about patients awareness toward illness so, a high level of education means a high level in their awareness toward the disease, and low level of education means less awareness with increasing stress levels in their lives. This finding comes along with Hu et al. (2018) who discovered that the bulk of the study subjects came from elementary school and lower (50 percent).

In terms of employment status, the current study’s results show that the majority of the participants (48%) were housewives and unemployed, as showed in (Table 4-1). This result is supported by Hu et al. (2018) found that 85.1 percent of the people in the study were unemployed. The higher the educational standard, the higher the number of people who can read and write.

In terms of home ownership, the majority of the study patients (51%) are homeowners, as shown in Figure 1. (Table 4-1). This contradicts the findings of Ni et al. (2018), who found that the majority of the study participants were share (85 percent).

Regarding residency, the bulk of the lung cancer cases in the sample, (62%) from lung cancer patients are urban, as mentioned, one of the most important causes in increasing risk of cancer is the environment. In Iraq, highly increment of environmental pollution as a result of the chemical factors affecting air like industrial pollution and explosions also the remnants of War, participates in being the most important risk leading to cancer factors especially in big cities. This finding disagree with Choenyi et al., (2016) in Uttarakhand shown the area of living most of the cancer patients 35 (58%) belonged to rural area, 25 (42%) were from urban area.

Related to monthly income, the majority of the sample patients are insufficient monthly income (46.8%). Monthly income may be play a role in patient information about self-care, poverty is considered as an important indicator that may raise the risk of developing the cancer and delay the early detection due to money shortage of the family. This result is supported by Cancer Research UK (2012) in their reports, The study found that as the prevalence of cancer rises in low and middle-income countries, the global risk of cancer and cancer-related death rises.

It has been shown out of the analysis that 69% of patients are with 3-4 years duration of illness and 16% are diagnosed since 1-2 years. This mean that are recently diagnosed with cancer and this duration may be a source of stress for these patients as diagnosed with such illness. This finding is slightly different from findings of Polanski and others who report that patient with limited stage are between 1 and 1.5 year while those with end stage are between half year to one year (Polańska J, Rosinczuk J, Chabowski M, and Szymanska-Chabowska A, 2015).

The number of admission referred that 66% of patients are admitted more than three times to hospitals and 32% are admitted only twice. This finding indicates that patients are on regular treatment which may contribute to their stress and markedly increase their depression and anxiety. Skaug and his colleagues found in their study and stated “Median survival time was 170 days. Mean age at the first admission was 67.4 years (range 21–89 years). Median number (inter quartile range) of admissions was 3 (2, 5) and total hospitalization days 35 (18, 58)”.

Part II Assessment of Depression Levels among Patients with Lung Cancer:

According to the findings, patients with lung cancer experience mild depression as a result of their illness. These findings are along with study performed by, who revealed the lung cancer patients experience a lot of anxiety and depression. Hospitalization is linked to higher rates of anxiety and depression, necessitating effective interventions. Hu et al. (2018) published another study that found that
the diagnosis and treatment of lung cancer patients has a significant impact on their mood.

**Part III Assessment of Depression Levels among Patients with Lung Cancer:**

Patients with lung cancer experience mild anxiety as a result of their illness, according to the findings of the report. In most of the questions, anxiety levels were higher. Patients with lung cancer may be increase sensitive and feel the pressure, which can impact their recovery and make them more frustrated. These findings are along with study performed by Khue et al., (2019). Anxiety and depression were found to have the highest proportion of respondents having any issues (92.8 percent).

**Conclusions**

1. Most of lung cancer patients have severe levels of anxiety.
2. Most of lung cancer patients have severe levels of depression.
3. Most socio-demographic characteristics of the sample are: age (59 and more) years old, males, married, insufficient monthly income, reads and writes, housewives, live in urban area, owned house, duration of lung cancer (3-5) and admitting frequently three times through month.
4. There is no significant association between level of anxiety and level of depression with the patient’s age, gender, educational level, marital status, monthly income, occupation, residence, frequency of admission, duration of lung cancer.
5. There is significant difference in depression symptoms with the patient’s age.
6. There is significant difference in anxiety symptoms with the patient’s level of education and occupation.

**Recommendations:**

The present study recommended that:

1. Increase the level of awareness for lung cancer patients and their families about the nature and stage of lung cancer and how to minimize their distress which caused by the disease.
2. Improve the psychological and emotional status of lung cancer patients; especially by nursing staff after taking chemotherapy treatment use psychological treatment reduce anxiety and depression for cancer patient.
3. By using educational programs and posters about lung cancer, development stages, treatment and side effects of treatment and how to prevent anxiety and depression for cancer patient.
4. Coordinate between oncology center and the Department of Psychiatry in the hospital for giving treatment to reduce anxiety and depression levels.
5. Support for lung cancer patients through the government economically and provide the required treatment.
6. Conducting similar studies at the national level on the largest sample to assess anxiety and depression among lung cancer patients.

**Financial Disclosure:** There is no financial disclosure.

**Conflict of Interest:** None to declare.

**Ethical Clearance:** “All experimental protocols were approved under the Department of Psychiatric and Mental Health Nursing and carried out in accordance with approved guidelines”.

Self-esteem of Children Living with their Parents for Secondary Schools in AL-Rusafa: Comparative Study to the Children Living in Orphanage

Rehab K. Habsi¹, Zaid W. Ajil²

¹M.Sc., Student, Department of Nursing, Ministry of Health, Baghdad, Iraq, ²Lecturer, Dr., Department of Nursing, College of Nursing, University of Baghdad, Iraq

Abstract

Objectives: to find out differences in the level of self-esteem between orphanage children and children who live with their Parents.

Methods: A descriptive studies that use comparative design. The method of A Purposive sampling is used which is located in Rusafa, Baghdad. The sample size was 200 students (male and female) from all secondary schools in Baghdad al-Rusafa who lived with their parents, and another 200 adolescent who lived in an orphanage. The data was collected during January 11th to March 2nd, 2021. Short form of (coopersmith,1967) scales for assessing self-esteem level.

Results: The result of the study shows that highly significant differences are accounted between studied groups at P<0.01 regarding of studied “Negative’s Items Domain”, and “ Overall Evaluation”, while no significant different was accounted with reference to “Positive’s Items Domain”. Through the results of the significant comparisons, it becomes clear that the trends of the negative items of the scale are the distinguishing evidence between the two studied groups at the time when the outcomes of the positive trend items didn’t formed the presence of significant differences between the two groups.

Keywords: Self-esteem, Children, Orphanage, Secondary School

Introduction

Self-esteem is a term related to the concepts of self-image and self-consciousness. There are many attempts used to describe self-esteem, the best of them admitted that it represents the manner in which each individual evaluates himself related to the group. William James was the first who puts the term self-esteem in 1890, making it one of psychology’s oldest concepts. The development of the phase of self-esteem is critical especially during the age of adolescence. The development of self-esteem may it encourages by both teachers and parents. Self-esteem level is expressed in the attitude of adolescent and behaviour at home as well as at school. Adolescence is a critical period for developing self-esteem and self-identity. When self-esteem is low may threaten adolescent emotional control.

Adolescence is a time of transition, both physical and Psychological, and often a time when they develop a sense of their own identity in which interactions between families and peers play a crucial role. Some adolescents do not receive the individual affection and love that others of their age receive from both parents. Some are left to fend on their own, while others are packed off to live in institutions or with relatives. While an alternative choice is given for the child to be in a foster family or an orphanage home.

Material and Methods

Descriptive study was use comparative design.
The method of sampling was Purposive sampling is used. The research design was used and carried out in order to achieve the study’s goals that evaluate the self-esteem of children living with their parents of secondary schools in al-Rusafa comparative to children living in orphanages which is located in Rusafa, baghdad. The research instrument consists of three axes: 1-a list of common items for the participating students’ demographic data assessment, II-a list of common items for the Orphan demographic data assessment, III Coopersmith self-esteem scale. The study instrument is then revised by a variety of experts From inside and outside the college of nursing. The research was conducted in baghdad, in forty-one secondary schools. It was carried out in Rusafa for secondary schools, which includes (Rusafa I, Rusafa II, Rusafa III Sadr City), Baghdad governorate general directorate of education and orphanages in baghdad governorate in rusafa. The data was collected during January 11th to March 2nd, 2021. The content validity and reliability was performed to the tool of study before used, a pilot study was conducted before data collected with (10) children living with their parents and (10) children living in orphanage and they were excluded from study sample. The score are consists 25 items of short form introduced by (Coopersmith, 1967) using (Likert) score of the fifth categories scales, such that (Strongly Disagree, Disagree, Neutral, Agree, and Strongly Agree) by the integer numbers (1, 2, 3, 4, and 5) respectively, and The data was analysed by (SPSS) ver. (21.0), frequencies and percentages, mean of score, standard deviation, relative sufficiency, as well as evaluation for observed responding through using differentiated intervals: [(20.00 – 46.66) for Low (L) evaluation; (46.67 – 73.33) for Moderate (M) evaluation; and (73.34– 100) for High (H) evaluation].

Testing based on Mann-Whitney test.

In the table (2) most of children living with their parents from secondary schools has a better responses to the phrases of coopersmith scale, this findings mean that children living in orphanage had low self-esteem compare to children living with their parents for secondary school, from the researcher point of view may be related to school environment, teacher-student interaction, and activity structure, such as debate competitions, are likely to aid in the promotion of self-esteem and serve as a nurturing factor in the development of confidence in all school-aged children. In Pakistan clarified that students showed high self-esteem.

Figure (1): Negative and Positive Percentile (Grand/Global) mean of score for “Self-Esteem” Score in the studied groups

Results shows that highly significant differences are accounted between studied groups at P<0.01 regarding of studied “Negative’s Items Domain”, and “ Overall Evaluation”, while no significant different was accounted with reference to “Positive’s Items Domain”.

Through the results of the significant comparisons, it becomes clear that the trends of the negative items of the scale are the distinguishing evidence between the two studied groups at the time when the outcomes of the positive trend items didn’t formed the presence of significant differences between the two groups.
Discussion

Self-Esteem of Children living with their parents for secondary schools at Al-Rusafa in comparative with the study group of Children living in orphanage home through the short form of (Coopersmith, 1967) scales shows that most of Children living with their parents has a better responses due to their self-esteem than Children living in orphanage home. The trends of the negative items of the scale are the distinguishing evidence between the two studied groups, and orphan who are living in the orphanage are more reliable for this study.

The present study results showed that highly significant differences in self-esteem between orphan children and children living with their parents regarding overall evaluation where the negative items of the scale are the distinguishing evidence between the two groups. This finding is supported by study conducted in Anantnag district of Jammu and Kashmir by 6, in their study on self-esteem of institutionalized orphan children and family reared. Stated that orphans children have a lower degree of self-esteem than children living with both parents.

Agree with study conducted by 1, in Dubai-UAE (United Arab Emirates) in titled orphan and non-orphan children’s self-esteem and depression who reported that non-orphan children received a high self-esteem score relative to their orphan children’s counterparts. Also, agree with study conducted in India done by 9, in their study A comparison of self-esteem and depression levels in adolescents living in orphanages with those living with their parents. They reported that low self-esteem and high depression in orphan children. Furthermore, Mr. Siyad and Mr. Muneer, (2016) consistent with the findings of the current study, they mention that lower self-esteem was reported by orphan children than by children living with their parents, and Farooqi and Intezar (2009) supported this results and, they reported that Children have lower levels of self-esteem in orphanages than children living with their parent’s

Conclusion

Self-Esteem of children living with their parents for secondary schools at Al-Rusafa in comparative with the study group of Children living in orphanage home through the short form of (Coopersmith, 1967) scales shows that most of children living with their parents for secondary schools has a better responses due to their self-esteem than children living in orphanage home in light of studied items, and especially at the negative trend items.

Recommendation

The study recommend that future studies need to apply a wide and diverse sample of participants from various schools and orphanage in Iraq’s provinces will be repeated to obtain more externally valid results.

Abstract

Background: Coronavirus disease (COVID-19) is a contagious disease caused by a newly discovered coronavirus. Coronaviruses transmits through personal contact and infection severity ranges from mild to severe one. Methods: Descriptive cross-sectional design study to assess Knowledge, Attitudes and Practices towards Coronavirus Disease 2019 (COVID-19) Among the Public in Baghdad city. The study started from 10th April until 15th August 2020 during pandemic of COVID19 in order to complete the study The data collection has been achieved by internet (online) through Google forms. Results: the finding of the study demonstrated moderate level for knowledge, moderate level for attitudes, and high practice level of study participants related to Coronavirus Disease 2019 in addition knowledge and attitudes variables have significant impact upon practices of the study participants. Conclusions: the study has concluded that practices of population were influenced by age, living place, educational level, living place and presence of COVID19 cases in residence area finally knowledge and attitudes of community has impact on practices regarding COVID19.

Keywords: Knowledge, Attitudes, Practices, COVID-19, Baghdad city

Introduction

Coronavirus disease (COVID-19) is a contagious disease caused by a newly discovered coronavirus. Many patients with pneumonia in Wuhan city were found and many causative agents were rule out like influenza and adenovirus, severe acute respiratory syndrome coronavirus (SARS-CoV), and Middle East respiratory syndrome coronavirus (MERS-CoV). After that Chinese center for disease control and prevention (China CDC) notified World Health Organization (WHO) about the situation. The virus was identified and named (COVID-19) which is the new name for novel coronavirus on January 7 2020. COVID-19 is more infectious than both SARS-CoV and MERS-CoV.

COVID-19 affects sinuses, nose, and throat as upper respiratory tract or lungs as lower respiratory tract. It transmit the same way in other Coronaviruses through personal contact furthermore infection severity ranges from mild to severe one. The major symptoms are low-grade fever, shortness of breath, and fatigue despite the virus can last in the human body from two days to fourteen days without any symptoms. Some risk factors should be taken in considerations that make some people more susceptible for COVID-19 infection which are cancer, diabetes mellitus type II, chronic kidney disease (CKD), chronic obstructive pulmonary disease (COPD), obesity, coronary heart disease (CAD), and heart failure (HF).

The COVID-19 has fatal complications ends with death in some patients. The major causes of complications is by condition known as “cytokine release syndrome or a cytokine storm” this happens when infection attacks immune systems by triggering it leading to saturation of blood stream with cytokines as inflammatory proteins which can
damage internal organs especially kidney, lungs and heart. More importantly, these complications occur as one out of six persons with COVID-19. The spread of COVID-19, which is affected by people’s knowledge, attitudes, and practices (KAP) towards COVID-19 hence to control this disease population should be educated toward prevention measures to control the situation. The knowledge, attitudes and practices (KAP) is important tool to estimate that community is ready or not toward promoting behavioral changes to control the virus also KAP studies give us feedback about KAP level of community to tailor appropriate interventional programs to raise prevention and awareness level for the public. The objectives of the present study to assess (KAP) of public toward Coronavirus Disease 2019 (COVID-19) in Baghdad city during pandemic of the virus and to compare KAP toward COVID19 by demographic characteristics of studied samples.

Methodology

Descriptive cross-sectional design study to assess Knowledge, Attitudes and Practices towards Coronavirus Disease 2019 (COVID-19) Among the Public in Baghdad city. The study started from 10th April until 15th August 2020 during pandemic of COVID19 in order to complete the study. Official request and Ethical approval were taken from Deanship of the college of nursing for approval of the study and permission for data collection. The study was conducted by google form online. Convenient sample of (278) participants. Instrument of the study was questionnaire form consisted of two parts the first part consists of socio-demographic characteristics, which are (agreement of study participation, age, gender, marital status, educational level, occupation, monthly income, living place, and Have you seen or heard previously about anyone in your place infected COVID19 ). Second part consist of eleven questions related to knowledge variable, four questions about attitudes, and six questions regarding practices which were built, based on extensive and related literature review. Content validity of the instrument was established through a panel of six experts they were faculty members from college of nursing/University of Baghdad. The purpose of reviewing the questionnaire validate the items of questionnaire in terms of clarity, relevance, and understandability. A pilot study is conducted on a convenient sample of fifteen samples. They were excluded from original sample of the study to achieve to estimate the average time to fill the entire questionnaire, and to validate understanding of items. The data collection has been achieved by internet (online) through Google forms. The form was sent to respondent to fill it by self-reported method via social media which are Facebook channel, WhatsApp, and telegram. Statistical Analysis was applied by statistical package for social sciences (SPSS version 26). Frequency, mean, and standard deviation for descriptive analysis and independent two-sample t test and analysis of Variance (ANOVA test) for inferential analysis.

Results

The majority of the study were female who accounted for (50.4%) of the total participants. More than of one-third (44.6 %) of the study participants within age group (16-26) years old. More than half of studied samples (51.4%) were married. Preparatory graduates (33.8 %) were high percent in regard educational level of studied samples. High percent of study participants were student and their percent was (32.7 %). More than half of samples (51.4 %) had sufficient monthly income and most of samples were from Al Rasafa (55.8%). Finally, nearly two thirds of study participants (72.7%) had seen COVID19 people in their living place.

The results indicate that knowledge and attitudes variables have significant effects on practices of studied samples at p value < 0.05.

**Discussion**

This cross-sectional study is one of the first studies regarding COVID19 in Iraq specifically in Baghdad city. Hence, the disease is infectious as it can transmit through communication between human beings especially in crowded areas. The people are to protect themselves they should be knowledgeable toward disease in terms of incubation period, transmission routes, signs and symptoms and most importantly the prevention methods, and treatment strategies. The study’s findings revealed that participants had moderate level of knowledge toward COVID19 indicated by mean of score (0.65±0.324) although vast majority of study participants were highly educated ;This Finding disagrees with results from cross-sectional study was done in china to assess knowledge, attitudes, and practices (KAP) regarding COVID19 where high mean score was found toward knowledge related to COVID19 \(^{(8)}\).

Study participants had high mean score regarding the main clinical symptoms of COVID-19 and they can recognize that there is no cure for COVID19 now. High educational level may induce them to be curious about COVID19 to know how disease symptoms starts and what the best cure method to be free from disease. However, the study samples have low level of knowledge toward items related to “Antibiotics are an effective treatment for COVID-19 and the virus can be live on plastic surfaces for 24 hours”. It is a reasonable some people may believe that antibiotics had powerful effect toward viruses. The belief might come from news published in social media and some malpractices of health care professional, which make people, think that antibiotic is an effective solution against the virus, So that the community should be educated about role of antibiotics during pandemic of COVID19 to avoid improper use of antibiotics that can end with unhealthy complications. Findings from cross-sectional study done in (Tanzanian residents) stated that high mean scores regarding major clinical symptoms and cure from COVID19 had been showed. \(^{(10)}\)

COVID19 is a new virus so most people have no idea toward hours of virus life on plastic and other surfaces this is considered a new concept that should orient community during pandemic of COVID19 by health education campaign such as posters ,social media regarding duration of coronaviruses on surfaces to avoid the disease and protect them.

The results of the current study revealed low level of attitudes regarding population confidence toward Iraq to win against pandemic of COVID19. This may be due to the population in Baghdad city had negative attitudes regarding the health system in Iraq based on
their experiences with it. However, they had positive attitudes concerning precautions, and instructions that are targeted to control COVID19 pandemic. In contrast to, Outcomes from study conducted in Malaysia that reported 95.9% from study participants were confident toward winning of battle against COVID19 that can reflect positive attitudes of population toward the health system in Malaysia. (7)

The current findings demonstrated high mean score for study participants regarding practices toward COVID19. Similarly, high practice level of the study participants in Saudi Arabia to assess their KAP (9). The curfew in Baghdad city may make perception about the risk of COVID19 in people residing in Baghdad furthermore high percent of the current study were highly educated which may considered cause for high practice level rather than our study revealed knowledge and attitudes variables impact significantly on practice variable.

The present study’s outcomes revealed that significant differences between educational level and knowledge and practices variables toward COVID19. These findings come in total agreement with results from study conducted in Saudi Arabia (9). It may be seem that individuals who have high educational level search information and practice instructions and precautions toward COVID19 more than individuals with low educational level. In addition, results demonstrated age groups has significant difference with knowledge and practice variables toward COVID19. This result is consistent with results from Chinese study, which reported age considered significant factor regarding knowledge of studied sample (11). The results showed that Living place has significant difference with practices of the studied samples. This may be due to there is geographical differences between territories in Baghdad concerning population crowd, services available furthermore in onset of pandemic the incidence of COVID19 was fluctuated where most cases were more in Rasafa than AlKarkh after that incidence rate become equal approximately between two sectors after that Baghdad as whole become pandemic in most its territories .The study has some limitations which are , convenient sample may place results of the study with limited generalizability. In addition, questions of the questionnaire were built on review so maybe there are questions important lost in this questionnaire. The collection of samples of the study have been collected by online google form, this may let study participants mandatory to answer all questions even poorly understood questions due to conditions of the pandemic .

Conclusions

The study has concluded that study participants from Baghdad city had moderate knowledge, moderate attitudes, and good practice levels toward COVID19. Factors that affect knowledge were age, educational level, and monthly income and presence of COVID19 cases in residence of population, in addition to attitudes are affected by hearing or seeing cases of COVID19. In addition, the study has concluded that practices of population were influenced by age, living place, educational level, living place and presence of COVID19 cases in residence area finally knowledge and attitudes of community has impact on practices regarding COVID19.

Recommendations

The study recommends involving the community in health education program to raise their knowledge, attitudes, and practices toward COVID19 .also especially practicing preventive measures to prevent infection of COVID19 especially in crowded areas. Giving high attention in low socioeconomic areas and low educational level individuals in Baghdad city to increase their knowledge level toward COVID19 thereby attitudes and practices levels will raise positively.

Acknowledgements: The author acknowledge all participants of the study and their efforts to complete this study that help as tool to control the pandemic in Iraq in addition author acknowledge all efforts of experts who reviewed the questionnaire of the study .

Molecular Detection of BK Polyomavirus in Patients Under Hemodialysis

Eman Yousuf Rasheed1, Fidan Ghanim Reshad2, Muhannad Abdullah Allazzawy3

1Bacteriologist, HD in Hospital Management, Department of Microbiology, Al-Karkh, Health Directorate, Baghdad, Iraq, 2M. Sc. Microbiology, 3Ph.D. Medical Microbiology/Virology, Department of Microbiology, Kirkuk Health Directorate, Iraq

Abstract

The study was conducted in Kirkuk city-Iraq from February 2018 to September 2018. The number of chronic kidney disease patients under study were 60 patients whose ages were between 40-70 years old. These patients admitted to Kirkuk general hospital (hemodialysis unit). The control group who were matched to the patients studied, included 30 healthy blood donor and their ages were between 30-75 years old. Blood samples were collected for detection of BK polyomavirus DNA by real time-PCR. The study showed that the highest rate of BK polyomavirus DNA occurrence were recorded in patients with chronic kidney disease when compared with control group (51.66% versus 3.33%) (P: <0.01). The study showed that the highest mean level of IL-6 was recorded in patients with chronic kidney disease comparing with the control group (78.42 v.s. 3.40 ng/ml). The result was highly significant. The present study demonstrated that the highest mean level of IL-6 was found in prostates cancer patients who were positive to BK polyomavirus DNA comparing with BK polyomavirus DNA negative (52.54 versus 25.88 ng/ml)

It was concluded that BK polyomavirus was frequently detected in chronic kidney disease patients and could play a relevant role in the development and progression of human hemodialysis

Keyword: Hemodialysis; BK polyomavirus, CKD

Introduction

BK virus (BKV) belongs to genus Polyomavirus within the Polyomaviridae, a family of small, nonenveloped, double-stranded DNA viruses (1). Its genome is divided into 3 regions: the early, late and transcriptional control region (TCR). Early genes code the regulatory small and large T proteins and late genes code the viral capsid proteins (VP1, VP2, and VP3) and agnoprotein [1-3]. The major prognostic factor of BK virus nephropathy is the stage of the disease at the time of diagnosis. When documented in advanced stage with associated chronicity changes, it has worse prognosis with a renal survival at 12 months from 10 to 40%. In contrast, an early stage diagnosis with only viral cytopathic changes, survival is over 80% at 12 months [5-6]. The primary infection with BKV usually occurs in early childhood. It is estimated that 35-90% of the general population will acquire the primary infection during infancy and its seroprevalence reaches 46%-94% in adults depending on the studied regions [7-9]. Primary infection is usually asymptomatic, but after initial infection, BKV may persist lifelong in the kidney and genitourinary tract epithelium and possibly peripheral blood mononuclear cells, tonsils and other hematopoietic tissues [10,11]. Since the pre-transplant status affects the renal transplantation success and ultimately the survival rate, identifying the probable risk factors that increase the chance of BK virus replication in end-stage renal disease patients can be included in
proposing proper surveillance guidelines during pre and post-transplantation \cite{12,13}. The aim of the study was to study the relation of BK polyomavirus (BKPyV) in hemodialysis

**Material and Method**

The study was conducted in Kirkuk city-Iraq from of February 2018 to September 2018. The number of chronic kidney disease patients under study were 60 patients whose ages were between 40-70 years old. These patients admitted to Kirkuk general hospital/ Hemodialysis unit. The control group who were matched to the patients studied, included 30 healthy blood donor and their ages were between 30-75 years old. Blood samples were collected (3ml EDTA and 2ml for serology) for detection of BKPyV DNA by real-time-PCR and the level of IL-6 by immunefluorescent technique.

**DNA extraction**

DNA was extracted from all prostate samples by lysis and proteinase K digestion in EDTA , and 0.1% sodium dodecyl sulfate (SDS), the samples were extracted with phenol chloroform and precipitated with ethanol. DNA concentration and purity was determined by spectrophotometry at $\lambda=260/280$nm. The extraction process was performed in an area that was BKV free while great care was taken during the tissue sectioning procedure in order to avoid any contamination. Sectioning of the tissues was carried out using a clean microtome and a separate new blade in each case, as well as clean gloves and forceps. The sections were placed in autoclaved DNAse-free microtubes for the DNA isolation procedure.

**Real time PCR**

The BKPyV Real-TM Quant kit (SaCycler Biotechnologies) is a Real-Time test for the Qualitative and Quantitative detection of BKPyV in the biological materials. DNA is extracted from samples, amplified and detected using fluorescent reporter dye probes specific for BKPyV DNA.

![Figure 1: Real-time curves of BKPyV DNA detection](image-url)
Statistical analysis: Computerized statistically analysis was performed using Minitab ver 18.0 statistic program. Comparison was carried out using Chi-square ($X^2$) for determination of the $P$ value.

Findings

The study showed that the highest rate of BKPyV DNA occurrence were recorded in patients with chronic kidney disease when compared with control group (51.66% versus 3.33%) ($P: <0.01$), Table 1.

Discussion

Recent studies have confirmed that chronic hemodialysis could raise the chance of BK virus replication in ESRD patients as compared to control group [11-15]. Nevertheless, we previously demonstrated that prolonged pre-transplant dialysis could be a potential risk factor for shedding of BK virus into urine in renal transplant recipients during post-transplantation [16,17]. Therefore, it can be concluded that chronic hemodialysis is a risk factor for reactivation of BK virus pre and post-transplantation. In present study we assessed the potential predictive factors for development of BK virus viremia during hemodialysis period among end-stage renal disease patients. Overall, 192 ESRD patients who were under hemodialysis were enrolled without preliminary screening. The number of patients enrolled in our study was higher than previous studies, which can be helpful to gain more accurate and reliable results. The prevalence of BK viremia was 7.3% among our patients. The prevalence of BKV infection in patients with ESRD under hemodialysis or peritoneal dialysis has been reported from 0 to 33.3% in various studies [18,19]. These differences can be due to the difference in the number of studied patients, the duration and frequency of dialysis and the difference in the sensitivity of the PCR method used to identify BK virus. In general, deliberate or non-deliberate immunosuppression can cause the reactivation of BK virus. Hence, high incidence rate of BK virus infection among patients who received corticosteroid drugs is not surprising [20,21]. There are contradictory reports on the presence of BKV DNA in urinary tract tumors: the authors of one study detected BKV DNA using PCR in 31 of 52 samples, whereas other authors were unable to find it [17]. An other study detected BKV in 4 of 30 fresh tissue prostate samples and were unsuccessful with archival specimens, and observed the virus in atrophic lesions in prostate tumors. One of the most important proteins for BKV is the replicational regulatory protein, the large T-antigen that binds onto the tumor suppressor proteins p53 and pRb1, inhibiting their functions and leading to a variety of transforming effects. Given the low frequency of either TP53 or RB1 mutations in hemodialysis, it was intriguing to investigate the prevalence of BKV in prostate tumor samples [23].

Conclusions: BKV was frequently detected and could play a relevant role in the development and progression of human hemodialysis

Conflict of Interest: non

Source of Findings: self findings.

Ethical Clearance: This research was carried out with the patient’s verbal and analytical approval before the sample was taken. According to this approval, all the samples were collected and the tests were carried out. A copy of the results of the tests was then given to the patients

The Relationship of Aerobic Voltage to the Most Critical Physiological Variables Related to Health for Women Players of Some Group Games in the Faculty of Education for Girls

Ivan Nemeh Kazem¹, Rana Hussein Abdul Sada²

¹Assistant Prof., ²Assistant Lecturer, University of Kufa/Faculty of Education for Girls / Department of Physical Education and Sports Sciences, Iraq

Abstract

The research aims to identify the most critical physiological variables for the players of some group games in the College of Education for Girls (basketball - futsal - volleyball) and to compare the essential physiological variables for the players among group games (basketball - futsal - volleyball) in the College of Education for Girls. The research community consisted of the players of some group games in the College of Education for Girls / the University of Kufa. Their number was (30), by (10 basketball players, ten futsal players, ten volleyball players) and the researcher used the descriptive approach to suit the research problem and the most important conclusions were, was Aerobic effort has an apparent effect on physiological variables compared to rest time, showing apparent significant differences in blood pressure variable, especially systolic pressure.

Keywords: Women, Critical physiological variables of some group, Faculty of Education for Girls

Introduction

Sports physiology is concerned with identifying the various functional responses of the organs and systems of the body and the reactions of different exercises on the physiological and chemical aspects. Significantly since the functions of the human body’s organs and their responses are constantly changing throughout the day, the week and the month, whether at rest or when making physical effort, which leads to identifying the various responses to benefit from them when planning training, the players need aerobic effort to complete the match. In the performance practiced to reach the required level and through the foregoing highlights the importance of the research in the researchers’ attempt to identify the relationship of air effort between some team games (basketball - futsal - volleyball) in the physiological variables and health-related fitness variables for female players in the College of Education for Girls, University of Kufa for the academic year 2020-2021 and to identify the difference between the games under the influence of Aerobic effort (movement belt) and the objectives of the research were to identify the air voltage and its relationship to the most essential physiological variables for female players in some team games (Cr Basketball - Futsal - Volleyball) in the College of Education for Girls.(1)

Practical Part

The researchers chose the descriptive approach in a one-group style, the pre-test and the post-test for suitability in solving the nature of the research problem on female players (basketball - and futsal - volleyball) in the College of Education for Girls / University of Kufa for the season 2020-2021 and
their number was (30 players), and a sample chose the number of basketball players (10 players), futsal (10 players) and volleyball (10 players) randomly among the students facing the work, the researchers conducted the homogeneity of the research sample, if the researchers used the skew coefficient as shown in table (1)

**Sample homogeneity**

To avoid the problem of individual differences

**Table (1): It shows the mean, standard deviation, and skewness coefficient of the research sample**

It shows through the skew coefficient limited between (+-1), where the research sample was homogeneous and distributed normally, and this indicates that the members of the research sample are homogeneous.

**Field Research Procedures:**

**Determine the physiological variables used in the research:**

After seeking the opinions of experts and specialists in the physiological field to determine the variables most relevant to the title of the research, the researchers presented a set of physiological variables in a questionnaire form to the experts in the field of physiology to select the most appropriate variables. After collecting and unloading the questionnaire, the researchers extracted the relative importance and accepted the variable that obtains a more percentage (60). %) as shown in table (2).

The scientific basis for research tests:

The scientific foundations extract from the exploratory experiment tests on the treadmill.

The stability of the tests: The researchers tested a sample of the exploratory experiment (6) players from the research community. The researchers worked to provide the atmosphere in which the first measurements take; then, the test results extract using the correlation coefficient (Pearson) between the first and second tests. (2)

Description of the tests used in the research:

First: the number of breathing times: the number of respiratory chest movements during one-minute call breathing speed. Breathing occurs by respiratory movements that renew the air of the lungs continuously. The speed of breathing decreases in the state of rest so that it becomes sufficient to provide the amount of oxygen that secures the basic need of the body, and the speed of breathing varies for people. According to age and gender, it increases in children and ranges between 30-40 times/minute, in adults 16-22 times/minute, and in females 18 times per minute during rest. The respiratory movement occurs every 3-4 seconds, and the movement takes place in two stages: inhalation and exhalation, and air enters the lungs in the process of inhalation and exits from them.

In the exhalation process, the number of breathing times, the percentage of oxygen in the blood and the pressure measure simultaneously. (3)

Second: Measure the percentage of oxygen in the blood:

The researchers used the direct method to measure the percentage of oxygen in tissues using an oximeter, as the device installed on the index finger of the left hand, where the device works automatically as soon as the index finger place inside it, and the result appears on the device’s screen with the pulse, and then the reading is taken and fixed in the form. (4)

Third: - Measuring blood pressure and heart rate:

1- Systolic blood pressure measurement:-

2- Diastolic blood pressure measurement:-

The Rossmax measured the heart rate and blood pressure, and this device contains two parts, one of which wraps around the arm above the elbow joint area. The other is the measuring part and is placed on the table and gives measurements of the pulse and pressure so that the measurement is done immediately after the end of the physical effort and quickly. It should be taken into account when taking a blood pressure measurement that the person for whom the
measurement take should be seated. (5)

Pre-test

The Pre-test conduct on the primary research sample of players (basketball - futsal - volleyball), which numbered (30 female students) representing the players of the Girls’ College of Education team for the season (2020-2021), then tests were conducted in the fitness hall, and tennis court at the College Physical Education and Sports Sciences / the University of Kufa On Sunday and Monday, 10-11/2021, tests of physiological variables (number of breaths - number of heartbeats - systolic pressure - diastolic pressure - blood oxygen percentage) were conducted on the research sample for each game on the side in order to reach Objectives and solution to the research problem. (6)

Main experience:

After the scientific foundations of the research were confirmed, the students’ air effort was applied, which is a moving treadmill, after collecting data for the tribal tests:

pneumatic tension (treadmill)

After completing the tribal tests and measurements, the research sample subject to a pneumatic effort through performance on a moving treadmill, where the researchers conducted personal interviews with experts and specialists. The experts were approved as it is suitable for performing aerobic effort. Then the warm-up was conducted by the research sample for a period of (5) - (10) minutes; the player climbs on the Treadmill device, as it starts operating the device within the specified speed (5.1) km / h, the device starts quickly gradually up to the prescribed speed, and this allows the player to work on the device in a consistent and compatible manner for safety and security from the occurrence of injury. (7) When the prescribed speed reach, the time specified for performance begins, and after the time expires, the device gradually stops to avoid the player falling. The angle of inclination of the device is (1) degrees (20%) and the time specified for the air effort (15 minutes) With the help of the work team, taking measurements after the effort, as was done in the pre-measurements, to obtain data for the research variables. (8)

Presentation of the results of the variable blood oxygen content of the subjects of the research sample and their analysis:

**Discussing the results of the physiological variables of the research sample members**

The statistical results indicated significant and statistically significant differences between team games (basketball - futsal - volleyball) in some physiological variables after aerobic effort (walking). Moreover, the variables (number of breaths - blood oxygen percentage - systolic blood pressure - diastolic blood pressure - number of heartbeats), the researchers attribute the presence of these significant differences to the air effort (moving walking), where the difference in the variable number of breaths between the game of basketball, volleyball and in favour of basketball in order for the players to move in rapid attack and running during an attack, defence and volleyball. A lack of running and fast running, as the air effort (moving belt) is related to the number of breaths, the need for oxygen increases to produce energy to perform the activity. (9) The need for oxygen increases in abundance to get rid of Carbon dioxide and thus cause an increase in the number of breathing times to compensate the body for the energy consumed and an attempt to reduce acids in the case of moderate-intensity physical activity, such as brisk walking for a long time, the speed of breathing increases, which was the reason for the difference. (10) We intend between the basketball and volleyball games in the table (6). Where the number of breathing times varies according to the sporting specialities, related to the player’s level in terms of training and according to the type of game where primary variables occur for the process of inhalation and exhalation; hence, it notices that it increases and increases the number of times of breathing. (11)

As for the presence of significant differences for the players in the variable percentage of oxygen in the blood between basketball and futsal and in favour of basketball, the researchers attribute the reason for these significant differences in the performance of the aerobic effort (moving treadmill) exerted. Basketball players use oxygen in a more significant proportion than futsal due to the frequent movement and also due to the lack of Resisting breathing and increasing breathing muscles, the lungs’ capacity increases, and thus the volume of breathing air increases. Regular exercise leads to positive functional changes in the respiratory system. (12)

As for the systolic blood pressure variable, the differences were significant after performing the aerobic effort (moving walking), so the difference occurred between the two games of futsal and volleyball, favouring the game of futsal and volleyball, and in favour of the game of futsal football. As for the diastolic blood pressure, significant differences between the two ball games occurred. Basketball and
futsal and between basketball and volleyball, and the difference favoured basketball between the two teams. The researchers attributed this difference to the body’s need for oxygen during aerobic effort.\(^{13}\) It leads to an increase in blood pressure on the walls of blood vessels as well as an increase in the body’s need for energy through blood, which in turn leads to Increasing the process of sending blood pressure receptors by giving orders to the Cardiovascular Control Center to reorganize the blood flow to the working muscles according to the body’s need for blood.\(^ {14}\) This process leads to an increase in systolic blood pressure, and this linear increase in heart rate and the cardiac output shows the need to increase blood pressure for flow blood flow to the muscles to supply them with nutrients, and this result is consistent with what was mentioned by (Fletcher) and others that systolic blood pressure increases when there is an increase in blood pressure. For muscular contraction due to increased cardiac output.\(^ {15}\)

As for the diastolic blood pressure, there is a slight increase because the vascular expansion in vessels in the vessels of the working muscles occurs little in the diastolic blood pressure if the differences in diastolic blood pressure are minor if they are small.\(^ {16}\)

As for the number of heartbeats, the significant differences after performing aerobic effort (moving treadmill) between basketball and futsal and between basketball and volleyball, and this difference favoured basketball, as the researchers attributed the difference to a direct rise in the number of heartbeats—the heart rate increases at the beginning of an exercise.\(^ {17}\) Due to the retaliation of the heart centre, the medulla region with a signal from the cerebral cortex and the signal reflected from the muscular movement; the heart, and this increase follow the flow of the heart parasympathetic nerve signals towards heart and blood vessels.\(^ {18}\) The increase in heart rate during the performance of the inotropic effort is of a linear nature commensurate with the workload on the body systems and the amount of oxygen consumed during the effort.\(^ {19}\)  

Conclusions

1. Aerobic effort (mobile walking) has great importance and a positive relationship in the occurrence of changes in physiological variables (number of breaths - blood oxygen percentage - systolic blood pressure - diastolic blood pressure - heart rate) and health-related fitness variables (cardiorespiratory fitness - muscular fitness Structural (abdominal muscle strength)

2. Significant differences appeared for the female players between some team games in some physiological and health-related fitness variables for the research sample.

3. Effort had an apparent effect on physiological heart variables compared to rest time

4- In general, there were no appreciable differences in the body temperature variable among the female athletes.

Abstract
Open-heart surgery is considered a major surgery with potential risks and complications, but it is a lifesaving operation that can treat a variety of diseases such as heart valve disease, heart birth defects, and coronary artery disease. A Quasi-experimental design has been used in the existing study to evaluate the effect of clinical guideline concerning cardiopulmonary bypass on nurses’ knowledge in open heart surgery center in AL-Najaf AL-Ashraf city at Al-Najaf center for cardiac surgery and trans-catheter therapy through the period October 1th, 2020 to, April 19th, 2021. The results of the study show there is a high significant effect of the educational program, it also, show that high significant mean difference among study group concerning pre-test and post-test scores at p-value (0.0001). Also, in this study there is a significant association between post-test knowledge and year of experience as a perfusionists and number of training courses at p-value (0.02) and (0.01). The study concluded that educational program can improve in nurses’ knowledge and to produce perfusionists who are able to successfully apply their knowledge and skills to improve patients’ outcome. The study recommended a written program for all new nurses working in heart-lung machine department, and improving the expertise of nurses and medical staff through use the finding of the present study to give care for the patient.

Keyword: Guideline, Cardiopulmonary bypass, Nurse, Knowledge, Perfusions.

Introduction
Open-heart surgery is considered a major surgery with potential risks and complications, but it is a lifesaving operation that can treat a variety of diseases [1]. Surgical care has become an increasingly important part of global health in recent years due to its ability to save lives, prevent disability, and the need to promote economic growth [2]. The price of such a procedure varies greatly across the globe. The United States had the highest cardiac bypass prices of any country in 2019. In contrast, (India) had the lowest cost for a heart bypass [3].

Study Objectives:
1. To assess nurses’ knowledge regarding cardiopulmonary bypass machine pre and post-exposure to guideline.
2. To determine the effect of clinical guidelines regarding cardiopulmonary bypass on nurses’ knowledge about cardiopulmonary bypass machine.
3. To find out the relationship between Sociodemographic data and nursing knowledge regarding cardiopulmonary bypass machine.

Methodology
Study Design
The present study was using a quasi-experimental design to evaluation the effect of clinical guidelines on nurses’ knowledge of cardiopulmonary bypass in the open heart surgery center in AL-Najaf AL-Ashraf city at Al-Najaf center for cardiac surgery and trans-catheter therapy from October 1st, 2020 to April 19th, 2021.
Setting of the study:

The study is conducted in Al-Najaf City/Al-Najaf Al-Ashraf Health Directorate / Al-Najaf center for cardiac surgery and trans-catheter therapy.

Study Sample:

The researcher study is being conducted directly in the Al-Najaf center for cardiac surgery and trans-catheter therapy. Probability (purposive) study sample consist of 15 nurses. All samples are exposed to an educational program and there are no control groups are found because the 15 nurses represent all available samples that work on the cardiopulmonary bypass machine.

Statistical Analysis

Through the use of excel and statistical package of social sciences (SPSS) version 25 the data of present study are analyzed.

Table (1) reveals that the high percentage of nurse that participant in this study is at age group (25-29) years, (46.7%). In addition, the table shows that the high percentages of male participant in the study was (53.3%). Regarding the level of education, the highest percentage is (100%) of the sample in study graduated from nursing college. In regards to years of experience in hospital, the table shows that (53.3%) of the sample in the study is at group of (1-5) year. In regards to years of experience in perfusion, the results show that the majority of study sample (93.3%) has (1-5) years. while (80%) of the sample in the study have no training session regarding cardiopulmonary bypass machine. In relation to number about cardiopulmonary bypass machine there is only one person who have two session of training at (13.3).

</table>

Table (4) shows that there is no significant difference in nurses’ knowledge at post-test regarding gender. While regarding to year of experience as a perfusionist there is a significant difference at p-value (0.027).

**Discussion**

According to (table 4.1) in the results, the study shows some variation difference regarding the Socio-demographic data of the study sample.

Concerning their age, the majority of the study sample are in the age group of (25-29) years. This result matches with the result of [4] who finds in his study that the largest group of age was between (24-30) years. While our result disagree with [5] which found that the highest percentage of age was (55%) above (50). This difference, according to researchers, occurs due to the Iraqi cardiac centers being newly established centers and the number of staff in these centers was at a young age, while cardiac centers in Europe and America were old centers and staff were at middle age.

About the gender of the study subjects, the highest percentage were males in the study sample, which is in consistency with [5] in his thesis about “The relationship between self-efficacy and employee commitment among perfusionists “, he mentioned that males are the dominant gender in his study (63%). While our findings contradict [6]. This difference, according to researchers, occurs due to the Iraqi ministry of health suffering from a shortage of female sex because an old Iraqi family refused any female members to participate in the nursing field, while in other countries there is no idea like this.

Regarding the level of education, the largest group sample of the study graduated from the nursing college for the study sample. Many previous studies were in agreement with this result. They found that the majority of the nurses working in the heart-
Concerning the year of experience, the result of the present study revealed that the majority of nurses in the study sample are between (1-5) years of experience. This result is supported by [8,1], as their results indicated that the higher percentage of the study groups for years of experience in nursing is less than (5) years.

Regarding years of experience in the cardiopulmonary bypass department, the present study shows that the majority of the study sample are between (1-5) years. These results disagree with another study done by [9] discovered in his study “Fundamental clinical skills of adult cardiopulmonary bypass” that the majority of the study sample had more than (25) years of experience in cardiopulmonary bypass machine, and (Long & Matthews, 2016) discovered that the majority of the nurses in the study groups had more than (30) years. This variation, I think as a researcher, occurred due to the oldest building of these centers with staff at the same time as these centers while our centers were assembled later.

About training sessions toward cardiopulmonary bypass machine, the study show that few number of the sample in this study had training sessions. This result disagrees with several studies that indicate in their results that the majority of the study sample had good numbers of training sessions [10]. These differences, I think, are related to the weak interest of the health governorate and the low budget of these centers.

Concerning the number of training courses, the study shows that a very small study sample has training courses, while other studies have results that disagree with this study as the sample has more than 1000 hours of training course [4].

The current study’s findings indicated that the study sample’s knowledge is lacking in the pre-test, with approximately 53% of the study sample failing the pre-test and approximately 40% of the study sample having a fair level of knowledge. Many studies support this result where they found pre-test knowledge was poor [11].

[12] also shows that in her study on knowledge of nurses’ care for patients connected to extracorporeal membrane, they discovered that nurses’ knowledge of educational programs improved compared to before the educational program.

[13] In their study “impact of an evidence-based educational program about pediatric open-heart surgery care on both nurses and patients’ outcomes” they concluded there a deficit knowledge of nurses about cardiopulmonary bypass machine before participation in the educational intervention.

In regarding to the result in the above tables show that nurses knowledge regarding management of cardiopulmonary bypass machine has been improved after exposure to educational program on guideline. This indicates by the significant difference between pre-test and post-test result, which is supported by a previous study, which indicated that there is a high significance difference between pre-posttest [12].

Present study is supported by many studies that mentioned there are highly significant differences for nurses’ knowledge in pre and post-test of the study sample [13].

This result is in agreement [14,15], who indicates that providing postoperative education classes to nurses can be successful in increasing nurses’ knowledge. Therefore, the implemented educational program is effective and has an impact on nurse’s knowledge about cardiopulmonary bypass machine. Concerning the result related to associations between post-test and demographical data in

Regarding to the age, the result of the present study show that a significant association between age and nurses’ knowledge at p-value (0.035). This result is agreed with [5] who stated in their study that there
is a significant association between age and nurses’ knowledge toward cardiopulmonary bypass machine.

According to year of experience in hospital, the study explains that is a significant association with nurses’ knowledge about clinical guide line of cardiopulmonary bypass machine as the study explain that highest mean was (2) at rating (16-20) at P-value (0.014).

Regarding years of experience in heart lung machine department, the present study show that a significant association between years of experience as a perfusionist and nurses’ knowledge at p-value (0.027). This result is agreed with [9]

The study reveals that there is no significant association between post-test and gender. The results of the present study are supported by other studies that indicated no significant association between gender and knowledge. [16]

Conclusion

1. The level of nurses’ knowledge towards cardiopulmonary bypass machines in open-heart surgery was a deficit in different domains. Also, there was a significant relationship between nurses’ knowledge and experience in the hospital as well as nurses as a perfusionist in Al-Najaf center for cardiac surgery and trans-catheter therapy.

2. Because patients are exposed to several complications undergoing extracorporeal circulation, therefore the improving in nurses’ perfusionist knowledge that occur during educational program can have favorable effect on the incidence of these complications..

3. The study concluded that educational program can improve in nurses’ knowledge and to produce perfusionists who are able to successfully apply their knowledge and skills to improve patients’ outcome.

Recommendations:

1. There is a need for a written program for all new nurses working in heart-lung machine department. Moreover, there is a need for implement an active updated educational activities through seminar and symposium to all nurses concerning cardiopulmonary bypass machine.

2. Further study with larger sample to include other Iraqi governorates is necessary in nurse’s knowledge concerning cardiopulmonary bypass machine in order to demonstrate more clearly

3. The study recommended a written program for all new nurses working in heart-lung machine department, and improving the expertise of nurses and medical staff through use the finding of the present study to give care for the patient.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: “All experimental protocols were approved under the College of nursing and carried out in accordance with approved guidelines”.

Effectiveness of an Instructional Program on Teachers’ Knowledge about Epilepsy in Elementary Schools at Al-Rusafa Third Education Directorate in Baghdad City/Iraq

Ahmed Jasim Mohammed Aldraje¹, Aqeel Habeeb Jasim²

¹M.Sc. Student, University of Baghdad, College of Nursing, Community Health Nursing Department, ²Assist Prof (PhD), University of Baghdad, College of Nursing, Fundamentals of Nursing Department

Abstract

Background: Teachers knowledge about epilepsy is an important issue since teachers have lots of effect when children spend epileptic seizure at the school, and plays a vital role on providing an educational support for epileptic child and to keep good communication between epileptic and normal child.

Objectives of the Study: The aim of this study is to determine the effectiveness of an instructional program on Elementary school teacher’s knowledge concerning epilepsy.

Methodology: A quasi-experimental design used in the present study with the application a (pre-posttest approach) for the study group and control group after implementation of instructional program. Data collection was done at two times: for both study and control group and (15) days after giving the instructional program in the study group.

Results: The results of the study shows that there is a highly significant differences related to teacher’s knowledge concerning epilepsy at Al-Rusafa Third Education Directorate in Baghdad City, There is a significant association between teacher’s knowledge with their socio-demographic characteristics in term of educational level, marital status, and family monthly income.

Keywords: Teachers, Knowledge, Epilepsy.

Introduction

Epilepsy is a continuum of disorders, in which a child, can experience often irregular seizures (fits). Most seizures are well managed by medications and other therapies, but epilepsy may cause problems in social, school and work conditions, making it difficult to live independently ¹¹. Students with seizures appear to have both physical problems (e.g. fractures, bruises and a significantly greater chance of sudden death) and psychological issues due to the stigma attached to the disorder. Epileptic students and their families may lack social support or experience social isolation, humiliation, fear and prejudice and some parents may feel guilty ⁹. Epilepsy self-management refers to, a broad variety of health habits, and practices which can be practiced and adjusted by epileptic students to monitor their seizures, and improve their wellbeing. This strategy includes a collaboration between its students and the service providers ¹¹.

Teachers play a critical role in, students with epilepsy becoming mentally, socially and academically well-rounded. Teachers who know how to respond to seizures can boost school safety levels and influence fellow students’ and school staff reactions. A teacher who calmly and supportively responds to the seizures will help others learn to do the same. In certain cases, the teachers are the first to note and understand a student’s signs of seizures. Teachers who recognize,
encourage and inspire epileptic students foster learning, confidence and self-esteem.

**Methodology**

A quasi-experimental design used in the present study with the application a (pre-posttest approach) for the study group and control group after implementation of instructional program. The study instrument and program were constructed by the researcher to measure the aim of the study. Data collection was done at two times: for both study and control group and (15) days after giving the instructional program in the study group. The period of the study was from (1st of October, 2020) to (1st of June, 2021) to. A non - probability (purposive) sample selected from Al-Rusafa Third Education Directorate schools in Baghdad City. The sample divided into two groups (30) teachers considered as study group, and another (30) teachers considered as control group. The study group was exposed to an instructional program, while the control group was not exposed to the program. Data collection performed through the use of the study instrument and the application of the instructional program both constructed and developed by the researcher through extensive review of previous literature. Validity is determined through panel of (14) experts in health care fields who have more than (10) years of experience. Reliability of instrument is determined through the use of the computation of Alpha Cronbach’s test (Alpha Correlation Coefficient); internal consistency method was used for determining the reliability, the results was (0.73), Data analysis is done through the use of descriptive statistics via SPSS version 20 with and excel application (frequency, percentage, mean of score, and standard deviation) and inferential analysis procedure (Cronbach’s alpha, Pearson Correlation Coefficient, and Paired sample T-test).

This table show that teachers in the study group are with age 20-29 years as referred by the highest percentage (39.9) and the highest percentages also refer for those in the control group refer to 40% for age 20-29 years.

Regarding gender variable, the finding indicates that more than half of teachers are females for those in study group (56.7%) and in control group (53.3%).

The level of education indicates that teachers are with diploma among the study and control group (study= 66.7% and control= 70%)

This table presents the overall evaluation of teachers’ knowledge; the findings indicate that teachers in the study group are showing poor level of knowledge during the pre-test time (100%) while they are showing good level of knowledge during the post-test time (100%) that indicate the significant changes in their level of knowledge.

The teachers in the control group are showing poor level of knowledge over both times; pre-test and post-test (100%) that doesn’t reveal changes in their level of knowledge.

Table (1): Discussion of the socio-demographic characteristics.

Age

The study shows that the highest percentage (12; 39.9%) of study participants in both study and control groups were age (20-29 years).

This results agree with a cross sectional study was conducted in Kathmandu, Metropolitan City done by Khanal, Maharjan, Pkhairel, and Sanjel (2015) which stated that the median age of (165) teachers are (29 years). Additionally, comparable to Toudou-Daouda and Ibrahim-Mamadou (2020) which certain that a high percentage of participants were age less than 30
years old.

**Gender**

The finding of the present study indicate that more than half of teachers are females in study group and control group (56.7%) (53.3%) respectively.

This totally agree with 18 that it results showed a percentage (65.5%) of the study participants were female. Moreover, agree with Bhesania, Rehman, Savu, and Zehra (2013) which point out that the female and male percentage was (36.56 ± 10.92).

**Educational level**

The highest percentage of teachers are with diploma among the study and control group (66.7%), (70%) respectively.

This finding similar to a cross sectional study with analytic portion, conducted in Baghdad done by 3 which displayed that a percentage (63.4%) of study participants were institute graduate. Furthermore, agree with results obtained in a study done by Salih (2015) which presented that (54.0%) of participants were graduate from Institute.

Table (2): Discussion of the instructional program effectiveness on teacher’s knowledge (comparison significance of participant’s knowledge, pre and post the intervention between study and control group’s related to overall domains).

The findings indicate that teachers in the study group are showing poor level of knowledge during the pre-test time (100%) while they are showing good level of knowledge during the post-test time (100%). The teachers in the control group are showing poor level of knowledge over both times; pre-test and post-test (100%).

The findings reveals that educational program is highly effective on teachers’ knowledge regarding epilepsy in children as indicated by high significant difference in times of pre-test and post-test (at p-value=0.01) among the study group on the contrary of control group.

Poor knowledge at pretest for both groups were common and may be due to few serious conditions of epilepsy occurs in Iraqi schools or due to the absence of statistics related to confirm such conditions; as well supported by many relevance and recent international studies which revealed deficient knowledge about epilepsy among teachers both in developing countries such as the results obtained in a study done by Kadhim et al. (2021) supported the results of this study which mentioned that the majority of participants have a moderate level of knowledge. Others studies like Mohammed (2018), Elhassan et al. (2017), additionally in Goal, Singh, Lal, and Singh (2014).

As this topic is a public health condition, it appears that the educational program has a good impact in improving teacher’s knowledge toward epileptic children.

**Conclusion**

The study concluded that the majority of study sample has poor knowledge regarding epilepsy in elementary schools at Al-Rusafa third education directorate in Baghdad city. Teacher’s knowledge concerning epilepsy at Al-Rusafa Third Education Directorate in Baghdad City has been improved after application of the instructional program in the study group, which confirmed the effectiveness of the delivered program toward improving knowledge teacher’s knowledge concerning epilepsy.

**Recommendations**

The study recommended to applying this program as an instructional booklet in all the directorate of Ministry of Education in all Iraqi governorates and on a larger sample to increase teachers knowledge about epilepsy.

Effectiveness of an Educational Program on Nurses Knowledge toward Pre and Post Nursing Interventions Laparoscopic Cholecystectomy at Surgical Ward in AL-Imam AL-Hussein Teaching Hospital in Al Nasiriya City

Badr Kareem Ibrahim1, Suad Jasim Muhamad2

1Academic Nurse, Ministry of Health/ Dhi Qar Health Directorate, Iraq, 2Assist. Prof, University of Baghdad, College of Nursing, Adult Nursing Department, Iraq

Abstract

Background: Laparoscopic cholecystectomy is the gold standard treatment for gallstones. Because of the numerous advantages of open surgery, such as limited incisions, short hospital stay, no drainage tube and stomach tube use, fewer analgesic and fewer complications.

Aims: This study aimed at determine the effectiveness of an educational program on nurses knowledge toward pre and post-operative nursing intervention for patient with laparoscopic cholecystectomy; and identify the relationship between study findings and selected variables (age, level of education, and years of experience).

Methods: A pre-experimental design one group (pre-post test) is conducted for the periods of December 26th 2020 to Jun 1st 2021. The study is carried out at the at AL-Imam AL-Hussein Teaching Hospital in AL- Nasiriya city. By non-probability purposive sample is selected from nurses who in surgical wards before and after implementing educational program, data were collected and analyzed through the application of descriptive and inferential statistics.

Results: Findings indicate that nurses age at mean 24.2, (54%) females, (52%), nursing diploma graduated (46.0%) have 1-5 years of experience and no participated in training sessions. Knowledge statistically significance differences between pre and post -test for study group at (P < 0.05). There were statistically significances differences between (level of educational, years of experience and number of years of work in surgical wards) and effectiveness of educational program among the two period (Pre and Post-Test).

Conclusion: More years of experience in training the staff nursing in surgical wards by local officials help raising professionals’ nurses. Provide the health resources and exploiting young energies of nurses which indeed helps to develop their knowledge.

Key-words: Effectiveness, Knowledge, Nursing Interventions, Laparoscopic Cholecystectomy.

Introduction

Cholecystectomy is gallbladder surgical removal. A common therapy for symptomatic gallstones and other gallbladder disorders is cholecystectomy [1]. Laparoscopic cholecystectomy is recommended for the treatment of acute / chronic cholecystitis, symptomatic Cholelithiasis, biliary dyskinesia, calculus cholecystitis, pancreatitis of the gallstone and polyps / gallbladder mass [2]. Laparoscopic cholecystectomy (LC) is the most common abdominal surgery in the United States and has an annual
incidence of over 500,000 per year [3]. Around 66,000 cholecystectomies are performed annually in the UK, costing the National Health Service around £110 million [4]. Most of these cases, due to substantially lower morbidity and mortality rates relative to traditional open surgery, are now conducted laparoscopically. A national multicenter study recently reported that 96% of cases are conducted laparoscopically, establishing laparoscopic cholecystectomy as the central treatment of multiple benign gallbladder diseases [5]. Biliary colic or acute cholecystitis is responsible for > 70% of the cholecystectomy indications [6]. With an aging population, surgery requirements are projected to increase with associated growing frailty over the next decade [7]. In parallel, the numbers of elderly patients are projected to present with gallstone disease, and 28 percent and 42 percent of male and female patients are assumed to account for patients aged 80-89 years [8]. Developing nurses’ knowledge and practices will help to prepare a planned nursing care for improving patients’ health condition [9]. Preoperative and postoperative care is important to reduce hospital stays and contain costs and enhance the healing without complication. Has resulted in patients undergoing cholecystectomy preadmission testing and preoperative preparation before admission to the hospital many facilities have a pre-surgical services department to facilitate testing and to initiate the nursing assessment process, which may focus interventions laparoscopic cholecystectomy.

Methodology

A pre-experimental design one group (design of pretest and posttest) was performed on the effectiveness of an educational program on nurses’ knowledge of nursing interventions pre and post laparoscopic cholecystectomy in the surgical ward. It was conducted with the application of the pre-test approach to the study group in assessing their knowledge, and then the post-test was applied to the study group three weeks after they were given the educational program. It was implemented in order to achieve the stated initial goals. The study started from (21st December, 2020 to 15th April, 2021).

A non-probability sample was randomly selected from the nurses working in the surgical wards of Al-Imam Al-Hussein Teaching Hospital in Dhi/Qar. The sample consists of (50) nurses. It consisted of one group, which is the study group, and this sample was all exposed to the educational program to evaluate their knowledge. Random sample allocation was performed to avoid selection bias and control for potential confusion.

The educational program was arranged into three sessions for the study group. Each session, divided into two groups of nurses, each group lasted about (30-45) minutes over the course of one lecture for the morning staff and one lecture for the evening staff.

The data collection process uses the self report and questionnaire and analyzed through the descriptive and inferential statistic.

 means Arithmetic Mean ( ) and Std. Dev. (S.D.), F = Fisher test, d.f. = degree of freedom, P = probability value, , NS : Non Significant at P ≥ 0.05 , S : Significant at P < 0.05.
Findings show their no statistically significances differences between demographics variables (age, gender and participation in the Nursing intervention courses that laparoscopic cholecystectomy at the hospital, and participation in courses for nursing at the other hospital), while there is statistically significances differences between demographics variables (level of educational, Number of years of Experience and Number of years of work in surgical wards) and effectiveness of educational program among the two period (Pre and Post-Test) for nurse’s knowledge toward the Pre and Post nursing interventions laparoscopic cholecystectomy for study sample, when analyzed by ANOVA.

Discussion

The study sample consists of (50) nurses working in the surgical wards of Al-Imam Al-Hussein Teaching Hospital.

According to Table 1, findings indicated that 20 (40.0%) of the nurses are in the age group (26-30) years with an average of (24.2) years. This result was supported by findings of study investigated performance among nurses regarding laparoscopic cholecystectomy patients. Their findings showed that nurses (20-30 years) are (52%) with mean age (31.4±2.8) \[10\]. Nurses in surgical wards need to be young.

With respect gender, cooperative in study the majority of study sample were female 27 (54.0%) of all study sample. This result disagree with findings of study has been assessed postoperative nurses’ interventions in Baghdad Teaching Hospitals, which indicated that two-third of the nursing staff are male \[11\]. In fact, the surgical wards need to males nurses due to workload and covers all duties.

With regard to the educational qualifications of the studied sample, the current study indicated that almost half of them are from technical institutes and their percentage is 26 (52.0%) and less than half of them (6-10) years of experience 16 (32.0%). This result agreed with study of AbdElGhil et al. (2020), where it was found that less than half of the sample 24 (48%), have a technical institute of nursing, while less than half of them, 20 (40%), have an experience of 5 to less than 10 years in the hospital with the mean of (9.18±8.4) \[12\]. Hospitals insinuations were depends on nurses institute graduated due to the academic nurses were numbers are still small, unlike the institutions that graduate diplomas.

Regarding the number of years working in the surgical wards, the majority of the study sample ranges between (1-5 years) and represents 23 (46.0%) of the entire sample. This result is agreed with (Kadhim, 2014) that was conducted in Baghdad hospitals, which showed the results of the study sample in the surgical wards of (1-5) years, they represented 23 (46%). These results contrast with findings evaluated nurses’ practices toward postoperative wound dressing in surgical wards. It reported that most of the nurses had 24 (43.6%) of (6-10) years of experience in surgical wards \[13\]. This results come because the diploma graduated immediately after graduation, they are appointed.

Regarding the question (participation in nursing intervention courses before and after laparoscopic cholecystectomy, which the hospital conducts periodically), the majority of the study sample had answers with (No participation) and represented 46 (92.0%) of all the study sample.

Regarding the question (participation in courses of nursing interventions before and after laparoscopic cholecystectomy, which are conducted by other hospitals), the majority of the study sample had answers with (No participation) and represented 49 (98.0%) of the entire study sample.

Regarding the question (number of training sessions), the majority of the study sample was 45 (90.0%) of all study sample individuals who did not have a share in any training sessions. While only 5 (10%) of the course participants answered.
To the question (duration of the course), the majority of the study sample had answers with (No participation) and represented 45 (90.0%) of all the study sample individuals. While those who answered (yes participation), of them 3 (6%) for one week and 2 (4%) for two weeks and therefore did not have sufficient time or the duration of the training session.

These results are consistent with findings of Kadhim (2014), who mentioned that there was significant relationship between sharing in training sessions which established (by the hospital or by other hospitals), duration of the training session, number of training sessions and which reported that the majority of the results answered (No) 47 (94%) of the study sample did not have the opportunity to participate in the training sessions related to nurse surgical interventions for patients with (LC) established by the hospital. All study samples answered (No) 50 (100%) did not have the opportunity to participate in training sessions related to nursing interventions for (LC) established by other hospitals. Regarding the topics of “number of training sessions”, the majority of the sample, 47 (94%), did not have a share in any training sessions, while only 3 (6%) answered that their participation was less than a week and therefore they did not have sufficient time or duration for the training session [11].

With regard to the question (place of the session), the majority of the study sample had their answers (inside Iraq) and they represented 45 (90.0%) of the total study. This study is supported by study investigated the effectiveness of the educational program in the knowledge of nurses in relation to nursing management before and after surgery. Demonstrated findings that all the courses held inside Iraq, in addition to the absence of any of the sample members who had a training course outside Iraq [14].

There is statistically significance differences between pre and post -test for study group at P < 0.05, which mean effectiveness of educational program among the two period (Pre and Post-Test) for nurse’s knowledge toward the Pre and Post nursing interventions laparoscopic cholecystectomy for study sample. These results are supported by Kreem and Hamza (2019) as it shows that the educational program related to nursing management before and after surgery with an increased knowledge of the study group, where the p-value is (0.001) [14].

Our show their no statistically significances differences between demographics variables (age and gender and participation in the Nursing intervention courses about laparoscopic cholecystectomy at the hospital and participation in courses for nursing at the other hospital) ,while there is statistically significances differences between demographics variables (level of educational, Number of years of Experience and Number of years of work in surgical wards) and effectiveness of educational program among the two period (Pre and Post-Test ) for nurse’s knowledge toward the Pre and Post nursing interventions laparoscopic cholecystectomy for study sample, when analyzed by ANOVA. These results are inconsistent with the study conducted by (ElSayed et al. 2021) on knowledge of nurses and practices related to the care of patients undergoing cholecystectomy, which was studied in Zagazig University Hospitals, which showed that the result of the study there is a statistically significant relationship between the total knowledge of nurses regarding patients who have undergone for cholecystectomy and age and training course [15]. However, this study is in agreement with the results of the current study, as it showed that there is a positive statistically significant correlation between knowledge degrees and years of experience. This explained that the increase in years of experience in surgical units enhances the knowledge of nurses as a result of the increase in the number of follow-up cases and dealing with them. Also, nurses with years of experience become more experienced and knowledgeable. The results of the current study also showed a statistically significant relationship between the nurses knowledge the level of nursing qualification.
It is also supported by a study, which found that years of experience in the field of surgery are statistically related between nurses’ total knowledge of patients undergoing cholecystectomy and work in surgical wards.

Regarding participation in the training courses, the results of the current study are disagree with, who indicated that the nurses who participated in the surgical or perioperative training courses were exposed to their satisfaction with preoperative teaching.

This result also differs from the current study with (Arab et al. 2016) on the effects of training programs on the knowledge and attitudes of nurses after surgery, which stated that despite the increased knowledge of general surgery compared to other units, there is no statistically significant relationship between hospital units Increasing levels of knowledge and attitudes.

In general, the researcher suggests that to provide high-quality nursing interventions for patients with cholecystectomy before and after surgery in the surgical wards by nurses, the nurses’ knowledge should be further developed through their participation in training courses inside and outside Iraq, and the continuing education of nurses who were working in the surgery wards and the increase in the number of nurses Professionals graduating from the College of Nursing in the surgical wards. In addition, the use of guidelines for nursing interventions to improve the efficiency of nurses in the care of patients with laparoscopic cholecystectomy to avoid complications after the operation.

**Conclusion**

More years of experience in training the staff nursing in surgical wards by local officials help raising professionals’ nurses. Provide the health resources and exploiting young energies of nurses which indeed helps to develop their knowledge.

Effectiveness of an Instructional Program on Gastric Carcinoma Patients Knowledge Undergoing Chemotherapy toward Self Care after Gastrectomy at Oncology Unit of AL-Haboby Teaching Hospital in AL-Naseria City

Hussein Ali Jabbar¹, Suad Jasim Muhamad²
¹Academic Nurse, Ministry of Health/ Dhi Qar Health Directorate, Iraq, ²Assist. Prof, University of Baghdad, College of Nursing, Adult Nursing Department, Iraq

Abstract

Aims: To determine the effectiveness of instructional program on self-care knowledge patients undergoing chemotherapy after gastrectomy. Methods: Pre-experimental pre-post test design was conducted in Al-Naseria City. The data collection process uses the interview technique and analyzed through the descriptive statistic. Results: There is statistically significance differences between pre-post test knowledge, which mean effectiveness of instructional program knowledge of self care after gastrectomy. Conclusion: In the post-test, there was a big difference in the patients’ knowledge level towards self-care. Establishing specialized centers to educate patients importance of early detection of cancer.

Key-wards: Effectiveness, Patients, Knowledge, Self Care, Gastrectomy.

Introduction

Gastric cancer, especially among older males, remains one of the most common and deadly cancers worldwide. Stomach cancer is the 5th most prevalent neoplasm and the 3rd most deadly cancer, based on GLOBOCAN 2018 results, with an estimated 783,000 deaths in 2018 [1]. Less than a century ago, in the United States and maybe all over the world, gastric cancer was the most prevalent cancer. While gastric cancer is no longer the world’s most common cancer, it remains the world’s second leading cause of cancer-related mortality and the most prevalent cancer in Eastern Asia [1]. Gastric cancer is a worldwide health epidemic, with over 1 million people hospitalized worldwide with gastric cancer every year. Gastric cancer is the leading third cause of cancer-related death, although it has fallen globally in prevalence and death in the past 5 decades [2]. One of the world’s most frequent causes for death is the growth of malignant cells in some region of the stomach, known as gastric cancer. It is important to develop the decision-making method to lead a greater and more effective range of treatment options to maximize the survival rate of patients with this disease [3]. Self-care exists even before traditional insurance services and contributes significantly to health outcomes. For certain individuals, self care may be the only healthcare they have access to under well defined cultural and social standards. Where there are healthcare systems, self-treatment is a critical element of health care [4]. Improve home self-care of patients with chemotherapy, which leads to a decrease in the complication of chemotherapy treatment. Patients undergoing chemotherapy without treatment knowledge and side effects can lead to a decline in the patient’s health. Patient self-care teaching helps to recognize the patient and family member’s learning needs since the cancer diagnosis and treatment crush the patient and family. Previous research has found that 50-90 percent of cancer patients want to die at home. There was a downward trend in home self-deaths,
dropping between 1974 and 2003 from 31 percent to 18 percent. If the pattern continues, by 2030, less than 10% of deaths will occur at home [5]. Therefore, the study aim to determine the effectiveness of an instructional program on knowledge of self care for gastric carcinoma patients undergoing chemotherapy after gastrectomy; and to identify the relationship between study findings and selected variables.

Methodology

A pre experimental (one-group pre-/posttest) design was carried out to assess Effectiveness of an Instructional Program on Gastric Carcinoma Patients Knowledge Undergoing Chemotherapy toward Self Care after Gastrectomy at Oncology Unit of Al-Haboby Teaching Hospital in Al-Naseria City, through application of Instructional Program and application of pre-test and post-test approach for the study group, the study lasted from 21th of December, 2020 to the 14th April 2021.

In patients with gastric cancer and undergo chemotherapy after gastrectomy at Al-Haboby Teaching Hospital Oncology Unit in Al-Naseria City, a non-probability deliberate sample was randomly picked. The study is consist of (40) patients. Whole the study group was exposed to an instructional program.

A questionnaire consists of the following parts including:

**Part 1**: Socio-demographic data of nurses includes age, gender, level of education, marital status, occupation, residents, and monthly income.

**Part 2**: Knowledge of gastric carcinoma patients undergoing chemotherapy after gastrectomy towards self-care. This domains divided into three sub-domains include

A. Knowledge of gastric carcinoma patients undergoing chemotherapy after gastrectomy about general information about stomach cancer and gastrectomy which include of (8) items.

B. Knowledge of gastric carcinoma patients undergoing chemotherapy after gastrectomy about general information of chemotherapy which include of (6) items.

C. Knowledge of gastric carcinoma patients undergoing chemotherapy after gastrectomy about self-care of side effects of chemotherapy and self-care of daily activities which include of (14) items.

A content validity were achieved through a (11) panel of experts and reliability were achieved through a pilot study. It conducted on (10) were selected among chemotherapy patients at Oncology Unit of AL-Haboby Teaching Hospital. Cronbach’s Alpha= 83 which indicate a pass questionnaire items. The data collection process uses the interview technique and questionnaire and analyzed through the descriptive statistic.

$\bar{x} \pm S.D.$ = Arithmetic Mean ($\bar{x}$) and Std. Dev. (S.D.), $F$ = Fisher test, d.f. = degree of freedom, $P$ = probability value, NS : Non Significant at $P$ $\geq$ 0.05, S: Significant at $P$ $<$ 0.05.

Findings show their no statistically significances differences between demographics variables (patients gender, monthly income and family history of current disease), while there is statistically significances differences between demographics variables (patient age, educational level, marital status and duration of current disease) and effectiveness of instructional program among the two period (Pre and Post-Test) for patient’s knowledge toward the Pre and Post effectiveness of instructional program for study sample, when analyzed by ANOVA.

**Discussion**

The highest age group was 56-60 years old with a percentage of 13 (32.5%) with mean of (73.8) years, and this result was consistent with Chen et al. (2016) [6]. The average age of those living with stomach cancer was 60.6 ± 6.6 years.

The prevalence is increasing with age of gastric cancer. Aging is linked to increased injury susceptibility, delayed cure of gastric mucosa, and expression of cancer stem cell markers. Furthermore, H. pylori gastritis rises with age. It was not clear, however, whether the prediction of gastric cancer already known worsened with age [7].

Related to the gender cooperative in study the majority of study sample were male 26 (65.0%) of all study sample. There are no obvious explanations for these disparities. Exposures to the environment or work may take on a function. For example, men have traditionally been more likely to smoke tobacco products, including in countries where men and women have equal levels of smoking, but higher concentrations of men tend to exist. Alternatively, sex distinctions may represent variations in physiology. Estrogens can protect against gastric cancer growth [8].

Regarding to educational level of patients in study sample the majority with primary school graduation 24 (60.0%). Increased education of both sexes has been linked to a declining risk of esophagogastric cancer. Compared with elementary school graduation, higher education posed a lower risk to both sexes. This relationship was close for each of the 4 esophagogastric cancer subtypes and may be greater for gastric cancer [9].

Concerning to the social status , the greater number of study sample are 35 married and account for (87.5%). This result was consistent with findings investigated the prevalence and prognostic implications of psychological distress in patients with gastric cancer [10].

Regarding to the level of occupation status, the greater number of them with house wife and they are accounted for 13 (32.5%) of the sample. This finding disagrees with the outcome of the environmental factors in etiology of gastric cancer [11].

Rural people only see physicians as problems occur. This could lead to higher mortality in rural areas compared to urban areas through delayed diagnosis and treatment. Policymakers should propose improving the understanding of gastric cancer through education in health care and extending early detection screening and early therapy to minimize the disparity in gastric cancer mortality across urban and rural areas [12].

With respect to patients monthly income the majority of study sample with insufficient monthly income and account for 24 (60.0%) of the whole sample. This result was consistent with gastric cancer screening in low-income countries that reported; Gastric cancer shows significant geographical variations in and within regions with over 70% of the incidence cases clustered in countries that have low and mid-income [13].

Findings shows that information of study sample were presented low level of knowledge at all items
except (In a complete gastrectomy surgery the doctor is performed by) which presented as (Moderate) level of evaluation at pre-test for study group, So the results show high level of knowledge at post-test for study group. That there are statistically significance differences between two periods (pre and post-tests) of study group in all items of the patient’s knowledge of gastric carcinoma patients undergoing chemotherapy after gastrectomy about general information about stomach cancer and gastrectomy of the Study Sample (Study Group), This reflects that the patients’ knowledge was affected by educational program.

Findings shows that information of study sample were presented Moderate level of knowledge at items (Chemotherapy is a treatment that is used to eliminate, One of the factors that increase the chances of responding to chemotherapy? and As a side effect of chemotherapy?) at pre-test for study group. While presents low level of knowledge at items remaining at pre-test for study group , So the results show high level of knowledge at post-test for study group. That there are statistically significance differences between two periods (pre and post-tests) of study group in all items of the patients’ knowledge of gastric carcinoma patients undergoing chemotherapy after gastrectomy about general information of chemotherapy (Study Group), This reflects that the patients’ knowledge was affected by educational program.

Findings shows that information of study sample were presented low level of knowledge at all items except (Should you avoid high-fiber foods because they?) which presented as (Moderate) level of evaluation at pre-test for study group, So the results show high level of knowledge at post-test for study group. That there are statistically significance differences between two periods (pre and post-tests) of study group in all items of the knowledge of gastric carcinoma patients undergoing chemotherapy after gastrectomy about self-care of side effects of chemotherapy and self-care of daily activities of the study sample (Study Group), This reflects that the Patients’ knowledge was affected by educational program.

Kamil & Mohammed, (2020) show that statistically meaningful difference is seen in the plurality of items for the patient information community between the pretest and posttest sample analysis. The overall mean of expertise for patients in the field of guidance program has been seen to be mid-scale knowledge and posttest, fields of Patient cancer and chemotherapy know-how, self-care of chemotherapy side- effects and self-care awareness in day-to-day life [14].

Davoodi et al., (2015) it’s do not agree with this results an show After gastrectomy, a short self-care training program was not sufficient to substantially increase the quality of life of gastric cancer patients [15].

Show their no statistically significances differences between demographics variables (patients gender, monthly income and family history of current disease), while there is statistically significances differences between demographics variables (patient age , educational level , marital status and duration of current disease) and effectiveness of educational program among the two period (Pre and Post-Test) for patient’s knowledge toward the Pre and Post effectiveness of educational program for study sample.

Kamil & Mohammed, (2020) found that statistically relevant information was available at the post p-test at p value (0.010,043) between patient’s knowledge and (age and level of education) [14].

Choenyi et al., (2016) They stated that selected variables existed in their data. Height, degree of education, have no important connection with understanding and home control of harmful effects of chemotherapy [16]. The study findings indicate that there was no statistically significant difference between patients’ experience and their knowledge (marital status, job status, monthly revenues, when were you diagnosed with cancer in the past family, after diagnosis and type of care provided after diagnosis, and have chemotherapy information?).
Conclusion

In the post-test, there was a big difference in the patients’ knowledge level towards self-care, which indicates the smoothness of the program that was prepared for this purpose and the ease with which it was accepted by all participating patients. Establishing specialized centers to educate patients about self-care stomach cancer and disease-causing risk factors and importance of early detection of cancer.

Abstract

Aim: The aim of this study was assess the change in fetal and uteroplacental circulation following antenatal dexamethasone administration to high-risk of preterm labor pregnant women.

Patients and Methods: Prospective study was conducted between January and May 2021 in Tikrit city at Salahadeen General Hospital /genealogy and obesterts department The study included 30 pregnant women with high risk of preterm labor with gestational age from 24 to 34 weeks. Doppler Study were performed just before dexamethasone administration and will be repeated 24 h after completion of the dexamethasone course.

Results: The study showed the highest means of Fetal MCA pulsitility index. levels were recorded in women who at risk of preterm uterine contractions, placenta previa and pre-eclampsia respectively before dexamethasone administration as compared with the same groups at 24 hour after dexamethasone administration (P<0.05). The study showed the highest means of Fetal MCA resistive index levels were recorded in women with preterm uterine contractions, placenta previa and pre-eclampsia respectively before dexamethasone administration as compared with the same groups 24 hour after dexamethasone administration (P<0.05). The study showed the highest means of Uterine artery pulsitility index. levels were observed in women with preterm uterine contractions, placenta previa and pre-eclampsia respectively before dexamethasone administration as compared with the same groups 24 hour after dexamethasone administration.

Keywords: dexamethasone, fetal Doppler velocimetry, antenatal administration

Introduction

Preterm birth is the delivery of a baby before 37 completed weeks’ gestation. Most mortality and morbidity affects “very preterm” infants (those born before 32 weeks’ gestation), and especially “extremely preterm” infants (those born before 28 weeks of gestation) (¹). Doppler assessment of the placental circulation plays an important role in screening for impaired placentation and its complications of pre-eclampsia, intrauterine growth restriction and perinatal death (²). Assessment of the fetal circulation is essential in the better understanding of the pathophysiology of a wide range of pathological pregnancies and their clinical management (³). Doppler ultrasound provides a non-invasive method for the study of fetal hemodynamics. Investigation of the uterine and umbilical arteries gives information on the perfusion of the uteroplacental and fetoplacental circulations, respectively, while Doppler studies of selected fetal organs are valuable in detecting the hemodynamic rearrangements that occur in response to fetal hypoxemia (⁴). Doppler velocimetry is used to assess small-for-gestational-age (SGA) fetuses at risk of adverse perinatal outcome. Doppler abnormalities in the umbilical artery (UA) are related closely to placental disease. On the other hand, changes in
the fetal middle cerebral artery (MCA) reflect fetal cardiovascular adaptations to hypoxia or blood flow redistribution\(^5\). Thus, decreased pulsatility index (PI) has been considered a compensatory phenomenon to protect the fetal brain in the context of intrapartum growth restriction (IUGR). Poor uterine artery blood flow is associated with biochemical and cellular evidence of impaired placental development and function\(^6\). Uterine artery Doppler assessment appears effective in screening populations at high-risk for preeclampsia.\(^1\) Poor uterine artery blood flow is also associated with adverse pregnancy outcome from other placental syndromes such as fetal growth restriction, abruption, and stillbirth\(^7\).

Maternal administration of synthetic corticosteroids (dexamethasone), by accelerating the maturity of the fetal lung, reduces neonatal mortality, respiratory distress syndrome, intraventricular hemorrhage and necrotising enterocolitis in preterm infants. Previous studies have shown that steroids have an effect on fetal behaviour and fetal heart rate variability\(^8,9\). In fact, conflicting results concerning the effects of betamethasone and dexamethasone on fetal heart pattern have been reported. Dexamethasone was associated with an increase in long term and short term variability and decreased fetal movements on the first day after steroid administration followed by a decline in fetal heart rate variability on the second day \(^10\). Different studies found that betamethasone treatment is associated with significant reduction of the middle cerebral pulsatility index, especially at gestation before 32 weeks\(^11-13\). The aim of this study was assess the change in fetal and uteroplacental circulation following antenatal dexamethasone administration to high-risk of preterm labor pregnant women.

**Patients and Methods**

Prospective study was conducted between January and May 2021 in Tikrit city at Salahadeen General Hospital /genecology and obstetrics department. The study included 30 pregnant women with high risk of preterm labor with gestational age from 24 to 34 weeks.

**Inclusion criteria :**

1) Women with singleton uncomplicated pregnancy.

2) Women with risk of preterm labor

3) Women with normal utero-placental vascular resistance at the time of initial scanning (umbilical artery flow-velocity waveforms values above the fifth centile according to the reference limits as published by Arduini and colleagues); and

**Exclusion criteria**

1- Women who were unfit for conservative management patient actually in labor and fetal demise.

2- women with infants with known major structural malformation, complicated pregnancy, preterm, rupture of the membranes (PROM), vaginal bleeding as in (placenta previa and abruption placentae), .

3- suspected chorioamnionitis

3- maternal medical conditions e.g. PET, autoimmune diseases, DM.

4- maternal obstetrical conditions e.g. Polyhydramnios and oligohydramnios

5- non-reassuring fetal wellbeing e.g. presence of fetal bradycardia (FHR<120bp) or tachycardia (FHR>160bp) detected by sonicaid.

Doses of 12 mg dexamethasone intramuscularly 12 hours apart

1-Standardized questionnaire: designed by researcher

2- Doppler Study were performed just before dexamethasone administration and will be repeated 24 h after completion of the dexamethasone course. Blood flow velocity waveforms were obtained from the umbilical artery, fetal middle cerebral artery (MCA), and maternal uterine arteries.
Eligible participants were evaluated through full history taking and detailed anatomical scan by level II sonographer before inclusion to confirm their gestational age and exclude any structural anomalies.

Each woman received the recommended course of corticosteroids to induce fetal lung maturity consisting of two doses of 12 mg dexamethasone (Dexamethazone 8 ml, Sigma Pharam, Egypt) intramuscularly 12 hours apart.

Doppler studies were performed just before dexamethasone administration and repeated 24 hours after completion of the dexamethasone course using a SonoAce X6 machine (Medison, Korea) with 3.75 MHz transabdominal probe. All patients underwent Doppler examination by 2 different level II sonographers.

Doppler examination was done with the fetus in a quiet state, in absent of fetal movements and fetal breathing movements. The angle of insonation was optimized to be as low as possible, never exceeding 45°. The sweep speed was 2.5 cm/s and the pulse repetition frequency ranged from 3.5 - 5.5 Khz. The Doppler spectrum was recorded during maternal voluntary apnea.

Blood flow velocity waveforms were obtained from the umbilical artery, fetal middle cerebral artery (MCA), fetal descending aorta and maternal uterine arteries. Spectral pulsed wave Doppler analysis was done after that; RI and PI were calculated for each vessel. The formulas used for PI and RI were PI = (S-D)/mean and RI = (S-D)/S respectively, when S is the peak Doppler frequency shift and D is the minimum. At least 5 uniform waves forms of the spectrum were recorded and analyzed. Blood flow velocity waveforms were recorded from the umbilical artery in the free floating mid-portion of the umbilical cord. Doppler signals registered from the fetal MCA in its proximal third. The MCA vessels were located with color Doppler ultrasound overlying the anterior wing of the sphenoid bone near the base of the skull. Doppler signals obtained from the uterine arteries in the region of the lower uterine segment. Insonation of the uterine artery was done at its crossover the iliac artery. Velocity waveforms from the fetal descending aorta were recorded at the lower thoracic level just above the diaphragm, keeping the angle of insonation of the Doppler beam below 45°.

**Results**

The study included 30 women with risk of preterm birth. We anticipated the risk of preterm birth on the basis of; preterm uterine contractions (n=17), placenta previa (n=9) and pre-eclampsia (n=4). The demographic data are presented in Table 4.1. The mean age of the study group was 28.4 ± 3.9 years. At the time of dexamethasone administration, mean gestational age was 30.6 ± 3.1 weeks.

The study showed significant differences among studied women with risk of of preterm uterine contractions, placenta previa and pre-eclampsia regarding the average of Uterine artery resistive index, before and 24 hour after dexamethasone administration (P>0.05), Table 4.7.

**Discussion**

Fetal biophysical profile and Doppler ultrasonography have been used to assess fetal well-being in utero. Studies have reported transient reduction of fetal body movements, fetal breathing and fetal heart rate variation after antenatal betamethasone administration (1,2). Likewise, Doppler velocimetry of the umbilical (UA) and middle cerebral arteries (MCA) has also been found to be affected by corticosteroid administration. Prior studies revealed that the maternal administration of betamethasone was associated with a transient decrease in the pulsatility index (PI) (3-5). However, the mentioned studies had methodological limitations in some aspects. First, precise timing of the onset of the steroid effect was not determined due to the retrospective review of pregnancies (6,7). Second, other components of fetomaternal vasculature such as ductus venosus and uterine arteries were not assessed in a majority of the studies (8-11). The study included 30 women at risk of preterm birth. We anticipated the risk of preterm birth on the basis of; preterm uterine contractions (n=17), placenta previa (n=8) and pre-eclampsia (n=45). In this study, dexamethasone administration was found to have a beneficial effect on fetuses at risk for preterm birth as evident by the decrease in the Doppler indices of umbilical artery, MCA and uterine artery. Umbilical artery Doppler indices showed statistically significant reduction 24 hours after dexamethasone administration. Our results agreed with Senat et al (12) study that reported an association between betamethasone treatment and decreased placental vascular resistance as reflected by waveforms obtained from umbilical artery. This is similarly agreed by Nozaki et al (13) who found a reduction in the umbilical artery PI within 24 hours following antenatal corticosteroid therapy. MCA Doppler indices decreased after the treatment. These findings are in agreement with the results of Chitrit et al (14) who observed a transient and significant decrease in fetal MCA (PI, RI) after maternal dexamethasone administration. However some studies disagree with
our results as Miracle et al (15) and Wijnberger et al (16), they were on growth-restricted preterm fetuses; no effect was found from betamethasone on PI in fetal MCA. In the latter study, circulation in fetuses was studied for up to 14 days, indicating that placental insufficiency was probably not severe enough to indicate early delivery(17). Moreover, Piazze et al (18) examined the effect of steroids on blood flow waveforms in IUGR fetuses and found no significant changes of PI, RI values in the different vessels after dexamethasone course. There was statistical significant reduction in the uterine artery Doppler indices before and 24 hours after dexamethasone administration in the present study. These findings are in agreement with data published by Chitrit et al who observed similar transient and significant decrease in uterine artery PI and RI after maternal dexamethasone administration in healthy fetus(19). However, other studies reported that there was no significant influence of betamethasone therapy on Doppler indices in uterine circulation in pregnancies with imminent preterm delivery(20,21). A study on human placentas by some authors showed that the mechanism behind dexamethasone-induced vasodilatation might be an endothelium independent mechanism, as they did not find any involvement of endothelium-derived products such as prostaglandin I and nitric oxide(22,23). In concordance with our findings, a previous retrospective cohort study showed that corticosteroids administration was associated with significant change in umbilical artery PI and a transient return of end-diastolic umbilical artery flow(24). Another study showed that maternal antenatal corticosteroids resulted in a significant transient change in the velocity waveform and a decrease in the PI in the umbilical artery and ductus venosus(25). Similarly, Elnsosy and colleagues(26), concluded that maternal dexamethasone administration to pregnant women at risk of preterm improves the blood flow of umbilical artery and MCA. In addition, a previous report showed that the MCA PI showed a trend to decrease 24–48 h and 4–7 days after steroids were given to the mother when compared to pretreatment values(27). In contrary, Yvon Chitrit and colleagues(17) showed that no significant change was documented on days 2 and 7 in umbilical artery PI after dexamethasone administration. Additionally, Salama et al (28) reported no significant variations were observed in the umbilical artery PI throughout dexamethasone therapy. In addition, a previous report showed no significant effects of corticosteroids were observed in the uteroplacental circulation(29). The exact causes of such discrepancies between our findings and the abovementioned studies is unclear, however, it can be attributed to many factors. Firstly, the dose and type of antenatal corticosteroids were different between our study and those reports; for example, Salama and colleagues administered 24 mg of dexamethasone intramuscularly in three divided doses 8 h apart), while Müller and colleagues administered betamethasone. Secondly, the sample size varied greatly among the abovementioned studies which may have attributed for such heterogeneity. The characteristics of the included women were apparently different which can be considered as another factor.

**Conclusion**

The administration of dexamethasone to pregnant women at risk of preterm birth could improve the blood flow in the uterine arteries, fetal MCA, and umbilical artery 24 hours after its administration.

Advanced Glycation End Products and Malondialdehyde Serum Level Association with Nephropathy in Type Two Diabetic Patients

Alaa Abdullah Hassan¹, Sami A. Zbaar², Khedhair Abbas Khedhair²

¹M. Sc. Medical Biochemistry Stud, Erbil Health Directorate, Iraq.²Assistant Prof. Dr. Medical Biochemistry, College of Medicine, Tikrit University, Iraq

Abstract

Aim of the Study: Evaluate the relation of serum level of AGEs and MDA with the development of diabetic nephropathy in patient with type two diabetes mellitus and to evaluate the possible mechanism by which AGEs and MDA induce nephrotic complication in type two diabetic patients.

Patients and Methods: This case-control study was carried out in Erbil city from the period started from 1st of December 2020 to the end of March 2021. The study included 62 type 2 diabetic patients (31 patients nephropathy and 31 patients T2DM without nephropathy), their age between 40–69 years, these patients who attended Rizgari General Hospital. The study also included 28 healthy control individuals defended as subjects who apparently haven’t any chronic diseases. Blood was collected from each for determination of HbA1c level, AGE3 and MDA and RBS.

Results: The study revealed that, the highest mean of RBS and HbA1c was recorded in DN group followed by diabetic non-nephropathy and the control group. The study revealed that, the highest mean of UACR was recorded in DN group (258.6±28.56 mg/gm) followed by diabetic non-nephropathy (35.6±11.95 mg/gm) and the control group (20.39±1.72 mg/gm) (P<0.001). The study showed a significant positive of AGEs and MDA with each of duration of DM, blood sugar, HbA1c and UACR.

Conclusions: This study showed elevated of AGEs, MDA and Poor glycemic control were associated with diabetic nephropathy.

Keywords: AGES; MDA; Diabetic nephropathy; Type 2 Diabetes; HbA1c

Introduction

Diabetic nephropathy is the most common cause of end-stage renal disease in the world, and could account for disability and high mortality rate in patients with diabetes. According to the World Health Organization, it is expected that the number of patients with diabetes will rise to 370 million by 2030 in the world. Diabetic kidney disease is a major cause of morbidity and mortality in diabetes(1). Diabetic kidney disease is the single most common cause of ESRD in many parts of the world including Europe, Japan, and the United States, with diabetic patients accounting for 25% to 45% of all patients enrolled in ESRD programs (2,3). Reducing sugars can react non-enzymatically with the amino groups of proteins to form reversible Schiff bases, and then Amadori products(4,5). These early glycation products undergo further complex reactions such as rearrangement, dehydration and condensation to become irreversibly cross-linked, heterogeneous fluorescent derivatives termed AGEs(6). The formation and accumulation of AGEs have been reported to progress at an accelerated rate under diabetes. The pathological role
of the nonenzymatic glycation of proteins has become increasingly evident in various disorders including diabetic vascular complications\(^7\). Proteins are also susceptible to post-translational modifications that could alter their structure, function, and half-life during normal aging and pathological conditions such as diabetes. One such post-translational modification is non-enzymatic glycation (NEG, also called non-enzymatic glycosylation). NEG of client proteins ensue crosslinking and aggregation that may adversely affect the structural and functional properties of proteins\(^8\). Although NEG occurs at a lower rate over a lifetime, it occurs more rapidly in clinical conditions such as diabetes and is implicated in the pathophysiology of several complications of diabetes and other age-related disorders such as cataract, renal failure, cardiovascular complications, and Alzheimer’s disease. Oxidative stress has been defined as a loss of balance between reactive oxygen species (ROS) and protective antioxidant defense system. Increased oxidative stress induced by hyperglycemia may be due to multiple\(^9,10\). Experimental and clinical studies suggest an association between hyperglycaemia, malondialdehyde (MDA), and diabetic complications\(^8\). Malondialdehyde plays an important role in the pathogenesis of DN and its progression to end-stage renal disease (ESRD)\(^11\). The aim of this study was to evaluate the relation of serum level of AGEs and MDA with the development of diabetic nephropathy in patient with type two diabetes mellitus and to evaluate the possible mechanism by which AGEs and MDA induce nephrotic complication in type two diabetic patients.

**Patients and Methods**

This case-control study was carried out in Erbil city from the period started from 1\(^{st}\) of December 2020 to the end of March 2021. The study included 62 type 2 diabetic patients (31 patients nephropathy and 31 patients T2DM without nephropathy), their age between 40–69 years, these patients who attended Rizgari General Hospital. We collated all baseline clinical parameters including gender, age, body mass index, duration of DM, level of hemoglobin A1c, blood sugar, urine creatinine, urine albumin. The study also included 28 healthy control individuals defended as subjects who apparently haven’t any chronic diseases.

Urine have been collected from each subject in the study by using disposable urine cup for measuring urinary albumin / creatinine ratio UACR by testing micro-albumin and creatinine in urine (manual biochemical kits ) . Five ml of venous blood was collected from each subject by using sterile disposable syringe and transferred into two tubes, 1 ml added to EDTA tubes for determination of HbA1c level by immunofluorescence technique (i-chroma II ), the 2\(^{nd}\) part was 4 ml which transferred to sterile gell tubes, left to clot at room temperature for 20 minutes , then centrifuged at 3000 rpm for 15 minutes , sera were then removed and added in eppendorf tubes and stored at -30ºC for determination of AGE3 and MDA by using ELISA technique, RBS (manual biochemical kit ).

**Results**

The study showed non-significant difference among the studied group regarding their age (P>0.05), and Diabetic nephropathy group showed high BMI as compared with Diabetic non-Nephropathy and the control groups (P<0.05), Table 1

The study revealed that, the highest mean of UACR was recorded in DN group (258.6±28.56 mg/gm) compared with diabetic non-nephropathy (35.6±11.95 mg/gm) and the control group (20.39±1.72 mg/gm) (P<0.001), Table 7.

Discussion

The study showed the mean of AGEs was elevated significantly in diabetic nephropathy (DN) group followed by diabetic non-nephropathy and the control group. Recent studies have suggested that advanced glycation end-products (AGEs) may be a key factor in the development of metabolic memory in diabetic complications, because AGEs are produced and accumulated irreversibly in the body, depending on the degree of blood sugar regulation and duration (5-7). Another study done by Nenna et al (8) found that, AGEs was elevated significantly in DN patients comparing with the control group and suggested that, AGEs may contribute to the development of diabetic complications. Pasupulati et al (9) found that, patients with nephropathy showed significantly increased AGEs activity compared to DM patients as well as controls and reported that a highly significant correlation exists between an accumulation of AGEs on collagen and the severity of diabetic complications. Several other studies reported an elevation in AGEs levels in DN patients and suggested that AGEs may play an important etiological role in the development of diabetic complications (10,11). The study showed the mean of MDA was elevated significantly in DN group. In agreement with our finding, Mistry et al (5) found that, patients with nephropathy showed significantly increased MDA activity compared to DM patients as well as controls. Moreover, one study showed that there was a significant increase in MDA concentrations in patients with DN compared with both normal subjects and patients with T2DM (10,11). Additionally, several recent studies observed that, Oxidative stress markers like MDA is suggested to be an essential factor in the development and progression of DM as well as in the development of diabetic complications like DN (12-14). Moreover, Sifuentes-Franco et al (15) found that, investigated the status of markers of oxidative stress in DM and reported a significant elevated level of oxidative stress markers in DN group. Singh et al (16) revealed that, levels of MDA was elevated significantly in DN individuals as compared to controls. Different other studies were also found and increase in production of MDA level in the diabetic nephropathy and suggested that, feature of oxidative stress is one of intrinsic factors of diabetic complications (17-19).
without nephropathy regarding duration of diabetes (P<0.001). These findings were close to that reported Shahwan et al (90) showed that a significant difference was observed in the mean duration of diabetes (9.5 ± 1.7 vs. 5.9 ±1.5 years, (P<0.05). In agreement with our findings, Mistry et al (5) showed that, blood sugar glycosylated haemoglobin (HbA1c) in DN patients and in NDN were significantly (P< 0.05) higher than control subjects. Several studies showed that poor glycemic control as measured by HbA1c and blood sugar were strong predictor of nephropathy16-18. Other studies clearly demonstrated the benefits of improving glycemic control and decreasing HbA1c concentration in decreasing the complication rate of T2D (9,14,19). It has been hypothesized that the mechanism by which high glycaemic variability favours diabetic complications may be an increase in oxidative stress, as oxidative stress has been reported to correlate with glycemic variability as reflected by continuous glucose measurements among patients with Type 2 diabetes (20). The study revealed that, the highest mean of UACR was recorded in DN group (258.6±28.56 mg/gm) followed by diabetic non-nephropathy (35.6±11.95 mg/gm) and the control group (20.39±1.72 mg/gm) (P<0.001). Other studies which reported that elevated UACR is one of the major markers of progressive renal damage as complication of diabetes mellitus (21,22). An other study showed that, an increase in urea level is seen when there is damage to the kidney. Increase in blood urea level in the presence of high blood sugar level in diabetic patient indicates damage to the kidney (20). Study conducted by Rohitash et al (23) had found that increase urea and serum creatinine in diabetic rats indicates progressive renal damage. In agreement with our finding, Makita et al (24) found a significant association between serum levels of AGE peptides with duration of DM glycemic control in diabetic patients by analyzing the results from all the diabetic patients. Increased AGE levels have been associated with elevation in renal function tests and referred to renal damage as diabetic complications nephropathy (25). The study showed a significant positive correlation of MDA with blood sugar and HbA1c in diabetic nephropathy patients. Krishnamurthy et al (26) concluded that the inflammatory markers and oxidative stress are raised with elevation in levels of blood sugar and HbA1c in patients who have diabetic nephropathy because of hyperglycemia induced oxidative stress. This indicates that MDA influenced glycemic control in T2DM. In T2DM, the glycaemic control improves, the oxidative stress will partially decrease. The result as well showed that MDA when compared to FBS and HbA1c correlated positively, thus, as fasting blood sugar increases, MDA and HbA1c increase as well. There is growing evidence that more synthesis of highly reactive free radicals, due to hyperglycaemia causes oxidative stress, which further exacerbates the development and progression of type 2 diabetes and its complications (27,28).

Conclusions

This study showed elevated of AGEs, MDA and Poor glycemic control were associated with diabetic nephropathy.

Effect of Sperm Morphology on Normal Pregnancy

Samraa Maki Hamed¹, Yusra Salih Khudair²

¹M.B.Ch.B. HD.G.O Stud. Diyala Health Directorate, Iraq. ²Assistant Prof Dr. Obstetric and Gynecology, College of Medicine, Tikrit University, Iraq

Abstract

Background: Sperm morphology has been demonstrated to be a better predictor of fertilization potential than other semen analysis parameter.

Aim: The aim of this study is to determine the influence of the values of sperm morphology in men with normal sperm concentrations, according to the World Health Organization criteria, on the normal pregnancy.

Patients and Methods: A Prospective study conducted in Salah Al-Din general hospital from January to May 2021. The study included 60 pairs of infertile couples and recorded male partner sperm morphology. Based on the sperm morphology of the semen sample collected for the initial evaluation, patients were divided into three groups: Group A (n:20): patients with sperm morphology values between 0% and 4%. Group B (n:20): between 5% and 14%. Group C (n:20): patients with sperm morphology greater than 14%. A study was excluded when mean female age was less than 25 or greater than 40 years to avoid confounding due to extremes in maternal age.

Results: The study revealed that 35% of infertile men (group A) were smoker and compared with 20% of group B and 15% of group C, although the result was non-significant. The study showed that the mean of duration of infertility in group A was 45 year. The highest rate of infertile patients in the study (35%) was with duration of infertility for ≥5 year while only 10% was suffered from infertility less than one year, the study showed no significant differences among the studied groups regarding semen volume, sperm concentration, pH, rate of motility and WBCs cells. The study demonstrated that only 5% (1 of 20) of women who their husbands with abnormal sperm morphology (Group A) succeed to be pregnant normally during the period of the study compared with 30% of the group B and 65% of group C.

Keywords: Sperm morphology; Infertility; Pregnancy rate; Seminal fluid

Introduction

For years, sperm morphology has been a debated indicator of male fertility and success with assisted reproductive technologies (ARTs). While subfertile men have a lower percentage of normal forms when compared with men with proven fertility, the question of “Does form impact function?” remains. While an assessment of sperm morphology is a component of the standard semen analysis, the clinical utility of this is debated⁴. Despite routine application, semen analysis does not provide a direct measure of functional capacity of sperm⁵. No single semen parameter definitely predicts the potential of an individual couple to achieve success with assisted reproduction, however the percentage of sperm with normal morphology is positively correlated with In vitro fertilization (IVF) and pregnancy rates⁶. The 2010 WHO manual defines a morphologically “normal” sperm as having a head (with acrosome), midpiece, and tail. Specifically, a “normal” head has an oval shape with smooth contours⁷. The acrosome
Indian Journal of Forensic Medicine & Toxicology, October-December 2021, Vol. 15, No. 4

is clearly visible, well-defined, exhibits a homogenous light-blue staining, and covers 30–60% of the anterior portion of the sperm head. A “normal” midpiece lacks cytoplasmic residues and is axially attached to the head, without forming a definite angle with respect to the head, ≤ 1 μm in width and approximately 1.5 times the head length. The tail should also lack cytoplasmic residues, be apically inserted to the post-acrosomal end of the midpiece, have a length of approximately 45–50 μm long, and be lacking any sharp bends (1). Sperm should be analyzed after being stained via a modified Papanicolaou method. The analyzer should assess at least 200 spermatozoa per sample (6). However, the overall appearance of a sperm preparation does not always reflect the quality of the sperm cells injected into the oocyte. The number of cycles in which individual sperm morphology has been described remains limited (6). In addition, individual sperm morphology has not been evaluated when epididymal or testicular sperm cells were injected or when morphologically abnormal spermatozoa were used for microinjection (in most cases because no other sperm cells were available) (7). The aim of this study is to determine the influence of the values of sperm morphology in men with normal sperm concentrations, according to the World Health Organization criteria, on the normal pregnancy.

Patients and Methods

A Prospective study conducted in Salah Al-Din general hospital from January to May 2021. The study included 60 pairs of infertile couples and recorded male partner sperm morphology. Based on the sperm morphology of the semen sample collected for the initial evaluation, patients were divided into three groups:

1- Group A (n:20): patients with sperm morphology values between 0% and 4%.

2- Group B(n:20): between 5% and 14%.

3- Group C(n:20): patients with sperm morphology greater than 14%.

Group C was considered the control group, and groups A and B were compared to group C. All couples had been trying unsuccessfully to conceive for at least 1 year before being enrolled in the trial.

A study was excluded when mean female age was less than 25 or greater than 40 years to avoid confounding due to extremes in maternal age, and when mean TMC was less than 10 million since prior studies have demonstrated no difference in IUI pregnancy rates after semen samples exceed 9 million TMC. We excluded all studies that reported clinical pregnancies not verified by ultrasound, chemical pregnancies (a positive test for β-human chorionic gonadotropin that did not correlate with clinical or ultrasound findings) or live births that did not provide a count of pregnancies that underwent demise prior to delivery.

Before enrollment, each couple underwent assessment for infertility, by Careful history and physical examination, age of female partner, duration and type of infertility, details of menstrual history, previous pregnancies and miscarriages, illnesses, smoking, drugs, surgery, infertility investigations and/or treatments including previous IUI and/or IVF. It is also important to ask about sexual history including coital frequency and any history of contraception. Written informed consent was obtained from each patient.

The semen sample of the husband was collected by masturbation after 3 - 5 days of sexual abstinence into a clean, dry, wide mouthed container in a private room near the laboratory. The container was labeled with the name of patient and his wife’s’ name, age, time of sample collection and abstinence period. The specimens were kept in an incubator at 37 C° till complete liquefaction. Semen samples were analyzed depending on the guidelines of WHO (2010). Lower reference limits for semen characteristics according to WHO- 2010 criteria.
Results

The present study showed non-significant difference between the studied groups regarding their, Table 1.

**Discussion**

The study revealed that 35% of infertile men (group A) were smoker and compared with 20% of group B and 15% of group C, although the result was non-significant, Figure 1. In a cross-sectional on a rural Chinese population, Yang et al. (1) analyzed the relation of male smoking with couple’s infertility. Their study included data from 7,025 couples and found that after adjusting for the confounding factors, the couples were more likely to suffer from infertility if the husband smoked before the first pregnancy. In-depth analysis showed that the risk started after a longer duration of 5-10 years of smoking. Among studies on large number of smokers, Meri et al. (2) analyzed 396 smokers and 546 non-smokers and found that smokers had poor sperm motility and a higher proportion of abnormal sperm and leukocytes. In similar finding, Sarhat et al. (3) in Thi-Qar Province found that, the rate of infertile patients was (33.85%) with duration of infertility for ≥5 year and 9.23% was suffered from infertility less than year with mean duration 4.9 year. The study demonstrated that only 5% (1 of 20) of women who their husbands with abnormal sperm morphology (Group A) succeed to be pregnant normally during the period of the study compared with 30% of the group B and 65% of group C. The importance of sperm morphology has been a topic of debate since the 1970s, and the controversy has increased since the World Health Organization (WHO) adopted the Kruger strict morphology classification system in 1999 (4). When reviewing semen analysis methodology, morphology is the parameter that has undergone the most scrutiny and change over the years. Starting with the McLeod classification and proceeding to the WHO second through fifth editions, the definition of normal sperm morphology has changed significantly (5,6).

Accordingly, the normal reference ranges have transformed from >60% to >50% to >30% to >14% normal forms, and now, according to the WHO fifth edition, >4% normal forms is considered to be within the 95th percentile reference range (7,8). The debate over the significance and utility of morphology is so split that in many forums there is no middle ground or gray area. There are some who believe sperm morphology is the single most important seminal parameter in
determining pregnancy rates(9-11).

Then there are others who believe that sperm morphology is so unreliable that it should be stricken as a component of the semen analysis altogether and should not be considered when counseling couples(12-14). The definition of morphology has changed so many times over the past several decades that it has become nearly impossible to meaningfully compare data from the literature across time(15,16). To complicate matters even more, the interobserver variability in determining normal morphology and the non-standardization of techniques in many labs has resulted in literature that is very heterogeneous and difficult to critique(17-19). Nonetheless, several studies stand out as illuminating this contentious topic(20-24).

In 2006, Nallella et al. reported that a majority of proven fertile men had sperm morphology values in the abnormal range (25). After performing receiver operator characteristic curve analysis, the authors proposed a cutoff value of >11% for Tygerberg/strict morphology. Although their study did not address pregnancy rates in assisted reproduction, it did offer insight into the limitations of morphology and the significant overlap between fertile and infertile males. Karabinus et al. assessed morphology in the context of IUI outcomes, and they found no statistical difference in IUI pregnancy rates among patients stratified by morphology results(22). More specifically, they showed similar outcomes when sperm morphology was <5%, 5%–9%, 10%–19%, 20%–29%, or even R30%. These findings are in contrast to a study by Nikbakht et al. that reviewed 445 women undergoing 820 IUI cycles with controlled ovarian hyperstimulation (25). These authors reported an overall IUI clinical pregnancy rate of 9.9%, and they that found sperm morphology was significantly predictive of IUI success. The most profound differences were seen when comparing subgroups of sperm morphology <5% versus 5%–10% versus >10% (2.1% vs. 10.1% vs. 12.6% pregnancy rates, respectively). Sun et al. have also contributed to the morphology discourse (26). They evaluated IUI outcomes in patients with normal sperm concentration and motility, and they observed no difference in IUI success rates based on morphology in women younger than 35 years. They further reported, however, that IVF/intracytoplasmic sperm injection should be offered as a first-line therapy if normal morphology is <5% and female age is >35 years.

Conclusion

Morphology of sperms is a unique semen parameter, as it is not a direct measure of a specific aspect of sperm activity. Morphology might, however, act as a surrogate marker for other facets of sperm function. The key for investigators will be to determine those aspects of sperm function for which morphology serves as a surrogate.

Serum β HCG as a Predictor and Potent Marker for Pregnancy Induced Hypertension in Salah Aldeen General Hospital

Marwah Abdulrahman Ftaikhan¹, Musryia Rashad Hassein²
¹M.B.Ch.B. HD.G.O Stud. Al-Anbar Health Directorate, Iraq, ²Assistant Prof Dr. Obstetric and Gynecology, College of Medicine, Tikrit University, Iraq

Abstract

Aim: This study was conducted to predict gestational hypertension by using serum beta HCG and thereby to follow up the risk patients and to reduce both maternal and perinatal morbidity and mortality.

Patients and Methods: A prospective study was carried out in Tikrit city from the beginning of October 2020 to May 2021 and included 150 women, 25 were lost to follow-up. The rest 125 patients followed up in their second trimester (13-20) weeks, attending Salah Aldeen General Hospital. Routine antenatal investigations were done. All patients underwent thorough clinical and routine obstetrical examination. Venous blood sample was collected for determination of serum β HCG level.

Results: The study showed no significant difference between women with pregnancy induced hypertension (PIH) and Normal mothers regarding their age at the time of booking (P>0.05). The mean age of PIH women was 32.2±5.9 year and normal women was 32.2±6.2 year. Although 26.67% of PIH women were below 20 year of age compared with 12.73% of Normal women. The relationship between β−hCG (absolute) levels and PIH and the association between mean β−hCG level of PIH patients and Normotensives was statistically significant (p< 0.001) and as the level of β−HCG increases the PIH also increases. The study showed that, 66.67% of PIH women have severe elevation in hypertension and majority of women with severe PIH (90%) have Beta hCG level above 80000 mIU/ml and only 10% have level ≤80000 mIU/ml while 60% of women with mild PIH have level ≤80000 mIU/ml. The mean increase of SBP of PIH mothers was 40.1 mm/Hg.

Introduction

Hypertensive disorders of pregnancy complicate 5 - 10% of pregnancies worldwide and constitute one of the greatest causes of maternal morbidity and mortality and perinatal morbidity and mortality (1). In developed countries 16% of maternal deaths are attributed to hypertensive disorders. Hypertensive disorders are a frequently encountered complication of pregnancy and remain a major cause of maternal and perinatal morbidity and mortality (2). The Confidential Enquiry into Stillbirths and Deaths in Infancy report cites one in six stillbirths as occurring in pregnancies complicated by maternal hypertension. Hypertensive disorders vary from mild gestational hypertension to severe preeclampsia and have a number of possible etiologies (3). Several tests have been proposed but none has been accepted widely due to their low predictive value (4). The abnormal placentation has been considered as one of the initial events in the disease process hypothesized that during mid-trimester, immunological changes occur in the trophoblasts, resulting in a secretory response, which is seen as a rise in the beta Human chorionic gonadotropin (HCG) levels (5). Hypertensive disorders are also responsible for perinatal mortality and morbidity. Pre-eclampsia is a risk factor for stillbirth, Intrauterine growth restriction (IUGR), Low birth weight (LBW), Preterm delivery, Respiratory distress syndrome, and admission in the neonatal intensive care unit. Hypertensive disorders account for 8-10%
of all preterm births. A variety of biochemical and biophysical markers have been proposed for predicting the development of preeclampsia in pregnancy(6). Pregnancy Induced Hypertension, Gestational Hypertension or Transient Hypertension of pregnancy are terms used to describe new hypertension which appears after mid-term (20 weeks) and resolves within 10 days postpartum without other symptoms of pre-eclampsia in a previously normotensive woman(7). In pregnancy, the placenta forms especially large quantities of Human Chorionic Gonadotropin which is essential to a normal pregnancy and more so in Pregnancy Induced Hypertension. Elevated serum β-hCG in the second trimester has repeatedly been shown to be significantly associated with later PIH. The patients with abnormal β-hCG levels and in very few reports, the free β-subunit (free β-hCG) were reported as possible predictors of pre-eclampsia, pregnancy-induced hypertension, spontaneous miscarriage, low birth weight, preterm delivery and intrauterine growth retardation (IUGR) (8). This study was conducted to predict gestational hypertension by using serum beta HCG and thereby to follow up the risk patients and to reduce both maternal and perinatal morbidity and mortality.

Patients and Methods

A prospective study was carried out in Tikrit city from the beginning of October 2020 to May 2021. The study conducted to determine the role of β HCG in pregnant women, the included 150 women, 25 were lost to follow-up. The rest 125 patients followed up in their second trimester (13-20) weeks, attending Salah Aldeen General Hospital. Routine antenatal investigations were done.

Inclusion criteria

Pregnant women with:

- Singleton
- Gestational age 13-20 weeks as determined by last menstrual period or ultrasound scan.

Exclusion criteria

- Chronic hypertension.
- Molar Pregnancy.
- Diabetes mellitus.
- Anomalous foetus.
- Multiple pregnancies.

All patients were informed about the study and informed written consent was taken before they were enrolled in the study. At the time of enrollment, demographic details were noted, detailed obstetric and medical history was taken. Gestational age was calculated from reliable menstrual history dates and/or 1st trimester ultrasonographical measurement of fetal crown rump length. All patients underwent thorough clinical and routine obstetrical examination. Baseline blood pressure (average of 3 readings) using a sphygmomanometer was recorded using the auscultatory method. Routine antenatal tests were performed as required and indicated.

A routine antenatal investigation was done. 5 ml of venous blood sample was collected and tests were carried out. Estimation of serum β HCG level was done by immunofluorescence immunoassay as manufacture instructions. The cases were followed up in antenatal clinic and were examined 4 weekly till 28 weeks, fortnightly up to 34 weeks and thereafter weekly till delivery. At every visit. Serum β HCG as a predictor and potent marker for pregnancy induced hypertension. Blood pressure was recorded and urine was examined for albumin. PIH included gestational hypertension and preeclampsia. Gestational hypertension was defined as blood pressure 140/90 mmHg on two occasions at least 6 hours apart after 20 weeks of gestation. Preeclampsia was defined as gestational hypertension and proteinuria of at least 1
Severity of PIH

The severity of PIH is assessed by the extent of symptoms. Both blood pressure and proteinuria are dependable indicators of severity. (1)

v Mild PIH: Blood pressure is ≥140/90 mmHg but <160/110 mmHg after 20 weeks gestation, and proteinuria is ≥300 mg/24 hours without exceeding 2.0 g/24 hours or 3+ dipstick

v Severe PIH: Blood pressure is ≥160/110 mmHg, and proteinuria exceeds 2.0 g/24 hours or 3+ dipstick.

Data collection form

A structured format was prepared for collecting the demographic details, personal, obstetric and medical history, data related to all ANC visits, outcomes of serum β-hCG assessment, perinatal events and outcomes.

Results

In this study, 150 women completed the study, 25 were lost to follow-up. The rest 125 patients followed, 15 women developed PIH constituting 12% of the study population. Thus, the incidence of PIH was 12% in our study (Figure 1). When further subdivided, the incidence of preeclampsia was 20% of the PIH (n = 3). Of these 3 preeclamptic patients, 2 women had early-onset preeclampsia (onset before 34 weeks), whereas the rest 1 had late-onset disease. Most of the patients (83.33%) had late-onset PIH (after 34 weeks), whereas the incidence of early-onset PIH (before 34 weeks) was only 16.67% (Table 2).

Discussion

Hypertension and proteinuria are important complications of pregnancy. Abnormal placentation is one of the important pathologies for the development of GHT. Because of abnormal placentation, there may be an increased synthesis of beta HCG (1). There may be deregulation of lipoprotein lipase in GHT prone women, that causes elevated plasma lipid and lipoprotein levels, may induce endothelial dysfunction is the prominent pathology, usually occurs in early trimester (8-18 weeks) but signs and symptoms occur in a late trimester (1). In this study serum beta HCG estimated in the early second trimester, women with elevated levels, categorized under the high-risk group. So it is easy to identify the high-risk women and kept under regular follow up. It helps in preventing the development of complication in GHT. Since the year 1950 HCG is reported to be elevated in toxemic pregnancy (2,3). Like in present study, Mazhari and Varun (9), Soudararajan et al (10) Muthulakshmi et al (11), Kulkarni et al (12) and Rajesh et al (35) also use hCG production level as a measurement tool for the prediction of pregnancy induced hypertension. In the present study the prevalence of PIH was observed to be in 12% which was comparable to the studies performed by Mazhari and Varun (9) who found that the prevalence of PIH was 13.33% and Pawar et al (14) (11.53) which were in agreement with our finding Table 2 shows the relationship between β−hCG (absolute) levels and PIH and the association between mean β−hCG level of PIH patients and Normotensives was statistically significant (p< 0.001) and as the level of β−HCG increases the PIH also increases. Elevated serum β-hCG in second trimester has repeatedly been shown to be significantly associated with PIH (41). It has been reported that women with markedly elevated maternal serum β-hCG levels has significantly increased risks of having spontaneous miscarriage, preterm delivery and IUGR (15). The estimation of serum β-hCG levels may be helpful in both the early detection of PIH and to initiate necessary treatment to avoid associated complications (16). This will perhaps bring down the maternal and foetal morbidity and mortality (17,18) reported from their study that all those who developed PIH had higher levels of serum β-hCG confirmed 100% correlation between high serum β-hCG levels and development of PIH which in turn significantly increased risks of having poor/adverse pregnancy outcomes (Spontaneous miscarriage, Intra Uterine Growth Retardation (IUGR) and Preterm delivery), where the magnitude of risk correlates with the levels of β-hCG. The present study results indicate that β-hCG determination may have value in the prediction of PIH (19). It is evident from the different studies that, the serum β-hCG levels were significantly higher and significantly correlated with increased risk of PIH in women with increased β-hCG levels in the hypertensive group as compared to those in the normotensive group; which indicates the strong correlation between higher serum β-hCG levels and development of PIH later on during pregnancy (20,21). It seems reasonable to presume from the results of the present experimental study that the increased synthesis and secretion of free β-hCG is associated with immunosuppressive activity of hCG which helps to initiate early treatment so as to minimize and/or avoid adverse effects of PIH (22,23). The study showed that, 10 of 15 (66.67%) of PIH women have severe elevation in hypertension, The study also showed that, majority of women with severe PIH (90%) have Beta hCG level above 80000 mIU/ml and only 10% have level ≤75000 mIU/ml while 60% of women with mile PIH have level ≤80000 mIU/ml. Our study is in accordance to the study performed by Chowdhary et al (24) who reported 60% with severe hypertension and 40.0% with mild hypertension.

Conclusion

The study showed that measuring second trimester beta HCG levels is useful in clinical practice to identify women who will develop PIH in the same pregnancy.

Determination of Effectiveness of Exclusive Breastfeeding Preparing Program on Knowledge of Primipara Mothers in Kirkuk City Hospitals

Muntaha Hameed Hussein¹, Suhad H. Khairi², Mahasin T. AL-Harbawe³

¹Ph.D, ²Assist. prof. Dr., Department of Maternal and Newborn Nursing - College of Nursing / University of Baghdad.; ³Assist. Prof. Dr., Community Health Nursing / Al-Maarif University College

Abstract

Objective: To determine of effectiveness of exclusive breastfeeding preparing program on knowledge of primipara mothers in kirkuk city hospitals

Methodology: A quasi-experimental design of thirty Primipara women in three hospitals in kirkuk city for the period from March 1st to October 1st 2020. The data collected through stages which include pretest, posttest.

Results: The finding indicate that among thirty study sample the MS and SD were higher in posttest in compare with pretest, and significant differences were found within study sample before and after program at (P=0.05) which indicated that educational program positively effect on the study sample regarding exclusive breastfeeding.

Conclusions: The study concludes that after assessing the knowledge of the study sample, it found that their knowledge was poor and exclusive breastfeeding educational program was effectively improved their knowledge.

Keywords: Effectiveness, Exclusive breastfeeding, Preparing program, Knowledge, Primipara mothers.

Introduction

Breastfeeding is an important origin of food for infant at firstly six months of lifetime, according to the World Health Organization ¹, which confirmed maternal to use it as their primary source of nutrition. Mothers should feed their babies complementary foods in addition to breastfeeding between the ages of 6 months and 2 years.

Exclusive breastfeeding” is interpreted as Only breast milk is given to the newborn; no fluids or hard are given – not even water – except for oral rehydration liquid or vitamin, mineral, or medication droplets / syrups.” It is advised to use it during the first six months of a child’s lifetime, after which supplement feeding should be introduced. on the other hand, Breastfeeding should be continued for at least 2 years age or beyond ²³.

Performance for Natural Growing and progression for neonate and child feed , these practices involve starting breastfeeding during first hour of childbirth, exclusive breastfeeding during first six months of lifetime , adding suitable and sufficient goal of 21.9 million exclusively breastfed infants during the first six months of lifetime in 49 nations by 2015 (United Nations Secretary General, 2013).

As a result of the multiple predictor cluster survey (MICS) in Iraqi (2018), 32.4 % of babies were breastfed during the first hour of delivery,
and (26 percent) of infant were received exclusive breastfeeding within aged (0-5), (85 %) of infant were getting firm nourishment or semi-solid diet in aged (6-8) months while (45 %) of infant aged (6-23) months received the lowest nutritional variety. Five types of described developmental food groups, In the first year of life (12-15 months), 45 % of children continue to breastfeeding whereas in the second year of life (20-23 months), 27 % of infant continue to breastfeeding.

The provision (or lack thereof) of adequate information and support to the mother during both the antenatal and postnatal periods is one of the most important factors that influences the initiation and continuity of breastfeeding. Several studies have found that mothers who receive professional breastfeeding support and advice have more optimistic attitudes about breastfeeding and tend to breastfeed longer 6,7. Breastfeeding initiation rates have been shown to improve with interventions aimed at increasing healthcare providers’ breastfeeding awareness, and additional professional support from healthcare providers continues to enhance the duration of exclusive breastfeeding for mothers 8,9. On the other hand, breastfeeding results are negative when the upholding and advice given by healthcare providers is insufficient and suitable (Montalto et al., 2010). Knowledge of breastfeeding information has a direct and indirect influence on breastfeeding practice. Directly, a more enlightened individual on breastfeeding may practice it but the less enlightened, may doubt its potency and its benefit and therefore may not find it attractive to practice. Society may not accept the practice of breastfeeding due to cultural, religious and economic reasons, coupled with poor health staff attitude 11.

Objective of The Study

To determine of effectiveness of exclusive breastfeeding preparing program on knowledge of primipara mothers in kirkuk city hospitals

Methodology

A quasi-experimental design of thirty Primipara women in three hospitals in kirkuk city for the period from March 1st to October 1st 2020. The study instrument consist of three parts, it include demographic characteristics, reproductive history ,and mothers Knowledge. The data collected through three stages ; pretest stage to assess mothers knowledge , second stage , the educational program design to provide primipara woman with exclusive breastfeeding knowledge, it consisted from 27 items .The program intervention covered through lectures, videos, films, role play and pictures .The third stage was posttest , this done after two weeks from intervention the educational program. Pre and posttest fill questionnaire form by themselves .A descriptive and inferential statistic used to analyzed the data .

Results

Figure 1. Wives’ Age (Years)
The mean age of participants is $24.33 \pm 4.54$; Most of them age 18-24-years ($n = 18; 60.0\%$), followed by those who age 25-31-years ($n = 10; 33.3\%$), and those who age 32-40-years ($n = 2; 6.7\%)$.

![Figure 2. Wives’ Educational level](image)

Concerning wife’s level of education, less than a third are primary school graduates ($n = 9; 30.0\%$), followed by those who each of preparatory school graduates, institute graduates, and college graduates and above ($n = 5; 16.7\%$) for each of them, those who intermediate school graduates ($n = 3; 10.0\%$), those who are unable to read and write ($n = 2; 6.7\%$), and one who reads and writes ($n = 1; 3.3\%)$.

![Figure 3. Husbands’ Educational level](image)
Regarding husband’s level of education, a third are college graduates and above (n = 10; 33.3%), followed by those who are primary school graduates (n = 6; 20.0%), those who are preparatory school graduates (n = 5; 16.7%), those who are institute graduates (n = 4; 13.3%), those who are intermediate school graduates (n = 3; 10.0%), and those who read and write (n = 2; 6.7%).

With respect to wife’s occupation, most are housewives (n = 21; 70.0%) compared to those who are employees (n = 9; 30.0%). For husbands, more than a half are freelancers (n = 16; 53.3%), followed by those who are employees (n = 7; 23.3%), those who are students (n = 5; 16.7%), and those who are out of work (n = 2; 6.7%). Concerning family’s monthly income from family point of view, most reported that they have barely sufficient income (n = 19; 63.3%), followed by those who have a sufficient income (n = 7; 23.3%), and those who have an insufficient income (n = 4; 13.3%). Regarding the residence, the vast majority live in urban areas (n = 29; 96.7%) compared to those one who live in rural area (n = 1; 3.3%).
3.3%). Lastly, With respect to “Family type, less than a half reported that they have been living in nuclear families (n = 14; 46.7%), followed by those who have been living in shared families (n = 11; 36.6%), and those who have been living in extended families (n = 5; 16.7%).

</table>

Concerning abortion, most study sample reported that they did not experience abortion (n = 21; 70.0%) compared to those who have experienced it (n = 9; 30.0%). Regarding pregnancy-related problems, the majority reported that they do not experience such problems (n = 24; 80.0%) compared to those who experienced them (n = 6; 20.0%). With respect to breast care, all study sample reported that they are caring for their breast (n = 30; 100.0%). All study sample have intend to breastfeed their babies (n = 30; 100.0%). Study sample gave birth through normal vaginal delivery (n = 15; 50.0%) compared to those who delivery cesarean section (n = 15; 50.0%). All study sample gave birth in the public hospitals (n = 30; 100.0%).

Discussion

Socio-Demographical Characteristics Variables

Among thirty study sample who completed the questionnaire, the main age of the study sample ranged from (18-24) years was (SD 24.33 ±4.54 years), the majority (30%) of the study sample are primary school graduate and (33.3%) of their husband graduate from college and above

Occupationally (70%) of the study sample are house wife, while more than half (53.3%) of their husband are freelancer, (63.3%) of the study sample consider their socio-economic status barely sufficient from their point of view, (96.7%) of them lived in urban area and (46.7%) lived in nuclear families.

The study’s findings concluded that highly percentage of the study sample were young, low socio-educational status, without work, and low economic status as shown in table (1), and figure(1,2,3).

Studies found that age, educational level, no occupation leads to minimize breastfeeding (Rocci & Fernandes, 2015)

Many studies show that socio demographic factors characteristics such as age, education level, occupation, family income and types of family were coincide with this study results (Usha Rani & Bhattacharjee, (2018); Hasan, (2016); Najem & Al-Deen, (2011); Shommo & Al-Shubrumi, (2014)).

Habibil et al., (2018) concluded that a significant relationship between exclusive breastfeeding and mother education, socio-economic status and length for age, and maternal employment. Breastfeeding was closely associated to all socioeconomic variables, maternal educational level, maternal unemployment benefit, and income (Flacking et al., 2007).

Reproductive Characteristics

The reproductive criteria of study sample included (70 %) of study sample with no abortion, the majority (80%) of them do not experience pregnancy-related problems. All (100%) of study sample get care for their breast during pregnancy and have an intention to breastfeed their babies respectively. Half (50%) of
them their delivery type was normal vaginal delivery compared (50%) of Cesarean section respectively. All (100%) of women gave birth in the public hospitals.

Breastfeeding intentions of maternal before conception have an effect on practice of baby feeding (Donath & Amir, 2003). Breastfeeding for 6 months is more likely when mothers have high intention and self-efficacy (Wilhelm et al, 2008). During the antenatal period, all women should be encouraged to plan for breastfeeding their children.

Women’s breastfeeding self-efficacy and intent to breastfeeding were the most significant indicators of breastfeed beginning, continuance, and duration in the first six months following delivery (Brockway et al., 2017).

The type of birth (vaginal vs. caesarean) have no effect on breastfeeding patterns, according to DiGirolamo et al. (2008). While Patel et al., (2003) discovered that the mode of delivery had no influence on breastfeeding.

Mothers who gave delivery naturally had a more favorable attitude toward breastfeeding and had less stress breastfeeding practices than mothers who underwent a caesarean delivery (Imhonde et al., 2012; Carlander et al., 2009).

Bottle-feeding and reduced milk supply are associated to Caesarean deliveries (Zhang et al, 2004).

Concerning of the delivery place, the current study found that all of the mothers gave delivery at hospital. The finding was confirmed by Ravi et al., (2015), who mentions the majority of women’s gave delivery in a hospital.

This finding is confirmed by Pushpa & Chowti (2012), who state that there is no significant association among the site of delivery and women’s information on breastfeeding.

Differences in Study Sample Knowledge between Pretest and Posttest

Thirty mothers who breastfeeding for the first time received sessions about exclusive breastfeeding. Twenty seven questions covered the entire process of exclusive breastfeeding. After statistical assessing, the knowledge of the study sample through pre and posttest.

Before the program only (26.7%), (6.7%) and (20%) of the study sample know the correct definition and the duration and advantages for baby of exclusive breastfeeding respectively.

This results indicate that many study sample have general information about breastfeeding but few of them knew accurate information and how breastfeeding done (Hanafi & El-Ammari, 2014).

The finding indicate that Although most of study sample are primary school graduated the results shows that at pretest 10(3,5,6,8,9,13,18,19,21,22) out of 27 items assessment degree record high which mean that study sample had back ground about breastfeeding information regard less of educational level.

The majority of primigravidas in India (78%) did not know that EBF should be continued for six months, according to a survey (Dhandapany etal., 2008). The majority of primigravidas were unaware that EBF reduces the risk of neonatal jaundice (Kumer et al., 2015). In respect to table (3) the overall analysis revealed that there is a positive significant improvement in the study sample knowledge at p: value (0.05). Kumar et al., (2015) several research reinforce the previous findings, stating that insufficient information, a negative attitude, or inappropriate breastfeeding technique lead to negative results for both mother and newborn. Insufficient breastfeeding is one of main reasons of baby deaths and morbidity, because the mother’s lack of awareness of its importance and benefits. During antenatal education in the waiting room, however, education can play a large role in changing mothers’ attitudes and knowledge about breastfeeding. Iraq and neighboring countries have a common culture that is similar to that for countries with Islamic
religious roots which has a positive attitude toward breastfeeding. Finally, the study participants have a positive response, and the sessions have a good impact on their knowledge.

Conclusions

Based on data analysis and critical interpretation of the finding. The study concluded that after assessing the knowledge of the study sample, it found that their knowledge was poor and exclusive breastfeeding educational program was effectively improved their knowledge.

Recommendations:

1. Developing and implementing of educational programs support and counseling routinely during pregnancy (antenatal and postnatal period through primary health care centers and hospitals.

2. Nurse need to motivate and monitoring the promotion of exclusive breastfeeding for six months by home visit or telephone call and provide mothers with pamphlets and guideline to increase knowledge and practices regarding breastfeeding.

3. Engage family members and husbands effectively in the educational programs, family have a big role in encouraging pregnant women to breastfed their babies after birth.

4. Further studies about changing the conception of insufficient breast milk for mothers.

5. Enhance new mothers understanding rather than education to change their misconception and attitude and behavior through mass media.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: “All experimental protocols were approved under the College of Nursing and carried out in accordance with approved guidelines”.

Detection the Level of Anxiety and Depression among Diabetic Foot Patients at Al-Najaf Al-Ashraf Teaching Hospitals

Ali Dawood Salman¹, Serwan Jafar Bakey²

¹M.Sc., Department of Psychiatric and Mental Health Nursing, ²Lecturer, Dr., Ph.D. in Adult Nursing, Faculty of Nursing, University of Baghdad, Iraq

Abstract

Objective: The study was done to assess the level of anxiety and depression among diabetic foot patients at Al-Najaf Al-Ashraf Teaching Hospitals. Also to find out relationships between anxiety and depression of diabetic foot patients and their demographic characteristics. Methodology: a descriptive correlational design, the study established for a period from 10th October, 2020 to 1st June, 2021. The study was conducted on a probability (accidental) sample of 120 patients who have a diabetic foot which was selected from Al-Sadder teaching hospital and Al-Furat teaching hospital in Al-Najaf Al-Ashraf Governorate. The researcher is using the Hospital Anxiety and Depression Scale to assess the level of anxiety and depression. Results: The result of the study showed (37.5%) of the study sample had moderate anxiety. Furthermore, the study shows (36.6%) of the study participant have moderate depression. Contingency correlation analysis showed that anxiety and depression is a significant correlation with the number of hospital admission, duration of current admission, and previous amputation. In addition, anxiety was significantly correlated with gender, educational level, duration of the diabetic foot. Besides, depression was significantly correlated with age, economic status, having other chronic diseases.

Keywords: Anxiety, Depression, Diabetic foot

Introduction

Diabetes Mellitus (DM) is one of the most important chronic diseases worldwide, with regards to the impact on health and the fifth leading cause of death worldwide ¹, DM is a chronic genetic disorder that has been recognized as one of the main causes of life with disabilities ².

Diabetes mellitus is a multi-system disorder characterized by impaired glycemic control and is associated with a range of medical complications. Adverse events may occur due to medication dosing and complications of the disorder may slow progress, these factors make individuals with diabetes predisposed to have psychological disturbance such as depression and anxiety ³.

Diabetes mellitus has become a worldwide problem as its prevalence rises. In 1980, 108 million people were diagnosed with diabetes, rising to 422 million in 2017. By 2035, it is expected that 592 million people will have the disease (Sari et al., 2018). All types of diabetes mellitus can lead to complications in many parts of the body and increase the risk of dying prematurely, diabetes was the direct cause of 1.5 million deaths globally (World Health Organization[WHO], 2020). Iraq is living with a DM epidemic, with a prevalence of about 20 percent, this prevalence has risen fourfold in the last four decades, and it is predicted to continue increasing in the future. Long-term DM complications are more frequent in Iraqi patients than in other parts of the world, approaching 80 percent for certain microvascular complications [retinopathy and neuropathy], and 25 to 48 percent for macrovascular complications [cardiovascular diseases and stroke, respectively] .
Diabetic Foot (DF) is a severe diabetic complication characterized by deep tissue lesions in the lower limbs, as well as neurological problems and peripheral vascular disease. The diabetic foot has become more common as the global prevalence of diabetes mellitus has increased 4.

Diabetic Foot Ulceration (DFU) is a serious and potentially limb-threatening complication of diabetes that can lead to pain, tissue necrosis and amputation, and may significantly affect an individual’s well-being and mobility 15. Around 25 percent of people with diabetes will be suffering from DFU during their lifetime. In addition, every 20 seconds a lower limb is amputated due to diabetic complications. In fact, every year 5 percent of all the patients with diabetes develop foot ulcers, and 1 percent require amputation 5.

Foot complications can be the most common cause for hospitalization in people with diabetes, and the duration of stay may be up to 59 percent longer than in people with diabetes hospitalized for a non-foot-related reason. Diabetes complications are associated with amputation rates and life-threatening problems. A foot ulcer affects about 15 percent of diabetic patients, and 14-24 percent of those with foot ulcers need amputation 6.

Diabetic patients suffer from a variety of health problems, including mental and psychological challenges that have an effect on their overall health (Yavati et al., 2011). On the other hand, diabetic foot patients are more likely to experience depression and anxiety than diabetics without foot problems, and depression and anxiety levels increased with hospitalization 6.

Diabetes mellitus and depression are two of the most serious public health problems in the United Kingdom (UK) and around the world 11. Anxiety and diabetes-specific distress, such as not accepting diabetes, worries about complications, concerns about food, feelings of guilt or shame, and distressing social interactions, are often common causes of disability, occupational absenteeism, and lost productivity 7.

Methodology

Design of the Study:

A Descriptive correlation design was conduct on diabetic foot patient in Al-Najaf Al-Ashraf teaching hospitals. The study was carried out to assess the level of anxiety and depression among diabetic foot patient and to find out the relationship between the anxiety and depression and their socio-demographic characteristic.

The Setting of the Study:

The study is conducted in Al-Najaf city/ Al-Najaf Al-Ashraf Health Directorate/ Al-Sadder teaching hospital and Al-Forat teaching hospital.

Sample and Sampling of the Study:

Anon-probability (accidental) sample including 120 diabetic foot patients which were selected from Al-Najaf Al-Ashraf teaching hospitals.

Instrument of the Study:

The research instrument which was consisting of two parts, part 1 list of common items for assessing demographic characteristics of patient with diabetic foot and information about their illness and part 2 Hospital Anxiety and Depression Scale (HADs) to assess the anxiety and depression among diabetic foot patients.

Part I: Socio-Demographic Characteristic

This section is dedicated to the collection of socio-demographic data including age, gender, residence, marital status, economic status, education level, occupational status, and information about their disease including duration of diabetes mellitus, duration of diabetic foot, if they have other chronic diseases, smoking history, alcohol history, number of admissions, duration of current hospitalization if they have a previous amputation and complications of diabetes mellitus.
Part II: Hospital Anxiety and Depression Scale

This scale assesses psychological morbidity (depression and anxiety) the scale consists of 14-item: seven items for anxiety (e.g. “I feel tense or wound up”; “Worrying thoughts go through my mind”) and seven items for depression (e.g. “I enjoy the things I used to enjoy”; “I have lost interest in my appearance”) \(^8\). The score for each scale ranges from 0 to 21 and each item has a choice of four response statements (scored 0–3). A Total score which divided into four levels: Scores represent: normal 0-7, Mild 8-10, Moderate 11-14, severe 15-21 for anxiety and depression.\(^{33}\)

Validity and Reliability of Scale:

Validity of Scale:

The instrument was introduced to a panel of (12) experts with more than ten years of experience in their field to make the instruments more valid using content and face validity methods.. The changes have been made in accordance with the recommendations of the experts.

Reliability of the Scale:

The scale was previously used and according to Terkawi et al (2017), the reliability had shown that for Time 1 and Time 2, Cronbach’s alfa for the HADS anxiety subscale were 0.83 (95 percent confidence interval [CI]: 0.79–0.88) and 0.87 (95 percent confidence interval [CI]: 0.83–0.91), respectively. For Time 1 and Time 2, Cronbach’s s for the HADS depression subscale were 0.77 (95 percent CI: 0.7–0.83) and 0.8 (95 percent CI: 0.75–0.86), respectively. Internal consistency was found to be adequate for both HADS subscales at both time points among patients.

Method of Data Collection:

After determining the validity and reliability, data was collected using an ‘Arabic version’ self-report questionnaire as a means of data collection, as well as an semi-structured interview with patients who do not read or write, unless they refused to participate in the research. The questionnaire takes about 15 to 20 minutes to complete. Where the data was collected from 10th January 2021 to 10th May 2021.

Method of Statistical Analysis

The statistical package for social sciences (SPSS) version 24.0 application of statistical analysis framework was used to analyze the results. The resulting research was analyzed and evaluated using the subsequence statistical data analysis technique.

Part I: Discussion of Socio-demographic Data of the Study Sample:

Table(1) shows that nearly thirds of the age of the study sample were between (50-59) years at an age mean of 53.43 ± 9.65 years, this result coincides with the result of previous studies, Chen et al. (2020) asserted that the mean age of DFU patients was 59.4±10.1 years. Polikandrioti et al. (2020) reported that 32.8% of their study participant had ages from (51-60) years. Ahn et al. (2018) reported that the median age of the study sample was 58 years. Saber & Daoud (2018) reported that the mean age of the patients was 53.7 ± 12.08 years. Mohammed et al. (2016) stated that most of the study sample was that at age mean 54.8 ± 11.05 years. Sehlo et al (2016) noted that 56.55 ± 3.32 mean of the age in their study. Neeru et al.(2015) found that the mean age of the patients having diabetic foot ulcers was 52.36 ± 7.8 years. 

Regarding gender, the results of the current study showed that males were more than females with diabetic foot, according to the findings of this study, which are consistent with earlier findings that show that the males were more than females.

Regarding residence, the study reported that less than two-thirds of the study sample living in the urban area, the result of this study congruent with other studies, Saber & Daoud, (2018) stated that more than two-thirds of diabetic foot patients who participate in their study dwelled in urban areas. The result also agree with determining that there are just 21.3% DF patients living in the rural area and the other lives in the urban areas. Agree with asserted that more than half of the study participants was lives in urban areas. While noted that more than three-quarters of their study sample resided in urban areas.

Concerning the marital status, the study finding shows that three-quarters of DF patient participant in the study were married, this result is agree with previous studies reported that more than three-quarters
of DF patients were married 29.

As for the presence of other chronic diseases, the patients who didn’t have another chronic disease are more than half of the study sample, the result of this study congruent with Mohammed et al. (2016) documented that the patients with other comorbid conditions were more than one quarter while the patients without other chronic diseases they were less than three quarters in their study sample, furthermore, the study by 24 noted that more than three-quarters of DF patients did not have other chronic diseases.

As for those who have chronic diseases, the current study showed that most of them had hypertension, this result agree with previous studies showed highly percentage of DF patients have hypertension 4,6,23,25,27,32.

Regarding the duration of diabetic foot, the study shows that the majority of the study sample have diabetic foot more than one month, this result agrees with Messenger et al. (2018) stated that less than three quarters have diabetic foot more than 1 month, Also documented 34 the mean of DF duration was 1.6 months. While noted 24 the median of DF duration was 11 weeks that also agree with our study.

With regard to previous amputations, the result found that half of DF patients had a previous amputation, and this result does not completely agree with previous studies that showed that the percentage of patients who did not have a previous amputation was more than those who had it 16, 18, 25, 31.

Table (2) shows that more than one-third of patients with diabetic foot participants in the current study have moderate anxiety and a quarter of them have mild anxiety. The study by Chen et al. (2020) asserted that less than two-thirds of the study sample were had mild anxiety while nearly one-quarter of them suffering from moderate anxiety. Likewise, reported 26 that DF patients who had low anxiety were more than two-third while just (16.9%) had moderate anxiety. Besides that, indicated by 24 that the mean score of anxiety was 11.46 ± 5.14 (moderate anxiety) this result agrees with the current study that indicated the mean score of anxiety was 11.29 ± 3.42.

Table (3) indicates that more than one-third of the patients in the current study have moderate depression and about a quarter of them have mild depression. the study by Chen et al. (2020) stated that more than half of the study sample had mild depression while less than one-third of them had moderate depression. In addition, 26 found that more than two-thirds of the DF patients in their study experienced mild depression. According to Pearson et al. (2014), 28.3 percent of DF patients suffer from moderate to severe depression. Moreover, 24 that the mean score of depression was 9.39 ± 5.90 moderate depression.

Concerning the result related to the correlation between anxiety and socio-demographic data in table (4) the existing study exposes that there is no significant correlation between anxiety and demographic data of the study sample related to (age, residence, marital status, economic status, occupational status, if they have another chronic disease, type of other chronic diseases, duration of DM, smoking history, alcohol history, and complication of DM.

Regarding the result related to the correlation between depression and socio-demographic data in table (4) the existing study exposes that there is no significant correlation between depression and demographic data of the study sample related to (gender, residence, marital status, educational level, type of other chronic diseases, duration of DM, duration of DF, smoking history, alcohol history, and complication of DM.

Conclusion

The researcher concluded that the level of anxiety and depression among diabetic foot patients was moderate and was associated with the number of times patients were admitted to hospitals and the length of stay of patients in the hospital, and was also significant associated with patients who had a
previous amputation.

Assessment the Complications of Caesarean Section among Women’s attending AL - Diwaniyah Maternity and Pediatric Hospital/ Iraq

Ghufran Fadhil Abo-Khuwait¹, Najmah Mahmood Meran²

¹Academic Nurse, Ministry of Health/ AL Diwaniyah Directorate, Iraq, ²Assist. Prof, Collage of Medicine/ University of Baghdad, Iraq

Abstract

Aims: This study aimed to assess complications of caesarean section among pregnant women attending AL Diwaniyah Maternity and Pediatric Hospital; and find out relationship between complications of caesarean section and socio-demographic data of women.

Methods: A descriptive cross-sectional study design is conducted for the period of December 26th 2020 to June 1st 2021. The validity of the questionnaire is determine through a panel of experts and reliability was achieved through a pilot study. By a purposive sample is selected among pregnant women who undergo caesarean section, data was collected through the use of questionnaire and interview techniques; and analyzed through the descriptive and inferential statistic.

Results: Findings indicate participants age, the mean age was 29±7.723, the age 20-29 years old (n=217; 43.4%), a not read and write (n=149; 29.8%), more than half of studied participants were housewife (n=339; 67.8%), most of study participants were overweight (n=248; 49.6%). Findings showed that the factors associated with caesarean section were post-partum hemorrhage, prolonged operation wound infection and postpartum infection among studied sample. Regarding fetal complication, Low Apgar score (n=348; 69.6%), respiratory distress syndrome (n=352; 70.4%), and perinatal asphyxia (n=468; 93.6%), among studied sample. The education and BMI have been significant relationship with their associated factors of caesarean section at p-value <0.05.

Key-wards: Assessment, Caesarean Section , Complications.

Introduction

The importance of caesarean sections in preventing difficulties during childbirth and lowering maternal and fetal mortality rates was widely recognized [1]. However, in the recent decade, the rise in caesarean section births has been a major source of concern for public health officials around the world. In most countries, the caesarean section rate (CSR) has above the World Health Organization’s recommended range of 10–15 percent (WHO) [2]. Within the first 10 days after a cesarean delivery, infection is the most common consequence. Infection rates without prophylactic antibiotics are around 85%, whereas infection rates with prophylactic antibiotics were only around 5% [3]. All patients undergoing cesarean delivery should get prophylactic antibiotics; a single dose of a first-generation cephalosporin or ampicillin is sufficient [3]. Although CS was a safe procedure, it puts mothers and their newborns at risk of short- and long-term health concerns when it is performed without medical necessity. The majority of CS problems, on the other hand, stem from the underlying source of the condition Obesity, huge infant size, extended labor, multiple pregnancy, and early birth are all factors that increase the risk of problems in some women [4]. The additional risk connected with the procedure itself must be considered in the absence of a clear medical
justification. Maternal care, both short- and long-term [5]. Therefore, this study aimed to assess complications of caesarean section among women’s attending AL Diwaniyah Maternity and Pediatric Hospital; and find out relationship between complications of caesarean section women’s and socio-demographic data.

**Methodology**

A descriptive cross-sectional study design is conducted for the period of December 26th 2020 to June 1st 2021. A questionnaire deal with complication of caesarean section related to women’s which composed of (11) items; and complications of caesarean section related to fetus which composed of (6) items. The validity of the questionnaire is determine through a panel of experts and reliability is achieved through a pilot study. By a purposive sample is selected among those who are undergo caesarean section, data was collected through the use questionnaire and interview techniques; and analyzed through the descriptive and inferential statistic.

</table>
Findings shows that there were no-significant relationship between women demographic characteristics and their complication of caesarean section at p-value >0.05 except, the education and BMI have significant relationship with their complications of caesarean section at p-value <0.05.

**Discussion**

Table 1: Concerning participants age, the mean age is 29±7.723, the age 20-29 years old (n=217; 43.4%), followed by those who are age 30-39 years and old (n=158; 31.6%), followed by those who are age 40 years and older (n=69; 13.8%) and those who age <20 years old (n=56; 11.2%). This results come because those age groups were the age of production. In terms of residents, more than half of studied sample are urban residents (n=271; 54.2%) compared for those who are rural residents (n=229; 45.8%) due to the hospital covered by the study were located in urban areas so, the women residents in those areas. As well as, urban residents were four times more likely to give birth through cesarean section than those who came from rural resident [6].

With respect to education level, studied sample express a not read and write (n=149; 29.8%), followed by those who were collage graduated (n=87; 17.4%), followed by those who are institute graduated (n=72; 14.4%), and followed by those who are primary and secondary graduate (n=44; 8.8% and n= 32; 6.4%) respectively. Occupation related findings, more than half of study participants are housewife (n=339; 67.8%), followed by those who were employed (n=102; 20.4%), and followed by those who are students and retired. In regards with body mass index, most of study participants were overweight (n=248; 49.6%), followed by those who were normal weight (n=213; 42.6%), followed by those who are thin (n=21; 4.2%), and followed by those who were obese (n=18; 3.6%).

The above findings come with findings of study conducted in Kurdistan region, Iraq. Results indicated that the (55.5%) were within age 20-29 years at mean age=28, (51%) were basic education, (61.7%) urban residences with normal to overweight [7].

In recent years, caesarean section rates continue to evoke worldwide concern because of their steady increase, lack of consensus on the appropriate caesarean section rate and the associated short- and long-term risks. Our findings showed according to mean that the surgical site infections were the most common complications with cesarean section followed by post-partum hemorrhage and endometritis among studied sample. The perinatal asphyxia were most common complications of cesarean section among fetus followed by respiratory distress syndrome and low Apgar score.

This findings come consisting with findings of study conducted in Public Hospitals in Northern Ethiopia. Their findings showed that the post-partum infection and post-partum hemorrhage were the most complications occurs after delivery [8].

According to the American College of Obstetricians and Gynecologists report, cesarean birth significantly increased a woman’s risk of pregnancy-related fatality (35.9/100,000) compared to a woman who delivered vaginally (9.2/100,000) deaths. The rates of operation wound infection, post-partum hemorrhage and babies respiratory distress syndrome were also common after cesarean section [9, 10].

**Conclusion**

Surgical site infection and post-partum hemorrhage were the most common complications of cesarean section among women. Perinatal asphyxia, respiratory distress syndrome and low Apgar score were most common fetal complication of cesarean section.

**Recommendation**

Health providers should follow WHO recommendations for the cesarean section. A manual booklet of side effects of cesarean section and how to manage it should be write in simple words and use
attractive pictures given to the women and family.

Prevalence of Drugs Use among Secondary-School Students in Al-Diwaniya City

Noor Adil Mayeh¹, Kareem Rishaq Sachit²

¹M.Sc., Department of Psychiatric and Mental Health Nursing, College of Nursing, University of Baghdad, Iraq. ²Assist. Prof. Department of Psychiatric and Mental Health Nursing, College of Nursing, University of Baghdad, Iraq

Abstract

A descriptive study design using a convenience random sample of (N=423) students. This sample is distributed throughout AL-Diwaniya Teaching Directorate. Data were collected through the use of an online questionnaire; and analyzed through the descriptive and inferential statistical approach. This study aims to identify the prevalence of Drug abuse among secondary school students. Results indicate that drugs use is low prevalent among secondary school students. Conclusion and Recommendations: Drug use prevalence is associated with students’ gender, age, family member, residency, house ownership, monthly income, parents’ education, and mothers’ occupation. The Ministry of Health should prioritize the Drug use in public health by educating the parents and adolescents the health hazards of substance use through health programs and social media.

Keywords: Drug use, Nursing, Secondary School Students.

Introduction

Substance misuse is linked to a variety of social and health issues, as has been shown in recent years. Substance misuse is the leading cause of death and disability in the world. UNODC estimates that about 5.2% of the world population has used illicit drugs (¹). Using of illicit drugs and the misuse of therapeutic drugs has elevated over the last two decades and has spread to every corner of the globe; nearly 7 billion people abuse narcotics worldwide, with 76 million suffering from their effects; the youth in this country are the most affected (⁷). Studies on substance abuse among young people conducted in different parts of the world show that there is a growing trend in drug use among this population. According to a study conducted in Nigeria on social demographic factors correlated with psycho active substance abuse by motorcycle operators, those who used drugs the most were those who were younger in age (⁴). In secondary schools, the use of psychoactive substances and other medications tends to be widespread and varies across African countries. Senior students in Ghana, for example, have been found to misuse different forms of substances at a lower rate than in other parts of the African continent and West Africa as a whole (⁸). Kenya is also grappling with the widespread use of narcotics and other addictive substances in secondary schools. Alcohol, tobacco, bhang, and miraa were the most frequently abused substances in Kenyan schools, according to a survey. These results revealed that substance abuse was widespread in secondary schools, with 57.9% of students admitting to having used drugs ⁶. In Eastern countries, substance abuse has skyrocketed to the point that it has become a major social issue. According to figures from 2003, the average age of initiation of substance addiction has dropped to 14-16 years. According to statistics, addiction and issues linked to substance abuse was the cause of 34% of divorces ⁵. Substance abuse most often starts in early adolescence as a result of social economic issues and cultural norms prevalent...
at this period. Long-term studies of drug misuse have discovered that the use of tobacco, alcohol, marijuana, and other drugs occurs in this order \(^3\).

**Methodology**

A quantitative descriptive study used assessment approach with questionnaire items is conducted to explore prevalence of drug use among secondary-school students in AL-Diwaniya City for the periods of 27.2.2021 to 8.4.2021.

Students were informed that their participation was voluntary in the study. The purpose and the benefits of the study was explained by the researcher. After they agreed to participate in the study, anonymous questionnaire was published online for the participants to participate in present study.

A convenient sample of \((N=423)\) students is selected throughout the use of non-probability sampling approach. The study sample is distributed throughout AL-Diwaniya Teaching Directorate.

The students test their prevalence of drug use with the constructed questionnaire. This questionnaire was created as a screening method to identify those who are likely to have drug use or not. A constructed questionnaire was used as a method for collecting data.

After completing the required approvals, data was collected by the use of a present questionnaire with the self-report techniques with students online. The researcher introduced himself to the participants and explained the purpose of the study in order to get oral agreement. The questionnaire fill out an answer by the participants (students). The researcher gathered the questionnaire after participant’s self-administration online on individual bases. Approximately each self-report took (15 to 20) minutes. Data collection was performed for the period of 27.2.2021 to 8.4.2021.

**Results of the study**

**M.S: Mean of Score, Assess: Assessment**

This table presents the assessment of drugs use prevalence; the table shows that 6.1% of students are sometimes taking some medication for non-medical purpose; 11.1% of them are rarely used more than one drug at a one time; 8.7% are sometimes consume drugs more than once a week; 6.4% are sometimes misuse drugs they stopped using drugs; 5.9% are sometimes feel guilty when using drugs; 5.9% are sometimes have affected relationship because of drug use; 6.1% are sometimes feel easier to be in the company of friends who use drugs than people who don’t; 5.9% are sometimes indicated by others that abuse is a big problem; 5.7% are rarely violent due to drug use; 6.6% are sometimes have affected ability in works due to drug use; only 5.4% are responding they rarely arrested for drug use, possession or driving; 5.7% are sometimes have physical symptoms of withdrawal when they stopped using drugs; and 5.4% are rarely lost consciousness while using drug.

**Discussion of the Study Result**

The table 1 indicated that drugs use are prevalent low among 5.7% of students, and prevalent moderately among 3.8% only. The table 2 showed
that 6.1% of students are sometimes taking some medication for non-medical purpose; 11.1% of them are rarely used more than one drug at a one time; 8.7% are sometimes consume drugs more than once a week; 6.4% are sometimes misused medication in the past; 5.4% are sometimes tried to stop using a certain drugs and found difficulty to do; 6.1% are often feel guilty when using drugs; 5.9% are sometimes have affected relationship because of drug use; 6.1% are sometimes find it easier to be in the company of friends who use drugs than people who don’t; 5.9% are sometimes indicated by others that abuse is a big problem; 5.7% are rarely violent due to drug use; 5.6% are sometimes have affected ability in works due to drug use; only 5.4% are responding they rarely arrested for drug use, possession or driving; 5.7% are sometimes have physical symptoms of Withdrawal when they stopped using drugs; and 5.4% are rarely lost consciousness while using drug. The low prevalence of drug use may be explained by the religious and tribal factor in the governorate, as the use of narcotic drugs is considered socially unacceptable behavior. In addition, the role of the Ministry of Interior that limits the spread of such phenomena is not lost because they are crimes punishable by law. Although most studies indicate an increase in drug use prevalence, one study supports the current results that found 9.8% of adolescents are using illegal drugs (2).

Conclusion

Drug use is low prevalent among 5.7% and moderately prevalent among 3.8% of secondary students. Drug use prevalence is associated with students’ gender, age, family member, residency, house ownership, monthly income, parents’ education, and mothers’ occupation. Cultural factor, socioeconomic factor, and level of education are key moderators in prevalence of substance use among secondary schools.

Abstract

Excellence in the sports field has become one of the essential metrics on which the progress of nations and peoples is viewed. In order to draw up valid scientific policies represented in the use of modern strategies and methods to prepare the appropriate educational and training curricula in order to reach the learners to the highest levels, individual learning strategies must be used, which is self-learning, as they take into account the individual differences between the learners and reduce the time and effort required for this process. Keller’s strategy is for individual or personal learning. One of the strategies that achieve this goal.

The researchers believe that learning with the Keeler strategy is a personal process, as learning cannot be given or indoctrinated but must result from the educated person’s experience and ability to retrieve his memory to perform better than what he witnessed. The field of physical education and education. The researchers identified the research community with students of the second stage in the College of Physical Education and Sports Sciences - the University of Kufa for the academic year 2017-2018, numbering 30 students, divided into two groups, each group consisting of (12) students, one of whom was chosen randomly to represent the experimental group to which the educational program will be applied. Under consideration is what will be applied to the other, which is the control group, the prescribed curriculum, and according to the method used, and the seven female students were chosen to represent the sample that will be conducted on the exploratory experiment.

Key words: cognitive achievement Keeler’s strategy, skills, volleyball

Introduction

Excellence in the sports field has become one of the essential metrics on which the progress of nations and peoples is viewed 1. And in order to draw up valid scientific policies represented in the use of modern strategies and methods to prepare appropriate educational and training curricula in order to reach the learners to the highest levels, individual learning strategies must be used, represented by self-learning, as they take into account the individual differences between learners and reduce the time and effort required for this process 2. Keeler’s strategy is for individual or personal learning. One of the strategies that achieve this goal.

Here, the researchers believe that learning with the Keeler strategy is a personal process, as learning cannot be given or indoctrinated but must result from the educated person’s experience and ability to retrieve his memory perform better than what he saw. In the field of physical education and education.

Research Problem

By informing researchers of many studies and research and through their experience that they have
been working in the educational field for quite some time, the teacher and the teacher alike must pay attention to modern education and move learners from education based on indoctrination often to positive education and the transfer of knowledge to The learner is an active medium that goes in line with recent developments and makes the learner more effective in the educational process by creating situations in which he is more upbeat and active.

Therefore, the researchers decided to use a new strategy in education using the Keeler strategy and identify its impact on cognitive achievement and learning offensive volleyball skills for students.

**Research objectives**

- Designing an educational curriculum according to Keeler’s strategy in cognitive achievement and learning offensive skills in volleyball for students.
- Recognizing the effect of Keeler’s strategy on cognitive achievement and learning offensive skills in volleyball for students.

**practical part**

Research Methodology:

Research Methodology: The researchers used the experimental method for its suitability and research requirements and the appropriate means to prove its hypothesis.

**Research Community and Sample**

The researchers identified the research community with students of the second stage in the College of Physical Education and Sports Sciences - the University of Kufa for the academic year 2017-2018, numbering 30 students, divided into two groups, each group consisting of (12) students, one of whom was chosen randomly to represent the experimental group to which the educational program will be applied Under consideration is what will be applied to the other, which is the control group, the prescribed curriculum, and according to the method used, and the seven students were chosen to represent the sample that will be conducted on the pilot experiment.

**Steps of conducting a search**

achievement test:

To identify the effect of Keeler’s strategy on cognitive achievement and in order to achieve the goal of the research, the researchers used the modified cognitive test by “Thaier Rashid (and others)” (), which measures its 31 paragraphs on the cognitive aspects of the offensive skills understudy with three alternatives for each paragraph that the laboratory chooses The correct answer is among them.

**The pilot experiment:**

To ensure obtaining reliable results, an exploratory experiment was conducted on (6) female students who did not enter the main experiment and from the same research community at exactly eight-thirty in the morning on Saturday 17/11/2017 in order to identify the most critical obstacles and errors that the researcher may face when Implementation of the main experiment as well as knowing the time taken to implement the skill tests and the extent of the research sample’s interaction in its Implementation Grades according to the skill performance appraisal forms.

**Scientific basis for the tests:**

In order to identify the scientific bases for the tests used, and after the researcher was informed of many sources, it became clear that they are codified on the Iraqi environment and were used in several studies as well as using them on similar samples. Constancy, objectivity).

**Equivalence of the two research groups:**

“In order for the researcher to return the difference to the experimental factor, the experimental and control groups must be completely equal in all their conditions, except for the experimental variable that
affects the experimental group”, the researchers divided the sample into two groups at random, and in order to achieve this, the researcher performed the equivalence process between the two research groups for the tests understudy, a t-test was used for independent samples, and the results showed that there were no significant differences between the two groups, which confirms the equivalence between them as shown in Table (1)

Table (1). It shows the equivalence between the experimental and control groups in cognitive achievement tests, serving skills, crushing hitting and blocking in volleyball, and the calculated and tabular (T) values and their statistical significance

**Pre-test:**

The control and experimental groups were pre-tested to determine the students’ skill level at 8:30 a.m. on Sunday and Monday, 22 and 23/11/2017, and the same assessors gave their scores to each student.

**Curriculum**

After preparing the requirements to implement the research experiment, work on the program (the experiment) began on the corresponding Tuesday, at a rate of two academic units per week for eight weeks, at a rate of (16) sixteen academic units.

Below is an explanation of how to apply the tutorial:

The researchers distributed the educational material into independent academic units and placed it in the time frame as follows:

The educational material was divided into 16 educational units distributed over eight weeks, with two educational units per week, with a time of 90 minutes for each educational unit.

According to Keeler’s strategy, the researchers applied for the educational program to the first group (experimental). In contrast, the curriculum was applied to the second group (control) for students of the second stage in the Faculty of Physical Education, in which the following steps were followed:

1- The academic unit time for the experimental and control groups is (90) minutes.

2- Inform the students of the date of the academic unit and prepare before its start (at the break).

3- Read the instructions and explain how to use the Keeler strategy with an explanation of how to deal with the program.
4- The beginning of the academic unit is in the classroom instead of the external arena in the college, starting with the educational section, during which the lecture is displayed on a 51-inch plasma screen (LCD) via a computer (laptop), starting with displaying the written and readable text and then displaying the images. Explanations that show what has been read in the text, noting that this is followed by a presentation of a video clip that also expresses the content of the text. At the end of this part, the evaluation questions are presented to the students, consisting of three Annex 2 questions, and the students must answer them with supervision by the observers, provided that they are informed of the extent to which the answer is correct or not. This is called feedback, which is a characteristic of reinforcement, which means that notifying the student of the correctness of his answer reinforces him and increases the probability of repeating the correct response later.

5- After completing this part of the lesson and with the help of the assistant staff, we move to the outside arena to apply the rest of the educational unit parts.

6- The second part of the educational unit takes place in the external arena and according to the sequence of the educational unit as in the method followed, except for the educational section that was given in the classroom for the experimental group.

7- In this part, the student applies the skill to teach himself and according to what he understood, absorbed and learned from the educational part under the supervision of the assistant staff, through skill training according to three levels, and each student must start from the level he deems appropriate for his abilities and capabilities, and then move to the higher level. Then the higher only after he has mastered the performance of that skill, provided that this is done under the direct supervision of the responsible professor and the staff who helps him in carrying out the lecture, as follows:

8- In performing the exercises for the skill of serving from the top, three circles were drawn, the first with a diameter of 7 m, the second with a diameter of 5 m, and the third with a diameter of 3 m. That this be done under the supervision of the observers present during the performance of the exercises.

9- As for the skill of crushing, three squares have been created in three levels, the first of which is 3 m long, the second 2.5 m, and the third 2 m. A space with full supervision of the observer present while performing the exercises.

10- As for the skill of the wall, three sites are created, each site contains a certain height of the network, the first height is 1.70 cm, the second is 1.90 cm, and the third is 2 m. Which he chose under the supervision of one of the observers present in the exercise ground. However, it was emphasized that the sample members need to constantly attend the educational units, not to be absent, and to cooperate with the assistant staff.

11- In the last section of the lecture, i.e. the concluding section, its duration is (3 minutes), which includes general relaxation and calming exercises, as well as a small game for the purpose of recreation and suspense, after which the tools and balls are collected and orderly withdrawal to the classroom.

Post-Tests

The post tests were conducted for the period from 25-1-2018 -27-1-2018 and included skill tests and cognitive achievement for the experimental and control groups.

Statistical means:

The researcher used the statistical bag (SPSS) to process the data.

Results

(*) Below the significance level (0.05) and the degree of freedom (22)

Discussing and analyzing the results of the post-tests of the experimental and control groups in cognitive achievement, transmission skills, smash hits, and individual blocking:

It is evident from the results of Table (4), after processing the results of the post-tests for the experimental and control groups, that the calculated T-value in the cognitive achievement test amounted to (8.272), as for the skill tests in question (sending, crushing and individual blocking) for the control and experimental groups and after Statistically processed, the value of (T) calculated in the transmission skill test reached (5.990), in the crushing beating skill test, it amounted to (5.011), and in the individual blocking wall skill test, it reached a value of (5.042), and it is clear from the above that the calculated (T) values for the variables under research are it is greater than the tabular value of (2.20) at a degree of freedom (22) and a probability of error (0.05), and the researcher attributes that the superiority of the experimental group is due to the use of the Keeler strategy, including the principles it contains, including self-learning, since this strategy is the best credible for this type of learning. Which has outperformed many well-known teaching strategies as it provides sufficient opportunity for the learner through freedom in the time he takes to learn and gives the student the opportunity to start learning from the level he considers appropriate for his mental abilities and physical capabilities.

Through the foregoing presentation, analysis and discussion of the results of the tribal, follow-up and posterior tests for the experimental and control groups, and the superiority of the experimental group over the control group by using Keeler’s strategy in cognitive achievement and teaching offensive skills in volleyball through the clear impact of using Keeler’s strategy on cognitive achievement and teaching offensive skills in volleyball. Through the superiority of the experimental group that learned according to this strategy, whether in the cognitive achievement of the educational material included in the educational program, or in teaching offensive skills in volleyball, which are the skills of (serving from the top, crushing beating, and individual blocking).
The researcher would also like to confirm that the good application of this strategy with all its components and the emphasis on the cognitive aspect contributed to the achievement of the research objectives.

Based on the foregoing, we find that the skill performance has a close and direct relationship with the cognitive aspect of the individual, as the educational process for any skillful performance in volleyball must be at the beginning of the early stages of learning to focus on the cognitive aspect of these skills in order to help in gaining performance faster and better than Learn it.

Thus, the objectives of the research have been achieved in the impact of Keeler’s strategy on cognitive achievement and learning offensive skills in volleyball, and to identify the priority of the two research groups, which was represented by the superiority of the experimental group over the control group.

Conclusions

In light of the results of the tests, their analysis and discussion, the researcher reached the following conclusions:

1. There are significant differences between the results of the pre and post tests for the experimental and control groups in all research variables in favor of the two groups.

2. The advantage of learning using Keeler’s strategy over the adopted strategy.

3. The use of Keeler’s strategy has a clear and significant effect in increasing the cognitive achievement, the learning process and the speed of learning the skills of serving, smashing and blocking in volleyball.

Effectiveness of an Educational Program on Nurses- Midwives Knowledge about Preterm Labor in Maternity Hospitals at Baghdad City

Bushra Thiab Obead1, Iqbal Majeed Abbas2
1Ph.D. Student, Academic Nursing Specialist, Baghdad Health Directorate Al-Risafa Sector, Ministry of Health Iraq, 2Ph.D. Emeritus Professor and Academic Supervisor, Baghdad College of Medical Sciences / Nursing Department

Abstract

Objectives: To determine the effectiveness of the educational program on nurses-midwives knowledge concerning preterm labor and to identify the relationship between nurses- midwives knowledge and study variables.

Methodology: A quasi-experimental design conducted on non-probability (purposive) sample of forty five nurses- midwives selected during period 17th October 2020 to 1st March 2021. The study is conducted at the four hospitals of Ministry of Health (Baghdad health directorate in Al-Karhk and Al-Risafa) sector. in obstetric wards and delivery room and neonatal Unit. The questionnaire form is consisted of two parts which included socio-demographic characteristics of the nurses-midwives and knowledge about preterm labor and birth. Reliability of the questionnaire was determined through internal consistency of correlation coefficient (R=0.807) and validity of content was determined through reviewing it by ten experts in different specialists was determined through pilot study. Descriptive and inferential statistics were used to analyze the date.

Result: The result of study revealed that their (33.3%) of study sample their age was (26-30) years old with mean and standard deviation is (32.68 ± 8.31) years, and less of half of the study sample was graduated from midwifery secondary school, half of study sample were married, 46.7% of them had less than / equal to (5) years of experience in nursing and midwifery field. And (80%) of the them did not practices midwifery as a profession inherited, (78%) of them were working in Government Hospital only , (70%) of (Nurses- Midwives) were not practicing midwifery at midwife home , (91%) of them having knowledge about preterm labor from Practical experience and (30%) of them suffered from preterm labor during their fertile age.

Keywords: Education, Effectiveness, Preterm labor, Nurses-Midwives, Knowledge

Introduction

Preterm birth (PTB) is still a widespread public health problem responsible for high perinatal mortality and long-term morbidity worldwide despite improved perinatal care programs, it still remains a major leading cause of perinatal mortality, mainly in developing countries (1). In developing countries, the main causes of preterm births include infectious diseases and poor availability and accessibility of health care resources. In high-income countries, the increase in the number of preterm births is linked to conception among older women and increased number of multiple pregnancies as a result of usage of fertility drugs. In some developed countries, medically unnecessary
inductions and cesarean section deliveries before full term also increase preterm birth rates. In rich and poor countries, many preterm births remain unexplained (2).

Preterm labor and birth are associated with traumatic life sites (eg, close family death, domestic violence, Anxiety about losing food, home or partner) either indirectly by associated risk behaviors. Many of these risk factors present together, such as chlamydia endocervicitis and third trimester bleeding. Rarely, cervical insufficiency results in spontaneous PTB. Preterm labor occurs for a variety of reasons. Most preterm births happen spontaneously, but some are due to early induction of labor or caesarean section, whether for medical or non-medical reasons. Common causes of preterm labor include multiple pregnancies, infections and chronic conditions such as diabetes and high blood pressure; however, often no cause is identified. There could also be a genetic influence. Better understanding of the causes and mechanisms will advance the development of solutions to prevent preterm birth (3).

Preterm labor is defined as the presence of uterine contractions of sufficient frequency and intensity to effect progressive effacement and dilation of the cervix prior to term gestation (between 20-37 wk). It has been the most concerning complication among pregnant women and affects 10% of all pregnancies. Annually 1 million neonatal deaths occur due to preterm birth. Unfortunately, there are no statistics in the Ministry of Health on preterm labor, but only on caesarean sections, normal vaginal delivers and abortion. The four major factors leading to preterm labor are: decidua hemorrhage, intrauterine infection, excessive uterine stretch, and maternal or fetal stress. Nurses-midwives are often the main fact of contact during the primary assessment and direct bedside care to women experiencing signs and symptoms of PTL; therefore, knowledge of identification, care, and treatment is essential. Nurses as frontline clinical experts are in an ideal position to address the complete needs of pregnant women and their support systems (4).

Nurses-midwives Knowledge about medications used to inhibit PTL enhances the nurse’s ability to recognize efficacy of tocolysis therapy and potential harmful side effects. Nurses-midwives should focus education on individualized pregnant women needs, home care and supplier follow-up instructions, and signs and symptoms that require seeking immediate medical attention such as ruptured membranes, bleeding, increasing frequency and intensity of contractions as well as decreased fetal movement (5).

Nurses-midwives knowledge and skills, timely identification of signs, symptoms, complications, cooperative and communication are essential for nurses-midwives caring for women in PTL and who give birth preterm.(6)

The most common interventions suggested to prevent preterm birth, such as bed rest, tocolytics, antibiotics and cervical cerclage have been proven to have little or no benefit. The goal of treatment is only to delay delivery in order to allow for the transfer of the pregnant woman to the most appropriate hospital and for administration of corticosteroids. Premature preterm labor newborn are at greater risk for cerebral palsy, delays in development, hearing problems and sight problems (7).

Methodology

A quasi-experimental design was conducted from 17th October 2020 to 1st March 2021 to determine the effectiveness of the educational program conducted on nurses-midwives in the labor room about general knowledge concerning preterm labor, in obstetric wards and delivery room and neonatal unit in five maternity hospitals at Baghdad city: Fatima Al – Zahra, Al -Elwia maternity, iben Al-Balady and Al-Karkh maternity Teaching hospital. Questionnaire format and education program were constructed to determine the effectiveness of educated program. None probability (purposive) sample was used to select the sample of 45 nurses and midwives.
A pilot study was carried out for the period from (1st of September to 9th of October /2020). The validity of the questionnaire was estimated through a panel of experts related to the field of the study, and its reliability was estimated through split half approach which was statistically accepted. The study instrument consisted of two parts which include:

- demographic data such as age, Level of education, Social Status, Years of experience in nursing and midwifery field, Sources of knowledge about preterm labor, Reproductive statues for the midwife, and knowledge of nurses - midwives towards preterm labor which consisted of four main domains include:
  - (26) questions related nurses-midwives knowledge regarding Preterm Labor,
  - (13) questions related nurses-midwives knowledge about premature birth.

Scale of the questionnaire is (multiple choice) the correct answer code was (2) and the wrong answer code was (1). The implementation of the educational program was done within nine educational sessions during one week at delivery room In addition each nurses/midwives had one (30-45) minute session with the researcher how give information about preterm labor and answered questions on preterm labor, pretest and giving lectures.

The researcher distributed the questionnaire for nurses after taking their agreeable to participate in this study the interview was conducted with volunteer nurses It took about 20 to 40 minutes for interviewing and after that the questionnaire was collected. Statistical analyses were conducted by using statistical package for social science (SPSS) version (20) Data analysis was employed through the application of descriptive and inferential statistical approaches which were performed through the computation of the following: frequencies, percentage, standard deviation, t-test and Chi-squar.

### Results and Discussion

**The present study as shown in table (1)** that the highest percentage (33.3%) of study sample was (26-30) years old with mean and standard deviation (x̅ ± SD) is (32.68 ± 8.31) years, and less of half of the study sample was graduated from midwifery secondary school, half of study sample were married, 46.7% of them had less than / equal to (5) year of Experience in Nursing and midwifery field. And (80%) of them did not practices midwifery as a profession inherited , (78%) of them were work in Government Hospital only , (70%) of (Nurses- Midwives) were not practicing midwifery at midwife home , (91%) of them having knowledge about preterm labor from Practical experience and (30%) of them Suffered from preterm labor during their fertile age. These results agree with other study finding indicate that that the highest percentage (were in the age group ranging between 20 years to less than 30 years) and disagree with study was conducted by Hasan who reported that the highest percentage at age group ranged between (26-30) years with mean and standard deviation was (33.84 ± 9.40). The present study shows the majority (86.6%) of them had secondary nursing school. The finding agrees with study stating that the highest percentage (57.5 %) of the nurses are graduated from secondary school.

**Table (2)** show the highest percentage (35.6%) their job description were skilled midwife this result is consistent with study stating that the highest percentage (77.3%) of the sample were skilled midwives. Regarding years of experience the majority of study sample had less than 5 years in all field of nursing and midwifery such as (nursing field emergency department, delivery room, neonatal intensive care unit (NICU)).

this result was in agreement with study by Qusay who reported that more than forty of the participants (78%) had less than five years of nursing experience in premature units (NICU). Ramasamy et.al found that the highest percentages (76.7%) of the participant had (1-5) years of experience in nursing field. The present study was disagreement with other study who reported that more than half of nurse/midwives (53.3%) had 1– 9 years’ experience in the labor room. The highest percentage 41(91.1%) of
the (Nurses and Midwives) having knowledge about preterm labor from Practical experience as shown in figure (1): The present study was disagreement with Nury who reported that the majority of them (73.3%) had participated in training courses regarding care during labor and delivery. 15(33.3%) of them having knowledge about preterm labor from academic study 10 (22.2%) of them having the same percentage knowledge about preterm labor from attending training courses and browse the Internet respectively and 8(17.8 %) of them having knowledge about preterm labor from medical journals and scientific books and magazines. Also Nuriy reported that the majority of sample (73.3%) had participated in training courses regarding care during labor and delivery (13).

The present study shows there are (low MS & RS) in most items in pretest period, this current study agree with Niazi who stated that the majority of (60.3%) midwives were poor knowledge in Baghdad City hospitals due to several reasons (14). Except item No: (1): Definition of preterm labor, Item No: (17): Secondary of postpartum hemorrhage and item No: (21): When are cervical ceceral suture removed: Had (moderate MS & RS) in pretest (before implementation of the program) for study sample this indicates that the nurses- midwives had good information about preterm birth. As shown in table (3).

While the current study revealed there are (high and moderate mean score &relative sufficiency ) in some of items in post1 test (after implementation of the program) for study sample. The finding of present study is similar with study was conducted at Sudan by Hassan & Nasr who reported that the impact of an educational program on nurses’ knowledge and nursing management of preterm labor patients receiving tocolytics. they reported all nurses archived better scoring in both knowledge and skills after implementing the program (15)

The current finding is in agreement with hassan et al to assess nurses midwives practices about pain management during labor before and after implementation of educational program, they found there are (high MS&RS) after implementation of education program (16).

The current study revealed there are show (Low MS &RS) in post 1 test in item No (5): Rupture of the amniotic fluid, item No : (6): Pregnant women with a BMI above 35 , item No : (8): cause and predisposing factors for preterm labor, item No : (14): Test is performed for the pregnant mother who suffer from preterm labor after the implementation of the educational training program this is may be due to over loaded work in delivery room in addition to the lack in the number of staff to conducting the job in the delivery room.

The present study shows that (high and moderate MS &RS) in most items related to knowledge of nurses and midwives regarding preterm labor in post 2 test period, Except item No: (2) Signs and symptoms of preterm labor, item No (5): Rupture of the amniotic fluid, item No (6): Pregnant women with a BMI above 35, item No (7): There are causes and risk factor for preterm labor, item No (9): Methods of diagnosing preterm labor, item No (13): Complications of premature birth to the newborn on Longtime, item No (18): The most common indicator of (stimulation) to preterm labor, item No (22): Termination of pregnancy when the pre rupture of membranes occurs , item No (23): Information about vaginal progesterone supplements, item No (25): Side effects of, item No (26): modern treatments for rupture of the amino membrane at 32week. Had (Low MS &RS) after implementation of the program in Post-2- test period. related to general knowledge of nurses and midwives about preterm labor. The weak of results regarding Tocolytics drugs that have occurred through the research indicate that the midwife or nurse is not interested in understand and search for knowledge related to pharmaceutical field when given to the pregnant woman during labor and adopted only to the attending doctor and this therefore leads to undesirable results. So the current
result show the (low MS & R.S) in nurses – midwives knowledge about medications of preterm labor in pre and post 2 test. The present study was disagreement with study conducted in Egypt by Hassan & Nasr who revealed that there were an improvement of the nurse’s knowledge in all items (definition, indication, contraindication and side effect) regarding the knowledge of tocolytics drugs (8), as show in table (3).

Table (4) show that there was (low MS&RS) in all items of nurses and midwives knowledge in pretest for study sample. The current study agrees with other study conducted in Punjab city and reported that the majority of nurses had less than “good” in the pretest. While in the post test had good and excellent level of knowledge after teaching program regarding care of low birth weight baby (17).

Also item No (5): (Low body temperature of premature birth ) had (moderate MS &RS) in pretest (before implementation of education program) for study sample, Similar findings were reported by a study in Sudan which showed that the nurses knowledge improved to be good by majority of the nurses when testing their knowledge in preventing hypothermia premature babies’ (18). While there are (high and moderate MS&RS) in some items of nurses-midwives knowledge in (post 1 and post 2 test). This result agreement with Young el at who reported that the training intervention highly improved of nurses –midwives in knowledge after implementation of education program (19).

Table (5): show there are significant differences between (pretest and post 1 knowledge test). The results of current study are similar with other studies stating to assess the effectiveness of information booklet on management of preterm babies this result revealed the overall mean posttest knowledge score was higher than the mean pre-test knowledge score (20).

While there are no significant differences between (post 1 and post 2 knowledge) after the implementation of education program for nurse-midwives regarding pre-term labor.

The present study disagreed with other studies stating that there are significant correlations between pretest and posttest periods after the implementation of education program for nurses- midwives’ knowledge regarding fetal investigations (10).

Table (6) shows that there are no statistical significant differences between overall knowledge of nurses-midwives about Pre-term labor (pre and post term) and studied variables such as: ( Level of education , marital status, years of service in nursing, years of experience in emergency, years of service in delivery room, years of service in NICU, midwifery profession inherited , specialized training courses in preterm birth and preterm labor.

Also Ali who reported that there were no statistical significant difference between nurse-midwives knowledge and some socio demographic characteristics such as: age ,educational level,marital status, number of years of total service, number of years of service (experience) in the delivery room, number of training courses related to pregnancy and childbirth (21).

There is statistical significant differences between overall knowledge of nurses-midwives and Age groups in (pretest). This findings were similar with Hassan who reported that a significant direct (positive) correlation had been found between age of participants and their overall knowledge score (8).

This findings were disagree with Farrell who found a total of (31) nurse and (36) midwives were included in the study and control respectively. There were no differences regarding the Age and other Socio-Demographic Variables (22).

There is a statistical significant association between pre and post variables and overall knowledge at (p.value: 0.005) and there is no statistical significant association between socio-demographic variables and overall knowledge, except age groups there was a
statistical significant with overall knowledge in pretest as shown in table (6).

**Conclusion**

The study was concluded that there was a statistically significant difference in nurses-midwives overall knowledge related to preterm labor between the pretest and posttest for study sample. While there are no statistically significant association between post 1 knowledge and post 2 knowledge. After the implementation of education program for nursery-midwives regarding Pre-term labor. There is statistical significant differences between overall knowledge of nurses-midwives and studied variables such as: Age Groups in (pretest). While there was no any association between knowledge of nurses – midwives and studies variables.

**Recommendation:**

Based on the study results, the study recommended that: Continuous and update of education program for nurses –midwives development and improvement of their knowledge for dealing with pregnant women who suffering from preterm labor.

**Financial Disclosure:** There is no financial disclosure.

**Conflict of Interest:** None to declare.

**Ethical Clearance:** All experimental protocols were approved under the Ministry of Health and all experiments were carried out in accordance with approved guidelines.

Abstract

Objectives: determined the effectiveness of an educational program on nurses - midwives performance related to preterm labor and to Identify the relationship between the performance of nurses- midwives and study variables.

Methodology: A quasi-experimental design (one group pre & post ) was conducted on non-probability (purposive) sample of forty five nurses- midwives selected during period from (17th October 2020 to 1st March 2021).The study is conducted at the four maternity hospitals (Baghdad health directorate in Al-Karhk and Al-Risafa) sector. The study sample was selected from obstetric wards and delivery room and neonatal unit .The questionnaire form is consisted of socio-demographic characteristics and Performance of nurses -midwives towards preterm labor through (checklist).

Result: The result of study revealed that the (33.3%) of study sample was (26-30) years old with mean and standard deviation (x̅ ± SD) is (32.68 ± 8.31) years, and less of half of the study sample was graduated from midwifery secondary school, half of study sample were married, 46.7% of them had less than / equal to (5) year of Experience in Nursing and midwifery field. And (80%) of the them did not performances midwifery as a profession inherited , (78%) of them were working in Government Hospital only , (70%) of (Nurses- Midwives) were not practicing midwifery at midwife home , (91%) of them having knowledge about preterm labor from Practical experience and (30%) of them Suffered from preterm labor during their fertile age.

The result of study revealed there are (low GMS &RS) in most items in pretest period regarding Performance of Nurses – Midwives. While there are (high and moderate GMS &R.S) in all items in post 1 test and post 2 observation (after implementation of the program) for study sample.

Keywords: Education, Effectiveness, Nurses-Midwives, Program, Preterm labor and Performance.

Introduction

Preterm birth (PTB) is still a widespread public health problem responsible for high perinatal mortality and long-term morbidity worldwide despite improved perinatal care programs, it still remains a major leading cause of perinatal mortality, mainly in developing countries (¹).

Preterm birth is one of the most troubling problems facing obstetrics today. In spite of all of the available refined research and therapeutic technology, the preterm birth rate has remained the same for the last 40 years. One birth in 10 occurs prematurely. Preterm labor demonstrates itself in a variety of ways. It is essential to differentiate true preterm labor from preterm contractions or other conditions that present with similar symptoms. True preterm labor requires
rapid clinical intervention in the obstetric triage setting. The prevention of preterm birth may be the most important problem facing maternity care providers.

In developing countries, the main causes of preterm births include infectious diseases and poor availability and accessibility of health care resources. In high-income countries, increase in the number of preterm births is linked to conception among older women and increased number of multiple pregnancies as a result of usage of fertility drugs. In some developed countries, medically unnecessary inductions and cesarean section deliveries before full term also increase preterm birth rates. In rich and poor countries, many preterm births remain unexplained.

To prevent preterm labor and delivery, a number of strategies have been developed. When choosing a strategy to prevent preterm birth, however, physicians must remember that preterm delivery arises from three separate conditions: iatrogenic preterm labor, premature rupture of membranes, and idiopathic preterm labor.

Preterm labor and birth are associated with traumatic life sites (e.g. close family death, domestic violence, Anxiety about losing food, home or partner) either indirectly by associated risk behaviors. Many of these risk factors present together, such as chlamydia endocervicitis and third trimester bleeding and cervical insufficiency.

Nurses and midwives are key players in empowering individuals and families and in promoting health safety and changes in health behavior throughout the life-course. The vital role of nurses or midwives in antenatal care is screening of pregnant women who are at risk for premature labor.

The role of nurses or midwives in childbirth is to ensure a safe environment for the mother and the birth of newborn and provide physical and emotional support. Nurses begin evaluating the mother through obstetrics history and determine the frequency, duration, intensity of uterine contraction, cervical dilatation and effacement and evaluating fetus during the labor, various techniques are used to assess maternal status. These techniques provide an ongoing source of data to determine the woman’s response and progress in labor which included: Assess maternal vital signs temperature, blood pressure, pulse, respiration, and pain, Prepare pregnant women for possible ultrasonography, amniocentesis, administer tocolytic agent or steroid therapy as prescribed. And assess for side effects of tocolytic therapy such as decreased maternal Blood pressure, Dyspnea, Chest pain, FHS >180beats/min FHS >180beats/min.

Objectives: To determine the effectiveness of an educational program on nurses - midwives performance related to preterm labor and to identify the relationship between the performance of nurses-midwives and study variables.

Methodology

A quasi-experimental design (one group pre & post) was conducted from (17th October 2020 to 1st March 2021), on nurses - midwives in five maternity hospitals at Baghdad city: Fatima Al-Zahra, Al-Elwia maternity, Iben Al-Balady, Dhari Al-Fayyad and Al-Karkh maternity Teaching hospital. None probability (purposive) sample was used to select the sample of (45) nurses and midwives. A pilot study was carried out for the period from (1st of September 2020 to 9th of October 2020). The validity of the questionnaire was estimated through a panel of ten experts related to the field of the study, and its reliability was estimated through Split half approach which was statistically accepted. The study instrument was consisted of two part: socio-demographic characteristics of the nurses-midwives and performance of nurses -midwives towards preterm labor through (checklist). used by the researcher for three observations, with sufficient time (30 to 45 minutes). An instrument comprised of (18) items It was constructed through the use of three levels of likert scale for the implementation of Performance items. The rating score of checklist was (three) for always, (two) for some times and (one) for...
never with cut-off point (2). Performance tests were used for pre, post1, and post 2 observation after one month.

The checklist consists of (131) items (nine main domains), each one of these included several items: Infection control and prevention includes (5) items, pregnant woman during stages of labor) includes (10) items, Preparing pregnant woman for birth) includes (9) items, to first stage of labor) includes (12) items, second stage of labor includes (10) items, second stage of labor includes (10) items, premature newborn includes (23) items, third and fourth stage of early labor includes (19) items, instructions for mothers and their relatives includes (29), nursing documentation includes (14) items.

By observation and recorded checklist immediately after implementation of an educational program regarding preterm labor. Nurses- Midwives were exposed to the post2 test questionnaire about (Performance) was conducting from the end of program during the first follow-up after 4 weeks of the post1test to identify their Performance regarding preterm labor. Data analysis was employed through the application of descriptive and inferential statistical approaches.

**Results and Discussion**

The present study was reported that the highest percentage (33.3%) of study sample are at age group ranged between (26-30) years old with mean and standard deviation (x̅ ± SD) is (32.68 ± 8.31) as shown in table (1). These findings are consistent with A quasi-experimental study it used three tools: (structured interview questionnaire, pre-post-test knowledge assessment sheet and an observation checklist) who reported that the highest percentage (were in the age group ranging between 20 years to less than 30 years)(7).

Also the present study was disagreement with other study who reported who reported that the highest percentage at age group ranged between (26-30) years with mean and stander deviation was (33.84 ± 9.40). (8)

The highest percentage of the study sample (44.4%) were secondary of midwifery school graduate. While the lowest percentage (4.40 %) and (6.70) were graduated from nursing school and (6.70%) graduate from college of nursing as shown in table (1). This result agreed with other study who reported that majority (86.6%) of them had secondary nursing school (9). Also agreed with other study who reported that the highest percentage (57.5%) of the nurses are graduated from secondary school, also mentioned that the (2.5 %) are from college of nursing. Half of the study samples were married. (10)

**Table (2)**: The result in current study shows that the highest percentage (35.6%) their job description were skilled midwife this result is consistent with other study employed who reported that the highest percentage (77.3%) of the sample were skilled midwives(8).

The majority of study sample had less than 5 years in all felid of nursing and midwifery such as (nursing field Emergency department, Delivery room, Neonatal intensive care unit (NICU)), this result was agreement with other study who reported 11 that more than forty of the participants (78%) had less than five years of nursing experience in premature units (NICU)(11). Ramasamy et al., found that the highest percentages (76.7%) of the participant had (1-5) years of experience in nursing field (12). The present study disagreement with study who reported that more than half of nurse/midwives (53.3%) had 1– 9 years’ experience in the labor room (13).

The Result

Reveals That there are (low GMS &RS) in most items in pretest period regarding all performance of Nurses – Midwives toward preterm labor. Except item No (2.1) Preparation the necessary instrument and equipment for delivery room, item No (2.2): Assessment of the health status of the pregnant
woman, item No (2.3): Assessment of the health status of the fetus, item No (2.5) performance related to first stage of labor, item No (2.6): performance related to second stage of labor, item No (2.8): Nurses-Midwives performance during forth stage of labor, regarding Nurses- midwives performance related to premature newborn item No (3.3): If the new born heart rate lasts below than 60 minutes despite the effective ventilation for 30 seconds, Domains (4): instruction and dominoes (5): Documentation. Had (high and moderate GMS &R.S) in all items in post 1 and post 2 test (after implementation of the program) for study sample. as show in table (3).

There are significant differences between (pre and post 1 observation and there are significant differences between (pre and post 2 observation). There are significant differences between (post 1 and post 2 observation) after the implementation of education program for nurse- midwives regarding pre-term labor. The percent study agreed with study Who revealed that there were a high significant relation between studied nurses’ total performances and personnel characteristics in post intervention (14).

There is no statistical significant differences between socio-demographic variables and overall performance of nurses-midwives about preterm labor.

The results of this study was disagreed with study who reported that there are insignificant relation between studied nurses socio-demographic characteristics and their performances strategies used in the prevention and management of PPH and normal labor (15).

The findings of the present study are almost similar with the results of previous study who found there is no significant association between performance of nurses/midwives and their level of education during labor and delivery (16).

Also findings of the present study disagree with study who reported that Nurses’ specialty had a significant effect on their total score of performances in the field of post-natal care (17).

This study differ with study who approved that there were no relation between nurses performances and general characteristics P value at 0.05 level. (18)

Ass = Assessment  F = Frequency, Percentage, GMS = Grand Mean Score, R.S = Relative Sufficiency (L = Low less than 75) , M = Moderate = 75 - 87.5 , H = High = 87.6 – 100).
Conclusion

The study was concluded there was (low GMS & RS) in most items of Nurses - Midwives performance regarding preterm labor before implementation of educational program, while there are (high & moderate GMS & RS) in most items after implementation of educational program.

The study was concluded there was a statistically significant difference in nurses - midwives overall performance related to preterm labor between the pretest and post 1 test for study sample, also there are significant differences between (post 1 and post 2 performance) after the implementation of education program for nurse- midwives regarding pre-term labor and there are no statistical significant differences between socio-demographic variables and overall performance of nurses-midwives.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the Ministry of Health, Iraq and all experiments were carried out in accordance with approved guidelines.

Recommendation:

Every hospital should update the guidelines during the intervention during stages of labor and immediate resuscitation of premature baby Guidelines for nurses- midwives to instruction and prevention of preterm labor should be used as routine hospital care.

Effectiveness of Instructional Program Regarding Health Protective Behaviors for Women with Gestational Diabetes on their Self Efficacy in Primary Health Care Centers at Baghdad City

Sagdh Hameed Kareem¹, Iqbal Majeed Abbas²
¹Ph.D., Student, Academic nursing Specialist, MScN, Ministry of Health, Iraq, ²Ph.D. Emeritus Professor and Academic Supervisor, Baghdad college of Medical Sciences/ Nursing Department

Abstract

Objective: The present study to identify the relationship between these pregnant women’s self efficacy study variables, and determine the effectiveness of Gestational Diabetes health protective behaviors-oriented Instructional program on their self-efficacy.

Methods: A descriptive analytic study (two-groups Pretest-Posttest) used to determine the Effectiveness of Instructional Program Regarding Health Protective Behaviors for Women with Gestational Diabetes on Their Self Efficacy on Pregnancy Outcome in Primary Health Care Centers at Baghdad City.

Keywords: Women, Health Protective Behaviors, Gestational Diabetes, Primary Health Care Centers, Baghdad.

Introduction

Diabetes has become a global pandemic because of sedentary self efficacy, urbanization, and increasing incidence of obesity. Prevalence of diabetes is on the rise in developing countries such as India and China. As the incidence of diabetes is rising in epidemic proportion, more women of childbearing age are at increased risk of diabetes during pregnancy. In fact, a high prevalence of gestational diabetes mellitus (GDM) of the order of 18% has been reported from India. agreed with Women with GDM are at high risk for developing diabetes later in life. Thus, GDM provides a unique opportunity to study the early pathogenesis of diabetes and to develop interventions to prevent the disease.

Abnormal metabolic environment due to hyperglycemia has a profound impact on maternal and fetal outcome. Indians belong to higher risk for developing diabetes due to their ethnicity. The present study was conducted to determine the maternal and fetal outcomes of pregnancies complicated with diabetes mellitus vis-a-vis non diabetic pregnancies, in a the city of Baghdad Iraq

Methodology

A descriptive analytic study conducted from 17th October 2020 to 30th January 2021, purposive sample consisted of 50 pregnant women with gestation diabetic were selected from (8) primary health centers, four from Al karkh department, and another four from Al Rusafa in Baghdad City.

The questionnaire from was designed and data collection consists of three main parts include: socio- demographic characteristics, reproductive characteristics & This part is comprised of 49 items in five domains of Self Efficacy of Pregnant Women with Gestational Diabetes,

Diabetes during pregnancy is associated with higher maternal and fetal morbidity. Therefore, early screening, detection, close monitoring, and
Intervention is essential to reduce maternal and fetal short- and long-term adverse effects, especially in high-risk groups. Pregnancy provides an opportunity to the clinician to control the disease process and inculcate self efficacy practices in these pregnant woman.

**Dissection**

The present study reports that the highest percentage (29%) of study sample is at age group ranging between (40 – 44) years old, with mean and SD = 32.38±7.22 years); this result disagree with agreed with (2) it was reported that the half of the study age ranged between 35 and 40 years; participants were and also reported that lowest percentage (14 %) of their study sample is within ideal age between (45-49) years for pregnant.

The highest percentage (24%) of the study sample was graduated from Graduate junior high, while the lowest percentage (9% ) were Neither read nor write. This result was in agreement by a study who reported that a majority of pregnant women (65.5%) indicated that pregnant women should receive on the education agreed with (3) and The highest percentage (30%) of study sample was government of self employed while the lowest percentage (16 %) of study sample were retired. Diabetes mellitus is the leading cause affect their continuous absenteeism from their work and between 10 % to 18% of pregnant believed that it hampers functions of daily life agreed with (4). The highest percentage (40 %) of study sample with enough to some extent Socio-economic status. The finding of the present study is not consistent with a study which revealed that pregnant women who belong to a low socio-economic status had severe symptoms of diabetes mellitus than the pregnant women of high Socio-economic status agreed with 5-7.

The study shows that The finding of present study indicates that majority of the study sample was 5 pregnancy & above and Grand multi Para (had ≥ 5 deliveries ), the lack of health education , in correct and lack of using of family planning methods and vogues of having large families (especially in rural areas) accounted for increased the complication associated with high parity. agreed with (5) indicate also that is one of these causes of frequent births lead to women with gestational diabetes; the result is in consistent with agreed with (7). Nearly Approximately less than half of the sample in present study had ≥ 5 deliveries pregnancies which are in ideal reproductive numbers while the other half may expose too many complications. So, the health protective Behaviors for women with gestational diabetes on their self efficacy and pregnancy outcome is of high obstetrical complications agreed with (8) who has reported that women with parity are greater than five this is almost inducted to complications as many great of number pregnant with diabetes have then less parity The result indicates that the highest percentage (42%) of the study sample have used Mixed feeding; while (28%) of study sample have used Artificial feeding who reported that through increasing breast feeding rate in Australia, the future rates of obesity in Australia will be reduced; a recent publication from the U.K. presents a more comprehensive way of calculating the benefits to be realized in the future from reducing diabetes mellitus, obesity and asthma as a result of breast feeding; the finding agrees with American Academy of Pediatrics, which report that breastfeeding is important because of the nutritional, health, immunological, development, and psychological benefits that breast milk provides for infant and newborn. previous studies have also show that breastfeeding is associated with a lower risk of gestational with diabetes in the mother, agreed with (9). and The result of study sample indicated that the highest percentage (44%) was first pregnancy at age between (21-25 ) years old which means ideal age for become pregnancy. While the lowest percentage (6 %) was the first to have them in the age (31years & above) which means was old prima.

The study resulted ( 42 %) shows that the highest percentage (38%) of study sample has Caesarean births; while the lower percentage (8%) has Normal delivery with forceps agreed with (10) who reported
that schedule the date delivery (either an induction of labor or cesarean delivery), especially if there are risk factors, such as: hypercalcemia levels, nephropathy, worsening retinopathy, hypertension or preeclampsia, or if the Newborn is smaller or larger than normal; if delivery before the due date is planned. agreed with (11) USF Health.

</tbody>
</table>

Table (2) shows that there are no statistical significant relationship between overall self-efficacy in pretest and reproductive variables. In posttest there are a statistical significant relationship between overall self-efficacy and studied variables (gravidity, parity, family history of diabetes, and type of delivery), while there are no a statistical significant relationship between overall self-efficacy and the rest of reproductive variables.

**Conclusion**

Health behaviors during pregnancy are those that encourage or improve health-related self-efficacy, both maternal and fetal and also decrease risk factors. One of the challenges is to fully understand gestational diabetes and the hormonal changes and altered carbohydrate metabolism that are associated with it during fetal development.

Abstract

Background:- Diabetes is a chronic disease in which pregnant with gestational Diabetes require lifelong health Protective Behaviors for Effective on Pregnancy Outcome

Methods: descriptive research design group Pre test used to determine the Effectiveness of Instructional Program Regarding Health Protective Behaviors for Women with Gestational Diabetes on Pregnancy Outcome in Primary Health Care Centers and Maternity Hospital at Baghdad City.

Methodology: descriptive research -l study conducted from 17th October 2020 to 30th January 2021, purposive sample Consisted of 50 pregnant women with gestation diabetic were selected from (4) primary health centers, and tow from Al karkh department, and another Two from Al Rusafa in Baghdad City. And selected from (4) Maternity Hospital Two from Al karkh department, and another Medical City Department.

Results : The present study reports that the highest percentage (29%) of study sample is at age group ranging between (40 – 44) years old, with mean and SD = 32.38±7.22 years) the study sample was graduated from Secondary school graduate, while the lowest percentage (9% ) were Neither read nor write This result was in agreement by a study who reported that a majority of pregnant women (65.5%) indicated that pregnant women should receive on the education and The highest percentage (30%) of study sample was government of self employed while the lowest percentage (16 %) of study sample were .

Keywords: Instructional Program Regarding, Behaviors, Women, Diabetes Pregnancy

Introduction

Diabetes has become a global pandemic because of sedentary health behaviors, urbanization, and increasing incidence of obesity. Prevalence of diabetes is on the rise in developing countries such as India and China. As the incidence of diabetes is rising in epidemic proportion ¹ more women of childbearing age are at increased risk of diabetes during pregnancy. In fact, a high prevalence of gestational diabetes mellitus (GDM) of the order of 18% has been reported from India. agreed with (¹) Women with GDM are at high risk for developing diabetes later in life. Thus, GDM provides a unique opportunity to study the early pathogenesis of diabetes and to develop interventions to prevent the disease. Abnormal metabolic environment due to hyperglycemia has a profound impact on maternal and fetal outcome. Indians belong to higher risk ² for developing diabetes due to their ethnicity agreed with (²) The present study was conducted to determine the effect of the health behaviors of pregnant women with gestational diabetes and the outcome of pregnancy in the city of Baghdad, Iraq.
Objective: To assess the health protective behaviors of pregnant women with gestational diabetes for the study group before implementation of program. & to determine the effectiveness of Gestational Diabetes health protective behaviors-oriented Instructional program on pregnancy outcome.

Decoction

The present study reports that the highest percentage (29%) of study sample is at age group ranging between (40 – 44) years old, with mean and SD = 32.38±7.22 years as shown in table 1. This result disagree with agreed with (3) that the study sample was graduated from Secondary school graduate, while the lowest percentage (9%) were Neither read nor write. This result was in agreement by a study who reported that a majority of pregnant women (65.5%) indicated that pregnant women should receive on the education agreed with 4 and The highest percentage (30%) of study sample was government of self employed while the lowest percentage (16%) of study sample were. agreed with 5 . and the majority of study sample was grand multi gravida and grand multi Para, equal and more than (had ≥ 5 deliveries it was reported that the lack of health education, in correct and lack of using of family planning methods and with having large families) accounted for increased the complication associated with high parity. by6 and nearly Approximately less than half of the sample in present study had ≥ 5 deliveries pregnancies which are in ideal reproductive numbers while the other half may expose too many complications agreed with 8 .

The findings of present study supported evidence is available in the study reported that in cross-sectional analysis of over 200,000 women delivered between 1992-1998 in New South Wales Australia, the incidence of diabetes mellitus complications found to be increased significantly from parity onwards. agreed with 9 and the result indicates that the highest percentage (42%) of the study sample have used Mixed feeding; while (28%) of study sample have used Artificial feeding agreed with 10 and The result of study sample indicated that the highest percentage (44%) was first pregnancy at age between (21-25 ) years old which means ideal age for become pregnancy. While the lowest percentage (6%) was the first to have them in the age (31years & above) which means was old prima gravida . and The study resulted in (42 %) shows that the highest percentage (38%) of study sample has Caesarean births; while the lower percentage (8%) has Normal delivery with forceps agreed with 11 . Table (5 ) shows that is statistical significant relationship between gravidity and type of delivery. In posttest there are a statistical significant relationship between overall health behaviors and studied variables (parity, Personal history of a previous gestational diabetes and type of delivery), while there are no a statistical significant relationship between overall health behaviors and the rest of reproductive variables.

Health behaviors before , from pre-pregnancy to 15–20 weeks’ gestation and older age were associated with an increased risk of gestation diabetes mellitus.

Result

Data were collected through the use of questionnaire by personal interview technique

Abstract

Polycystic ovary syndrome (PCOS) is a common endocrinopathy that, by the most strict definition, affects 5 to 10% of women of reproductive age. There is not complete consensus about the definitive criteria for the diagnosis of PCOS, which necessitates the searching for new biomarkers for definitive diagnosis. This study is a case/control study carried on one hundred (100) women divided into two groups: 50 women with PCOS, and 50 women were with absent features of PCOS represent a control group who were attending the outpatient clinic of Gynecology department at Baghdad Teaching Hospital during the period from March to September, 2018. A fasting blood sample was obtained from all women during the early follicular phase (days 2–4 of the spontaneous cycle). Lipid profile, fasting blood glucose and fasting blood insulin, luteinizing hormone (LH), follicular stimulating hormone (FSH), and testosterone were analyzed by immune chemiluminescence method. There were no significant differences between the two groups regarding total cholesterol, low density lipoprotein -cholesterol, high density lipoprotein -cholesterol and fasting blood glucose. On the other hand, PCOS patients showed higher serum concentration of triglycerides and insulin resistance than controls.

Key words: Polycystic ovary syndrome, insulin, Lipid profile

Introduction

Polycystic ovary syndrome (PCOS) is one of the most common endocrine illnesses in women of reproductive age. It is characterized by chronic oligo-or anovulation, hyperandrogenism and polycystic ovaries, and is associated with several long-term health consequences, such as infertility, obesity, hypertension, dyslipidemia, insulin resistance and type II diabetes mellitus [¹]. There are three main definitions for PCOS. The Rotterdam definition is the most widely used which proposes that PCOS can be diagnosed in any woman presenting with at least two of the three hyperandrogenism, ovulatory dysfunction and polycystic ovarian morphology (PCOM). By contrast, the 2006 Androgen Excess and PCOS Society (AE–PCOS) Position Statement requires the presence of hyperandrogenism, which must be accompanied by evidence of ovarian dysfunction in the form of ovulatory dysfunction and/or PCOM [²].

Each individual criterion used to define PCOS has clinical consequences by itself. Androgen excess might result in cutaneous manifestations, such as hirsutism, acne and alopecia; ovulatory dysfunction and chronic oligomenorrhea might result in infertility and endometrial hyperplasia and/or carcinoma; and isolated PCOM is associated with a risk of ovarian hyperstimulation syndrome only during ovulation induction [³]. The pathophysiology of PCOS is far from fully understood. However, over the last decades potential underlying mechanisms have been proposed. An increased GnRH pulse frequency resulting in LH hypersecretion has been reported. LH stimulates the ovarian theca cells to produce androgens, such as testosterone. Because of a relative FSH deficiency,
testosterone is incompletely aromatized by the granulosa cells, resulting in hyperandrogenemia. Moreover, although the ovaries are the main source of androgen excess in PCOS, also the adrenal glands contribute to the existing hyperandrogenism\[4\].

In PCOS, hyperandrogenism, hyperinsulinemia and altered intraovarian paracrine signaling can disrupt follicle growth. Moreover, FSH does not seem to increase to the threshold levels which are required to stimulate normal follicular maturation resulting in follicular arrest. The accumulation of small antral follicles result in elevated AMH levels. These increased AMH levels seem to add to the anovulation in PCOS by reducing both primordial follicle growth and follicle sensitivity to FSH\[5\].

Materials and Methods

1: The Study Population: This study is a case/control study carried on one hundred women all are married who were attending to the outpatient clinic of Gynecology department at Baghdad Teaching Hospital during the period from March to September, 2018. The study sample divided into two groups: Group I: fifty women with PCOS and Group II: fifty women were healthy matched for age and BMI with absent features of PCOS represent a control group.

All women were subjected to the following:

1- Verbal consent was obtained from each subjects included after explaining aims and dimensions of the study.

2- Socio-demographic information about age, weight, height, obstetric and gynecological history also obtained

3- General physical, vital signs, abdominal examination have been performed to all women.

4- Transabdominal ultrasound done by senior doctor (Radioloist) by ultrasound machine (Philips HD 11xE) using the curvilinear probe.

2: Biochemical Assays: Serum levels of glucose, total cholesterol (TC), triglycerides (TG), high-density lipoprotein cholesterol (HDL-c) were measured by the enzyme-calorimetric methods. Low-density lipoprotein-cholesterol (LDL-c) levels were calculated by using Friedwald et al.\[6\] equation as follows:

\[
\text{LDL-c (mg/dl)} = \text{TC - HDL-c - (TG/5)}.
\]

3: Enzyme-calorimetric method was used for measurement of fasting blood insulin with a commercial ready kit according to the manufacturer’s instructions.

4: Homeostasis Model of Assessment-Insulin Resistance (HOMA-IR) index for the assessment of insulin resistance was measured by calculation using Matthews et al.\[7\] equation as follows:

\[
\text{HOMA-IR} = \frac{[\text{glucose (mg/dl)}* \text{insulin (IU/ml)}]}{405}.
\]

Insulin resistance (IR) was accepted as HOMA-IR \( \geq 2.5 \)

5: Hormone analyzes: Luteinizing hormone (LH), follicular stimulating hormone (FSH), and testosterone were analyzed by immune chemiluminescence method (Roche-Hitachi Modular Analytics E-170, Indianapolis, IN, USA)

6: Statistical Analysis

Statistical package for Social Sciences (SPSS version 20) was used for data analysis, and Microsoft Excel to generate graphs. Continuous variables were expressed as a mean\( \pm \) standard deviation (SD). The student test (t-test) was used to compare means of these variables. The statistical tests were two sided, and a \( P \leq 0.05 \) was considered statistically significant.

Results and Discussion

1: Anthropometric Data and Hormonal Status of the Study Population:

Table (1) shows the anthropometric data and hormonal status of PCOS patients and controls. The
two groups were comparable in age, BMI, W/H ratio as well as FSH concentration with no significant differences. However, PCOS patients showed higher serum concentration of LH (7.12±1.91 IU/L) than controls (4.42±1.44 IU/L) with a highly significant difference (p<0.001). Accordingly the LH/FSH ratio was significantly higher in PCOS patients (1.51±0.08) than controls (1.04±0.4)(p=0.016). Likewise, PCOS patients showed higher serum testosterone than controls (0.84±0.27 ng/mL vs. 0.44±0.18 ng/mL) with a highly significant difference (p<0.001).

</tr>
</tbody>
</table>

Data are presented as mean ± SD. BMI, body mass index; W/H: waist/hip; FSH: follicular stimulating hormone, LH: luteinizing hormone.

The hormonal profile of PCOS patients and controls revealed a significant elevation in LH, LH/FSH ratio in patients compared with the controls. Such results were frequently reported by several previous studies (8,9). In fact, LH is an essential player in the pathophysiology of PCOS. Increased levels of LH (with consequence increased LH/FSH) ratio is caused by pulsatile release of GnRH from the hypothalamus. However, some other studies reported no significant differences in serum levels of LH between PCOS patients and controls (10). Likewise, testosterone levels were found to be significantly elevated in PCOS women compared with controls. This results also agree with vast majority of previous studies (11,12).

However, total serum testosterone cannot be a reliable markers for PCOS because about 65% of testosterone % is bound to SHBG. This is particularly important for obese women with IR because they are very likely to have low SHBG levels.

2 : Metabolic Status Data of the Study Population

The metabolic status data of PCOS patients and controls are listed in table (2). There were no significant differences between the two groups regarding total cholesterol, LDL-cholesterol, HDL-cholesterol and fasting blood glucose. On the other hand, PCOS patients showed higher serum concentration of...
triglyceride than controls (89.12±9.81mg/dL vs. 77.41±8.44, p=0.038).

Likewise, PCOS patients had significantly higher concentration of HOMA-IR than controls (2.12±1.04 vs. 1.1±0.92, p=0.041).

<td>0.041</td>
</tr>
</tbody>
</table>

Data are presented as mean ± SD. LDL: low density lipoprotein, HDL: high density lipoprotein, HOMA-IR: Homeostatic model assessment-Insulin resistance.

The metabolic profile analysis in the present study revealed a significant higher TG and HOMA-IR levels than controls. These results are comparable with many previous studies. In one study including 166 women with PCOS and 277 controls, Chae et al. (38) reported an elevation of TG (≥150 mg/dL) in 26.7%, of PCOS patients versus 1.0% among controls (P < 0.001); prevalence of low HDL-C (<50 mg/dL) 30.0% among patients and 3.0% among controls (P = 0.004). More recently, Lath et al. (13) studied lipid profile in 80 women with PCOS and other 40 healthy women. They found that each of TC, TG and LDL-c were significantly higher in patients with PCOS than controls. Dyslipidemia is common in PCOS compared to weight matched controls, with higher triglycerides and lower high density lipoprotein cholesterol (14). Several mechanisms have been proposed to explain this disorder mainly attributed to IR which present in 50%-70% of PCOS. For example, Resistance to the action of insulin on lipoprotein lipase in peripheral tissues may contribute to elevated TG levels. The significantly higher value of HOMA-IR in PCOS group compared with controls has also been reported frequently (15,16).

Depressions Level among Adolescents Undergoing Chemotherapy Treatment at Pediatric Teaching Hospitals in Baghdad City

Ali K. Ouda¹, Qahtan Q. Mohammed²
¹MSC Student, ²Assistant Prof, University of Baghdad, College of Nursing, Psychiatric and Mental Nursing Department, Baghdad City

Abstract

Objectives: A descriptive correlational study, using an evaluation approach, is conducted to evaluate the level of depression for adolescents undergoing chemotherapy at pediatric hospitals in Baghdad City from December 15th 2020 to June 17th 2021.

Methodology: A self-report questionnaire is developed for the purpose of the study. Content validity and internal consistency reliability are determined through a pilot study. A purposive “non-probability” sample, of (45) adolescents, is selected for the present study. All adolescents have signed a consent form for their agreement to participate in the study with no obligation as part of the ethical considerations.

Results: Results of the study indicate that adolescents, who are middle age and males, develop depressive symptoms greater than others after being treated with chemotherapy. Adolescents’ depression has highly significant relationship with their socio-demographic characteristics of relapse, complications, mothers’ occupation, gender, education, monthly income, duration of treatment, age, fathers’ occupation, fathers’ education, mothers’ education and age at diagnosis.

Conclusion: The study concludes that most of the adolescents have experienced moderate level of depression as a result of their being exposed to the chemotherapy treatment and the study confirms that the issues of looking forward, sleeping, feeling, walking, energy, pain, appetite have major influence on the prognosis of the health problem of depression.

Recommendation: The study recommends that counseling services are important issue to deal with in providing treatment to these adolescents especially those who are males, middle age, and developing complications and relapse. Well-designed and constructed education program can be presented to these adolescents for the purposes of increasing their awareness toward the disease and making them able to prevent complications and relapse associated depression.

Keywords: Depressions Level, Adolescents, Chemotherapy Treatment

Introduction

On a global scale, cancer and depression, when viewed separately, are responsible for immense human suffering. In 2008, cancer affected an estimated 169 million years of healthy life worldwide, and the World Health Organization (WHO) predicts that by 2030, unipolar major depression will be the leading cause of disease burden. When cancer and depression coexist, the symptom burden and mortality of each illness are amplified, as the treatment of one complicates the management of the other¹. These issues are particularly pressing for Adolescents and Young Adults (AYA), who have seen the rates of cancer and depressive disorders ².

The prevalence of cancer in the AYA population continues to grow, despite the fact that the majority
of cancer patients are elderly. These younger patients have specific psychosocial issues, such as depression, that necessitate complex clinical management. Despite these challenges, there is a noticeable lack of research literature on the best psychiatric treatment for depression in AYA cancer patients [3].

Each year, nearly 70,000 adolescents and young adults are diagnosed with cancer in the United States, with tens of thousands more completing cancer care[4]. Cancer is still the leading cause of disease-related death among teenagers in the United States, trailed only by death from injuries, suicide, and homicide. Adolescents with acute lymphocytic leukemia have a 50% 5-year survival rate compared to 80 percent for children with the disease. 9 The annual rate of improvement in 5-year survival for adolescents has been less encouraging across all cancer types, especially for those with breast cancer and leukemias [5].

Physical symptoms including fatigue, anorexia, and sleep disturbance are typical side effects of an underlying malignancy or its treatment. It’s still up for discussion whether and how these somatic symptoms can be included in the diagnosis of a depressive disorder. Furthermore, clinicians and patients’ common assumptions that depression is a “anticipated” reaction to a cancer diagnosis or a life-limiting disease cloud reliable measurement of depression prevalence[6]. Young women with breast cancer are more likely than older women to develop triple-negative basal-cell breast cancer, which is an aggressive type of the disease. Despite the fact that colorectal cancer incidence is declining in the United States, rates of diagnosis (as well as worse outcomes) have increased among the AYA population [7].

Psychiatric syndromes are common in people who have cancer. Adjustment conditions with signs of depression or anxiety have a wide range of incidence, ranging from 16 percent to 42 percent. Minor depression or dysthymia is estimated to affect 20% of cancer patients. 28 Although exact figures are difficult to come by, cancer patients have significantly higher rates of all mood disorders than the general population, with MDD occurring up to three times more often in cancer patients[8].

Methodology

A descriptive correlational study using an evaluation approach is designed to examine the degree of depression among adolescents undergoing chemotherapy at pediatric hospitals in Baghdad City, From December 15th 2020 to June 17th 2021

Setting of study

The study was conducted at Oncology Teaching Center and Central Teaching Hospital of Pediatric in Baghdad city, this hospital and center is the designated agencies for data collection.

Sampling

A purposeful “non-probability” sample of (45) adolescents undergoing chemotherapy was chosen. This sample was chosen from Oncology Teaching Center and Central Teaching Hospital of Pediatric in Baghdad city.

Instrument of study

To evaluate depression level among adolescents undergoing chemotherapy treatment at Pediatric Teaching Hospitals in Baghdad City, a self-administered questionnaire was developed to assess it was constructed through the review of related literatures and previous studies. The questionnaire consisted of two parts:

Part 1: The socio-demographic characteristics of the patient:

Patients’ socio-demographic characteristics consist of (9) items which include age, gender, age at diagnosis, education level, parents’ education level, parents’ occupation, monthly income, duration of chemotherapy, complications and relapse.
Part II: Knowledge of nurses regarding nursing management of thrombolytic therapy for patients with acute myocardial infarction.

This part embraces (21) item which are measured on 3-level type Likert scale of always =3, sometimes =2 and never = 1 and valued as mild = (21-35), moderate = (36-49) and high = (50-63).

Statistical Methods

The analysis of the data was used through descriptive statistics (frequencies, percentages, and the mean of score and standard deviation) and statistical inferential. It includes the following:

1. Cronbach Alpha Correlation Coefficient:
   This test is used for the determination of the internal consistency of the study instrument.

2. T-test:
   This test is employed for the comparative differences between adolescents’ depression relative to their age and gender.

3. Multiple linear Regression:
   This test is applied to determine the relationship between adolescents’ depression and their socio-demographic characteristics.

Results and Discussion

Part I: Discussion of Adolescents’ Socio-demographic Characteristics (Table 1):

Based on these factors, the majority of the adolescents in the present sample who have developed depressive disorders are in their middle years. In terms of gender, the current research discovered that male adolescents account for more than half of the patients. Boys have a higher relative risk of depression during early and late adolescence than children, according to study findings. A randomized clinical trial is being performed on ninety-two (92) cancer-stricken adolescents and young adults (48 PRISM, 44 Usual Care). They are (43 percent) females, and (73 percent) are (12-17) years old, according to the results.

According to the findings, the majority of depressed adolescents are diagnosed between the ages of 12 and 14, and are treated for 1 to 5 months. These results show that these adolescents developed cancer while still in their early teenage years.

Park and colleagues (2015) found that cancer is diagnosed in advanced school years in their assessment descriptive research. Many teenagers and their parents have been reported as having low achievement levels in relation to their education (Table 1). These results show that low-educated teenagers and their parents are more likely to develop depressive disorders than those who are well-educated and have never had cancer. Unfortunately, there is no supporting evidence for these findings in the literature.

According to the report, more than half of adolescents have sufficient family income, with more than a third of their fathers working and the majority of their mothers being housewives. A randomized clinical trial is being performed on ninety-two (92) cancer-stricken adolescents and young adults (48 PRISM, 44 Usual Care). According to the findings, a quarter of them (24%) come from low-income households.

According to the findings, many suicidal adolescents have acquired depression-related complications and have relapsed after treatment.

And compared to children who did not obtain a depression diagnosis during primary school, children who receive a depression diagnosis during primary school have a significantly higher chance of a depression relapse during adolescence.

Part II: Discussion of Adolescents’ Level of Depression (Table 2):

During the data analysis, the researchers discovered that many adolescents developed and endured mild...
depression as a result of their chemotherapy treatment (Table 4-2). This finding suggests that teenagers who are diagnosed with cancer and are undergoing chemotherapy treatment.

Adolescents with cancer are more likely to experience depression due to delays in their developmental trajectory, increased physical symptom burden, and a higher risk of developing aggressive disease, according to the literature. Adolescents with depression have significantly higher rates than those without cancer when compared with older adults\[11\].

**Part II: Discussion of the Comparative Differences between Adolescents’ level of depression Relative to their age and Gender (Table 3,4):**

According to the results of such a comparison, middle-aged and male teenagers grow and experience, as well as becoming more susceptible to depression following chemotherapy treatment, than others (Table 4-4). According to a national survey of US adolescents aged 12–17 (N=101 685), the average incidence of depression between the ages of 12 and 17 is (13.6 percent) among male subjects and (36.1 percent) among females. At the age of (12) years, the sex disparity in incidence is substantial (5.2 percent in female subjects versus 2.0 percent in male subjects, P0.0001), and it is substantially greater at the ages of (13) through (17) years than at the age of (12) years (P-values0.05)\[12\].

Female participants are (2.8) times more likely than males to experience depression at the age of twelve, and between (3.1 and 4.0) times more likely to develop depression at the ages of thirteen and fourteen (13 through 16). At the age of 17, the relative risk of (2.2) is smaller than at the age of (12)\[13\].

**Conclusion:** It has been well-founded throughout the course of the study that male and middle age adolescents experienced depressive disorders more than others. The study ascertains that many depressed adolescents have developed complications associated with depression and experienced relapse far along. Most of the adolescents have experienced moderate level of depression as a result of their being exposed to the chemotherapy treatment.

The study confirms that the issues of looking forward, sleeping, feeling, walking, energy, pain, appetite have major influence on the prognosis of the health problem of depression. Adolescents, who are middle age and males, develop depressive symptoms greater than others after being treated with chemotherapy. Adolescents’ depression is affected by their socio-demographic characteristics of relapse, complications, mothers’ occupation, gender, education, month income, duration of treatment, age, fathers’ occupation, fathers’ education, mothers’ education and age at diagnosis.

**Recommendations:** The study recommended Counseling services are important issue to deal with in providing treatment to these adolescents especially those who are males, middle age, and developing complications and relapse. Well-designed and constructed education program can be presented to these adolescents and their parents for the purposes of increasing their awareness toward the disease and making them able to prevent complications and relapse associated depression. Regular and periodic investigations should be carried out to monitor the adolescents’ health status. And Further research can be conducted on the same topic with wide-range sample size, variety of variables and different setting.

Abstract

A descriptive correlational study was conducted to assess the quality of life of mothers toward their children with nephrotic syndrome on in children’s teaching hospitals in Baghdad, which received mothers of children with nephrotic syndrome during the period from (the nineteenth of September 2020 to the twenty-second June 2021).

The results of the study showed the age of children ranges from one to five years, and most of the diagnostic age is less than three years. mothers were mostly between the ages of 20-29. More than half of mothers are unemployed. The highest percentage of mothers were found to have a bachelor’s degree. the results of the study showed that mothers of children with nephrotic syndrome suffer from moderate (63.0%) overall level of quality of life in the five domains of, physical, psychological, social, environmental, beliefs and spiritual. All social and demographic characteristics of the mother do not affect the quality of life except for age, monthly income, level of education, and psychological distress.

Recommendations: Health and educational institutions should hold special meetings and celebrations for mother and child. Nephrotic Syndrome is educational and entertaining at the same time. Availability of multidisciplinary team of supportive care as well as follow-up out-patient clinic that include pediatric nurses, renal physicians, social workers, dietitian, psychotherapists and physiotherapist to assist children and their mother in maintaining near normal lifestyle at highest possible level of emotional feeling.

Keywords: Mothers Quality, children and nephrotic syndrome.

Introduction

Nephrotic syndrome (NS) presents with symptoms including massive proteinuria, hypoalbuminemia, hyperlipidema, and edema. The disorder can occur as a first primary disease known as idiopathic nephritis, childhood nephritic or minimal change renal syndrome. (MCNS). Second, a secondary defect that occurs as a clinical presentation after or associated with damage to the glomeruli. Third, the congenital type is inherited as an autosomal recessive disorder. This is caused by increased leakage of proteins by the glomeruli into the body, resulting in a significant lossing of urinary protein. The glomerulus is responsible for the first steep in the formation of urine, and the filtration rate depende on the integrity of the glomerular membranes

[1]. The incidence of the nephrotic syndrome (2) per (100,000) children, (9 - 16) per (100,000) between Arab and Asian population and a peak incidence between (1) and (5) years old. Males are commonly affected more than females (2.5:1). Approximately (85%) as major cause children with NS have minimal change type[2]. Morbidity and mortality were high in NS and infection was the leading cause of death in children with nephrotic syndrome, in addition the effects of immunosuppressive therapies which are used as treatment may increase the susceptibility of infection[3].

Nephrotic syndrome often affects the physical and psychosocial condition of children in the short and
long term, particularly the child who suffers severely from frequent relapse, steroid dependence or steroid resistance. Steroids and other immunosuppressive treatments for these conditions have particularly negative effects on the physical and mental health of children [4].

Mothers are assisting health workers, especially younger children, such as weighing diapers, checking the jar for albumin, weighing day after day, measuring the circumference of the abdomen, and secondly, assessing edema by staring at the swelling around the eye and the dependent area, third, it must be restricted Diet such as salt, fluid, and excessive protein at some point from the onset of edema and IV, and protecting the infant with NS from contamination all these responsibilities fall on the mothers, which inevitably affects the quality of life [5].

Methodology

Design of the study:

Using a quantitative data collection approach, the analysis was descriptive (cross-sectional). Knowing and evaluating the quality of life of mothers towards their children with Nephrotic Syndrome in i children’s educational hospitals in Baghdad City during the study period from the period of 19th September 2020 to the 22th June 2021.

Ethical Consideration:

The researcher obtained the approval of the Specialized Nursing Department at the College of Nursing / University of Baghdad. Additional approval was obtained from Al-Karkh Health Directorate / the Child’s Central Teaching Hospital At AL-iskan sector and the children Welfare Teaching Hospital of the Medical City Directorate in Baghdad to meet with each child and mother. Finally, the subject agreement was also from mothers during a cover letter and verbal consent to participate in the current study. They answer the questionnaire, after which the researcher explains to them the purpose of the research. The researcher seeks informed consent and provides respect for members ’privacy as well as volunteer input to answer questionnaire questions . These approvals made it easier for the researcher to enter hospitals and centers and meet the children and their mothers and Ethical ethics in the College of Nursing / University of Baghdad regarding confidentiality and disclosure of participants’ identities.

Settings of the Study:

The study was conducted on a child with Nephrotic Syndrome and mothers of infected children in the city of Baghdad / Al-Karkh Health Directorate / Teaching Housing Hospital and the Medical City Health Department / children Welfare Teaching Hospital

Sample of the study:

Non-probability sampling technique (purposeful sampling) for a sample of (100) mothers having children with nephrotic syndrom (70) from children Welfare Teaching Hospital (30) the Child’s Central Teaching Hospital At AL-iskan sector.

Instrument of the study:

A Self-management questionnaire was created to achieve the objectives of the study. The mothers ’quality of life was assessed using (WHOOol.-BREF Arabic version) that contains 26 items,

Data Collection Methods:

The sample was collected through a questionnaire designed to study the quality of life of the mother of a child with Nephrotic Syndrome, conducting direct interviews with them, asking questions, and leaving them free in educational children’s hospitals for a period of 5 days a week. Mothers who meet the research criteria and who are accepted to participate in the research were included in the study. 100 mothers with sick babies were treated in a face-to-face fashion. Data were collected during the period from 1february to 10 march 2021. The estimated time to complete the questionnaire is 15-20 minutes and data collection is
from 9.00 AM to 1.00 PM every day visiting five days a week.

**Statistical Analysis**

The following statistical data analysis approaches were used in order to analyze and assess the results of the study under application of the statistical package (SPSS) ver. (22.0):

**Results and Discussion**

**The Socio-Demographic Characteristics Related mother and Child of the Child with Nephrotic syndrome. Table (1):**

The results were shown the presence of (38.0%) of mothers in the age group (20-29) years. The results of the study also indicated that (80.0%) of mothers are housewives. This is in agreement with a study by (Zyarah, 2011). For 80 participating samples, (28.8% and 27.5%) of mothers were found in the age group (30-34) years and (25-29) years respectively, and (77.5%) were housewives. Table (1-4) show with regard to mother occupational, the study found that (80.0%) of mothers were housewife, and this is agreement with the results of the study conducted by (Mishra et al., 2015) which found that the majority of mothers are housewife.

The demographic characteristics of mothers in Table (1) show that all mothers participating in this study were 94% from urban areas. This can be explained by the study that was conducted in the city of Baghdad, the hospitals were in the center of the city. This finding was consistent with Malhotra and colleagues (2012) who reported that all participants belonged to an urban habitat.

Table(1) show that 81.0 % of families reported an Barely Sufficient. This result may be due to the fact that children with Renal Syndrome have medical treatments and reviews, which causes a financial burden on the family. The inability of mothers to work may also add to the financial pressure on families. As reported by (Mitra & Banerjee, 2011) The spending on illness was more in families with NS patients, ranging between 30% and 60% of the monthly income depending on the severity of the disease compared, but it caused great psychological and economic stress on families.

During the analysis of the data of the current study, regarding gender, the result shows that more males than females, males (77%) versus (23%) (Table 2-4), as evidenced by some research. Participants study chronic kidney diseases such as (Guha and Gossal, 2009), who reports that the majority of the study subjects were 66% were male and (34%) female.

With regard to the child’s age, the results of their study showed that the age of the study sample is (47%) within (3-4) years and the majority of age of the child at diagnosis (44.0%) after the first year old and the Second year (39.0%) were after Three years (13.0%) It is agree with (Trautmann, et al., 2015). who showed results on( 68%) of patient referred with possible Nephrotic syndrome aged within (1-5 ) years. And It agrees with a study by( Zyarah,2011) (55.0%) at the age of <5 years, onset of nephrotic syndrome takes high percentage at age ≥ 5 years and <2 years (26.2%, 22.5%) respectively, (41.3%) of children have NS at 1 year.

**The Level Mothers’ Quality of Life towards their children with Nephrotic Syndrome. Table (2):**

The present study finding revealed that the overall main domains Table (2) shows the level of physical health ranging from mild, moderate and severe. The majority of the mothers’ physical health (62.1%) was moderate, This result was consistent with (Mitra and Banerjee, 2011) who found that the defect of physical well-being is higher in mothers than in fathers, as it was 65.3% in mothers and the current study showed that mothers of children with nephrotic syndrome had physical health problems.

According to my opinion of researcher, the majority of mothers were between the ages of 20 and
39, and most of them do not have chronic diseases, but suffer from some health diseases as a result of intensive care for the child due to nephrotic syndrome.

Table 2 also shows that 65.8% of mothers reported a moderate level of social interaction. This finding was consistent with what (Tsai et al., 2015) reported that quality of life correlates with higher scores in social relationships and psychological state of caregivers of kidney disease children undergoing dialysis. Peritoneal kidney.

Table (2) reveals the majority of participants (70.1% - 65.8%) have a moderate burden level of psychosocial burden these results have the same agreement with the study of (Zyada, et al., 2013) who reported Parent of the child with Nephrotic Syndrome are more likely to have a psychosocial problem, had less social adjustment and had a poorer quality of life than the healthy parents of healthy children.

Table (2) shows Regarding the environmental domain, a proportion (68.6%) of mothers are moderate level. This result was consistent with (Mungo and colleagues, 2007) who found that mothers scored lower than fathers in the environmental domain of quality of life.

Table (2) shows the level of spirituality / religious beliefs and their relative impact on mothers’ quality of life. 48.6% agree With (WHO’s 2006 Quality of Life Assessment) reporting on spirituality, religion, and personal beliefs about quality of life (QoL). The aspects deal with issues such as inner peace, faith, hope, optimism, and spiritual connection. Where it was found that 52% of them have a negative impact on the quality of life. The results showed that the women still felt a greater sense of spiritual connection and faith.

According to the researcher, this is possible within normal conditions because nephrotic syndrome is the largest cause of the impact on the quality of psychological and social life on patients and their mothers. This may be related to patients and needs that include physical, psychological and emotional support. This requires a lot of knowledge and more skills from mothers that have developed and responsibilities towards them. These responsibilities may lead to a significant impact on the quality of life in terms of social and economic. Therefore, the mother is constantly exposed to the largest impacts on the quality of life and does not care for himself.

The above result is also in agreement with (Tsai, et al., 2006) who reported that mothers play a major role for their child, including maintaining their health, providing professional advice, as well as a typical request for patient upbringing. Therefore, it is not uncommon for mothers to experience a significantly lower quality of life compared to mothers of healthy infants.

The study showed that a child with kidney syndrome has an effect on mothers QoL. This is consistent with a rapid study of the impact of a child’s illness on the family, and on the mother’s quality of life. The results showed the impact of the child with kidney syndrome on the mother’s life. The lowest scores were found in two domains, ‘anxiety’ and ‘emotional function’, although there were other domains of quality of life that were significantly affected.

The Association among study characteristics and Mothers’ QoL. Table (3):-

Table (4-3-2) shows the results of the relationships. The results showed that weak relationships were obtained, as statistically significant levels at P > 0.05 were not calculated with respect to the studied overall evaluation in light of SDCv. , weak relationships are counted, as no significant levels were recorded at P > 0.05 between children (SDCv.) and the main areas studied. This is due to the fact that the child in the advanced stages of life is more responsive and understands his health condition.

Conclusion

The results of the study showed that mothers
of children with nephrotic syndrome suffer from moderate (63.0%) overall level of quality of life in the five domains of, physical, psychological, social, environmental, beliefs and spiritual. All social and demographic characteristics of the sample do not affect the quality of life.

**Recommendations**

Health and educational institutions should hold special meetings and celebrations for mother and child. Nephrotic Syndrome is educational and entertaining at the same time. Availability of multidisciplinary team of supportive care as well as follow-up out-patient clinic that include pediatric nurses, renal physicians, social workers, dietitian, psychotherapists and physiotherapist to assist children and their mother in maintaining near normal lifestyle at highest possible level of emotional feeling.

Assessment of Pregnant women’s Practices Concerning Measures taken by Pregnant Women for Prevention of (Covid19) at Primary Health Care Centers in Baghdad City

Athraa Kadeem Kareem1, Rabea Mohsen Ali2

1MSc. Student, 2Professor, University of Baghdad, College of Nursing, Maternal and Neonate Nursing Department

Abstract
Corona virus is one of the major pathogens that mainly target the respiratory system of humans. Pregnant women considered to be a special population group because of the unique ‘immune suppression’ caused by pregnancy. The immunologic and physiologic changes might make pregnant women at higher risk of severe illness or mortality with Covid-19, compared with the general public.

Objectives: To assess pregnant women’s practices concerning measures taken by pregnant women for prevention of (Covid19) at primary health care centers in Baghdad City. Methodology: A descriptive (cross sectional) study has been carried out on Non-probability sample of (150) of pregnant who attend five Primary health care centers. Study has been conducted for the period of February 8th to 18th March 2020.

Results: The results of the current study indicate that (33.3%) of pregnant women are with age group (21-25) year, (28%) with age group (16-20), and (27.3%) with age group (26 -30) years. (22.7%) of study sample are graduated from intermediate school, (76.7%) of pregnant women are housewives, (51.3%) of sample are resident in a high class neighborhood, (76%) of pregnant women are moderate monthly income, (34.7%) of pregnant women are gravid for (3) times, (81.4%) have (1-2) births, (53.3%) of pregnant women reporting they have normal vaginal delivery, (34%) of pregnant women have good level of practices regarding measures taken by pregnant women for prevention of (Covid19), (34%) have fair levels of practices, and (32%) have poor levels.

Conclusion: The study concludes that half of pregnant women have good level of practices regarding prevention of corona virus, and more than half of pregnant women are showing fair level of health behaviors toward reduction of corona virus spread.

Recommendations: the pregnant women should be supplied with instructional booklets in order to raise practice level of preventive measures of COVID-19 infection at the beginning of their pregnancy.

Keywords: Assessment, Pregnant, Precaution Measures, Practices, COVID-19.

Introduction
Corona virus is a severe disorder that mainly affects the respiratory systems of individuals. Severe acute respiratory syndrome (SARS)-CoV and Middle East respiratory syndrome (MERS)-CoV have both been reported as Corona virus epidemics in the past[1]. The variations are in the genetic make-up, clinical manifestations, case mortality, and global spread rate. SARS-CoV2, also known as the coronavirus virus, is a virus that causes coronavirus disease 2019 (COVID-19), which has become the world’s newest health threat [2]. The most common COVID-19
symptoms include fever, dry cough, dyspnea, headache, sore throat, rhinorrhea, and hemoptysis, which can range from mild (or no symptoms) to severe illness [3].

Pregnancy is a state of partial immune suppression which makes pregnant women more vulnerable to viral infections, and the morbidity is higher even with seasonal influenza. Therefore, the COVID-19 epidemic may have serious consequences for pregnant women. However, information on the effect of COVID-19 on the course and outcome of pregnancy in the first and second trimesters is not available yet. As COVID-19 still appears to be spreading, more infections in pregnant women are likely to be encountered in different regions, countries, and continents. Therefore, it is important that pregnant women and their families, as well as the general public and health-care providers, receive as accurate information as possible. During infectious disease outbreaks most frequently researched preventive behaviors and have proven to the spread of pandemics [4].

**Materials and Methods**

A descriptive (cross sectional) study has been carried out on Non-probability sample of (150) of pregnant women’s Practices Concerning Corona Virus Disease Precaution Measures who attend five Primary health care centers. Study has been conducted for the period of February 8th to 18th March 2020. The questionnaire has been used as a tool of data collection and consist of three main parts; including Socio-Demographic Information, Pregnant Women History, and pregnant women’s practices regarding measures to be taken by pregnant woman to prevent (COVID 19). A pilot study conducted on (15) pregnant women to determine the study reliability, descriptive and inferential statistic approaches are used for data analysis. Data are analyzed through the use of (SPSS) ver.24.

**Results and Discussion**

Discussion their Socio-demographic Characteristics of study (Table 1):

The present study has reported that the highest percentage (33.3) of the study sample is at age group range (21 – 25) years old. This finding is consistent with, Abdulla, Akram, & Mardan Abullah,( 2021) in Iraqi study which indicated that the highest percentage of the participants in the study were between the ages of 20 and 29, accounting for 50.5 percent of the total. And the study found that the age group range (36) years old has the lowest percentage (2.7) of the study sample than any other age group[5].

Regarding the education level refers that the highest percentage among pregnant women are graduated from intermediate school (22.7%), (21.3%) are graduated from primary school, while (20.6%) are graduated from secondary school, and (18.7%) are Institute/college graduate. This finding is consistent with, Ferdous, et al. (2020) which indicates that the level of education for study sample was primary in (35%), secondary in (50%), and tertiary (15%) [6].

Regarding the occupational status indicates that (76.7%) of pregnant women are housewives and only 23.3% of them are working as governmental employee. This result supported by Maharlouei et al [7] who reported in the study that the majority of the sample (House wives) account for approximately 488 (90.4%) of the total sample, and the lowest percentage of the group, 52 (9.6%), was employed (7), and Lee et al,(2020) reported in the study that the majority of the sample are (House wives), accounting for approximately 116 (69.5%) of the total sample, while the lowest level, 51 (30.5%), are employed[8].

Regarding monthly income, (76%) of pregnant women are perceived moderate monthly income. This study agree with yassa et al,( 2020) who reported that (52.9%) of pregnant women are perceived moderate monthly income [9]. This study disagree with Maharlouei et al (2020) also observed that majority of study are high socioeconomic status[7].
Discussion of Reproductive Health Characteristics (Table 2):

Regarding reproductive history the results of present study reveals that pregnant women are gravid for (3) times as referred by high percentage (34.7%), the parity is shows that (81.4%) of pregnant women have (1-2) births, while (14.6%) of them have (3-4) births. Regarding mode of delivery, (53.3%) of pregnant women reporting they have normal vaginal delivery and (46.7%) having cesarean section, (61.3%) have delivered in hospital and only (38.7%) are delivered at home. This result agree with: Nie, et al., 2020 who found that the majority of the participants in the study are pregnant for (1) time, as evidenced by a high number of 1 13 (39.4%), while the most of the participants have (1-2) parity, accounting for 66.7 percent of the total (3.0 percent) (10). Regarding the mode of delivery and delivery place, this study disagree with: Nile, et al., 2020 who found that Twenty-two (81.5%) women delivered via cesarean section, and 5(18.5%) had vaginal deliveries , (74%) of women were worried about being infected with COVID-19; (53%) of women would choose having a caesarean section over a vaginal delivery [10].

Overall Assessment of Measures taken by Pregnant Women for Prevention of Corona Virus among) Table 3):

Regarding the measures taken for prevention of corona virus among pregnant women the study results presents the mean scores which indicate fair level. The overall assessment of measures taken by pregnant women for prevention of corona virus the results reveals that pregnant women have fair (34%), good (34%) , and poor (32%) levels of practices regarding measures taken to prevent corona virus.

The present results study supported by Metwally, & Desoky (2020) Who have reported that all of the women (100%) were aware of ongoing COVID-19 infection. Most of them reported fever and cough to be symptoms of COVID-19 infection (87.3% & 85.1% respectively). More than two thirds of women (70.8%) reported to wear face mask when they had that symptoms, (62.7%) of them reported to stay at home and (52.7%) reported to inform their health care provider before going to hospital. The majority of women (89.2%) reported that the COVID-19 virus spreads via respiratory droplets of infected individuals[11]. While Abdulla, Akram, & Mardan Abdullah (2021) that about 2/3rd of the participants were presented with poor practice (67.25%), while less than 1/3rd (32.75%) with good practice .For the participant practice response for preventing COVID-19 show that 73 (18.25.0%) choose the washing hands frequently as major preventive way, 59 (14.75%) said that a distance for 2 meters and more between the people can prevent the infection with disease, 123 (30.75%) choose wearing mask, (75.16%) choose do not touch eye, nose and mouth common way to prevent the infection, and 78 (19.5%) mentioned staying home was the way to prevent infection with the disease [5].

Correlation among Practices related to Measures for Prevention COVID19 among Pregnant Women with regard to their Socio-demographic Characteristics (Table 4):

The current study results shows that there are significant relationships (positive) among pregnant women practices with regard to their level of education and occupation at p-value= 0.003 and 0.006, and there are high significant relationships (strong positive) among pregnant women practices with regard to their monthly income at p-value= 0.001 respectively. This result of the study agrees with Metwally & Desoky (2020), that reported there were statistically significant relations between the studied women’s level of practice about preventive measures against COVID-19 infection and their education level and parity with p-value <0.05. Women who had university education had higher practice level than other education levels (26.53% & 20.77% respectively), and the women whose income level was inadequate and just meet life expenses had higher positive practice about COVID-19 infection than those who had insufficient income (90.63%,

P: probability, Sig: Significance, N.S: Not Significant, S: Significant, H.S: High significant

The study results present that there is significant relationships (positive) between pregnant women practices and their parity at p-value= 0.041, while there is no significant relationship has been reported among pregnant women practices with regard to gravidity, mode of delivery, and delivery place. This study supported by Metwally& Desoky. (2020), Multiparous women had a higher level of practice than primiparous women, according to the study (64.40 % & 6.98%) respectively [11].

Conclusion

The study finding manifests that overall assessment of measures taken by pregnant women for prevention of corona virus, the results reveals that pregnant women have fair to good levels of practices regarding measures taken to prevent corona virus, also there is significant relationship relationships (positive) among pregnant women practices with regard to their level of education and occupation at p-value= 0.003 and 0.006, and there are high significant relationships (strong positive) among pregnant women practices with regard to their monthly income at p-value= 0.001 respectively, and significant relationships (positive) between pregnant women practices and their parity at p-value= 0.041.
Recommendations: The study suggests further research studies are needed to determine the impact of COVID-19 on pregnant women and fetal outcomes.

Impact of Normal and Overweight Pregnant Women upon Neonatal Outcomes in Al-Nasiriya Hospitals: Comparative Study

Sara Ahmed Rashed¹, Rabea Mohsen Ali²
¹MSc. Student, University of Baghdad, College of Nursing, Maternal and Neonate Nursing Department, Al-Nasiriya City, Iraq, ²Professor, University of Baghdad, College of Nursing, Maternal and Neonate Nursing Department, Baghdad City, Iraq

Abstract

Background: Maternal obesity is a major risk for both the mother and the fetus, and it is considered an obstetrical risk factor that leads to a high incidence of complications throughout the prenatal period, as well as an increased risk of many adverse pregnancy outcomes.

Objectives: To assess the impact of normal and overweight pregnant women upon Neonatal outcomes at Al-Nasiriya city.

Methodology: A descriptive analytic study was conducted from January 11th, 2021 to March 18th, 2021 at Al-Nasiriya City Hospitals for Maternity and Children on (100) pregnant women who attending labor room, (50) were overweight and (50) normal weight pregnant women with gestational age for 08-40 weeks were included. A non-probability (Purposive sample) was used to select the participants of study sample.

Results: The result of study revealed that (34.1%) (36.4%) of study sample aged (26-30) years in normal, and overweight pregnant respectively. The study results clarifies the previous and current body mass index among normal weight pregnant women (100% & 95%) respectively, while in overweight (63.6%) overweight previously and (65.9%) obesity class (I) at current. The impact of weight upon neonate outcomes; the findings indicates that weight has significant impact up on outcomes related to neonate, at p-value= 0.006, while there is no impact has been reported among group of normal weight pregnant women.

Conclusion: The study concluded that overweight impact upon outcomes related to neonate condition, while there is no impact has been reported among group of normal weight pregnant women.

Recommendations: Increased physical activity and knowledge of healthy eating habits among pregnant women as part of primary health care centre initiatives to reduce obesity in women.

Keywords: Pregnant, Overweight, Normal weight, Adverse neonatal outcomes.

Introduction

Overweight and obesity are steadily growing in all age groups worldwide, especially in countries with low and medium incomes [1]. Given the correlation with negative short- and long-term maternal and child outcomes, pre-pregnancy obesity (body mass index, BMI> 30 kg/m²), excessive gestational weight gain (GWG) and postpartum weight retention (PPWR) are seen as new public health threats [2]. These findings include, in later life, obstetric or neonatal complications, obesity, type 2 diabetes (T2D) and cardiovascular disease (CVD) [3].
Overweight is defined by a BMI of $\geq 25$ and obesity by a BMI of $\geq 30$ \[^4\]. Several maternal, fatal and neonatal complications are associated with overweight and obesity. Maternal complications are associated with maternal obesity as well as fatal and neonatal complications, such as hypertensive disorders, diabetes and venous thrombo-embolism, including miscarriage and stillbirth, foetal abnormalities, macrosomia, preterm birth, extended pregnancy, Caesarean delivery, postpartum haemorrhage and complications in anesthesia \[^5\].

**Materials and Methods**

A descriptive analytic study was conducted to determine the Impact of normal and overweight pregnant women upon neonatal outcomes in Al-Nasiriya city Hospitals: Comparative Study. The study was performed from January 11\(^{th}\), 2021 to March 18\(^{th}\), 2021. Non-probability (purposive sample) used to collect the data from (100) pregnant women. The study sample consists of (50) pregnant women with normal weight and (50) pregnant women with overweight. A pilot study conducted in order to determine the reliability of the questionnaire in a sample of (10) pregnant women. Content validity was determined through a panel of (16) experts who had more than 8 years of experience in their field. The data was collected after obtaining the agreement from women to participate in this study. Data are analyzed through the use of (SPSS) ver. (24.0).

**Results and Discussion**

**Discussion of Socio-demographic Characteristics of study (Table 1):**

The present study results reveals that the highest percentage (34.1\%) of normal weight pregnant are with age group of (26 - 30) years, with mean $\pm$ SD (24$\pm$5) years, and the highest percentage (36.4\%), among overweight pregnant is also refers to (26 - 30) age group, with mean $\pm$ SD of (27$\pm$6) years. Khan & Qianli, (2017) stated that the most important cause for increase in weight gain with age is the activity of the metabolism decreases with increase of age, and this lead to fewer of body burns calories and this ends up accumulating lipid in the body and thus an increase in weight \[^6\].

Regarding the level of education, the highest percentage among pregnant women are graduated from primary school; (47.7\%) among overweight pregnant and (38.6\%) among normal weight. These findings are consistent with Pakniat & Ranjkesh, (2015) and with Stanford et al., (2015) and with Teixeira et al., (2012) they found that lack of appropriate understanding and adequate competence regarding obesity likely contributes to ambivalent belief development and negative attitudes toward obese individuals, who are described as unmotivated, lazy, and lacking self-control \[^7,8,9\].

Regarding Income, the highest percentage among pregnant women are perceived barely sufficient monthly income (70.5\%) among normal weight pregnant and (65.9\%) among overweight pregnant women. The study by Ogden et al., (2017), stated that obesity prevalence decreased with increased levels of income and educational attainment among women \[^10\] and, May et al., (2013) have suggested that obesity prevalence varies by income and educational level, although patterns might differ between high-income and low-income countries \[^11\].

**Discussion of Pregnant Women According to BMI (Table 2):**

The study results clarifies the previous and current body mass index among pregnant women that refer to normal among the group of normal weight pregnant (100\% and 95.5\%), while refer to overweight previously (63.6\%) and obesity I (65.9\%) at current among the group of overweight pregnant women. This result agree with Eren et al., (2015) they found the mean of pre-pregnancy body mass index is (27.18 $\pm$ 5.38), also one third of the study sample are within normal weight status and then followed by overweight and class-I obesity \[^12\], also agree with Machado et al., (2020) pregnancy BMI: (29.6\%) women (n = 918).
were classified as overweight and (27.3%) (n = 846) as obese \(^{(13)}\). Also agree with Subhan et al., (2019) that most women (64%) had a normal pre-pregnancy BMI \(^{(14)}\).

Discussion of Assessment the Effect of Weight on Neonate Condition among Pregnant Women (Table 3):-

Regarding the outcomes related to neonate conditions; the results shows that “macrosomia” is seen among (2.3%) of normal weight and (13.6%) of overweight; the “child weight less than 2500 g” is seen among (9.1%) of normal weight and (22.7%) of overweight; “small gestational age” is reported among (2.3%) of normal weight and (20.5%) of overweight; “Large gestational age” is seen among only (2.3%) of overweight; “admission of neonate to NICU” is associated with (9.1%) of normal weight and (40.9%) of overweight; “umbilical cord problems” is only seen in (2.3%) of overweight; “newborn death” is reported in only (20.5) of overweight; the “birth defect” is seen among only (4.5%) of overweight pregnant; “hypoglycemia” is reported among only (13.6%); “hyperbilirubinemia” is reported among (4.5%) of normal weight and (6.8%) of overweight; “delayed intrauterine growth” is reported among only (2.3%) of overweight; the “childbirth before 37 weeks” is reported among (6.8%) of normal weight and (15.9%) of overweight; the “postdate birth after 42 weeks” is reported among only (4.5%) of overweight; the “shortness of breath” is reported among (6.8%) of overweight and (13.6%) of overweight; the “inhalation of amniotic fluid” is seen among (4.5%) of normal weight and (11.4%) of overweight; the “Apgar score less than 7 in 5 minutes” is seen in only (25%) of overweight; and “neonatal asphyxia” is reported in (2.3%) of normal weight and (9.1%) of overweight.

Simple Linear Regression for Assessment the Impact of Normal and Overweight upon Neonate Outcomes among Pregnant Women (Table 4):-

The results illustrate that there is no significant relationship between pregnant women’ weight with regard to neonate’s outcomes among the normal weight pregnant women, but among the overweight pregnant women, it shows there is significant relationship among weight with regard to neonate’s outcomes of: macrosomia, admission to the neonatal intensive care unit, hypoglycemia in newborns, and shortness of breath at p-value= (0.022, 0.015, 0.022, and 0.022). Bhavadharini et al., (2017) (Ram et al., (2020) they found in their study consistently higher macrosomia which was more frequently present (16.1%) in the obese and overweight group (2.0%) category of woman compared to normal (2.5%) [15,16].

Papazian et al., (2017) found that (LBW) significantly was present in overweight (1.0%) category of women compared to normal (2.0%) [17]. Lamminpää et al., (2016), and Black et al., (2013) found that with overweight and obesity significantly contributing to the growing prevalence of large for gestational age infants and increasing the risk of pregnancy-related complications[18,19]. Liu et al., (2013) found that of neonatal intensive care admission (AOR, 2.07; 95% CI, 1.32–3.23) and Apgar score of under 7 at 5 minutes (95%) in overweight compared with normal weight [20]. Also Hartge et al., (2016) , and Hanneman et al., (2020) found that neonates born to obese women were associated with significantly increased rates of hypoglycemia (95%)[21,22].

Conclusion

The study finding manifests that there is no significant relationship between pregnant women’
weight with regard to neonatal complications among the normal weight pregnant women, but among the overweight pregnant women, it shows there is significant relationship among weight with regard to neonate’s outcomes of: macrosomia, admission to the neonatal intensive care unit, hypoglycemia in newborns, and shortness of breath at p-value= (0.022, 0.015, 0.022, and 0.022).

**Recommendations:** The study suggests that nursing and health-care professionals play a bigger role in educating pregnant women and raising awareness about their health, especially natural weight gain before and during pregnancy.

**Funding:** this research was funded by Author. Moreover,

**Conflict of Interest:** None declared.

**Ethical approval:** clearance was taken from committee in College of Nursing/ University of Baghdad.

**Acknowledgments:** we would like to thank all the pregnant women who participated in this study.

Instruction Program for Nurses Knowledge about Applying the Communication Strategies (SBAR) in Critical Care Units

Haneen Qahtan Abadi¹, Huda Baker Hassan²

¹MSC Student, University of Baghdad, College of Nursing, Department of Adult Nursing, Iraq,
²Assist. Professor University of Baghdad, Adult Nursing Department, College of Nursing, Iraq.

Abstract

Background: Effective communication can improve patient care and safety by ensuring complete and correct information transmission and preventing misrepresentation and misinterpretation of patient-centered data. Situation, Background, Assessment and Recommendation (SBAR) is one of the most effective communication strategies that are used in transmitted the clinical information between the health professionals.

Objectives of the Study: Present study aims to determine the effectiveness of Instruction program on nurses’ knowledge regarding communication strategy (SBAR) and find out the association between the effectiveness of instruction program and nurses’ level of education, year of experiences, year of experiences in critical units and training course.

Methodology: A pre-experimental study design was carry out in the critical care units of Imam Al-Hussein Medical City at Holy Karbala City between the periods 17th of September 2020 to 25th of May 2021. A non-probability (purposive) sample of (25) nurses were selected based on the study criteria.

Results: The results of the study indicated that there were high statistically differences between the pre and post-test of the instruction program related to the communication strategy. The study found a high statistically significant relationship between the effectiveness of the instruction program related to the communication strategy, educational level, training courses for nursing documentation, years of experience in nursing, and years of experience for nurses in the critical care units.

Conclusion: The study concluded that the instruction program had a positive effect on nurses’ knowledge concerning communication strategy (SBAR).

Recommendations: Testing the current program on a wide group of health-care providers in hospitals.

Key Words: Instruction, Communication Strategy (SBAR), Nurses Knowledge, Critical Care Units.

Introduction

One of the effective communication strategies in nursing services is the SBAR (Situation, Background, Assessment, and Recommendation). SBAR is an easy framework for communicating critical information between health professionals[1]. In hospitals, structured communication techniques have been widely used to improve communication between healthcare staff. These techniques have been demonstrated to improve patient safety, prevent unexpected deaths, and reduce communication-related mishaps[2].

Communication strategy (SBAR) situational awareness has been demonstrated as an inner element in the method for providing patient concern and basic leadership that assists health care practitioners, particularly in critical care settings[3]. Communication
failure may trigger a delay in the rapid response team’s activation, which has related to a rise in in-hospital deaths. The number of SBAR components in the vital message has a direct relationship with in-hospital survival. As a result, nurses’ education on the use of the SBAR tool for transmitting critical information to physicians will increase situation sensitivity and likely improve patient outcomes [4].

Intensive care Nurses play an effective role in patient protection in their workplace. With the SBAR situational awareness approach, they should be able to recognize and interpret patient safety events using procedures, work as a team, learn from mistakes, and recognize behaviors and guidelines on how to avoid communication error incidents [5].

The technique of SBAR has helped nurses to have a focused and easy communication during transition of care during handover. Importance and relevance of capturing information need to be reinforce. An audit to look for reduced number of incidents related to communication failures is essential for long-term evaluation of patient outcomes. Use of standardized SBAR in nursing practice for bedside shift handover will improve communication between nurses and thus ensure enhance and improve patients health conditions [6].

Nurses often take more of a narrative and descriptive approach to explain a situation, while physicians usually want to hear only main aspects of a situation. The SBAR technique closes the gap between these two approaches allowing communicators to understand each other better. It is specially use for communication between a physician and a nurse when there is a change in patient condition or between a nurse and nurse during patients shift to a new department or during shift change. It is a technique used to deliver quality patient care [7].

**Methodology**

**Design and setting of the study:** A pre-experimental study design was carried out in the critical care units at Imam Al-Hussein Medical City of Karbala Holy City from the period of 17th of September 2020 to 25th of May 2021, in order to find out the effectiveness of instruction program on nurses’ knowledge regarding communication strategy (SBAR).

**Sample of the study:** A purposive sample was consists of (25) nurses was selected according to study criteria and after obtains verbal and written consent permission from them.

**The study instrument:** First part, concerned with the nurses’ demographic data. Second part, concerned with nurses’ knowledge regarding communication strategy (SBAR) includes (27) items.

**Statistical Analysis:** The IBM Statistical Package of Social Sciences (SPSS) Version 22 was used to analyze the results. Both descriptive statistical analysis and inferential statistical analysis approaches were used in order to investigate or predicts the relationships between variables.

**Results and Discussion**

1. Discussion demographic information (table 1):-

The characteristics of the participants in the present study was high percentage of them 52% at age group 18-28 years old, (Achrekar et al. 2016) including in their study 80% nurses at age 21-30 years old, 60% of the present study was females [8]. (Nagammal et al. 2016) their sample was high percentage of females which of 87.3% [9]. Regarding the years of experience in nursing, the characteristics of the present study indicated that the majority of nurses have experience from (1-5 years) with percentage 52% and according to years of experience in critical care units, the majority of nurses have experience from (1-5 years) with percentage 76%. (Sankpal et al. 2020) their study sample who included in their study have years of experience in nursing within (1-5 years) which of 83.9% of nurses [10].
nursing institute, (Coolen et al. 2020) reported in their study that the diploma degree have high percentage in their study High percentage of the study sample not included in the nursing documentation training courses which of 72% [11]. (Müller et al. 2018) stated in their study that the most of the participants not having courses of nursing documentation [12].

2. Discussion overall nurses knowledge and difference regarding communication strategy (SBAR) at the pre-test and post-test period of the program( table 2,3):-

The effectiveness of program was clear improved the practical knowledge of nurses regarding communication strategy which of their level was moderate at pretest then improved to high level and the result revealed that were high statistically significant differences between the pre-test and the post-test at (p<0.05). (Dalky et al. 2020) conducted a quasi-experimental approach with a pretest–posttest was adopted. 71 ICU nurses took part in the study as a convenience sample. SBAR effectiveness was examine using the 43-item ICU physician-nurse questionnaire, which included subscales for general relationship and communication, teamwork and leadership, and job satisfaction. The finding indicate that there was a significant improvement in posttest knowledge scores [13]. (Jiang et al. 2020) stated their study that conduct in hospital in Guangzhou research subjects were 100 clinical nurses. To explore and assess the clinical nurses’ understanding of SBAR’s blood glucose management, data were obtain via a questionnaire survey. The finding shows that SBAR strategy in addition to improving the communication between medical staff; it could also optimize the knowledge structure of nurses and make quick and accurate judgment of problems [14]. (Hadi et al. 2021) conduct a cross-sectional study was adopted in the investigation. Purposive sampling was used to choose the 102 nurses who took part in this study. A questionnaire was employed in the study to assess the SBAR’s perceptions, knowledge, attitudes, motivation, and application. The results showed that there was a significant relationship between perception, knowledge, attitude, motivation, and the application of the SBAR method [15].

3. Discussion Association between the effectiveness of the interventional program and Demographic information of study ( table 3):-

The result of present study indicates that there were highly significant association between the effectiveness of interventional program on nurses’ knowledge and years of nursing experience, years of experience in critical care units, levels of education and nursing documentation training courses. (Jeong & Eun, 2020) conduct a single-blind randomized control pretest–posttest approach use 54 nursing students in their third semester at a Korean university were chosen (SBAR group 26, handoff group 28). The finding stated there was no statistically significant difference between the SBAR group and handoff group knowledge with age groups, gender of the participants. However, there is significant association between nurses’ knowledge and levels of education and years of experience in nursing [16]. In the end that led us to accept the alternative hypothesis H₁: The program of communication strategy (SBAR) is improve the nurses’ knowledge, and reject the null hypothesis H₀: The program of communication strategy (SBAR) is not effect on nurses’ knowledge.
Table (1): Distribution of the participants according to their demographic information (n=25).

**Conclusion and Recommendations**

The study concluded that the instruction-nursing program had a positive impact on nurses’ knowledge concerning communication strategy (SBAR). The researcher is recommended; testing the current program on a wide group of health-care providers in hospitals. Use the SBAR formula in all hospital units. All nurses should attend an SBAR training session. Incorporating the SBAR into nursing education at all levels and expanded research to include more hospitals.

Investigation of the Antibiotic-Resistant ESKAPE Pathogens in Ramadi Hospitals, Iraq

Hamid M. Sharqi¹, Omar M. Hassan¹, A.S. Obaid²
¹MsC Student. ²Ass. Proff. Department of Biology, ³Ass. Proff. Department of Physics, College of Science, University of Anbar, Ramadi 31001, Iraq

Abstract

Bacterial species of the ESKAPE group (Enterococcus faecalis, Staphylococcus aureus, Klebsiella pneumoniae, Acinetobacter baumannii, Pseudomonas aeruginosa, and Escherichia coli) are often resistant to antibiotics. The purpose of this study was to find out the antibiotics resistance formed by ESKAPE pathogens in hospitals in the city of Ramadi, in Iraq. All bacteria within this clinically relevant ESKAPE group were isolated from September 2020 to April 2021. Identification of isolates was performed by Vitek 2 system and the Sensitivity Test was carried out using a disk diffusion method. The majority of pathogens isolated from patients at Ramadi Hospitals belong to the ESKAPE group. The percentage of bacterial isolates was K. pneumoniae (33.96%), E. coli (20.75%), S. aureus (20.13%), P. aeruginosa (11.32 %), E. faecalis (9.43%), and A. baumannii (4.41%). Some isolates of E. coli were Resistance to all antibiotics, while P. aeruginosa and K. pneumoniae were 100% resistant to Vancomycin and Tetracycline. The presence of the ESKAPE group of pathogens is a major problem in Ramadi city hospitals. The results of this study support the implementation of special antimicrobial strategies to specifically target these microorganisms.

Keywords: ESKAPE, MDR, antibiotic, resistance, susceptibility

Introduction

The term ESKAPE includes six genera of pathogens with multi-drug resistance (MDR) and high virulence. ESKAPE pathogens are responsible for the majority of nosocomial infections and are able to “escape” from the biocidal effect of antimicrobial agents [¹]. The World Health Organization (WHO) has also recently included ESKAPE pathogens in the list of 12 bacteria that urgently need new methods and antibiotics [²]. Antimicrobial resistance between both Gram-positive and Gram-negative bacteria has been on the rise in the past few years [³]. The presence of multidrug resistance (MDR) pathogens has become a cause of serious concern with regard to nosocomial infections. In fact, the World Health Organization recently recognized antimicrobial resistance as one of the top three human health concerns [⁴]. The most common and threatening multidrug-resistant pathogens were grouped together under the acronym “ESKAPE”, which stands for E. faecalis, S. aureus, K. pneumoniae, A. baumannii, P. aeruginosa, and E. coli. [¹]. Three decades ago, A. baumannii was sensitive to most antibiotics, but today it is exceptionally resistant to most antibiotics, with carbapenem resistance increasing more than 50% in some countries [⁵]. Recently, statistics have been recorded on meropenem resistance (MEM) of 69% [⁶]. A major factor contributing to antibiotic resistance is the production of extended-spectrum β-lactamases (ESBLs) by Enterobacteriaceae species, especially K. pneumoniae [⁷] ESBL producing Gram-negative pathogens in hospitals is an emerging global
problem that deserves special attention [8]. Another important species of the ESKAPE group is \textit{S. aureus}, especially methicillin-resistant \textit{S. aureus} (MRSA), which has an incidence and prevalence that continues to increase rapidly in many regions of the world. Mortality associated with invasive MRSA infections is estimated to be around 20\% [9] and bloodstream infections caused by these bacterial species are associated with high mortality and length of hospital stay [10]. Finally, \textit{E. faecalis} isolates are the third to the fourth most prevalent pathogen in hospitals worldwide. Acquired resistance, in particular to glycopeptides, has been reported for a number of these isolates, which limits the number of therapeutic options [11]. Global and regional surveillance of ESKAPE pathogens is essential to control infections caused by these bacterial species [12]. The purpose of this study was to monitor the occurrence of ESKAPE pathogens and their resistance to diseases in hospitals in Ramadi, Iraq.

**Materials and Methods**

**Sampling**

This study was conducted at Al-Ramadi General Teaching Hospital and Women’s and Children’s Hospital, Iraq. This hospital provides medical care to its patients and residents. This study was conducted in the medical field (from September 2020 to April 2021), 53 clinical isolates were obtained from patients referred to these hospitals. The first private isolate species was recorded for each patient, regardless of a body location. Patient samples taken for diagnostic purposes only are included.

**Identification of isolated bacteria**

Two hundred samples from various sources such as urine, faeces, burns, wounds, and sputum were collected from patients in the Ramadi hospitals. Blood agar and MacConkey agar were used to culture the samples. Culture plates were incubated aerobically at 37 °C for 24 h. After incubation, bacterial isolates were identified by performing Gram staining and using the Vitek-2 Compact system (bioMerieux). A total of 159 bacterial isolates were collected from different clinical samples.

**Antimicrobial susceptibility assays**

The antibiotics susceptibility was determined using the disc diffusion according to Kirby-Bauer method by using Mueller’s solid agar plates [13]. Antimicrobials were tested against both Gram-negative and Gram-positive bacteria including Piperacillin (PRL), Amikacin (AMK), Aztreonam (AZT), Ciprofloxacin (CIP), Imipenem (IPM), Vancomycin (VA), Azithromycin (AZM), Tetracycline (T), Ceftriaxone (CRO), and Tigecycline (TGC). Multidrug resistance MDR has been defined as resistance to three or more classes of antimicrobials. Class definitions used in this study were: Penicillins (PRL), Cephalosporins (CRO), Carbapenems (IPM), Beta-lactam (AZT), Fluoroquinolones (CIP), Aminoglycosides (AMK), Glycopeptide (VA), Tetracyclines (T), Macrolides (AZM), and Glycylcyclines (TGC). Extensive drug resistance XDR was defined as the lack of susceptibility to at least one agent in all but two or fewer classes of antibiotics (for example, bacterial isolates remain susceptible for one or two classes only) and Pandrug resistance PDR was defined as resistant for all agents in all classes of antibiotics [14]. The diameters of the inhibition zone were measured and compared with the susceptibility breakpoints recommended by the Clinical and Laboratory Standards Institute (CLSI) [15].

**Results**

Two hundred different samples obtained from patients in Ramadi hospitals were processed. A total 159 (79.5\%) of ESKAPE pathogens were included in this study. The ESKAPE pathogens were distributed into 112 (70.4\%) Gram-negative isolates. The pathogens belonging to the family Enterobacteriaceae (\textit{K. pneumoniae} \& \textit{E. coli}) were 78 (54.7\%) and non-intestinal (\textit{A. baumannii} \& \textit{P. aeruginosa}) 25 (15.7\%), and the Gram-positive isolates (\textit{S. aureus} \& \textit{E. faecalis}) were 47 (29.6\%). \textit{K. pneumoniae} 54
(33.96%) was the most common isolate, followed by E. coli 22 (20.75%), S. aureus 32 (20.13%), P. aeruginosa 18 (11.32%), E. faecalis 15 (9.43%), and A. baumannii 7 (4.41%). The isolates were recovered mostly from feces (78 isolates), followed by urine samples 33 isolates, wounds 25 isolates, sputum 15 isolates, and finally burns 8 isolates. The distribution of ESKAPE pathogens isolated from different samples is shown in Table 1.

**Antibiotic Resistance levels**

The results of the current study showed the existence of a common resistance of ESKAPE groups toward classes of antibiotics such as penicillins, cephalosporins, fluoroquinolones, and aminoglycosides, which makes it have multi-resistance to the antibiotics, as the term multi-resistance to this group of bacteria is called (Multidrug resistance), which means the ability of bacteria to resist three or more antibiotics used, provided that the bacteria have the ability to resist at least one antibiotic within the class. The isolates were distributed according to Table (2), the types of resistance, and their proportion to the isolates of the (ESKAPE) group. Among all 159 isolates, 146 were found to be MDR (100% from E. coli, 94.4% from K. pneumoniae, 88.9% from P. aeruginosa, 87.5 from S. aureus, 86.6% from E. faecalis, and 71.4 from A. baumannii). There were only 13 isolates that were found to be sensitive to most antibiotics. E. coli isolates of the ESKAPE group that were understudy has an Extensive drug resistance (XDR) of 21.2%, followed by K. pneumonea of 18.5%, as the danger of Extensive resistance strains lies in their endemicity within hospitals, their rapid spread, the high rate of resistance and their transformation into strains resistant to all drugs. The term (Pandrug resistance) is applied to the recorded resistance of all classes of antibiotics studied. The isolates of the (ESKAPE) group were recorded with resistance to the ten classes of antibiotics, represented by three isolates of E. coli (9.1%), also three isolates of K. pneumoniae (5.5%), and one isolate of P. aeruginosa (5.5%) Table (2).

**Antibiotic Susceptibility Pattern**

Antibiotic sensitivity testing showed that the rate of resistance of *E. faecalis* to Amikacin and Tetracycline was 100%. It was noted that the lowest resistance was in the case of ciprofloxacin (6.67%), while *S. aureus* showed the highest resistance rate of Aztreonam which was (75%). The results also showed that Imipenem was the most successful antibiotic in the treatment of Gram-positive ESKAPE pathogens (Table 3).

</table>
The frequency rate of resistance of *E. coli* to vancomycin, piperacillin, and tetracycline was 100%. As well, the resistance frequency rate of *K. pneumoniae* against vancomycin and piperacillin was 100%. Imipenem was again effective against (81.82%) of the tested *E. coli* isolates, while Ceftriaxone was effective against (81.48%) of *K. pneumoniae* (Table 4). None of the isolates were 100% sensitive to all antimicrobials tested. Furthermore, some *E. coli* and *K. pneumoniae* isolates were found to be highly drug-resistant as they showed resistance to all antimicrobial agents evaluated.

Discussions

The emergence of isolates resistant to a wide range of antibiotics poses a threat to health and this is a result of the wide and indiscriminate use of these wide groups of antibiotics and the lack of care for the emergence of such resistant isolates, the increase of which poses a danger to patients, and this situation remains uncontrolled at the hospital and community levels, and this is the reason for the emergence of multidrug-resistant strains, especially the broad-spectrum Multidrug-resistant strains [16-17]. In a hospital environment, there may be different bacterial species that are the causative agents of infectious diseases. For them, with a high level of proliferation and association with antibiotic-resistant microorganisms, the ESKAPE group of pathogens deserves special attention. To control the incidence of infection caused by ESKAPE pathogens, site-by-site observational studies are necessary to establish hospital-specific guidelines for effective empirical therapy [18]. In this study, ESKAPE pathogens were followed up and the incidence of K. pneumoniae and the presence of resistance to Vancomycin in Ramadi hospitals were described. The organisms most often recovered from our bodies were intestinal infections from ESKAPE pathogens (54.61%), with a predominance of Gram-negative bacteria. The most common organisms in ESKAPE are K. pneumoniae, E. coli, and S. aureus. These common bacterial pathogens were found to be similar to other predominant pathogens reported in other countries [19]. In general, an elevated MDR was observed in E. coli deserves special attention because it showed a high MDR (100%). The reason is that these bacteria in the (ESKAPE) group possess many resistance mechanisms, such as the production of aminoglycoside-modifying enzymes and beta-lactamase enzymes, and their exogenous pumping mechanism and other mechanisms that work together causing the phenomenon of multiple resistance [20]. The noticeable rise in the percentage of isolates of the (ESKAPE) group with multiple resistance in Al-Ramadi Teaching Hospitals is an indication of the outbreak of multi-resistant strains of antibiotics, which leads to the possibility of failure of the treatments currently used to treat infections caused by these bacteria.

Conclusion

Rapid identification and susceptibility testing of ESKAPE pathogens with the compact VITEK-2 system helps treat these pathogens with appropriate antibiotics and leads to a reduction in total antibiotic consumption. It was found that the Enterobacteriaceae ESKAPE group (K. pneumoniae & E. coli) are the highest prevalence among other bacterial species, and all ESKAPE pathogens have shown multi-drug resistance (MDR). Also, most ESKAPE species have Extensive resistance to antibiotics, in addition to the occurrence of resistance to all classes of antibiotics in some isolates of E. coli. In this study. Most ESKAPE isolates were found to be sensitive against Imipenem and Ceftriaxone. These antibiotics can be good treatment options for infections due to the etiology of ESKAPE.

Outcomes of Laparoscopic Surgery of Liver Hydatid CYST

Nasser M. Meazher¹, Fadhil Abbas Al-Janabi², Bashar Mohammed Hamzah³, Haider Nadum Obaid³
¹FICMS, Dr., Dept. of Surgery, College of Medicine / Kufa University, Iraq, Nasserm, ²CABS, FACS, Dr., ³FICMS, Dr., Dept. of Surgery, AL Sadder Medical City, Al-Najaf Health Care Center /Iraq, ⁴CABS, FICMS, Dr., Dept. of Surgery, Al-Khadymia Teaching Hospital,Baghdad/ Iraq

Abstract

Objective: To evaluate the outcomes of laparoscopic management of liver hydatid disease regarding intra-operative and post-operative advantage and disadvantage.

Patients & Methodology: The study conducted from October 2014 to April 2018 at Alsader teaching hospital by management of liver hydatid cysts laparoscopically. All patients with four or less liver hydatid who underwent laparoscopic surgery for liver hydatid were included. Evaluation of intra-operative and post-operative outcomes regarding: hospital stay, pain, complications, cost effectiveness and recurrence of hydatid cyst were been studied.

Results: Forty eight patients had laparoscopic operation for liver hydatid cysts. The mean age was 37.89 ± 17.03 years (ranging from 8 to 85 years). There were 21 male (43.75%) and 27 female (56.25%). The most common cause of presentation was pain, which occurring in 38 (79.16%) of patients, and the second cause was abdominal mass, found in 9 (18.75%) of patients, and there is no conversion to open surgery. The complications were occurred in 17 (35.41%) of patients, such as ports site infection in 3 (6.25%) of patients, and bile leak in 5 (10.41%) of cases. Other complication include, collection in residual cavity in 3 (6.25%) and fever in 5 (10.41%). Neither recurrence nor mortality happened in our study. The mean operation time was 56.27 ± 13.84 minutes.

Conclusion: The laparoscopic approach for liver hydatid cysts is safe and effective in selected patients.

Key words: hydatid cyst, laparoscopic surgery.

Introduction

Echinococcal disease is caused by tapeworm infestation in its larval stage. In humans, four Echinococcus species cause infestation. The most common are E. granulosus (cystic echinococcosis) and E. multilocularis, (alveolar echinococcosis). The other two species, E. vogeli and E. oligarthrus, are less common [1].

The echinococcus life cycle includes a definitive (dogs or its related species) and an intermediate host (sheep, cattle, camels, goats, etc). The typical hydatid cyst has a three-layer wall cavity containing fluid. The outer layer is the pericyst, a thin fibrous tissue layer representing an adventitial reaction to the parasitic infestation. Over time, the pericyst may calcified.

The outer layer of the cyst itself is the ectocyst (laminated membrane) and is bluish-white, gelatinous. The inner layer or endocyst is the germinal membrane, responsible for the production of ectocyst, clear fluid, scoleces, brood capsules and daughter cysts (endogenic vesiculation). [3] The diagnosis of liver hydatid is based on laboratory test represented ELISA test (enzyme-linked immune sorbent assay) for antigens and are positive in approximately 85% of cases. If the
parasite is no longer viable or does not contain scolices, or the cyst has not leaked, the test results may be negative. In approximately 30% of cases, eosinophilia is seen. CT scanning and Ultrasonography are both sensitive for detecting liver hydatid. The cysts appearance on images depends on the stage of development. Typically, hydatid cysts are well-defined hypo-dense lesions with a distinct wall. Ring-like calcifications of the pericysts are present in 20% to 30% of cases. Daughter cysts generally occur in a peripheral location within the main cyst and are typically slightly hypo-dense compared with the mother cyst [4].

The specificity of ultrasound in hydatid diseases around 90%. The classification proposed by Gharbi and associates provides a morphologic description [5]. Abdominal MRI of the may be useful for evaluation of the cyst characteristics [6].

Clinically, the hydatid cyst is mostly asymptomatic until complications developed. The most common symptoms are dyspepsia, abdominal pain and vomiting. Hepatomegaly is most frequent sign. Fever and Jaundice are present in approximately 8% of patients [7].

Treatment is indicated to prevent progressive cysts enlargement and rupture. A course of albendazole or mebendazole may be tried perioperatively. Many articles mention that percutaneous treatment (PAIR) of hydatid cysts is effective and safe [8].

The surgical options range from deroofing with evacuation of the contents to liver resection or local excision of the cysts.

Intrabiliary rupture of liver hydatids may result in acute cholangitis or obstructive jaundice. This may be managed endoscopically by ERCP prior to cyst removal from the liver [8].

**Patients and Methods**

This study designed as case series conducted in the General Surgical department in Alsader Medical City at Al-Najaf, Iraq, from October 2014 to April 2018, with acceptance and permission of scientific council of board center and patients consents for surgery, video recording and taking pictures.

**Exclusion criteria for laparoscopic intervention include:**

1. The site of hydatid cyst within the liver parenchyma or segment VII and VIII.
2. If the number of cyst is more than 4.
3. The diameter of cyst less than 4 cm
4. Those were treated in the emergency due to ruptured hydatid cyst.
5. Dead cyst (calcified)
6. If laparoscopic surgery was refused.

The diagnosis of the liver hydatid cysts based on:-

a- History
b- Clinical examination.
c- Imaging (abdominal ultrasound and Computerized tomography scan (CT scan).

We start oral albendazole(15 mg/kg/day or 400 mg orally twice daily to all patents for two weeks before surgery and continue after surgery for 28 days followed by a 14-day drug-free period. Repeat for 2 more cycles.

Intra-operative and post-operative outcome regarding, hospital stay, pain, complications, cost effectiveness and recurrence of hydatid cysts were evaluated.

The type of anesthesia was general anesthesia for all patients. At the time of induction, intra venous prophylactic antibiotics was given. Prophylactic injection Hydrocortisone before surgery also given. Inflation of abdomen by CO2, using veress needle to make pneumoperitoneum, then insert a zero or thirty degree telescope (10mm) through infra-umbilical port, this is the 1st port, after that Hydatid cyst was identified on the liver surface. The 2nd port (10mm) was inserted.
either at 1 cm below xiphoid process (if the cysts on the right lobe of liver) or at left mid-clavicular line, about 2 cm below costal margin (if the cysts at left lobe of liver). The last port (5 mm) inserted about 2 cm below costal margin at right mid clavicular line placed, for making access and mobilization of hydatid cysts.

At first, we do packing of the peritoneal cavity with 10% povidone iodine-soaked packs to control spillage if happened.

Then we puncture hydatid cyst wall and aspirate the fluid from the cysts, followed by instillation of 10% povidone iodine solution inside the cavity (scolicidal agent), lastly we do re-aspiration, sometime followed by deroofing of the hydatid cysts wall. The cyst contents were evacuated by using 10 mm sucker and irrigated with povidone iodine then 0.9 Normal saline. The endocyst extracted to outside by endo bag. Any remaining contents in the cavity should be examined (daughter cysts and bile leak). A tube drain placed inside the residual cavity for drainage later on.

In most cases, the drain was removed after 4-5 days, but in case of bile leak, the drain was kept longer. Usually the patients were discharged home two days after surgery post-operatively, after three months the cyst cavity was monitored by ultrasound. CT scan was performed if the ultrasound report was inconclusive or suspicious.

Results

Forty eight patients with liver hydatid were treated by laparoscopic surgery. The age range 8 to 85 years. The males were 21 (43.75%) while 27 (56.25%) of them were females.

The most common cause of presentation was pain, occur in 38 (79.16%) of cases, while 9 (18.75%) of patients complained from a mass in addition to pain. One of series has jaundice (2.08%) treated by ERCP preoperatively. It was 4 (8.33%) of cases incidental diagnoses, by abdominal ultrasound examination performed for another causes (Table I).

In 37 (77.08%) of cases were present with single liver hydatid cyst, two cysts in 7 (14.58%) of cases, three and four cysts in 2 (4.16%) of cases. (Table II). The most common site of liver hydatid cysts was the right lobe, 40 (83, 33%). Left lobe of liver were 5 (10.41%), lastly in bilateral liver lobes were reported in 3 (6.25%) of cases.

Mean time of surgical duration 56.27 minutes, if the patient has single or small hydatid cyst the surgery will take shorter time. Anaphylactic cyst the surgery will occur in one of patient during surgery.

However, Complications were occurred in this study to 17 patients (35.41%), listed in Table III.

The Port site infection happened in 3 (6.25%) of patients and bile leak in 5 (10.41%) they stopped by conservative treatment in 4 to 7 days, except in one case, the leak not stopped until underwent ERCP. Other complications were reported in 3 (6.25%) with residual cavity collection, and fever in 5 (10.41%).

All patients’ procedure was completed laparoscopically, with no conversion to open surgery. Recurrence of hydatid cysts were not reported in this series after follow-up for 6 months to one year. No mortality in this study. In table IV, there were 28 (58.33%) of patients need only 2 days hospital stay, 8 (16.66%) of patients 3 days stay, others (4 – 5) days. Regarding to return to normal activity, after 5 days in 33 (68.75%) of patients, 7 days in 12 (25%) and 12 days in 3 (6.25%) of patients.

Discussion

Our study is for evaluation of results of minimal invasive technique in the treatment of liver hydatid cysts in a selected patients group.

The mean age was 37.89 ± 17.03 years (ranging from 8 to 85 years), which is near other series age of presentation [9, 10].

In fact, all age are affected equally, in other areas, usually with the average age being older at presentation [7]. Female’s gender was affected predominantly in our study look like in some others [7, 10]. However other studies have predominance in male’s gender or equally reported in both gender [9, 11].

The most common cause of presentation was abdominal pain, occurred in 38 (79.16%) of patients, this also previously reported by another authors [7, 9, 10]. Liver hydatid cysts should be in differential diagnosis to all patients with abdominal pain, fever, abdominal mass and jaundice, however, a lot of cases are asymptomatic, mostly in non-endemic area, and they diagnosed incidentally [9, 12].

In our study, the pathology was single liver hydatid cyst most commonly, and in the right lobe of liver. Which was similar reported in other studies, from India in Uruguayan community [9, 11]. Abdominal ultrasonography and CT scan are very effective for identification and diagnosis of liver hydatid cysts. Ultrasound is clearly identify the membranes of hydatid cysts, its septa in addition to hydatid sand, while calcified cyst wall and infected cysts are best identified by CT scan [8]. Specific criteria on US or CT scan may indicate biliary communication and this confirmed on MRI. US and CT scan both were done to all patients in this study. Surgery is the corner stone for treatment of liver hydatid cysts. Laparoscopic treatment of hydatid cysts disease was reported in 1994 for the first time [9]. However, the reports regarding long-term results are limited in this technique [13]. Many different laparoscopic techniques are present, total pericystectomy, marsupialization following puncture and aspiration, deroofing then drainage, deroofing then omentopexy [14, 15, 16].

In our study, 48 patients with liver hydatid cysts were managed with laparoscopic technique, we applied the principles of usual surgery including scolices deactivation with 10% povidone iodine solution (scolicidal agent), aspiration of contents inside hydatid cysts, deroofing the cavity and entire cysts contents were evacuated. Similar studies in Turkey from University Hospital, they reported cysts drainage simply with a specific trocar and cannula in 18 patients and deroofing with drainage in other 22 patients and have good results and low recurrence [16]. Other study, in Pakistan from Khyber Teaching Hospital in 2010, also report low recurrence rate and complications such as, recurrence in 4.65% of patients, bile leak in 9.3% and conversion 6.97% of patients [17], Ertem et al. has successful result in laparoscopic cystectomy and partial cystectomy with drainage in 33 patients along with omentopexy in 15 cases and have 2 cases converted to open surgery [13]. In another study from India, evacuation and marsupialization, trans-cystic fenestration and lobectomy were performed by lap using a Palanivelu Hydatid System (PHS), especially trocar design for control contamination and spillage from hydatid cysts [9].

The disadvantage of the laparoscopic surgery is difficulty to control spillage; different tools have been designed to evacuate the hydatid cysts contents without spillage. Bicket et al. used a beveled transparent cannula, Al-Sharif et al. used cannula of liposuction, however, Bickel et al. described the isolated hypobaric technique, he has attempted to deal with spillage problem [18, 19]. PHS not only for preventing spillage, but also for assisting complete evacuation of the hydatid cysts in addition to allows magnified intra cystic visualization of biliary communication to it [9]. Unfortunately these specific devices not available in the our hospital. In our study, no conversion to open surgery happened in comparison to others study have conversion rates of 3% and 23% mainly due to difficult access, anatomy and exposure [13-16]. Also we have no mortality.
Complications included, port site infection, fever, collection in residual cavity, bile leak, all treated by conservative management, except one treated by ERCP for bile leakage. In other study, they report infection in 5 (4%), bile leak in 10 (14.5%) cases and peritonitis, also their complication managed conservatively [9].

Open surgery studies reported recurrence rate much higher (ranges from 3% to 10%), following liver hydatid cysts surgery [13].

So, with laparoscopic surgery, the morbidity and recurrence rate decrease versus in open surgery.

**Conclusion**

Laparoscopic surgery of liver hydatid cyst was effective and safe treatment in selected patients, with decreased risk of spillage in the abdominal cavity, lower rate of complications and recurrence. It also given to patients the advantages of minimal invasive surgery.

**Recommendation**

- New study involves larger number of cases.
- Using new technologies to control of spillage such as Palanivelu Hydatid system.
- Long term follow up.

Study the Behavior of Activity and Express for Enzymes

Antesar Rheem Obead1, Anmar Hameed Bloh2, Haider Rasol Abbass Alwahami3

1Lecture, Babylon University, College of Education, Science Dept., Hilla, Iraq, 2Lecture Department of Radiology and Sonography Technique, AL-Rafidian University College, Pediatric Teaching Hospital in samawah

Abstract

Enzymes are be defined as soluble, colloidal, organic catalysts which are produced by living cells. Enzymes are biologic catalysts to accelerate the rate of biochemical reactions.

in this study Quantification of the Enzyme Activity, Where: E = enzyme concentration; S = substrate concentration; ES = enzyme-substrate complex concentration; k1, k3= 1st order reaction rate constants (l-1); P = product concentration; k2= 2nd reaction rate constant (M-1.t-1).At first, it must be stressed that the formation of ES (enzyme-substrate complex) is an obligatory step to any type of enzyme-catalyzed reaction. The ES, depending on the reaction conditions, can form the product (forward reaction) or not (reward reaction). The immobilization technique allowed a more frequent use of biomaterials in industry, therapeutics (confection of subcutaneous capsules for controlled delivering of hormones), and lab analysis (automatic dosing equipments, enzyme electrode, biosensors and enzyme immunoasays). In industry, the use of glucose isomerase for the conversion of glucose into fructose (high fructose corn syrup), the aminoacylase for the separation of racemic mixture of amino acids, microbial lipase in triglyceride hydrolysis, and the lactase for removing lactose from milk and/or whey are stressed.

Key word : enzyme , activity , immobilization, Specificity, factors, thyromodynamic

Introduction

Enzymes are be defined as soluble, colloidal, organic catalysts which are produced by living cells. Enzymes are biologic catalysts to accelerate the rate of biochemical reactions. All enzymes are protein in nature; they are water soluble, precipitated by usual reagents like alcohols, ammonium sulfate and alkaloid reagents.

Most enzymes are present in cells at much higher concentrations than in plasma.

Normal plasma levels reflect the balance between the synthesis and release of enzymes during ordinary cell turnover and their clearance from the circulation, therefore, enzymes can be used as markers to detect and localize cell damage proliferation. The enzyme (holo-enzyme) composed of inactive protein (apo-enzyme) with cofactor which may be organic (coenzyme) or inorganic (elements like Mn, Mg, Fe). If the cofactor linked forced to the protein portion of enzyme then it called prosthetic group (1).

Enzyme unit: the amount of enzyme required for transformation one micromole of substrate (reactant molecules) in one minute. Turnover number: the number of substrate molecules transformed per one minute by a single enzyme molecule

Specificity

Enzymes catalyze a reaction accepting only one substance as substrate. When it accepts two or more substrates, one ofthem is always preferred .The enzyme specificity is determined by the active site, a particular domain of the peptide molecule. There are two main theories seeking to explain the enzyme-substrate interaction. One –proposed by Fischer in the beginning of the 20th century –states that the
substrate-enzyme interaction would resemble a key-
lock mechanism, in which the key (substrate) fits into
the lock (active site), since two conditions are satisfied:
the substrate and the active site have complementary
structures and compatible polarity and size(2). The
other –proposed by Koshland in the 1960–states that
the substrate nearest the enzyme molecule induces on it
some structural modifications that favor the enzyme-
substrate fitting

Nowadays, it is accepted that the active site can
be subdivided into two particular regions, one called
bond site (responsible for enzyme specificity) and
the other called catalytic site (in which a sequence
of well-defined 1st and 2nd order reactions occur
transforming the substrate into the product or vice-
versa) (3).

Enzyme Activity

When enzymes are used in industrial processes
and analytical procedures, the precise evaluation of
the enzyme activity becomes important. Focusing
on the industrial scale, the decision to use or not an
enzyme in a process must be based on issues such as1)
the amount of enzyme required for carrying out the
process properly, 2) the duration of the reaction, 3) the
amount of substrate to be converted, 4) the conditions
under which the reaction occurs, and 5) the overall
cost of the process. Once the decision for using an
enzyme is taken, and considering that the enzyme
has a cost, the impact of this cost on the overall
process must be evaluated (4). Thereby, the increase
in product yield and/or the value added to the final
product, as well as the reduction of the overall energy
consumption, could minimize the effect of enzyme
cost on the overall process cost. Thereby, it is clear
that the success of the enzyme process depends on the
optimization of three factors, i.e., amount of enzyme
needed, operation conditions (pH, temperature,
agitation etc.), and reaction yield. Theoretically, as
the enzymes are catalysts not consumed during the
reaction, a small amount could transform into huge
amount of substrate. However, an optimized and finite
correlation among the amount of catalyst, its initial
activity and the amount of substrate to be converted
to product must be found. Moreover, the duration
of industrial processes can take one hour (such as
the mashing of malted barley in brewing), three
hours (such as the saccharification of the liquefied
starch with glucoamylase in syrup production), or
about twenty hours (such as the hydrolysis of lactose
by lactase in milk or whey (5). Of course, the enzyme
technology aims to perform quick reactions at a low
cost, albeit respecting the restrictions imposed by the
operational conditions and the scale of the process.

Quantification of the Enzyme Activity

Let us consider the simplest model for an enzyme-
catalyzed reaction: (6)

\[ E+S\overset{E}{\rightarrow}E+P \]

\[ k_1 \ ] \ [ k_2 \ ] \ [ k_3 \ ] \]

Where: \( E \) = enzyme concentration; \( S \) = substrate
concentration; \( ES \) = enzyme-substrate complex
concentration; \( k_1, k_3 \) = 1st order reaction rate
constants (t\(^{-1}\)); \( P \) = product concentration; \( k_2 \) = 2nd
reaction rate constant (M\(^{-1}\).t\(^{-1}\)). At first, it must be
stressed that the formation of \( ES \) (enzyme-substrate
complex) is an obligatory step to any type of enzyme-
catalyzed reaction. The \( ES \), depending on the reaction
conditions, can form the product (forward reaction)
or not (reward reaction). An enzymatic reaction can
be divided in three phases (Figure 1). During phase I
(reaction onset), there is the accumulation of the
enzyme-substrate complex (ES) without product
formation and significant substrate consumption.
The existence of the ES was predicted by Brown in 1892,
reinforced by Henry in 1902 and experimentally
demonstrated in 1936 (3). The presumption of
ESexistence allowed Michaelis and Menten (1913) to
postulate the first mathematical model for quantifying
enzyme activity. Briggs and Haldane improved it in
1926. Phase II begins as soon as the ES concentration
reaches a maximum value, remaining invariable for
a period. The duration of the steady stateregarding
the ES concentration depends on the relative concentrations between the enzyme and the substrate. Along phase II, the substrate is consumed and the product accumulates in the reaction medium. Along the phase III—when the ES concentration is no longer constant—the substrate consumption and product formation occur slowly. The quantification of the enzyme activity considers the conditions observed in phases II and III.

![Figure 1: Variation of enzyme (E), substrate (S), product (P) and enzyme-substrate complex (ES) concentrations in relation to reaction time](image)

The starting point for establishing the enzyme kinetic equation is the determination of the variation in the initial concentration of substrate in relation to the reaction time at a fixed amount of enzyme (E0). This is made by measuring the amount of substrate consumed along the period, followed by plotting the data in a \( S = f(t) \) graph (Figure 2). The inclination of the linear part of each curve related to a determined initial substrate concentration \( S_1, S_2, S_3, \ldots, S_n \) represents the initial reaction rate of the enzymatic reaction \( v_1, v_2, v_3, \ldots, v_n \). By plotting \( v \) versus \( S \), the result is a hyperbola, whose curvature tends asymptotically to a maximum \( v \) (Vmax), i.e., the reaction rate becomes invariable in relation to the substrate concentration (Figure 3). Under controlled reaction conditions, the Vmax becomes a kinetic constant, which describes the enzyme catalysis quantitatively. The phenomenon of saturation is seldom observed in non-enzymatic reactions. The asymptotic zone of the hyperbola would correspond to the condition in which the amount of substrate is enough to saturate the enzyme molecules present into the reaction medium completely, i.e., the ES concentration into the reaction medium is constant.
Figure 2: Variation of the substrate concentration versus time. The initial enzyme concentration ($E_0$) was constant. At the interval $T$, the substrate consumption varies linearly with time, i.e., the reaction rate is constant. Therefore, the initial substrate concentration ($S_1, S_2, \ldots, S_n$) was enough to saturate all the enzyme ($E_0$).

Figure 3: Reaction rate ($v$) versus initial substrate concentration. At the substrate concentration over $S_2$, the curve tends to a maximum value of reaction rate ($V_{\text{max}}$), which indicates that all enzyme ($E_0$) is saturated with substrate.
Considering \((ES \to E + P)\) as the limiting step of the overall reaction, then

\[
(-dS/dt) = v = k3.(ES) \quad (1)
\]

However, remembering that at any time along the reaction, the whole enzyme is distributed as

\[E0 = (E) + (ES) \quad (2)\]

Where \(E0\) = total amount of enzyme in the reaction medium; \(E\) = amount of enzyme not bound to the enzyme-substrate complex \((ES)\).

When all enzyme molecules are bound to substrate molecules, then \((E) = 0\), and the equation \(2\) becomes

\[E0 = (ES) \quad (3)\]

Replacing \(3\) in \(1\):

\[(-dS/dt) = v = k3.E0 \quad (4)\]

Equation \(4\) leads to the conclusion that when the enzyme is saturated with substrate, the reaction follows \(^{(4)}\) a “pseudo-zero order” kinetic, i.e., apparently the reaction rate is independent from the substrate concentration. In other words, the reaction rate is directly proportional to the whole enzyme concentration. Under this condition, the \(k3\) is called “turnover number” \((kcat)\), which indicates the number of substrate molecules transformed per unit of time by a single enzyme molecule when the enzyme is the rate-limiting factor\(^{(5)}\). Under the saturation condition, \(kcat.E0\) represents the maximum rate of the reaction catalyzed by the enzyme \((Vmax)\). Therefore,

\[
(-dS/dt) = v = Vmax \quad (5)
\]

Integrating Eq. \(5\):

\[
(S) = (S0) - Vmax.t \quad (6)
\]

Therefore, when the enzyme is saturated by the substrate, the substrate consumption decreases linearly along the period, i.e., the reaction occurs at a constant and maximum rate\(^{(6)}\).

Figure 3 – at low substrate concentration \((0 \to S1)\) clearly shows that \(v\) varies linearly in relation to \(S\), or in algebraic terms:

\[
(-dS/dt) = v = k'.(S) \quad (7)
\]

Where \(k'\) is a 1st order rate constant.

Integrating Eq. \(7\):

\[
LnS = LnS0 - k'.t \quad (8)
\]

Therefore, Eq. \(8\) shows that the substrate concentration decreases exponentially with time, when the reaction becomes under unsaturated and substrate concentration decreases \(^{(7)}\).

Along phase II, the \((ES)\) remains invariant for a time interval (Figure1). This means that

\[
d(ES)/dt = 0 \quad (9)
\]

Consequently,

\[
k1.(E).(S) = k2.(ES) + k3.(ES) \quad (10)
\]

Rearranging Eq. \(10\):

\[
(E) = \frac{KM.(ES)}{(S)} \quad (11)
\]

Where \(KM = (k2 + k3)/k1\).

Replacing Eq. \(11\) in Eq. \(2\) [this is valid insofar as the conditions under which the reaction is carried out preserve the full enzyme catalytic activity]:

\[
(ES) = \{[(S).E0] / [(S) + KM]\} \quad (12)
\]

Replacing Eq. \(12\) in Eq. \(1\):

\[
v = Vmax.(S)/[(S) + KM] \quad (13)
\]

Eq. \(13\) describes completely the hyperbolic curve shown in Figure 3. The terms \(Vmax\) and \(KM\) – the so called kinetic constants – characterize an enzyme\(^{(8)}\), when the catalysis is carried out under defined conditions (pH, temperature, agitation etc.). These constants are often calculated by the Eq. \(14\):

\[
1/v = (1/Vmax) + (1/S).(KM/Vmax) \quad (14)
\]

Equation \(14\) represents a straight line from
which the kinetic constants are calculated.

Regarding KM, three aspects must be stressed: 1) from Eq. (13), when KM = (S), then v = 0.5Vmax; 2) it is considered a referential for setting the operational substrate concentration. When (S) is at least 100 times lower than KM, the reaction occurs in an unsaturated substrate concentration, whereas when (S) is at least 100 times higher than KM, the reaction occurs in substrate saturation; 3) it is considered a characteristic of an enzyme when the catalysis occurs under defined conditions(9).

Along phase III, the (ES) is not constant, but the substrate continues to be transformed into product, although at a lower rate (Figure 1). To evaluate this phase, Eq. (13) must be integrated, resulting in

\[ t = \left[ (S_0 - S) - KM \cdot \ln\left(\frac{S}{S_0}\right) \right] \frac{V_{max}}{V_{max}} \ (15) \]

Defining substrate conversion (Y) as:

\[ Y = \frac{(S_0 - S)}{S_0} \ (16) \]

Replacing Eq. 16 in Eq. 15:

\[ t = \left[ Y \cdot S_0 - KM \cdot \ln \left(1 - Y\right) \right] \frac{V_{max}}{V_{max}} \ (17) \]

The practical aspect of Eq. (17) is that the duration of the reaction can be estimated from a desired substrate conversion.

**Expression of the Enzyme Activity**

The enzyme activity can be expressed by several manners. For example, the hydrolysis of sucrose by invertase is expressed as total-reducing sugars formed per minute, the collagen hydrolysis by collagenase is expressed as the viscosity diminution of a standard collagen solution per minute, and the amylase activity expressed as a SKB unit(10),(11),(12). However, it is recommended to express the enzyme activity using International Unit (U), which is defined as the amount of enzyme that catalyzes the formation of 1 mole of product per minute in fixed conditions. The specific activity is defined as U/mg protein (if the enzyme preparation is impure), or U/mol enzyme (for pure enzymes) (15).

**Funding:** The authors received no financial support for the research, authorship, and/or publication of this article.

**Conflict of Interest** there has been no conflict of interest of any kind with the authors of this work

**Ethical standard:** The study was formally approved the research plan by the ethical committee board at the Babylon health directorate.

Frequency and Determinants of Neurological Symptoms of COVID-19 Patients

Mohammed Radhi Radeef, Fatimah Mustafa Mohammed Alattraqchi, Ahmed Abbas Shlaka, Shaymaa Abdul Lateef Alfadhul

1Lecturer, Department of Neuro Medicine, Faculty of Medicine, University of Kufa, Iraq. 2Doctor, Department of Community and Family Medicine, Ministry of Health, Iraq. 3Doctor, Al Najaf Health Directorate, Ministry of Health, Iraq. 4Assistant Professor, Department of Family and Community Medicine, Faculty of Medicine, University of Kufa, Iraq

Abstract

Objective: To determine the frequency, type, and associated determinants of neurological symptoms among COVID-19 patients.

Methods: A cross-sectional study was conducted among 161 doctors from different Iraqi cities using online questionnaires. They were provided information about their documented case. Data were collected from the 1st to 30th of October 2020. The questionnaire consists of 2 parts, first part concerns sociodemographic data of patients (age, gender, and severity of COVID-19 infection), while the second part deals with details of COVID-19 neurological symptoms. Data were stored and analyzed using SPSS version 24.

Results: A total of 161 COVID-19 cases were described in this study. Headache was found in 120 patients (74.5%); loss of smell in 108 patients (67.1%); and loss of taste in 86 patients (53.4%). It was found that ataxia more predominant in females (34.0%) than males (17.9%), statistically, there was a significant difference (P=0.024). Sever COVID-19 disease showed a significantly higher presentation of vertigo, hearing loss, loss of smell, disturbance of level of consciousness, sensory symptoms, motor symptoms, and stroke (p<0.05). Statistical analysis showed a significantly higher presentation of disturbance in level of consciousness, and stroke symptoms in patients older than 40 years (P<0.05).

Conclusion: Different neurological presentations are reported from COVID-19 cases. Headache, loss of smell, and taste are the most frequent symptoms. Some neurological manifestations are found more predominant in females, older age, and severe cases.

Keywords: SARS-CoV2 · COVID-19, neurological symptoms.

Introduction

Coronavirus disease 2019 (COVID-19) is an infectious acute respiratory disease. The first patient was confirmed to have COVID-19 on 1st of March 2020 in Wuhan, China (1).

The pathogen, later on, was identified as severe acute respiratory syndrome coronavirus 2 (SARS-CoV2). Globally, until the 16th of August 2020, there have been 21,260,760 confirmed cases of COVID-19, including 761,018 deaths, reported to WHO [1]. Severe COVID-19 can cause progressive respiratory failure and death. Susceptibility is high among elderly
patients and those with comorbidities, recent surgery, and intrinsically or iatrogenically compromised immunity (2).

Neurological symptoms were reported in 0.04% of SARS and 0.2% of MERS, also, 28.2 million people of COVID-19 cases have neurological symptoms (3).

The most frequent question of neuroscientist is that if a virus direct infects CNS so need treatment with antiviral or virus is cleared from the body then treated with anti-inflammatory therapy, Michael said the is difficult to find the virus in the brain, compared with other organs. The polymerase chain reaction (PCR) often do not detect it there, despite their high sensitivity, and other studies have failed to find any virus particles in the cerebrospinal fluid, this is maybe due to that the ACE2 receptor, a protein on human cells that the viruses use to gain entry, is not much found in brain cells (3).

Coronaviruses may cause Central nervous system manifestations (Headache, dizziness, consciousness disorder, acute brain disease, seizures, and ataxia) (4), and peripheral nervous system symptoms (loss of smell, loss of taste, visual impairment, and nerve pain) (5).

Coronaviruses are thought to cause neurological manifestation either directly through neuroinvasive capacity (ACE2 receptors on neuronal tissues) or indirectly through the response of the immune system (an inflammatory mechanism). Also both SARS-CoV-2 and COVID-19 have neurological manifestation, so the diagnosis of SARS-CoV-2 infection should be kept in mind when patients presented with neurological symptoms during the pandemic (6).

The current study aimed to determine the types, and frequency of neurologic manifestations of COVID-19 infection, and to find its association with age, gender, and severity of COVID-19 infection.

Methods

An internet-based cross-sectional survey was conducted. The survey was distributed among doctors who deal with covid19 patients. The participants’ doctors were provided with an internet link to the survey created with the Google Forms application. After opening the invitation link, the respondent needs to agree to participate in research, before answering the questions. The data were collected from the 1st to 30th of October 2020. The questionnaire consists of 2 parts, of which part 1 concerns sociodemographic data (age, gender, and severity of COVID-19 infection). Part 2 deals with COVID-19 neurological symptoms. Data were analyzed using SPSS version 24, Mean and standard deviations were used for numerical variables, while frequency and percentages were used for categorical variables. A Chi-square test was used to test the significance of the association between variables.

Results

A total of 161 COVID-19 cases were described in this study. More than half of cases (94, 58.4%) are females. Their mean age (standard deviation) is 38(14.8) years. The higher number of cases (71, 44.1%) are in the age group 18-29 years, followed by (42, 26.1%) in the age group 30-39 years. According to COVID-19 Severity, 116 (72 %) patients had a mild infection, 37 (23%) had a moderate infection, the rest had a severe infection, table1.

Considering neurological symptoms, the headache was found in 120 patients (74.5%); loss of smell in 108 patients (67.1%); and loss of taste in 86 patients (53.4%). Other symptoms like generalized weakness, vertigo, unsteadiness, and drowsiness were reported from (54.2%), (28.6%), (27.3%), and (34.2%) of patients, respectively, table1.

Table 2 described the gender differences in neurological symptoms. It was found that ataxia more predominant in females (34.0%) than males (17.9%), statistically there is a significant difference(P=0.024).
Meanwhile, loss of taste sensation is more in females than males (74.5% vs 23.9%), statistical analysis shows a highly significant difference (P = 0.001).

Considering association of severity with presence of neurological symptoms, current results showed significantly higher percentages of neurological manifestation including vertigo, hearing loss, loss of smell, disturbance of level of consciousness, sensory symptoms, motor symptoms, and stroke in severe COVID19 disease (P < 0.05), table (3).

Table 4 demonstrated variation of neurological symptoms according to age groups, disturbance of level of consciousness is significantly higher in older (≥40 years) than younger age group (<40 years) (P = 0.009), also, four patients (12.9%) of older age recorded stroke symptoms in comparison to only two (1.5%) of younger age group. Statistical analysis shows a highly significant difference (P = 0.003).

Discussion

Recent evidence suggests that COVID-19 patients commonly had neurological symptoms manifested as acute stroke (6%), consciousness impairment (15%), and skeletal muscle injury (19%) (5). Therefore, the current study conducted to demonstrate the types, and frequencies of neurological manifestations in COVID-19 patients through online reports of physicians dealing with laboratory documented COVID-19 cases.

In this study, different neurological symptoms were reported by participants, the highest frequencies were headache (74.5%), loss of smell (67.1%); and loss of taste (53.4%). The cause of headache in COVID-19 could be explained by trigeminal vascular activation, in addition to systemic inflammation (increased cytokines) that is caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) binding to ACE2 on trigeminal nerve endings within the nasal cavity. This is also most likely the cause of the loss of the sense of taste and smell (7).

Consistent with other findings (7,8) muscle symptoms like generalized weakness were highly reported in this study. These symptoms could be explained by muscle injury caused by SARS-CoV2 as recognized by high creatine kinase levels (7). Other symptoms like vertigo, unsteadiness, and drowsiness were reported in more than a quarter of cases. These presentations could be due to viral vestibular neuritis or due to damage to nerve tissue from hypoxia or hypercoagulopathy. A review of 14 studies that investigated dizziness as a symptom in COVID-19 cases reported dizziness in 4 to 30 percent of patients which was similar to the present finding (9).

Regarding gender differences in the presence of neurological symptoms, this study found that females reported ataxia and loss of taste sensation significantly higher than males(P<0.05). Females are more significantly affected by gustatory dysfunction (10). The higher susceptibility of females to develop gustatory dysfunctions could be attributed to the gender-related differences in the inflammatory reaction process (11).

Similar to previous findings (5), severe cases of COVID-19 infection were more likely to develop neurologic manifestations including vertigo, hearing loss, loss of smell, disturbance of level of consciousness, sensory symptoms, motor symptoms, and stroke. Therefore, close attention should be taken to the neurologic manifestations of COVID-19 patients, especially for those with severe infections, which may have contributed to their death. Also, during the epidemic period of COVID-19, physicians should consider SARS-CoV-2 infection as a differential diagnosis when seeing patients with these neurologic manifestations, to avoid misdiagnosis or delayed diagnosis.

In this study, disturbance of level of consciousness and stroke symptoms are significantly higher in older (≥40 years) than younger age group (<40 years). Whereas other neurological symptoms are not significantly differed between the two age groups. A previous study conducted in Tunisia among patients with COVID19 reported no significant differences in neurological manifestation according to age groups (12). Acute stroke is a commonly reported neurologic complication of COVID-19, particularly in the elderly population (13,14). Researchers have reported increasing trends of double-positive ACE2+TMPRSS2+ cell proportions with increasing age which could be a factor for disease severity in the elderly. These receptors had been found in tissues beyond the respiratory system, including oligodendrocytes in the brain. Additionally, neurologic autoimmunity had been suggested as a cofactor through the invasion of ACE2+TMPRSS2+ cells in organs such as the lungs and gut (15).

A limitation of this study is that all data were obtained through an online survey of physicians depending on their recall for cases, hence additional associated risk factors cannot ascertain. Besides, laboratory data and imaging studies were not available for comparison with the current results. However, this
is one of the earlier studies that focus on neurological manifestations in COVID-19, and documented reports of the physicians were dependent.

**Conclusion**

Different neurological symptoms have been reported from patients with COVID-19 infection. The most frequent neurological symptoms are headache followed by loss of smell and loss of taste. Some neurological manifestations are found more frequent in females, older age, and severe cases.

Abstract

Background: Dental Health Education in teachers has prominently invested the knowledge about various aspects of paediatric dentistry. Oral health theories and implementations can be augmented and reinforced by teachers who can work allied with dental professionals thereby bringing noteworthy improvement in oral health status of children. Therefore it is analytical to ascertain knowledge and positive attitude towards various aspects of paediatric dentistry of primary school teachers who are a primary care giver and mentor to children.

Material and Methods: The interventional study was outlined by two stage cluster sample. A total of four thirty seven primary school teachers took part in the research where the data was first collected by a close ended questionnaire. Re-evaluation was conducted after the education intervention and the results were statistically examined.

Results: Pre tests revealed that only 52% primary school teachers had sufficient knowledge and positive attitude towards various aspects of paediatric dentistry. After the education intervention, post tests revealed 75.5% primary school teacher’s good knowledge and positive attitude towards various aspects of paediatric dentistry which was appreciated. It was found statistically significance after post intervention with p<0.05.

Conclusion: The study observes that there is a notable innocence and knowledge gap concerning the knowledge about oral health and various aspects of paediatric dentistry that a primary school teacher holds and this has accentuated more the requirement of education intervention among primary school teachers to bring out better oral health status in children.

Keywords- Attitude, Primary school teachers, Knowledge, Education intervention, Dental Health Education.

Introduction

Dental Health Education in teachers has prominently invested the knowledge about various aspects of paediatric dentistry. Oral health theories and implementations can be augmented and reinforced by teachers who can work allied with dental professionals thereby bringing noteworthy improvement in oral health status of children. Therefore it is analytical to ascertain knowledge and positive attitude towards various aspects of paediatric dentistry of primary school teachers who are a primary care giver and mentor to children.
Teacher’s awareness about dental trauma, fluoride application and elimination of dental decay, their point of view and blockade of execution of Dental Health Education programmes can be assessed through surveys. Inadequate training and productions and time within the syllabus were pinpointed as major roadblock to application of a Dental Health Education programme in primary school. Expanding teacher’s training programme that inserts oral health knowledge and evidence based proposal to Dental Health Education within the academic world could authorize primary school teachers to play a remarkable role in oral health encouragement for children in Trinidad. [4]

Inspirational method using ‘the smiling robot’, through demonstration, exhibition and macro models have reduced the risk in dental decal and plaque accumulation. [5] A teacher should be instructed broadly concerning the consciousness of oral health advancement and significance of oral health for their students in amalgamation with health care assistants. [6]

Oral health standard results from degree of information available, attitude, routine and subsistence. [7] Origin of details about oral can be acquired through dental office (82%) accompanied by books and magazines (74%). When grading the ten methods of averting dental caries in children, teacher did methods such as fluoridated water and pit and fissure sealants lower than making methodical dental visits and lessening the ingestion of sugared foods. [8]

Despite of immense possible work force resources and growing economy, India stand behind in expression of education, quality of livelihood and peculiarly health even though there are different plan of action of National oral health programme that are used in up skilling the teachers, children and health care workers about oral health. [9]

There are numerous researches revealing about poor knowledge teachers have in dental education in western countries. [10] In numerous formerly school educational programmes have seemed to fail to bring any transition in children’s behaviour quantifiable improvement in oral hygiene. [11]

Few studies have been carried out to demonstrate the impact and effectiveness of school based Dental Health Education programmes in India and to evaluate the efficacy and feasibility of using primary school teachers for imparting Dental Health Education to school children. Thus, we intend to access the improvement in knowledge and attitude of primary school teacher’s towards various aspects of paediatric dentistry after education intervention.

Need of the Study

In today’s scenario, ideas of prevention, maintenance and awareness of dental health education have become topmost rime concern as per suggestions attained. In this study, three education intervention in the form of power point presentation, play act and exhibition will be used to improve the overall knowledge and attitude of primary school teacher’s towards various aspects of paediatric dentistry.

Aim:

To evaluate and compare the improvement in knowledge and attitude of primary school teacher’s towards various aspects of paediatric dentistry after education intervention.

Objectives:

1. To evaluate the knowledge and attitude of primary school teacher’s towards various aspects of paediatric dentistry before education intervention.

2. To evaluate the improvement in knowledge and attitude of primary school teacher’s towards various aspects of paediatric dentistry after education intervention.

3. To compare the knowledge and attitude of primary school teacher’s towards various aspects of paediatric dentistry with education intervention.
Material and Methods:

This was an interventional study conducted among 437 primary school teachers in Karad city, Maharashtra, India. The range of subject were selected by two stage cluster sampling. Two out four sector were selected in first stage. All the schools were then drafted out from the selected sector. This was used as a sampling figure in which 20% of school in the sector was selected using random sampling tactic. The teachers who teach age groups of 8 to 14 years in the selected school agreed to participate in the study after written consent were inserted.

The collection of data was done by a single trained investigator to avoid inter examiner changes. Firstly, a close ended questionnaire and survey per forma was handed over to the primary school teachers to collect the knowledge on attitude towards deciduous teeth problems and its importance, necessity of pulpectomy, dental caries and diet correlation, dental and mental health correlation, awareness about paediatric dentistry, oral habits and jaw growth correlation, attitude towards child first dental visit, fluoride treatment and dental caries correlation, dental health and overall development correlation and need of awareness programme for paediatric dentistry.

The primary school teachers were then given education intervention through power point presentation, play act and exhibition concerning various aspects of paediatric dentistry. The data is collected again after the education intervention for post interventional analysis.

To compare the knowledge and attitude of primary school teachers towards various aspects of paediatric dentistry after education intervention,

Ethical Consideration- This is an interventional study conducted after due approval from ethical committee (protocol number)

Statistical Analysis: First the data was transformed into MS-Excel. Frequency and Percentage was done by using MS-Excel itself. Comparison of knowledge, attitude in pre and post test score was done by using Paired t-test. It was found significant when p<0.05. The SPSS (Statistical Packages for Social Sciences) 20.0 was used to do analysis for Paired t-test.

Result

The demographic characteristics of all 437 teachers who participated in the study are primary school teachers from Karad, For getting this 437 primary school teachers we found to be Out of the 21 schools in each group, 15 (71.4%) from the Marathi medium and 6 (28.6%) from the English medium responded. Out of 437 school teachers 298 (68.1%) were males, 139 (31.8%) were females. The average age of school teachers were 43±6.7 years.

Table 1 shows the knowledge and attitude of teachers prior to the educational intervention, and also compares it after the educational intervention as a post-test response. The understanding was consistently lacking in almost all questions prior to the invasion. The level of correct answer varied from 18.54 to 89.93%. In contrast, the attitude was seen to be more positive, and most teachers wanted to learn proper management skill for handling the dental paediatric intensity. Significant differences were found in knowledge and attitude score concerning
teachers work experience and gender (p < 0.05). After the health education, significant improvement was observed in knowledge about the correct management of dental injuries. The level of correct answers increased significantly which varied from 62 to 87%. Improvement in positive attitude was also seen in teachers after receiving the intervention.

Table 2 shows that comparison of knowledge and attitude Score by transforming responses of 437 of primary school teachers towards various aspects of paediatric dentistry it was found that mean score of before intervention was 225.21±94.76 and after intervention the mean score was 330.64±30.33. We had used the paired t-test for comparison and found statistically significant with p<0.05.

**Discussion**

In today’s framework or storyline, schools are in necessity of having perfect acknowledgement about maintenance, application and importance of oral hygiene. Most of the oral hygiene practice do come from home but since a child spends most of the time in school, it has been a prime prerequisite for their teacher to have knowledge about paediatric dentistry and its various aspects. A teacher can strongly create an impact about oral hygiene practice, various treatment in emergency situation like dental trauma, diet and dental caries correlation to children in order to bring a good oral health standard in them. So, it is important to educate the teachers in today’s academic setting about various aspects of paediatric dentistry to ensure a better outcome of the clinical treatment.

There are many researches and studies done to evaluate the knowledge and attitude of school teachers about dental education. However, numerous researches done in Zanzibar12, Trabzon13, Saudi Arabia 14-15 and Nigeria16 has shown the lack of knowledge and poor attitude of teacher’s towards dental education and its benefits. Various researches from different part of India in Davengiri6, Mumbai17 and Manglore18 have also concluded similar results regarding school teacher’s knowledge and attitude regarding the same. In the present study too we have observed the insufficiency of knowledge in primary school teachers about various aspects of paediatric dentistry, importance of oral health and its importance was indistinguishable to the national and international data.

In the first section of the questionnaire for the study was about attitude towards deciduous dentition problems dental trauma, dental caries and gingival infection. A study done in Pondicherry by Vidya Shekhar et al19 has revealed that 47% of school teachers were aware the reason of dental caries due bacteria and high intake of sugar and 42% of school teachers were aware of the reason of plaque and
calculus accumulation causing gingival diseases. Similarly, studies conducted by Ehizele et al\textsuperscript{15}, Amjad H Wyne et al\textsuperscript{13}, Khalid Almar et al\textsuperscript{14} has revealed that 60\%, 97.4\% d and 80\% of male school teachers and 90\% female school teachers knew that the reason for dental care was due to intake of sugar, poor oral hygiene and wrong brushing technique respectively. In the present study, only 63.39\% primary school teachers knew about deciduous dentition problems prior to the education intervention which was observed that there is increase of 78.72\% in post-test after the education intervention.

In the second section of the questionnaire for the study was about the importance of deciduous dentition. In the present study, 68.42\% primary school teachers do have knowledge about the importance of deciduous dentition compared to the study done by Ankita Mota et al\textsuperscript{17} where the results showed that 53.2\% of primary school teachers knew about deciduous dentition. In the third section of the questionnaire for the study was about the dental trauma and its management which included the knowledge about management of avulsion and fractured tooth. In the present study, the results revealed that primary school teacher had prior knowledge about dental trauma management. These results were compared with studies by Neha Nashine et al\textsuperscript{9} where 26.6\% of school teachers had knowledge on management of fractured tooth and 3.2\% on management of avulsed tooth. Management of avulsed tooth and their storage are not widely believed due to the common acceptance that they are not restorable.

Fourth section of the questionnaire was about the knowledge on dental visit of the child. In the present study, 41.19\% were aware about the importance of regular dental visit for maintenance of oral hygiene during the pre-test and was increased to 77.35\%. Studies by Vidya Sekhar et al\textsuperscript{19}, Amjad H Wyne et al\textsuperscript{13} and Ezgi Baltari et al\textsuperscript{12} has revealed 32\%, 100\% and 83\% responses respectively about the need of regular dental visit of children. In the fifth section of questionnaire, general knowledge on fluorides were asked and it was shown in the present study that primary school teachers had 23.11\% knowledge prior to the education intervention which was increased afterwards to 73\%. Similarly, a Trabzon based study by Ezgi Baltari et al\textsuperscript{12} obtained 65.8\% knowledge on pre-school teachers on the same subject.

It was clearly seen in the present study a knowledge gap in all five sections of questionnaire which suggested the innate importance to recognize the education on oral health and various aspects of paediatric dentistry and the implementation of the same to the children to bring out more significant oral health status.

The last section of questionnaire for the study was featured on the need of awareness programme for paediatric dentistry where the present study shows that many primary school teachers had prior knowledge and positive attitude of various Dental Health Education programmes and their importance in the curriculum before education intervention. Present study emphasised 89.93\% of primary school teachers are having knowledge and positive attitude about need of awareness programmes for paediatric dentistry. All teachers participated in the study with variable job experience had similar attitude towards the subject which gave no statistical difference compared to their job experience. The primary school teachers participated in the study also felt the need for informing the parent about the oral health of their children. A study done in Mumbai by Ankita Mota et al\textsuperscript{17} has specified that 78.9\% of primary school teachers were unaware about the school water fluoridation programme and 54.8\% of primary school teachers had never discussed about the oral health of the children to their parents during the parent’s meet. Whereas, a study done in Trabzon by Ezgi Baltari et al\textsuperscript{12} has revealed that 35.1\% of pre-school teachers has appositive attitude on taking up activities and programmes in educating the children. In another study of Jaya Naidu et al\textsuperscript{20} have also exhibited about how different Dental Health Educational programmes has as impact on schoolchildren on a regular basis.
To observe the effect of education intervention on primary school teachers, power point presentations, play act and exhibition was conducted which drastically improved the knowledge and attitude of primary school teachers towards various aspects of paediatric dentistry. There has not been an Indian study according to our knowledge which emphasis the- bring about of education intervention with pre and post-test scheme that had a significant effect of educating the primary school teachers. A similar study done in Dubai by Al Sari S et al\textsuperscript{21} has shown that knowledge attained by physical education teachers and school nurses had increased after the education intervention and improvement was seen in pre-test (26%) and post-test(95%). In the present study, there is improvement in knowledge and attitude of primary school teachers in some questions 18.54% to 70.94% substantial increase was noted. The use education intervention by the mode of power point presentation, play act and exhibitions has been first study in India where there was significant difference shown in knowledge and positive attitude attained in post-test compared to pre-test. This study pointed more on the importance of educating primary school teachers about various aspect of paediatric dentistry so that it helps in inculcating more knowledge about the same and imparting the knowledge to children. However, power point presentation, play act and exhibitions was agreeable for the presenter in presenting the study and the importance oral health education to primary school teachers.

**Conclusion**

In today’s academic setup, it is elementary need for the primary school teacher to be educated in oral hygiene, dental health programmes and awareness of the same. In the present study, it calls attention for the importance of dental education. There is a big necessity of more studies, education intervention and implementation of these in both urban and rural arts of India. Through the present study, it is understood that more dental health programmes should be enhanced in the current curriculum of teacher’s in order to improvise healthy status and good oral practices in children.

However, parents and primary school teachers should be given more opportunities and privileges to attend more oral health education programmes and to work more associated with health care professionals. Having a positive overview about conservation, prevention of tooth related diseases by giving a healthier environment of understanding the importance of dental education, reinforcing the importance of dentition and topmost guidance given to children would bring a better outcome of oral health in society.

Abstract

Background. To determine the effect of soaking red betel leaves against the hardness of nanofiller composite resins. Materials and Methods. The research applied True Experimental Laboratory method with one group pretest posttest. The 18 samples of nanofiller composite resin were obtained through purposive sampling. The samples were light cured then soaked in red betel leaf solution for 28 minutes. Then, the hardness measurements were performed using VickerHardness Tester. Results. The results of paired sample t-test indicated the effect of soaking red betel leaf (p 0.002 <0.05) and sterile aquadest (p 0.026 <0.05) on the surface hardness of nanofiller composite resin. Conclusion. The effect of soaking red betel leaves on the surface hardness of nanofiller composite resin was obtained.

Keywords: Nanofiller Composites, Composite Surface Hardness, Red betel leaves

Introduction

In dentistry, the term composite resin refers to polymer systems in hard tissues such as enamel and dentin. Where composites are also commonly used to improve dental and aesthetic contours.¹ Initially the composite consisted of two components and used chemical polymerization for anterior dental lifts. Since then composites have developed rapidly, mainly to improve their clinical performance.² Composite resins are mixtures of two or more different materials with superior or better properties than each material itself.³ This composite resin consists of four main components, namely the organic polymer matrix, inorganic filler particles, coupling agent, and the initiator-accelerator system. [⁴] Particle filler nanosized causes more even distribution of particles, so the particle content of fillers increases followed by reduced polymerization shrinkage and increased mechanical properties of the material. [⁵]

The filler component in nanofiller composite resins Contains a unique combination of individual nanoparticles and nanocluster. Nanoparticles are separate, non-grouped particles that are 20 nanometers in size. A nanocluster consists of nano-sized particles that easily bond to form groups of particles. This group of particles acts as a single unit that allows high filler loading and strength in this composite.⁶ Absorption of fluids in the oral cavity can affect color stability and durability of composite resin. This composite resin

Corresponding author:  
email: arimasriadi@gmail.com  
Adress: Jl. Abd. Dg. Sirua No. 155B Makassar, Indonesia
undergoes a color change that is associated with the level of water absorption and hydrophilicity of the resin matrix. [6] Color change in composite resin is caused by two factors, namely internal factors and external factors. Color changes caused by external factors are caused by liquids or color carriers surrounding the composite resin restoration environment. [6]

In Indonesia various types of plants have been widely used as traditional medicine, one of which is betel plants, various types of betel plants have been found in Indonesia, but in Central Sulawesi there are only two types of betel plants, namely green betel and red betel. [7] Betel leaf is a plant that has been widely used as medicine. There are several types of betel leaves which are distinguished based on the shape of the leaves, taste and aroma, namely green betel, betel betel, betel betel, black betel, and red betel. These alkaloids function as antibacterial. [8] where people have long used red betel leaf as a toothache medicine, mouth ulcer medication and eliminate bad breath, as a mouthwash and also has antioxidant and antiseptic properties. [9]

According to Handayani et al, in 2016 in his study said that the acidity of the pH of red betel leaf decoction water was around 6 and would experience the release of small amounts of H+ and would break the siloxane bond in addition to the presence of phenol content in the red betel leaf decoction water could also reduce the hardness of composite resin. Composite resins soaked in red betel leaf (Piper crocatum) and sterile aquadest are caused by the acidity (PH), where the red betel leaf (Piper crocatum) is classified as more acidic than sterile aquadest resulting in a decrease in the hardness of the composite resin. [10] Where the red betel leaf (Piper Crocatum) contains poly phenols which can reduce the hardness of nanofiller composite resins. Polymers in composite resins contain unstable bonds, so they can be easily degraded by acids or low pH. [11]

### Materials and Methods

This research is an experimental laboratory with the design of The One Group Pratt Posttest. The sampling technique used was purposive sampling. The samples used were 18 pieces which were divided into 2 groups, namely soaking red betel leaves and sterile distilled water. criteria for sterile aquadest immersion. Inclusion criteria for fine nanofiller composite resin surface. While the exclusion criteria were box-shaped nanofiller composite resin, red betel leaf.

Preparation of nanofiller composite resins prepare 18 nanofiller composite resin specimens, by layer-by-layer inframental technique. where the composite resin is applied in the straw, where the straw is 6 mm high, and the straw diameter is 4 mm. then applied in a straw about 2 mm in diameter. then illuminated light cure for 40 seconds. Then the composite was reapplied about 2 mm in diameter and then reapplied again up to 6 mm, and exposed to light cure for 40 seconds until it was finished, and put it into a plastic drug in each sample.

Measurement of sample hardness before treatment, Measure the surface hardness of nanofiller composite resins by using a microhardness tester to determine the surface hardness value of nanofiller composite resins before being treated with Sample Treatment. In group 1 9 samples were soaked with red betel leaf decoction and in the control group were group II using 9 samples which were immersed using sterile aquadest. The treatment process takes 28 minutes then the sample is carefully removed using tweezers in an immersion container. Measurement of composite hardness after treatment. The analysis used is the Paired Sample T-test.

### Results

This research was conducted with two times the data collection, namely before and after immersion (The one group pretest post test design and control group design), to see the effect of soaking the red betel leaf (Piper crocatum) on the hardness of nanofiller composite resins. The researchers’ results are shown in the following table.
Table 1 Average hardness of nanofiller composite resins in a solution of red betel leaf (piper crocatum) at Makassar Laboratory of Work Training Center

Table 2 explains that the hardness values of nanofiller composite resins were measured before and after immersion for 28 minutes in a sterile Aquadest (control group) in each of the 9 samples. The average value before immersion was 91.02 kg/mm² while the average value after immersion in a sterile Aquadest decreased the average hardness value of nanofiller composite resin is 73.45 kg/mm².

Table 3 explains that the results of the Paired Sample t-test on the reduction in the hardness value of nanofiller composite resins based on immersion of nanofiller composite resins in a solution of red betel leaf (Piper crocatum) and sterile Aquadest (control group) at Makassar vocational training center in 2018. Paired test results t-test sample showed p of 0.002 (p <0.05) and on the immersion of red betel leaf decoction (Piper crocatum), and p value of 0.026 (p <0.05) sterile aquadest (control group) meant that there was an influence significant between soaking of red betel leaf and Aquadest sterile (control group), based on the value of the reduction in hardness of nanofiller composite resins before and after immersion in the test solution. The results obtained showed a decrease in the mean hardness of nanofiller composite resins by soaking the red betel leaf decoction (Piper crocatum) from 9 samples with a mean change of 18.37 kg/mm² with a standard deviation of (± 11.81). The average value of hardness of nanofiller composite resin in sterile aquadest immersion (control group) with a mean change of 17.56 kg/mm² with a standard deviation of (± 19.38). In table 3 shows the value of the effect of soaking the red betel leaf (piper crocatum) which causes a decrease in the surface hardness of the nanofiller composite resin which shows a p value of 0.002 and a sterile aquadest p value of 0.026.

Discussion

Research has been conducted by researchers using the True experimental laboratory method to see the effect of soaking the red betel leaf decoction (Piper crocatum) on the hardness of nanofiller composite resins at the Makassar Work Training Center Laboratory.

Betel leaf is a plant that has been widely used in Indonesia, where the red betel leaf (Piper Crocatum) where the red betel leaf is widely used in the community for a long time has used red betel leaf as a toothache medicine, mouth ulcers and eliminate bad breath, as a mouthwash and also has antioxidant and antiseptic properties based on the shape of the leaves, taste and aroma and there are several kinds of betel leaves, namely red betel leaf (Piper Crocatum) green betel leaf.[12]

Red betel leaf (Piper Crocatum) has phenol content which can reduce the hardness of nanofiller composite resins in this research. Immersion on red betel leaf (Piper crocatum) The decrease in hardness of nanofiller composite resin is caused by red betel leaves containing polyphenols.

Bonding materials have more hydrophilic properties compared to composite resins. This causes
the bonding material to have greater water absorbing properties compared to composite resin. Water absorption will cause plasticization which results in weak mechanical strength of the bonding material. The solubility of composite resin reflects the amount of unreacted monomer (residual monomer) released into water.\textsuperscript{[13]} The phenol hydroxyl group will release and bind to the siloxan bond which results in the breakdown of the Si-O-Si siloxane to Si-OH, but degradation runs very slowly so that the decrease in violence goes very slowly and takes a long time to experience a decrease in violence.\textsuperscript{[14]}

This study is in line with Handayani’s research which states that composite resins immersed in sterile aquadest have smaller surface hardness differences compared to composite resins soaked with red betel leaves (Piper Crocatum), this is due to differences in pH of the acidity of the cooking water Red betel leaf which ranges from 6 and sterile Aquadest around 7. Besides the presence of phenol content in boiled water, red betel leaf can also reduce the hardness of nanofiller composite resin

The nanofiller composite resin is a universal restoration material that is activated by visible-light which is designed for the purposes of restoring anterior and posterior teeth. Nanofiller composite resins have good physical properties, especially in the results of polishing and strength. Nanofiller composite resin restoration material that has a very small filler, so it can improve physical properties and abrasion resistance Polymers in composite resins contain unstable bonds, so they can be easily integrated by acids or low pH. Acid causes degradation of the polymer and filler components which can affect the surface roughness of the composite resin.\textsuperscript{[15]}

Composite resins exposed to acidic solutions will affect surface roughness. This happens due to degradation in the filler component caused by acid particles which will result in a decrease in physical properties and strength of the nanofiller composite resin. Composite resins exposed to acidic solutions will cause surface roughness. This occurs due to degradation in the filler component caused by acid particles which will result in a decrease in physical properties and strength of the nanofiller composite resin.\textsuperscript{[15]}

Based on the research of the red betel leaf immersion (Piper Crocatum) on the hardness of nanofiller composite resin, it was concluded that the red betel leaf can reduce the hardness of the nanofiller composite resin. with a hardness value after immersion with a mean value of 71.43 kg / mm\textsuperscript{2}, because the red betel leaf (Piper Crocatum) has an acidic pH and phenol content which can reduce the hardness of nanofiller composite resin.

The acid has many H\textsuperscript{+} ions which diffuse into the composite resin and bind the negative ions contained in the matrix so that the composite resin becomes damaged and a residual monomer of methylmethacrylate will form. This results in unstable chemical bonds so that the matrix dissolves and breaks down.

This study is in line with research conducted by June, 2017 where red betel leaves contain polyphenols which can reduce the hardness of nanofiller composite resins. Polymers in composite resins contain unstable bonds, so they can be easily integrated by acids or low pH. Acid causes degradation of the polymer and filler components which can affect the surface roughness of the composite resin.\textsuperscript{[16]}

Research has been conducted by researchers using the True experimental laboratory method to see the effect of immersion of sterile aquadest on the hardness of nanofiller composite resins in the Makassar Work Training Center Laboratory in 2018. The number of samples 18 each sample was divided into 2 groups and each group had 2 trials namely pretest and posttest. In the table shows the average level of violence before immersion in sterile aquadest is higher than after immersion. This shows that sterile aquadest can cause a decrease in hardness of nanofiller composite resin.
Water absorption is a physical property of composite resins that can affect the surface hardness of composite resins [17]. A decrease in the surface hardness of the composite resin results in wear and tear on the composite resin. A decrease in the hardness of the composite resin can occur when the polymer material absorbs water then causes hydrolytic breakdown and loss of bond between the resin matrix and the filler. [18,19]

Water absorption by composite resin can also occur because the resin contains Bis-GMA which has several disadvantages including high viscosity, thus requiring the addition of diluent, TEGDMA. This diluting monomer is added to the resin matrix to reduce viscosity and serves to make composite resin easy to apply. The solubility of the Bis-GMA and TEGDMA matrices is greater than UDMA and BisEMA. HEMA in bonding material has a very large solubility due to the low degree of conversion of monomers so that there are many remaining monomers that will dissolve in water. Water absorption and solubility events affect the effectiveness of the composite resin binder and bonding material in the composite resin restoration.

Based on this research, sterile aquadest immersion against hardness of nanofiller composite resins concluded that the hardness value of nanofiller composite resins before immersion had an average of 91.02 kg/mm² and after soaking for 28 minutes in a sterile Aquadest (control group) in 9 samples, the average value after sterile Aquadest immersion, the average hardness of the nanofiller composite resin decreases to 73.45 kg/mm². This shows that sterile Aquadest also has little effect on nanofiller composite resins which occur due to water absorption due to the process of water diffusion into the composite resin. Composite resins and bonding materials that are immersed in water will experience two different mechanisms, namely water absorption and solubility of the material in water. Water absorption between the matrix and the filler will result in a weakening of the bond between the matrix and the filler. Hardness changes in composite resins have the tendency to absorb water. Water absorption processes in the resin matrix and filler material occur simultaneously. Bis-GMA contained in the resin matrix has a hydroxy group (-OH) which is negatively charged on its lat metraki compound, so it is able to attract and absorb water into the composite by diffusion. In the 2013 study of Erlinawati et al. Composite resins containing zinc fillers and barium glass showed easier absorption of water than those containing quartz fillers. nanofil composite resins contain sirconia / silica fillers. Which is easier to absorb water. [20,21]

Research has been conducted by researchers using the True experimental laboratory method to see the effect of soaking red betel leaf on the hardness of nanofiller composite resins in the Makassar Work Training Center Laboratory in 2018. The total sample of 18 was divided into 2 groups, namely the test group and the control group, where the nanofiller composite resin test group was soaked using red betel leaves and the composite resin control group was soaked with sterile aquadest. Each group has 2 trials namely pretest and posttest. Based on the results of research conducted in the group obtained composite resin soaked with a solution of red betel leaf (Piper crocatum) has more influence on the hardness of nanofiller composite resin compared with sterile aquadest, this shows the cause is due to the pH acidity where red betel leaves classified as more acidic in bandigkan with sterile aquadest. As it is known that composite resin material immersed in acidic liquid has a higher solubility and a higher solubility can result in the erosion of the surface of the composite resin. In addition, the phenol content found in red betel leaves can reduce the hardness of nanofiller composite resins.

Concluded in the research conducted in Table 3 shows the value of the effect of soaking the red betel leaf (Piper crocatum) which results in decreased surface hardness of the nanofiller composite resin which shows a p value of 0.002 and a sterile aquadest p value of 0.026 p <0.05 is significant. This research shows that red betel leaf (Piper crocatum) has more effect on reducing the hardness of nanofiller composite
resin than sterile aquadest.

According to Hengtracol et al in 2011, acidic drinks resulted in surface damage and the aesthetic quality of the composite resin soaked in several types of drinks experienced a decrease in hardness. The greatest decrease in hardness is in drinks that contain acid. That immersion of composite material in an isotonic solution that is a drink with acidic ph can cause erosion of the spilled material and can cause degradation of the polymer matrix matrix composite network that does not react due to acidic drinks compared to aquadest. The process of water absorption is influenced by several factors, namely the type of resin sorted from the most soluble in water, namely TEGDMA, Bis-GMA, and UDMA. The filler content also affects the absorption of water in the material, the higher the filler content the less water absorption. Dental fillings or shades from composite resin also affect the water absorption process. [22,23,24]

Conclusion

It was concluded that there was a decrease in the hardness of nanofiller composite resin in the soaking of betel leaf (Piper Crocatum) and in sterile aquadest

Abstract

Background: Ototoxicity is a harmful feature of the cochlea or auditory nerve and sometimes vestibular apparatus. Gentamicin is known to cause irreversible bilateral ototoxicity. Autophagy induction has been proposed as a target for prevention of gentamicin ototoxicity. Aim of the work: to investigate the possible protective effect of autophagy induction by verapamil compared to rapamycin. Methods: This experiment was conducted on 32 male guinea pigs. At the beginning each animal’s hearing status was assessed using auditory brainstem response (ABR) audiometry. Then, they were divided into 4 equal groups: Group 1: control group, Group 2: untreated gentamicin-induced ototoxicity group. Group 3: gentamicin-induced ototoxicity treated concomitantly with rapamycin. Group 4: gentamicin-induced ototoxicity treated concomitantly with verapamil. At the end of the experiment, ABR was repeated then the animals were sacrificed, and blood samples were obtained for assaying of reduced glutathione and malondialdehyde levels. The left cochlea was processed for scanning electron microscope, while the right cochlea was processed for histopathology and LC3-II immunohistochemistry. Results: Verapamil revealed superiority compared to rapamycin proved by significant improvement in ABR, histopathological results, in addition to its antioxidant effect. Conclusion: verapamil could be suggested as a potential therapeutic approach to decrease gentamicin ototoxicity.

Keywords: Autophagy, Gentamicin, Ototoxicity, Rapamycin, Verapamil.

Introduction

The most common sensory condition in humans is hearing loss [1]. Ototoxicity is the functional damage of the inner ear contributing to hearing and/or vestibular function loss. Aminoglycosides, cisplatin, macrolides, loop diuretics are the most common ototoxic drugs [2]. Gentamicin is one of the most frequently used aminoglycosides, but it causes nephrotoxicity and ototoxicity [3]. Gentamicin ototoxicity is frequently bilateral, symmetrical. It affects mainly the basal hair cells of organ of corti. The incidence of aminoglycoside hearing loss is up to 25% [4, 5]. There are multiple mechanisms of aminoglycosides ototoxicity: mutation in mitochondrial DNA [6], oxidative stress [7], phosphoinositide lipids involvement [8], and autophagy has recently been proposed to play a crucial role [9]. There are two pathways for autophagy induction: rapamycin (mTOR)-dependent mammalian target, and mTOR-independent pathway [10]. Rapamycin is established as an autophagy inducer and approved clinically as immunosuppressive drug,
but it has several side effects\textsuperscript{[11, 12]}. Verapamil is a calcium channel blocker that was suggested to be an autophagy inducer through mTOR-independent pathway. Moreover, verapamil might have antioxidant properties\textsuperscript{[13, 14]}, besides having considerable safety profile.

**Materials and Methods**

The study protocol has been approved by the research ethics committee, Quality Assurance Unit, Faculty of medicine, Tanta University, Egypt (Approval no. #32511/08/18).

**Drugs and chemicals**

Gentamicin sulphate (80 mg /2ml ampoule; Memphis Co. for Pharm. & Chem. Ind. Egypt). Rapamycin (1 mg tablet; a product of Wyeth Medica Ireland. United Kingdom). Verapamil hydrochloride (240mg Sustained-Release tablet; a product of Kahira Pharmaceuticals & Chemical Industries Co). Ketamine (50 mg/ml solution; Rotexmedica GmbH, Germany). Xylazine (100 mg/ml vial; BIMEDA Company).

**Animals and study design**

32 male guinea pigs (350-500 gm) were allowed one week of acclimatization and unrestricted access to food and water was provided \textit{ad libitum}. At the start of the research and after its completion, each guinea pig’s auditory brainstem response audiometry (ABR) was assessed under anesthesia. Only guinea pigs with normal ABR were included and divided randomly into four equal groups (n = 8 for each) where group 1; served as control group, received vehicle of 0.5% CMC orally by gastric gavage daily. Ototoxicity was induced in the other three groups using gentamicin by intraperitoneal (ip) injection at a dosage of 120 mg/kg/day\textsuperscript{[15]} where group 2; served as untreated gentamicin ototoxicity group, group 3; was treated concomitantly with rapamycin suspended in 0.5% CMC\textsuperscript{[16]} in a dose of 0.13 mg/kg/day orally by gastric gavage, group 4; was treated concomitantly with verapamil hydrochloride dissolved in distilled water\textsuperscript{[17]} in a dose of 30mg/kg/day orally by gastric gavage. Rapamycin and verapamil doses were calculated according to human equivalent dose equation\textsuperscript{[18]}. Treatment protocol in all groups started from 1st day of the experiment (zero point) and continued for 14 consecutive days. The ABR was reevaluated after completion of the experiment. The animals were ketamine and xylazine anesthetized by intraperitoneal (ip) injection in a dose of (40 mg/kg, ip) and (5mg/kg) respectively\textsuperscript{[15]} and blood was obtained through intracardiac blood sampling and processed for assay of reduced glutathione and malondialdehyde levels. The animals were sacrificed, and each cochlea was extracted and infiltrated with a fixative solution immediately. Left cochlea was prepared for scanning electron microscopy, while right cochlea was prepared for histopathology and immunohistochemistry.

**ABR audiometry**

ABR was achieved while animals were anesthetized through two channel tracking using three electrodes connected to preamplifier: two electrodes were placed as negative electrode on the left and right mastoid and high frontal Fz site as a positive electrode. In response to click stimuli introduced at 90 dBnHL, ABR was registered ipsilaterally, and when response was recorded, the strength was decreased in steps of 10 dB until a threshold was detected. Using alternating polarity, 19.3 / second repeat rate, 150–1500 Hz filter setting, 50,000 gain factor, and 0–10 ms time span, ER3A-insertphone transmitted click stimuli.

**Biochemical assays**

**Blood level determination of reduced glutathione (GSH) (mg/dl)**

GSH level was performed using Biodiagnostic supplied Kit (Cat. No TA 2511.), based on the Beutler spectrophotometric process\textsuperscript{[19]}.

**Serum level determination of malondialdehyde (MDA) (nmol / ml)**

Lipid peroxidation was assessed by calculating
serum (MDA) levels according to the Ohkawa et al. method [20] using Biodiagnostic supplied kit (Cat. No. MD 2529).

**Histopathological examinations of hematoxylin and eosin (H&E) stained tissues**

The right cochlea of each animal was fixed by EDTA formalin 10% for 4 weeks [21]. Paraffin sections (4μm) were examined by light microscope for histopathology.

**Scanning electron microscope (SEM)**

Fenestration was made at left cochlear apex for infiltration with 2.5% glutaraldehyde. The cochlea was processed for examination then dried using critical point dryer then examined with a JEOL (SEM) [22].

**Immunohistochemical examination of LC3-II**

It was carried out in the right cochlea using a rabbit polyclonal antibody (purchased from Sun Red Bio Laboratories Cat. No. 201r-1501) according to scoring method of Schläfli et al [23].

**Statistical Analysis**

Values are interpreted as mean ± standard error of mean (SEM), while in immunohistochemical (IHC) expression of LC3-II scores, median was used. Differences were found to be significant at p < 0.05.

**Results**

**Results of ABR measures**

**Detectability of ABR waves**

At zero point all waves of the ABR were detectable in 100% of animals. Then at the end point ABR showed these results: group 1: ABR was present in all animals (n=8) and all waves of ABR were detectable in 100% of animals while, in group 2 ABR was detectable in 25% of the animals (n=2) and absent in 6 animals indicating severe hearing affection. In group 3 and 4, drug treatment by rapamycin and verapamil respectively led to detection of ABR was in 75% of the animals (n=6) and its absence in 2 animals (Fig.1).

![Fig.1. Results of ABR (A) control group, (B) gentamicin induced ototoxicity group, (C) gentamicin induced ototoxicity group treated with rapamycin, (D) gentamicin induced ototoxicity group treated with verapamil. Results of ABR latencies](image-url)
Regarding latency of waves (I, III, V); there was non-significant difference between all groups at the start point of the study. Moreover, group 1 showed non-significant difference in all latency of waves (I, III, V) at the start and the end point of the study. Regarding Group 2, latency of wave (I) showed non-significant difference comparing zero and end points of the experiment, while latency of wave III showed significant increase at end point compared to zero point (P=0.02), and similarly latency of wave V (P=0.001). On comparing latency of the three waves in group 2 with control group at the end point; there was significant increase in latency of both waves III (P=0.004), and V (P=0.001). Group 3 showed significant increase in latency of wave I and wave V at the end point compared to zero point (P=0.02) and (P=0.05) respectively, Moreover, latency of wave III showed a significant decrease on comparing group 3 with group 2 (P=0.03). On verapamil treatment in group 4 there was a significant increase in latency of wave I (P=0.002), and latency of wave V at the end point compared to the zero point (P=0.003) (Table 1).

Results of ABR threshold

Regarding threshold there was no significant difference between all the studied groups at zero point and in group 1 till the end of the study while, in group 2 gentamicin administration induced significant increase in the threshold at the end point compared to zero point (P=0.02). On rapamycin treatment ABR threshold elevated significantly at the end point (P=0.001) and the same change was found on treatment with verapamil (P=0.002). In addition, group 2 showed significant increase in the threshold.
in comparison to group 1 at the end point (P=0.001). Co-treatment with both rapamycin and verapamil exhibited decrease in ABR threshold when compared to group 2 treated with gentamicin alone. This decrease was significant only in case of verapamil (P=0.004) which also exhibited a significant decrease in the threshold compared to group 3 (P=0.05) (Table 2).

MDA levels in the serum (nmol/ml)

In group 2 there was significant increase in MDA level as compared to the control (P<0.01). Group 3 showed non-significant increase as compared to group 2. However, Group 4 showed significant decrease as compared to both groups 2 and 3 (P<0.05) (Table 4).

**H&E-stained histopathology sections of right cochlea**

Group 1 showed normal outer, inner hair cells (IHCs), normal straight stria vascularis without vacuolations and normal spiral ganglion. Vestibular membrane was intact without vacuolations. In group 2 there was loss or total absence of organ of corti (OC). Others showed hydropic degenerations in outer hair cells (OHCs), broken vestibular membrane, vacuolations and cracking in the stria vascularis and spiral ganglion. Group 3 revealed preservation of hair cells with mild hydropic degeneration, waved basilar membrane in addition to focal degeneration in spiral ganglion. Group 4 showed preservation of normal OC, stria vascularis, spiral ganglion neurons with less degeneration (Fig.2).

**SEM of left cochlea**

Group 2 revealed complete fusion of stereocilia, and massive damage of the normal u or v shaped order. While group 3 showed to some extent preservation of stereocilia with focal fusion or complete loss. Group 4 showed minimal loss of stereocilia with preservation of normal shape (Fig.2).

---

**Fig. 2.** H&E-stained cochlea photomicrographs (A: H) and micrographs of scanning electron microscope SEM (I: T) of different studied groups:
**H&E:** Group 1 (A, B) where (A) showing normal (OHCs) & (IHCS), stria vascularis, straight intact basilar membrane (H& E X40) and (B) normal spiral ganglion with no degenerations (H& E X100). Group 2 (C, D) where (C) showing complete destruction of HCs and basilar membrane with hydropic degeneration, edema in stria vascularis (H& E X40) and (D) showing hydropic degeneration in spiral ganglion (H&E X100). Group 3 (E, F) where (E) showing preservation of HCs with waved basilar membrane, hydropic degeneration in stria vascularis (H&E X40) and (F) showing focal degeneration in spiral ganglion (H&EX100). Group 4 (G, H) where (G) showing preservation of OC architecture and waved basilar membrane with mild hydropic degeneration in stria vascularis (H&E X40) and (H) showing no degeneration of the spiral ganglion (H&E X100).

**SEM:** Group 1 (I: K) where (I) showing panoramic overview of the three and half turns of the cochlea (SEM x35), (J) showing normal stereocilia of HCs of OC (SEM x200), (K) showing (u or v) shaped rows of HCs (SEM x350). Group 2 (L: N) where (L, M) showing complete fusion of stereocilia of HCs (SEM x500-1000), and (N) showing complete damage of the normal order (SEM x350). Group 3 (O: Q) where (O, P) showing to some extent preservation of stereocilia with focal loss of stereocilia in others (SEM x350), (Q) showing preservation to less extent of (U or V) shaped in some areas (SEM x150). Group 4 (R: T) showing minimal loss of stereocilia with preservation of appearance of normal order of HCs (SEM x350).

**LC3-II Immunohistochemical scores**

Group 2 revealed significant increase in LC3-II score as compared to group1 (P=0.001) while, in both groups 3 and 4 a significant decline in LC3-II scoring as compared to group 2 was found (P=0.03) and (P=0.006) respectively (Fig.3, Table 5).

**Discussion**

Autophagy may be double edged sword. Meanwhile in many diseases, it plays an important role in cell survival, but it is still being debated if its activation increases or reduces cell death [24]. It has a protective effect in many diseases [25]. On the contrary it has been reported to cause pathological changes [26]. In addition to that, too much autophagy activation was believed to cause ischemia/reperfusion cardiac cell death [27] and promotion of hepatic fibrosis [28]. Our research aims to examine autophagy role in gentamicin- induced ototoxicity. At the start point, there was non-significant variation between groups with normal ABR in all animals, while at the end point there was significantly increased ABR threshold compared to the start one. Our results in group 2 compared to group 1 showed absence of ABR response in 75% of animals indicating sever hearing loss, while others showed significant increase in wave III latency, wave V latency and significant ABR threshold increase which coincides with many studies [5, 22, 29]. The ABR results are matched with histopathology in light and SEM where there are variable degrees of HCs death, pathological changes in stria vascularis and degeneration of spiral ganglion which are in line with many studies [22, 30, 31]. ROS role in gentamicin ototoxicity is documented in different studies [32, 33]. When there is imbalance between ROS and intrinsic antioxidants, apoptotic cell death is activated [34]. This is represented by marked elevation of MDA and marked reduction of GSH which coincide with Draz et al. [22]. To investigate the role of autophagy, LC3-II immunohistochemistry is determined using Schläfli et al. scoring (0-3) [23]. Our results in group 2 exhibited accumulation of autophagosomes represented by heavy LC3-II staining compared to group1 which shows presence of low basal level of autophagy that coincides with Kim et al. [12] who suggested that this accumulation is due to reducing lysosomes autophagosomes fusion. To investigate HCs survival autophagy role, rapamycin has been used [11, 12]. We used rapamycin orally according to Saegusa et al. who reported effectiveness of oral low dose rapamycin to induce autophagy [33]. There is no definitive oral rapamycin dose in guinea pigs was investigated to induce autophagy, so we depended on the human equivalent dose [35]. Rapamycin group as compared to group 2, it showed significant decrease regarding wave III latency, non-significant difference in wave V latency and ABR threshold. SEM and light
microscope showed to some extent preservation of normal OC with focal vacuolations or loss of some stereocilia. While there are non-significant differences in GSH, and MDA level. Regarding LC3II level there is significant reduction which indicates reduction in autophagosomes suggesting induction of autophagic flux which coincides with Cui et al. [36]. Whether rapamycin enhances HCs preservation or causes cell death, it is a matter of debate because the role of mTOR in cochlea is still unclear. Our results coincides with Leitmeyer et al. [37] who found that mTOR inhibition by rapamycin treatment led to dose dependent (HCS) death due to elevation of oxidative stress [37]. On the other hand, these findings are contradictory to He et al. [38] who documented elevated survival rates of HCs after rapamycin autophagy activation, decreased levels of ROS and decreased cell death, in addition to Kim et al. [12] who found that hearing thresholds were significantly better in rapamycin injected ear group, and reduction of ABR threshold via alleviating cisplatin ototoxicity [39]. This variability can be explained by that the efficacy of rapamycin can depend upon cellular type and mTOR target. Also, it is affected by the level of phosphatidic acid (PA) which is a competitive antagonist to rapamycin. The level of rapamycin which is needed to inhibit mTOR is affected by PA level in the cell [40]. Another explanation is occurrence of excessive autophagy which may lead to cell death as reported in different tissues [27]. So, the concentration of rapamycin in the cochlea is critical for cell survival. Away from the mTOR dependent pathway, verapamil was suggested in previous studies to be an autophagy inducer by decreasing the intracellular Ca\textsuperscript{2+} and increasing autophagosome formation, so help in clearance of mutant aggregate-prone proteins [13, 14]. It was also found to increase fusion between autophagosome and lysosome in liver, so it was tried for autophagic flux restoration and treatment of obesity [41]. It was also reported to have cytoprotective effect via induction of autophagy [42], in addition to recent study that suggested that verapamil extends lifespan by promoting autophagy [43]. As far as we know there is no definitive dose for verapamil to induce autophagy in guinea pigs, so we depended on human equivalent dose (FDA label dose is 240: 480 mg. The average daily dose is 360 mg/day)[44]. Verapamil treated group showed significant decrease in ABR threshold compared to group 2, significant reduction in MDA and significant elevation in GSH which are in line with Kedziora-Kornatowska et al. [13]. SEM and light microscope showed decline in HCs death and less pathological changes compared to group 2 and group 3. Regarding LC3-II expression there is significant decrease as compared to group 2 suggesting induction of autophagic flux. These are in consistence with previous reports which suggested that verapamil allowed lysosomes and autophagosomes to re-associate leading to autophagosome accumulation reduction [41]. Verapamil demonstrated superiority in protection of HCs against gentamicin induced ototoxicity compared to rapamycin due to its antioxidant and significant improvement ABR results.

**Conclusion**

Autophagy induction via Ca\textsuperscript{+2} channel antagonist verapamil may be a new therapeutic target to decrease gentamicin ototoxicity by its autophagy inducer effect and antioxidant properties.

**Recommendations**

More autophagy markers such P62 and different doses of rapamycin could be used to better present autophagy activity in gentamicin ototoxicity.

Evaluate the Prevalence, Natural Course, and Final Visual Acuity in Patients with Stages III or IV of Diffuse Lamellar Keratitis Following Laser in Situ Keratomileusis

Afshin Mansourian¹, Bahman Sharifi²

¹Assistant Professor, Department of Anesthesiology, School of Medicine, Yasuj University of Medical Science, Yasuj, Iran, ²Assistant Professor, Department of Ophthalmology, School of Medicine, Yasuj University of Medical Science, Yasuj, Iran

Abstract

Background: The prevalence of DLK has been reported differently in different centers based on its severity. Hence, the aim of present study was evaluate the prevalence, natural course, and final visual acuity in patients with stages III or IV of diffuse lamellar keratitis following laser in situ keratomileusis.

Methods: In the present descriptive study, 3941 eyes files from 2125 patients underwent LASIK surgery; were examined. All patients had a complete ophthalmologic examination before LASIK and had suitable conditions for LASIK.

Result: Among the studied cases, 39 eyes (0.98%), out of 16 patients (0.75). The mean time interval between LASIK and DLK diagnosis was 3±2.4 days. A history of allergy was negative in all patients. The mean post-operative spherical refractive error in all eyes was in the range of 1 diopters and the average cylindrical refractive error in 33 eyes was -0.66±1.2 diopters. The mean of final spherical refraction in 34 eyes was 0.5±1.2 diopter and the mean of final cylindrical refraction in 35 eyes was -0.75±1.3 diopter. Severe turbidity at the flap surface in the first week decreased over time in all patients with stage III and IV DLK. So that only in four eyes (10.25%)

Conclusion: The prevalence of stages III and IV in DLK is negligible compared to the large number of LASIK procedures and all patients respond well to topical and systemic corticosteroid therapy.

Keywords: laser, diffuse lamellar keratitis, visual outcome

Introduction

Lamellar diffuse keratitis (DLK) is a non-infectious accumulation of inflammatory cells on the submandibular surface that often occurs within the first week after LASIK surgery. Numerous causes have been implicated in the occurrence of DLK, including the presence of particles and debris during surgery, glove powder, red blood cells, tissue particles, endotoxins, secretions, and infiltration of betadine solution.

Treatment with corticosteroids before and after surgery reduces the severity of DLK, but treatment with fabric membrane stabilizers and nonsteroidal anti-inflammatory drugs have less effect on the DLK process after surgery. Increased intraocular pressure (IOP) following surgery can create a clinical picture similar to DLK (false DLK). Therefore, IOP control
is necessary in patients with suspected DLK\textsuperscript{10}.

The prevalence of DLK has been reported differently in different centers based on its severity. Hence, the aim of present study was evaluate the prevalence, natural course, and final visual acuity in patients with stages III or IV of diffuse lamellar keratitis following laser in situ keratomileusis.

**Method**

In the present descriptive study, 3941 eyes files from 2125 patients underwent LASIK surgery; were examined. All patients had a complete ophthalmologic examination before LASIK and had suitable conditions for LASIK.

In none of the subjects was there a major systemic disease that precluded LASIK. Follow-up examinations were performed in all patients on days one, two, three and seven, and in the absence of symptoms indicating the onset of DLK, in months one, three and six, and then annually. Accepted of these patients with stage III and IV DLK, in terms of age, sex, history of previous underlying disease (except for LASIK, history of drug use, history of allergies, refraction, topography, type of treatment, duration of treatment, duration of follow-up The response to treatment and the best corrected vision were assessed before LASIK and at the end of follow-up.

**Result**

Among the studied cases, 39 eyes (0.98%) (Figure1), out of 16 patients (0.75) including 12 women and 4 men had stage III or IV of DLK (Figure2). None of the unilateral cases had stage III or IV DLK, depending on whether LASIK was unilateral or bilateral. The mean time interval between LASIK and DLK diagnosis was 3± 2.4 days. A history of allergy was negative in all patients. Four patients had a history of taking non-ophthalmic drugs such as sedatives, antihypertensives and dermal drugs. The mean of preoperative spherical error in these 39 eyes was -2/1±1.1 and the mean of preoperative cylindrical error was -0.96±1.3 diopter.

</tbody>
</table>

The mean final spherical refraction in 36 eyes was 0.4±1.8 diopters and the mean refraction of the final cylinders in 38 eyes was -0.76±1.2 diopters.

The mean post-operative spherical refractive error in all eyes was in the range of 1 diopters and the average cylindrical refractive error in 33 eyes was -0.66±1.2 diopters. The mean of final spherical refraction in 34 eyes was 0.5±1.2 diopter and the mean of final cylindrical refraction in 35 eyes was -0.75±1.3 diopter. Severe turbidity at the flap surface in the first week decreased over time in all patients with stage III and IV DLK. So that only in four eyes (10.25%) at the end of the follow-up period, the location of turbidity was barely visible.

DLK was in 32 eyes (82.05%) in stage II and III, in five eyes (12.82%) in stage III and in the other two eyes (12.5%) in stage IV.

No corneal epithelial defect was seen in any eye with stage IV DLK. All patients in the acute inflammatory phase at the end of the first week had a camera higher than +1.9 diopters with astigmatism. The best initial corrected vision of patients before
surgery according to LogMAR was zero on average (equivalent to 20/20). In none of the patients did the reduction of more than two lines in the corrected vision occur. None of the patients underwent refractive surgery during the follow-up period.

**Discussion**

LASIK is the most common surgical procedure for correcting myopia, hyperopia and astigmatism in recent years. Diffuse layer keratitis, especially in advanced stages III and IV, is an important complication that has been reported in many studies as a potentially threatening visual complication if left untreated\textsuperscript{11}. Although many factors have been implicated in the development of DLK, the clinical appearance and findings are all the same. The first and second stages of DLK are mild and transient and may be diagnosed only on the basis of findings and clinical signs\textsuperscript{5, 12, 13}.

In this study, the prevalence of DLK in stages III and IV in patients undergoing LASIK was 0.98%. In the present study, none of the patients had a history of allergies. In a study conducted by Scot et al.,\textsuperscript{14} Conflicting results were reported 46% of patients with a history of atopic dermatitis, severe allergies and asthma in childhood. Noda et al.,\textsuperscript{15} Showed that the prevalence of DLK in stages III and IV was 0.8%, which were almost similar to the present study. Reinstein, et al.,\textsuperscript{7} also reported in a study that the prevalence of DLK in stages III and IV was 0.7%, which was lower than in our study. In an animal-based study, the results showed that corticosteroids were recognized as the best drug for the prevention and treatment of this complication\textsuperscript{16}. In other studies, BCVA and ultimate refraction in these patients have not been reported in the long term. Studies conducted in the short and medium term (up to 2 months) confirm the improvement of camera changes with irregular astigmatism\textsuperscript{7, 17}.

Although post-LASIK refraction stabilization is delayed by the development of the third and fourth advanced stages of the DLK, two major results can be obtained; First, with timely initiation of appropriate treatment, along with inviting patients to be patient and hope for recovery, only the necessary measures are needed. Prescribing a contact lens in a situation where the corneal center is very flat due to DLK. Another conclusion is that in the third and fourth stages of DLK, at least one year delay is required to perform any secondary and corrective surgery, and the results of the intervention earlier than this time are uncertain due to continuous refractive changes and lack of stabilization\textsuperscript{18, 19}.

Although initially hoping to reduce the risk of DLK due to not using a surgical blade, its occurrence has not yet been completely ruled out. On the other hand, re-approach of surgeons to laser ablation methods in possible cases, will eliminate the risk of this complication.

**Ethical Clearance**- Not applied.

**Source of Funding**- No funding was received.

**Conflict of Interest** – The authors declare that there is no conflict f interest.

**Conclusion**

The prevalence of stages III and IV in DLK is negligible compared to the large number of LASIK procedures and all patients respond well to topical and systemic corticosteroid therapy. The patient’s final vision due to this complication will not decrease compared to the best preoperative vision, if treated in a timely and appropriate manner. Although a camera with astigmatism (often irregular) in these patients in the short and medium term causes changes in refraction and visual impairment, but due to the slow recovery of this complication, these patients can be promised improvement in vision and refraction in the long run.

Prognostic Significance Association of Neutrophil-To-Lymphocyte Ratio and Platelets-To-Lymphocyte Ratio with Mortality in COVID19 Patients

Hoda Elsayed Mohammed¹, Sama Mohammed N. Attiyah²

¹Assistant Professor of Immunology and Parasitology, Biology Department, Faculty of Sciences and Arts, Al Kamel Branch, University of Jeddah, Jeddah, Saudi Arabia, ²Assistant Professor of Immunology And Cardiology, Biology Department, Faculty of Sciences and Arts, Al Kamel Branch, University of Jeddah, Jeddah, Saudi Arabia

Abstract

Background: Inflammation is a key factor in COVID-19 progression and is potentially an important predictive factor. The ratios of neutrophils to lymphocytes and platelets to lymphocytes may show significant inflammatory progression, which may contribute to the development of some major complications and mortality problems as observed in COVID-19. Objective: To examine and investigate the correlation of neutrophil lymphocytic ratio (NLR) and platelets to lymphocytes ratio (PLR) with increased mortality risk.

Methods: 124 patients admitted to King Abdulaziz hospital with confirmed COVID-19 were enrolled in our study. The blood cell count was used to obtain NLR and PLR. The receiver operating characteristic (ROC) curve was used to determine the sensitivity and specificity of NLR and PLR for severity and mortality of admitted patients with COVID-19. The logistic regression model was used to explore the risk factors associated with mortality and severity.

Results: The mortality rate was 23.4%. Among non-survivors’ patients’ lymphocyte significantly declined with 96.5%, while neutrophil counts increased. The Empirical optimal cut point of NLR correlated with mortality is 4.647, with a sensitivity of 93% and a specificity of 61% (AUC: 0.847, 95% CI 0.774-0.921; P = 0.001). Moreover, the optimal cut point of PLR associated mortality is 17.358, with a sensitivity of 90% and a specificity of 64% (AUC: 0.791, 95% CI 0.703-0.878; P = 0.005).

Conclusions: NLR and PLR variables were significantly correlated with severity and mortality. NLR and PLR can be considered independent biomarkers in COVID-19 patients which play a significant role to predict mortality cases.

Keywords: coronavirus, inflammation, mortality, neutrophil-to-lymphocyte ratio, platelet-to-lymphocyte ratio.

Introduction

COVID-19 is a disease caused by the severe acute respiratory syndrome coronavirus-2 (SARS-CoV-2), a virus thought to start in late December 2019 in Wuhan ¹. The number of infected people around the world has been raised significantly now a day. Patients diagnosed with COVID-19 showed different symptoms vary from asymptomatic illnesses to death ². Consequently, it is important to define risk factors linked to the poor prognosis of COVID-19 patients.
Several hematologic anomalies were revealed in COVID-19 patients which were prevalent in lymphopenia and thrombocytopenia. NLR and PLR are available values that correlate and reflect indirectly the inflammation conditions. Their values can be easily obtained from blood routine counts in laboratory. The NLR is determined by dividing the absolute number of neutrophils into the absolute count of lymphocytes, while PLR is calculated by dividing a count of platelets by the absolute count of lymphocytes. They are inflammatory markers with low-cost and are replicable to measure, which can be assessed easily with a blood sample. Generally, NLR and PLR are quantitative and convenient suitable factors to assess the susceptibility of death through COVID patients.

Immunological research has shown that the severity characteristic in extreme COVID-19 cases is due to elevated levels of proinflammatory cytokines known as a cytokine storm. This intense elevation of cytokines leads to a major proinflammatory reaction occurring in MODS and ARDS, resulting in mortality. From this point of view inflammatory markers can help to evaluate the severity and mortality cases of COVID-19 patients.

Few studies assessed the role of NLR and PLR in severe and non-severe COVID-19 patients. The present study was carried out to determine the association of NLR and PLR to COVID-19 severity and mortality.

**Material and Methods**

Our retrospective study on one hundred twenty-four positive COVID-19 cases in patients hospitalized at King Abdulaziz hospital. All patients were confirmed using reverse transcription-polymerase chain reaction (RT-PCR Abbott company, USA). The study was approved by Unit of Biomedical Ethics Research Committee (Reference NO. 301-20). Demographic parameters and laboratory assessments of the complete blood count of the patients were obtained exclusively from the Laboratory Information System (phoneix) in the hospital. Patients with complete data, including 95 survivors and 29 non-survivors’ cases, were randomly selected. Whole venous blood samples have been collected on BD EDTA tube and CBC profile analysis has been performed on Sysmex xn-10 and Sysmex xn-20 analyzer (JAPAN).

**Statistical Analysis**

The statistical analysis and graphical representation were done using SPSS Statistics 25 (IBM SPSS) and R version 4.0.4. The categorical variables were described as the number/total number (%), and continuous variables were described using the mean, median and interquartile range (IQR) values. The Kolmogorov–Smirnov test was used to test the variables for the normality distribution. Otherwise, the Mann–Whitney test was used to compare the medians for continuous variables. The categorical data were compared by $\chi^2$ test or Fisher’s exact test. The receiver operating characteristic (ROC) curve was used to determine the sensitivity and specificity of NLR and PLR for all-cause mortality and severity. The logistic regression model was used to explore the risk factors associated with mortality and severity. A p-value $< (\alpha =0.05)$ was considered statistically significant, where $\alpha$ is a significant to test level.

**Results**

The current study enrolled 124 diagnosed patients of COVID-19. The number of male patients was 77(62.1%) while 47(37.9%) were female. The mortality rate was 23.4% as 29 deaths had occurred. The mortality is more likely to present with older age ($\geq 60$) with 62.1%, and more common in male than female (75.8%). At admission time all positive patients underwent blood routine examinations, most of them had peripheral blood system anomalies. Moreover, non-survivors’ patients obtained low value of MCH and hemoglobin levels, 75.9% and 100% respectively.
regarding the reference range. The increase of neutrophils counts percentage was obvious within 89.6% of non-survivors’ patients. More importantly, we found that 96.5% among non-survivor’s patients showed significant lymphopenia. Furthermore, 66.1% of all patients exhibited eosinopenia, while this percentage was 75.9.1% of non-survivors’ patients. The results revealed normal platelet counts with 98 (79%) among COVID-19 patients. While amongst survivors’ patients 26 (27.4%) were in intensive care unit ICU, whereas 28 (96.6%) were in ICU of non-survivors.

A null hypothesis Ho has no significant affiliation between mortality and the categorical variables. It was tested using Chi-squared test. For the continuous variables, the significance differences of median value between the two groups were tested using Man Whitney Test. Results show that the null hypothesis is rejected for all variables except gender, Hb, MCH, platelet, and eosinophils. This indicates a statistically significant difference between the two groups in the median values for age, WBCs, lymphocyte, neutrophils, and monocyte variables.

Table 1 shows the results in comparisons of the values of NLR and PLR between survivors and non-survivors’ patients using Man Whitney Test. The results show a significant difference for NLR and PLR variables between the two groups. Moreover, this indicates a statistically significant difference for NLR and PLR variables between ICU and Non-ICU patients. Among the non-survivors’ group, NLR and PLR were significantly elevated compared to survivors’ group. Moreover, PLR and PLR were considerably raised in severe cases, when compared to non-severe group.

Table 2 shows the logistic regression model analysis. The univariate analysis revealed that several clinical factors were statistically significant risks associated with COVID-19 mortality, which included age, WBCs, monocyte, eosinophils, NLR, and PLR. The forward stepwise logistic regression regression is used to explore the most important risk factors associated with mortality. According to forward stepwise logistic regression results. The multivariate analysis shows that NLR and monocyte are risk factors associated with mortality with OR 1.081(95%CI :1.013-1.154) and 0.657(95%CI :0.503-0.857), respectively. The results reveled that NLR a valuable biomarker in relation to the mortality in COVID-19. However, PLR was not found to be an independent risk factor for death in multivariate analysis.

According to multivariate analysis, Table 3 shows that NLR and Hb are significantly correlated with severity with OR 1.480 (95%CI:1.266-1.731) and 0.652 (95%CI: 0.520-0.817), respectively. However, PLR was not found to be an independent risk factor for severity in multivariate analysis.

From Fig. 1 and Table 4 based on the ROC curve analysis, NLR, PLR, Monocyte, and the combined effect (NLR and Monocyte together) had diagnostic values for COVID-19 mortality (P-value<0.05), and the AUC from highest to lowest was (combined>NLR>PLR> Monocyte) respectively. The Empirical optimal cut point of NLR correlated with mortality is 4.647, with a sensitivity of 93% and a specificity of 61% (area under the curve (AUC): 0.847, 95% CI 0.774-0.921; P = 0.001). Moreover, the optimal cut point of PLR associated mortality is 17.358, with a sensitivity of 90% and a specificity of 64% (area under the curve (AUC): 0.791, 95% CI 0.703-0.878; P = 0.005). Moreover, Fig.2 showed that NLR, PLR, Hb, and the combined effect (NLR and Hb together) had diagnostic values for COVID-19 severity (P-value<0.05), and the AUC from highest to lowest was (combined >PLR>NLR> Hb) respectively.

Discussion

Several recent reports have described the correlation of age with survivors and non-survivors COVID-19 patients. Our finding is compatible with the recent study that the older patients had worse health results and higher mortality rate than the young age group. Thus, it can be said that COVID-19 is most found with older age males.

Moreover, the current study found an increase in the neutrophil counts percentage of non-survivors’ patients compared with the survivor’s patients. Furthermore, we found that 96.5% of non-survivors’ patients showed a significant substantial reduction in the number of lymphocyte counts. Additionally, 7.5% among non-survivors’ patients showed eosinopenia. The findings of our study were aligned with the results of other previous studies.

The immune response is highly lymphocytic-based, and activation of the immune system is mainly due to neutrophils. Moreover, the systemic inflammation will destruct the CD4+ T lymphocytes and induce the suppressor CD8+ T lymphocytes which leads to an increase of the neutrophil-lymphocyte ratio (NLR). Moreover, platelets play an essential role in innate immunity and inflammatory response, and their count reflects the inflammation and infection condition. COVID-19 can cause pulmonary endothelial damage, which leads to pulmonary endothelial injury, activation, accumulation, and preservation of platelets in lung, followed by platelet depletion. The cytokine storm induces the inflammation in SARS-CoV-2 patients to worsen, and the platelet-to-lymphocyte (PLR) ratio reflects the level of cytokine inflammation that can be used for evaluation purposes.

The evaluation of inflammatory diseases progression and their changes may be a crucial factor that scientists must take in consideration. In COVID-19 patients, inflammatory biomarkers can be used as potential prognosis predictor factor. Most studies show that inflammation plays a central role in the pathogenesis of the disease. More concerning, the severity and mortality characteristic of COVID-19 was identified by several inflammatory factors.

SARS-CoV-2 can lead to various infection conditions, particularly respiratory tract infection diseases, which can develop into serious complicated conditions exhibiting pneumonia, pulmonary edema, acute or multiple organ failures leading to patient death. So, it is highly demanded to discover biological markers that can be used to identify COVID 19 at an early stage, helping to save people’s life. The early detection will aid to decrease the progression of severity, decrease the mortality, and support the decline of financial expenses of the ministry of health all over the world. Therefore, any parameter that can help for the early diagnosis is crucial.

Recent studies considered NLRs and PLRs as a precursor element for COVID-19 admission condition in the intensive care unit, and they consider it as a useful marker to evaluate the severity and mortality. NLR and PLR are easily calculating from a complete blood count with a differential count.

In this study, we found a higher NLR and PLR values in non-survivors COVID-19 patients compared to survivors’ patients. However, univariate analysis identified high NLR and PLR as an independent prognostic factor for survival. After changing the other confounding variables in multivariate Cox analysis, the NLR remained as a risk factor of survival in patients with COVID-19. Our findings were consistent with earlier studies. Whereas other studies reported that PLR not correlated with COVID-19 prognosis at all.

Moreover, monocytes are pro-inflammatory cells that can induce inflammation by producing many
cytokines\textsuperscript{12,33}. A recent study detected significant decreased in monocytes count within critical COVID-19 patients\textsuperscript{34}. Our results demonstrated that monocyte has risk factors associated with mortality with OR 0.657 (95\%CI :0.503-0.857).

ROC analysis of our study showed that patients with non-serious symptoms compared to patients with severe COVID-19 signs had higher NLR and PLR values, and they have a diagnostic value for COVID-19 severity and mortality. It was also demonstrated that the empirical optimal cut point of NLR correlated with mortality is 4.647 with a sensitivity of 93\% and a specificity of 61\%. Moreover, the optimal cut point of PLR associated mortality is 17.358, with a sensitivity of 90\%.

Moreover, our results shown that NLR and PLR had diagnostic values for COVID-19 mortality (P-value<0.05). The measurement of their values is a reliable and low-cost test, which can be easily applied in a daily routine blood tests in the lab and may be act as an independent prognostic factor for severity and mortality of COVID-19 patients.

Finally, no universal cutoff value has been found to date for NLR and PLR, especially in patients with COVID-19. Future research should focus on the optimum cutoff value to use it as an important prognostic indicator before medicinal application and patient hospital admission.

Conclusions

NLR and PLR had diagnostic values for COVID-19 severity and mortality. The daily CBC routine blood test can be used to identify COVID-19 patients at early stage of the infection. This type of detection well saves people life and reducing mortality rates by avoid going through complication stages. Additionally, this is an economical diagnosis tool easily available in cases where logistics and financing are limited.

Limitation

Our retrospective study was done in a single center and as a result the sample size was limited due to logistic problems and administrative acceptance of many patients that need more processing time, so a multiple centers prospective research is recommended. Also, since this study was conducted on blood laboratory parameters, patients were not constantly tracked for all clinical manifestations.

Effects of Nutrition and Physical Activity in Prevention of Neurological and Cognitive Disorders- A Review Study

Shweta Patel¹, Diwakar Chauhan², Ranjana Patnaik³

¹PhD Scholar, Department of Bio-Sciences, ²Professor and Head Department of Basic Sciences, ³Professor, Department of Bio-Sciences, School of Basic and Applied Sciences, Galgotias University, Greater Noida, Uttar Pradesh, India

Abstract

Background: As neurodegenerative and psychiatric disorders are rising rapidly, unexpected demand for cost-effective and practical treatment is also growing. The present study reveals the synergistic role and mechanism of nutrition and physical activities in the transition of cognitive functions and mental wellbeing.

Objectives: To unravel the effect of nutrition and exercise in maintaining cognitive function and mental health. In this study some of these points were reviewed such as what is the influence of nutrition and exercise over mental health. How well the combined effects can help to combat neurological and behavioural disabilities. What mechanism is involved in promoting mental health.

Methods: A non-systematic approach was used in the present review study. This study summarizes the synergistic role and mechanism of nutrients and physical exercise in the transition of cognitive function and mental balance.

Results: The most important outcome is nutritional therapy in combination with regular physical exercise is a reliable, effective and economical alternative that can intensify the effects of standard drug therapy.

Key Words: Physical Activity, Exercise, Nutrition, Mental Health, Cognition, Memory

Introduction

As per World Health Organization, central and peripheral nervous system is centre of neurological disorders. Such diseases include epileptic syndrome, Alzheimer’s disease, dementia, stroke, migraine, multiple sclerosis, Parkinson’s disease, neuronal motor dysfunction, brain tumours, head injuries because of trauma and neurological problems due to poor nutrition.¹

It is widely accepted that the lifestyle pattern, eating habits and environmental changes have a strong influence on the mental and physical wellbeing of individuals, particularly in our modern societies where the lack of physical activities and low nutritious diet are the major risk factors for several
neurodegenerative and psychiatric disorders.2

Impact of physical activity on the brain functions influences the fundamental aspects of brain plasticity. Exercise increases the level of neurotropic factors (Brain Derived Neurotropic Factor) which is originated from the brain in hippocampus an important region for cognition and reminiscence.3-7 Conversely, high fats diet, sugar and a calorie-rich diet are found to be harmful for neuronal functions because they elevate oxidative stress and thereby decreasing the synaptic plasticity as well as cognitive functions.8,9 Adequate levels of physical exercise and a nutritious diet can be an alternative non-invasive, highly efficacious treatment approach to the standard drug therapy of neurological disorders.10 Accordingly, under this review we will examine the process by which nutrition and physical activity regulate brain health and synaptic plasticity along with circumstances under which potential benefits can be derived from their combined application.

MICRONUTRIENTS AND NERVOUS SYSTEM

Some microelements such as vitamins, minerals, trace elements, carotenoids and essential fatty acids impart role in the flourishing and maintaining nervous system at the initial stages of life and during aging.11 Different nutrients are involved in sustaining the regular functioning of brain; they take part in producing cellular energy, creating myelin, preserving and restoring cells and synthesizing neurotransmitters.12,13

Vitamin B₆ is essential for the breakdown and consumption of amino acid, and consequently for the synthesis of neurotransmitter such as dopamine, GABA particularly serotonin neurotransmitters.12 In one study, scientists suggested to give folic acid to the people suffering with Parkinson’s disease for reducing the level of homocysteine due to standard medication known as levodopa.14 As reported in multiple cases, haematological and gastrointestinal symptoms along with vitamin B₁₂ deficiency (150pmol/L) are sign of increased risk of neuropathy, demyelination, cognition impairment and dementia.15-17 In a recent research, experts found that sufficient supplies of Docosahexaenoic Acid (DHA) with long-chain omega-3 fatty acid would avert dementia.18 There is another components that is minerals that can attenuate the transmission of nerve stimuli by magnesium and calcium for proper functioning of the nervous system.

Nutrients as antioxidant

Antioxidant can arrest, suppress as well as restore any damages to cells what can happen because of oxidative stress (Figure 1).19,20 The minerals are non-enzymatic antioxidants, they works by promoting the activity of different catalytic enzymes or by repairing the damage, reducing hydro-peroxide, ion sequencing as well as free-radicals scavenging along with the suppression of ROS formation.21 Enzymes that protect from reactive oxygen species damage need amino acids and dietary minerals such as copper, zinc, manganese as cofactors for their synthesis. Fat soluble vitamins such as vitamin A, C and E are active dietary antioxidants present in fruit and vegetables can prevent the cytotoxic effect of free radicals, serve as ROS scavenger and enhance antioxidant activity of enzymes.19

Research Bridging Antioxidants and Mental Health

Some studies reported the convergent proof on the role of different antioxidants in protecting cell membrane from oxidative stress, alteration of mood as well maintenance of mental health. Some of the antioxidants are Vitamin A, C and E, carotenoids, polyphenols, zinc and selenium.20 A recent study showed the link of low carotenoids and depression.21,22 Another randomized controlled trial indicated that
ascorbic acid modulates catecholaminergic activity, releases prolactin and oxytocin which reduces anxiety and stress and is also associated with the sexual behaviour thereby increases intercourse frequency and improves mood.23

**Nutrition and cognition**

Non-invasive pictorial techniques shown that food thought alone can alter neural activity in some specific region of brain, known for taking part in appetite control and contributing to physiologic reactions such as involvement of saliva, gastric acid and insulin secretion.24,25 Polyphenols are abundant antioxidant-derived micronutrients. The most important source of polyphenols is various drinks and fruits such as coffee, tea, cocoa and red wine. They have been proved to shield neurons from neurotoxin-induced injuries, to suppress neuroinflammation, improve memory, learning and cognitive function using neuroprotective activities.26

Flavonoids are the diverse group of polyphenols. The dietary polyphenols have numerous protective effects in the brain which include neuroprotective effect against neurotoxin-induced injury, suppressive effect on neuro-inflammation; it also promotes learning and cognition.27 Long Term potentiation is commonly recognized by the activation of neuronal signal pathway as one of the key mechanisms that play role in memory development, strengthening and storage.28 Some of these pathways consist of protein kinase C, calcium – calmodulin kinase, protein kinase A, phosphatidylinositol-3 kinase /Akt, and protein kinase pathways activated by mitogen. Brain Derived Neutrotropic Factor is one of the neurotrophins that is known to control the growth of synapse, increases synaptic receptor and dendrites spinal density.29 (Figure 2).

Docosahexaenoic Acid (DHA) is a type of omega-3 polyunsaturated fatty acids essentially required for the brain development and neuroplasticity.30,31 Docosahexaenoic Acid exerts its effect by enhancing the function and fluidity of synaptic membrane, mediating cell signalling, regulating gene expression and enhancing long term potentiation.7

**Research Linking Nutrition and Cognitive Functions**

Research on the age related degenerative disorders has shown an association between mitochondrial aging and DNA disruption due to deficiency of micronutrients resulted into higher risk of cognitive impairment and stroke.29,32 The neural signalling pathway of flavonoids and its rich fruits is well known to attune, especially with extracellular receptors, synaptic plasticity. The neuronal signaling pathway, in particular with the extracellular receptor kinases and protein kinase B and Akt pathways, have been well-reported for modulating neuronal signalling pathways that is crucial for inducing synaptic plasticity.33,34 In children with Attention Deficit Hyperactivity Disorder, a randomized controlled analysis of Pycnogenol (containing phenolic acid, catechin, taxifolin and procyanidines) reported improved symptoms along with higher level of glutathione and overall antioxidant effects.35,36 In a past research, schizophrenia patient were given dose of vitamins C and E along with n-3 Polysaturated Fatty Acids, Eicosapentaenoic Acid and Docosahexaenoic Acid for four months has decreased psychopathology in different indicators.37

**EXERCISE, MEMORY AND COGNITION**

Exercise has demonstrated positive effects on cognitive efficiency in healthy individuals. A 12-week longitudinal study found that participants in exercise group had improved memory and cognitive skills compared to control group.38 Research has shown that the regular strength training has a positive effect on cognitive efficiency, acts by increasing synaptic
plasticity in the hippocampus. It has also been reported that in healthy brain, strength training is associated with structural changes in grey matter, white matter and putamen volume.\textsuperscript{39,40} Thus, a combination of moderate aerobic and resistance exercise would provide an ideal benefit to overall cognitive function.

**Benefits of physical activity in neurological condition**

Physical exercise can be beneficial in many ways, such as by maintaining cardiovascular health, by increasing blood supply to the brain, by minimizing inflammation, by reducing stress hormone levels. All of these factors have significant role in cognitive function.

- The Review study indicated that physical activity serve as a prototypic preconditioning stimulus that provides protection to the brain in patients with acute or chronic strokes.\textsuperscript{41,42}

- Exercise significantly improves the emotional and physical health of patients with Alzheimer’s disease.\textsuperscript{43}

- Patients with neurodegenerative conditions indicated that physical activity can improve posture, balance, tremor, mobility, handgrip as well as motor coordination in patients with Parkinson’s disease.\textsuperscript{44,45}

**POTENTIAL MECHANISM OF IMPROVED COGNITION WITH EXERCISE**

Important source of energy for neurons is brain glycogen which is mainly present in astrocytes.\textsuperscript{34} Extensive exercises with hypoglycemia contribute in reduction of brain glycogen. However some studies shown that loss of astrocytes glycogen are overcompensated by brain.\textsuperscript{35} Another research supported the hypothesis that the ability of brain to increase energy metabolism during activation is limited by the glycogen depletion.\textsuperscript{36} It means that the daily exercise would increases the stock of astrocyte glycogen, providing the brain protection from future potential hypoglycemic bouts and thereby enhancing cognition. Exercise is linked to the enhancement of neurotransmitter levels, neurotrophic factors, growth factors and to improve functional connectivity in temporal lobes.\textsuperscript{39} One of these factors Brain Derived Neurotropic Factor is indicated to modify brain mitochondrial respiratory efficiency; but this role tends to be inhibited by the presence of inflammatory cytokines.\textsuperscript{46,47} Brain Derived Neurotropic Factor controls energy homeostasis by regulating eating habits, physical activity and by modulating the peripheral metabolism of glucose.\textsuperscript{48}

Parkinson’s disease is a neurodegenerative disease where person with disease losses dopaminergic neurons and eventually, reduced mitochondrial activity. Exercise helps in elevate the dopamine level of that has many benefits such as increase antioxidant activity, Brain Derived Neurotropic Factor, IGF-1 level (Figure 3).\textsuperscript{48}

PGC-1\(\alpha\) plays important role in promoting beneficial effects of exercise on mental health. It has been reported that PGC-1\(\alpha\) takes part in the process through which exercise induces hippocampal Brain Derived Neurotropic Factor expression.\textsuperscript{50,51} Myokines help in maintaining biological homeostasis along with the metabolism of energy, angiogenesis and myogenesis.\textsuperscript{52,43} Myokines, Interleukin (IL-6), (IL-10), and (IL-1ra) are produced during exercise and attribute to their beneficial effects, studies reported that IL-6 would also have anti-inflammatory effects. Exercise induced IL-6 has been found to suppress the synthesis as well as activity of interleukin -1\(\beta\) and tumor necrosis factor-\(\alpha\).\textsuperscript{44} Animal study showed that the hippocampal TNF-\(\alpha\) (Tumour Necrosis Factor) level was considerably lower and IL-6, IL-1ra, and IL-12 were found to be higher in hippocampus among the exercise group when compared with control group.\textsuperscript{53}
SYNERGISTIC ROLE OF DIET AND EXERCISE

The diet and exercise became a part of the continuum with which the environment played a crucial role for millions of years in the development of human brain. Studies demonstrated that exercise acts as a supplement to a DHA-rich diet to affect cognitive function-based molecular systems. Exercise exerts its positive effects by repairing of the membrane homeostasis after brain injury, which is essentially needed to promote neuroplasticity and cognitive functions. The cumulative effect of a food rich in polyphenols along with exercise encourages the development of genes which usually benefit synaptic plasticity as well as mental wellbeing, at the same time reduces the growth of genes that are involved in adverse processes such as inflammation and cell mortality. (Figure 4)

![Image of healthy diet and brain benefits](image1)

Figure I Effect of healthy food on brain: Nutrients rich diet helps the brain to increase brain agility and vitality, enhance energy metabolism and neuronal survival. This reduces the oxidative stress, neuroinflammation and neurodegeneration in brain. (19)

![Image of Flavanoids mechanisms](image2)

Figure II Mechanism of action of Flavanoids: Flavanoids activates and inhibits several signalling pathways in brain. Flavanoids improves the oxygen delivery, increases synaptic plasticity, neuronal communication and memory through the activation of extracellular receptor kinase (ERK), Akt and protein kinase A (PKA). They inhibit the JNK, ASK and p38 involved signalling pathways. This reduces the neuroinflammation, apoptosis, neurodegeneration and brain ageing. (28)
Figure III Exercise balances the hormonal level in body: alteration of hormones in different regions of brain is linked to Parkinson disease, Alzhiemer disease. Dopamine (happy hormone) helps in alertness, motivation, clarity, pleasure and working memory. Serotonin hormone helps in relaxation, contentment, positivity. Norepinephrine promotes vigilance, concentration, energy level.\(^{(48)}\)

Figure IV Impact of Exercise on Brain function: Exercise increases motor control and improves cognitive and performance and learning power.

Conclusion

The present study summarizes multidimensional evidences indicating the role and functions of various nutrients in the healthy functioning of brain and cognition. Modification of the lifestyle with regular exercise and nutritious diet appears to advance brain functioning by activating specific cortical areas, stimulating the release of neurotransmitters, and promoting neural activity that is crucial for cognitive and emotional well-being, thereby stopping the progression of neurocognitive disorders. The causes behind the neurological disorders are described by different elements and cannot be related to the one source thus combined effects of nutrition and exercise may be used as a therapeutic approach for targeting
cognitive and neurological disorders. This means that nutritional therapy in combination with regular physical exercise can be a reliable, effective and economical alternative that can intensify the effects of standard drug therapy. Even though various studies have reported the beneficial effects of nutrients alone or exercise alone only very few researches exploring there synergistic role and mechanism. There is need for more human studies for in depth understanding of synergistic properties of different nutrients and physical activities at biochemical, physiological or psychological levels.

The Flipped Teaching of Middle School Students from the Viewpoint of PE Teachers

Hussein Farhan Sheikh Ali

Associate Professor Misan Education Directorate Department, Ministry of Education, Iraq

Abstract

The research aims to the extent of the possibility of using inverted (flipped) teaching in the physical education lesson in the manner of video or via e-mail. Learning platforms after the process of reducing the official time for middle school students from the point of view of physical education teachers. Scientific research was limited to physical education teachers in the Directorate of Public Education in Misan Governorate for the academic year 20-20-20 21, the research sample consisted of a college (100) A teacher in secondary education, the researcher adopted an initial exploratory questionnaire to determine the extent of inversion of the teaching of T. And the evaluation, according to its stability by the method of re-testing, as it reached a degree of stability (0.83) on the basic sample consisting of (60) teachers and schools, and after processing the data statistically, the results of the research indicated that there are a number of reasons leading to the possibility of using (reverse education) in education Sports. The lesson and in light of the results, the researcher presented a set of conclusions and recommendations.

Keywords- Flipped Teaching, Middle School Students, PE Teachers

Introduction and Importance of Research

According to Beda Jogia’s educational competencies the state of the educational curricula cannot be preserved for years without changing or modernizing the educational process in Iraq and the attempts of educational movements by experts and thinkers in the field of education by providing insights about the possibility of high accuracy of Iraqi education. Even his transition from education focuses on the culture of memorization and repetition and a return to digital (electronic) education in line with developments in the educational field that explode human and creative energies, freedom and including flipped education and its teaching. Integration into our curricula, including the preparatory school curriculum in physical education, in line with this change with the current situation the world is going through in terms of difficulties, disasters and diseases, by introducing and spreading a new culture equipped with educational technologies outside the school walls. The importance of the research is evident: by presenting an identity represented in the method of reverse teaching, training teachers to use it, encouraging them to open up to different cultures, and the extent to which these technologies are used in schools and used as a tool. For intermediate studies by supporting freedom of thought and creativity and activating the culture of citizenship that works to achieve national and social cohesion 1.

Research Problem

Unfortunately, we do not have any developmental plans to change the student’s path towards using his creative powers to build life and embrace the future. Our educational and educational institutions are still keen on the culture of silence, memory and exclusivity without qualitative transformation and raising the student’s awareness and maturity at the
level of thought, behavior and vision of life, and there is no doubt that knowing the causes of weakness and weakness. Lack of curricula or study materials is the way to suggest solutions. When we say: The prevailing paper-based curricula are incompatible with our current era, the era of information flow, how can students absorb this vast amount of knowledge resources? The research problem is illustrated by the introduction of (reverse) electronic teaching in the physical education curricula for the preparatory stage through electronic platforms and submitting it to middle schools. You will witness a digital shift in our curricula and move away from rigid ones that are not up to date\(^2\). The researcher formulated the study problem and defined it with the following question: Is it possible to introduce the flipped teaching into the physical education curricula for the middle stage from the point of view of physical education teachers in the center of Maysan governorate?

**Research aims**

1. Preparing a questionnaire form for physical education teachers about the introduction of flipped teaching in the physical education curricula for the middle stage.

2. Knowing the reverse teaching method for middle school students from the teachers’ point of view

**Limit search**

Through this research and physical education, the separation of teachers in preparatory schools at the General Administration of Education in Misan has been determined for the academic year for the period from 11/29/2020 1/7/2021 instead of the specialist’s supervision.

**Defining terms**

- Teaching is upside down: Defined it as a digital educational model that aims to use modern technologies and the Internet in a way that allows the teacher to prepare the lesson through videos or platforms\(^3\).

- Intermediate stage: well-known\(^4\).

- This stage, which aims to help students, acquire concepts and form relationships with others, takes the age stage for students to stay in or to be deported.

- Procedural definition of the intermediate stage: It is the second stage after the primary stage at the age of (13) years, we start with the first intermediate grade and end with the third intermediate grade, after which the student moves to the preparatory stage.

**Research procedures**

To achieve the research objectives, the researcher undertook the following procedures

**First: Defining the research community**

Including teachers of the research community assigned to teach physical education at the middle stage in the schools of the General Directorate of Education in Misan Governorate 20 years 20 - 2021 School.

**Second: The research sample**

The sample is that part of the community chosen according to scientific rules and methods, which is a research that represents the community within O and because of the difficulty of conducting research on all elements of the original community. The research tends to choose a molecular group that represents the best representation of the elements of society, so that it is able to generalize its results to the study population\(^5\).

Where this sample was described as follows

- The Exploratory Sample: This sample was
chosen randomly from the original community of (40) teachers and schools, and directed to them for an open questionnaire that includes the following question:

- Is it possible, in your opinion, to include flipped online teaching instead of traditional teaching in the middle school physical education lesson? «

The original sample: the number of individuals reached (60) teachers and schools that were presented to them.

**Third: Research Tool (Questionnaire)**

Questionnaire: one of the information gathering tools through which the opinions of teachers and parents are determined.

**Fourth: The validity of the tool**

It is that the scale, questionnaire, or test measures what has been confirmed. If the tool measures any behavior or trait other than the one it was prepared to measure, then it is in this case a dishonest tool.

The researcher relied on the opinions of a group of experts in the field of teaching methods in physical education, measurement and evaluation to explore their views on the validity of the paragraphs of the closed questionnaire in measuring the content that was prepared. In light of the experts’ observations and suggestions, the researcher modified the wording of some paragraphs without deleting any paragraphs. If all paragraphs obtain approval of (85%) from expert opinions.

**Fifth: the stability of the tool**

Stability means the consistency of the tool product with itself, if it is applied again or multiple times to the same individuals in this way (retest - test (one of the best methods used to find the stability of the instrument (accuracy) in this type of research is to find the correlation coefficient) that you use to recognize perseverance.

The closed questionnaire was distributed to a sample from outside the main research sample of (30) teachers, and after (15) days is the best period of time to use this method, as shown where the questionnaire was distributed again to the same sample, and after performing the statistical operations, it was found that the stability factor of the resolution was (0.83), which is a good stability factor for the tool.

**Sixth: Application of the tool**

The researcher applied the final questionnaire (0 closed) to the basic sample on 3/1/2/2020. The researcher explained how to answer the regular paragraphs, a tool for them, and after completing a closed application. Questionnaire: The researcher examined the questionnaires and then completed the answers of the sample members in special forms prepared for this purpose and on which statistical operations were performed.

**Seventh: Statistical Means**

- correlation coefficient (Pearson)
- Percentage: used to convert the frequencies in each paragraph of the questionnaire
- Weighted position
- The researcher extracted the hypothesis with which the weighted average is compared through the questionnaire scale so that it is \( (1 + 2 + 3) \div 3 = 2 \)

**Presentation and discussion of the results**

Presentation of Results: This chapter includes the results of the researcher in light of the objectives of the research by revealing the extent to which reverse teaching is employed in the physical education lesson for the preparatory stage. The repeated answers of physical education teachers were counted in the closed paragraphs of the questionnaire. Then calculate the weighted average for each paragraph and the percentage of its weight, then the paragraphs are
arranged in descending order from the highest severity to the least serious, and in the following the results are presented.

Table 1: Yes, employment in the middle stage of the physical education lesson is reversed from the teachers’ point of view, in descending order, in terms of percentage and percentage weighted

Discussing the Results

1. Table No. (1) includes a group of (30) paragraphs that represent the inverted teaching of middle school students from the viewpoint of physical education teachers. The severity of the vertebrae (weighted average) ranged between (2.91 - 1.69) and weight between (97% - 55.33%).

2. The results showed the sequence of Paragraph (3) (that the Ministry of Education can provide Internet system services to all schools) It ranked first among the negative vertebrae with a weighted average (1.66) and a weight ratio (55.33%). We also find that the state has withdrawn from driving the wheel of development in society due to unstable conditions, including the educational field. There is an absence of a vision and a political project that adopts education issues in Iraq. Perhaps the budget allocated to education in Iraq reveals the state’s lack of seriousness in providing Internet services and electronic devices to all schools, the problem of traditional culture that calls for preservation, hadiths and imitation, and the absence of a culture of criticism, creativity, dialogue and tolerance.

3. The sequence of paragraph (23) (increasing interaction between students while taking physical education lessons according to the teaching inverse) with a central weighted rate of (1.71) and weight ratio (57%) ranked second in the negative paragraphs, with the aim of starting. If the interaction prevails in the discussion room and the exchange of views between the teacher and the student and among the students themselves, we find here in the lesson outcomes through reverse teaching, the interaction between them will decrease.

4. The sequence of paragraph (5) (most physical education teachers have visions and experiences in teaching upside down) with a weighted average (1.82) (60.66%) came in third place of the negative paragraphs that do not match their responses. Physical education teachers. Where we see: Physical education teachers still have a blurry vision about inverted teaching, where the problem of stagnating the entire educational system in terms of educational content and teaching methods in Middle Eastern schools. In addition, there is teacher’s Physical education. They need skills and experience in educational technology, including flipped teaching, especially those who did not touch on online programs.

5. The sequence of paragraph (19) (there are workshops and training courses to confront teaching inverted in physical education curricula) with a weighted average (1.85) and relative weight (61.66) came fourth in the negative paragraphs. Since we do not find any kind of courses offered by the Preparation and Training Department, they are trained to face reverse electronic teaching in the physical education curricula and go that what any society goes through and social transformations require a change. The educational institution is just a cup of these shifts and changes in readiness to educate of electronic politics.

6. The paragraph came in its sequence (12) (Teaching flipped in the physical education lesson achieves creativity in educational curricula) with a weighted average (1.87) and a relative weight (62.33%) within the negative paragraphs that are not. Consistent with the responses of physical education teachers. As says: Education, in its current state in third world societies in general, allows generations of less skill, experience and knowledge, and contributes to the formation of traditional non-creative minds that are distinguished through a molecular point of view and they lack a holistic vision and thus do not possess awareness of the spirit Era and its requirements.

7. While the sequence of paragraph (21) (dispensing with physical education courses in school yards and moving towards electronic teaching) came sixth in the negative paragraphs with a weighted
average (1.89) and a weight ratio (63%) we see that the physical education lesson is a skill and an educational lesson, so it is necessary to teach directly in the boxes because it is a lesson that deals with students and corrects the wrong conditions and touches the body of the learner about how to perform the right and the right conditions, because he needs to correct the body from the wrong habits.\(^{16}\)

### Conclusions and Recommendations

#### Conclusions

The following can be concluded

- Teaching flipped (electronic) needs attention from specialists in teaching it, as well as providing supplies and internet networks for all schools.

- There are some physical education teachers who are averse to teaching flipped through electronic platforms due to their lack of experience in this field.

- There are several reasons that affect the introduction of flipped teaching in the physical education curriculum.

#### Recommendations

- Through the findings of this research, the researcher recommends the following

- The introduction of educational techniques, including the flipped teaching in the teaching of physical education.

- The diversity between online platforms and official teaching in physical education curricula.

- Physical education teachers include developmental courses in electronic technologies; in addition to that, the teacher must be an artist in communicating the course material to students.

Building and Standardizing the Location of Perceived Control of Young Footballers

Mohammed Fadhil Anber¹, Mustafa Abdulzahra Abbood², Ali Mutair Humedi³

¹Researcher, ²Lecturer, ³Prof. College of Physical Education and Sports Sciences, Misan University, Iraq

Abstract

The research aims to build and legalize the site of perceived control of young football players. The areas of research included the human field that represents football players’ clubs in Misan Youth Governorate, and defining the time zone for a period of (1/12/2020) until (10/5/2021), while the spatial domain was in the halls of the studied clubs.

The researchers used God C in a descriptive survey method, and the community research is (239) players from Misan Governorate youth football clubs, and the (SPSS) system was used to obtain the results of the research, the researchers concluded the following:

1- A tool was developed for measuring the position of perceived control in its three dimensions for young soccer players.

2- The perceptual control site scale that the researcher built and codified through the applied scientific procedures demonstrated the ability of this scale to recognize the individual differences between the players in the perceptual control site scale and its three dimensions.

3- Young players in Misan governorate have an average level in the perceptual control position variable.

The researchers recommended the following:

ü Adopting the scale as a tool to measure the psychological variable (location of perceived control in its three dimensions) for young footballers.

ü The perceptual control position measure can be used by coaches and the need to use it on players periodically during the sports season, which allows identifying this important psychological variable in competition as well as identifying the positive things that support it and the negatives to overcome and develop them with the players.

ü Conducting other similar studies according to the variables (gender, age, different sporting events).

Keywords: Young Footballers, Psychological Variable, Perceived Control Site

Introduction

The development witnessed in the world of scientific prospects and a huge information revolution that pushed people to search for new ideas, as the success of any work must depend on a set of appropriate rules and principles that depend on correct and accurate foundations and standards in the sports field in a manner commensurate with the type of sports activity. Good sports results are the result of the harmony of physical, skill, planning and psychological abilities, and achievement can only be achieved if all of the above are developed.

It is a football game that captures the interest of the people of the world at different ages, including
young people, youth and advanced, in an exciting and enjoyable way that is characterized by the games, and the world is competing with each other to determine even tournaments at various continental and international levels because football is the popular game. The first in the world, so it is receiving great interest from governments, agencies and institutions, and researchers are racing to present literature and research on this game. Everyone knows the importance of sports psychology in the process of preparation and access to achievement, which has become the mainstay in changing the results from negative to positive; Among those things that a coach should look at is the player’s control and control over the situations he is going through, and his close association with many positive outcomes such as mental health, optimism, achievement, self-esteem and adaptation.

Hence the importance of research in identifying the levels of players in this important psychological variable because it distinguishes the players among them, in addition to that it reflects the personal side of the players towards the team as a whole, which contributes to raising the level of the players. The team, because football is a team sport that needs solidarity and proper control in order for one team to reach the desired goals, as well as to be a scientific guide for the players and coaches to benefit.

Research Problem

Through the researchers’ review of many messages and theses, it was found that there is a lack of studies and research that dealt with this important psychological variable, which is the (perceived control site). The Perceived Control Site the researchers decided to study this problem by constructing and standardizing the scale and identifying the level of players in this important psychological variable; As well as to be a scientific guide to supplement the libraries and show the situation reached by the players skillfully and psychologically by extracting grades and standard levels and comparing his degree with his peers from the players and knowing his level in the future.

Research Objectives

1. Building the Perceptual Control Site Scale for Young Footballers in Misan Governorate.
2. Creating benchmark scores and levels for the Perceptual Control Position Scale for Young Footballers.
3. Recognizing the level of players in the scale of the perceived control position and its three dimensions for young football players.

Research areas

1. The human field: a player and clubs in Misan governorate in youth football
2. Spatial field: the halls of the clubs discussed
3. Field Temporal: from 1/12/2020 to (10/05/2021).

Research Methodology

The researchers used the descriptive approach in the survey approach, due to its relevance to the nature of the problem.

Community and Sample Research: All individuals, objects, or persons are the subject of the research problem, and all the elements related to the study problem are the ones that researchers seek to generalize the results of the study on (1).

The research community consisted of (239) players distributed from (12) clubs registered in the lists of the sub-federation of Misan football governorate. As for the research sample, it amounted to (200) players and they were published as follows:
A survey experience sample (15) players is higher by (6.28%), and the building of the sample included 130 players and a percentage (54.39%) of the research community, and the application of the sample included 70 players and by (29.29%) from the research community, (24) Players were eliminated with (10.04%) 2.

Means, equipment and tools used: Arab and foreign references and sources, personal interviews with experts and specialists, a personal computer (laptop) of the type (Compaq 6101), a portable electronic calculator, ballpoint pens.

Field research procedures:

Basic steps for building the scale (1):

The steps that can be followed when building a test or questionnaire are subject to many scientific steps, the most important of which are:

The purpose of building the scale: The first step to building the scale is to clearly define what purpose it is built and what it is needed for, and one of the goals of building the scale is to define the level of perceived control location of young footballers.

Determine the phenomenon to be studied: The phenomenon to be measured must be defined and its concept and limits be completely clear, and the phenomenon that the research aims to determine the location of control in the perceived range of young football players The concept of researchers for the location of perceived control of some of its dimensions (behavioral control, cognitive control, decision-making control decision) 3.

Determine the dimensions of the perceived control site scale:

See through the literature and resources on sports psychology knowledge and resources related to the specific research problem, researchers are controlling the behavioral personality theory that includes three dimensions of which he proposed (Skinner 1996), a (behavioral control, cognitive control, control over decision making) 4.

Scale dimensions validity: The dimensions of the perceived balance control site on persons with experience and competence within the competence of knowledge of sports psychology, testing and measurement and its dimensions Statement of validity, modification or suggestion of other dimensions and making any observations, all experts agree on the validity of the dimensions and with a percentage (100%) 5.

Determine the style and principles of drafting paragraphs.

The researchers adopted Likert’s method (Likert in correction of paragraphs and this method is one of the best methods of predicting behavior or phenomenon, and by reviewing the literature on the nature of the scale construction and how to formulate paragraphs and benefit from interviews with experts and specialists. Since (64) paragraphs were formulated distributed into (3). The dimensions of my devices (behavioral control (24 items), cognitive control (21 items), decision-making control (19 items) 6.

Scale Paragraphs Validity:

After preparing the scale in its initial form, which contained (64) items distributed in three dimensions, the researchers did the following:

The scale was presented in its initial form to a group of experienced and competent judges in the fields of mathematical and psychological sciences, testing and measurement. Next, the researchers analyzed the scale scores using percentage as a criterion for accepting or excluding scale elements 7. Agreed upon clauses are accepted (75%) or more of the arbitrators’ claim that they are correct and appropriate to the scale, and
(Bloom) notes, “Researchers must obtain agreement (75%) or more of the arbitrators’ opinions regarding this type of truthfulness (2), as well as Deleting the paragraphs in which the degree of (Ca₂) is calculated less than the order of the degree (Ca₂) arranged at the level (0.05) and at the temperature of freedom (1) equal to (3.84), and Table No. (1) Illustrates that ⁸.

Table (1) shows the percentage and score of Ca 2 experts’ responses in each scale paragraph

Choose the scale rating:

Appropriate grading of the scale, a group of arbitrators with experience and competence in the field of sports psychology, testing and measurement, was handed to a statement behind them in the grading scale. The arbitrators on the proposed scale agreed a rating of 100%.

Correction method for scale paragraphs:

For the purpose of obtaining the total score for each individual of the sample, appropriate weights are given to replace the scale paragraphs, and clarify the importance of the paragraphs in a gradual manner, and by collecting the respondent’s scores on the five-point classification, we obtain the total score for each individual ¹⁰, and since the scale paragraphs are formulated in the negative and positive direction. Paragraph weights were determined from (1-5) degrees for each positive paragraph and (1-5) for negative paragraphs, and Table No. (3) Shows this.

Preparation counter instructions

After the completion of the readiness to apply the scale as the first instructions for the history of business and how to respond to its paragraphs, the instructions specified that the answer to the sample intended to be used for the purpose of scientific research only will not be seen by one of the researchers, and the sample members were asked to accurately answer all the paragraphs in order to reach objective and fruitful results.

Experimental experience:

After the scale was ready for application, the researchers conducted an exploratory experiment before the final application of the research at an appropriate time, by applying it to a sample of (15) players for the purpose of finding the reasons for success when applying the main test sample and making sure that you understood the sample paragraphs of the scale, in order to avoid any errors or difficulties when applying during the main research test, researchers have done several things, namely:

1. Clarify the answer method for the individuals of the sample.

2. Knowing the difficulties faced by researchers and the assisting work team.

3. It will be a clear picture for the researcher that the assistant work team for the answers to the paragraphs of the scale.

The researchers found appropriate paragraphs, and the average time spent on answering ranged between (18-25 minutes).

Key Experience:

In conducting the main experiment, the researchers aimed to build a measure of the perceived control position in its final form on the research community, and after collecting the samples, the results were statistically analyzed to find the discriminatory strength of each paragraph in order to exclude and delete the unmarked paragraphs and find the correlation coefficient for the paragraphs, and to achieve this, the researchers applied the scale on the building sample numbered (130) players.

Statistical Analysis of Paragraphs:

1. The use of appropriate statistical methods is largely determined by the method of research design and the type of data to be collected. So:

2. Discrimination Indications:

3. The two final groups (discriminatory power):

4. It is intended to test the ability to distinguish between individuals who have a degree of personality or trait, and between individuals who have a low degree of capacity or disassociation or trait (1).

The discriminatory power is revealed by knowing the total degree of the response of the sample members, and then the models are arranged in descending order, after which two circumferential groups are selected at 27% of the total sample that was measured, a high group represented by the individuals with the highest scores, and a lower group represented by the individuals. Those with the highest score Lowest score. Then the T-Test for two independent samples is applied to determine the statistical significance of the difference between the two means - Ali from the minimum standard items promised with the value (T) calculated and evaluated) indicating the validity of paragraph (3) where the number of requests with higher scores reached (35) forms and the minimum The number of approved forms becomes (70). The W-shape from the night results shows that all the scale paragraphs are distinguished by using the Statistical Bag for the Social Sciences (SPSS), and it was found that all the scale paragraphs are distinct.
Whereas, the level of statistical significance was less than (0.05), which means that there are statistically significant differences between the upper and lower groups, and therefore all these items were approved, thus the number of scale items became (56) items.

**Internal consistency of paragraphs:**

This validity is formed by preparing a test consisting of a number of dimensions to measure a phenomenon, and the sum of the scores of these dimensions is the total score of the test, and to calculate the internal consistency of this test, the Pearson correlation coefficient for this purpose, by finding the correlation between the scores of each paragraph. The overall score of the scale, based on the responses of the research sample consisting of (130) players.

Paragraph relationship from undergraduate degree to scale:

I use the (Pearson) Bo S. A Plan pouch Statistical (SPSS) correlation coefficient between the scale items and the scale’s overall score, and it was found that all scale readings have a high direct correlation.

**Stability**

Reliability means “the extent of the apparent accuracy of the test in measuring the subject matter (1)”. The test results are consistent in preparing and approving the results of the tests. There are several methods for extracting the stability parameter, and the researchers have chosen, including:

**Alpha Cronbach method:**

To extract stability in this way, the (Alpha Cronbach) equation was applied to the scores of the sample members and their number (130) players. The value of the scale stability coefficient was (0.980), which is an indication that the test reliability coefficient is very high, and the closer the test reliability coefficient is to one. Indicate the correct one through the strength and firmness of the test (2).

**Half-split method:**

The split in half method is one of the most widely used persistence methods in paper and pencil tests. In this method, it is possible to obtain two scores for each individual by dividing the test into two halves, so that the first half includes odd numbers, and the second half includes even numbers, and accordingly we obtain two scores for each individual and the relationship between these two grades (scores of the two halves of the test) is considered as internal consistency. For the half of the test only and not for the test as a whole (3), since the Pearson correlation coefficient was (0.822) and in order to obtain the value of the reliability coefficient for the entire scale, the researchers used the Spearman - Brown equation, using the statistical bag (SPSS), and its value reached (0.902), which is Indicator of the gauge’s stability.

**Objectivity:**

The researchers consider that clear instructions and a model for how to answer, as well as clarity of statements, ease of interpretation, multiple answer alternatives, and the exclusion of questionnaires in which the answer is repeated for the same paragraph or where the answer is not completed in all paragraphs, all this makes answering the paragraphs of the scale a goal.
The scale in its final form:

Sample scale completed by Perceptual Control site

**Discussion of the Site Perceptual Control Scale:**

It is clear to us from Table No. (6) that the arithmetic mean of the research sample reached (187.67), which is at the average level, and as shown in Table No. (7), which is greater than the default average of (168), while the value of (t) is calculated (6.249) and at the level of significance 0.00), which is less than the level of significance (0.05). This indicates the existence of statistically significant differences between the two arguments and the arithmetic introduction in favor of the arithmetic mean of the research sample.

The researcher attributes these differences to the youth players’ ability to control their behavioral and cognitive behavior and even decision-making, since the youth stage is an important stage of life, and they transform during periods of time from one category to another. This puts them up to greater challenges to grasp as they go along. With them time was more mature and conscious; Despite this, they need to think of new ways and methods of building their futures, which make them more knowledgeable and knowledgeable about their life. The perceived control in this stage (the stage of youth) is of great importance through the regulation of the situations and duties of daily life, and it is one of the characteristics that distinguish the owners of organized thinking, as well as their ability in how to shape their future. The goals and setting the appropriate means to achieve them that make them able to face the difficulties or tasks that need to be managed in a distinct and effective manner, how to keep up with that and take the appropriate decision, and draw a picture of the required duty according to their abilities and capabilities in order to determine adaptation to the current situation by changing themselves. Or they change the environment around them for that.

Young people at this stage are more aware and aware of their capabilities and ideas to achieve the goals they aspire to achieve, and they have the ability to control and perceive life and its conditions by developing their ideas, beliefs and abilities to achieve positive results in order to realize the multiple options available to them and evaluate their potential and their ability to draw a vision of what is possible and this He agrees with the study which asserts that “young people have the ability to control their actions and choose what is best for them and feel responsible for what they adds, however, that perceived control is a relatively accurate assessment of their ability the individual’s actual control over life conditions and response to life events.
Conclusions

1- It was found to build a tool for measuring perceived locus of control in its three dimensions for young footballers.

2- It was reached to extract scores and record levels for the three-dimensional perceived control position scale for young footballers as a scientific guide for coaches and players to take advantage of.

3- The perceptual control site scale, which the researcher built and standardized through the followed scientific procedures, indicates the ability of this scale to identify individual differences between the players in the perceptual control site scale and its three dimensions.

4- Young players in Misan governorate have an average level in the perceptual control position variable.

Recommendations

1- Adoption of the perceptual control locus scale for young football players.

2- Coaches can use the perceptive control attitude measure and the need to use it on players periodically during the sports season, which allows identifying this important psychological variable in competition, as well as identifying positive and negative things to overcome in personal areas. Players’ preference and development.

3- Conducting other similar studies according to the variables (gender, age, different sporting events).

The Effect of Sudden Weight Loss During Competitions For Young Weightlifters in (RMR) and the Concentration of (Sodium-Potassium) Salts in the Blood

Natiq Abdulrahman Werytha Allami¹, Waritha Al-Lami²

¹Associate Professor, ²Researcher, College of Physical Education and Sports Sciences, Misan University, Iraq

Abstract

The study aimed to identify the level of the weight difference between young weightlifters when a sudden drop occurred during the competition period, to identify the level of (RMRF) difference in the concentration of salts (sodium - potassium) in their blood during this period, and to identify the effect, relationship and contribution of sudden weight loss during this period. The period of competition in (RMR) and the concentration of (sodium potassium-) salts in their blood, and they adopted the descriptive method of relational relations on weightlifting youth (18) - 20 years under the weight category 69 kg were chosen randomly and (20) weight lifter, as That the number of those who lost weight unapproved is (12) weightlifters make up the percentage (22.917%) from the origin of their community. Fitmate pro) at rest time after weight loss, at rest time after weight loss, and withdrawing (5 cc) of blood every before and after intentional weight loss to measure sodium and potassium cytokine by laboratory examination, and the researcher verified that the data were processed by the cyst system Statistical Abstract (SPSS) for conclusions and extrapolations Bikat that the process of sudden weight loss is associated with a negative relationship in the level of (RMR) and the concentration of salts (sodium - potassium) in the blood, and affects and contributes to reducing the levels of young Al Rafi ‘i for weightlifting during the competition period, and it is necessary to nurture the coaches to support the culture of the ideal weight and the true athlete of the youth of Al Rafei to lift Weights, as can be the coaches who influence them a lot. To prevent sudden weight loss disorder, they should reduce this phenomenon, which can easily cause eating disorders, as can those in charge of men’s tournaments. Agement at the local weightlifting association and its training, providing advice to the youth eye class on the unhealthy DONC weight loss, if there are no other professionals who can intervene (physiologists, doctors ... and others), it is necessary for the basic trainers to have the information. Correct information about the risks of eating disorders in sport and to be fully aware of the symptoms and consequences, to be able to act and build a level of preventive discoveries for the relevant predictions and to take the necessary steps when these problems arise, and whoever learns adequately about nutrition supervises the diet and gives Lempid tips to reduce Weight healthily for the prevention and treatment of eating disorders and counseling (for example, when an athlete needs to lose a kilo or more of body weight).

Keywords: Weight Loss, Young Weightlifters, Treatment, Concentration

The Research Problem and Its Importance

Most of the youth’s ideas revolve around in general practice, about to be, and a little less weight, especially the weightlifters for them to compete, which merged this reality with the diet of modern day pressures that civilization has created today, and those around them to victims of beauty. The socially imposed models, and that many of them are dissatisfied with the shape and weight of their bodies, although this fact does not expect weight disorders in the future according to what weight loss regimes bring, but it effectively contributes to the emergence of dietary
disorder factors in sport, this fact calls for Reconsidering the education of sports nutrition for those who exercise to be an essential element in evaluating food habits and means of losing weight, especially sudden before the race, as the term disorders refer to the sudden weight that some individuals suffer Eating disorders by eating too little quantities of foods forcefully to the point that it puts them at risk to their health or life, and other neglect. O eat frequently, can take risky actions; To get rid of the calories consumed as studies and scientific research have proven that health and proper nutrition are not only responsible for the formation and building of the body but they play an important role in guiding society and morals. And the intellectual behavior of the individual, and direct evidence of the quality of life, and indirect evidence of the extent of social and economic development of the importance of proper nutrition. In normal growth and optimal mental development in the health and health of the patient, and the maintenance of good health throughout a person’s life, where weight-loss disorders are defined by the presence of distorted attitudes and behaviors rooted in eating, weight and obesity, or as a compulsive eating misuse with the aim of achieving a desired type of psychology. It is also known as disorders represented in the presence of wrong behaviors towards eating in an unusual way in an attempt to reach a certain shape of the body or to participate in competitive programs that depend on a certain weight, and some mental illnesses appear as well as some organic diseases that lead to death. The development of today’s world is always affected by the advancement of new technologies, as a clear spread scenario has recently started, which is an ideal scenario for preventing sudden weight loss disorders in websites that cover these matters depending on the results of the benefit, and can be used to inform athletes about the dangers. Associated with poor nutrition or diet, which is the result of anxiety about weight and physical appearance, as well as in the case of dissatisfaction with weight and body shape, although this fact does not expect eating disorders in the future according to what has been done of weight loss regimens, but it contributes in a way. Effective in the emergence of disorders of weight-loss factors in sports, and this fact calls for a review of sports nutrition education. For those who participate in training and providers to compete to be a necessary component of assessing dietary habits. As is the case in this particular era, the report of young athletes begins to continue their sporting activity in a more serious way, and to continue training and competing in dangerous environments, and this fact is in contrast to what some studies have produced results, and this call to direct coaches and parents to Encouraging healthy eating and different habits because they most influence the prevention of such a disorder. Which will definitely lead to a decrease in the level of training and competition as well, it is imperative for coaches to recognize the fact that they have the correct information about the risks of disruptions to losing weight in sport and to be fully aware of the symptoms. The results to be able to act and build a preventive level discovers the relevant predictions, and applies the necessary steps when these issues show weakness in PDM including the thoughtful and non-specialist lifting of views, and is characterized by the jumping and jumping weightlifters that they are the most athletes who have the ability to provide a stock of phosphorus creative from other athletes. (Theodore and Michael), as is the process of weight loss, it is the reduction of weight lifter weights from the normal average in a deliberate and intentional manner in order to make all players ready to compete in the higher weight, and this process often takes place in sports with a single bout, where the weight plays The body plays a major role in achieving results like weight lifting. In the context of sports and in this particular era, young athletes begin to report that they continue their sporting activity in a more serious way,
and to continue training and competing in these truly dangerous environments, in contrast to what came with the results of some studies, as participation in the activity. The normal is associated with a high degree of approval of a person's body shape and then comparing it with non-athletes, in order to maintain a high degree of control in this case, the achievements and level of the athlete must be taken into account, and in an interesting investigation with adolescents, we concluded that the messages from parents predicting the strength of both strategies for losing weight. Among the children more than the media, and the best of friends, as it is known that the source of my energy, the human being is the food intake, which consists of the head of carbon, hydrogen and oxygen as well as nitrogen in the case of Protina T, and it is known in the number of food that these bonds are weak, and therefore they only provide (Molecular bonds) as well as to bind the limited molecular thread when broken down, and thus the energy stored in food is chemically dissolved inside the cells of the body and stored on the body an energy-rich compound called adenosine triphosphate (ATP), which turns into (ADP) in the metabolism processes, then ended up transformed into (ADP), a charge recycled again to become a high-energy ATP, that food is important for athletes in sports that emphasized the importance of lightening body shape or weight and reducing eating. As far as possible within levels of exposure to disorders and in these cases prevention of sudden weight loss that can actually appear in the athletic field, it is necessary to understand the significance of these types of weight and their number related to each other. The researcher believes that it is certain that any sudden case of body mass for a weightlifter will cast its evidence on the cell physiology, composition and effectiveness of the elements and minerals in which there is a kind of disorder that calls for a balance and avoids the risks of blocking the body to cause the type of compatibility between the internal environment and the requirements of the external environment are from The duties of this body in this new situation in which the weight is unbalanced and the imposition of chemical changes on the state of the body, and the means of ridding the body of excess weight is in fact the process is not in the amount of fat because burning it in a short or limited period of time is a difficult process, so the loss is in relation to For fluids that come out of the body through urination and intense sweating, or in abnormal physiological conditions, where sodium, potassium and chlorine are linked to each other by you will see the interconnection relationship between their functions in the body, and each depends on the other to become complementary functions of utmost importance in general and for athletes who they lift it not particularly foul, becoming human sodium chloride and potassium chloride. The body needs (8-15 grams of sodium chloride per day, (3-4) turbid potassium chloride, and this amount increases, when practicing training. The importance of the availability of potassium and sodium in it is responsible for the absorption of E. The absorption of sugars in the
The intestine, which is responsible for the contraction of muscles, supports the amount of water inside the cells of the body, and regulates the acids in the intestine blood and various body fluids. The role of sodium helps in maintaining blood pressure at normal levels and supports neuromuscular work and regulates fluid balance in the body, and the normal level of sodium ranges. Blood between (135-145) milliliters is equivalent to a liter of plate D, hyponatremia occurs when the level of sodium in the blood falls below (135) milliequivalent/liter (RAA - Renin Angiotensin Aldosteron System). Sodium consumption and potassium excretion by the kidneys. Therefore, the increased secretion of one of these substances (renin, angiotensin, and aldosterone) leads to the excretion of excessive amounts of potassium from the kidneys, which in turn leads to a lack of potassium in the blood, which causes weakness and muscle pain. Muscle weakness. In more difficult cases, failure of the face may occur. Respiratory bladder due to weakened breathing muscles, and abnormalities in the ventricular rhythm of the heart, where there is a living substance in the form of positively charged ions and it actively contributes to the catabolism and synthesis of proteins and carbohydrates, and the regulation of fluid movement in the body, the regulation of blood pressure and body fluids. Al-Baalouji or the graduation muscle with the effectiveness of the carpenter’s hand to produce the required strength for competition in the sport of weightlifting. The required proportions must be of the availability of mineral elements, salt and metabolic efficiency, and the sudden weight loss process during the period of the lifter competition for youth weightlifting effects that must be studied academically to avoid risks that may occur. On this cat of athletes, through the work of an academic researcher in the physiology of sports training and as a specialized trainer for the youth category, he noted that weightlifters had to resort to this process that requires delving into some of the accompanying effects that may occur to them in the short term. The research aims to determine the level of the weight difference between young weightlifters when a sudden drop occurs during the competition period. And to know the level of difference (RMR) and the concentration of salts (potassium-sodium-). In the blood of young claimants in weightlifting in a surprising and irreducible duration, and to identify the effect of the relationship and the contribution to sudden weight loss. During the RMRF competition period, the concentration of salts (sodium-potassium) in the blood of young weightlifters.

**Research Methodology**

In this type of research, the ethics of scientific research dictates that a person should not suffer some kind of health harm by the experience. For this reason, I adopt the descriptive approach in studying the problem as it is to clarify the related relationships, by adopting relational studies from this descriptive approach, which is defined as the research that seeks to try to define the relationship between two or more.

**Research and Designated Community**

The limits of the research community for weightlifting represented the youth (18-20) years of age between (69-77-85 kg) with a total of (48) lifters because they represent a phenomenon observed by the community in the research problem of themselves, as they compete in championships. Clubs and institutions set up by the Iraqi Central Weightlifting Federation at Tameem Hall in Baghdad late (2020) officially registered within the youth category. A sample of (69) weight class was purchased randomly (20) weight lifter, and the number of those who lost unaccredited weight is (11) weight lifter. (22.917%) of their original community, and this is a phenomenon that requires a number of field study and important calls.
Measurement tests and research procedures

The specificity of the study required knowing the weight difference (mass) for each weight lifter because before the deliberate reduction of its weight and after to measure the values of this quantitative difference are influenced by an electronic unit balance of the kilogram and its weight. The components, according to the RMR measurement) by the Italian Fitmate pro system (COSMED) made of a respirator with a chest strap with a (Bluetooth) pulse device at rest time before weight loss, and at rest time after weight loss to extract quantitative values of the RMR difference), and (5 cubic centimeters) of blood from each lifter was withdrawn before and after the intentional weight loss, and each of them was placed in a tube (1.5) mL with added (1000 μl) of RBC solution by means of tests. Lab for both sodium and potassium to extract quantitative values for this difference as well. These differences are matched by each of the tests for examining each lifter for measurements of the difference in weight (mass) resulting from the sudden decrease in diuretics that these young men take from the lifters and with that, and after collecting data for each verification of the weightlifter the researcher can completely process the data Statistical Package System (SPSS) version (V 26) Elijah extracted each of the values of percentage, central arithmetic mean, standard deviation, single-eye (t-test) test, linear (regression) coefficient (linear correlation coefficient), contribution ratio, error criterion evaluation, and test (F) Corresponding quality, tilt test (influence) (T) your mind of linear regression.

Signal level (0.05) N = 11 significant (t) values if (Sig)> (0.05)

The results of the negative contribution decrease and the Thayer difference sudden weight loss for the rest of the variables surveyed were valid, as the greater the weight difference decreases during the competition period, the greater the difference caused by both sodium, potassium and average. From cellular metabolism at rest, and this result is a decrease in the stress of the events of the weightlifter, which is supposed to support its performance in producing the energy required for you in terms of energy, and the negative impact caused by the nervous overreach required for that. Muscular action also abolishes this imbalance that leads to harm to the contraction process if these results are scrutinized. The first effects of such a mechanism are according to its impossible interpretations, especially the mechanical
interpretation, which requires its availability. The energy required for protein sliding chains to shrink muscles, leading to increased weight of the lifter, the negative effect on wasting muscle strength gain by stressing the mechanism that contracts the muscles responsible for lifting, and it is also assumed that standard training will have a positive effect in creating positive and healthy adaptations for the weightlifter to prepare To participate in competitions while he is in a state of physiological adaptation. Positive, not vice versa, when you lose weight suddenly, this is like a loss of coaches’ efforts and a decrease in the level of effectiveness rather than progress, which leads to a decline in the professional level that it is hoped that they will be able to do so. The international move to reach the tournaments of the Olympics and in this only entrenched case they have false beliefs about sudden weight loss that they will resort to other quick ways and means to reach the lead regardless of the cost of the matter in terms of damage. On their bodies, and this goes against the Olympic Ideology Charter in competitive sports that place health and safety as a priority.

Since changes in attitudes and behavior require reduced risk in terms of sports according to the prevalence of eating disorders, these changes about athletes should not be directed only but rather extend to a social context, they serve in the opposite culture and an environment surrounding a thousand answers, as young people lack the skills The mentalities to overcome these changes, and some of them within the social nature do not have enough experience to know how to help them do so during this transitional time. Judy, 2007) and (Driskell) Mineral salts help in preserving the internal environment and in the formation of many tissues and to show the need for them because they give strength and vitality and help many vital functions during the motor work of the body ... and keeping muscle contraction during motor performance is crucial with minimal stress. Stress on the joint during movement and increase muscle contraction with a negative performance, and this serves the arena of players more than others and in the field and a faster rate of work. In muscles, they must be equipped with (ATP), and a biochemist believes that fatigue occurs due to the ineffectiveness of energy processing for (ATP) and it is fast in the use of muscles 16, as potassium, sodium and magnesium work to regulate the acid-base balance within the muscle cell and require compensation, to maintain high physical activity, which results in chemical reactions that increase as well as its role in regulating the pressure of insects 17. Potassium is also an important mineral for the heart muscles and has a direct role in lowering blood pressure, and the action of potassium is closely related to the action of magnesium in the body, as it works. To relax muscles, which helps to regulate the cellular regulatory mechanism through this action, the lost sodium level from the blood must also be maintained. At the normal level, because the increase and decrease in its concentration in the blood is inversely proportional to the blood and vice versa, as is its role in regulating the permeability of perforation of the cell membrane 18. The importance of sodium availability and avoiding its deficiency or impairment in neurotransmission causes the release of the peripheral plate that drives the neurotransmitter Acetyl Kolayn, which is the specialized connecting nerve between the nerve end and the muscle fibers (neuromuscular forum) and binds to the receptor for the my fiber sheath acetylcholine , Which is the reason for the opening of the sodium channels, it leads to the influx of sodium into the muscle fibers, which leads to the depolarization of the membrane, so the effect of the instruction applies to the length of the sarcoplasmic muscle fibers in both directions and below the membranous joints and leads to a complete contraction of the muscle fibers, sending the instructions to the sites where the links are located. The membrane adjacent to the sarcoplasmic
reticulum (FR) the latter causes the release of calcium (temporarily the calcium ion) and the sarcoplasm releases a calcium concentration that rises above 10a (μM), this is the lowest level that begins to form cross bridges as previously described. Then the active calcium pump continuously returns the calcium to the grid. Sarcoplasmic (usually in the range of 30 °C) ms and when the calcium concentration in the sarcoplasm becomes too low, it inhibits terbomycin again, and this chain is repeated when another motor neuron stimulus reaches the plate from the moving limb, and at a high burst frequency, the calcium ions persist in Escape from the sarcoplasmic reticulum, and the calcium concentration in the sarcoplasm that surrounds capillaries greatly increases. In this condition, the muscle fibers do not completely rest between the stimulation and the successive contraction and will be stronger and more stable (somewhat) until the stimulation of the nerve stops. This deficiency in sodium and potassium concentrations will lead to a loss (acclimatization) in the individual, and an adaptation to physiological compensation that lasts for days or weeks as a result of an external factor change or internal environmental factors. To damage endogenous homeostasis responses (local equilibrium responses), which are another set of reflections of responses other than actions, when a change occurs in the internal environment or the external environment, this change is in an alert state and this stimulus causes a change in cellular activity town as a result of the final control of Stimulation, so that this E. responds like all electronic responses that start and end with a response, but differs from other responses (reflexive action) in that they only occur in the stimulus region. Special adaptations must occur in the biochemical muscle in training the specialist with the difficulty experienced by the athlete. Proper nutrition and weight loss programs should go hand in hand with athletic training goals, which during high exertions naturally increase RMRs during exertion and this, is reflected in the increase in the rest of the time and this requires muscles Able to maintain chemical content balance. It is the duty of coaches to notice sudden changes in young people who play sports that require muscle strength and should quickly view it as a kind of continuous evaluation of their planning for their future. The lack of water and fluids from inside the body leads to decreased plasma volume, which leads to a decrease or decrease (stroke volume, cardiac impulse, and hypotension). A study also showed that low serum sodium intake indicates access to this salt and in such cases, a lack of serum sodium leads to a loss of water, which is the clearest, and a rapid body weight loss is evident. What is known is that when the mind is stored from carbohydrates during a violent muscular effort, the body begins to represent the stored fatty substances, and this leads to the oxidation of large amounts of fatty acids, which increases the formation of other (ketones). Acids that increase the acidity of the blood, so the abuse of alkaline salts such as citrate has a benefit in removing this acidity to a large extent, and among the natural substances that contain abundant substances, citrate is citrus and lemon in particular. Where weight disorders lead to eating disorders are extreme attitudes and behaviors related to eating and weight, and in the form of anorexia or bulimia nervosa, which reflects psychological and physiological problems that can have devastating effects, and severe consequences on the lives of those who suffer.

Conclusions and applications

1. The process of sudden weight loss is associated with a negative relationship in the level of (RMRF) salt concentration (sodium-potassium) in the blood, which affects and contributes to reducing the levels of young weightlifters during the period of competition.

2. The need to pay attention to coaches to support the culture of the true ideal athlete who has
the leverage for weightlifting youth, as coaches can influence them a lot to prevent sudden weight loss disorder in them to reduce this. Which can easily cause nutritional disruptions, and tournament administrators at the local weightlifting federation and their training can advise young eyes that Wayne should go to lose weight. But DONC is unhealthy. If there are no other specialists who can intervene (physiologists, doctors ... and others), it is necessary and basic trainers to have the correct information about the risks of eating disorders in sport and for Dr. Preventive detects relevant predictions and applies confidential appearance steps when these problems arise, and who learns adequate nutrition to be a nutritional supervisor and provides advice on healthy weight loss methods to prevent and treat eating disorders and a counselor for example (when an athlete needs to lose a kilo then of His body weight).

**Ethical Clearance:** People identified as potential research participants because of their status as relatives or carers of patient’s research participants by virtue of their professional role in the university and departments.

The Effect of Human Resource Management Practice on Sharing Tacit Knowledge of Managers an Applied Study on Misan Center for Cardiac Diseases and Surgery

Soulaf Abdalqadir Hameed Alsady

Research Scholar Department of Nursing, College of Nursing, Misan University, Iraq

Abstract
The aim of the research is to identify the impact of human resource management practices used on the exchange of tacit knowledge, which were represented in each of (the practice of recruitment, selection and appointment, training practice, and the practice of motivation). The management of human resources is an effectiveness on which the future strategy of the organization depends, since previous decades, strong companies were those companies that possessed machines, technology and materials where the human element was insignificant and was treated as machines without taking into account its potential, feelings, development and capabilities, witnessing the economic market An accelerated daily development, and through this, the important role played by the human resources department in raising the performance of employees is evident, as it provides the specialized and efficient human element that affects the organization and its performance. The main objective of this research is to indicate the effect of human resource management practices on the sharing of implicit knowledge of managers, as well as to explain the importance of implicit knowledge in employee formation in reaching executive positions in a business organization. The topic of knowledge management has received great attention all over the world by academics, including writers, researchers, and executives from managers and officials, due to the economic and competitive advantages this practice achieves, bearing in mind that the most important goal of this research revolves around the business organization. It is one of the most important keys to the success of the organization, and thus it is a source of competitive advantage and its importance is widely accepted at the present time. Therefore, many individuals in executive positions acknowledge that knowledge creation has an important role in their companies. The trend towards knowledge management began in the 1990s, when companies are now being urged to consider knowledge creation as a source of success, because the tremendous benefit that knowledge management promises is innovation.

Keywords: Human Resource, Management Practice, Knowledge, Business Organization

Introduction
We live today in an era in which crises abound as a result of changes and openness to the world and thus the employees and managers of institutions in the contemporary environment have no choice but to think and act in a strategic way ¹. Numerous at the global and Arab level, and the practice of human resource management is one of the most important management concepts that have gained attention and spread in recent years. Knowledge management processes are of great importance in business organizations and the health sector by providing competitive advantages, but most organizations face challenges in managing and developing tacit knowledge and converting it into explicit, tacit knowledge refers to knowledge stored in the human mind, such as good things, skills and ideas, and represents an urgent necessity to ensure the success of organizations and individuals in general and tacit knowledge represents one of the types of knowledge in addition to explicit knowledge ².
**Research problem**

The health sector - like other aspects of human activity - is witnessing an unprecedented stage of change, as it has become difficult to predict the future, and human resource management practices have become an effective means of honesty and maintaining movement in the right direction. It is an ongoing process. Based on the above, it becomes clear that the impact of the human resource management practice on the exchange of tacit knowledge, in order to achieve the desired development, and to face the successive societal changes such as globalization, communications revolution, technological revolution, and for this reason the research problem can be crystallized in the following questions:

1- What is the concept of human resource management practices, and what is the terminology associated with it?

2- Implicit knowledge and its dimensions?

3- Dimensions of human resource management practices?

4- The concept of tacit knowledge?

**Research objectives:**

The research seeks to achieve the following objectives:

1- Understand the concept of human resource management practices, and what terminology is associated with it?

2- Clarify the reality of applying human resource management practices in the health sector.

3- Standing on the dimensions of implicit knowledge.

4- Determine the importance of human resources.

5- Determine the justification for the introduction of human resources in the health sector.

6- Applying a questionnaire on the impact of human resource management practices on the sharing of implicit knowledge of managers.

**Research hypothesis**

The first main hypothesis: This states that there is a moral correlation between the practice of human resource management and the tacit knowledge.

\[ H: \text{There is no significant correlation between HRM practice and tacit knowledge.} \]

\[ H_1: \text{There is a significant correlation between the human resource management practice and the tacit knowledge.} \]

The second main hypothesis: which states that there is a significant moral effect between the practice of human resource management and the tacit knowledge?

\[ H_0: \text{There is no effect between HRM practice and tacit knowledge.} \]

\[ H_1: \text{There is an effect between the practice of human resource management and the tacit knowledge.} \]

**The importance of research**

The importance of this research stems from the importance of human resources, which is the main and important resource capable of achieving the goals of the organization, especially in light of the intensification of competition and the rapid environmental changes that are imposed on organizations to keep pace with them constantly. The importance of this research is evident in identifying the impact of the practice of human resource management on the exchange of knowledge implicit in managers. Nor does it show the role of tacit knowledge present in the minds of experts and its role in developing procedures for
securing facilities, and that it represents an important source and reference for building future plans, and a key factor in developing procedures for securing the health sector, and this is based on feedback and using it in filling gaps and addressing errors that were exploited in previous operations.

**The importance of the current research is crystallized in:**

Ø The current research may open new vistas in the field of human resource management; As it is considered an extension of previous studies in the field of human resource management practices in the health sector, and at the same time it is a prelude to other new studies.

Ø The current research may benefit both the competent authorities in the health sector and its institutions, and those responsible for its administration; as it contributes to crystallizing the concept of human resource and its importance ... etc.

**Research community and sample**

The research sample is represented by the Misan Center for Cardiac Diseases and Surgery, and since the aim of the current research is to know the relationship and effect of the practice of human resources management on the implicit knowledge of managers, so the research is directed to the community being represented by everyone who occupies administrative positions (general manager, assistant director, head of department Division director, unit official, lounge official, ward official, counseling officials, pharmacy officials) who have the authority to make decisions, as the study population reached (177).

**Research variables**

The search variables are as follows:

1. The independent variable: the human resource management practice that includes the dimensions (recruitment and selection, training and development, incentives, compensation).

2. Dependent variable: Tacit knowledge

**The theoretical model for research**

The research is based on a theoretical framework indicating the nature of the objective of the current research, which is to determine the effect of the human resource management practice on the exchange of implicit knowledge of managers at Misan Center for Cardiac Diseases and Surgery, and to test the influential relationships between the practice of human resources as an independent variable on the implicit knowledge as a dependent variable, as illustrated by it. The following figure:
Methodology

Human Resources Management Practices

It is a group of activities that would put human resources strategies into practice and are directed towards improving performance. Human resource management practice is the process of attracting, motivating and retaining employees to ensure the survival of the organization. Human resource management practices are designed and implemented in a way in which employee performance plays an important role in achieving the goals of the organization, and the proper use of human resource management practices positively affects the level of commitment of the employer and the employee. Human resource management practices such as training, development and performance evaluation encourage employees to work better in order to achieve organizational performance. The practices selected for this research depend on the impact of human resource management practices on the sharing of implicit knowledge of managers. Human resource management (HRM) is a managerial function concerned with recruiting, motivating and maintaining people in an organization, focusing on people in organizations, policies and practices involved in implementing “people” or human aspects of resources for a management position, including recruitment, screening, training, and reward from the Human Resources Department. In short, human resource management (HRM) can be defined as the art of purchasing, developing and maintaining an efficient workforce to achieve the goals of the organization in an effective manner. The Human Resources Department works to direct all activities and events in the organization to achieve optimal use of the human resources in the organization and contribute to achieving the organization’s goals such as attracting, selecting, appointing, wages and incentives to meet its needs of human resources in terms of quantity and quality.

The importance of practicing human resource management

Behind the success of every successful organization stands a successful human resource management in its programs, whether these programs are within the framework of selecting individuals, training them, evaluating their performance, maintaining and retaining them, or through good programs for rewards and incentives, so there is a strong correlation between the success of the organization and its programs human resources.

Dimensions of the practice of human resources management

Recruitment and selection

The recruitment process is one of the most important jobs that the human resources department in the organization must accomplish. Success in that determines the course of career activities in the organization. The essence of the recruitment process is related to attracting the largest possible number of qualified individuals and encouraging them to submit job applications in companies to allow the company to choose and appoint the most efficient individuals. Polarization can be defined as the discovery of potential applicants to fill actual or anticipated organizational vacancies, and the sources of polarization have been identified with two main sources (internal polarization and external polarization).

Training and Development

Training is defined as that organized and continuous process that aims to provide and acquire the individual with new knowledge, capabilities and skills, and training is an investment in the human assets of the organization, so training is a useful means with the changes that are sponsored by technological innovations, as training and development constitute three main activities. Training, Education, and
Development. Training and development in general refers to the organized efforts that contribute to teaching job-related knowledge, skills and employee behavior, and it is also a knowledge system for human resources in the organization and developing their current skills.

**Incentives**

The existence of an effective incentive system applied in the organization is considered one of the most important components of a successful and effective work environment, and the importance of an effective incentive system is highlighted in that it mainly contributes to raising the morale of workers, developing their loyalty to the facility and making them feel stable and secure, and incentives were defined as the process of activating the reality of working individuals in ways positive or negative, with the aim of increasing production rates and improving performance, and satisfying their material and moral needs.

**Compensation**

Compensation relates to compensation of the employee with all kinds of wages or returns that he obtains in connection with working a certain job, and these compensation include two basic elements, namely, direct financial payments, which may take the form of wages, salaries, incentives, and indirect financial payments, which take the form of financial benefits such as insurances and paid leave (2007). As the information resulting from the job analysis process allows estimating the size and quality of compensation that is commensurate with the characteristics of each job and helps in assessing the relative importance of this compensation for all jobs in the organization.

**Tacit knowledge**

It is knowledge acquired through the accumulation of previous experiences and it is present in the minds of individuals, and it is often of a personal nature, which is difficult to obtain despite its great value because it is stored within the mind of the owner of knowledge. (Coakes) believes that tacit knowledge contains important cognitive dimensions such as (mental models, beliefs, and intuition), and therefore this type of knowledge is generated through the use of past experience in new contexts.

The knowledge implicit in consists of:

1- Hard facts, data, and mental patterns.
2- Views, shapes, images and concepts.
3- Judgments, expectations, general assumptions and beliefs.
4- Thinking strategies, and theological approaches.

Tacit knowledge is subjective and circumstantial and its implementation requires overlap and coordination, and thus the more implicit knowledge is, the more difficult it is to transfer and share and knowledge possesses an important implicit dimension, which makes the processes of studying about it, obtaining, transferring, storing and exchanging it difficult and sometimes impossible to achieve. There are controversial relations between the two types of explicit and implicit knowledge, as much of the implicit knowledge is affected by what is available to its owners of explicit knowledge, and the latter is due in its origins to the tacit knowledge that its owners decided to release and declare, as it is also a partial product of that knowledge. The first (implicit), when declared, contributes to forming the second (explicit). Tell can we than more know we” This phrase sheds light on the fact that many human knowledge and skills remain implicit and unregistered until the owner takes them out, so they do not appear and cannot be employed or defined except through dialogue and discussion, and this is what is considered the greatest
challenges in Knowledge management applications for modern organizations that strive towards excellence.

**Dimensions of tacit knowledge**

The dimensions of tacit knowledge are represented by experience, thinking and skill, in a way that gives a clear meaning to the tacit knowledge that relates to people and their intellectual perceptions rather than acquiring the knowledge they need.

**Expertise** - is the accumulated knowledge over time and experience with all facts, rules and procedures in a specific field of work. The experience is due to the technical dimension of knowledge, which is knowing how, which is the knowledge accumulated over the course of a person’s life that he has acquired through his exposure to many situations and his learning from them. There are two approaches to interpreting the experience. During his work in a specific field, the second is seen as a feature of individuals and is a result of the human capacity for widespread adaptation in the physical and social environment.

**Thinking** - Thinking is defined as the ability to perceive various alternatives to deal with the problem. It is also a series of mental processes that the brain performs when it is exposed to a stimulus that is received through one of the five senses.

**Skill** - Skill is the level of personal merit in accomplishing tasks from the point of view, while sees it as the tacit knowledge that is embodied in multiple forms. If the organization embraces this skill, it will generate a logical feeling for decision-making.

Attributes or characteristics of implicit knowledge (Al-Otaibi is a source previously mentioned)

1- Composition and accumulation complex.

2- It cannot be shared, shared or stored.

3- Self-configuring.

4- You can direct the behavior individually only.

**Nonaka and Takushi SECI model**

The cycle of knowledge developed by Nonaka and his colleagues, known for short as the (SECI) cycle, and this model assumes that individuals create their knowledge through the interaction between explicit knowledge and their tacit knowledge.

Knowledge passes through the process of its quantitative and qualitative expansion through four stages, namely:

1- The stage of socialization - the process that takes place through the creation of tacit knowledge through the exchange of experiences, ideas and skills among individuals.

2- The externalization stage - meaning the transformation of tacit knowledge into explicit knowledge, in a form that is easy to share with others.

3- The combination phase - which is the process of converting explicit knowledge into a more complex form.

4- The internalization phase - is the stage that individuals give to knowledge.

The explicit and transforming it into tacit knowledge through practice or learning by doing, and it is done through self-education.

**The role of learning in developing tacit knowledge of human resources**

Education, both formal and informal, contributes to the development of tacit knowledge of human resources by enriching all components of its dimensions. However, informal education has some peculiarities that are available in it and are not available in formal education (training), as follows:

1- In the field of friction with competencies:
Individuals interact with each other according to team spirit, and they learn from each other some necessary knowledge, skills and behaviors. Therefore, the institution’s management is responsible for providing the appropriate climate for its members in order to guarantee them learning (direct or indirect) through Good selection of team members and taking into account the balance between them in knowledge levels.

2- The field of ability to transfer implicit knowledge: Nonaka and Takeshi presented a model for knowledge transfer within the organization, and the various processes related to tacit knowledge are manifested in:

Input: transferring explicit to implicit knowledge, by means of learning by doing.

Output: transferring knowledge from implicit to explicit by modeling or codifying that knowledge.

Sublimation: transferring knowledge from implicit to implicit through social interaction and discussions between individuals.

3- In the area of skill: The skill is known by some as synonymous with tacit knowledge, as the contact of individuals with varying levels of skills would contribute to the transfer of skills from an efficient person to an incompetent person.

4- In the field of knowledge application: The culture that encourages human resources, which is embodied in the evaluation of what the individual has learned inside and outside the work of implicit knowledge related to work.

A practical framework for research

First: Description of the study sample

Study sample:

The sample of the study included an applied study on the Misan Center for Cardiology and Cardiac Surgery, where (180) questionnaires were distributed to an employee, and (177) questionnaires were retrieved.

Sample collection method:

The researcher used the simple random sample method in distributing the questionnaire forms to employees on the assumption that the community is homogeneous. Therefore, the researcher used the simple random sample, and then the appropriate sample was drawn, as the sample size reached (177) employees, which represented the study population.

Statistical indicators:

In the statistical analysis, the researcher relied on the data and information obtained from the research according to the Likert five-point scale, and the researcher used the most important statistical indicators to fit the research hypotheses and questions related to it, which are as follows:

1- Frequencies and percentages: to find out the number and percentage of respondents within the research sample.

2- The weighted arithmetic mean: It is used to find out the degree of agreement of the questioned sample to the questions.

3- Standard deviation: It is used to find out the extent of dispersion of the answers of the researched sample from the degree of approval.

4- Person correlation coefficient: It is used to measure the extent to which the research variables are related to each other and to determine the type of relationship whether it is positive (positive) or opposite (negative).

5- F test: It is used to find out the presence of an effect of the independent variables in the search on the dependent variable.
6- Regression equation: It is used to find out the effect of the independent variable on the dependent variable.

**Notice**

The significance value (sig.) was adopted in testing the research hypotheses instead of the tabular values for the accuracy of the results calculated from the significant value (sig.). It should be noted here that all these indicators were calculated by the Statistical Package for Social Sciences (SPSS V26) program 16.

Second: The demographic variables of the research: It shows a description of the demographic variables of the individuals of the research sample

<table>
<thead>
<tr>
<th>Table No. (1) Frequencies and percentages of demographic variables for the research</th>

We note in Table (1) the following:
With regard to the period of job experience in research, where the frequency of the category (3-6) years was the highest, reaching (64) with a rate of (36%). With regard to the level of education in the research, the highest frequency of university qualification was (51) by (28%). With regard to the field of work in research, the frequency of the highest was in the field of director, reaching (56) by (31%) 17.

Third: Description and diagnosis of research variables

This paragraph includes a description of the main study variables and their diagnosis represented by the practice of human resources management as an independent axis and tacit knowledge as an approved focus in the research. To achieve this, appropriate statistical analyzes were used 18.

Arithmetic means and standard deviations of the sample responses for human resource management practice

Table No. (2) Below describes the research variables for the practice of human resources management

<td>0.872362</td>
</tr>
</tbody>
</table>
The results of Table No. (2) indicate that the practice of human resources management has obtained a general arithmetic mean of (4.1525) and a standard deviation (0.872362), and this indicates the homogeneity of the sample answers about the value of the arithmetic mean. This axis, which is (there is a diversity in the types of training), is the most homogeneous, as it obtained an average (4.4500) and a standard deviation of (0.30534) and that the direction of this paragraph is (agree), and the general trend in the practice of human resources management is (agree) 19.

The arithmetic mean and standard deviations of the sample responses for implicit knowledge

**Table No. (3) Below describes the variables of the special research implicit knowledge**

<table>
<thead>
<tr>

<td>8</td>
</tr>
<tr>
<td>The overall average</td>
<td></td>
</tr>
</tbody>
</table>

The results of Table No. (2) indicate that the implicit knowledge has obtained a general arithmetic mean of (3.8359) and a standard deviation (1.160973), and this indicates the homogeneity of the sample answers about the value of the arithmetic mean, and as for the paragraphs level, paragraph No. (5) Came in this dimension. Which is (the provision of systems and technologies that allow workers to share what knowledge they possess) is the most homogeneous, as it obtained an average (4.3200) and a standard deviation of (1.07457), and the direction of this paragraph is (agree), and the general trend of implicit knowledge is (agree) 20.

**Third: Testing the hypotheses**

**The first main hypothesis test:** which states that there is a significant correlation between the practice of human resource management and the tacit knowledge?

H0: There is no significant correlation between
HRM practice and tacit knowledge.

H1: There is a significant correlation between the human resource management practice and the tacit knowledge.

Table (4) represents the correlation relationship

<table>
<thead>
<tr>
<th>Correlations</th>
<th>Tacit knowledge</th>
</tr>
</thead>

<td>N</td>
</tr>
</tbody>
</table>

**. Correlation is significant at the 0.01 level (2-tailed).

Table No. (4) Indicates the existence of a significant correlation between the practice of human resources management and the knowledge implicit in the research, where the value of the Pearson correlation coefficient was significant and equal to (0.720), because the significant value is sig. It is equal to (0.001) and it is less than 0.01 with 99% confidence. This means that the first main hypothesis is fulfilled, meaning there is a significant correlation between the human resource management practice and the implicit knowledge.

The second main hypothesis test: This states that there is a significant effect between the practice of human resources management and the tacit knowledge.

H0: There is no effect between HRM practice and tacit knowledge.

H1: There is an effect between human resource management practice and tacit knowledge ²¹.

Table No. (5) Represents a schedule for analysis of variance

</tr>
</tbody>
</table>

a. Predictors: (Constant), Human resource management practice

b. Dependent Variable: Tacit knowledge
The results of the F test indicate the presence of the impact of the human resource management practice and the tacit knowledge shown in Table (4) that the calculated F value reached (37,622) at a significant level (0.05) where the P-value was equal to (0.000), which is less than 0.05 this means rejecting the null hypothesis and accepting the alternative hypothesis, and this means that there is an impact of human resource management practice and tacit knowledge.

Table No. (5) Represents the impact of human resource management practice and implicit knowledge

<table>

Table No. (5) Indicates that the value of R² is equal to (0.437). This means that the practice of human resources management has explained (43.7%) of the changes that occur in the implicit knowledge, and the values of B = (0.670) that is, the increase in the variable of the resource management practice Humanity one unit of standard deviations will increase the implicit knowledge by 67% of the standard deviation unit.

Conclusions and Recommendations

Conclusions:

1- There is a lot of confusion between information and implicit knowledge management, which causes confusion.

2- In order to raise the efficiency of workers in the management of human resources, it is necessary to create what helps them in the completion of their work.

3- Job experience is the highest in the research community, and the level of education comes second after it.

Recommendations

1- Urging the spread and learning of tacit knowledge, its empowerment and action.

2- Creating activities in Misan Center for Cardiac Surgery and Diseases related to public relations in order to coordinate work and ideas to enable knowledge.

3- The need for health institutions to realize the importance of the role that human resources management plays and to work on developing it.
through developing the capabilities and capabilities of workers.

4. Motivation of human resources, taking into account the difference in individual skills and abilities, as material stimulation will be an important incentive for better performance.

5. There is a close correlation between the practice of human resources management in all its dimensions as a practice of human resources strategy and the implicit knowledge.

6. Conducting a study on human resource management practices and their role in achieving institutional excellence.

The Effect of Mental Maps on Creative Abilities in Learning the Two Skills of Correction from High Jumping and Shooting Accuracy with Hand Ball

Yasser Mohsen Aliwi¹, Wissam Qais Khazal²

¹Lecturer, ²Teaching Assistant Misan Education Directorate Department, Ministry of Education, Iraq

Abstract

Mind maps are one of the modern means of expressing ideas through symbols and shapes, and it is one of the techniques used in the art of teaching and education through the use of mental skills in the transfer of external stimuli that are formulated to the inner world. The brain (nervous system) and thus stimulating the processes of remembering, creativity and thinking, it is a successful method for the teacher and the student, as the teacher uses it to convey the idea and the student uses it for memory and memorization. It is also a great model for increasing the common senses in the learning process. Hence the researchers formulated the problem with the following question: Do the exercises prepared by the researchers using the mind mapping method develop my creativity and learn my corrective skills from high jumping and accurate handball? One of the aims of the research is to prepare exercises according to mental maps to teach high jump correction skills and accuracy of shooting with handball to school students. The research also assumes that there are differences between the tests and measurements of pre and dimensions in the creative abilities and learning the skills of correction of high jump and accuracy in manual shooting for the two experimental and control in favor of the meta-tests. The researchers used an experimental Lee approach on a sample of Yeh fringe students. The most important finding of the researchers is that prepared exercises, formulation and application contribute to the development of creativity among school students. They added that the mind mapping strategy is better than the traditional method through research results in the creative abilities and basic skills under study.

Keywords: Hand Ball, High Jumping, Shooting Accuracy, Witnessing

Introduction

The world is now witnessing a tremendous development beyond its imagination, and this development is the result of great efforts in which everything new has been used at the level of educational technologies and the possibility of using the human mind in dealing with it in all differences. Including the educational field, which has now become one of the fields that give an impression on the progress of countries and their progress, so it was necessary to conduct a lot of studies and research in order to achieve progress in the use of modern educational methods and through solving the problems facing this progress, as it is noticed that countries the applicant spends huge sums in order to access everything new and developed to achieve the best ways to use modern technologies in the educational process and that this development did not stop at a specific category, but it included all academic groups from the primary level to the university level, which are maps that represent the symbols and shapes that the basic pillars of the art of teaching and education are formed by transferring those external stimuli that have been formulated to the inner world, the brain (nervous system), which stimulates the processes of memory, creativity and thinking, as it is a method of memorization.
information in memory in a manner consistent with the memory pattern the man (190: 2) The physical and skill levels of handball players and mental abilities all affect performance and winning in matches, and that the skill and physical and mental familiarity and how to employ them to reach the top in performance has become an important element for winning and its development through training and training, which made the trend in the study of capabilities Mental control to control it in other abilities and determine its results, hence the importance of searching for numbers for a set of exercises based on the method of mental maps, raising creative abilities and teaching the two skills of correction for high jumping and accuracy of shooting with the hand ball.

**Research Problem**

The researchers pointed out that the process of learning skills in the game of handball, especially correction, requires repeated training and condemnation, and it is not an easy skill, especially among students, and therefore requires diversity in education and training techniques and finding modern alternatives as well as attention to the factor of individual differences, in accordance with their abilities and capabilities. Physically and mentally, which drives them to seriously participate in the educational process, as well as search for all new methods and means that develop and develop the learner’s ability to use his mind and thinking in order to learn new skills in the best way. The researchers also indicated that there is a weakness in the use of modern methods such as mind maps, which are considered one of the strategies that rely on drawing everything you want on one sheet in an organized way, where words are replaced by drawings. Refer to it in a concise, beautiful and easy to remember, and it helps to develop ideas about a topic in an easy, organized and artistic way that simulates the work of the brain, develops thinking skills and stimulates creativity and the learner. The desire to learn the educational material because it delivers the joy of learning the researchers also believe that the exercises that are formulated should take me into consideration considering how they contribute to the development of creative abilities in addition to discovering learners and their future readiness in any type of activities, as well as tests in creativity abilities that did not occupy enough space, and from here the researchers formulated the problem with the question Next (Do exercises prepared by researchers using the mind mapping method develop my creativity and learn my skills in correction from high jumping and accurate handball shooting).

**Research Objectives**

1. Preparation exercises in accordance with the mental maps to teach the skills of the correction of the high jump and precision correction roller hand for middle school students marginal.

2. Identify the differences between pre and dimensional tests and measurements in creative abilities and learn the two correction skills of high jumping and the accuracy of shooting with hand ball for the experimental and control groups.

3. Identify the differences in tests and dimensional measurements in creative abilities and learn some basic handball skills between the experimental and control groups.

**Research hypotheses**

1. There are differences between the pre- and post-tests and measurements in the creative abilities and learning some basic hand reel skills for the experimental and control groups and for the benefit of the post tests.

2. There are differences in the tests and dimensional measurements in the creative abilities and learning of some basic handball skills between
the experimental and control groups and in favor of the experimental 9.

Research areas

- Field of human: a sample of medium students’ marginal b for boys in the province of Misan.
- Spatial area: Hall Square and middle school marginal b.

Research Methodology

The experimental approach was chosen by designing the equivalent groups for its suitability to solve the research problem and its objectives

Research community and sample

A research community for middle and marginal students was identified in Yahya Governorate, Maysan Governorate, for the academic year 2019. 135 students were selected. Two sections were selected from each section (15). Any sample that was taken was (30) and the sample was divided by (22.22%) into two groups, where each section represents one group, which is the experimental group and the second the control group. The researchers did not need to perform the homogenization process, as the research sample was not from the specialist players, but rather a raw sample of the same age and school stage, so the conditions for homogeneity were provided 10.

Defining tools for measuring research variables

Tests and measures used in the research

First: Creative Capabilities

After reviewing the sources and references, the researchers chose the Creative Abilities Scale translated by Sayed Khairallah, 1974 (5: 123)

Second: The tests used in the research

1- Test the technical performance of the shooting skill from high jump.

- Name of the test: Technical performance of the skill of shooting from high jump.

- The objective of the test: - Evaluating the technical performance of the shooting skill from jumping high: 175.7

- Tools used: Legal handball court (3) legal hand balls. A pre-prepared evaluation form.

- Performance specifications: The test student performs the correction skill by jumping high from a point located on a right angle with the middle of the goal line and 10 meters away from it. The laboratory is given three consecutive attempts to perform the skill.

- Registration: Each laboratory student is granted three consecutive attempts, the best assignment for each evaluator is calculated, and after that the arithmetic mean of the best three attempts of the three evaluators is calculated. Note, “The final score for the evaluation is (10) degrees, as shown in Figure

Figure (1) The technical performance evaluation test demonstrates the skill of shooting high through the handball
2- Accuracy test of high jump aiming skill.

- Name of the test: Test of the accuracy of the skill of shooting from high jump: (175,7)

- The objective of the test: To measure the accuracy of the correction from jumping high with the handball.

- Tools used: Legal handball court. Legal handballs, count (6) Pre-prepared evaluation form. - Squares accuracy (60 cm - 60 cm)

- Performance specifications: The test student performs the correction skill by jumping high at a point located at a right angle with the middle of the goal line and a distance of (10 m) and the correction is done by jumping high with taking three steps and from a distance of (10) meters where the correction is done on the square The right, then the left square

- Registration: Each laboratory student is awarded six consecutive attempts, counting the number of successful and failed attempts recorded by the laboratory student. Note that the maximum score for evaluation is (6) scores, as shown in Figure (2)

![Diagram of high jump aiming skill](image)

Figure 2: The precision evaluation test demonstrates «high jump scoring skill» with handball

Pre-exams

The researchers over two days on 13-12/ 15/2020, and in at ten Saba Ha Square and in the middle school marginal b tests tribal research sample group experimental and control, as follows: On the first day were tested and measured in the experimental group:

A measure of creative abilities

The two shooting skills of jumping high and the accuracy of shooting with hand ball. On the second day, the control group was tested in the same place, timing and verse used for the experimental group.

Educational curriculum (experimental variable)

After reviewing the sources and references, the researchers formulated the exercises in the content of the educational curriculum according to the mental maps, and arranged the mechanism of the
mental maps strategy in a way that includes first the educational section, which is the teacher explanation. The skill clearly and accurately for all its stages and its division in detail as well as the presentation of the model in the performance near the ideal and then the use of students who are able to implement the skill correctly, and includes the use of mental presentation. Maps prepared by researchers that were hung on the walls and yard of the school throughout the education period. In addition, students were assigned, starting with the third unit of each skill, to draw different mental maps of the acquired skills to familiarize students and teach them how to plan their minds as well as anchoring information in the student’s mind. Attempt to fix the information. Moreover, the researchers gave students an incomplete mind map of a certain part so that they would be asked to complete the missing part. The practical side, which lasted for 25 minutes, included the application of all that the student had learned in the educational aspect, in addition to the accompanying performance notes. The two researchers took several points in implementing its educational approach, namely:

1. The main research experiment was carried out on 11/11/2019 until 2/9/2020
2. The educational curriculum was implemented for a period of 12 weeks, at a rate of (2) educational units per week, and the total number is (24)
3. As (8) educational units were allocated for each skill.
4. The time of one educational unit is (45) minutes, in which the introduction and warm-up time is (10) minutes
5. The educational section time (10) minutes
6. The applied section time is 25 minutes

Note that the only variable between the control and experimental groups is only the applied section, as the experimental group implements the educational curriculum prepared by the researchers and the control group, it implements the educational curriculum of the (traditional) teacher, while the rest of the sections are similar to the two groups.

**Dimensional tests**

Researchers after the end of the educational variable over two days on 14-15/2/2020, and in at ten in the morning of and in the yard middle school marginal b tests tribal research sample group experimental and control, as follows: On the first day were tested and measured the experimental group in:

1. A measure of creative abilities
2. The two correction skills of high jumping and accurate shooting with hand ball.

In the second, the control group was tested with the same place, timing and verse followed for the experimental group.

The researchers also tried to simulate the conditions in the post-tests with the pre-tests.

**Statistical methods: (6: 335)**

The researchers used a set of statistical methods

)The arithmetic mean - a standard deviation - coefficient of variation -T For correlated and non-correlated samples(

**Chapter Three: Presentation, Analysis and Discussion of Results**

**Presentation and analysis of results**

Presenting the results of tests and measurements of pre and dimensional creative abilities, the two correction skills of high jumping and the accuracy of shooting with hand ball for the experimental and control groups:

It appears from the table that there are significant differences between the post-tests and in favor of the experimental group.

Discussion and Analysis of the results of the tests and measurements of tribal and dimensionality of creative abilities and the skills of voting by jumping high and the accuracy of the correction experimental and control groups:

The researcher attributed the reason for the difference, disparity, progress and differences that occur in the experimental group in the creative abilities and skills of jumping shooting and the accuracy of correction in the dimensional tests to the educational method tests based on mental maps and exercises carried out in them. And the characteristics it contains that enable learners to understand and interact with the teacher quickly. Increased alerts about solution finding, engagement and exploration in learning the skills he receives from the teacher. It also helps them increase their cognitive abilities so that it will facilitate them to perform mental operations and apply them in the practical side (12: 167). The researchers also attributed the improvement and higher level of learning to the skills under study. The use of mental maps that increase the motivation and desire of the
learners due to the use of images, colors, shapes and written texts, which is a modern method that raises the individual learner to explore and track them to improve the state of learning and motivate students. The internal motivation plays a crucial role in the creativity process, because it stems from the inside of a specific goal. It shows the desire for research, knowledge, and a feeling of happiness in discovering reality and giving new ideas. Researchers consistent with what was indicated by Wissam Salah: “A study that increases the clarity of the skill and the method of learning it, in addition to increasing the ability to remember, in short and not branching, nor are you limited to presenting facts but rather than relationships. Between facts and this achieves meaningful learning” (14: 105). This is in agreement with a study confirming that the use of graphics and images in the mind map makes the learning process easier, as pictures and drawings represent a large part of memory, so it is easy for one to remember the mental map. The control that depends on the traditional method of the teacher showed some differences while other variables did not occur. The researchers attribute this to the nature of the traditional curriculum and the method of explanation in it for the educational department, and the method of the applied department is the other that allows and helps in progress, but within relative limits due to the old method and method. Reduces student interaction and not actually utilizing lesson time as in the experimental group. Therefore, the mind mapping strategy requires the student to be able to think about how the diagrams are formed and thus get a complete idea of the pain. Which helps to learn the skill better and this strategy is one of the new and unconventional strategies, which leads to an increase in learners’ desire and enthusiasm for learning while eliminating their boredom factor, as well as the presence of drawings and Pictures and colors that increase learners’ interest and thus help them learn. As this method of learning raises alerts to more than one sense among the learners, including the use of modern technologies such as the plasma device, which increases mental processes such as attention and focus and confirm that the use of more than one sense during learning has an effect. Effective in the learning process (8: 134). The researchers also attributed the reason for the difference and the disparity in the results of the two groups of research to the fact that the educational curriculum and the sequential exercises that they prepared from easy to difficult. Repetition and method of performance also contributed to increasing the effectiveness of learning basic skills. Emphasized: “It is necessary to focus on the implementation of the educational activity from the lesson using modern methods to repeat the task of the movement and its training, in addition to making the most of the implementation time in the lesson and achieving more effectiveness. (89: 8) Handball is a game. Their performance requires mastering all basic skills, whether physical, skill or planning, in order to succeed in the offensive plans in place and thus score more points that lead to winning matches, and these requirements depend on the existence of a sufficient number of physical numbers for the players. The close connection between physical attributes and skilled performance is what leads the team to optimal performance and achieving the best levels and under the most difficult circumstances, and we note that these physical characteristics are explosive power, speed, flexibility and accuracy. Sports training depend on raising the efficiency of the functional body organs through the internal load that will lead to the adaptation of the body systems and the acceptance of the load. Handball confirms interest in the principle of using pressure (training load) and rest properly, when given high pressure or high training load, adequate positive rest periods must be provided for the purpose of restoring the nervous system the ability to function through the sensory receptors as well as “to save energy.
The researchers agree with what pointed out that (determining the training load depends on knowledge of the basic power supply system) (1998, (75)). The sample has a clear difference in the explosive force variable of the arm and its connection to the good performance of the shooting skill, and the researchers also noted that some players had physical requirements for better performance than others, and there are some players who have good performance with high technology and thus lead to achieving points, which formed a clear picture for the researchers of the relationship between these requirements and the shape of the performance and the end of the movement is one of the important factors in achieving a high score in the test, which leads us to say that these two matters require emphasis and training. Equally and with different intensities to stabilize the performance form and access the performance mechanism, researchers agree with what he indicated. The basic motor skills of the game are the backbone of the training process at the present time, as it is difficult to correct errors later on, and the unskilled player cannot “control the ball E and its movements”.

**Conclusions**

1. The prepared exercises and their formulation and application contribute to the development of students’ creative abilities

2. The mind map strategy is better than the traditional method through the research results in the creativity and shooting skills of high jumping and shooting accuracy

3. The use of mental maps in the learning process reduced the wasted time and shortened time in the learning process in learning the skills of correction and accuracy.

**Recommendations**

1. Emphasis on the application of the mental maps method in learning correction and accuracy in handball.

2. It is necessary to emphasize in formulating exercises how to use them to develop creative capabilities.

3. You must choose the appropriate method and method with the mental, age and physical stage of the learners, to make use of time fruitfully.

4. The necessity of creating the educational environment with the capabilities and tools necessary to implement the mental maps strategy.

5. Conducting similar studies to develop mental processes, motor abilities and intelligence, using the mental mapping strategy.

Effectiveness of Antenatal Educational Guidelines on Maternity Nurse’s Performance

Samah Abd Elhaleim Said1, Amira Mohammed Salama1, Hemmat Mostafe Elbana1

1Assistant Professor of Obstetrics and Woman’s Health Nursing. Faculty of Nursing, Benha University, Egypt.

Abstract

Antenatal care is a detailed, systematic examination and follow-up of pregnant female that includes education, counseling, monitoring and therapy to address and treat minor issues and provide appropriate screening during pregnancy. Aim of the study: Evaluate Antenatal education guidelines’ effectiveness on maternity nurses’ performance (Knowledge and Practice). Design: A quasi-experimental design (pre-test-post-test). Setting: study was conducted in obstetric skill lab of faculty of nursing, Benha university. Sample: A purposive sample was used to recruit 140 maternity nurses from Maternal and child health centers at kalioubia governorate. Tools: two data collection tools: A self-administered questionnaire sheet and an observational practice checklist. Results: Highly statistically significant improvement in maternity nurse’s knowledge score, it changed from 51.4% to 85% at post-intervention. Maternity nurses’ practice mean score was satisfactory improved, as the mean score increased from 56.4% to 82.1% at the post-intervention phase. Highly positive correlation between total nurse’s knowledge and practice score regarding antenatal care was found. Conclusion: Provision of antenatal educational guidelines helped strengthen the awareness and practice of maternity nurses on the various aspects of the antenatal period. Recommendations: The care of pregnant women should be an integral part of the educational curriculum for nursing students.

Keywords: Antenatal care, Educational guidelines, maternity Nurses’ performance, pregnant women, Misconceptions.

Introduction

The antenatal period is considered one of the most stressful events in every woman’s life. It is often associated with some complications and diseases that may threaten the mother and baby’s life. Hence, antenatal care is very important to ensure a healthy baby’s delivery from a healthy mother and reduce maternal and fetal morbidity and mortality (1).

The key aim of antenatal care is to reduce child and maternal mortality rates. (ANC) is pregnant women’s support for safe pregnancy and healthy infants. ANC is essential to healthy motherhood, but its use varies widely. ANC is potentially one of the most successful health strategies to prevent maternal morbidity and mortality, especially where women’s overall health status is low (2). Education is an essential component of prenatal care, particularly in the 1st time pregnancy (3).

Regular interaction during pregnancy with nurses or midwives enables women to access services vital to women’s health. In order to minimize perinatal mortality and improve the experience of women in treatment, the World Health Organization (WHO) recommends a minimum of eight antenatal care contacts. However, important measures can be given at prescribed intervals over four visits, at least for
healthy women without any underlying health issues (4).

Preventing unwanted pregnancy outcomes depends on an organizational continuum of service before and during pregnancy, childbirth, and the postnatal period, with affordable, high-quality care. It also relies on the assistance available to help pregnant women access facilities, particularly when complications arise. The reliable ANC is an essential element in this continuum of treatment. The purpose of the ANC plan is to prepare for birth and parenthood and to avoid, recognize, mitigate or treat the three forms of pregnancy health problems that affect mothers and babies (5).

In the advancement of reproductive health, maternal health services have a potentially important role. The use of health care is related to availability, efficiency, cost of services, social structures, health values, and personal characteristics. Every year, over half a million women die from pregnancy or childbirth complications. Most maternal deaths occur during childbirth, and these numbers could be significantly decreased by the involvement of skilled medical professionals (6).

Behaviors related to the health of their patients, the awareness and practices of health professionals, especially maternity nurses, have an important role. During pregnancy, this effect can be much greater since there is regular interaction between women and health providers during periodic prenatal visits. These professionals will serve as health promoters when educated, assisted, and inspired (7).

Nurses play a major role in helping the pregnant woman to achieve the goal of optimal health through ongoing assessment and education so, Awareness and qualification of the practitioners participating in the care process must be raised, so that the requisite technical and scientific information is coupled with the dedication to a satisfactory health care outcome (8).

Significance of the study:

There is no more tragic situation as a mother loses her life when she gives life to her baby. Millions of women in developing countries are unable to receive antenatal care for a variety of factors. This results in increased maternal and newborn mortality and morbidity rate. The world health organization estimated that 4.3 million fetal deaths occur before or during delivery due to poorly managed pregnancies and delivery (9).

There is exceptionally high maternal mortality. In 2017, nearly 295,000 women died during and after pregnancy and childbirth. In low-resource environments, the vast majority of these deaths (94 percent) occurred, and most could have been avoided. Approximately 86 percent (254,000) of the reported global maternal deaths in 2017 were in Sub-Saharan Africa and Southern Asia. Sub-Saharan Africa alone accounted for about two-thirds (196,000) of maternal deaths, whereas approximately one-fifth (196,000) of maternal deaths were in Southern Asia (58,000) (9).

The maternal mortality rate in Upper Egypt is higher than in Lower Egypt (74-61 percent), according to the Egyptian Ministry of Health. In addition, post-partum hemorrhage (19.7 percent) is the most common cause of maternal mortality in Egypt, while cardiovascular disease (16 percent) is the most common indirect cause (1400 women and 50 percent of their newborns die each year in Egypt due to complications of pregnancy and childbirth). MMR is still high in Egypt according to global standards, so more efforts should be made (10).

The available Egyptian research that measures the satisfaction of women with prenatal care obtained from primary health care centers of various aspects of standard of care reported that sixty percent of mothers were very low or low satisfied with the data they
received during prenatal care (11).

Current study was carried out to evaluate maternity nurses’ knowledge and practices regarding antenatal care, design, implement and evaluate guidelines focusing on pregnant women’s health promotion.

**Aims of the Study**

The present study aimed to evaluate the effectiveness of antenatal education guidelines on maternity nurse’s performance (Knowledge and Attitude) through:

- Assessing nurses’ knowledge and practice about antenatal care.
- Designing and implementing an educational guideline for nurses to improve their knowledge and practice regarding antenatal care.
- Evaluating the effect of an educational guideline on maternity nurse’s knowledge and practice of antenatal nursing care.

**Research hypothesis:**

Maternity nurses who receive antenatal educational guidelines will exhibit an improvement in their knowledge and practice regarding antenatal care after intervention than before.

**Subjects and method:**

**Design:** A quasi-experimental design (pre & post-test) single group. The beginning was in January (2020) to the end of September (2020)

**Setting:** study was conducted in obstetric skill lab of faculty of nursing, benha university.

**Sample:** A purposive sample of 140 maternity nurses from 25% of the total 185 maternal and child health centers at kalioubia governorate. They were randomly selected. **Extracted from the research project.**

**Tools:** two data collection tools were used:

**Tool I: Self-administered questionnaire sheet:**

After reviewing current and related national and international literature, the researcher constructed this tool. It consisted of two parts:

**Part one:** Personal and socio-demographic data.

**Part two:** Assessment of maternity nurses’ knowledge regarding pregnant women’s antenatal care included three sections.

**Section (1):** Knowledge about nursing care during antenatal care included five items (the concept of antenatal care, antenatal care objectives, and the principle of antenatal care, first visit procedure, and follow-up appointments).

**Section (2):** Knowledge about pregnancy included nine items (symptoms of confirmation pregnancy, early signs of pregnancy, investigation required for pregnant women, vaccinations required during pregnancy, minor discomfort and danger signs during pregnancy, the group at risk during pregnancy, physiological and psychological changes during pregnancy).

**Section (3):** Knowledge about health education during antenatal care included 12 items (health education about the importance of nutrition, essential elements for pregnant women and fetus, exercise, reduce fatigue, sleep, clothes, occupation during pregnancy, sexual relationship, personal hygiene, taking medication, travel during pregnancy and preparation for breastfeeding.)

**Scoring:** When the answer was completely correct, each item was scored as (2), a score (1) was given when the answer was not completely correct, and a score (0) was given when the answer was incorrect. The overall knowledge score was categorized as follows:
-Inadequate knowledge: < 60% of total knowledge score.

Adequate knowledge: ≥60% of total knowledge score.

**Tool II: Practice Observational checklist:** The researcher designed this tool after reviewing related literature (12) to assess the practice of maternity nurses during antenatal care: it was included seven sections (history taking, physical, abdominal examination-uterine fundus, auscultation of fetal heart rate, urine analysis, and breast care).

**Scoring:** Each item was scored as (0) for not done and (1) for done. Then adding up the scores of the items in each procedure and the overall scores gave practice score. Total practice score was classified as the following: -

- Incompetent practice < 75% of total practice score.

- Competent practice ≥75% of total practice score.

**Supportive material :-( Arabic Leaflet booklet)**

The researcher designed the educational guideline in the Arabic language supported by figures after reviewing related literature. It included two theoretical and four practical parts. The theoretical part, the concept of antenatal care, antenatal care objectives, and the principle of antenatal care, first visit procedure and follow-up appointments, investigation required for pregnant women, discuss pregnancy’ signs and symptoms, and minor discomfort of pregnancy. Vaccinations required during pregnancy, minor discomfort and danger signs during pregnancy, group at risk during pregnancy, physiological and psychological changes during pregnancy the basic elements of the requirements of a pregnant woman and fetus while the practical part explained the procedure’s nurses need to take care of women during the antenatal period, such as history taking, abdominal examination, auscultation of fetal heart rate, urine analysis, and breast care and so on.

**Tools Validity**

By presenting the questionnaire to five maternity nursing experts, the tool validity was tested by face validity and asked them to read it and assess the content in terms of whether it represents the principles intended to test and to decide its readability and consistency in order to achieve a consensus on the best method to be implemented. The required adjustment was done in the form of some questions being added and omitted.

**Reliability:**

The test-retest was replicated on two occasions on the same sample of maternity nurses and then the findings were compared. The Cronbach alpha coefficient for the knowledge questionnaire was 0.7 and 0.82 for practice.

**Pilot study:**

After designing instruments, a pilot study was performed on 10 percent of the studied subjects (14) maternity nurses. It was aimed at determining the tools’ usability and clarity. It also helped to predict the time required for the forms to be filled in. As no change was done, participants of the pilot study was included in our sample.

**Fieldwork:** Maternity nurses were recruited and followed-up from the beginning of January (2020) to the end of September (2020), completing nine months. From 9 am to 2 pm, two days weekly, until the previous predetermined sample size, the researchers attended the pre-mentioned study setting. Written permission was obtained from the predetermined institutional authority of health centers prior to conducting the research. After that, the researchers introduced themselves to women and told them of the purpose of this study in order to obtain their
approval and cooperation. Data confidentiality was ensured to gain the trust and confidence of women. The researchers designed and created the various data collection instruments, developed the materials for antenatal educational guidelines, and updated them by maternity nursing and obstetric medicine experts. Data collection included two periods: pre-test and post-test periods; data from pregnant nurses was collected in the pre-test. At the same time, after applying educational guidelines, the researchers initiated the intervention and assessed them immediately. Data collection was carried out in four phases: the assessment phase, the planning phase, the implementation phase and the evaluation phase.

1- Pre-implementation phase (Initial assessment):
   A. Interviewing Phase:

   This phase encompassed interviewing to collect personal and socio-demographic data and maternity nurses’ knowledge regarding antenatal care of pregnant women. It was used two times (pre-post-test). The questionnaire (pre-test) self-administered to each maternity nurse individually. It was directed in simple Arabic language, and answers were recorded immediately. The researchers greeted the maternity nurse, introduced themselves to each maternity nurse included in the study, explained the study’s purpose, and explained how to fill the tools accurately after obtaining their acceptance to share in the study. The tools of data collection required approximately (15-25 minutes).

   A- Practice observational checklist: It was filled by the researchers using an observational checklist for pregnant women’s antenatal care to assess maternity nurses’ practice pre implementing educational guidelines. The checklist was used two times (pre-post-test). The maternity nurses were unaware that they were being observed. Each observation sheet was filled immediately while observing the maternity nurse when performing the procedure. The average time needed to complete each observational checklist took about (30 – 45) minutes.

   **Planning phase:**

   The researchers developed the educational guidelines based on the interview sheet results from the pilot study, assessment phase (pre-test) and review the related literature. Identified needs, requirements and weaknesses were translated into educational guidelines’ goals and objectives. The educational guidelines’ contents were selected based on identified needs about knowledge and practice regarding antenatal care. Different teaching strategies and methods were chosen to fit small group discussion. An objective of the educational guidelines was to improve knowledge and practices for maternity nurses regarding antenatal care.

   **Implementation phase:**

   The theoretical and practical parts of educational guidelines were discussed and demonstrated through group discussion sessions. The researchers conduct six sessions (two theoretical sessions, the duration of each session was ranged from 30-45 minutes, including periods of discussion according to nurses’ achievement and feedback followed by four practical sessions, and the duration of each session was ranged from 45-60 minutes included) used for each group. Nurses have been split into small groups (10-14 nurses/session). Each group perceived the content of the educational guidelines using the same teaching strategies and handouts. The total number of groups was (10 groups) and the total time for achieving the educational guideline was (6 hours) for each group under the study.

   - **First theoretical session:** concerned with introducing the theoretical part of the educational guidelines and provided nurses with general knowledge about pregnancy.
- **Second theoretical session**: started with feedback about the previous session and an introduction to the new session’s objective. The researcher then provided nurses with knowledge about nursing care during antenatal care and health education provided during antenatal care. At the end of the session, the researchers allowed nurses to ask questions and provided a discussion period.

- **Third practical session**: It implied the implementation of the practical part of the educational guidelines for all antenatal care cases and concerned with training nurses regarding history taking and physical examination.

- **Fourth practical session**: started with feedback and re-demonstration of the previous session and introducing the new session’s objectives. Then the researchers demonstrated the procedure abdominal examination.

- **Fifth practical session**: included re-demonstration of previous procedures and demonstration Auscultation of fetal heart rate.

- **Sixth practical session**: included re-demonstration of previous procedures and demonstrating auscultation of heart rate and urine analysis for albumin and sugar and breast care.

**Evaluation phase:**

The educational guideline’s effect was assessed using the same format of tools used before implementing the educational guideline tool I theoretical session and tool II practical parts (pre-test). An immediate evaluation was conducted after implementing the educational guidelines to evaluate nurses’ knowledge gain and practical skills.

**Data Analysis**

Data was summarized and analyzed using statistical package for social sciences (SPSS) software, version 20. Frequency distribution for categorical variables was used for their description. means with standard deviations was used for continuous variables description. To measure tool reliability, Cronbach’s alpha was used.

**Results**

Discussion

Pregnancy is a crucial time for promoting good habits and parenting abilities. Strong antenatal care (ANC) integrates the mother and the family of women with the formal health system, improves the likelihood of using a trained birth attendant and leads to good health across the life cycle. Insufficient support during pregnancy breaks a vital connection in the continuum of care and impacts women and infants alike (WHO)\(^{(9)}\).

The present study aimed to evaluate the effectiveness of antenatal educational guidelines on maternity nurses’ performance (knowledge & practice). The present study results significantly proved the research hypothesis that an educational guideline help improving maternity nurses’ knowledge and practice regarding antenatal care.

The current study’s findings were discussed in the following four sections: Section I: shows the socio-demographic characteristics. Section II: related to mean score of nurses’ knowledge regarding antenatal care of pregnant women. Section III: related to mean score of nurses’ practice related to antenatal care of pregnant women, and Section IV: represent the correlation between total knowledge and practice among studied maternity nurses pre and post-application of educational guidelines.

Regarding socio-demographic characteristics, the present study findings revealed that the mean age of study nurses was 38.24±7.84, and half of them had Bachelor’s degrees. More than two-thirds of them had years of experience, more than ten years. The minority of the studied nurses had training programs regarding antenatal care. These findings followed maria et al.,\(^{(7)}\) who found that the health professionals’ mean age was 39.4 years, with more than ten years of antenatal care experience. On the other hand, these results disagreed with Ruby et al.,\(^{(13)}\) who found that most nurses belonged to the age group 18-32 years. This may be because nurses are full of energy and hyperactivity at a young age, which is always required in such crucial departments.

Additionally, this result disagreed with Babulal \(^{(14)}\) who stated that most studied nurses had less than ten years of experience.

Concerning educational level, this result disagrees with Nasser et al.,\(^{(15)}\) who found that most of participants (two thirds) hold a diploma in midwifery and nursing secondary school graduates.

Additionally, regarding the training course, this result agrees with Lisette \(^{(16)}\) who reported that nurses were not always given sufficient training during education or after begun clinical work, which increases stress and makes them less efficient in the work.

Moreover, concerning studied nurses’ total knowledge about antenatal care of pregnant women at the pre-test, the study revealed that more than half of the studied nurses had inadequate knowledge regarding antenatal care, which improved their knowledge after implementing educational guidelines. This result may be due to the absence of training courses regarding antenatal care among study nurses, the absence of refreshing guidelines related to the concept and objective of antenatal care, and the limited number of nurses who attended the training courses.

Additionally, these results were supported by Mohamed & Salem,\(^{(17)}\) they suggested that near two-thirds of studied nurses had inadequate and low scores of knowledge related to antenatal care. This may be due to improper knowledge and lack of motivation to update their knowledge.

Moreover, the present study findings elaborated that there were highly statistically significant differences at pre & post-application of educational
guidelines (p<0.001) mean total scores of maternity nurses knowledge was (13.68 ± 4.20 & 21.31 ± 3.24) pre and post-intervention, respectively. These findings were congruent with Saber, (18) they reported that there was a statistically significant difference regarding all items of the knowledge before and after implementation of educational guidelines with increased knowledge of nurses after implementation regarding antenatal care during pregnancy (p=< 0.000**).

In addition to the studied nurses’ total knowledge about pregnant women’s nursing care at the pre-test, the study revealed that there were highly significant differences of the studied nurses in the nursing care of pregnant women (2.32±1.04 & 4.15± 0.61) pre and post-intervention, respectively. These results were in the same line with Mohamed et al., (19) who reported a significant improvement in the nurse’s knowledge score about nursing care during pregnancy.

Regarding nurses’ knowledge about health education given to women during antenatal care, the present study findings showed a highly significant difference in the mean scores of the studied nurses (5.65±1.71& 9.61±2.21) pre and post-intervention, respectively. Lee et al.(20) supported these findings, they found that the women had inadequate awareness of the nutritional guidelines and minimal knowledge obtained from their providers of service. Similarly, as well as time constraints, insufficient knowledge of nutrition and a lack of nutrition preparation have impaired the ability of clinicians to provide adequate nutrition education.

Regarding nurse’s total antenatal care practice, the present study findings reported that more than half of nurses had incompetent practice regarding antenatal care. This finding was in line with (Mohamed et l., (19) who stated that about half of the nurses studied had an unsatisfactory pre-program total practice score, which improved to a highly satisfactory post-program total practice. On the other hand, this result was in contrast with Gooda et al(21) who reported a significant improvement in nurses” practice regarding antenatal care at the pre-intervention phase.

Concerning the mean total practice score of nurses regarding pregnant women’s care, the present study revealed a highly statistically significant difference between pre & post-intervention (p<0.001). The mean total score of maternity nurses’ practice was(38.92 ± 7.91& 67.65±12.25) at pre-post intervention respectively. This result agrees with Mohamed et al., (19) who reported that most of the studied nurses had unsatisfactory total practice score pre-program, which improved to high satisfactory total practice post-program. This result was also consistent with Elmorsy(11) who reported unsatisfactory practice of most nurses regarding antenatal period pre-application of educational guidelines. Meanwhile, the majority of them had satisfactory practice regarding the antenatal period post-application of the educational guideline. This result could be explained by lack of nurses’ knowledge, which reflected in their practice.

Regarding the correlation between total scores of maternity knowledge and practices, the present study’s finding showed a statistically significant positive correlation between total knowledge and total practice scores pre and post-application of the educational guideline. This result may be because a good level of knowledge positively affects the level of practice.

This result is in the same line with Gooda et al. , (21) who reported a positive, statistically significant relationship between nurses’ knowledge and practice and their age and years of experience before and after application of the nursing protocol (p<0.001).

Conclusion

Based on our findings, the research hypothesis is supported, and nurses’ performance (knowledge &
practice) shows a significant improvement in post-implementation of educational guidelines regarding antenatal care for maternity nurses compared to pre-implementation. Furthermore, there was a positive correlation between total knowledge and total practice of studied nurses at pre-implementation phases, while there was no correlation between total knowledge and total practice of studied nurses at post-implementation phases.

**Recommendations**

- The care of pregnant women should be an integral part of the educational curriculum for nursing students.
- Implementing regular training programs for nurses to update their knowledge and practice towards antenatal care.
- Further research:
  - Applying health education for all maternity nurses about antenatal care schedules in all Maternal and Child Health Centres (MCH).
- Effect of simulation training on nurses’ performance regarding antenatal care.

Abstract

Background of Study: Despite the significance of the problem with respect to overall health and its undesirable health consequences, high blood pressure still is not adequately controlled and far from being optimal. An estimated 1.13 billion people worldwide have hypertension (WHO may 2019). In India incidence rate of hypertension is 29.8% (WHO September 2018). In Gujarat incidence rate of hypertension is 27.1% (JNC-7). Quasi experimental research design (pre test post test research design), Quantitative research approach was used to assess the effectiveness of deep breathing exercise on blood pressure and heart rate among hypertensive patients in selected area of Kheda district. The collected data was tabulated and analyzed using descriptive and inferential statistics. Mean, and standard deviation was calculated by the obtained data in which mean score of blood pressure was 127.46 in pre test and 78.63 in post test and score of standard deviation was 5.44 in pre test and 4.88 in post test. The mean score of heart rate was 86.2 in pre test and 63.01 in post test and score of standard deviation was 3.86 in pre test and 2.59 in post test.

Keywords: - Deep breathing exercise, Blood pressure, Heart rate, Hypertensive patient.

Introduction

Hypertension is a widespread health problem and is called the “silent killer” because it often has no warning signs or symptoms, and many people don’t realize that they have it. Hypertension is another name for high blood pressure. It can lead to severe health complications and increase the risk of heart disease, stroke, and sometimes death. Many pharmacological and non-pharmacological interventions effective in treating essential hypertension, Pharmacological therapy depends on antihypertensive drugs, while non-pharmacological therapy involved five lifestyle modifications are recommended by JNC 7 for reducing blood pressure: reducing sodium intake, increasing exercise, limiting alcohol consumption, dietary changes, losing weight in addition to; other lifestyle interventions as smoking cessation, dietary supplements and meditation. The last one includes careful attention to the process of breathing, to achieve a state of inner calm, detachment, and focus (Mancia et al.,2013, McElroy, et al., 2012, a Deep breathing increases blood and oxygen flow to the brain to function in its optimal state. It improves circulation, which improves heart health, energy levels and helps the body eliminate toxins, as well as reduces

stress (Shakeshaft, 2012). Hence, practicing deep breathing exercise influence autonomic functions and has therapeutic benefit to hypertensive patients (Almahrezi, et al., 2008) and (Ribeiro, et al., 2011).

Need of the Study:

Hypertension is major health problem in India, contribute to significant morbidity as well as mortality among with the significant sociology economically losses. Study on the hypertensive patients either in community, inpatient, outpatient, or different hospital have shown that hypertension is the commonest medical health problems. Previously study has found that breathing exercise is very beneficial for hypertensive patients.

Deep breathing is an easy exercise, non-invasive and painless. It can be done at any place, less time consuming, and cost effective. Therefore, this study was conducted to examine the efficacy of deep breathing exercises on hypertension and heart rate as a non-pharmacological complementary approach to treat essential hypertensive patients; make these gentle practices a worthwhile activity to incorporate into a healthy lifestyle. Hopefully this study could add an important evidence based practice to the concerned patients and health care providers.

In that Deep Breathing exercise is one of the exercise and relaxation technique which helps to maintain the normal blood pressure. The goal of the study is to determine the effectiveness of deep breathing exercise on blood pressure among patient with hypertension.

Objectives of the Study

1. To assess the blood pressure level of the hypertensive patient.

2. To evaluate the effect of deep breathing exercise on blood pressure among the hypertensive patients.

3. To assess the pre test and post test level of blood pressure and heart rate among hypertensive patient between control and interventional group.

4. To find out the association of heart rate and blood pressure level with selected demographic variable among hypertensive patients.

Hypothesis

H1 There will be a statistical significant difference in blood pressure before and after deep breathing exercises intervention at the level of p<0.05.

H2 There will be statistical significant difference in heart rate before and after deep breathing exercise intervention at the level of p<0.05.

Material and Methods

Research Approach: Quantitative research approach is used for this present study.

Research Design: Quasi experimental research design (pre test post test research design).

Population:

Target population of study was all hypertensive patients in selected area of Kheda district.

Sample Technique:

Purposive non probability sampling technique used to select sample

Sample Size:

The sample size comprised of 60 hypertensive patient (30 experimental group and 30 control group)

Description Tool:

Part A: Demographic data

Part B: modified deep breathing exercise
Inventory was used.

MAJOR FINDINGS OF THE STUDY:-

Findings related to demographic variables of samples:

1. According to demographic variable of age, the majority of the patients 19(31.66%) belonged to 51-60 years, 14(23.33%) patient belong to 61-70 years, 17(28.33%) patients belong to 41-50 years and only 10(16.66%) belonged to 71-80 years in group of hypertensive patients.

2. Regarding gender, 27 (45%) were males and 33(55%) were females in selected group.

3. Regarding duration of hypertension, majority 27(45%) were suffering from hypertension for 5-10 years duration, only 0(0%) sample in group was suffering from hypertension below 15 years.

4. Regarding the number of years one is taking medication majority of 26 (43.33%) patients belongs to 8-12 years of age.

5. Assessment of dietary pattern revealed that regarding 37 (61.66%) of them were vegetarian

6. According to blood pressure outcome among hypertensive patient, in experimental group, the mean pre-test score is 127.46 with standard deviation 5.44 and the post test mean is 78.63 with standard deviation 4.88. The obtained paired t test value is 45.73.

7. According to heart rate outcome among hypertensive patient, in experimental group, the mean pre-test score is 86.02 with standard deviation 3.86 and the post test mean is 63.010 with standard deviation 2.59. The obtained paired t test value is 28.0031.

8. According to variable of blood pressure outcome, mean is 128.30 with standard deviation of 7.713.

9. According to variable of heart rate outcome, mean is 73.10 with standard deviation of 2.894.

**Conclusion**

The main conclusion drawn from the present study was that most of the hypertensive patients had high level of Blood Pressure. After receiving breathing exercises there was a significant reduction in the level of Blood Pressure. Samples became familiar and found themselves comfortable and also expressed satisfaction. It is concluded that the breathing exercises is effective and a simple strategy to maintain the blood pressure and heart rate.

Abstract

The present analysis article points out numerous analytical methods for the quantitative identification of ACE inhibitor (ACE Inhibitor) by one in all the spectroscopical techniques (UV-spectrophotometry) and separation techniques, like superior liquid natural action (HPLC). additionally, we tend to examine the contribution of optical biosensors to the clinical and pharmaceutical study of ACE inhibitor, which has applicable analytical procedures for internal control, pharmaceutical drug formulations and human.

In this report, a comprehensive sample of scientific papers published in different journals relating to medicinal, clinical and analytical chemistry was collected. Captopril was chosen because it is a popular medication in the pharmacy, a first-line antihypertensive agent, with a fast release, limited course of operation.

Key words : - Captopril, ACE inhibitor, HPLC, UV, biosensor

Introduction

Captopril is the first oral angiotensin converting enzyme inhibitor to become available. It was used mainly for hypertension. In mild to severe hypertension, captopril is nearly as effective as normal doses of hydrochlorothiazide or propranolol, nearly one-half of these patients need the use of a diuretic to gain satisfactory regulation of blood pressure. (¹)

In extreme hypertension captopril plus a diuretic (and in some cases a beta-blocker) blood pressure has typically lowered considerably better than could be done with ‘normal combination treatment’ in cases whom have not responded sufficiently to this protocol, and this also resulted in an increased sense of well-being in highly hypertensive patients that have previously undergone comprehensive multiple drug therapy. Indeed, at the present stage of drug production, patients who do not respond to or accommodate ‘ordinary’ antihypertensive treatment are the most effective candidates for captopril therapy (²).

Ultimately, the final role of captopril in the treatment of hypertension may depend on further confirmation of its profile of adverse effects. Captopril has shown promising changes in a limited number of patients with serious congestive heart failure resistant to traditional treatment, in addition to research on hypertension (³).

Captopril must be considered an interesting addition to the clinical armamentarium; it will continue to create a lot of excitement as its final role in therapy is best described by additional well-designed experiments to evaluate captopril, such as HPLC, UV-visible spectroscopy, GLC, optical biosensor, etc. (⁴). Captopril tablets are shown in Fig.1.
Discovery and synthesis of captopril

One of the primary medications marketed for lowering blood pressure. Three researchers at the U.S. drug maker Squibb (now Bristol-Myers Squibb) made-up angiotensin converting enzyme inhibitor in 1975: Miguel Ondetti, Claude Bernard Rubin, and David Cushman. In February 1976, Squibb applied for U.S. patent rights for the drug and the U.S. In September 1977, a patent was issued (5). Captopril’s development was one of the early achievements of the groundbreaking idea of ligand-based drug design.

In the mid-20th century, the renin-angiotensin -aldosterone pathway was thoroughly researched and this mechanism provided many important goals in the production of new therapies for hypertension. The first 2 goals that were tried were proteinase associate degree an angiotensin converting enzyme inhibitor. ACE inhibitor was the results of {attempts|makes associate degree attempt|tries} by Squibb’s labs to supply an angiotensin converting enzyme inhibitor. Ondetti, Cushman, and colleagues distended on work undertaken among the 19 Sixties by a team of researchers semiconductor unit by John Vane at the Royal college of Surgeons of European nation. (6). Kevin K.F. created the first breakthrough. In 1967, the transfer of angiotensin I to angiotensin II was discovered to take place in the pulmonary circulation rather than in the plasma. Sergio Ferreira, on the other hand, noticed that bradykinin dissolved after its transit through the pulmonary circulation. It was believed that angiotensin I to angiotensin II conversion and bradykinin inactivation were regulated by the same enzyme (7).

In 1970, the transfer of angiotensin I to angiotonin was blocked throughout its passage through the circulation mistreatment bradykinin potentiating factor (BPF) equipped by Sergio Ferreira metric Ng and Vane. Later, BPF was found to be a peptide in the lancehead viper venom (Bothrops jararaca),
which was the transforming enzyme’s “collected-product inhibitor.” A sting from this snake triggers an immediate decrease in its prey’s blood pressure, rendering it difficult to run. After it absolutely was found by QSAR-based modification that the terminal sulphydryl moiety of the amide created a high efficiency of ACE inhibition, Captopril was formed from this peptide.

A non-peptide with a proline residue at the C-terminal is found in the venom. An effective regulator of the so-called angiotensin-converting enzyme (ACE) was found to be this non-peptide. It is a zinc-containing enzyme that catalyzes the synthesis of the angiotensin I peptide into the hormone angiotensin II active peptide that raises blood pressure. While the venom peptide’s very quick action can be useful for a starving snake, it is not helpful for humans (8).

Medicinal chemists have produced a sequence of proline-containing zinc-binding compounds using the catalytic mechanism of similar zinc-containing enzymes as the starting point. Succinyl-(S)-proline was the first ACE inhibitor to be synthesized. Medicinal chemists were able to improve the production of the ACE inhibitor more than 1000-fold by replacing the succinyl group with a structurally similar sulfhydryl group. In 1980, Captopril entered the market as the first inhibitor of ACE (9), as seen in Fig.2.

![Figure 2: ACE-inhibitor activity.](image)

It was proprietary in 1976 and approved in 1980 for medicative use. Attributable to its mechanism of action and conjointly attributable to the event method, it absolutely was the primary angiotensin converting enzyme inhibitor developed and was thought-about a breakthrough. At E, Captopril was found and grown. Centered on ideas pioneered by Nobel laureate Sir John Vane, R. Squibb & Sons Pharmaceuticals is now sold by Bristol-Myers Squibb.

On April 6, 1981, Captopril received FDA approval. In Feb 1996, once the business exclusivity maintained by Bristol-Myers Squibb for Capoten all
over, the medication became a generic medication within the U.S. The production of Capoten was claimed as an indication of ‘biopiracy’ (marketing standard medicines), as no benefits flowed back to the associate estral Brazilian community WHO 1st used viper venom as an point poison (10).

Indication

1. Hypertension

Adult / Initially twelve.5-25 mg doubly daily, then augmented to a hundred and fifty mg daily in a pair of separated doses if necessary, doses to be augmented at periods of a minimum of a pair of weeks, once daily dose are often decent if any concomitant medicine medications square measure measure taken.

Initially 6.25 mg doubly daily, then augmented to a hundred and fifty mg daily if needed in a pair of split doses, doses to be augmented at intervals of a minimum of a pair of weeks, once daily dose are often decent if any concomitant medicine medicines square measure taken.

2- Prophylaxis of symptomatic internal organ failure in clinically healthy patients with symptomless left chamber malfunction (beginning 3-16 days when infarction) following infarction (under close to surgical supervision)

Adult / at first 6.25 mg daily, then hyperbolic to twelve.5 mg three times daily for two days, then hyperbolic to twenty five mg three times daily if tolerated, then hyperbolic to 75-150 mg daily if tolerated in 2-3 separated doses, rising steady to doses larger than seventy five mg daily.

3-Diabetic nephropathy in type 1 DM

Adult/75-100 mg in split doses daily.

4-Heart failure

Adult/(under shut medical supervision) at first 6.25-12.5 mg 2-3 times every day, then hyperbolic more and more at periods of a minimum of a pair of weeks, if tolerated up to a hundred and fifty mg daily in divided doses.

5-Short-term treatment of clinically competent patients with myocardial infarction within 24 hours of onset.

Captopril analytical measurement

Several assay strategies, like coulometric (13), conductometric, and colorimetrical, are developed for the quantitative determination of Capoten (14). Infrared spectroscopy (15), mass spectroscopy and nuclear magnetic resonance spectroscopy (16) are used to determine Captopril. Captopril’s UV spectrum with one band at two hundred nm was obtained, whereas the CD spectrum consists of one peak at 210 nm (17).

Captopril by spectrophotometric method was calculated by Alberto (18) and iron and copper complexation with ACE inhibitor was additionally assayed (19) by ultraviolet illumination photometer. the amount of chromatographical strategies for the determination of ACE inhibitor has been defined as gas chromatography-mass spectrometry (20) Ahmed et al. (21) also published HPLC stability-indicating methods for its determination.

This approach is employed for the assessment of angiotensin converting enzyme inhibitor in pure type within the presence of the disulphide chemical compound and in pharmaceutical preparations, an answer containing 0.025 C and w / w Pd(II) chloride was used as a mobile step in a very mixture of acetonitrilemethanol-water comprising ten millimetre Britton-Robinson [BRb] pH scale 4.00 and 0.25 M KCl solution [1:4:5 v / v / v].

Another HPLC methodology determined by Stulzer et al. angiotensin converting enzyme inhibitor in controlled unleash tablets and analyzes
were performed at temperature at the inverted part Phenomenex Luna column C18 (250 millimetre × 4.6 mm), mobile part water: methyl alcohol (45:55; v / v) and pH scale 2.5 at 1.0 mL.min⁻¹, and also the response was linear at zero.3–1.5 mg.mL⁻¹ (r² = 0.9983) (22).

Ivanovic et al. have revealed a valid RP-HPLC method for analyzing hydrochlorothiazide and Capoten in tablets. Jankowski et al., calculated by HPLC in blood with captopril (23). The captopril adduct recovery achieved 93.1% and the detection limit was 15 ng.mL⁻¹, while the conceptual limit was 30 ng.mL⁻¹. Inter and intra-assay RSD were below 9%, but precision was found to be below 8%. Captopril was calculated by Saleem et al. and Amini et al. (24) in plasma.

For the quantitative determination of angiotensin converting enzyme inhibitor by the quantity of scientists victimisation HPLC (25), variety of assay strategies are developed. a range of examinations are recorded victimisation HPLC for the determination of angiotensin converting enzyme inhibitor in bulk drug substances and their formulations (26). Direct determination of the four ACE-inhibitors Zestril, Enalapril, angiotensin converting enzyme inhibitor and Fosinopril in prescription drugs and blood serum by HPLC analyst separation was accomplished by RP-HPLC gradient with a mobile step consisting of acetonitrile: water (60:40 v / v) with ortho oxyacid changed to pH 3.0 (26), Fig.3 demonstrates captopril’s chemical composition.

Figure 3: captopril’s chemical structure.
Monitoring of in vitro trials of ACE inhibitor association with LC-UV symptom agents and parallel LC determination of rosuvastatin, lisinopril, captopril, and angiotensin converting enzyme inhibitor in API, medicament formulations, and human blood serum (27).

Another Facile and Manifest Liquid chromatographical method for coinciding Determination of ACE inhibitor and NSAIDs in API and Pharmaceutical Formulations has been according and CAP has been isolated from NSAIDs by means that of a column of Purospher STAR C18 (250.4.6 mm, five μm) and a mobile section consisting of alcohol, water (80:20, v/v) (28).

Therefore, ACE inhibitor with water pill HydroDIURIL and diuretic in active pharmaceutical ingredients, medicative indefinite quantity formulations and human body fluid area unit used as combination indefinite quantity forms for alternative distinctive forms of drug substances like metal channel block medicinal drug, diuretics, etc. (29).

Other hypoglycaemic Capoten, medicinal drug and H2 receptor antagonist ways ar recorded in bulk, formulations, and human humor by RP-HPLC (30-32).

Biosensors have become important bioanalytical instruments in the last few years for environmental testing, biotechnology, pharmaceuticals, food safety and other consumer industries. Due to their high sensitivity, high precision, low expense, compact size and simple activity, the use of biosensors to test chemical species is an exciting opportunity.

High sensitivity and fast detection are key criteria for a sensor for detecting biomaterials. There has been a great deal of study over many decades to develop quick and responsive biosensors for various applications. In particular, owing to the probability of fast and direct (unlabelled) detection, optical methods have been reported to have a high potential.

A variety of biosensor instruments, including several interferometers, surface plasmon resonance sensors and micro ring resonator sensors, have been used to detect various biomaterials. While all these sensors offer sensitive and quick detection, they are only suitable for items up to 100 nm in size (33).

A light detector resistance (LDR) is AN optical device mounted in an exceedingly black PTFE cell and paired to a cheap multimeter (Ohmmeter). The chemical analysis is based on the reduction of ammonium ion molybdate by Capoten, producing a green-yellow compound in the presence of sulphuric acid (λmax 407 nm). By plotting the electrical resistance of the LDR against the CPT concentration, the standardization curves were obtained within the vary of 4.60 x 10^-4 to 1.84 x 10^-3 mol.L^-1 with an affordable constant of determination (r^2 = 0.9962) (34).

Moreover, as a result of their uncommon optical properties and catalytic ability, Molybdenum compound nanomaterials have recently attracted widespread interest. There is, however, no literature up to now on the utilization of photoluminescent nanomaterials of Molybdenum compound in biological and pharmaceutical sensing.

Via Associate in Nursing easy method, photoluminescent Molybdenum oxide compound quantum dots (MoOx QDs) were synthesized and so the synthesized MoOx QDs were more additional as a replacement sort of photoluminescent probe to create a replacement off-on angiotensin converting enzyme inhibitor (Cap) detector supported the idea that the quenched photoluminescence of MoOx QDs by Cu^{2+} was fixed up to Cap by precise interaction between thiol cluster of Cap and Cu^{2+}.

The rebuilt photoluminescence strength showed a powerful linear relationship with the Cap material, variable from 1.0 to 150.0 μM, with a 0.51 μM (3σ / k) detection most, beneath ideal conditions. Additionally,
with the recently designed off-on device, the content of Cap was with success known in pharmaceutical samples, and therefore the recoveries were 99.4-101.7 percent, indicating that the newest off-on device includes a high accuracy.

Replicate (n = 10) measurements were created on an equivalent answer comprising the equivalent of \(1.15 \times 10^{-3}\) mol.L\(^{-1}\) of CPT to check the repeatability and preciseness of the measure methodology. Determinations (n = 10) were created with an equivalent answer containing CPT adequate to \(1.15 \times 10^{-3}\) mol. L\(^{-1}\).

This resolution was tested in conjunction with the prescribed approach for measurement the CPT content of pharmaceutical formulations. In terms of share relative variance (% RSD)\(^{(36)}\), the accuracy was measured.

**The Biosensors Specifications**

The essential specifications for biosensors are the following:

Ø Ability to provide real-time data during a project at each development stage or at multiple time points. This would help in improved tracking and regulation of blood sugar levels, for example.

Ø It is feasible to customise several biosensor technologies to permit continuous flow analysis that’s terribly helpful in food process, observance of installation, and air quality.

Ø Through miniaturization, biosensors can reduce usage costs and can be incorporated into efficient, highly capable lab-on-a-chip tools.

Ø Biosensors is used for point-of-care or on-the-spot analysis wherever progressive molecular analysis is conducted while not the requirement for a progressive laboratory\(^{(37)}\).

**Biosensor system**

In general, a biosensor uses a facet of biological recognition that detects the presence of an analyte (the species to be detected) and produces a physical or chemical change that’s remodeled into a symptom by an electrical device (detector). The general block diagram of the framework of biosensors is defined in Fig. 4. Specific system for biosensing. An analyte is inserted into the detector by the sampling machine. The identification issue attaches or responds to a specific analyte, giving a biodetection specificity. Enzymes, antibodies, proteins, DNA or additionally cells like yeast or bacterium are used as parts in biorecognition\(^{(38)}\). In general, stimulus may be generated by optical, electrical, or other kinds of force fields that, as a result of biorecognition, extract a reaction. The transduction mechanism converts the physical or chemical process of biorecognition into an optical, electrical or another variety of signal within the presence of external stimuli that’s then detected by the detector device. For identification of the analyte, the detection device may provide pattern recognition.

A broad variety of real life applications are defined by biosensors\(^{(39)}\). In essence, future uses are medicinal and nonclinical\(^{(40)}\). The use of biosensors to track toxins\(^{(41)}\), micro-organisms, microbes, viruses\(^{(42)}\) and chemical and biological defense against terrorism is of more recent concern. In agricultural and environmental applications\(^{(43)}\), it is also common. A few days now, applications based on nanotechnology\(^{(44)}\) are also being created.
The Immobilization Techniques (Mechanism)

The biological part has to be correctly attached to the transducer to make a biosensor. Immobilization is called this method. On a solid support, the biorecognition components are typically immobilized. A membrane, rubber, copolymer, or semiconductor material are typically the solid supports. A biorecognition component, either by a physical methodology (such as adsorption) or by chemical association, is immobilized on the solid support. In sure ways, the issue of biorecognition is cursed with controlled porosity within the volume of the matrix (solid support), wherever solid support typically provides property against associate analyte of a precise size in step with its pore dimension (44).

Conclusion

A significant variety of drugs for effective treatment are administered to people diagnosed with hypertension, raising the risk of adverse effects and drug reactions. But Gupta et al. (37-44) have documented some electro analytical approaches.

UV and HPLC strategies and optical biosensors for the determination of ACE inhibitor in active ingredients, pharmaceutical formulations and biological specimens square measure investigated alone or in conjunction with different medication during this study.

In general, pricey instrumentation, provision for the utilization and disposal of solvents, labour-intensive sample preparation procedure and private skilled chromatographical techniques were needed for HPLC strategies.

Furthermore, several of the examined HPLC approaches have the ability to apply drug combination, multi-drug pharmacokinetics trials and association studies to clinical science.

Thus, optical biosensors are one of the most interesting alternatives in this situation, since they play an important role in drug quantification and are one of the most specific, sensitive, low-cost and
easy-to-use options available at the moment. This has provided a niche for them as new clinical instruments that allow more precision medicine to be controlled therapeutically by minimizing symptoms or secondary effects as much as possible and contributing to safer patient treatment and prescription.

In addition, the use of biosensors offers doctors a benefit when making the most precise choices for real-time dosing at the bedside of a patient, since biosensors are compact instruments that are easy to use and miniaturized. When formulating medicines, they have stricter and more effective regulation. There is an immediate need for more research based on the quantification of blood medications and including all pharmacological classes to ensure that a greater range of medications have personalized doses in accordance with the premise of usage.

Call for Papers / Article Submission

Indian Journal of Forensic Medicine & Toxicology has commenced publication since 2007. IJFMT will be published two times in a year.

Purpose & Scope: Indian Journal of Forensic Medicine & Toxicology is a peer reviewed six monthly Journal. It deals with Forensic Medicine, Forensic Science, Toxicology, DNA fingerprinting, sexual medicine and environmental medicine. It has been assigned International standard serial No. p-0973-9122 and e-0973-9130 website: www.ijfmt.com. This journal is also indexed with Index Copernicus (Poland).

The journal encourages research from theoretical perspectives, research reports of evidence based practice as well as praxis research work that focuses on the interface between theory and practice and how each can support the other. In addition, the journal strongly encourages reports of research carried out within or involving countries in the Asia- Pacific region.
